8:48AM P30.00005 Atomic control and characterization of surface defect states of TiO2 terminated SrTiO3.\(^1\) A. KAREEV, University of Arkansas, M. KAREEV, S. PROSANDEEV, J. LIU, C. GAN, J.W. FREELAND, MIN XIAO, J. ZHANG, L. BRILLSON, J. CHAKHALIAN — By using a new wet-etch procedure\(^1\) we have obtained high-quality atomically flat TiO2 terminated surfaces of STO (100) single crystals with the surface morphology equivalent or better to that of the conventional routes. By applying a combined power of CL and PL, RHEED, AFM, and resonant XAS, we are able to identify and monitor the complex evolution of oxygen defect states and Ti ion valency at the surface and near-surface regions. Our data reveal a high level of local defects resulting in the presence of the Ti\(^{3+}\) states at the surface in the conventionally treated STO surface. We have developed an efficient method to control the defect states capable of a marked reduction of the defect concentration. We have demonstrated that the PL, CL and XAS are able to distinguish the surface-related Ti states from oxygen vacancies trapping charge transfer vibronic excitons. \(^1\)M. Kareev et al., Appl. Phys. Lett. 93, 061909 (2008).

9:00AM P30.00006 Polar and non-polar oxide interfaces: charge and spin behaving badly\(^1\). WARREN PICKETT, UC Davis — Interfaces between two dissimilar materials are well known to lead to new behavior and often useful properties. Whereas covalent semiconductors have been studied and used for decades, and the interfaces of magnetic metals also have assumed great importance, the use of oxides in such juxtaposed systems is much more recent. Oxides add the huge impact of ionicity, and the correlated electron behavior that occurs if open shells are present. Even without correlation effects, finite overlayers (slabs) involving a polar discontinuity can sustain a surprisingly large separation of charge, as will be illustrated with calculational results on LaAlO\(_3\) slabs on SrTiO\(_3\) substrates: a strong polar distortion, uniform over several unit cells, creates the necessary screening. The most recent results on the mechanism and character of the insulator-to-metal transition with thickness will be discussed. Polar discontinuities are not necessary to create exotic behavior, as we illustrate with rutile-structure VO\(_2\)/TiO\(_2\) multilayers, where a topologically protected zero-gap two-dimensional half-metal arises in a thickness regime between thin insulating and thick conducting VO\(_2\) slabs. Work done in collaboration with R. Pentcheva, V. Pardo, and K. Ott.

9:36AM P30.00007 Prediction of a switchable two-dimensional electron gas at KNbO3/ATiO3 (A = Sr, Ba, Pb) interfaces, YONG WANG, MANISH NIRANJAN, SITARAM JASWAL, EVGENY TSYMBAL, University of Nebraska, Lincoln NE, USA — The demonstration of a quasi-two dimensional electron gas (2DEG) at the (LaO\(^+)/\((/TiO2)\(^0\)) interface in LaAlO\(_3\)/SrTiO\(_3\) heterostructure has fuelled intense research activity in recent years. The 2DEG has a high carrier mobility and electron density that are promising for applications in all-oxide electronic devices. For such applications it is desirable to have the ability to control the properties of the 2DEG by external stimulus, e.g., by an electric field. In this study we use density functional calculations to explore a ferroelectric KNbO\(_3\)/SrTiO\(_3\) heterostructure for this purpose. The polar discontinuity at the (NbO\(_2\))\(^+)/\((/SrO)\(^0\))interface in KNbO\(_3\)/SrTiO\(_3\) heterostructure is similar to that at the (LaO\(^+)/\((/TiO2)\(^0\)) interface in LaAlO\(_3\)/SrTiO\(_3\) heterostructure. Our results suggest that a 2DEG is created at the (NbO\(_2\))\(^+)/\((/SrO)\(^0\))interface due to the electronic reconstruction with properties strongly determined by the orientation of the electric polarization. We further explore the formation of 2DEG at the interfaces of all ferroelectric KNbO\(_3\)/BaTiO\(_3\) and KNbO\(_3\)/PbTiO\(_3\) heterostructures and its dependence on polarization orientation. Finally, we discuss how the properties of 2DEG in aforementioned heterostructures are influenced by the compensation of polarization charges by free carriers, rendering it switchable.

9:48AM P30.00008 A Novel Quantum Well of Embedded SrTiO\(_3\) in LaAlO\(_3\), HANGHUI CHEN, ALEXIE KOLPAK, SOHRAB ISMAIL-BIEGI, Department of Physics, Yale University — Inspired by the novel behavior of LaAlO\(_3\)/SrTiO\(_3\)(001) heterointerfaces, we propose new sets of interfaces in which one TiO\(_2\) or SrO layer is embedded in LaAlO\(_3\). These interfaces can form quantum wells which trap electrons or holes in a single atomic layer of TiO\(_2\) or SrO, respectively, when the “polar catastrophe” occurs. This narrow confinement, in contrast to the situation at the LaAlO\(_3\)/SrTiO\(_3\)(001) interfaces, sheds light on the still uncertain origin of the charge carriers and provides ideas for engineering their properties. In addition, we study the field effect on these systems to predict the critical external electric field required to induce an insulating-to-metallic transition.

10:00AM P30.00009 Resonant Tunneling Through a Two-Dimensional Electron Gas in All-Oxide Heterostructure Tunnel Junctions, J.D. BURTON, E.Y. TSYMBAL, University of Nebraska, Lincoln, USA, J.P. VELEV, University of Puerto Rico, San Juan, USA — Oxide heterostructures exhibit a variety of very interesting physical properties and have tremendous potential for new types of multifunctional device applications. For example, very recently it was discovered that a two-dimensional electron gas (2DEG) is formed at the (001) interface between two perovskite oxides that are otherwise insulating in the bulk. We examine, within the framework of first-principles density functional theory, the effect of a complex SrTiO3-LaO-SrTiO3 barrier forming a 2DEG on conductance and TMR in all-oxide magnetic tunnel junctions. The replacement of one SrO atomic layer by LaO in the otherwise pure SrTiO3 barrier can be understood as precision substitutional doping of trivalent La for divalent Sr, leading to the formation of a 2DEG. Such precision atomic layering is within the reach of current experimental fabrication techniques. Our calculations reveal that the pure SrTiO3 barrier, the tunneling conductance can be substantially enhanced due to resonant tunneling through the 2DEG. However, this effect is sensitive to lattice polarization effects in the SrTiO3 barrier as well as the choice of electrode material. We will discuss these effects with the goal of stimulating experimental studies.

10:12AM P30.00010 Modulation of the low-temperature magnetoresistance of Ar-irradiated SrTiO\(_3\) via field-effect gate doping, J.H. NGAI, Department of Applied Physics, Yale University, Y. SEGAL, J. HOFFMAN, F.J. WALKER, C.H. AHN, CENTER FOR RESEARCH ON INTERFACE STRUCTURES AND PHENOMENA TEAM — Recent experiments have shown that irradiating single crystal SrTiO3 with Ar ions can create an amorphous surface layer with a quasi-2-dimensional electron gas (Q2DEG) below. We present low-temperature magnetotransport measurements of this Q2DEG system, as a function of gate doping. The magnetoresistance can be tuned as n-type carriers are doped into the interface between the amorphous and crystalline SrTiO3 layers. Anisotropy in the magnetoresistance is also measured with respect to the direction of the applied magnetic field. These results will be compared with the magnetotransport properties of LaAlO\(_3\)/SrTiO3 heterostructures, where the possibility of novel magnetic behavior will be discussed.
10:24AM P30.00011 Nanoscale Electrical Properties of Oxide Heterostructures Revealed Via Introspection\(^1\). CHENG CEN, STEFAN THIEL, JOCHEN MANNHART, JEREMY LEVY — Previous work shows that conductive regions can be formed via lateral nanoscale confinement of a quasi-two-dimensional electron gas at the LaAlO\(_3\)/SrTiO\(_3\) interface\(^2\). Here we demonstrate how structures constructed in this method serve not only as novel nanoelectronic devices but also as tools for studying fundamental physics in the underlying material system. Nanowires, tunnel junctions, field effect transistors (FETs), together with associated phenomena that we observed such as negative differential resistance, provide insight into the mechanism responsible for the existence and spatial confinement of the interfacial metal-insulator transition. We discuss several examples of nanodevices and the constraints they place on models and mechanisms that govern their properties. \(^2\)Cen et al, Nature Materials 7, 298 (2008).

10:36AM P30.00012 A metal-insulator transition tunable by lattice deformation in LaTiO\(_3\) thin films\(^1\), FRANKLIN WONG, University of California, Berkeley, SEUNG-HYUB BAEK, HO WON JANG, University of Wisconsin, Madison, RAJESH CHOPDEKAR, VIRAT MEHTA, University of California, Berkeley, CHANG-BEOM EOM, University of Wisconsin, Madison, YURI SUZUKI, University of California, Berkeley — Strong electron-electron and electron-lattice correlations play critical roles in electronic transitions of complex oxides. LaTiO\(_3\) is a narrow bandgap Mott insulator on the verge of a metal-insulator transition, substrate-induced lattice distortions offer a route to tuning its electronic properties. We have observed metallic to insulating behavior in LaTiO\(_3\) films depending on choice of (001) substrates: SrTiO\(_3\), LSAT, and LaAlO\(_3\). Tetragonal distortions induced by epitaxial in-plane compression from the SrTiO\(_3\) substrates result in metallicity in LaTiO\(_3\) films, while films on LSAT substrates exhibit a range of electronic properties depending on the degree of lattice relaxation. Whereas thinner LaTiO\(_3\) films on LSAT exhibit “semimetallic” behavior, in thicker films, the out-of-plane lattice parameters surprisingly converge to values greater than the bulk lattice constant, and the films become more insulating. We will discuss the profound consequences thin-film lattice deformation has on electrical transport. We speculate that stabilization of lattice distortions via epitaxy may open a new avenue for materials engineering of oxides through careful control of structural perturbations.

Wednesday, March 18, 2009 8:00AM - 11:00AM – Session P31 GMAG: Focus Session: Spin Ice 335

8:00AM P31.00001 Magnetothermodynamics of spin ice and related compounds\(^1\). XIANGLIN KE, The Pennsylvania State University — Geometrically magnetic frustration, which results from the competition of spin-spin interactions of magnetic ions on a regular magnetic lattice, leads to a variety of exotic low temperature states including “spin ice.” “Spin ice” refers to a magnetic state wherein the two-in-two-out spin configurations of rare earth pyrochlore compounds mimic the proton positions in the water ice, characterized by the “zero point entropy” of (R/2) \(\ln(2)\). In this study, we examine how structural disorder affects spin dynamics and the magnetic “zero point entropy.” By diluting the “spin ice” materials with nonmagnetic ions on the rare earth sites, we have found that the entropy of the diluted species depends non-monotonically on the dilution concentration, and we explain this behavior using a generalized Pauling approximation. Nonmagnetic doping on B sites leads to only a small decrease of the “zero point entropy,” indicating the robust nature of “spin-ice.” We have also studied Dy2Ge2O7, which has the same chemical formula as “spin ice” materials and Ising-like spins but a tetragonal structure. Dy2Ge2O7 undergoes a long range antiferromagnetic ordering transition, but the spin dynamics at temperatures above the order transition is similar to that observed in the canonical “spin ice” systems, suggesting that such dynamics are generic to a broader class of Ising-like rare earth systems.

8:36AM P31.00002 Magnetic charge order in kagome spin ice with dipolar interactions\(^1\). GIA-WEI CHERN, University of Wisconsin - Madison, PAULA MELLÁDO, OLEG TCHERNYSHYOV, Johns Hopkins University — Dipolar interactions in spin ice are described most effectively in terms of magnetic charges residing on the dual lattice \([1]\). While spin ice on the pyrochlore lattice contains no magnetic monopoles at low temperatures, spin ice on kagome \([2]\) contains a unit magnetic charge \((\pm 1)\) on every triangle. With the aid of Monte-Carlo simulations, we show that long-range Coulomb interaction between the monopoles lifts the degeneracy of the spin-ice states and induces a phase transition into a state with ordered magnetic charges but no spin order. The residual entropy is reduced from the spin-ice value but remains extensive. The phase transition is continuous with critical exponents close to the two-dimensional Ising universality class. \([1]\) C. Castelnovo, R. Moessner, and S. L. Sondhi, Nature 451, 42 (2008). \([2]\) A. S. Wills, R. Ballou, and C. Lacroix, Phys. Rev. B 66, 144407 (2002).

8:48AM P31.00003 Comparing artificial frustrated magnets: geometric effects in nanomagnet arrays\(^1\), JIE LI, XIANGLIN KE, The Penn State Univ, CRISTIANO NISOLI, Los Alamos National Lab, PAUL LAMMIERT, VINCENT CRESPi, PETER SCHIFFER, The Penn State Univ — We have studied arrays of single-domain ferromagnetic islands arranged on lattices such that the magnetostatic interactions between the islands are frustrated by the geometry of the arrays. We compare results for the different lattice geometries: the previously studied square “artificial spin ice” lattice\([1,2]\), a hexagonal lattice, and a ladder lattice which is topologically-equivalent to the former one. After the ac demagnetization the magnetic moment configurations are imaged via Magnetic Force Microscopy (MFM). We find that the ladder lattice shows local correlations which are similar to those of the square lattice, suggesting it as basis for comparison of the energetics of the other two lattices. The normalized magnetostatic energy of all three geometries decreases with decreasing demagnetization step size, but the lattices approach their ground states at different rates. 1. R. F. Wang, C. Nisoli, R. S. Freitas, J. Li, W. McConville, B. J. Cooley, M. S. Lund, N. Samarth, C. Leighton, V. H. Crespi, and P. Schiffer, Nature 439, 303 (2006). 2. X. Ke, J. Li, C. Nisoli, P. E. Lammiert, W. McConville, R. F. Wang, V. H. Crespi, and P. Schiffer, Phys. Rev. Lett. 101, 037205 (2008).

9:00AM P31.00004 Cooperative Paramagnetic Behavior in the Stuffed Pyrochlore Tb$_{2-x}$Ti$_x$Nb$_2$O$_7$. B.G. UELAND, J.S. GARDNER, NIST Center for Neutron Research, National Institute of Standards and Technology, M.L. DAHLBERG, P. SCHIFFER, Department of Physics and Materials Research Institute, Pennsylvania State University, A.J. WILLIAMS, J.C. KIM, R.J. CAVA, Department of Chemistry and Princeton Materials Institute, Princeton University — The pyrochlore Tb$_2$Ti$_2$O$_7$ is a cooperative paramagnet that has generated much interest in the frustrated magnetism community due to the presence of persistent short range spin-spin correlations and its apparent lack of long range magnetic order down to temperatures below $T = 0.05$ K, despite an effective spin-spin interaction strength given by $\theta_{V} \sim 10$ K. Motivated by recent work on the stuffed spin ices, we have begun investigations into stuffed variants of Tb$_2$Ti$_2$O$_7$, in which we replace some of the nonmagnetic Ti$^{4+}$ with magnetic Tb$^{3+}$, thus gradually altering the geometry of the magnetic sublattice from a lattice of corner sharing tetrahedra to a disordered lattice of side sharing tetrahedra. Here, we present results from magnetization and neutron scattering studies on powder samples of Tb$_{2-x}$Ti$_x$Nb$_2$O$_7$, where $x = 0$.2.0, 0.6, or 1, where diffraction data indicate that the $x = 1$ material has a disordered fluorite lattice. Preliminary results indicate that short range magnetic correlations similar to those present in Tb$_2$Ti$_2$O$_7$ exist in all of the materials studied, and that long range antiferromagnetic order may exist in the $x = 1$ material.

9:12AM P31.00005 Quantized Berry phase and entanglement entropy for a spin ladder system. ISAO MARUYAMA, Osaka university, SHOU TANAYA, MITSUHIRO ARIKAWA, YASUHIRO HATSUGAI, University of Tsukuba — We have demonstrated that quantized Berry phases and entanglement can be used as a new tool for exploring gapped systems which do not exhibit symmetry breaking. Especially, using quantized Berry phases in several gapped systems we identified location of singlet pairs successfully which illustrate the valence bond solid (VBS)[1], the itinerant singlet [2], the Kondo singlet. Recently, we have studied four-spin ring exchange interaction in a spin-1/2 two-leg ladder, which introduces frustration and generates various phases, such as the dominant vector-chirality (DVC) phase. In the DVC phase, the Berry phase detects the plaquette singlet[3] while entanglement entropy shows that degree of freedom of the edge state is non-zero. It means that singlets are localized at every links and separated as a free spin by adopting the boundary as in the VBS phase. In fact, under the open boundary condition, we found $S=1$ three-fold degenerated excited states with the small gap depends on the system-size as in the Kennedy triplet. [1] T.Hirano, H.Katsura, Y.Hatsugai, PRB 77 (2008) 094431 [2] I.Maruyama, Y.Hatsugai, JPSJ 76 (2007) 113601 [3] I.Maruyama, T.Hirano, Y.Hatsugai, AX.0806.4416

9:24AM P31.00006 Tuning magnetic frustration of nanomagnets in triangular-lattice geometry. X. KE, J. LI, S. ZHANG, C. NISOLI, V. CRESPI, P. SCHIFFER, The Pennsylvania State University — We study the configuration of magnetic moments on triangular lattices of single-domain magnetic islands, examining the consequences of magnetostatic interactions in this frustrated geometry. By varying the island-island distance along one direction, we are able to tune the ratio of different interactions between neighboring islands, resulting in a corresponding variation in the local correlations between the island moments. Unlike other artificial frustrated magnets, this lattice geometry displays regions of ordered moment orientation, possibly resulting from a higher degree of anisotropy leading to a reduced level of frustration. Reference: X. Ke et al., Appl. Phys. Lett., in press (2008).

9:36AM P31.00007 Magnetization Reversal in Artificial Kagome Ice. STEPHEN DAUNHEIMER, YI QI, TODD BRINTLINGER, University of Maryland, PAULA MELLADO, OLEG TCHERNYSHYOV, Johns Hopkins University, JOHN CUMINGS, University of Maryland — Lorentz-force images of magnetic domains in artificial kagome ice in detail. Previously, no ice rule violations have been observed in this novel magnetic metamaterial [1], in contrast to artificial square ice, where ice rule violations appear to be a robust feature [2]. Theoretical considerations support this observation but predict the generation of transient defects violating the ice rules during magnetization reversal. Such defects are expected to self-annihilate upon completion of the reversal process or removal of the artificial magnetic field. We will present results on the experimental exploration for ice-rule violations in this system both during field rotation and uniaxial field reversal using both FMR and LTEM. [1] Y. Qi et al., Phys. Rev. B 77, 094418 (2008) [2] X. Ke et al., Phys. Rev. Lett. 101, 037205 (2008)

9:48AM P31.00008 Equilibration and response properties in spin ice systems. CLAUDIO CASTELNOVO, University of Oxford, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, SHIVAJI SONDHI, Princeton University — It was recently argued that magnetic monopoles emerge in a class of exotic magnets known as spin ice: the dipole moment of the underlying electronic degrees of freedom fractionalises into deconfined monopoles. Here we investigate analytically and numerically the effects that these peculiar excitations have on the equilibration and response properties of a system. In particular, we study temperature quenches in exhaustive detail. The implications of these results on the possibility of finding new experimental signatures of magnetic monopole excitations in rare earth titanates (Dy$_2$Ti$_2$O$_7$ and Ho$_2$Ti$_2$O$_7$) are discussed.

10:00AM P31.00009 Monopole and Dirac string constrained Dynamics in Spin Ice. LUDOVIC JAUBERT, PETER HOLDSWORTH, Ecole Normale Superieure de Lyon — Since its discovery approximately 10 years ago [1], spin ice has proved to be an abounding source of exotic collective phenomena, in particular long-range dipolar correlations and unconventional phase transitions. But its most impressive property is undoubtably the geometry of its fractionalized excitations. These elude simple classification, behaving like effective magnetic monopoles [2]. I shall present an experimental signature of their influence in magnetic relaxation measurements for a spin ice material Dy$_2$Ti$_2$O$_7$ [3] and show that the observed low temperature dynamical slow down can be explained quantitatively by the Coulomb interactions between monopoles and the overlapping of Dirac strings filling the quasi-particle vacuum [4].

10:12AM P31.00010 Slow spin relaxation in dipolar spin ice. MARTIN ORENDA, LUCIA SEDLAKOVA, ALZBETA ORENDACOVA, PETER VRABEL, ALEXANDER FEHER, P. J. Šafarík University and Inst. Exp. Physics SAS, Košice, Slovakia, DANIEL M. PAJEROWSKI, JUSTIN D. COHEN, MARK W. MEISEL, Dept. Physics, Univ. Florida, FL; MASAE SHIRAI, STEVEN T. BRAMWELL, Univ. College London, UK — Spin relaxation in dipolar spin ice Dy$_2$Ti$_2$O$_7$ and Ho$_2$Ti$_2$O$_7$ was investigated using the magnetocaloric effect and susceptibility. The magnetocaloric behavior of Dy$_2$Ti$_2$O$_7$ at temperatures where the orientation of spins is governed by “ice rules” ($T \ll T_{ic}$) revealed thermally activated relaxation; however, the resulting temperature dependence of the relaxation time is more complicated than anticipated by a mere extrapolation of the corresponding high temperature data [1]. A study of Ho$_2$Ti$_2$O$_7$ was performed at $T > T_{ic}$ and in high magnetic fields, and the results suggest a slow relaxation of spins analogous to the behavior reported in a highly polarized cooperative paramagnet [2]. [1] J. Snyder et al., Phys. Rev. Lett. 91 (2003) 102701. [2] B.G. Ueland et al., Phys. Rev. Lett. 96 (2006) 027216.

1Work supported by ESF-RNP-HFM, NSF DMR-0701400.
10:24AM P31.00011 Quantum Spin Ice for Pr Pyrochlore Magnets, SHIGEKI ONODA, YOICHI TANAKA, Condensed Matter Theory Laboratory, RIKEN — We theoretically propose a new state comprising a quantum-mechanical analogue of the spin ice for pyrochlore magnets. In classical spin-ice systems like Dy2Ti2O7, the ice rule is mainly driven by the magnetic dipolar interaction, which is proportional to the square of the total angular momentum J. Therefore, for Pr3+ ions having two f electrons forming the J = 4 localized moment, the dipolar interaction becomes an order of magnitude smaller than that for Dy ions. Then, the magnetic superexchange interaction should play an important role. In fact, the form of the exchange interaction is nontrivial because of the highly relativistic nature of f electrons with strong LS coupling and crystal-field effect. Here, we present a microscopic derivation of the effective relativistic spin-orbital Hamiltonian for the pyrochlore magnets Pr2Ti2O7 with a transition-metal element T. Then, it is shown that the nearest-neighbor exchange interaction is significantly modified from antiferromagnetic to ferromagnetic by quantum–mechanical processes through excited states split by the crystal field. This bears a quantum-mechanical formation of the ice rule for Pr magnetic moments. Solving the Hamiltonian for a Pr2O4 tetrahedral cluster, we obtain a further small energy splitting of the low-energy states, leaving doubly degenerate ground states per tetrahedron. Implications for the lattice model and possible relevance to experiments are also discussed.

10:36AM P31.00012 SrEr2O4 in an applied magnetic field—a quantum phase transition?, O.A. PETRENKO, G. BALAKRISHNAN, T.J. HAYES, University of Warwick, UK, P. MANUEL, D.T. ADROJA, L.C. CHAPON, ISIS, RAL, UK — SrEr2O4 belongs to a family of materials with the formula SrLn2O4, where Ln = Gd, Dy, Ho, Er, Tm and Yb. In these compounds the magnetic Ln ions are linked through a network of triangles and hexagons [1]. Despite the strong exchange interaction (θcW = ~12 K), long range ordering develops in SrEr2O4 only at 0.75 K [2]. The structure consists of FM chains running along the c axis, two adjacent chains being stacked antiferromagnetically. The moments point along the c direction, but only one of the two Er sites has a sizeable moment of 4.5 μB. An unusual behaviour in SrEr2O4 is observed in an applied field, where for Halce, a field of 0.5 T completely destroys long range magnetic order and introduces instead some sort of state with short range magnetic correlations. This conclusion is reached on the basis of neutron diffraction experiment at ISIS, where a replacement of the sharp Bragg peaks by broad diffuse scattering features is observed. A further increase in magnetic field causes a restoration of the long range order and a disappearance of the diffuse scattering. These observations resemble the behaviour seen around a quantum critical phase transition, although additional investigations are required to prove the presence of a QCP in SrEr2O4. [1] H. Karunadasa et al., Phys. Rev. B 71, 144414 (2005). [2] O.A. Petrenko et al., Phys. Rev. B 78, 184410 (2008).

8:36AM P32.00002 Magnetic and magnetotransport properties of organic trilayers of alkanedithiol self-assembled monolayers sandwiched between ferromagnetic thin films, WILLIAM RICE, JEREMY NISKALA, JEFF HALLER, PAUL HOERTZ, WEI YOU, FRANK TSUI, University of North Carolina at Chapel Hill — Magnetic and magnetotransport properties of organic spin valve structures have been studied. The organic trilayer structure consists of a self-assembled monolayer (SAM) of alkanedithiol sandwiched between two ferromagnetic metal contacts, a Ni film as the bottom contact and a Co film as the top contact. The SAM was formed using novel methods on the Ni surface on the bottom of the vertical structure. Two alternative designs have been developed, one uses an additional conducting polymer layer for electrical isolation during thermal evaporation of the top Co contact and another uses nanotransfer printing to directly apply the top Co contact. Each trilayer was examined in vacuum using 4-terminal transport measurements. Both designs have indicated tunneling as the transport mechanism between contacts. Magnetooptic Kerr Effect (MOKE) measurements show independent switching of the ferromagnetic layers at approximately 50 and 100 Gauss. Magnetotransport measurements were carried out as a function of bias voltage, temperature and field, in order to explore spin-dependent transport through the organic interlayer.

8:48AM P32.00003 Effects of interface microstructure on magnetotransport in organic spin valve structures1, YAOHUA LIU, TAEKWON LEE, M.E. KATZ, D.H. REICH, The Johns Hopkins University, S.M. WATSON, J.A. BORCHERS, NIST Center for Neutron Research — Organic semiconductors hold promise for spintronics because of their potentially long spin diffusion length. We have studied Fe/Alq3 (tris-(8-hydroxyquinoline) aluminum)/Co multilayer films with Alq3 thickness in the range 50 to 150 nm.[1] Similar to previously reported results, we found considerable variability in the magnetotransport properties for cross junctions made in nominally identical conditions. To explore the sources of these effects, we studied the microstructure of such multilayer films by X-ray reflectometry and polarized neutron reflectometry (PNR). We found that the films show well-defined layers with limited chemical intermixing (3-5 nm) at the Alq3/ferromagnet (FM) interfaces. However, larger magnetoresistance (MR) is associated with sharper Alq3/FM interfaces, and with a magnetically dead Fe-rich region at the Alq3/Fe interface, which may potentially circumvent the resistivity mismatch problem. The PNR data also show that the Co layer on top of the Alq3 can adopt a multi-domain magnetic structure at low field and a perfect anti-parallel state is not obtained. [1] Y. Liu et al., arXiv:0810.0289v1.

1Work Supported by NSF Grant No. DMR-0520491.
9:00AM P32.00004 Enhanced Magnetoresistance in Alq3-based spin valve using buffer-layer assisted growth1, DALI SUN, Oak Ridge National Laboratory / Institute of Physics, Chinese Academy of Sciences, CHENGJUN SUN, LIFENG YIN, HANGWEN GUO, ZHENG GAI, XIAOGUANG ZHANG, Oak Ridge National Laboratory, ZHAO-HUA CHENG, Institute of Physics, Chinese Academy of Sciences, JIAN SHEN, Oak Ridge National Laboratory / The Univ. Tennessee — In the field of organic spintronics, interfacial diffusion between magnetic electrodes and organic spacer layers is a serious problem for both understanding the underlying mechanism and achieving high magnetoresistance. Using buffer layer assist growth, we have successfully fabricated vertical organic spin valves with much sharper interface. Spin valves prepared by this method exhibit considerably larger magnetoresistance. The spacer layer thickness-dependent magnetoresistance suggests that field-dependent interfacial barrier plays the crucial role for the observed magnetoresistance.

1Supported by the Division of Materials Science and Engineering, U. S. DOE.

9:12AM P32.00005 Spin and Charge Injection and Transport in Ferromagnet/Organic Semiconductor/Ferromagnet Heterojunction1, JUNG-WOO YOO, Department of Physics, The Ohio State University, H. W. JANG, C. B. EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, CHI-YUEH KAO, Department of Chemistry, The Ohio State University, A. J. EPSTEIN, Department of Physics and Chemistry, The Ohio State University — We studied the spin injection and transport in organic semiconductor by employing LSMO and Fe as an anode and cathode in hybrid spin valve structure. Using thin layer (t < 10 nm) of rubrene as a spacer, our device displays MR as high as 50 % at low temperature and at low bias voltage. The charge injection into organic spacer in our devices is injection limited. At high applied voltage (V > Vth) field-driven current prevails in current density through the organic semiconductor. At low bias V, inelastic hopping followed by thermionic emission is dominant at high T, which decreases significantly as T lowered. And eventually the current density through the device becomes purely tunneling at low T and V. The spin and charge injection, effects of inclusion of tunneling barrier, and the effects of crystallinity of organic layer will be discussed.

9:24AM P32.00006 Spin filtering of Photo-excited charge from Organic Nanostructures1, ADITYA MOHITE, BRUCE ALPHENAAR, University of Louisville, TIFFANY SANTOS, JAGADEESH MOODERA, MIT, MIT COLLABORATION — In organic materials, coupling between the incident photon and the electron spin is very weak. Here we demonstrate that spin filtering materials can be used to induce intersystem crossing, and allow the spin polarized triplet excitonic states to be probed. A thin layer of EuS was deposited at the interface formed between a single-wall nanotube and an aluminum contact. EuS is a “spin filtering material,” a ferromagnetic insulator with large spin-orbit coupling, allowing preferential tunneling by electrons of a preferred spin direction. A small magnetic field is applied to align the electron spin in the EuS with the carbon nanotube. The enhanced spin-orbit interaction allows for observation of a low-energy peak in the capacitive photocurrent scan. The energy spacing between the two peaks matches closely with the theoretical predictions for the S−T1 spacing in nanotubes. Further measurements of the triplet peak reveal that its magnitude depends on the orientation of the B-field with maximum peak occurring when the spins in EuS line up with the nanotube axis. These measurements suggest that introduction of a spin filtering layer could be used to study the triplet formation in organic solar cell materials.

9:36AM P32.00007 Spin and charge transport study in single crystal organic semiconductors1, KARTHIK V. RAMAN, CARLIJN L. MULDER, MARC A. BALDO, JAGADEESH S. MOODERA, MIT — Spin transport studies in amorphous rubrene films have shown exciting and promising results [1]. A large spin diffusion length in these amorphous films has increased the motivation to perform spin transport study in high purity single crystal rubrene. This will provide the fundamental understanding on the spin transport behavior in OS; not influenced by defects or traps. We will present work on small channel single crystal rubrene FET device with magnetic electrodes. For example, our preliminary studies have show mobility for FET with Co electrode to be 0.014cm²/V-s. A study on the spin and charge transport properties in single crystals of OS with magnetic electrodes is being done and the results will be reported. The influence of gate voltage and applied magnetic field on the transport properties will be discussed. [1] J.H. Shim et al., PRL 100, 226603 (2008)

9:48AM P32.00008 Inter-Molecular Spin-Orbital Coupling Effects on Magnetoresistance and Spin-Dependent Excited Processes in Organic Semiconductors1, LIANG YAN, BIN HU, University of Tennessee — A low magnetic field can change electrical current and electroluminescence in organic semiconductors, leading to magnetoresistance and magnetic field effects due to magnetic field-dependent singlet/triplet ratio involved in charge transport and excited states. In general, an external magnetic field can change singlet and triplet ratios through two major pathways: spin-dependent electron-hole pairing and field-dependent intersystem crossing. We found that tuning inter-molecular spin-orbital coupling leads to a significant change in magnetoresistance, electro-fluorescence, and electro-phosphorescence. These experimental findings indicate that (i) inter-molecular and intra-molecular electron-hole pairs account for magnetoresistance and magnetic field effects, respectively, (ii) spin mixing occurs in inter-molecular excited states, and (iii) spin-mixing is a function of both spin-orbital coupling and singlet-triplet energy difference. This presentation will discuss the effects of magnetic field on both spin-dependent electron-hole pairing and spin mixing in magnetoresistance and magnetic field effects in organic semiconductors.

10:00AM P32.00009 Magnetoresistance in the High Magnetic Field Regime for Organic Semiconductors1, J. L. MARTIN, V. N. PRIGODIN, J. D. BERGESON2, Dept. of Physics, The Ohio State University, C.Y. KAO, Dept. of Chemistry, The Ohio State University, A.J. EPSTEIN, Dept. of Physics and Dept of Chemistry, The Ohio State University — While there has been much study of the low field (of order 100 Oe) magnetoresistance in organic semiconductor (OSC) materials, very little has been done in high fields of order 10kOe. Magnetoresistance studies in the high field were conducted on the OSC materials tris-(8-hydroxyquinoline) aluminum (Alq3) and alpha sexithiophene (α-6T). The high field shows a different response from that of the low field and displays several features suggesting that multiple mechanisms are at work. In addition, the two materials demonstrate behaviors that differ from one another, suggesting different classes of OSC. The experimental results are discussed in the context of the MIST model [1], which attributes magnetoresistance to the recombination of electron-hole pairs with interconversion of singlets and triplets.

10:12AM P32.00010 Iron Nanoparticle Driven Spin-valve Behavior in Aligned Carbon Nanotube Arrays* — MARK B. MURPHNEY, JEREMY D. BERGESON, STEPHEN J. ETZKORN, The Ohio State University, Columbus, Ohio 43210-1117, LIANGTI QU, JUNQING YANG, LIMING DAI, University of Dayton, Dayton, Ohio 45469-0246, ARTHUR J. EPSTEIN, The Ohio State University, Columbus, Ohio 43210-1117 — Spin-valve structures have been constructed from aligned arrays of carbon nanotubes, yielding a magnetoresistance reaching 25%. In addition to including vertically aligned carbon nanotube arrays, iron catalyst nanoparticles that form the array function as the second ferromagnetic electrode. Reversal of the magnetization of the electrode in an applied magnetic field results in a clear peak in the resistance of the device. A spin scattering length in excess of 9 µm shows excellent spin transport through the nanotube array. The effect of oxide barriers and device patternability are explored. 1. Bergeson, et al., Appl. Phys. Lett. 93, 172505 (2008) *This work is supported in part by DOE Grant Nos. 10:24AM P32.00011 ABSTRACT WITHDRAWN —

10:36AM P32.00012 Electrically controlled g-factor and magnetism in conjugated metal-organic molecules 1, ZHI-GANG YU, SRI International — Conjugated metalorganic molecules have localized spins at the central transition-metal ions and mobile π-electrons in the surrounding ligands. Here we construct model Hamiltonians based on first-principles calculations to describe spins at the ions and π-electrons in the ligands. It is shown that the g-factor and magnetic susceptibility in such a molecule can be tuned to a great extent by an electrical voltage across one of the ligands. The underlying physics is that the voltage modifies the charge distribution of the ligand, which in turn changes the interplay of the ion’s spin-orbit coupling and the energy splitting among its orbital states. The capability of controlling the g-factor and magnetism at the molecular level has great implications in quantum information storage and processing.

10:48AM P32.00013 Magnetic-Field-Driven Ising Quantum Criticality of Two-Dimensional Square-Lattice Antiferromagnet Cr(dien)(O2)2.H2O — N. KAUR, G. PREAMPLUME, N. DALAL, Department of Chemistry, Florida State University, A. KUMAR, Department of Physics, Florida State University, Y. H. KIM, Y. TAKANO, Department of Physics, University of Florida, S. NELLUTLA, Y. J. JO, L. BALICAS, National High Magnetic Field Laboratory, Tallahassee, FL — We report on a systematic study of magnetically driven quantum phase transition in a new compound based on Cr(IV). The compound, Cr(dien)(O2)2.H2O, is a low-dimensional antiferromagnet with a Neel temperature TN of 2.55 K in zero field. We have used torque magnetometry, heat capacity and magnetocaloric-effect measurements down to 200 mK, to obtain a complete magnetic phase diagram. A detailed analysis of the dependence of TN on magnetic field using the power law TN ∝ (Hc−H)α yielded the critical exponent α = 2.01±0.02, with Hc = 12.392±0.003 T, indicating that this system behaves like a 3-d Ising magnet at low temperatures.

Wednesday, March 18, 2009 8:00AM - 10:48AM — Session P33 DCMP: Superconductivity: Electronic Structure II 403

8:00AM P33.00001 Universality of momentum-dependent charge-transfer excitations in the undoped cuprates measured by resonant inelastic X-ray scattering — GUILLAUME CHABOT-COUTURE, Stanford University, JASON HANCOK, Stanford University/SSRL, LI LU, PATRICK MANG, OWEN VAJK, Stanford University, DIEGO CASA, THOMAS GOG, Advanced Photon Source, ANL, MARTIN GREVEN, Stanford University/SSRL — From its conception, the study of charge-transfer excitations in the cuprates has driven the majority of resonant inelastic X-ray scattering (RIXS) research. Still, to this day, there exists more variation among published RIXS spectra and their interpretation than common ground. By carefully studying the momentum-dependent spectral weight of three of the most important undoped cuprates — La2CuO4, Nd2CuO4, and Sr2CuO3Cl2—we present evidence of universality of the observed charge-transfer excitations. To clarify and highlight this observation, we construct dispersion diagrams and study the incident energy dependence. Comparison to Hubbard model predictions suggests that the essence of this universality is captured already by one-band physics, while material dependence and cross-sectional effects only obfuscate this behavior.

8:12AM P33.00002 Momentum-Resolved Cu K-edge RIXS Spectra in the Insulating Parent Compounds of High Tc Superconductors — C-C. CHEN, B. MORITZ, Stanford University and SLAC, F. VERNAY, Paul Scherrer Institut, S. JOHNSTON, University of Waterloo and SLAC, J. HANCOK, G. CHABOT-COUTURE, M. GREVEN, Stanford University and SLAC, I. ELFIMOV, G. A. SAWATZKY, University of British Columbia, T. P. DEVEREAUX, Stanford University and SLAC — Resonant inelastic X-ray scattering (RIXS) has the ability to highlight various many-body excitations that can be characterized by photon momentum transfer and energy loss. Exact Diagonalization calculations on small clusters were carried out to investigate the nature of the excitations seen in RIXS spectra in the parent compounds of high Tc superconductors. The model many-body calculation includes electronic orbitals necessary to highlight Zhang-Rice singlets, charge transfer and d-d excitations, as well as states with significant apical character. The influence of different orbitals on the RIXS spectra is studied, and the character of the excitations in different regions of the Brillouin zone is determined as well.

8:24AM P33.00003 Momentum dependence of the electron-phonon coupling, phonon-induced pairing interaction, and self-energy effects in YBa2Cu3O7 within the local density approximation — ROLF HEID, KLAUS-PETER BOHNNEN, Forschungszentrum Karlsruhe, IFP, Germany, DIRK MANSKE, ROLAND ZEYHER, Max-Planck-Institut for Solid State Physics, Stuttgart, Germany — Using the local density approximation (LDA) and a realistic phonon spectrum we calculate the momentum and frequency dependence of the electron-phonon coupling in YBa2Cu3O7 and determine its consequences for the phonon-induced pairing interaction and for the electronic self-energy in the normal state. The phonon-induced interaction has a pronounced peak for large momentum transfers and the interband contributions between bonding and antibonding band are of the same magnitude as the intraband ones. The dimensionless coupling constant in the d-wave channel λd, relevant for superconductivity, is only 0.022, i.e., even about ten times smaller than the small value of the s-wave channel. For electronic states at the Fermi energy, the maximum in the real part of the phonon-induced self-energy at low frequencies is about a factor 5 too small compared to the experiment, resulting in a very small and smooth change in the slope of the electronic dispersion [1]. These findings suggest that phonons are not the important low-energy excitations, and cannot produce well-pronounced peaks in YBa2Cu3O7, at least, within LDA. [1] Heid, Bohnen, Zeyher,Manske, PRL 100, 137001 (2008).
8:36AM P33.00004 Electronic Properties of Rocksalt Copper Monoxide, PAUL MICHAEL GRANT, W2AGZ Technologies — Rocksalt copper monoxide, although not yet synthetically realized in bulk form, can be studied computationally as a proxy for the family of layered HTSC copper oxides. We report results for a series of tetragonal CuO rocksalt structures with c/a lattice parameter ratios ranging from 1.0 to 1.5, employing the plane-wave pseudopotential method with exchange-correlation LDA+U. As expected, we obtain a metallic state for U = 0 at all values of c/a given that the nominal valence electron configuration for Cu in copper monoxides is 3d10 yielding a partially occupied conduction band. However, completely unexpected was our finding similar nominal properties in rocksalt CuO for all physically plausible values of U (up to 10 eV) and c/a between 1.0 to approximately 1.2. Only for c/a > 1.2 do our calculations reveal the opening of a Mott-Hubbard charge-transfer gap. We interpret our results as supporting the original motivations of Bednorz and Mueller that high temperature superconductivity in the layered copper oxide perovskites may begin with their tendency to exhibit Jahn-Teller strong electron-phonon coupling.1

8:48AM P33.00005 Electronic Structure of Superconducting FeSe Studied by Photoemission Spectroscopy1, RIKIYA YOSHIDA, Okayama University, TAKANORI WAKITA, RLSS-Okayama University, JST-TRIP, HIROYUKI OKAZAKI, Okayama University, YOSHIKAZU MIZUGUCHI, University of Tsukuba, NIMS, SHUNSUKE TSUDA, NIMS, WPI-MANA-NIMS, JST-TRIP, YOSHIIHIKO TAKANO, NIMS, University of Tsukuba, JST-TRIP, HIROYUKI TAKEYA, KAZUTO HIRATA, NIMS, TAKAYUKI MURO, JASRI/SPRING-8, MARIO OKAWA, KYOKO ISHIZAKA, ISSP-The University of Tokyo, SHIK SHIN, ISSP-The University of Tokyo, RIKEN, HISATOMO HARIMA, Kobe University, JST-TRIP, MASAACKI HIRAI, YUJI MUROKA, TAKAYOSHI YOKOYA, RLSS-Okayama University, JST-TRIP — We have performed soft x-ray and ultrahigh-resolution laser photoemission measurements on tetragonal FeSe, which was recently identified as a superconductor. Energy dependent study of valence band is compared to band structure calculations and yields a reasonable assignment of partial densities of states. However, the sharp peak near the Fermi level slightly deviates from the calculated energy level, showing the importance of self-energy correction. We have also performed an ultrahigh-resolution laser photoemission experiment on FeSe and observed the suppression of intensity around the Fermi level upon cooling.

9:00AM P33.00006 Generic phase diagram of “electron-doped” T′ cuprates, M. NAITO, O. MATSUMOTO, A. UTSUKI, Tokyo University of Agriculture and Technology, A. TSUKADA, Stanford University, H. YAMAMOTO, NTT BRL., T. MANABE, AIST — The electronic phase diagram of cuprate superconductors is a key ingredient to understand the still unresolved mechanism of high-temperature superconductivity. A particular interesting question is the differences and similarities between the hole- and electron-doped sides. The phase diagram of hole-doped high-Tc cuprates has been well established, and shows a well-known “dome” shape with maximal superconductivity at a doping level of about 0.15. In contrast, the phase diagram of the electron-doped side is controversial. This is because the superconductivity in the T′ cuprates deteriorates seriously by the presence of impurity oxygen (Oimp) atoms, which have to be cleaned up in order to unveil the generic phase diagram of the T′-cuprates. We investigated the generic phase diagram of the electron doped superconductor, Nd2−xCexCuO4 using films prepared by metal organic decomposition. After careful oxygen reduction treatment to remove interstitial Oimp atoms, we found that the Tc increases monotonically from 24 K to 29 K with decreasing x from 0.15 to 0.00, demonstrating a quite different phase diagram from the previous bulk one. The implication of our results is discussed on the basis of tremendous influence of Oimp “impurities” on superconductivity and also magnetism in T′ cuprates.

9:12AM P33.00007 Band-theory description of hole localization and singlet polarons in doped cuprates, ALESSIO FILIPPETTI, DANilo PUGGINI, VINCENTMO FIORENTINI, CNR-INFM SLACS and University of Cagliari, CNR-INFM SLACS TEAM — We use an advanced ad-initio band theory (the pseudo-self interaction corrected local density approach, pSIC) to describe spin-compensated polarons (e.g. Zhang-Rice singlets (ZRS)) typical of low-dimensional doped cuprates. Despite their many-body nature, ZRS can be transparently interpreted via (and, in fact, constructed from) single-particle states, provided that band theory describes accurately enough their localization in the limit of vanishing band dispersion. We provide examples of polarons in real materials, specifically chain-like Ca2+1−yFe+yCu3O4 and the high-Tc superconductor (HTSC) Y1−x−3Ba2+xCu3O6+y. The former is the ideal prototype of doped one-dimensional cuprate with zig-zag Cu-O interactions. Studying the electronic and magnetic properties over the full range of possible doping, we identify several different polaron-dominated ground states and the attendant phase transitions. Furthermore, ZRS are key to the behavior of doped CuO2 units in HTSC. We show how their occurrence can dramatically affect the electronic properties (e.g. the Fermi surface) in underdoped Y1−x−3Ca2+xBa2−xCu3O6+y.

9:24AM P33.00008 Interplay of Ca and O doping in Y1−x−3Ca2+xBa2−xCu3O6+y studied by first-principles calculations, VINCENTMO FIORENTINI, ALESSIO FILIPPETTI, DANilo PUGGINI, CNR-INFM SLACS and University of Cagliari — Experiments reveal an impressive asymmetry in most aspects (involving e.g. magnetic, superconducting, or structural properties) of high-Tc superconductors upon cation or oxygen doping, respectively. A thorough understanding of this asymmetry cannot eschew a rigorous description of the fundamental mechanism ruling electronic and structural properties for each (x,y) doping combination. Here we present results obtained by the pseudo-self-interaction free density functional (pSIC) method, which is capable to describe metal-insulating transitions in several cuprate materials. We describe in detail the chemistry of the distinct insulating-metal transitions occurring in the CuO chains and in the CuO2 planes in the YBa2Cu3O6+y for y=0[0.5]. We then show that interactions with chains crucially affect the ability of Ca doping to inject holes in CuO2 planes. The dramatic effects of this double-doping interplay on the magnetic and superconducting properties of underdoped Y1−x−3Ca2+xBa2−xCu3O6+y cannot be understood by the disentangled action of the individual doping sources.

9:36AM P33.00009 Possible enhancements of AFM spin-fluctuations in high-Tc cuprates, THOMAS JARLBORG, DPNC, University of Geneva, CH-1211 Geneva 4, Switzerland — Ab-initio band calculations for high-Tc superconductors based of a free electron like band, show a strong interaction between anti-ferromagnetic (AFM) spin waves and periodic lattice distortions as for phonons, even though this type of spin-phonon coupling (SPC) is underestimated in calculations using the local density approximation. The SPC has a direct influence on the properties of the HTSC cuprates and it can explain many observations. The strongest effects are seen for modulated waves in the CuO bond direction, and a band gap is formed near the X,Y points, but unusual band dispersion (like “waterfalls”) might also be induced below the Fermi energy (EF) in the diagonal direction. The band results are used to propose different ways of increasing AFM spin-fluctuations locally, and to have a higher density-of-states (DOS) at EF. Static potential modulations, via periodic distribution of dopants or lattice distortions, can be tuned to increase the DOS. This opens for possibilities to enhance coupling for spin fluctuations (Δω) and superconductivity. The exchange enhancement is in general increased near a surface, which suggests a tendency towards static spin configurations. The sensitivity of the band results to corrections of the local density potential are discussed.
9:48AM P33.00010 Interband Transitions in La$_2-x$Sr$_x$CuO$_4$ observed by Resonant Inelastic X-Ray Scattering, D.S. ELLIS, JUNGHO KIM, H. ZHANG, University of Toronto, S. WAKIMOTO, JAERI, J.P. HILL, Brookhaven National Lab., Y. ANDO, S. KOMiya, CREIEL, D. CASA, T. GOc, Argonne National Lab., Y.-J. KIM, University of Toronto — Resonant inelastic x-ray scattering measures the energy and momentum dependence of electronic excitations, whose probabilities are resonantly enhanced, in this study, by utilizing hard x-rays at the Cu K-edge absorption energy. Three main features in the resonant inelastic x-ray scattering spectrum of La$_2-x$Sr$_x$CuO$_4$ were observed to develop as the doping $x$ increased from the underdoped to the overdoped region of the high-temperature superconductor phase diagram. Measured at the zone-boundary momentum transfer ($\sim 0$), the spectra consist of three main peaks: one peak below an isosbestic point at 2.2 eV which strengthens at high doping, and two broad peaks above - one at 3.3 eV increasing in energy and decreasing in intensity, and the other stationary at higher energy. Taking a cue from existing band structure calculations, these peaks are interpreted as the transitions between stationary bands of non-bonding Oxygen, a Zhang-Rice singlet type band at the Fermi level, and the upper Hubbard band. These transitions are also discussed in the context of existing angle-resolved photoemission data.

10:00AM P33.00011 Off gap interface reflectivity of electron waves in Fabry Perot resonators, ARITZ LEONARDO, P.M. ECHENIQUE, E. CHULKOV, F. SCHILLER, J.E. ORTEGA — The interface reflectivity in the MgW(110) metallic quantum well is from line shape analysis of high resolution photo emission. A quick reflectivity drop is found away from high band of the appropriate symmetry near Ef, such that the interface overcomes the bulk like quasi particle lifetime as the line broadening mechanism. A nearly free electron model for the W(110) substrate band structure demonstrates coherent wave function scattering is the relevant mechanism determines the interface reflectivity in the resonator.

10:12AM P33.00012 Quasiparticle dispersion anomaly induced by the spin excitation in electron-doped cuprates, TAO ZHOU, CHIN-SEN TING, Texas Center for Superconductivity, University of Houston — It is proposed that the 50 – 70 meV dispersion anomaly (kink) in electron-doped cuprates revealed by recent angle-resolved photoemission spectroscopy experiments is caused by coupling with the spin fluctuation. We elaborate that the kink exists both along nodal and antinodal directions, and both in the superconducting and normal state. The renormalized effect for the density of states is also studied and the hump feature outside the superconducting coherent peak is established, consistent with recent scanning tunneling microscopy experiments.

10:24AM P33.00013 Weak flux pinning in the phase separated La$_2-x$Sr$_x$CuO$_{4+y}$ system, HASHINI MOHOTTALA, University of Hartford, BARRETT O. WELLS, JOSEPH I. BUDNICK, WILLIAM A. HINES, University of Connecticut — We have studied the magnetic characteristics of a series of super-oxygenated La$_2-x$Sr$_x$CuO$_{4+y}$ samples. According to our previous studies, these samples spontaneously phase separate to give an oxygen rich superconducting phase with a $T_c$ near 40 K and an oxygen poor magnetic phase that also orders near 40 K. All our samples showed a large reversibility in magnetization at different temperatures. Although the internal magnetic regions were expected to behave as pinning sites, our present study shows that they do not favor flux pinning. In terms of the matching principle between the defect and the coherence length, the regions that are larger than the coherence length cannot act as flux pinning centers. Thus our results imply that the magnetic regions are too large to act as pinning centers. Overall less flux pinning in the oxygen rich system also suggests that the separate superconducting regions in the system are more homogeneous.

This work was partially supported by the US-DOE through contract DE-FG02-00ER45801.

10:36AM P33.00014 Preparation of undoped superconducting T*-RE$_2$CuO$_4$ by MBE with ex-situ post-reduction, HIDEKI YAMAMOTO, NTT Basic Research Labs., OSAMU MATSUMOTO, MICHIO NAITO, Tokyo University of Agriculture and Technology — It has recently been revealed that the optimally-reduced end-member compounds T*-RE$_2$CuO$_4$ ($RE = Pr, Nd, Sm, Eu, Gd$) show superconductivity with $T_c$ over 30K [1] although they are commonly believed as Mott insulators. The superconducting specimens were produced by metal organic decomposition (MOD) with elaborated reduction procedures, where the advantage of thin-films, large surface-to-volume ratio, is fully utilized to achieve the optimal oxygen configuration. Their single-crystalline thin films prepared by UVH-based process may have a further advantage of providing a good opportunity to observe the superconducting order parameter highly in these materials using powerful but surface-sensitive probes such as ARPES and STM. With this motivation in mind, we grew 100-nm-thick T*-RE$_2$CuO$_4$ ($RE = Pr, Nd, Sm$) films on SrTiO$_3$ substrates by MBE. The as-grown films were semiconducting. However, with a post-reduction treatment in a tubular furnace, which is essentially identical to that for the MOD films, the MBE films became metallic and showed superconductivity at $\sim 30K$, indicating that the superconducting films are potentially obtainable through in-vacuo process by tuning up the reduction conditions. [1] O. Matsumoto et al., Physica C 468 (2008) 1148; M. Naito et al., J. Phys. Conf. Ser. 108 (2008) 012037.

Wednesday, March 18, 2009 8:00AM - 11:00AM — Session P34 DCMP: Superconductivity: STM 404

8:00AM P34.00001 Heating Effects in Interlayer Tunneling Spectroscopy of Bi$_{2}$Sr$_{1-x}$Ca$_{x}$Cu$_{2}$O$_{y+\delta}$ as Inferred from Single Junction Methods, C. KURTER, Argonne National Lab., J.F. ZASADZINSKI, Illinois Institute of Technology, L. OZYUZER, Izmir Institute of Technology, D.G. HINKS, K.E. GRAY, Argonne National Laboratory, EMERGING MATERIALS GROUP TEAM, ILLINOIS INST. OF TECH. COLLABORATION, IZMIR INST. OF TECH. COLLABORATION — In order to study Joule-heating effects on small intrinsic Josephson junction (IJJ) stacks or mesas, we compare their current-voltage curves, I(V), with those of single junctions, both using Bi$_2$Sr$_{1-x}$Ca$_x$Cu$_2$O$_{y+\delta}$ (Ca-Bi2212) intercalated by HgBr$_2$. Even for small volume stacks with reduced dissipation by intercalation, there can be self-heating despite the absence of the commonly seen backbending of I(V). This conclusion is based on distinctive features of I(V) of intermediate size mesas which were absent in single junctions.

8:12AM P34.00002 Development of a novel variable temperature scanning tunneling microscope and discovery of spectral weight shift between two bands across Tc in underdoped Bi2212, JIHINHWAN LEE, K. FUJITA, C.K. KIM, A. SCHMIDT, LASSP, Cornell Univ., H. EISAKI, AIST, Japan, S. UCHIDA, Dept. of Physics, Univ. of Tokyo, Japan, J.C. DAVIS, LASSP, Cornell Univ. — We investigated the quasiparticle interference as a function of temperature for underdoped Bi2212 with Tc=42K, using the newly developed variable temperature STM. Due to increased $S/N$ and resolution, we could observe for the first time the dispersing octet peaks well above Tc. With novel high momentum resolution analysis we also found that each octet peak actually consists of two bands with distinct dispersions and observed clear spectral weight shift from one band, corresponding to the Bogoliubov quasiparticle whose dispersion depends sensitively on the temperature, to the other, with dispersion roughly following the normal state band structure with no significant temperature dependence, as we cross Tc from the superconducting state to the pseudogap state. This new discovery may shed new insight to our understanding of the pseudogap state of the underdoped cuprate superconductor.
8:24AM P34.00003 Imaging the Vortex Liquid State in Bi$_2$Sr$_2$CuO$_{8+\delta}$, T.L. WILLIAMS, M. ZECH, YI YIN, Harvard University, T. KONDO, Ames Laboratory, Iowa State University, T. TAKEUCHI, H. IKUTA, Nagoya University, J.E. HOFFMAN, Harvard University — We use a low temperature scanning tunneling microscope (STM) to study the vortex state of the high-$T_c$ superconductor Bi$_2$Sr$_2$CuO$_{8+\delta}$ in magnetic fields up to 9 T. At a temperature of 6 Kelvin, we find no localized vortices down to H = 0.25 T. However, the gap depth from the spatially averaged $d_{1/2}$ spectrum decreases with increasing magnetic field, which indicates a vortex liquid state. By tracking atomically resolved locations at different magnetic fields, we apply a normalization technique to remove inhomogeneities in the underlying density of states, revealing a more homogeneous superconducting state.

8:36AM P34.00004 Coexistence of competing orders with two energy gaps in real and momentum space in the High $T_c$ Superconductor Bi$_2$Sr$_2$La$_x$CuO$_{8+\delta}$, JIJUA MA, Z.-H. PAN, F.C. NIESTEMSKI, M. NEUPANE, Y.-M. Xu, ZIQAING WANG, VIDYA MADHAVAN, Department of Physics, Boston College, M. ODA, M. IDO, Department of Physics, Hokkaido University, Sapporo 060-0810, Japan, N. MOMONO, Department of Materials Science and Engineering, Muroran Institute of Technology, Muroran 050-8585, Japan, M. ODA, M. IDO, Department of Physics, Hokkaido University, Sapporo 060-0810, Japan, NOKI MOMONO COLLABORATION, WPI ADVANCED INSTITUTE FOR MATERIALS RESEARCH, TOHOKU UNIVERSITY COLLABORATION, DEPARTMENT OF PHYSICS, TOHOKU UNIVERSITY COLLABORATION, INSTITUTE OF PHYSICS AND NATIONAL LABORATORY FOR CONDENSED MATTER PHYSICS OF CHINA COLLABORATION — We have performed scanning tunneling microscopy and angle-resolved photoemission spectroscopy on optimally doped and overdoped Bi$_2$Sr$_2$La$_x$CuO$_{8+\delta}$. We observe two distinct energy gaps that coexist both in real space and in the antinodal region of momentum space below $T_c$. We find that the small gap is associated with superconductivity. The large gap persists above $T_C$ and seems to be linked to observed charge order. We also find a strong correlation between these two gaps suggesting they are affected by similar physical processes.

8:48AM P34.00005 Coexistence of superconducting and pseudogap quasiparticles in underdoped Bi2212: Studies of STM/STS and ultra-fast optical spectroscopy, Y. H. LIU, T. KUROSAWA, Department of Physics, Hokkaido University, Sapporo 060-0810, Japan, Y. TODA, K. SHIMATAKE, Department of Applied Physics and Division of Innovative Research CRIS Hokkaido University, Sapporo 060-0810, Japan, N. MOMONO, Department of Materials Science and Engineering, Muroran Institute of Technology, Muroran 050-8585, Japan, M. ODA, M. IDO, Department of Physics, Hokkaido University, Sapporo 060-0810, Japan, NOKI MOMONO COLLABORATION, Y. TODA COLLABORATION — At present, the relationship between superconducting (SC) gap and pseudogap (PG) of cuprate superconductors is still under intense debate. Here, we present our recent results of the electronic structure and quasiparticle dynamics measured by STM/STS and ultra-fast optical spectroscopy on underdoped Bi2212 crystals, which provide direct evidence that SC and PG quasiparticles coexist below $T_c$. We will also discuss the origins of the periodic charge order and the nano-scale electronic inhomogeneity.

3}(Present address) Department of Physics and Astronomy, Ohio University, Athens, OH 45701

9:00AM P34.00006 Origin of electron-hole asymmetry in the scanning tunneling spectrum of Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$, A. Bansil, Northeastern U., JOUKO NIEMINEN, Tampere U. of Tech., Finland and Northeastern U., HSIN LIN, R. S. Markiewicz, Northeastern U. — We have developed a material specific theoretical framework for modelling scanning tunneling spectroscopy (STS) of high temperature superconducting materials in the normal as well as the superconducting state. Results for Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ show clearly that the tunneling process strongly modifies the STS spectrum from the local density of states (LDOS) of the $d_{x^2-y^2}$ orbital of Cu. The dominant tunneling channel to the surface Bi involves the $d_{x^2-y^2}$ orbitals of the four neighboring Cu atoms. In accord with experimental observations, the computed spectrum displays a remarkable asymmetry between the processes of electron injection and extraction, which arises from contributions of $d_{x^2}$ and other orbitals to the tunneling current. Work supported in part by the USDOE.

9:12AM P34.00007 The Impact of an Oxygen Dopant in an ideal Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ Crystal, STEVE JOHNSTON, University of Waterloo, Waterloo, ON, Canada., FRANCOIS VERNAY, Paul Scherrer Institut, Villigen PSI, Switzerland, T. P. Devreux, SLAC National Lab, Stanford, Menlo Park, CA — Scanning tunneling microscopy studies have shown that local nanoscale pairing inhomogeneities are correlated with interstitial oxygen dopants in Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$. Combining electrostatic and cluster calculations, we examine the impact of a dopant on the local Madelung and charge transfer energies, magnetic exchange $J$, Zhang-Rice mobility, and interactions with the lattice. It is found that electrostatic modifications locally increase the charge transfer energy and slightly suppresses $J$. It is further shown that coupling to c-axis phonons is strongly modified near the dopant. The combined effects yield broadened spectral features, reduced charge gap energies, and a sizable local increase of $J$ implying a strong local interplay between antiferromagnetism, polaron, and superconducting pairing.

9:24AM P34.00008 Tunneling Spectral Dip Feature in High Tc Cuprates: Experiment and Analysis, JOHN ZASADZINSKI, LIAM COFFEY, CHIAN KURTER, Illinois Institute of Technology, KEN GRAY, Argonne National Laboratory — A fully self-consistent Eliashberg analysis is presented to analyze the spectral dip feature observed in tunnel junctions on Bi2212. Methods include SIS break junctions, intrinsic Josephson junctions in mesas and SIN junctions from STM. This analysis is presented for a variety of doping levels and the resulting electron-boson spectral function and self-energy is compared with other spectroscopic probes. Evidence of spectral dip features in other high Tc cuprates is presented including Tl2212 to demonstrate the universality of the spectral dip and its relation to the mechanism of pairing.

9:36AM P34.00009 Phenomenological model of the bipartite electronic structure of Bi2Sr2CaCu2O8+d: Predicting bulk thermodynamic quantities from tunneling spectroscopy, J.W. ALLDREDGE, University of Colorado Boulder, K. FUJITA, Cornell University, JINHO LEE, Brookhaven National Laboratory, M. WANG, Cornell University, H. EISAKI, AIIST-Tsukuba, S. UCHIDA, University of Tokyo, P.J. HIRSCHFELD, University of Florida, J.C. DAVIS, Cornell University, K. MCELROY, University of Colorado Boulder — Using high quality local STM maps with corresponding quasiparticle interference data, we develop a complete phenomenological description of the density of states in Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$. This not only describes the local density of states but also consistently describes the spectral density of states derived from the QPI. The model consists of a d-wave gap structure at high energy. At low energies is has an additional higher harmonic term in the d-wave gap. Using this we capture not only the high energy gap signature but also the low energy features in the LDOS which accompany the termination of the QPI signal and this allows us to quantitatively measure the features across a wide series of dopings showing consistency between real and k-space. The use of this simple model allows us to successfully predict superfluid density, confirming that our model can successfully determine bulk physics from a local measurement.
there is a significant enhancement in the stability of vortices against thermal fluctuations. \[1\] Gorky Shaw, Shyam Mohan, Jaivardhan Sinha and S. S. Banerjee* the blind holes pins which creates a barrier against vortex redistribution inside the sample. We propose that this barrier leads to a phase separation creating significant magnetic field sweep rate dependent metastable magnetization response \[1\]. Our results are explained on the basis of a unique collective action of 1stitial vortices as bosonic modes. We investigate these modes with increasing oxygen reduction which represents the third dimension in the electron-doped superconducting crystal with otherwise C4 rotational symmetry, stripe orientations in the presence of quenched disorder map to the random field Ising model. While the low temperature scanning tunneling microscope (STM). The effect of individual atomic impurities on the superconducting state has been studied. Tunneling spectroscopy at 0.4 K reveals clear spectroscopic signature of the magnetic impurities at atomic scale. We find that Co is in the weak scattering limit and the tunneling spectra are homogeneous on the sample surface with sharp coherent superconducting peaks. Mn instead acts as a strong scatter destroying superconductivity at atomic scale, even when the number of impurities is limited to just a few in a correlation volume. The effect of intercalation on the charge density waves will be discussed as well. This work was supported by UChicago Argonne, LLC, Operator of Argonne National Laboratory (‘Argonne’). 10:12AM P34.00012 Observation of vortices and hidden pseudogap from scanning tunneling spectroscopic (STS) studies of electron-doped cuprate superconductor La$_{1.85}$Sr$_{0.15}$CuO$_2$ (La-112) M.L. TEGUE, A.D. BEYER, N.-C. YEH, Phys. Dept, Caltech, Pasadena, CA, USA, S.-I. LEE, Phys. Dept Sogang U, Seoul, Korea — We present STS studies on the electron-doped cuprate superconductor La-112 as a function of magnetic field (H). The spatially resolved spectra manifest vortices, and the average vortex lattice constant scales consistently with Abrikosov’s theory. A hidden pseudogap ($V_{CO}$) smaller than the superconducting gap ($\Delta_{SC}$) is revealed inside the vortex core, and the core radius is comparable to the superconducting coherence length $\xi_{ab} = 4.86 \text{ nm}$. Analysis of the energy histograms reveals that $\Delta_{eff}$, where $\Delta_{eff}= [(\Delta_{SC})^2+(V_{CO})^2]^{1/2}$, shifts downward with increasing H from $\Delta_{eff}=122 \pm 0.8 \text{ meV}$ at H = 0 to a base value of $V_{CO}=8.5 \pm 0.6 \text{ meV}$ at H > 0. This finding differs from the behavior of conventional superconductors where the vortex-state spectral weight would shift continuously to lower energies with increasing H and show peaks at zero energy due to suppression of $\Delta_{SC}$ inside vortices. Finally, Fourier transformation of the vortex-state tunneling spectra will be reported and compared with results from other cuprates. Ref.: Teague et al., arxiv:0809.0541. Work supported by NSF Grant DMR-0405088.

10:24AM P34.00013 Noise Predictions for STM in Systems with Local Electronic Nematic Order, ERICA CARLSON, Purdue University, YEN LEE LOH, Ohio State University, KARIN DAHMEN, University of Illinois at Urbana-Champaign — We propose that thermal noise in local stripe orientation should be readily detectable via STM on systems in which local stripe orientations are strongly affected by quenched disorder. Stripes, a unidirectional, nanoscale modulation of electronic charge, are strongly affected by quenched disorder in two-dimensional and quasi-two-dimensional systems. While stripe orientations tend to lock to major lattice directions, dopant disorder locally breaks rotational symmetry. In a host crystal with otherwise C4 rotational symmetry, stripe orientations in the presence of quenched disorder map to the random field Ising model. While the low temperature state of such a system is generally a stripe glass in two dimensional or strongly layered systems, as the temperature is raised, stripe orientational fluctuations become more prevalent. We propose that these thermally excited fluctuations should be readily detectable in scanning tunneling spectroscopy as telegraph noise in the high voltage part of the local I(V) curves. We predict the spatial, temporal, and thermal evolution of such noise, including the circumstances under which such noise is most likely to be observed. In addition, we propose an in-situ test for assessing whether such noise is due to correlated fluctuations rather than independent switches.

---

10:36AM P34.00014 STM Study of Bosonic Modes in the Cuprate Superconductor Pr$_{0.88}$LaCe$_{0.12}$CuO$_4$, VIDYA MADHAVAN, FRANCIS NIESTEMSKI, Boston College Dept. of Physics, SHILIANG LI, University of Tennessee, PENGCHENG DAI, University of Tennessee & ORNL — We use a low temperature (4 K) ultra-high vacuum scanning tunneling microscope (STM) to investigate the electron-doped high temperature superconductor Pr$_{0.88}$LaCe$_{0.12}$CuO$_4$ (PLCCO). We examine the superconducting gap and the satellite features identified as bosonic modes. We investigate these modes with increasing oxygen reduction which represents the third dimension in the electron-doped superconducting phase diagram. We relate our findings to neutron scattering results performed on the same sample.

---

10:48AM P34.00015 Collective action of nanopatterned pins: barrier towards creating inter-stitial vortices*, GORKY SHAW, SHYAM MOHAN, JAIvardhan SINHA, SATYAJIT BANERJEE, Department of Physics, Indian Institute of Technology, Kanpur-208016, U. P., India — We show that by nano-patterning a superconductor (NbSe$_2$ singlecrystal) with an array of blind holes produces significant magnetic field sweep rate dependent metastable magnetization response.[1]. Our results are explained on the basis of a unique collective action of the blind holes pins which creates a barrier against vortex redistribution inside the sample. We propose that this barrier leads to a phase separation creating distinct population of vortices viz., those pinned on blind holes and those confined in the interstitials between the holes [1]. We find that due to the barrier, there is a significant enhancement in the stability of vortices against thermal fluctuations. [1] Gorky Shaw, Shyam Mohan, Jaivardhan Sinha and S. S. Banerjee* (submitted; xxx.lanl.gov/abs/0811.1256) *satyajit@itk.ac.in

8:00 AM P35.00001 Low-temperature thermal transport properties of BaNi$_2$As$_2$. NOBUYUKI KURITA, FILIP RONNING, YOSHIFUMI TOKIWA, ERIC D. BAUER, Los Alamos National Laboratory, ALASKA SUBEDI, Oak Ridge National Laboratory and University of Tennessee, DAVID J. SINGH, Oak Ridge National Laboratory, JOE D. THOMPSON, ROMAN MOYSHOVICH, Los Alamos National Laboratory — Low-temperature specific heat $C(T)$ and thermal conductivity $\kappa(T)$ measurements under magnetic field have been performed on a recently discovered Ni-based superconductor BaNi$_2$As$_2$ ($T_c \approx 0.7 K$). In zero field, $\kappa(T)$ shows $T^4$-linear behavior in the normal state and exhibits a BCS-like exponential decrease below $T_c$. The field dependence of the residual thermal conductivity extrapolated to zero temperature is indicative of a fully gapped superconductor. This conclusion is supported by the analysis of $C(T)$ data, which are well fit based on the BCS theory.

8:12 AM P35.00002 Anisotropy of electronic transport in the iron-pnictide superconductor Ba(Fe,Co)$_2$As$_2$. MAKARIY A. TANATAR, Ames Laboratory, N. NI, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, C. MARTIN, Ames Laboratory, R.T. GORDON, H. KIM, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, V.G. KOGAN, G.D. SAMOLYUK, S.L. BUD'KO, Ames Laboratory, P.C. CANFIELD, R. PROZOROV, Ames Laboratory and Department of Physics and Astronomy, Iowa State University — The anisotropy of electrical resistivity in the iron pnictide superconductor Ba(Fe,Co)$_2$As$_2$ has been studied using the Montgomery technique and direct transport measurements in single crystals cut along principal directions of the conductivity tensor (tetragonal c-axis and a-direction perpendicular to it). A good quantitative agreement is found between two sets of data, with a $\rho_c/\rho_\|$ anisotropy of 5 ± 1 just above the superconducting transition temperature. This is in very good agreement with expectations based on the anisotropy of the critical fields, suggestive of orbital limiting of superconductivity at $T_c$.

8:24 AM P35.00003 C-axis transport of pnictide single crystals. YURI KOVAL, PAUL MUELLER, University Erlangen-Nuernberg, Germany, GUENTER BEHR, BERND BUECHNER, IFW Dresden, Germany — Mesta-type structures of ~1 $\mu$m$^2$ area were fabricated on the (ab) plane of small LaO$_{0.8}$F$_{0.2}$As FeAs single crystals. Resistance vs. temperature measurements showed a metallic behavior with a residual resistance ratio higher than 10. Both magnetic susceptibility and transport measurements showed the same value for the critical temperature, i.e. $\sim$80K. Current-voltage characteristics are typical for overdamped Josephson junctions with a critical current density of $\sim$10$^7$ A/cm$^2$. Moreover, the critical current vs. temperature dependence follows the Ambegaoker-Baratoff relation for the maximum dc Josephson current. One possible explanation could be that we have observed an intrinsic Josephson effect in $c$-direction. This is supported by recent measurements of radiation emission between 11 and 12 GHz. Finally, we discuss current injection effects on Josephson critical current and $T_c$.

8:36 AM P35.00004 Thermoelectric Power of RO$_{1-y}$Fe$_y$As. FENG CHEN, KALYAN SASMAL, MELISSA GOOCH, FENGYAN WEI, BERND LORENZ, YUYI XUE, C.W. CHU, Dept. of Physics and Texas Center for Superconductivity, University of Houston, Houston, TX 77004-5002, BING LV, ZHONGJIA TANG, ARNOLD GULOY, Dept. of Chemistry, University of Houston, Houston, TX 77204 — The thermoelectric power $S(T)$ has been measured on the RO$_{1-y}$Fe$_y$As samples with $0 \leq x \leq 0.3$ and $0 \leq y \leq 0.5$ and with the rare earth R = La, Ce, Sm and Pr. Together with Hall and lattice parameter studies, systematic x-dependence is observed, although rather weak for samples with $x > 0$ and $y = 0$. The $S(T)$ of the undoped samples with $x = y = 0$, however, appears to have rather different shape and amplitude. By comparing with the resistivity drop around 150 K, the change seems to be associated with the spin/lattice instability previously proposed.

8:48 AM P35.00005 A novel non-Fermi-liquid state in the iron-pnictide FeCrAs. WENLONG WU, ALIX MCCOLLAM, University of Toronto, IAN SWAINSON, National Research Council of Canada, PATRICK ROURKE, University of Toronto, DENIS RANCOURT, University of Ottawa, STEPHEN JULIAN, University of Toronto — We report transport and thermodynamic properties of stoichiometric single crystals of the hexagonal iron-pnictide FeCrAs. The in-plane resistivity shows an unusual “non-metallic” dependence on temperature $T$, rising discontinuously with decreasing $T$ from $\sim$ 800 K to below 100 mK. The $c$-axis resistivity is similar, except for a sharp drop upon entry into an antiferromagnetic state at $T_N \approx 125$ K. Below 10 K the resistivity follows a non-Fermi-liquid power law, $\rho(T) \sim T^\alpha$ with $\alpha < 1$. The specific heat, on the other hand, shows typical Fermi liquid behavior with a linear temperature dependence and a large Sommerfeld coefficient, $\gamma \sim 30$ mJ/mol K$^2$. The magnetic susceptibility does not follow Curie-Weiss law and it is rather weakly temperature dependent at low temperature. The high temperature properties of FeCrAs are reminiscent of those of the parent compounds of the new layered iron-pnictide superconductors, however the $T \rightarrow 0$ K properties suggest a new class of non-Fermi liquid. This low temperature state has some features expected of a fractionalized electron system, in which conduction electrons break up into a charge carrying part that scatters anomalously and a spin part that has the thermodynamic properties of a Fermi liquid.

9:00 AM P35.00006 Large quasiparticle thermal Hall conductivity in the superconductor Ba$_{1-x}$K$_x$Fe$_2$As$_2$. JOSEPH CHECKELESKY, LU LI, Princeton University, G.F. CHEN, J.L. LUO, N.L. WANG, Inst. of Physics, Beijing, China, N.P. ONG, Princeton University — We have measured the thermal conductivity $\kappa_{xy}$ and thermal Hall conductivity $\kappa_{xy}$ in single-crystal Ba$_{1-x}$K$_x$Fe$_2$As$_2$. Below the superconducting transition temperature $T_c (\sim 30 K)$, we observe a large peak in the weak-field $\kappa_{xy}$. A corresponding peak in the zero-field thermal conductivity $\kappa_{xy}$ is also observed. Together, these imply the existence of a large population of hole-like quasiparticles below $T_c$. In magnetic fields $H$ approaching 35 T, the peaks in $\kappa_{xy}$ are strongly suppressed. A fit of the $\kappa_{xy}$ vs. $H$ curves shows that the data are consistent with the scattering of long-lived quasiparticles by vortices. Using these fits, we have extracted estimates of the quasiparticle mean-free-path, and separated the zero-field electronic and phononic terms $\kappa_e$ and $\kappa_p$, respectively. We discuss the origin of the large quasiparticle population in terms a strongly anisotropic gap parameter or a gap with nodes.

9:12 AM P35.00007 Fe pnictides in high magnetic fields. FEDOR BALAKIREV, Los Alamos National Laboratory — High magnetic fields provide invaluable tool in probing such complex and phase-rich materials as novel pnictide superconductors, where upper critical field estimates surpass 100 Tesla for some of the compositions. We have investigated a number of tertiary and quaternary iron pnictides in pulsed magnetic fields exceeding 60 T and will present the latest data on their superconducting and normal state properties at high fields. We probe the importance of reduced dimensionality for high temperature superconductivity across different families of pnictides, where we find contrasting behavior between 122 and 1111 compounds. We find clear signature of the Fermi surface reconstruction in magnetotransport properties of the field-induced normal state, which coincides with reported structural and magnetic phase transitions.

1Supported by NSF grant DMR 0213706 and DMR 0819860. Research at IOP is supported by NSFC, 973 project of MOST and CAS of China. High-field experiments were performed at the National High Magnetic Field Laboratory, Tallahassee.

2The work at the NHMFL was supported by the NSF, DOE, and by the State of Florida.
9:48AM P35.00008 Spin density wave instability and pseudogap formation in EuFe2As2. JONG HOON SHIN, SOON JAE MOON, Seoul National University, JU-YOUNG KIM, Gwangju Institute of Science and Technology, SEUNG HYUN KIM, WOO SEOK CHOI, BYUNG CHUL JEON, Seoul National University, YUN SANG LEE, Soongsil University, BEONG KI CHO, Gwangju Institute of Science and Technology, KHEE KIM KIM, TAE WON NOH, Seoul National University — Recently, iron arsenide superconductors have aroused great amount of interest. In these compounds, by doping electron or hole, the superconductivity arises with the suppression of spin density wave (SDW) order. The close relation between the CDW and SDW instability suggests that the magnetic fluctuation might play an important role. Therefore, it is imperative to study the magnetic ground state of the parent compounds to understand the mechanism of the superconductivity. We investigated optical conductivity spectra of EuFe2As2 single crystals, which showed SDW order below about 190 K. Across the transition temperature, the optical spectral weight transferred from low energy (below 900 cm-1) to higher energy (above 900 cm-1), forming a pseudogap. In the SDW phase, the sharp Drude-like response still remained. Our results indicate that the SDW formation induce the partial gap opening in the Fermi surface of EuFe2As2.

10:00AM P35.00009 Electronic anisotropy from magneto-transport near Tc in SmFeAs(O1−xF2x) and (Ba,Rb)Fe2As2 single crystals. PHILIP MOLL, Laboratory for Solid State Physics, ETH Zurich, Switzerland, KARSTEN KUNZE, Electron Microscopy ETH Zurich, Switzerland, ZBIGNIEW BUKOWSKI, NIKOLAI ZHIGADLO, JANKUSZ KARPINSKI, High Pressure Materials Synthesis, ETH Zurich, ZHANG HU, BERTRAM BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — We derived thermally activated flux flow (TAFF) activation energies EF (H) and the upper critical fields HC2(T) parallel to the c-axis and in the Lorentz-force free configuration (H // ab || j) of SmFeAs(O1−xF2x) and (Ba,Rb)Fe2As2 single crystals from resistance measurements and compare them to the ones reported for other REFeAs(O) compounds. A perfectly rectangular rod (67x11x4 µm), aligned with the crystal axes, was cut from a larger SmFeAs(O1−xF2x) single crystal (~200 µm) by a Focused Ion Beam (FIB) which allowed us to precisely control its geometric factor L/A = 0.89 1/µm. The FIB was also used to deposit 4 Pt contacts. We found a slope of Hc2,50% (T), parallel to the c-axis, of 1.9 T/K for SmFeAs(O1−xF2x) and 3.7 T/K for (Ba,Rb)Fe2As2 near Tc. The electronic anisotropy, derived from magneto-transport, is significantly larger in the REFeAs(O) crystals than in (Ba,Rb)Fe2As2.

10:12AM P35.00010 Quantum critical regime in the phase diagram of KxSr1−xFe2As2. BERND LORENZ, MELISSA GOOCH, TCSUH and Dept. of Physics, University of Houston, BING LV, ARNOLD M. GULOY, TCSUH and Dept. of Chemistry, University of Houston, CHING-WU CHU1, TCSUH and Dept. of Physics, University of Houston — The electrical and thermoelectric properties of KxSr1−xFe2As2 are investigated. While the temperature dependence of the resistivity of SrFe2As2 (x=0) and KFe2As2 (x=1) is strongly nonlinear over a large temperature range it becomes surprisingly linear for x close to xcr = 0.4 above the superconducting transition. This apparent deviation from the Fermi liquid behavior is similar to the high-Tc cuprate superconductors and may indicate the existence of a quantum critical regime above the superconducting dome. We show that the temperature dependence of the thermoelectric power S follows a logarithmic scaling, S/T = const.·log(T) at the critical value xcr. The experimental results are consistent with a Ginzburg-Landau model for FeAs compounds predicting quantum critical scaling with a dynamical exponent d+z=4.

10:24AM P35.00011 Low temperature thermal conductivity of single crystal Ba1−xKxFe2As2. J.-P. REID1, M.A. TANATAR2, X. LUO1, N. DOIRON-LEYRAUD1, N. NI1, S.L. BUD’KO2,3, P.C. CANFIELD2,3, H. LUP4, Z. WANG5, H.H. WEN4, R. PROZOROV2,3, LOUIS TAILLEFER1, DÉPARTEMENT DE PHYSIQUE, UNIVERSITÉ DE SHERBROOKE, QUÉBEC, CANADA TEAM, 2AMES LABORATORY, AMES, IOWA, USA COLLABORATION, 3DEPARTMENT OF PHYSICS AND ASTRONOMY, IOWA STATE UNIVERSITY, AMES, IOWA, USA Collaboration, 4NATIONAL LABORATORY FOR SUPERCONDUCTIVITY, CHINESE ACADEMY OF SCIENCES, CHINA COLLABORATION — Novel iron-arsenic based superconductors with Tc up to 34 K for KxFe2As2 with x=0.25. We find no residual linear term in zero magnetic field and can therefore exclude a superconducting gap with a line of nodes.

10:36AM P35.00012 Effects of Co substitution on thermodynamic and transport properties and anisotropic Hc2 in Ba(Fe1−xCo2x)2As2. Y. NI, M. E. TILLMAN, J.-Q. YAN, A. KRACHER, S. L. BUD’KO, P. C. CANFIELD, Ames Lab / Iowa State University, S. T. HANNAHS, NHMFL, Tallahassee — Single crystal samples of Ba(Fe1−xCo2x)2As2, x<0.12, have been characterized by microscopic, thermodynamic and transport measurements. With increasing Co concentration, the features of the structural and magnetic transitions are suppressed at a rate of roughly 15K per percent of Co. Superconductivity is stabilized at low temperatures for 0.038 ≤ x ≤ 0.08 and up through our highest doping level of x = 0.114. The superconducting region has a dome like appearance with maximum Tc values (~23 K) found near x~0.07. The T−x phase diagram shows that either the existence of superconductivity in both the tetragonal and the orthorhombic (AFM) phase or there is a structural phase separation. Anisotropic Hc2 data clearly show that the superconductivity which occurs in samples that show features associated with the transition to the low temperature orthorhombic state is 50% smaller than that found in samples that remain in the tetragonal phase. These data show that the superconductivity is sensitive to the suppression of the higher temperature phase transition.

9:30AM P36.00002 Physics Q & A — APS’s latest publication, Physics (http://physics.aps.org/), highlights exceptional papers from the Physical Review Journals. Each week, editors from the journals choose papers that merit this treatment, aided by referee comments and internal discussion. Physics features expert commentaries written by active researchers who are asked to explain the results to physicists in other subfields. These commissioned articles are edited for clarity and readability across fields and are accompanied by explanatory illustrations. Please join us for a session that will include a brief presentation by the editors of Physics followed by a Q and A.

Wednesday, March 18, 2009 8:00AM - 10:36AM — Session P37 DCP: Focus Session: Structure and Dynamics of Interfacial Water I

8:00AM P37.00001 Electron Solvation Dynamics at D$_2$O Ice and Na/D$_2$O/Metal Interfaces. MARTIN WOLF, Free University Berlin and Fritz-Haber-Institut, Berlin, Germany — Electron transfer (ET) across interfaces is of vital importance in different areas of physics, chemistry and biology. Using time-resolved two-photon-photoemission spectroscopy we have studied the ultrafast dynamics of interfacial ET and solvation processes in amorphous and crystalline D$_2$O layers on single crystal metal substrates and the influence of coadsorbed Na ions. In these experiments, photoionization of electrons from the metal into the adsorbate conduction band is followed by ultrafast localization and solvation of the excess electrons. The subsequent energetic stabilization of these solvated electrons due to nuclear rearrangements of the polar molecular environment is accompanied by an increasing degree of localization. The observed ET rates strongly depend on the local structure of the ice. In crystalline D$_2$O layers we monitor the stabilization of trapped electrons at the ice vacuum interface continuously from femtoseconds up to minutes. This behavior observed for crystalline ice is fundamentally different from amorphous D$_2$O layers where the excess electrons have a much lower survival probability, which lifetimes of the order of 100 fs, which extend to several 10 ps if Na ions are coadsorbed at the ice surface.

8:36AM P37.00002 Electron dynamics and intermolecular energy transfer in aqueous solutions studied by X-ray electron spectroscopy. BERND WINTER, BESSY, Albert-Einstein-Strasse 15, D-12489 Berlin, Germany — X-ray photoelectron spectroscopy measurements from a vacuum liquid microjet are performed to investigate the electronic structure of aqueous solutions. Here, focus is on the excited-state dynamics of chloride and hydroxide anions in water, following core-level excitation. A series of Cl$^-$(aq) charge-transfer-to-solvent (CTTS) states, and their ultrafast relaxation, on the time scale of the core hole, is identified from the occurrence of spectator Auger decay. Resonant oxygen 1s excitation of aqueous hydroxide, in contrast, leads to non-local decay, involving energy transfer into a neighboring water molecule. This channel is argued to arise from the weak hydrogen donor bond of OH$^-$(aq), and thus identifies a special transient hydration configuration, which can explain hydroxide’s unusual and fast transport in water. Analogous measurements from pure water point to a similar relaxation channel, which is concluded from a strong isotope effect. The characteristic resonant spectral features are considerably stronger for H$_2$O(aq) than for D$_2$O(aq). As for OH$^-$(aq) the results can be understood in terms of energy transfer from the excited water molecule to a neighbor water molecule.

9:12AM P37.00003 Electrons tunneling through fluctuating water and proteins. DAVID BERATAN, Duke University — We have analyzed the characteristics of electron tunneling through thermally-fluctuating water and protein media [1]. A metric is defined that indicates when the tunneling propagation is well described by the average donor-acceptor tunneling interaction, as opposed to being dominated by medium fluctuations. Indeed, there is a transition distance that establishes a change in mechanism, and this distance is different for water-mediated compared to protein-mediated tunneling. Even in the fluctuation-dominated regime, we find that the three-dimensional protein fold controls the tunneling interactions. We also find that pairs of proteins in near contact may establish particularly strong water-mediated tunneling routes [2].

10:00AM P37.00005 X-ray studies of the Density Depletion at Hydrophobic Water-Solid Interfaces. MARKUS MEZGER, Lawrence Berkeley National Lab, Berkeley, HARALD REICHERT, HEIKO SCHRODER, JOHN OKASINSKI, ROLAND ROTH, HELMUT DOSCH, Max Planck Institute for Metals Research, Stuttgart, Germany, SEBASTIAN SCHODER, VEJO HONKIMAKI, European Synchrotron Radiation Facility, Grenoble, France, JOHN RALSTON, Ian Wark Research Institute, Mawson Lakes, Australia — Deeply buried hydrophobic solid-water interfaces were probed with high-energy x-ray reflectivity. The experimental data provide clear evidence for a thin density depletion with an integrated deficit corresponding to approximately 40% of a water monolayer extending over a maximum of two molecular layers. In addition, measurements on the influence of gases (Ar, Xe, Kr, N$_2$, O$_2$, CO, CO$_2$) dissolved in the water have been performed. No effect on the hydrophobic water gap was found. The presence of nanobubbles at the interface could also be excluded. By comparing the experimental results with an generic DFT model we can give a quantitative estimation for different contributions to the observed gap size.

The persistent demand for cheaper and high efficient catalysts in industrial chemical syntheses, such as ammonia, and in novel energy applications, hydrogen generation and purification in fuel cells motivated us to study the fundamental interaction involved in water-Cu system, with an intention to examine Cu as a possible competitive candidate for cheaper catalysts. Water structure and dissociation kinetics on a model open metal surface: Cu (110), have been investigated in detail based on first-principles electronic structure calculations. We revealed that in both monomer and overlayer forms, water adsorbs molecularly, with a high tendency for diffusion and/or desorption rather than dissociation on clean surfaces at low temperature. With the increase of the water coverage on the Cu (110) surface, the H-bond pattern lowers the dissociation barrier efficiently. More importantly, if the water molecule is dissociated, the hydrogen atoms can diffuse freely along the [110] direction, which is very useful in the hydrogen collection. In addition, we extended to study water on other noble metal (110) surfaces. The result confirms that Cu (110) is the borderline between intact and dissociative adsorption, differing in energy by only 0.08 eV. This may lead to promising applications in hydrogen generation and fuel cells.

8:00AM P38.00001 Nanoscale Architectures for Energy Applications¹, STANISLAUS WONG, Department of Chemistry at the State University of New York at Stony Brook — In my group, we have developed a number of different potential architecture systems for gaining insights into energy storage and photovoltaics. In one manifestation of our efforts, generating a heterojunction comprising nanotubes and nanocrystals, to create a sharp junction interface, whose properties are inherently manipulable, tailorable, and, hence, predictable. For example, the electrical resistance of nanotube-nanoparticle networks is dependent on the nanoscale junctions that exist between these constituent nanomaterials as well as on microscale and macroscale connectivity. Thus, rational design of these nanomaterials is critical to a fundamental understanding of charge transport in single molecules and the determination of their conductance. Results on these systems can therefore be used to increase understanding of intrinsic factors affecting carrier mobility, such as electronic structure, carrier trapping, and delocalization. In a second manifestation, three-dimensional, dendritic micron- scale spheres of alkali metal hydrogen titanate 1D nanostructures (i.e.: nanowires and nanotubes) have been generated using a modified hydrothermal technique in the presence of hydrogen peroxide and an alkali metal hydroxide solution. Sea-urchin-like assemblies of these 1D nanostructures have been transformed into their hydrogen titanate nanotube analogues by neutralization as well as into their corresponding semiconducting, anatase titanate nanostructured counterparts through a moderate high-temperature annealing dehydration process without destroying the 3D hierarchical structural motif. The as-prepared hollow spheres of titanate and titanita 1D nanostructures have overall diameters, ranging from 0.8 μm to 1.2 μm, while the interior of these aggregates are vacuous with a diameter range of 100 to 200 nm. We have demonstrated that these assemblies are useful for example as active photocatalysts for the degradation of synthetic Procion Red dye under UV light illumination. In a third set of experiments, a size- and shape-dependent morphological transformation was demonstrated during the hydrothermal soft chemical transformation, in neutral solution, of titanate nanostructures into their anatase titanita counterparts. Our results indicate that as-synthesized titanita nanostructures possessed higher photocatalytic activity than the commercial titanita precursors from whence they were derived.

9:12AM P38.00003 Electronic Dynamics in Nanocrystalline TiO₂ and ZnO Measured by Terahertz Spectroscopy, CHARLES SCHMUTTENMAER, Yale Univery, Department of Chemistry, JASON BAXTER, Dept. of Chemical and Biological Engineering — Understanding the microscopic details of carrier transport in nanocrystalline colloidal thin films is required for complete understanding of a variety of photochemical and photocurrent-driven cells utilizing interpenetrating networks. Measuring the photoconductivity in these materials, however, is a challenging problem because of the inherent difficulty of attaching wires to nanometer-sized objects. Furthermore, picosecond carrier dynamics play an important role in efficient charge separation and transport, but the low temporal resolution of traditional methods used to determine their photodetectivity precludes their use in studying sub-ps to ps dynamics. This talk will present recent advances utilizing THz spectroscopy to investigate and elucidate the microscopic behavior of carrier dynamics within the context of materials for energy applications such as dye-sensitized solar cells and solar-driven cells for catalytic and photoelectrochemical applications.

9:24AM P38.00004 Theoretical investigation of the high energy excitations in silicon nanocrystals, ADAM GALI, MARTON VOROS, Budapest University of Technology and Economics, DARIO ROCCA, GERELY ZSOMBOR, GIULIA GALLI, UC Davis — Recently, efficient multi-exciton generation (MEG) has been reported for several nanoclusters including silicon nanocrystals (SiNC). However, the existence of MEG has been disputed in the literature. The reported bi-exciton states in SiNC involve high energy empty states of SiNC. These states are expected to be very delocalized, and thus easily modified by the environment surrounding the SiNCs. In addition, the SiNCs are fabricated in a solution that usually contains CnHm molecules, e.g. hexane, that may bind to the surface of SiNCs, and modify their absorption spectrum. We have studied the absorption spectra of hydrogenated SiNCs by first principles calculations. The geometry was optimized within density functional theory (DFT), while absorption spectra were determined by time-dependent DFT. The effect of the environment on the SiNC was modeled by i) varying the distance between the nanoparticles ii) allowing for surface reconstruction and iii) monitoring the effect of absorption of CnHm groups on absorption spectra. We found that the high energy spectrum of SiNCs strongly depends on the environment. Our findings indicate that taking into account effects of surface states and SiNCs concentration in solution is crucial, in order to understanding multi exciton generation.

Wednesday, March 18, 2009 8:00AM - 11:00AM — Session P38 DCP: Focus Session: Nanomaterials for Energy Applications — 1
9:36AM P38.00005 Fast exciton relaxation and multiple exciton generation (MEG) in semiconductor nanocrystals: the role of defects. CHRISTOPHE DELEURIE, GUY ALLAN, IEMN-ISEN — Recent works have concluded that a single high-energy photon could generate multiple excitons in semiconductor nanocrystals but these results are debated and are not well understood theoretically. More generally, the physics of the relaxation of excitations in semiconductor nanocrystals receives growing interest. We show that surface defects must play an important role in these processes. We calculate the rate for the relaxation of hot carriers by impact ionization and we show that the presence of surface defects leads to an increase of the relaxation rate at lower excitation energy. We present simulations of the carrier multiplication in Si nanocrystals and we discuss the results of recent experiments in light of these results.

9:48AM P38.00006 First-principles study of LaSn3 as an anode for lithium-ion batteries. DONGWON SHIN, CHRISTOPHER WOLVERTON, Northwestern University, JOHN VAUGHHEY, MICHAEL THACKERAY, Argonne National Laboratory — Using both density functional theory (DFT) calculations and experiment, we investigate the tin-rich intermetallic compound LaSn3 as a possible anode for lithium-ion batteries. We use DFT calculations to compute the relative energies of structural insertion- and displacement-type reactions in an effort to elucidate the energetically-preferred reaction mechanism of Li with LaSn3. From our DFT calculations, we find: (i) lithium insertion reactions with LaSn3 are predicted to be energetically unfavorable and highly unlikely to occur; (ii) in contrast, the energetically preferred reaction is a displacement reaction in which Li is partially displaced from LaSn3 to yield La2Sn5 and Li reacts with the residual Sn to form Li2Sn4, corresponding to an electrochemical capacity of 307 mAh/g; (iii) this partial displacement reaction is preferred relative to the complete displacement and lithiation of Sn; and (iv) the lithiated-tin compound, Li2Sn5, is energetically much smaller favored than the commonly reported Li2Sn composition. Electrochemical and structural data largely confirm the DFT predictions; they demonstrate that lithium reacts with LaSn3 via a displacement reaction to provide a reversible specific capacity of 200-250 mAh/g.

10:00AM P38.00007 Ab Initio Prediction of the Size-Dependence of Nano-scale Platinum Dissolution in Water. KRISTIN PERSSON, LBNL, BYUNGCHAN HAN, GERBRAND CEDER, MIT — In low-temperature fuel cells, the mechanism behind the observed performance loss of the platinum catalyst is not well understood. Using ab initio methods, we calculate 0.5-2 nm diameter Pt nanoparticles with varying degrees of O and OH surface absorbates, optimized by site and particle surface structure. In fuel cells, the oxidation of the particle surface origins from the breakup of water molecules. To mimic these conditions we employ a grand canonical ensemble treatment of water as a source of O and H. Additionally, pH effects and dissolved species (from experiments) are incorporated, the latter by changing the experimental element reference state to that of calculated solids. This formalism allows us to determine the stability regions of nanoparticle Pt in equilibrium with water, as a function of particle size, potential and pH. As a result we find enhanced dissolution for the smaller Pt nanoparticles, compared to the larger. Furthermore, surface passivation effects from O and OH adsorption do not significantly increase the stability of the nano-particle phases in the potential-pH region relevant for fuel cell operating conditions. Thus, we can identify size-dependent dissolution as a mechanism which will promote the growth of larger particles at the expense of smaller ones and ultimately cause a degradation in the nanoparticle Pt catalyst performance.

10:12AM P38.00008 First-principles theory of capacitive and electrochemical energy storage. JOONGO KANG, YONG-HYUN KIM, National Renewable Energy Laboratory, Golden, CO 80401 — Recently there has been much interest in development of new electrochemical capacitors to meet high-power and high-energy applications. Pseudo-capacitors using fast surface redox reactions can store electrical energy of 10 to 100 times larger than supercapacitors and exhibit fast and reversible charge-discharge responses in contrast to batteries. Yet, energy storage mechanisms in super- and pseudo-capacitors have not been fully understood at the level of electrons. Here we have performed first-principles calculations for electrochemical double layers of a TiO2 (101) electrode and solvated lithium ions on the surface, with the ethylene carbonates (EC) as solvent molecules. As Li ions are desolvated from Li-EC2 to Li-EC3 and bare Li ions, the capacitance gets larger due to the reduced distance between the Li ions and the electrode. When Li ions are intercalated into the surface of the TiO2 electrode as supported in pseudocapacitors, the electrostatic energy due to charge separation is reduced for a given stored charge, but the electrochemical reaction starts to occur causing a large increase in the capacitance.

10:24AM P38.00009 Steps in hydrogen production from methanol on sub-nanometer palladium clusters. FAISAL MEHMOOD1, JEFFREY P. GREELEY, PETER ZAPOL1, LARRY A. CURTIS1,2, 1 Material Science Division and 2Center of Nanoscale Materials, Argonne National Laboratory — Extensive experimental and theoretical work has been done to understand the decomposition of methanol on various metal and metal oxide nanoparticles for hydrogen production. The activity of sub-nanometer sized particles <1nm however is not very well known, primarily because of technical challenges involved in preparation and stabilization of the clusters. To explore the properties of the Pd clusters computationally, we have carried out density functional calculations for the methanol decomposition reaction on Pd4 and Pd8 clusters. The thermodynamics and kinetics of three decomposition routes involving C–O, C–H and O–H scission were determined with the nudged elastic band method. A detailed analysis of the PES for methanol decomposition shows C–O activation to be the least favorable step. In addition, all possible reaction paths for the Pd4 cluster are much lower in comparison to single crystal surface and large nanoparticles. A detailed analysis of how particle size affects the elementary reaction steps, we also present a comparison of methanol decomposition on Pd4 with Pd8 clusters. Finally, we will discuss the implication of a linear correlation between the transition state and final state energies that is followed for all elementary reaction steps on Pd4 and Pd8 clusters.

10:48AM P38.00011 Electrochemical Double Layer Capacitors Using Aligned Multiwall Carbon Nanotubes Grown Directly on Conductive Substrates. RAKESH SHAH, XIANFENG ZHANG, SAIKAT TALAPATRA, Department of Physics, Southern Illinois University Carbondale, IL, 62901 — We report on the properties of Electrochemical Double Layer Capacitor (EDLCs) electrodes fabricated using aligned multiwall carbon nanotubes (MWN) grown on Ioncon sheets. Air assisted chemical vapor deposition technique was employed to synthesize the aligned MWN on these substrates. The capacitive behavior of the EDLC’s fabricated using different lengths of aligned MWNs was examined using cyclic voltammetry, constant current charge/discharge, and impedance spectroscopy. These measurements show that the charge storage phenomenon was non-Ohmic with equivalent series resistance in the range of 0.130-0.40. The maximum values of specific capacitance of the carbon nanotubes material used in these devices were in the range of 14.6-21.57 F/g. The maximum value of power density and energy density of the whole supercapacitor devices were 1.48 Wh/Kg and 2.7 kW/Kg, respectively. These results show that the multiwall carbon nanotubes grown directly on conductive substrates are promising results as electrodes for electrochemical energy storage device applications.
8:00AM P39.00001 Statistical analysis and modeling of collective cell motion and pattern formation1, ANDRAS CZIROK, ANDRAS SZABO, Eotvos University, Dept of Biological Physics — Cell motility and its guidance through cell-cell contacts is instrumental in vasculogenesis and in several other morphogenic processes as well. During vasculogenesis multicellular sprouts invade avascular areas, eventually creating an interconnected network pattern. Epithelial cell sheets migrate during organogenesis or wound healing. These phenomena were studied with time-lapse microscopy both in vivo and in vitro. Statistical analysis of cell trajectories reveals that motile confluent cultures may behave either as vortical fluids or as deforming elastic sheets. The observed flow fields and pattern formation can be explained by our generalized cellular Potts model — representing cell polarization and self-propulsion, links between the cytoskeleton of adjacent cells as well as an asymmetric preferential attraction to the surface of adjacent cells.

1This work was funded by the NIH and the Hungarian National Office for Research and Technology.

8:12AM P39.00002 Self-organization in Systems of Treadmilling Filaments., KONSTANTIN DOUBROVIN-SKI, Princeton University, KARSTEN KRUSE, Universität des Saarlandes — The cytoskeleton is an active intracellular network of polar filaments responsible for maintenance of cell shape, cell division, and cell locomotion. A broad variety of cellular processes depend critically on the ability of cytoskeletal filaments to treadmIll, i.e., to move by growing at one end while simultaneously shrinking at the other end. In particular, treadmilling is indispensable for cell crawling as well as for generation of various cellular appendages including stereocilia, microvilli, and filopodia. Quantitative modeling of systems involving treadmilling filaments is challenging since it requires describing long-range interactions of particles with many degrees of freedom. We introduce a novel framework for describing systems of treadmilling filaments. Within our framework, we identify a class of systems that admit exact solution of the underlying dynamic equations. We compare the corresponding solutions to those obtained by coarse-graining, an approximation which is valid on large length-scales. We apply our new framework to treat two biological systems: cytoskeletal dynamics in fish melanophores and locomotion of human neutrophil cells. In both cases our theory faithfully accounts for the qualitative and semi-quantitative properties of the intracellular structures observed in the corresponding experiments.

8:24AM P39.00003 Self-assembly of the yeast actomyosin contractile ring as an aggregation process: kinetics of formation and instability regimes1, NIKOLA OJKIC, DIMITRIOS VAVYLONIS, Department of Physics, Lehigh University — Fission yeast cells assemble an equatorial contractile ring for cytokinesis, the last step of mitosis. The ring assembles from ~ 65 membrane-bound “nodes” containing myosin motors and other proteins. Actin filaments that grow out from the nodes establish transient connections among the nodes and aid in pulling them together in a process that appears as pair-wise attraction (Vavylonis et al. Science 97:319, 2008). We used scaling arguments, coarse grained stability analysis of homogeneous states, and Monte Carlo simulations of simple models, to explore the conditions that yield fast and efficient ring formation, as opposed to formation of isolated clumps. We described our results as a function of: number of nodes, rate of establishing connections, range of node interaction, distance traveled per node interaction and broad band width, w. Uniform cortical 2d distributions of nodes are stable over short times due to randomness of connections among nodes, but become unstable over long times due to fluctuations in the initial node distribution. Successful condensation of nodes into a ring requires sufficiently small w such that lateral contraction occurs faster than clump formation.

1NIH R21GM083928

8:36AM P39.00004 Discrete and continuous models of protein sorting in the Golgi, HAUJUN GONG, Department of Physics, Carnegie Mellon University, RUSSELL SCHWARTZ, Department of Biological Sciences, Carnegie Mellon University — The Golgi apparatus plays an important role in processing and sorting proteins and lipids. Golgi compartments constantly exchange material with each other and with other cellular components, allowing them to maintain and reform distinct identities despite dramatic changes in structure and size during cell division, development, and secretory stress. We have developed two minimal models of membrane and protein exchange in the Golgi — a discrete, stochastic model [1] and a continuous ordinary differential equation (ODE) model — both based on two fundamental mechanisms: vesicle-coat-mediated selective concentration of soluble N-ethylmaleimide-sensitive factor attachment protein receptor (SNARE) proteins during vesicle formation and SNARE-mediated selective fusion of vesicles. Both show similar ability to establish and maintain distinct identities over broad parameter ranges, but they diverge in extreme conditions where Golgi collapse and reassembly may be observed. By exploring where the models differ, we hope to better identify those features essential to minimal models of various Golgi behaviors. [1] H. Gong, D. Sengupta, A. D. Linsteadt, R. Schwartz. Biophys J. 95: 1674-1688, 2008.

8:48AM P39.00005 ABSTRACT WITHDRAWN —

9:00AM P39.00006 Studying the Transition to Multicellular Life by Altering a Chemical Signaling Channel, CARL FRANCK, KAYVON DAIE, Cornell University — The starvation response of the eukaryotic microbial system Dictyostelium discoideum has continued to provide opportunities to explore the transition from solitary to collective life. Specifically, one observes a change of behavior from random to synchronized cellular motion reflecting successful long-ranged chemical signaling that leads to aggregation. In the typical experimental universe life goes on upon a flat substrate underneath an ocean of liquid media through which these chemical signals pass. In our observations of starvation development we have uniquely exploited the possibilities afforded by varying the depth of this signaling channel over an interesting range: from essentially infinitely thick (mm’s of depth) to an extremely thin wetting layer (below 1 micron). We also examine the development system over a wide range of surface density: from almost a full monolayer to a few percent areal coverage. Our key observation is a striking reduction of the time from the beginning of starvation to the onset of synchronized movement when we reduce the aqueous overlayer thickness to the thinnest values. We provide an interpretation for our observations by combining our results with a new framework describing systems of vortical fluids or deforming elastic sheets. The observed flow fields and pattern formation can be explained by our generalized cellular Potts model — representing cell polarization and self-propulsion, links between the cytoskeleton of adjacent cells as well as an asymmetric preferential attraction to the surface of adjacent cells.

9:12AM P39.00007 Simulation of cellular shapes on micro-patterned substrate using the Cellular Potts Model, BENOIT VIANAY, HERVE GUILLOU, Institut Neel - CNRS Grenoble - FRANCE, THERMODYNAMIC OF SMALL SYSTEMS TEAM — Cell adhesion and motility are processes involved in fundamental biological phenomena using biological structures as anchorage points and cytoskeleton filaments which are very dynamical and at non-equilibrium. We study cell adhesion on micro-patterned substrate where an introduction of a finite distance between anchorage points of the cell modifies drastically the organization of the cytoskeleton and the anchorage point’s distribution. Some of statistically most used shapes represent stationary states of the system which should minimize the energy dissipation. We verified this hypothesis reproducing morphologies by simulation of Monte Carlo using the Cellular Potts Model (Graner and Glazier, PRL69 p2013 (1992)). Shapes obtained by simulation depend of four phenomenological parameters as interaction between cell and ECM and are in excellent qualitative agreement with experimental shapes. The aim of this presented work is to link model parameters to physico-chemical properties of cells and to establish phenomenological relations between interesting parameters controlling the cytoskeleton organization. Collaborations : J. Kafer & F. Graner : Laboratoire de spectrometrie Physique – Grenoble; E. Plannus & M. Block : Institut Albert Bonniot – Grenoble.
or percolate through the entire population, leading to what might be considered as “homologous” traits even in species widely separated in morphospace.

The spread of inherited traits through the overall population, finding an “all or none” effect in which the properties of a traced organism either die out completely or persist indefinitely.

We have investigated as a function of the degree of variability, or “noise”, allowed in the morphology of new (children) organisms with respect to their parents. We find that the number of organisms in close proximity. The clustering of organisms in a morphospace overlaid on this landscape is considered an analog of speciation and is explored using analytical and numerical methods.

The bacterial strain

and shape during the early stages of Bacillus Subtilis subunit growth, simultaneously monitoring matrix expression levels. We show that the critical bioluminescence size scales with nutrient concentration as expected by a simple nutrient depletion model.

The ability of cells to move towards environmental cues is a critical process allowing the destruction of intruders by the immune system, the formation of the vascular system and the whole scale remodeling of tissues during embryo development. We examine the initial transition from single cell to group migration in the social amoeba Dictyostelium discoideum. Upon starvation, D. discoideum cells enter into a developmental program that triggers solitary cells to aggregate into a multicellular structure. The aggregation is mediated by the small molecule, cyclic-AMP, that cells sense, synthesize, secrete and migrate towards.

We obtain exact expressions for all these quantities, which we test using Monte Carlo simulations.

We study the stochastic dynamics of growth and shrinkage of single actin filaments or microtubules taking into account insertion, removal, and ATP/GTP hydrolysis of subunits. The resulting phase diagram contains three different phases: two phases of unbounded growth: a rapidly growing phase and an intermediate phase, and one bounded growth phase. We analyze all these phases, with an emphasis on the bounded growth phase. We also discuss how hydrolysis affects force-velocity curves. The bounded growth phase shows features of dynamic instability, which we characterize in the time needed for the ATP/GTP cap to disappear as well as the time needed for the filament to reach a length of zero (i.e., to collapse) for the first time. We obtain exact expressions for all these quantities, which we test using Monte Carlo simulations.

We quantify their structure using Edwards’ statistical mechanics of cellular systems.

We study 2D polygonal tilings as models of the en-face structure of single-layer biological tissues. Using numerical simulations, we explore the phase diagram of equilibrium tilings of equal-area, equal-perimeter convex polygons whose energy is independent of their shape. We identify 3 distinct phases, which are all observed in simple epithelial tissues: The disordered phase of polygons with 4-9 sides, the hexatic phase, and the hexagonal phase with perfect 6-fold coordination. We quantify their structure using Edwards’ statistical mechanics of cellular systems.

The sub-cellular oscillation of Min proteins. MinD interacts with the membrane and polymerizes into filaments. MinE binds to membrane bound MinD leading to the sub-cellular oscillation of Min proteins. MinD interacts with the membrane and polymerizes into filaments. MinE binds to membrane bound MinD leading to the self-organization of the MinD filaments. It has been observed experimentally that MinE forms a ring, known as the E-ring, near the end of the MinD polymers. We model and solve the self-organization of the E-ring. Rebinding of MinE to depolymerizing MinD filament tips controls MinE ring formation. We find two types of E-ring profiles near the filament tip: a strong plate-like E-ring as seen in vivo, controlled by 1D diffusion along the bacterial length, or a weak cup-like E-ring controlled by 3D diffusion near the filament tip. We discuss the initial instability that leads to MinD filament depolymerization and the formation of the E-ring. We also discuss the duration of transients leading towards strong or weak E-rings. We compare with experiment both in vivo and in vitro.

Upon starvation, D. discoideum cells enter into a developmental program that triggers solitary cells to aggregate into a multicellular structure. The aggregation is mediated by the small molecule, cyclic-AMP, that cells sense, synthesize, secrete and migrate towards in a head-to-tail fashion, which is changed periodically either by random fluctuations, or via a feedback mechanism based on the number of organisms in close proximity. The clustering of organisms in a morphospace overlaid on this landscape is considered an analog of speciation and is investigated as a function of the degree of variability, or “noise”, allowed in the morphology of new (children) organisms with respect to their parents. We find that a maximum number of species are formed at an intermediate value of this noise parameter, suggesting a stochastic resonance-like effect. We also address the spread of inherited traits through the overall population, finding an “all or none” effect in which the properties of a traced organism either die out completely or percolate through the entire population, leading to what might be considered as “homologous” traits even in species widely separated in morphospace.
8:12AM P40.00002 Cyclic Process as a Tool for Considering Evolution, VICTOR BONDARENKO, WSU
- Evolution is the process. The primary question is which tools we use to consider the process. In this work, basing on the original results of investigation of the intrinsic bistability in quantum systems, the concept of the cyclic process is developed for qualitative and quantitative consideration of processes as following: Everything that happens is the process of changing; the process is the cyclic process of "... → seed → plant → seed →..." type; the cyclic process is formed by two complement phase transitions of "seed → plant" and "plant → seed" type; the cyclic process is the manifestation of self-consistent interaction of interdependent two-state system, environment, and radiation, so that the whole Universe is involved in each process; the cyclic process can be described qualitatively and quantitatively by a real cubic equation with four generalized dimensionless real parameters, provided that one of the parameters undertakes cyclic change of its value and all four parameters belong to limited interdependent intervals to maintain cyclic process. Using the cyclic process approach as a powerful tool a variety of issues is considered. Preference of evolution, extinction, adaptation, and relation between microscopic structure and macroscopic behavior of the system are addressed. Seeing the evolution is the most transcending seeing of existence. The cyclic process approach is suggested to be a corner stone for scientific approach to seeing evolution.

8:24AM P40.00003 Stepping in the bacterial flagellar motor, THIERRY MORA, HOWARD YU, NED S. WINGREEN, Princeton University - Many bacteria swim by virtue of tiny rotary motors that drive rotation of helical flagella. These motors are powered by a proton flux that is converted into torque by a mechanism which remains largely unknown. Recently, it has been reported that at low speed, the bacterial flagellar motor proceeds by steps. To account for these steps, we propose a physical model in which the stator drives a "bumpy" rotor through a viscous medium. Our model is consistent with most of the available data, and allows us to make testable predictions, in particular on the speed and diffusion properties of the rotor.

8:36AM P40.00004 Actin-Polymerization-Driven Motility with Site Specific Tethering, EDWARD BANIGAN, ANDREA LIU, University of Pennsylvania - A recent numerical simulation by Lee and Liu (2008) has demonstrated a new possible mechanism for actin-polymerization-driven motility. The simulation is a physically consistent version of the Brownian dynamics formulation of the dendritic nucleation model. The model shows that motility can indeed be achieved with the constituent proteins of the dendritic nucleation model, but that motility arises from a mechanism completely different from those proposed before. In the simulations, thebuild-up of F-actin behind the moving surface drives the surface forwards if the surface has a net repulsion with actin. In this work, we extend the model to include a site specific tethering interaction between the moving surface and actin, to imitate, for example, the effects the Acta or N-Wasp protein. We study the effects of varying binding strength and binding site coverage.

8:48AM P40.00005 FKBP binding free energies obtained via non-equilibrium simulation, F. MARTY YTREBERG, University of Idaho - We discuss the advantages and disadvantages of estimating binding free energies (i.e., absolute binding affinities) via non-equilibrium unfolding simulations. The study utilizes the FKBP protein bound to two different ligands as a model system. The non-equilibrium methodology utilized is straightforward, requiring little or no modification to modern molecular simulation packages, and is trivially parallelizable. The approach makes use of a physical pathway, eliminating the need for complicated alchemical decoupling schemes.

9:00AM P40.00006 Computational Research Needs for Renewable and Alternative Energy: Studies of Natural and Artificial Photosynthesis, VICTOR BATISTA, Yale University - The atmospheric oxygen that sustains life on earth has been generated by plants during the light period of photosynthesis. At the molecular level, the reaction involves catalytic water splitting into dioxygen, protons and electrons in the subunit D1 of photosystem II (a transmembrane complex of about 20 proteins found in the thylakoid membranes of green plant chloroplasts). Both the reaction mechanism and the structure of the catalytic center responsible for this important reaction remain poorly understood. This talk will present recent advances in experimental and computational studies towards the development of rigorous models of the oxomanganese catalytic complex and the catalytic cycle responsible for oxygen evolution, as well as recent progress on studies of biomimetic systems for artificial photosynthesis.

9:12AM P40.00007 Systematic Coarse-Graining of Peptides to Understand their Effective Molecular Interactions, LUCA LARINI, GREGORY A. VOTH, Center for Biophysical Modeling and Simulation and Department of Chemistry, University of Utah, Salt Lake City, UT, 84112, USA - The process of building reliable coarse-grained models is a major challenge for both theory and simulation. Force matching is a systematic method to produce quantitatively accurate coarse-grained potentials from atomistic simulation data. This method provides a sound theoretical background that can also be used to gain deeper insight into the system under examination. In this way, force matching can be employed as a tool for analysis. Application to a simple biological molecule will be described in order to gain a better understanding of the effective forces acting on the system.

9:24AM P40.00008 Rigorous treatment of electrostatics for spatially varying dielectrics: how far can one go using energy minimization?, YI-KUO YU, OLEG OBOLENSKY, RAJARSHI RAY, T. DOERR, National Center for Biotechnology Information/NIH - A novel energy minimization formulation of electrostatics that allows computation of the electrostatic energy and forces to any desired accuracy in a system with arbitrary dielectric properties is presented. An integral equation for the scalar charge density is derived from an energy functional of the polarization vector field. This energy functional represents the true energy of the system even in non-equilibrium states. Arbitrary accuracy is achieved by solving the integral equation for the charge density via a series expansion in terms of the equation's kernel, which depends only on the geometry of the dielectrics. The streamlined formalism operates with volume charge distributions only, not resorting to introducing surface charges by hand. Therefore, it can be applied to arbitrary spatial variation of the dielectric susceptibility. The simplicity of calculation of the formalism to real problems is shown with three examples.

We thank the administrative group of the NIH Biowulf clusters, where all the computational tasks were carried out. This research was supported by the Intramural Research Program of the NIH, NLM.

9:36AM P40.00009 Ab-Initio Based Computation of Rate Constants of Spin Forbidden Transitions in (Bio)inorganic Complexes and Metalloproteins, ABDULLAH OZKANLAR, JORGE H. RODRIGUEZ - Some (bio)chemical reactions are non-adiabatic processes whereby the total spin angular momentum, before and after the reaction, is not conserved. These are named spin- forbidden reactions. The application of spin density functional theory (SDFT) to the prediction of rate constants is a challenging task of fundamental and practical importance. We apply non-adiabatic transition state theory in conjunction with SDFT to predict the rate constant of the spin- forbidden didehydrogen binding to iron tetracarbonyl. To model the surface hopping probability between singlet and triplet states, the Landau-Zener formalism is used. The lowest energy point for singlet-triplet crossing, known as minimum energy crossing point (MECP), was located and used to compute, in a semi-quantum approach, reaction rate constants at 300 K. The predicted rates are in good agreement with experiment. In addition, we present results which are relevant to the ligand binding reactions of metalloproteins. This work is supported in part by NSF via CAREER award CHE-0349189 (JHR).

1 Department of Physics, Purdue University, West Lafayette, IN 47907-2036
9:48AM P40.00010 Electrostatic properties of two finite width charged dielectric slabs in water, Y.S. IHO, UCSB, M. KANDUC, SI-1000 Ljubljana, A. NAJI, UCSB, M.W. KIM, KAIST/UCSB, R. PODGORNIK, SI-1000 Ljubljana, F.L.H. BROWN, P.A. PINCUS, UCSB — We study the electrostatic interaction between two like-charged membranes of finite thickness embedded (composed of five parallel dielectric interfaces) in a medium of higher dielectric constant. A generalized SC theory is applied along with extensive Monte-Carlo simulations which applied numerical algorithm based on the image charge method to calculate accurate electrostatic potential or forces. We found the dielectric discontinuity is important in a SC regime. They drive strong counterion crowding in the central region of the inter-surface space upon increasing the solvent/membrane dielectric mismatch and change the membrane interactions from attractive to repulsive at small separations.

10:00AM P40.00011 Electronic Structure Analysis for Proteins on the FMO Method, TOMOKI KOBORI, SHINJI TSUNEYUKI, KEITARO SODEYAMA, University of Tokyo, KAZUTO AKAGI, Tohoku University, KIYOHUKE TERAKURA, JAIST, HIDETOSHI FUKUYAMA, Tokyo University of Science — The enormity and complexity of proteins have rendered their electronic structure calculation very costly. Although recently established Fragment Molecular Orbital (FMO) method enables us to calculate total energy of a huge protein precisely based on quantum mechanics, the method does not refer to one-electron orbitals and one-electron energy spectrum. In this paper we propose a method of analyzing electronic structure of a protein based on first principles calculation with reasonable accuracy and CPU cost. We construct one-electron Hamiltonian of proteins by assembling the output of the FMO method: fragment orbitals are determined by fragment monomer calculation, while interaction and overlap between fragment orbitals in different fragments are obtained from dimer calculation. After one-electron Hamiltonian matrix of the whole system is fabricated with the fragment orbital basis, one-electron energy spectrum is obtained by its diagonalization. If the matrix dimension is too large, unimportant orbitals are eliminated from the matrix so that the diagonalization of the Hamiltonian becomes feasible. The method is applicable to both the Hartree-Fock method and the density functional theory. In this paper, validity of the method is verified by some test calculations of small peptides.

10:12AM P40.00012 Helical secondary structure of polyalanine peptides in vacuo: Ac-Ala$\alpha$-LysH$^+$ ($n=5,10,15$), experiment and theory, MARIANA ROSSI, VOLKER BLUM, PETER KUPSER, GERT VON HELDEN, FRAUKE BIERAU, GERARD MEULER, MATTHIAS SCHEFFLER, Fritz Haber Institute, D-14195 Berlin, Germany — The presence of a solvent is often viewed as indispensable to quantify the stabilization interactions. However, well defined secondary structure motifs (helices, sheets, ...) also exist in vacuo, offering a unique “clean room” condition to quantify the stabilizing interactions. We here unravel the structure of Lysine$^+$ capped polyalanine peptides Ac-Ala$\alpha$-LysH$^+$ ($n=5,10,15$), by combining experimental multi-photon IR spectra obtained using the FELIX free-electron laser at room-temperature with van der Waals-corrected all-electron density-functional theory (DFT) in the generalized gradient approximation in the FHI-aims code [1]. Earlier ion mobility studies of these molecules indicate helical structure [2], which we here demonstrate quantitatively. For $n=5$, we find a close energetic competition of different helix motifs ($\alpha$, $3_1\beta$), with similar and good agreement between measured and calculated vibrational spectra. We show how the Lys$^+$ termination acts to induce helices also for longer peptides, and how vibrational modes develop with helix length ($n=10,15$), yielding, e.g., a softening of collective modes towards the infinite helix limit. [1] V. Blum et al, Comp. Phys. Comm. (2008), accepted. [2] M. Kohtani et al., JACS 120, 12975 (1998).

10:24AM P40.00013 Hofmeister effect and the phase diagram of lysozyme, STEVEN LETTIERI, XIAOFEI LI, JAMES GUNTON, Lehigh University — The phase diagrams for lysozyme are calculated for two different precipitant salts, NaCl and NaSCN, using a potential of mean force that takes into account contributions from ion-dispersion forces (J.Phys.Chem.B, 110, 24757). Our results are consistent with a recent perturbation theory calculation (J.Phys.Chem.B, 110, 24775) in that the phase diagram for lysozyme with NaCl is quite different than for lysozyme with NaSCN for the same molar concentration (0.2M). However, in contrast to the perturbation theory calculation, we find that the lysozyme phase diagram with NaCl has a metastable fluid-fluid coexistence curve and that the metastability gap in the case of NaSCN is much larger than predicted by perturbation theory.

10:36AM P40.00014 Infrared Spectroscopy with ab initio molecular dynamics simulations : gas phase floppy peptides of increasing size and complexity, in relation with IR-MPD experiments, MARIE-PIERRE GAEGOT, Universite d’Evry val d’Essonne - LAMBE UMR8887, IR-MPD EXPS, GILLES GREGOIRE & J.P. SCHERMANN COLLABORATION, IR-MPD EXPS, L. SNOEK & T. VADEN COLLABORATION — We present finite temperature DFT-based Car-Parrinello molecular dynamics (MD) simulations for the calculation of infrared spectra of complex molecular systems, either in the gas phase or in the condensed phase. We will review the fundamentals of the method, as well as the applicability and originality of finite temperature MD simulations for the purpose of modeling infrared spectra. Illustrations are taken from the fundamentals of infrared spectroscopy of alanine peptides of increasing size and complexity (from dipeptides to an octo-peptide) in the gas phase, in relation with IR-MPD (Infrared Multi Photon Dissociation) experiments : 300-400 K gas-phase action spectroscopy as devised on the CLIO platform at the University of Orsay-France or on the platform developed in the group of L. Snoek at Oxford-UK. A special emphasis on vibrational anharmonicities and how they can be extracted from molecular dynamics simulations will be put forward. Furthermore, band assignments in terms of atomic movements from MD is challenging and we have introduced a general method for obtaining effective normal modes of molecular systems from MD simulations.

10:48AM P40.00015 Linear irreversible thermodynamics, efficiency and coefficient of performance of a thermal Brownian motor in tight coupling, MULUGETA BEKELE, ANTENEH GETACHEW, Department of Physics, Addis Ababa University, Addis Ababa, Ethiopia, ARUN JAYANNVAR, Institute of Physics, Sachivalaya Marg, Bhubaneswar, India — We analytically calculated the Onsager’s coefficients near a finite stall force in the spirit of recent development in non-equilibrium steady state thermodynamics. We show that the occupancy relation holds and the determinant of the Onsager’s matrix vanishes when heat leakage is neglected. This condition implies that the device is built with tight coupling and hence Carnot’s efficiency can be achieved for the quasi-static process. We also show that the efficiency at maximum power to be exactly half of Carnot’s efficiency. Under similar condition we explore the coefficient of performance when our model works as a refrigerator.

1International Programme in Physical Sciences, Uppsala University, Uppsala, Sweden and Office of External Affairs, ICTP, Trieste, Italy. Wednesday, March 18, 2009 8:00AM - 10:48AM Session P41 DCMP DMP: Models of Strongly Correlated Electrons 413
8:00AM P41.00001 Time-Reversal Symmetry Breaking and Spontaneous Anomalous Hall Effect in Fermi Fluids, KAI SUN, EDUARDO FRADKIN, UIUC — We study the spontaneous non-magnetic time-reversal symmetry breaking in a 2D Fermi liquid without breaking either the translational symmetry or the $U(1)$ charge symmetry. Using a Berry phase approach, we found that for a large class of models, including all one- and two-band models, the time-reversal symmetry breaking states can be classified into two classes, dubbed type I and II, depending on the accompanying spatial symmetry breaking patterns. The properties of each class are studied. In particular, we show that the states breaking both time-reversal and chiral symmetries (type II) are described by spontaneously generated Berry phases and exhibit anomalous Hall effect in the absence of magnetic fields and magnetic impurities. We also show examples of the time-reversal symmetry breaking phases in several different microscopically motivated models and calculate their associated Hall conductance within a mean-field approximation. In particularly, we found a simple lattice structure in which the time-reversal symmetry breaking phases is stabilized by infinitesimal interactions.

8:12AM P41.00002 String-nets, quantum loop gases and the sign problem for non-abelian anyons, ANDREA VELENICH, CLAUDIO CHAMON, Boston University, XIAO-GANG WEN, M.I.T. — Hamiltonians giving rise to topological ground states can be constructed explicitly as sums of local operators acting on Hilbert spaces where distinct classical string-net configurations are orthogonal. We show explicitly the connection between string-nets and quantum loop gas models with their non-orthogonal inner product. Also we emphasize the role of the “sign problem” for a Hamiltonian in enforcing the topological character of its ground state.

8:24AM P41.00003 Hydrodynamic description of spin Calogero-Sutherland model, ALEXANDER ABANOV, Stony Brook University, MANAS KULKARNI, Stony Brook University and Brookhaven National Laboratory, FABIO FRANCHINI, The Abdus Salam ICTP — We study a non-linear collective field theory for an integrable spin-Calogero-Sutherland model. The hydrodynamic description of this $SU(2)$ model in terms of charge density, charge velocity and spin currents is used to study non-perturbative solutions (solitons) and examine their correspondence with quantum numbers of elementary excitations [1]. A conventional linear bosonization or harmonic approximation is not sufficient to describe, for example, the physics of spin-charge (non-)separation. Therefore, we need this new collective bosonic field description that captures the effects of the band curvature. In the strong coupling limit [2] this model reduces to integrable $SU(2)$ Haldane-Shastry model. We study a non-linear coupling of left and right spin currents which form a Kac-Moody algebra. Our quantum hydrodynamic description for the spin case is an extension for the one found in the spinless version in [3].

8:36AM P41.00004 Supersymmetry in strongly correlated fermion models, DIMITRIS GALANAKIS, University of Illinois at Urbana - Champaign, STEFANOS PAPANICOLAOU, CHRIS HENLEY, Cornell University — We investigate the Fendley and Schoutens model of hard core fermions on lattice which have hopping elements $t$, and potential terms $V$ which include a second-neighbor repulsion with some multi-particle terms. At the special point $t = V$, they showed that the Hamiltonian is $H = (Q_t^\dagger (r), Q_t)$ with $Q = \sum q(r) = \sum c(r)^* P(r)$, where $c(r)$ is an annihilation operator and $P(r)$ enforces the hardcore. That means the system acquires an exact non-relativistic supersymmetry, and for a range of fillings has a large number of zero-energy ground state [1]. To obtain insights on the nature of the zero-energy states and excitations, we perform exact diagonalization studies on finite clusters for various interaction strengths, fillings and lattice geometries. We note that for fillings beyond $n \approx 0.3$, we find coexisting domains of the inert crystal at $n = 1/2$, in contrast to a related non-supersymmetric model [2]. Moreover, using both numerical and analytical tools, we investigate perturbative limits where $q(r)$ is changed so as to preserve supersymmetry but a particular class of ground-states becomes trivial.

8:48AM P41.00005 Hexatic and Microemulsion Phases in the 2d Quantum Plasma, BRYAN CLARK, Department of Physics, University of Illinois at Urbana Champaign, MICHELE CASULA, Centre de Physique Théorique, Ecole Polytechnique, CNRS, 91128 Palaiseau, France, DAVID CEPERLEY, Department of Physics, University of Illinois at Urbana Champaign — It has been long known that the two-dimensional one component plasma supports both a Wigner-crystal and liquid phase. Classically [1,2], it is known that a hexatic phase exists but it is not known how this hexatic phase extends into the quantum regime. Moreover, at low temperature, phenomenological arguments [3] from Jamiei, et. al. suggest the existence of microscopic phases including stripes and bubbles. We use diffusion and path integral Monte Carlo to map out this phase diagram. We are able to extend the hexatic phase into the quantum regime as well as quantify the nature of the defects and exponents in the long range quantum system. We also specify the nature, extent and existence (or lack thereof) of the expected low-T microemulsion phases. We use diffusion and path integral Monte Carlo to map out this phase diagram. We are able to extend the hexatic phase into the quantum regime as well as quantify the nature of the defects and exponents in the long range quantum system. We also specify the nature, extent and existence (or lack thereof) of the expected low-T microemulsion phases.

9:00AM P41.00006 Quantum phase transition in a staggered flux phase, CHRISTOPH PUETTER, HAE-YOUNG KEE, University of Toronto — We study the quantum critical point inside the staggered flux phase. We present the dynamics of the fermions at the critical point and discuss their relevance for the phenomena observed in high-Tc cuprates.

9:12AM P41.00007 Quantum correlated percolation, LIANG CAO, Syracuse University, M. JENG, Microsoft Corporation, J. M. SCHWARZ, Syracuse University — Abstract: Quantum percolation is the study of hopping transport of a quantum particle on randomly diluted percolation clusters. Inspired by correlated percolation models of geometrical jamming, we extend quantum percolation to investigate hopping transport on percolation clusters with geometric constraints on the occupation of bonds/sites. An example of a geometric constraint is each occupied site must have at least two occupied neighboring sites to remain occupied ($k$-core percolation). Another example is particular sets of neighboring sites containing at least one occupied site for an occupied site to remain occupied (spiral model). Both models exhibit long-range geometrical correlations differing from ordinary percolation and give rise to a discontinuous phase transition (in high dimensions for $k$-core percolation). To investigate how these atypical long-range geometrical correlations affect the hopping transport of a quantum particle, we numerically study the level statistics of quantum $k$-core percolation on the Bethe lattice and the two-dimensional quantum spiral model. While the quantum $k$-core model exhibits an insulator-to-metal transition as the occupation probability is increased, preliminary results indicate that there is no insulator-to-metal transition in the two-dimensional quantum spiral model. Studies of a three-dimensional quantum spiral model will also be addressed as well possible physical applications of quantum jamming.
9:24AM P41.00008 Frustration of dissipation in a spin-boson model. KEVIN INGERSENT, ALPER DURU, U. of Florida — The spin-boson model (SBM), in which a quantum two-level system couples via one component of its effective spin to a dissipative bosonic bath, has many realizations. There has been much recent interest in the SBM with a sub-Ohmic bath characterized by a power-law spectral exponent (0 < s < 1), where at zero temperature a quantum critical point separates delocalized and localized phases. Numerical renormalization group calculations have called into question [1] the validity of the long-anticipated mapping between the SBM and the classical Ising chain with interactions decaying with distance as $|i-j|^{-s}$ as $1/|i-j|^{1+s}$. Attention has also fallen on a variant of the SBM in which two components of the impurity spin couple to different bosonic baths. For Ohmic case ($s = 1$), competition between the baths has been shown to frustrate the dissipation and reduce the coupling of the impurity to the environment [2]. The present study addresses the SBM with two sub-Ohmic baths, where dissipative effects are intrinsically stronger than for $s = 1$. Numerical renormalization group methods are used to identify a continuous quantum phase transition in this model and to evaluate critical exponents characterizing the quantum-critical behavior in the vicinity of the transition. 9:36AM P41.00009 Fidelity susceptibility and quantum phase transitions1, SHI-JIAN GU, Department of Physics, The Chinese University of Hong Kong — In this talk, I will introduce the quantum fidelity approach to quantum phase transitions based on its leading term, i.e. the fidelity susceptibility. The fidelity susceptibility denotes the adiabatic leading response of the ground state to the driving parameter. Differ from traditionally approach based on the ground-state energy, the fidelity susceptibility shows distinct scaling and singular behaviours around the critical point. I will present also the ground-state fidelity approach to both Landau’s phase transition and topological phase transition, as illustrated by the Lipkin-Meshkov-Glick model and the Kitaev honeycomb model, respectively.

1This work is supported by an Earmarked Grant for Research from the Research Grants Council of HKSAR, China (Projects No. CUHK 400906)

9:48AM P41.00010 Scaling of logarithmic quantum fidelity in the Lipkin-Meshkov-Glick model1, CHING YEE LEUNG, HONG KWOK, SHI-JIAN GU, HAI-QING LIN, Department of Physics, The Chinese University of Hong Kong — The quantum fidelity is used to describe quantum phase transitions in many works. As the classical expression of logarithmic fidelity is shown to be an extensive value, it was suggested that the logarithmic fidelity can be averaged over the system size and named as fidelity per site. However, illustrated by the anisotropic Lipkin-Meshkov-Glick model, which exhibits different scaling behaviour in different phases, we show that the logarithmic fidelity in the ground state of the model scales like $N$ in the symmetry-broken phase and $N^{0}$ in the polarizing phase. It is suggested to be a pure quantum effect and generalization of fidelity per site is proposed.

1This work is supported by an Earmarked Grant for Research from the Research Grants Council (RGC) of the HKSAR, China (Project No. CUHK204/05).

10:00AM P41.00011 Multicanonical Monte Carlo simulations of anisotropic SU(3) and SU(4) Heisenberg models, KENJI HARADA, Kyoto University, NAOKI KAWASHIMA, ISSP, University of Tokyo, MATTHIAS TROYER, ETH, Zurich — We present the results of multicanonical Monte Carlo simulations on two-dimensional anisotropic SU(3) and SU(4) Heisenberg models. In our previous study [K. Harada, et al., J. Phys. Soc. Jpn. 76, 013703 (2007)], we found evidence for a direct quantum phase transition from the valence-bond-solid (VBS) phase to the SU(3) symmetry breaking phase on the SU(3) model and we proposed the possibility of deconfined critical phenomena (DCP) [T. Senthil, et al., Science 303, 1490 (2004); T. Grover and T. Senthil, Phys. Rev. Lett. 98, 247202 (2007)]. Here we will present new results with an improved algorithm, using a multicanonical Monte Carlo algorithm. Using a flow method-like technique [A.B. Kuklov, et al., Annals of Physics 321, 1602 (2006)], we discuss the possibility of DCP in both models.

10:12AM P41.00012 Topological stability of q-deformed quantum spin chains, CHARLOTTE GILS, ETH Zurich, EDDY ARDONNE, Nordita, SIMON TREBST, Microsoft Research, Station Q, ANDREAS LUDWIG, UC Santa Barbara, MATTHIAS TROYER, ETH Zurich, ZHENGHAN WANG, Microsoft Research, Station Q — Quantum mechanical systems, whose degrees of freedom are so-called $su(2)_q$ anyons, form a bridge between ordinary spin systems and systems of interacting non-Abelian anyons. Such a connection can be made for arbitrary spin-$S$ systems, and we explicitly discuss spin-$1/2$ and spin-1 systems. Anyonic spin-$1/2$ chains exhibit a topological protection mechanism that stabilizes their gapless ground states and which vanishes only in the limit $(k \rightarrow \infty)$ where the system turns into the ordinary spin-$1/2$ Heisenberg chain. For anyonic spin-1 chains we show that their phase diagrams closely mirror the one of the biquadratic spin-1 chain. This includes generalizations of the Haldane phase, of the AKLT point, and the appearance of several stable critical phases described by (super)conformal field theories.

10:24AM P41.00013 Momentum distribution of the one-dimensional hard-core boson Hubbard model, MIN-CHUL CHA, JONG-GEUN SHIN, Hanyang University-Ansan (Korea), JI-WOO LEE, Myongji University (Korea) — We investigate the momentum distributions, $n_k$, of the one- dimensional hard-core boson Hubbard model as a function of the nearest-neighbor interaction strength by exact diagonalizations for lattices up to 30 sites. It is well known that the ground state of this model shows a quantum phase transition between the Ising-ordered insulating phase and the XY-ordered superfluid phase at $V = 2t$. Predetermination of the critical point helps us to investigate various critical behaviors. At the critical point, the momentum distribution shows a linear dependence ($n_k \sim |k - \pi|$). $n_k (k = \pi)$ shows different critical behaviors upon approaching the critical point in the Ising or XY regions. Some other properties of the momentum distributions and the critical behaviors are discussed.

10:36AM P41.00014 Ring-exchange interaction in doubly degenerate orbital system with strong electron correlation, JOJI NASU, Department of Physics, Tohoku University, SUMIO ISHIHARA COLLABORATION — Degree of freedom is one of the attractive themes in transition-metal oxides. Since the inter-site orbital interaction depends explicitly on the bond direction, one orbital configuration which minimizes the bond energy in one direction does not minimize in other directions. This is a kind of frustration. We study the $e_g$ orbital model (EOM) where the $e_g$ orbital is represented by the pseudo-spin (PS) with nearest neighbor (NN) interaction in a cubic lattice. Due to this frustration, this model shows a macroscopic number of degenerate states in the classical ground states. It is known that these states are lifted by thermal and quantum fluctuations. We examine the long-range interaction effect in the EOM. This interaction is derived by the higher-order perturbational processes of the electron transfer under strong on-site Coulomb repulsion in the two orbital Hubbard model. In particular, roles of the orbital ring-exchange interaction are focused on. This includes the magnetic octupole operator which does not appear in the previous EOM with NN interaction. We analyzed this model by the mean field approximation and the classical Monte-Carlo method. We found that PS canted state is stabilized rather than PS collinear state which is realized in the previous EOM due to thermal and quantum fluctuations. It is also shown that the magnetic octupole polarization appears in a wide parameter region.

Wednesday, March 18, 2009 11:15AM - 1:39PM — Session Q1 DCMP: Memory and Focusing in Catastrophic Deformations Spirit of Pittsburgh Ballroom A
11:15AM Q1.00001 Tsunami Asymptotics. MICHAEL BERRY, Physics Department, Bristol University, UK — Optical analogies, and some singularity theory, give new information about tsunamis. For most of their propagation, tsunamis are linear dispersive waves whose speed is limited by the depth of the ocean and which can be regarded as diffraction-decorated caustics in spacetime. For constant depth, uniform asymptotics gives a very accurate compact description of the tsunami profile generated by an arbitrary initial disturbance. Variations in depth act as lenses and can focus tsunamis onto cusped caustics, and this “singularity on a singularity” constitutes an unusual diffraction problem, whose solution indicates that focusing can amplify the tsunami energy by an order of magnitude.

11:51AM Q1.00002 Memory encoding vibrations in a disconnecting air bubble. WENDY ZHANG, University of Chicago — The implosion that disconnects a submerged air bubble into several bubbles provides a simple example of energy focusing. The most efficient disconnection is an entirely symmetric one terminating in a finite-time singularity. At the final moment, the potential energy at the start of the disconnection is entirely condensed into the kinetic energy of a vanishingly small amount of liquid rushing inwards to disconnect the bubble. In reality, however, the initial shape always possesses slight imperfections. We show that a memory of the imperfection remains and controls the final fate of the focusing. Linear stability reveals that even an infinitesimal perturbation is remembered. A slight initial asymmetry excites vibrations in the cross-section shape of the bubble neck. The vibrations persist over time. Near the singularity, their amplitudes freeze, locking onto constant values, while their frequencies chirp, increasing more and more rapidly. The net effect is that the singularity remembers exactly half of the information about the initial imperfection, the half encoded by the vibration amplitudes. We check this scenario in an experiment by releasing an air bubble from a nozzle with an oblong cross-section. This excites an elongation-compression vibrational mode. We measure the vibration excited and find quantitative agreement with linear stability. When the initial distortion has a small, but finite, size, the saturation of the vibration amplitude causes the symmetric singularity to be pre-empted by an asymmetric contact between two distant points on the interface. Numerics reveal that the contact is typically smooth, corresponding to two inward-curving portions of the bubble surface colliding at finite speed. Both the contact speed and curvature vary non-monotonically with the initial distortion size, with abrupt jumps at specific values. This is because the vibration causes contact to occur at different values of the phase. A contact produced when the shape distortion is pronounced requires a smaller initial amplitude than a contact produced when the vibration is out of phase. (Joint work with Nathan C. Keim, Lipeng Lai, Laura E. Schmidt, Konstantin Turitsyn and Sidney R. Nagel.)

12:27PM Q1.00003 Pattern Transformation Triggered by Deformation. TOM MULLIN, Manchester Centre for Nonlinear Dynamics, University of Manchester, Oxford Road, Manchester M13 9PL, UK — Periodic elastomeric cellular solids are subjected to uniaxial compression and a novel uniform transformation of the structure is found above a critical value of applied load. The results of a numerical investigation reveal that the pattern switch is triggered by a reversible elastic instability. The mechanism has proved to be useful for controlled imprinting of complex patterns in phononic and photonic crystals. The material also provides an example of a simple, tunable and robust negative Poisson ratio foam. More recently, the inverse problem of an appropriate array of elastic particles has been shown to provide another example of an intriguing pattern switch.

1:03PM Q1.00004 Resonant generation of internal waves on a model continental slope. HEPENG ZHANG, Univ. of Texas at Austin — Away from shallow, well-mixed surface regions, the density of sea water increases with depth due to variation in salinity and temperature. This continuous density stratification supports internal gravity waves, which are the counterpart within the fluid interior of surface gravity waves. Internal gravity waves are important for many oceanic processes, such as sediment transportation and ocean mixing. We study internal wave generation in a laboratory model of oscillating tidal flow on a continental margin. Waves are found to be generated only in a near-critical region where the slope of the bottom topography matches that of internal waves. Fluid motion with a velocity an order of magnitude larger than that of the forcer occurs within a thin boundary layer above the bottom surface. The resonant wave is unstable because of strong shear; Kelvin-Helmholtz billows precede wave breaking. We construct a model to extrapolate our results to oceanic conditions. This work [1] provides a new explanation for the intense boundary flows on continental slopes.

Wednesday, March 18, 2009 11:15AM - 1:39PM – Session Q2 DCMP: New Insights into Hidden Order in URu2Si2

11:15AM Q2.00001 Sleuthing Hidden Order in URu2Si2. PREMALA CHANDRA, Center for Materials Theory, Dept. of Physics and Astronomy, Rutgers University — In this talk, I will provide an overview of recent experimentally-driven advances in our understanding of the hidden order in URu2Si2; constraints and implications for future theoretical work will be discussed. State-of-the-art pressure, neutron and transport measurements [1] on this material have led to the confirmation of the phase diagram proposed on theoretical grounds for URu2Si2 several years ago [2], while recent neutron [3], ARPES and STM studies provide growing evidence for the formation of a density wave of unknown character [2]. I will also describe the challenge of linking the observed excitations to the underlying hidden order, and will discuss ongoing theoretical advances in this direction.

References:

11:51AM Q2.00002 ARPES Clues to the Hidden Order in URu2Si21. JONATHAN DENLINGER2. Lawrence Berkeley National Laboratory — The three-dimensional electronic structure of UHV-cleaved URu2Si2 is investigated using photon-dependent angle-resolved photoemission (ARPES). Wide angle Fermi-surface (FS) maps as well as high-resolution spectroscopy focused on key high symmetry points reveal high-U 5f spectral weight at the hole-like regions of the FS. ARPES is made to LDA+DMFT calculations as several years ago [2], while recent neutron [3], ARPES and STM studies provide growing evidence for the formation of a density wave of unknown character [2]. I will also describe the challenge of linking the observed excitations to the underlying hidden order, and will discuss ongoing theoretical advances in this direction.

12:27PM Q2.00003 Neutron Scattering Studies of Hidden Order in URu$_2$Si$_2$. **CHRISTOPHER WIEBE.** Florida State University/NHMFL — The heavy fermion superconductor URu$_2$Si$_2$ has held the attention of physicists for the last two decades due to the presence of a mysterious hidden order phase below 17.5 K. Previous neutron scattering measurements indicate that the ordered moment is 0.03 $\mu_B$, much too small to account for the large heat capacity anomaly at 17.5 K. We present recent neutron scattering experiments which unveil a new piece of this puzzle – the spin excitation spectrum above 17.5 K exhibits well-correlated, itinerant-like spin excitations up to at least 10 meV emanating from incommensurate wavevectors.

The gapping of these excitations corresponds to a large entropy release and explains the reduction in the electronic specific heat through the transition. We also present new neutron scattering data linking the spin excitations to Fermi surface instabilities, and discuss the remaining candidates for the identity of the hidden order phase.

---

1:03PM Q2.00004 Competition of Hidden Order and Antiferromagnetism in URu$_2$Si$_2$ under Pressure. **ELENA HASSINGER, INAC, CEA Grenoble, France — URu$_2$Si$_2$ is a heavy fermion compound with an ordered phase below $T_d = 17.5$ K at ambient pressure. The signature of the transition at $T_d$ in macroscopic quantities is very large and indicates a partial gap opening on the Fermi surface. However, the order parameter could not be identified yet and therefore, the phase is called hidden order (HO). Additionally, the compound becomes superconducting below $T_{SC} = 1.4$ K. Here, we focus on the difference between HO and the pressure induced antiferromagnetic state (AF) in order to shed light on the HO itself. By specific heat and resistivity measurements under pressure we were able to confirm the pressure-temperature phase diagram determined by neutron scattering.**

For pressures higher than $P_c = 0.5$ GPa the antiferromagnetic phase develops and superconductivity is suppressed at the same time. The transition line between HO and AF can be seen as a small anomaly in resistivity and specific heat data until 1.3 GPa, where it seems to join the transition line between the paramagnetic and the HO phase. The nesting-like signature at $T_d$ in resistivity surprisingly does not change qualitatively between low pressures at the transition to HO and high pressures at the transition to the AF. The differences in the low energy excitations between the HO and AF phases have been investigated by neutron scattering measurements at 0.67 GPa where three phases can be detected on cooling: paramagnetic, HO and AF phase. The inelastic response at the antiferromagnetic wavevector $Q_H = (1,0,0)$ and at the position of the second minimum in the dispersion relation $Q_d = (1.4,0,0)$ was measured in the three distinct phases. The sharp excitation at $Q_d$ with a gap of 1.8 meV exists only in the hidden order phase and disappears in the antiferromagnetic phase whereas the excitation at $Q_1$ persists in both phases. Therefore only the excitations at the commensurate wavevector $Q_0$ are characteristic of the HO phase.

11:15AM Q3.00001 Computerized Comparison and Analysis of Vincent van Gogh’s Painting Brushstrokes. **JAMES Z. WANG, The Pennsylvania State University — With advanced digitization techniques, museums have routinely begun to assemble vast digital libraries of images of their collections. These images can be analyzed by computers to assist art historians for a number of tasks. In our work, we focus on three challenges: artist identification, dating of an art work, and finding distinguishing features among artists. Two complementary approaches were taken: (1) the analysis of the geometric statistics based on the extracted individual brushstroke, and (2) the modeling of overall brushstroke texture.**

These approaches aim at assisting art historians in comparing a painting or parts of a painting to a group of paintings based on multiple criteria. Statistical methods have been used to compare groups of paintings. Each painting image is divided into subimages. Individual brushstrokes are segmented automatically. Geometric features, including the curvature, the overall orientation, and the size, are computed for each brushstroke. We also compute the features representing the interaction of the brushstrokes extracted. The statistics, including average and standard deviation, of those features are used to model certain aspects of the artist’s brushstrokes. For capturing the local brushstroke texture, we first compute the wavelet transform to the image. A spatial model, the 2-D hidden Markov model, is used to model the texture features of each subimage. The methods have shown to be able to distinguish van Gogh paintings and non van Gogh paintings to a great extent. The techniques can provide clues for the dating of van Gogh paintings. A comparison of the van Gogh paintings, Monticelli’s paintings, and paintings by contemporary artists provides insights on their similarities and differences. The analysis has provided numerical statistics for further studying these and other paintings.

11:51AM Q3.00002 Prime-Time Science: The Beginning of a Beautiful Friendship? **JENNIFER OUELLETTE, National Academy of Sciences — The portrayal of science has often posed a challenge to Hollywood. Though it has provided some of the compelling storylines, the many complexities of science (and scientists) have confounded even the most talented writer or director, pitting creative license against scientific accuracy again and again. Likewise, the scientific community has struggled to find a conduit through which it can communicate its story to the general public on a mass scale. To bridge this gap, the National Academy of Sciences has partnered with leading Hollywood professionals to launch The Science and Entertainment Exchange; its mission is to connect entertainment industry professionals with top scientists from across the country to foster creative collaborations. The timing has never been better: there is a plethora of network TV shows currently on the air with science-based themes and plot lines, and a renewed interest – even with science fiction films and TV – in coming up with more plausible futuristic scenarios. Working together, the two communities can create a “win-win” synergy between accurate science and engaging entertainment.**

12:27PM Q3.00003 Hollywood Science: Good for Hollywood, Bad for Science? **SIDDNEY PERKOWITZ, Emory University — Like it or not, most science depicted in feature films is in the form of science fiction. This isn’t likely to change any time soon, if only because science fiction films are huge moneymakers for Hollywood. But beyond that, these films are a powerful cultural force. They reach millions as they shed light on current scientific issues and stimulate public interest.**

In this talk, based on my book _Hollywood Science_ [1], I’ll show examples of good and bad screen treatments of science, scientists, and their impact on society. I’ll also discuss efforts to improve how science is treated in film and ways to use even bad movie science to convey real science.

---

1:03PM Q3.00004 The Physics of the Blues, J. MURRAY GIBSON, Argonne National Laboratory — In looking at the commonalities between music and science, one sees that the musician’s palette is based on the principles of physics. The pitch of a musical note is determined by the frequency of the sound wave. The scales that musicians use to create and play music can be viewed as a set of rules. What makes music interesting is how musicians develop those rules and create ambiguity with them. I will discuss the evolution of Western musical scales in this context. As a particular example, “Blue” notes are very harmonic notes that are missing from the equal temperament scale. The techniques of piano blues and jazz represent the melding of African and Western music into something totally new and exciting. Live keyboard demonstrations will be used. Beyond any redeeming entertainment value the talk will emphasize the serious connections between science and art in music. Nevertheless tips will be accepted.

1:39PM Q3.00005 Joys and Pains in Making a Science Movie1, IVAN SCHULLER, UCSD — This talk will describe the joys and pains in making a multiple award winning science movie: “When Things Get Small.” We found that in order to reach a wide public of non-experts, the best approach is to develop a collaboration between a scientist and a TV producer. In order to keep scientific accuracy and at the same time maintain public interest it is crucial to keep the message well defined and crisp and not dwell on too many details. The creative process, coming from these two different cultures, makes this a very rewarding experience. However, there are also “pains” associated with it which will be described. Movie available at http://fischuller.ucsd.edu/movies/movies.php or http://uctv.tv/getsmall/ movie was produced in collaboration with R. Wargo and UC-TV(http://www.ucsd.tv/getsmall/) and had the contribution from many other movie professionals.

Wednesday, March 18, 2009 11:15AM - 2:15PM — Session Q4 DPOLY GSNP: Polymer Surface Instabilities 306/307

11:15AM Q4.00001 Elastic instabilities in rubber, ALAN GENT, University of Akron — Materials that undergo large elastic deformations can exhibit novel instabilities. Several examples are described: development of an aneurysm on inflating a rubber tube; non-uniform stretching on inflating a spherical balloon; formation of internal cracks in rubber blocks at a critical level of triaxial tension or when supersaturated with a dissolved gas; surface wrinkling of a block at a critical amount of compression; debonding or fracture of constrained films on swelling, and formation of “knots” on twisting stretched cylindrical rods. These various deformations are analyzed in terms of a simple strain energy function, using Rivlin’s theory of large elastic deformations, and the results are compared with experimental measurements of the onset of unstable states. Such comparisons provide new tests of Rivlin’s theory and, at least in principle, critical tests of proposed strain energy functions for rubber. Moreover the onset of highly non-uniform deformations has serious implications for the fatigue life and fracture resistance of rubber components.

References:

11:51AM Q4.00002 Creasing instability of solvent-swelled polymer films, RYAN HAYWARD, University of Massachusetts, Amherst — A thin layer of polymer bound to a rigid substrate develops compressive stresses when it is swelled by solvent, due to the constraint against lateral expansion imposed by the substrate. For sufficiently large stresses, the surface becomes unstable to a buckling mode in which tightly-folded “creases” form on the surface to relieve compressive stress. While this instability has been known in practice for more than a century, it remains poorly characterized and incompletely understood. I will describe experiments on model systems of surface-attached hydrogels to characterize the onset and growth mechanisms of creases, as well as methods that allow control of crease formation in both space and time. In addition to the implications that this instability has for any type of polymeric coating undergoing swelling, it also provides an opportunity to create surfaces with switchable topography and chemistry.

12:27PM Q4.00003 The macroscopic delamination of thin films from elastic substrates, PEDRO REIS, Massachusetts Institute of Technology — The wrinkling and delamination of stiff thin films adhered to a polymer substrate have important applications in “flexible electronics.” The resulting periodic structures, when used for circuity, have remarkable mechanical properties since stretching or twisting of the substrate is mostly accommodated through bending of the film, which minimizes fatigue or fracture. To date, applications in this context have used patterning of the substrate-film adhesion energy to produce a controlled array of delamination “blisters.” However, even in the absence of such patterning, blisters have a characteristic size. We use macroscopic experiments to study what sets the dimensions of these blisters in terms of the material properties, which we explain using a combination of scaling and analytical methods. This points to a novel method for determining the interfacial toughness. Finally, we suggest a number of design guidelines for the thin films used in flexible electronic applications.

1:03PM Q4.00004 Elastic Instability and Pattern Formation in Confined Soft Elastomeric Films, ANIMANGSU GHATAK, Department of Chemical Engineering, IIT Kanpur — When a rigid flat object or a flexible plate is removed from a thin soft film, instability patterns appear at the interface in the form of bubbles or fingers. The wavelengths of these instabilities are independent of all material and geometrical properties of the system except the thickness of the film. These observations contrast the classical Saffman-Taylor type instability in which the instability pattern depends on the viscous and surface tension forces in addition to the thickness of the liquid film. In the case of elastic instability of the kind described here, the wavelength depends on the material properties of the films only when soft films of different elastic properties are separated from each other. In the later case, a co-operative instability mode develops, which is a non-linear function of the thicknesses and the elastic moduli of both the films. In contrast to the wavelengths of these instabilities, their amplitudes are strong functions of several material and geometric properties of the system. These problems can be analyzed using regular perturbation technique to obtain the excess deformations of the film over and above the base quantities. Furthermore, by estimating the excess energy of the system, it can be shown that instability develops when the films are critically confined. This point can be illustrated by pre-stretching the film or simply by adjusting the contact width between the film and the plate. The instabilities that develop at the interface are critical to understanding adhesion and friction of soft thin films as they act like nucleated interfacial cracks. We performed a simple experiment, in which a flat rigid glass prism is sheared off a soft elastomeric film. At a given tangential force, the prism starts to slide on the elastomeric film accompanied with the formation of bubbles at the interface due to elastic instability. These bubbles, the lateral dimensions of which are comparable to the thickness of the film, move across the interface with speeds 1000 times faster than the overall sliding speed of the prism. The process continues till the critical condition for fracture is reached. These studies may shed some light on the fast dynamics of shear crack propagation in other systems.

1:39PM Q4.00005 Micro-Origami: Elastic Instability of Polymer Films, PASCAL DAMMAN, Université de Mons-Hainaut — Upon compression, thin (rigid) elastic membranes supported on a soft elastic solid spontaneously deviate from their flat geometry by forming regular wrinkles. How can we control the wavelength and the symmetry of the wrinkle patterns? What is the influence of defects? Why should we observe focalisation of deformation in folds for large strains? During my talk, I will review our approaches to tackle these questions.

Session Q5 FIAP: Plasmonics in Future Electronics 401/402

11:15AM Q5.00001 A Technique for Nanoscale Plasmonic Imaging via Photoemission . DANIEL S. PICKARD, Department of Electrical Engineering, National University of Singapore — The scientific community is witnessing increased research activity on Surface Plasmon Polaritons (SPPs). The potential applications of SPPs and plasmonic structures based on their control and manipulation are truly multi-disciplinary, spanning high speed nano-scale interconnects, meta-materials, chemical and biological sensing, sub-wavelength optics and waveguides, near-field optical trapping, high-density data storage, and the enhancement of non-linear effects. Measurement of the localized optical field intensity is a critical component in validating physical models and characterizing plasmonic structures. The dominant technique employed for this task is the Scanning Near-Field Optical Microscope (SNOM) or Photon Scanning Tunneling Microscope (PSTM), whose contrast mechanism is based on measuring light scattered from the near-field with a probe. These techniques can provide high resolution images of the localized fields, but they are slow. Furthermore, tip-sample interactions can perturb the fields, yielding ambiguity between electric and magnetic fields and frustrating attempts at accurate optical characterization. One way to facilitate the advance of plasmonics is to develop new techniques for imaging and characterizing SPP behavior on the nanoscale. Recent efforts employing photoemission to reveal the localized fields have demonstrated that this technique can provide both high spatial (∼10nm) and temporal (fs) resolution when combined with a Photoelectron Emission Microscope (PEEM)[1-3]. The PEEM does not require a probe so the fields can be imaged without perturbation. It also provides a parallel image of the full field, so acquisition times are fast. We are expanding the capabilities of the PEEM to exploit a novel contrast mechanism which will broaden the spectrum of plasmonic devices observable. We present our experimental efforts in this area, detail the underlying physics of the contrast mechanism and discuss how it can be controlled to enable unique spatial and temporal information on the propagation of SPPs within plasmonic structures.

11:51AM Q5.00002 Ultrafast and Quantum Nanoplasmonics: SPASER and Control . MARK I. STOCKMAN, Department of Physics and Astronomy, Georgia State University — Nanoplasmonics is presently experiencing a period of unprecedented growth and has numerous applications. These include sensing and detection of minute amount of chemical and biological objects for medicine and defense [1], near-field scanning optical microscopy [2], immunological tests, labels for biomedical research, nanoantennas for efficient coupling of light to semiconductor devices, etc. Nanoplasmonics still greatly needs active elements to generate optical energy on the nanoscale and serve as amplifiers. We have proposed a quantum nanoplasmonic generator and amplifier of the local optical fields, SPASER [surface plasmon amplification by stimulated emission of radiation]. A SPASER is analogous to laser except that light (photons) is replaced by local optical fields (surface plasmons). This is responsible for the principal difference: laser cavity must support photonic modes and its size is on order or much greater than the optical wavelength, cf. [6]. In contrast, the surface plasmons in the spaser are purely electric oscillations whose localization size is nanometric. SPASER will transform nanoplasmonics the same way as the laser transformed optics. In particular nanoplasmonic processors working at THz operation rates will become possible. Another important area is the active control of nanoplasmonic phenomena. One approach to it is coherent control, where a shaped optical pulse dynamically, on the femtosecond scale controls the nanoscale distribution of local fields [7-12].

12:27PM Q5.00003 Magnetic Light Emitters: Plasmon-enhanced Magnetic Dipole Transitions . RASHID ZIA, Brown University — Over the past decade, advances in both negative index metamaterials and resonant optical antennas have challenged traditional assumptions about light-matter interactions. While metamaterials research has shown that metallic structures can be engineered to support strong optical frequency magnetic resonances, resonant optical antennas have been designed to amplify and re-direct the emission from electric dipole emitters. In this talk, we explore the intersection of these distinct fields and investigate how resonant optical effects may be used to challenge the electric dipole approximation. Specifically, we will show how Purcell effects may be used to enhance the natural optical frequency magnetic dipole transitions in Lanthanide ions. We will present experimental and numerical results that demonstrate enhanced magnetic dipole emission from trivalent Europium ions near metallic films and nanoparticle composites. We will explore how the varying symmetries of electric and magnetic dipoles can be used to characterize and optimize magnetic light emission. Finally, we will discuss the implications of enhancing and controlling higher-order optical transitions for optical spectroscopy and photonic devices.

1:03PM Q5.00004 Plasmonic nano-circuitry . SERGEY BOZHEVOLNYI, University of Southern Denmark — Photonic components are superior to electronic ones in terms of operational bandwidth but suffer from the diffraction limit that constitutes a major problem on the way towards miniaturization and high density integration of optical circuits. The degree of light confinement in dielectric structures, including those based on the photonic band-gap effect, is fundamentally limited by the light wavelength in the dielectric used. The main approach to circumvent this problem is to take advantage of hybrid nature of surface plasmons (SPs) whose subwavelength confinement is achieved due to very short (nm-long) penetration of light in metals. After briefly reviewing various SP guiding configuration the results of our investigations of subwavelength photonic components utilizing SP modes propagating along channels cut into gold films are overviewed [Nature 440, 508 (2006); Nano Lett. 7, 880 (2007)], demonstrating first examples of ultracompact photonic components that pave the way for a new class of integrated optical circuits [Physics Today, May 2008, pp.44-50]. Recent results on the SP guiding along gold wedges at telecom wavelengths are also presented [Opt. Express 16, 5252 (2008)].
Field enhancement by Plasmonic Nanostructures

JOHN G. RADZILOWICZ, Carnegie Science Center — The late Carl Sagan opined that somehow we have managed to create a global civilization dependant on science and technology in which almost no one understands science and technology. This is an unacceptable recipe for disaster with social, political and financial implications for the future of scientific research. And so, like it or not, popular science communication, more than ever before, is an important and necessary part of the scientific enterprise. Public outreach programs, media interviews, and popular articles have become required parts of the scientist’s professional repertoire. But, what does it take to be a good science communicator? What is needed to develop and deliver meaningful public outreach programs? How do you handle non-technical presentations? And, what help is available in developing the necessary skills for good popular science communication? This presentation will look at the essential components of effective science communication aimed at a broad public audience. The components of successful science communication in programs, presentations and articles will be discussed. Specific attention will be given to how university-museum partnerships can expand the reach and enhance the quality of public outreach programs.

11:15AM Q6.00001 So, You Want to be a Science Communicator? , JOHN G. RADZILOWICZ, Carnegie Science Center — The late Carl Sagan opined that somehow we have managed to create a global civilization dependant on science and technology in which almost no one understands science and technology. This is an unacceptable recipe for disaster with social, political and financial implications for the future of scientific research. And so, like it or not, popular science communication, more than ever before, is an important and necessary part of the scientific enterprise. Public outreach programs, media interviews, and popular articles have become required parts of the scientist’s professional repertoire. But, what does it take to be a good science communicator? What is needed to develop and deliver meaningful public outreach programs? How do you handle non-technical presentations? And, what help is available in developing the necessary skills for good popular science communication? This presentation will look at the essential components of effective science communication aimed at a broad public audience. The components of successful science communication in programs, presentations and articles will be discussed. Specific attention will be given to how university-museum partnerships can expand the reach and enhance the quality of public outreach programs.

11:15AM Q6.00002 Public Outreach for the International Year of Astronomy Through Faculty and Science Center Partnerships1 , ANDREW ZENTNER, University of Pittsburgh — The International Year of Astronomy 2009 provides an opportunity to jump-start public education and outreach programs and to engage the community in a fascinating field. In my talk I will discuss a diverse program of education and outreach designed and implemented as a collaborative effort between the Astronomy faculty at the University of Pittsburgh and the Carnegie Science Center. I will highlight some of the unique benefits of such a partnership and some of the unique events such a partnership enables.

12:27PM Q6.00003 Public Education and Outreach Through Full-Dome Video Technology1 , JOHN POLLOCK, Duquesne University — My long-term goal is to enhance public understanding of complex systems that can be best demonstrated through richly detailed computer graphic animation displayed with full-dome video technology. My current focus is on health science advances that focus on regenerative medicine, which helps the body heal itself. Such topics facilitate science learning and health literacy. My team develops multi-media presentations that bring the scientific and medical advances to the public through immersive high-definition video animation. Implicit in treating the topics of regenerative medicine will be the need to address stem cell biology. The topics are clarified and presented from a platform of facts and balanced ethical consideration. The production process includes communicating scientific information about the excitement and importance of stem cell research. Principles of function are emphasized over specific facts or terminology by focusing on a limited, but fundamental set of concepts. To achieve this, visually rich, biologically accurate 3D computer graphic environments are created to illustrate the cells, tissues and organs of interest. A suite of films are produced, and evaluated in pre-post-surveys assessing attitudes, knowledge and learning. Each film uses engaging interactive demonstrations to illustrate biological functions, the things that go wrong due to disease and disability, and the remedy provided by regenerative medicine. While the images are rich and detailed, the language is accessible and appropriate to the audience. The digital, high-definition video is also re-edited for presentation in other “flat screen” formats, increasing our distribution potential. Show content is also presented in an interactive web space (www.sepa.duq.edu) with complementing teacher resource guides and student workbooks and companion video games.

1:03PM Q6.00004 A New Approach to A Science Magnet School - Classroom and Museum Integration , SAMUEL FRANKLIN, Pittsburgh Science and Technology Academy — The Pittsburgh Science & Technology Academy is a place where any student with an interest in science, technology, engineering or math can develop skills for a career in life sciences, environmental sciences, computing, or engineering. The Academy isn’t just a new school. It’s a new way to think about school. The curriculum is tailored to students who have a passion for science, technology, engineering or math. The environment is one of extraordinary support for students, parents, and faculty. And the Academy exists to provide opportunities, every day, for students to Dream. Discover. Design. That is, Academy students set goals and generate ideas, research and discover answers, and design real solutions for the kinds of real-world problems that they’ll face after graduation. The Academy prepares students for their future, whether they go on to higher education or immediate employment. This talk will explain the unique features of the Pittsburgh Science & Technology Academy, lessons learned from its two-year design process, and the role that the Carnegie Museums have played and will continue to play as the school grows.

1:39PM Q6.00005 Fractured Physics and the Great Color Caper: Large Scale Physics Outreach , MIKE HENNESSY, Carnegie Science Center — No abstract available.

Wednesday, March 18, 2009 11:15AM - 2:15PM –
12:27PM Q7.0003 Fast, continuous recirculation of germinal center B cell populations enhances robustness of immune response towards varying pathogens, MICHAEL DEEM, Rice University — The immune system normally protects the human host against death by infection. I will introduce a physical theory of the evolutionary dynamics that occurs in the antibody-mediated and T cell-mediated immune responses. The theory will be used to provide a mechanism for original antigenic sin, wherein an initial exposure to antigen can degrade the response of the immune system upon subsequent exposure to related, but different, antigens. A new order parameter to characterize antigenic distance will be introduced from the theory. This order parameter predicts effectiveness of the influenza vaccine more reliably than do results from animal model studies currently used by world health authorities. I will discuss how this order parameter might be a valuable new tool for making vaccine-related public health policy decisions. Next, I will briefly discuss dengue fever. Infection with, or vaccination against, one of the four serotypes of dengue fever typically increases susceptibility to dengue hemorrhagic fever from one of the other three serotypes. I will present a physical theory of this immunodominance and use this theory to quantify the predicted mitigation of immunodominance in a novel formulation of the dengue vaccine.

1:03PM Q7.0004 Fish Immunology, STEPHEN QUAKE, Stanford Univ — No abstract available.

1:39PM Q7.0005 Genetic Circuit Architectures Underlying Cell Fate Choices for Immunity, AARON DINNER, The University of Chicago — Antigen stimulated B cells follow an unusual developmental trajectory that transiently passes through a germinal center state, which promotes receptor affinity maturation and immunoglobulin class switching, before terminally differentiating into antibody secreting plasma cells. It was found that graded expression of the transcription factor IRF-4 regulates cell fate, but the relationship between antigen receptor signaling, the network of interactions with IRF-4, and cell fate was not known. This talk describes models that link ligand-receptor avidity with cell fate. The models have been validated experimentally by directly varying the levels and kinetics of IRF-4 accumulation. Furthermore, signaling through the antigen receptor is demonstrated to control the expression of IRF-4 and in turn the frequency of B cells that undergo class switching before differentiating into plasma cells. These findings provide an explanation for experiments that measure B cell numbers in transgenic mice. The architecture of our regulatory circuit provides a general mechanism for quantitative variations in a signal to be translated into a binary cell-fate choice involving transient expression of one of the two developmental fates. In collaboration with Arvye Warmflash, Ying Li, Roger Sciammas, and Harinder Singh, The University of Chicago.

Wednesday, March 18, 2009 11:15AM - 2:15PM — Session Q8 GMAG: Quantum Spin Dynamics and Relaxation in Molecular Magnets

11:15AM Q8.00001 Coherent Manipulation and Decoherence of S=10 Single-Molecule Magnets, SUSUMU TAKAHASHI, University of California Santa Barbara — A single crystal of high-spin single-molecule magnets (SMMs) is an attractive testbed for quantum science and technologies. High-spin SMMs are suitable for applications to dense quantum memory and computing devices. Because SMM clusters are identical and interact weakly, the ensemble properties of single crystals of SMMs reflect the properties of a single cluster. However coherent manipulation of high-spin SMM crystals has never been demonstrated due to strong spin decoherence. For spins in the solid state, an interaction with fluctuations of surrounding spin bath is a major source of spin decoherence. One approach to reduce spin bath fluctuations is to bring the spin bath into a well-known quantum state that exhibits little or no fluctuations. A prime example is the approach of using a fully polarized spin bath. In diamond, spin decoherence has been quenched using high-frequency pulsed electron paramagnetic resonance (EPR) [1]. We present coherent manipulation and decoherence of a single-crystal of S=10 Fe8 SMMs. Through pulsed polarization in Fe8 SMMs at 4.6 T and 1.3 K, we demonstrate that spin decoherence is significantly suppressed to extend the spin decoherence time (T2) up to 700 ns [2]. Investigation of temperature dependence of spin relaxation times reveals the nature of spin decoherence. This work is collaboration with J. van Tol, C. C. Beedle, D. N. Hendrickson, L.-C. Brunel, and M. S. Sherwin.

11:51AM Q8.00002 The Role of Antisymmetric Exchange on the Quantum Interference between States of Different Spin Length in a dimeric Molecular Nanomagnet, ENRIQUE DEL BARCO, University of Central Florida — We report direct evidence of quantum oscillations of the total spin length of a dimeric molecular nanomagnet through the observation of the splitting of NMR signals originating from EPR line broadening and tunneling. The EPR line broadening is given by the spin Hamiltonian for a single Mn12 wheel which behaves as a weak ferromagnetic exchange-coupled molecular dimer: each half of the molecule acts as a single-molecule magnet (SMM), while the weak coupling between the two halves gives rise to an additional internal spin degree of freedom within the molecule, namely that its total spin may fluctuate. This extra degree of freedom accounts for several magnetization tunneling resonances that cannot be explained within the usual giant spin approximation. More importantly, the observation of quantum interference provides unambiguous evidence for quantum mechanical superposition involving entangled states of both halves of the wheel. Magnetization results obtained in two other versions of this compound, in which the ligands have been modified, show that slight variations of the relative distance between the Mn ions determine whether the molecule behaves as a rigid magnetic unit of spin S = 7 or as two exchange-coupled halves of spin S = 7/2. We analyze the effect of the Dzyaloshinskii-Moriya anti-symmetric exchange interaction in a molecule with a centre of inversion symmetry and propose a formal model to account for the observed broken degeneracy that preserves the molecular inversion symmetry.
12:27PM Q8.00003 Spin dynamics in the single molecule magnet Ni₈ under microwave irradiation¹. GREGOIRE DE LOUBENS². Department of Physics, New York University — Quantum mechanical effects such as quantum tunneling of magnetization (QTM) and quantum phase interference have been intensively studied in single molecule magnets (SMMs). These materials have also been suggested as candidates for qubits and are promising for molecular spintronics. Understanding decoherence and energy relaxation mechanisms in SMMs is then both of fundamental interest and important for the use of SMMs in applications. Interestingly, the single-spin relaxation rate due to direct process of a SMM embedded in an elastic medium can be derived without any unknown coupling constant [1]. Moreover, nontrivial relaxation mechanisms are expected from collective effects in SMM single crystals, such as phonon superradiance or phonon bottleneck. In order to investigate the spin relaxation between the two lowest lying spin-states of the S = 4 single molecule magnet Ni₈, we have developed an integrated sensor that combines a microstrip resonator and micro-Hall effect magnetometer on a chip [2]. This sensor enables both real time studies of magnetization dynamics under pulse irradiation as well as simultaneous measurements of the absorbed power and magnetization changes under continuous microwave irradiation. The latter technique permits the study of small deviations from equilibrium under steady state conditions, i.e. small amplitude cw microwave irradiation. This has been used to determine the energy relaxation rate of a Ni₈ single crystal as a function of temperature at two frequencies, 10 and 27.8 GHz. A strong temperature dependence is observed below 1.5 K, which is not consistent with a direct spin-phonon relaxation process. The data instead suggest that the spin relaxation is dominated by a phonon bottleneck at low temperatures and occurs by an Orbach process involving excited spin-levels at higher temperatures [3]. Experimental results will be compared with detailed calculations of the relaxation rate using the density matrix equation with the relaxation terms in the universal form.

1:03PM Q8.00004 Multiphoton Coherent Manipulation in Large Spin Qubits¹. IRINEL CHIORESCU, Florida State University, Department of Physics and National High Magnetic Field Laboratory — Manipulation of quantum information allows certain algorithms to be performed at unparalleled speeds. Photons are an ideal choice to manipulate qubits as they interact with quantum systems in predictable ways. They provide a mechanism for measuring and controlling qubits located far apart. This has enabled new advances in quantum communication and quantum computing. Photons and qubits can also be manipulated with other methods such as atomic interaction. This talk will present multiphoton methods, which can be applied to qubits with more than 10⁶ spins. These multiphoton methods can be used to control quantum systems in a large spin qubit.

1:39PM Q8.00005 Understanding electron and nuclear spin dynamics in Cr₅⁺ doped K₂NbO₅¹. SARITHA NELLUTLA, North Carolina State University — Chromium(V) doped in the diamagnetic host potassium niobate, a simple spin S = 1/2, I = 0 system, has been proposed as an alternative standard for field calibration and q-standard for high-field EPR [1]. This system constitutes a dilute two-level model relevant for use as an electron spin qubit [2] and as such coherent electron spin manipulation at X-band (~9.5 GHz) was observed over a wide range temperature. Rabi oscillations are observed for the first time in a spin system based on transition metal oxides up to room temperature. At 4 K, a Rabi frequency Ω₅ of 20 MHz together with the phase coherence relaxation (spin-spin relaxation) time, T₂ of ~10 μs results in the single qubit figure of merit Q₅M = Ω₅T₂/π as about 500, showing that a diluted ensemble of Cr⁵⁺(S = 1/2) doped K₂NbO₅ is a potential candidate for solid-state quantum information processing. Also, the field and temperature dependence of the T₁ (spin-lattice relaxation) and T₂ times was investigated [3] for a further understanding of the relaxation mechanisms governing the phase decoherence in this system. These studies show that the coupling of the electron spin with the neighboring ⁴⁰K nuclei (I = 3/2) is one of the prominent T₂ mechanisms. The hyperfine and quadrupole interactions with ⁴⁰K nuclei was resolved by using the high-frequency (240 GHz) pulsed nuclear electron double resonance (ENDOR) technique.

Wednesday, March 18, 2009 11:15AM - 2:15PM — Session Q9 GSNP: Focus Session: Dynamics of Glassy Systems 303

11:15AM Q9.00001 Geometric interpretation of pre-vitrification in hard sphere glasses, MATTHIEU WYART, School of Engineering and Applied Sciences, Harvard University — I will derive a geometric condition for the stability of hard sphere configurations, and I will show empirically that this condition is saturated in the glass phase. The marginal stability observed explains the presence of slow modes in the short term dynamics of the glass, and supports a microscopic interpretation for the rapid initial rise of the viscosity, or pre-vitrification, when the packing fraction increases. This observation also suggests a possible cause for the collective nature of the structural relaxation near the glass transition.
11:51AM Q9.00002 Aging of a Colloidal Suspension of Thermosensitive Particles, KYAW WIN, GREGORY MCKENNA, Chemical Engineering, Texas Tech University, TX 79409, TETSUHARU NARITA, FRANCOIS LEQUEUX, Laboratory PPM, UPMC-ESPCI-CNRS UMR7615, SRINIVAS PULLELA, ZHENGDONG CHENG, Chemical Engineering, Texas A&M University, TX 77843 — We have studied the aging behavior of a concentrated suspension of thermosensitive particles (PNIPAM). We found that the characteristic time of the dynamics of the system as a function of waiting time obeys the usual power law with exponent $\sim 1$ both after shear melting the system and after a jump in temperature which is equivalent to a jump in concentration. We also report for the first time the observation of an extreme asymmetry of approach in the aging behavior with respect to down jump and up jump in temperature. While an asymmetry effect is already known in conventional glass formers such as polymers and small molecule liquids, it is both much more pronounced in the colloidal PNIPAM suspension and of a fundamentally different character.

12:03PM Q9.00003 Rejuvenation and memory in a 2D colloidal glass, JENNIFER M. LYNCH, Physics Dept., Emory University, ZEXIN ZHANG, PETER YUNKER, ARJUN G. YODH, Physics Dept., University of Pennsylvania, ERIC R. WEEKS, Physics Dept., Emory University — We work with a 2D colloidal system that has a glass transition and use this system to experimentally observe memory and rejuvenation effects as the sample ages. In particular, we study a system of colloidal particles made of thermosensitive poly(N-isopropylacrylamide) (NIPA) polymer. The sample is confined in a narrow quasi-2D gap between parallel glass plates, which allows easy observation and rapid temperature response. Lowering temperature increases the size of the colloidal particles, which can induce the glassy state due to the crowding of the particles. When our colloidal sample is quenched into the glassy state, particle motion slows over time; this is aging. In molecular glasses, prior experiments studied how aging is modified when the temperature is changed while the sample ages, finding that aging at a first temperature $T_1$ and aging at a later time with second temperature $T_2$ are mostly independent. “Memory” relates to the case $T_1 < T_2$ and “rejuvenation” to the opposite case. Our colloidal system allows us to observe both of these effects.

12:15PM Q9.00004 A continuous time random walk description of the hopping dynamics in an aging polymer glass, MYA WARREN, JOERG ROTTLER, University of British Columbia — Due to the non-equilibrium nature of the glassy state, structural relaxation becomes increasingly sluggish with the wait time $t_w$ since vitrification. As a result, dynamical correlation functions age, and often obey a simple rescaling with $t_w$: $C(t, t-w) = C_0(t) + C_{\text{vpc}}(t/t_w)$. It has recently been shown that, to first order, scaling also applies to the distributions of local correlations and displacements (the van Hove function). In this study, we use molecular dynamics simulations to measure the statistics of the discontinuous hopping events that characterize structural relaxations during aging. This allows us to map the particle dynamics onto a continuous time random walk, which successfully reproduces the entire distribution of displacements. Our results bear a striking resemblance to the popular trap model of aging. We find that the hop time distribution takes the form of a power law which is independent of $t_w$, whereas the time to the first hop shifts to longer times with $t_w$. This two-timescale behavior explains not only the scaling of the distribution functions for times $t \sim t_w$, but also small deviations from perfect scaling that have been observed at longer times.

12:27PM Q9.00005 The Defect Diffusion Model and Isochoric Energy and Isobaric Enthalpy for Glass Formers, MICHAEL SHLESINGER, Physics Department, U.S. Naval Academy, Annapolis, MD 21402-5026 and Office of Naval Research, Code 30, 875 N. Randolph St., Arlington VA 22203, JOHN BENDLER, Department of Chemistry, South Dakota School of Mines, Rapid City, SD 57701 and Physics Department, U.S. Naval Academy, Annapolis, MD 21402-5026 — The defect diffusion model produces stretched exponential relaxation, in supercooled liquids, through the sub-diffusive motion of defects. The aggregation of the defects produces a Vogel-Fulcher type law for the divergence of the time scale at a critical temperature. The model is employed to calculate the ratio of the apparent isochoric activation energy to the isobaric activation enthalpy, $E_{I}/H_{I}$ or $E_{V}/E_{P}$. This ratio measures the relative sensitivity of kinetic processes to changes in volume and temperature respectively. This ratio equation is tested using dielectric relaxation data for poly(vinyl acetate), viscosity data for glycerol and ionic conductivity data for poly(propylene glycol) containing LiCF$_3$SO$_3$. Good agreement between theory and experiment is found using model parameters previously published.

12:39PM Q9.00006 Fluctuations in the relaxation of a strong glass, AZITA PARSAEIAN, HORACIO E. CASTILLO, Department of Physics and Astronomy, Ohio University, KATHARINA VOLLMAYR-LEE, Department of Physics and Astronomy, Bucknell University — We present results of molecular dynamics simulations of amorphous silica, carried out by using the BKS inter-atomic potential. We quantify the evolution of fluctuations by studying the probability distributions of local observables such as individual particle displacements $\Delta r$ and local coarse grained intermediate scattering functions $C_{\vec{q}}$. We test for universality by comparing the probability distributions with those in small molecule glasses and in polymer glasses.

12:51PM Q9.00007 A percolation model for dynamics in glass-forming materials, GREGG LOIS, JERZY BLAWDZIEWICZ, COREY O’HERN, Yale University — We characterize the glass to liquid transition as a percolation of mobile regions in configuration space. We find that many hallmarks of glassy dynamics, for example stretched-exponential response functions and a diverging structural relaxation time, result from critical properties of mean-field percolation. Specific predictions of the percolation model include the range of possible stretching exponents $1/3 \leq \beta \leq 1$ and the functional dependence of the alpha relaxation time and stretching exponent on temperature, density, wave number, and entropy.

1:03PM Q9.00008 Finite Temperature Simulations of Glassy Models with Patchwork Dynamics, CREIGHTON THOMAS, ALAN MIDDLETON, Syracuse University — We present simulation results on aging effects in the late time dynamics of two glassy models: the Edwards-Anderson Ising spin glass and a disordered lattice dimer model. As these models have glassy dynamics, direct simulations take prohibitively long times. We use patchwork dynamics, in which we replace local Monte Carlo updates with efficient exact finite temperature equilibration of subsystems, or patches. We scale the simulation data and find a collapse to relate the dynamics for different patch sizes, with larger patches evolving the system more rapidly. We investigate the use of this technique to study rejuvenation and memory effects.

1:15PM Q9.00009 Connecting microscopic and phenomenological approaches to glassy dynamics, MALCOLM KENNEDT, Simon Fraser University, MATTHEW DOWNTON, Technische Universität Berlin — Kinetically constrained spin models are known to exhibit dynamical behavior mimicking that of glass forming systems. They are often understood as coarse-grained models of glass formers, in terms of some “mobility” field. The identity of this “mobility” field has remained elusive due to the lack of coarse-graining procedures to obtain these models from a more microscopic point of view. Here we exhibit a scheme to map the dynamics of a two-dimensional soft disc glass former obtained from Molecular Dynamics simulations onto a kinetically constrained spin model, providing an attempt at bridging these two approaches.

evident but with less consistent order. The 2-D lattice constant parameters in (0001) plane are consistent with previous literature values for pure YMnO
sharp growth fronts initiated at the free surface and at the interface with the substrate. For the free surface, the growth velocity is constant in time and has the
domain structure below and above the Curie temperature of \( \sim T_{C-L} \) of ferroelectricity, the handedness of cycloidal spin spirals exists, but vanishes above \( C \). The spin handedness perpendicular to the
domains are visible up from 500˚C to \( \sim 630 \) ˚C. The domain contrast in LEEM was lower upon cooling and we are exploring several
patterns were obtained for all samples with the sharpest LEED contrast near T
100 nm to \( 5 \) µm. The domains are evident from \( 500 ^\circ C \) to ~900 \(^\circ C\), giving possible evidence for the expected 180° ferroelectric domain structure below and above the Curie temperature of \( \sim 630 \) °C. The domain contrast in LEEM was lower upon cooling and we are exploring several
mechanisms for this result. In addition, we observed LEED patterns from ~24 to 1100 °C, with electron energies in the range of 15eV to 50eV. Above 500 °C, 1×1 and 2×2 patterns were obtained for all samples with the sharpest LEED contrast near T \( \sim 1000 ^\circ C\). In some cases a 2×4 surface reconstruction was also evident but with less consistent order. The 2-D lattice constant parameters in (0001) plane are consistent with previous literature values for pure Y MnO (see: Aberdam et al., Surface Science 14, pp.121-140 (1969)).

1:27PM Q9.00010 Glassy Dynamics in Systems of Ellipse-shaped Particles
1. CARL SCHRECK, Yale University, MITCH MAILMAN, BULBUL CHAKRABORTY, Brandeis University, COREY O’HERN, Yale University — Glass-forming materials possess a critical cooling rate \( r^* \); for thermal quench rates \( r > r^* \), these systems form disordered solids; for \( r < r^* \), they form (poly) crystalline materials. We investigate the influence of particle shape (or anisotropic interactions) on the critical cooling rate. In particular, we perform molecular dynamics (MD) simulations of elliptoiodal particles in 2D as a function of aspect ratio of the major to minor axes to optimize the local packing efficiency and the critical cooling rate to improve glass-forming ability. Also, previous mode-coupling theoretical studies have predicted that over a wide range of aspect ratios, the rotational and translational degrees of freedom undergo dynamical arrest at the same temperature. We will perform MD simulations as a function of the cooling rate, packing fraction, and aspect ratio to determine whether novel glass phases also exist in which the rotational and translational degrees of freedom freeze at different temperatures.

1:39PM Q9.00011 Self-Assembly of Spherical Colloidal Particles at Low N
1. NATALIE ARKUS, VINOTHAN MANOHARAN, MICHAEL BRENNER, Harvard University — The number of rigid structures that a system of N particles can form grows exponentially with N. Stabilizing any one structure over all others is thus a challenging problem. We consider a system of N spherical colloidal particles that cannot deform or overlap, and which exhibit a short-range attractive force. We present a method, using graph theory and geometry, that solves for all possible rigid packings of N particles - the resultant set of packings is provably complete. We then present a mechanism that is capable of stabilizing any one structure over all others (in the zero temperature limit), and which is experimentally realizable - thereby, potentially allowing us to direct the self-assembly of a desired structure. We compare to preliminary experimental results.

1:51PM Q9.00012 Aging in the shear-transformation-zone theory of plastic deformation
1. JOERG ROTTLER, University of British Columbia, PHILIPP MAASS, Technische Universitas Ilmenau — Aging phenomena in the plastic response of glassy solids are studied within the theory of shear transformation zones (STZs), which describes the kinetic rearrangement of localized defects in response to external stress. To account for the slow, non-equilibrium dynamics after a quench below the glass transition temperature, two possible models are considered. In the first model, transition rates between the internal states of STZs decrease with time, while in the second model aging occurs due to the relaxation of an effective temperature that determines the number density of STZs and other out-of-equilibrium degrees of freedom. We show that for reasonable choices of parameters, both models capture qualitatively typical aging features seen in computer simulations and experiments on polymer and other soft glasses: (i) Compliance curves measured for different waiting times after the quench can be superimposed when the observation times are rescaled with relaxation times, and (ii) stress-strain curves show a stationary plateau stress independent of waiting time and a peak stress that increases logarithmically with both waiting time and the strain rate.

2:03PM Q9.00013 Stable glass transformation to supercooled liquid via surface-initiated growth front
1. MARK EDIGER, STEPHEN SWALLEN, KATHERINE TRAYNOR, ROBERT MCMAHON, University of Wisconsin-Madison, THOMAS MATES, University of California-Santa Barbara — Recently it has been established that vapor deposition onto substrates at 0.85 Tg can produce high density, high stability, low enthalpy glasses. These glasses may be the most stable ever produced in a laboratory (using the glass formed by cooling the liquid as the reference state). Here we use SIMS to observe the transformation of isotopically layered stable glasses of trisnaphthylbenzene into a liquid during annealing above Tg. In contrast to the predictions of standard models, the observed transformation is spatially heterogeneous. The liquid grows into the stable glass with sharp growth fronts initiated at the free surface and at the interface with the substrate. For the free surface, the growth velocity is constant in time and has the

Wednesday, March 18, 2009 11:15AM - 2:15PM –
Session Q10 FIAP: Focus Session: Multiferroics III and Dielectrics 304

11:15AM Q10.00001 Low-energy Electron Microscopy (LEEM) Imaging and Diffraction of Ho1-x Yx MnO3 (0001)
1. M.D. ULRICH, ARO and NCSU, RELJIA VASIC, NCSU, J.T. SADOWSKI, Center for Functional Nanomaterials, BNL, J.E. (JACK) ROWE, NCSU, H.D. ZHOU, C.R. WIEBE, National Magnetic Field Lab, FSU — We have investigated the (0001) surfaces of several hexagonal perovskite alloys Ho1-x Yx MnO3 (x=0-1), by low-energy electron microscopy (LEEM) using both mirror-mode imaging and diffraction (LEED) techniques. We find LEEM structured domains for our (0001) surfaces of single crystals grown by a traveling-solvent-floating zone technique which are likely due to work function variations on a scale of ~100 nm to 5 µm. The domains are visible up from 500 °C to ~900 °C, giving possible evidence for the expected 180° ferroelectric domain structure below and above the Curie temperature of ~630 °C. The domain contrast in LEEM was lower upon cooling and we are exploring several mechanisms for this result. In addition, we observed LEED patterns from ~24 to 1100 °C, with electron energies in the range of 15eV to 50eV. Above 500 °C, 1×1 and 2×2 patterns were obtained for all samples with the sharpest LEED contrast near T ~1000 °C. In some cases a 2×4 surface reconstruction was also evident but with less consistent order. The 2-D lattice constant parameters in (0001) plane are consistent with previous literature values for pure YMnO3 (see: Aberdam et al., Surface Science 14, pp.121-140 (1969)).

11:27AM Q10.00002 Spin Correlation and Magnetically Induced Ferroelectricity in YMnO5
1. J. OKAMOTO, D. J. HUANG, W. B. WU, S. L. CHENG, C. T. CHEN, National Synchrotron Radiation Research Center, Taiwan, C. Y. MOU, National Center for Theoretical Sciences, Taiwan, K. S. CHAO, S. W. HUANG, National Chiao-Tung University, Taiwan, S. PARK, S-W. CHEONG, Rutgers University, USA — There is great interest in understanding the microscopic nature of the coupling between ferroelectricity and magnetic ordering in several multiferroic frustrated manganites \( R MnO_3 \) and \( R Mn_2 O_5 \) (\( R = \) rare earth and Y). For \( R MnO_3 \), the multiferroicity can be understood in terms of the anti- symmetric spin interaction, whereas the underlying mechanism of multiferroicity in \( R Mn_2 O_5 \) remains controversial, because of its structural complexity. We unraveled the temperature-dependent spin ordering of multiferroic YMnO3 by using resonant soft x-ray magnetic scattering at Mn L3 edge. For temperatures below the onset temperature \( T_C \) of ferroelectricity, the handedness of cycloidal spin spirals exists, but vanishes above \( T_C \). The spin handedness perpendicular to the induced polarization reverses at the temperature where the polarization changes its sign. The temperature dependence of spin correlation along the propagating direction of spin spirals resembles the temperature behavior of polarization. These data imply that both symmetric and antisymmetric spin interactions involve in the magnetoelectric coupling in YMnO5.
11:39AM Q10.00003 Magnetic field effects on charge and magnetic structures in a new multiferroic LuFe$_2$O$_4$¹, JINSHENG WEN, GUANGYONG XU, GENDA GU, STEVE SHAPIRO, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973, USA — LuFe$_2$O$_4$ is a new multiferroic where the ferroelectric polarization originates from valence order of Fe$^{2+}$ and Fe$^{3+}$ ions instead of cation displacements. It evolves from two- to three-dimensional charge ordered state upon cooling, and the bulk polarization appears when the charges order three dimensionally. A ferrimagnetic order appears with further cooling. Bulk polarizations and the charge order are both enhanced when the magnetic order occurs, suggesting a strong coupling between the two orders in the system. We have performed neutron scattering measurements on both the charge and magnetic orders under external magnetic fields. We will discuss the field effects and their implications.

¹The work at Brookhaven National Laboratory was supported by the U.S. Department of Energy under contract No. DE-AC02-98CH10886.

11:51AM Q10.00004 Reentrant ferroelectricity and the multiferroic phase diagram of Mn$_{1-x}$Fe$_2$WO$_4$, RAJIT CHAUDHURY, BERND LORENZ, YAQI WANG, YANYI SUN, CHING CHU. TCSUH and Department of Physics, University of Houston, Houston, Texas 77204-5002, USA — Recently MnWO$_4$ has attracted attention because of its multiferroic properties. In MnWO$_4$ the Mn$^{2+}$ ions can be substituted by Fe$^{3+}$ since MnWO$_4$ and FeWO$_4$ are isomorphic. This opens the possibility to tune the magnetic orders by Fe-substitution for a better understanding of the microscopic interactions resulting in the multiferroic properties. We report the discovery of reentrant ferroelectricity in the phase diagram of multiferroic Mn$_{1-x}$Fe$_2$WO$_4$ single crystals. At zero magnetic field (H) the spin-spiral ferroelectric (FE) state is completely suppressed at Fe substitutions (x) exceeding 0.04. For x<0.04 a ferroelectric phase exists in a narrow temperature (T) range at zero magnetic field. This FE phase shows a reentrant behavior at lower T above a critical magnetic field H$_c$(x). The reentrant FE transition is explored by polarization, dielectric constant, and magnetization measurements. The complete multiferroic x-T-H phase diagram of Mn$_{1-x}$Fe$_2$WO$_4$ is derived.

12:03PM Q10.00005 X-ray resonant magnetic scattering study of multiferroic R$\text{MnO}_3 (R=\text{Dy, Ho, Er})$ compounds, A.I. GOLDMAN¹, S. NANDI¹, A. KREYSIG¹, L. TAN¹, J.W. KIM¹, J.Q. YAN¹, M.D. VANNETTE¹, J.C. LANG², D. HASKEL³, T.A. LOGRASSO², R.J. MCQUEENEY¹, ¹Dept. of Physics and Astronomy, Iowa State University, Ames; ²Ames Laboratory US DOE, Ames; ³Advanced Photon Source, Argonne — Element specific x-ray resonant magnetic scattering (XRMS) investigations were undertaken to determine the magnetic structure of multiferroic hexagonal R$\text{MnO}_3$ compounds. In the intermediate temperature phase (ITP) (8-68 K for the Dy$^{3+}$ and 4.5-40 K for Ho$^{3+}$) the moments are aligned and antiferromagnetically correlated in the c direction according to the same magnetic representation $\Gamma_3$. Below the ITP, the Dy$^{3+}$/Ho$^{3+}$ moments order differently and according to the magnetic representations $\Gamma_1$/$\Gamma_2$. The temperature dependence of the observed intensity in the ITP can be modeled assuming the splitting of ground-state doublet/quasi-doublet crystal-field levels of Dy$^{3+}$/Ho$^{3+}$ by the exchange field of Mn$^{2+}$. No resonant signals could be found for Er$^{3+}$ from 2-80 K. Specific magnetic representations can be excluded for the magnetic order of Er$^{3+}$ moments but can not be uniquely determined within the sensitivity of XRMS. — The work supported by U.S. DOE (DE-AC02-07CH11358 and DE-AC02-06CH11357) is acknowledged.

12:15PM Q10.00006 Frequency dependent magneto-dielectric effect in bilayer manganite Pr$_{(Sr_{0.1}Ca_{0.9})_2}$MnO$_7$, BARNALI GHOSH-SAHA, S.N. Bose National Centre for Basic Sciences, D. BHATTACHARYA, Central Glass and Ceramic Institute, S. PATNAIK, Jawaharlal Nehru University, A.K. RAYCHAUDHURI, S. ARUMUGAM — We report novel frequency dependent magneto-dielectric effect and a strong dielectric anomaly near Neel temperature (T$_N$) in a single crystal of bilayer manganite Pr$_{(Sr_{0.1}Ca_{0.9})_2}$MnO$_7$ system. The magneto-dielectric effect measured in a field of 3T shows large frequency dependence and reaches a maximum (∼25%) near T$_N$ at a measurement frequency of 1 kHz. Change in frequency leads to a change in the sign of the effect. There is a sizeable dielectric relaxation process near T$_N$, which exhibits an activated behavior and strongly non-Nabeya nature at or below T$_N$ while becoming Debye like at higher temperature.

¹The work was supported by the Department of Science and Technology, Government of India.

12:27PM Q10.00007 Flexoelectricity in nanostructures, PRADEEP SHARMA, University of Houston — Crystalline piezoelectric dielectrics electrically polarize upon application of uniform mechanical strain. Inhomogeneous strain, however, locally breaks inversion symmetry and can potentially polarize even non-piezoelectric (centrosymmetric) dielectrics. Flexoelectricity—the coupling of strain gradient to polarization— is expected to show a strong size-dependency due to the scaling of strain gradients with structural feature size. In this study, using a combination of atomistic and theoretical approaches, we elucidate the “effective” size-dependent piezoelectric and elastic behavior of inhomogeneously strained non-piezoelectric and piezoelectric nanostructures. We argue, through computational examples, the tantalizing possibility of creating “apparently piezoelectric” nano-composites without piezoelectric constituents and the emergence of size-dependent “giant piezoelectricity” in paradigmatical nanostructures. Finally, we propose that flexoelectricity is an important and essential contributor to the intrinsic dead-layer effect in high permittivity ferroelectric based nanocapacitors.

1:03PM Q10.00008 Evidence for the Potential Barrier Height Reduction in Metal-Oxide-Metal Tunnel Junctions due to the Interface Dependent Metal-Induced-Gap-States, LEE HOSIK, NEC, HYUNTAE JUNG, YONGMIN KIM, KYOOHO JUNG, HYUNSIK IM, Dongguk University, YURI PASHKIN, O. ASTAFIEV, J. S. TSAI, NEC Nano Electronics Research Laboratories and RIKEN Advanced Science Institute, YOSHIYUKI MIYAMOTO, NEC, NEC TEAM, DONGGUK UNIVERSITY TEAM, NEC NANO ELECTRONICS RESEARCH LABORATORIES and RIKEN ADVANCED SCIENCE INSTITUTE TEAM — We have performed transport measurements on AI and Nb based metal-oxide-metal tunnel junctions with an AlO$_x$ tunnel barrier and found a strong dependence of the effective potential barrier height on the oxide-metal interface properties. Our estimations of the barrier height based on a phenomenological Simmons’ model are consistent with the values obtained from the first-principle calculations. The calculations clearly show that the barrier height is strongly affected by the formation of metal induced gap states originating from the hybridization between metallic bands and AlO$_x$ conduction band. These findings are important for nanoelectronic devices containing tunnel junctions with a thin insulating layer.

1:15PM Q10.00009 Role of defects in the interfacial conductivity at interfaces in Pt/ SrTiO$_3$/Pt heterostructures, NAGA PHANI AETUKURI, Stanford University/IBM Almaden Research, GUENOLE JAN, IBM Almaden Research/Magic; MAHESH SAMANT, KEVIN ROCHE, STUART PARKIN, IBM Almaden Research — Oxides exhibit a wide variety of diverse phenomena including ferromagnetism, anti-ferromagnetism, ferroelectricity, superconductivity and multiferroicity. Furthermore, they display complex phase diagrams which result from the sensitivity of their properties to subtle changes in structure, doping, temperature and pressure. We will present the effect of interfaces and interface defects on the electrical switching properties of metal-insulator-metal (MIM) structures where the insulator is strontium titanate (STO) grown by pulsed laser deposition. The role of growth temperature and pressure and the effect of intentionally created oxygen vacancies on MIM device characteristics will be discussed. An attempt will be made to rationalize the role of intrinsic mechanisms and interface effects on the variability seen in device properties.
1:27PM Q10.00010 High-quality SrTiO$_3$ films using a hybrid MBE approach, BHRAT JALAN, ROMAN ENGEL-HERBERT, NICK WRIGHT, SUSANNE STEMMER, University of California Santa Barbara — A novel hybrid molecular beam epitaxy (MBE) approach for atomic-layer controlled growth of high-quality, epitaxial, stoichiometric SrTiO$_3$ films is presented. A solid source is used for Sr, an rf oxygen plasma source for oxygen and a metal-organic source for Ti. High-resolution x-ray diffraction revealed high quality single crystalline films with rocking curve full width half maxima similar to those of the substrates (i.e., 0.0095° for a LSAT substrate). RHEED showed persistent layer-by-layer growth (> 180 oscillations), which has previously been observed only in a very few other systems (Si and GaAs). Surface reconstructions were observed during growth and related to the growth modes. Depending on growth conditions, step flow growth was also observed. The film surface RMS roughness was less than 0.2 nm. Excellent film stoichiometry was confirmed by homoepitaxy (prefect overlap of film and substrate reflections). Films were very insulating, consistent with oxygen stoichiometry. Oxygen gettering Ti contacts and vacuum anneals were used to produce n-type, oxygen deficient films to study carrier mobilities. We demonstrate the relative influence of hydrogen and oxygen vacancies on the electrical conductivity of SrTiO$_3$.

1:39PM Q10.00011 Conductance bistability in metal oxide junctions, ZHONGKUI TAN, VIJAY PATEL, ESTEBAN MONGE, SHIH-HENG CHANG, SHAW POTTORF, JAMES LUKENS, KONSTANTIN LIKHAREV, Department of Physics and Astronomy, Stony Brook University — We are exploring conductance bistability (memory) effects in junctions based on metal oxides, in the context of their possible applications in hybrid CMOS/nanoelectronic (e.g., CMOL [1]) circuits. So far, we have investigated Cu$_2$O, NbO$_x$ and TiO$_x$ formed by thermal and plasma oxidation, with or without rapid thermal post-annealing (at 200 to 800°C for 30 to 300 seconds). Conductance switching effects have been observed for all these materials. Particularly high endurance (over 1000 switching cycles) has been obtained for TiO$_x$ junctions plasma oxidized in 15mTorr oxygen and then post-annealed at 700°C. However, the ON/OFF conductance ratio for these junctions is only about 5, and the sample-to-sample reproducibility is much lower than required for integrated circuit applications. Our plans are to extend our studies to a-Si junctions with one Ag electrode, and multilayer TiO$_x$ junctions, with the main goal to improve device reproducibility. The work is supported in part by AFSOR.

1:51PM Q10.00012 Electrical characterization of epitaxial MgO/SiC capacitor structures, AGHAM POSADAS, FRED WALKER, CHARLES AHN, Yale University, TREVOR GOODRICH, ZHUHUA CAI, KATE ZIEMER, Northeastern University — Epitaxial heterostructures of MgO (111) have been grown on hydrogen-cleaned 6H-SiC (0001) substrates and characterized using capacitance vs. voltage (C-V) and current vs. voltage (I-V) measurements. Low frequency capacitance measurements of MgO/SiC under strong accumulation conditions as a function of MgO layer thickness show that the exciton MgO has a dielectric constant of 10. The C-V measurements show modulation of the SiC from accumulation to depletion, consistent with the wafer conductivity type. The density of interface states was determined from ac conductance vs. frequency measurements, indicating a density of 6 x 10^{11} eV^{-1} cm^{-2} at an energy level close to the conduction band edge, similar to what has been reported for native SiO$_2$ capacitor structures. In order to determine the dielectric breakdown field of the epitaxial MgO, leakage current as a function of gate voltage was measured for the capacitor structures. The median gate voltage at which the MgO breaks down was found to correspond to an electric field of 12 MV/cm, similar to that of bulk, single crystal MgO. These results show that epitaxial MgO has potential for use as a gate dielectric in Si MOSFET applications.

2:03PM Q10.00013 Observation and coupling of domains in a spin spiral multiferroic, DENNIS MEIER, MICHAEL MARINGER, THOMAS LOTTERMOSER, MANFRED FIEBIG, HISKP, University Bonn, PETRA BECKER, LADISLAV BOHATY, Institute for Crystallography, University of Cologne — The intrinsically strong cross coupling between magnetism and ferroelectricity in spin spiral multiferroics suggests these systems as prime candidates for novel multifunctional devices. Comprehension and controlling of the correlated antiferromagnetic (AFM) and ferroelectric (FE) domain structures by external fields is an indispensable prerequisite for future device design. However, very few is known about the domain topology and switching of AFM spin spirals and the magnetically induced FE domains. Here we present the spatial distribution of AFM and FE domains in MnW$_x$O, revealed by optical second harmonic generation. Electric fields are used to uniquely control the magnetic domain structure, while applied magnetic fields influence the polar behavior of the FE domains.

This work is supported by the DFG through SFB 608.

11:15AM Q11.00001 Dielectric Optical Antenna Emitters and Metamaterials, JON SCHULLER, Stanford University — Optical antennas are critical components in nanophotonics research due to their unparalleled ability to concentrate electromagnetic energy into nanoscale volumes. Researchers typically construct such antennas from wavelength-size metallic structures. However, recent research has begun to exploit the scattering resonances of high-permittivity materials to realize all-dielectric optical antennas, emitters, and metamaterials. In this talk, we experimentally and theoretically characterize the resonant modes of subwavelength rod-shaped dielectric particles and demonstrate their use in negative index metamaterials and novel infrared light emitters. At mid-infrared frequencies, Silicon Carbide (SiC) is an ideal system for studying the behavior of dielectric optical antennas. At frequencies below the TO phonon resonance, SiC behaves like a dielectric with very large refractive index. Using infrared spectroscopy and analytical Mie calculations we show that individual rod-shaped SiC particles exhibit a multitude of resonant modes. Detailed investigations of these SiC optical antennas reveal a wealth of new physics and applications. We discuss the distinct electromagnetic field profile for each mode, and demonstrate that two of the dielectric-type Mie resonances can be combined in a particle array to form a negative index metamaterial [1]. We further show that these particles can serve as “broadcasting” antennas. Using a custom-built thermal emission microscope we collect emissivity spectra from single SiC particles at elevated temperatures, highlighting their use as subwavelength resonant light emitters. Finally, we derive and verify a variety of general analytical results applicable to all cylindrical dielectric antennas and discuss extensions of the demonstrated concepts to different materials systems and frequency regimes. [1] J.A. Schuller, et al., Phys. Rev. Lett. 99, 107401 (2007)

11:51AM Q11.00002 Quantum Confined Stark Effect for Exciton-Plasmons in Carbon Nanotubes, IGOR BONDAREV, JUSTICE MCCONNELL, NC Central University — We study theoretically the perpendicular electrostatic field effect (the quantum confined Stark effect) for excitons and interband plasmons in small-diameter (<~1nm) semiconducting carbon nanotubes (CNTs). The exciton creation energy and the plasmon energy both shift to the red due to the decrease in the CN band gap as the fields increases. However, the exciton red shift is much less than the plasmon one due to the decrease in the absolute value of the (negative) exciton binding energy [1]. This brings the exciton in resonance with the interband surface plasmon. The exciton total energy may be tuned to the nearest interband plasmon resonance this way, to form the strongly coupled exciton-surface-plasmon excitation[2,3]. We propose this effect for the development of CN based tunable optoelectronic device applications in areas such as nanophotonics, nanoplasmonics, and cavity quantum electrodynamics.

12:03PM Q11.00003 Resonant Plasmonic and Vibrational Coupling in a Tailored Nanoantenna for Infrared Detection, JAVIER AIZPURUA, AITZOL GARCIA-ETXARRI, CSIC-UPV/EHU and DIPC, San Sebastian, Spain, THOMAS W. CORNELIUS, SHAFKAT KARIM, Gesellschaft für Schwerionenforschung, Darmstadt, Germany, FRANK NEUBRECHT, ANNEMARIE PIUCCI, Univ. of Heidelberg, Germany — Gold nanowires are introduced as plasmonic infrared antennas for effective molecular spectroscopy. A novel resonant mechanism involving the interference of the broadband plasmon with the narrowband vibration from molecules is presented in the context of Surface-Enhanced Infrared Absorption (SEIRA). With the use of this concept, we demonstrate experimentally the enormous enhancement of the vibrational signals from less than one attomol of molecules on individual gold nanowires, tailored to act as plasmonic nanoantennas in the infrared. By detuning the resonance via a change in the antenna length, a Fano-like behavior of the spectral signal is observed, which is clearly supported by full electrodynamical calculations. This resonant mechanism can be a new paradigm for sensitive infrared identification of molecular groups.

12:15PM Q11.00004 A novel near field transducer for efficient energy transfer, WILLIAM CHALLENER, AMIT ITAGI, CHUBING PENG, NILS GOKEMEIJER, GNAPING JU, MICHAEL SEIGLER, EDWARD GAGE, Seagate Technology — Interest in the localized surface plasmon resonance (LSPR) of metallic nanoparticles has been piqued by single molecule detection in surface enhanced Raman spectroscopy, scanning optical microscopy with sub-20 nm resolution, particle capture using the optical tweezers effect, and proposed applications in nanolithography and data storage. We have designed a gold near field transducer (NFT) that combines the LSPR effect, the lightning rod effect, and the dual dipole effect. Optical energy that is focused onto the NFT is coupled into a metallic thin film within a spot that is an order of magnitude smaller than the free space wavelength with an efficiency of about 5%. With approximately 40 mW of optical power from a laser diode at a wavelength of 830 nm, data has been recorded at a track width less than 50 nm onto a high coercivity magnetic medium by heating it to its Curie point of 650 K while the medium was rotating at 2700 RPM and the NFT was separated from the medium surface by 15 nm.

12:27PM Q11.00005 Near-field imaging and probe-assisted nano-mechanical control of plasmonic antennas, AITZOL GARCIA-ETXARRI, CSIC-UPV/EHU and DIPC, San Sebastian, Spain, ISABEL ROMERO, DIPC, San Sebastian, Spain, F. JAVIER GARCIA DE ABAJO, Institute of Optics, Madrid, Spain, RAINER HILLENBRAND, CIC nanoGUNE, San Sebastian, Spain, JAVIER AIZPURUA, CSIC-UPV/EHU and DIPC, San Sebastian — Imaging plasmon-resonant gold nanodisks acting as optical nanoantennas by scattering-type near-field optical microscopy (s-SNOM), we identify weak and strong coupling regimes between the near-field probe and the plasmonic nanoantenna sample. By means of rigorous electrodynamical calculations based on a model system, we find that in the weak coupling regime, s-SNOM can be applied for direct mapping of plasmonic nanoantenna modes, while in the strong coupling regime, the near-field probe allows for high-precision opto-mechanical control of the antenna response.

12:39PM Q11.00006 Direct Near-field Imaging of UV Surface Plasmon of a Bowtie Optical Nano-antenna, LIANGCHENG ZHOU, Department of Physics, Lehigh University, QIAOQIANG GAN, Department of Electrical and Computer Engineering, Lehigh University, VOLKMAR DIEROLF, Department of Physics, Lehigh University, FILBERT BARTOLI, Department of Electrical and Computer Engineering, Lehigh University, QIAO QIU and HUO WEI, Liquid Crystal Institute, Kent State University — We numerically study the optical properties of metal-dielectric-metal nanoantennas. The nanoantennas consist of two metal nanocylinders stacked vertically with a dielectric disk spacer. The numerical analysis using finite difference time domain method (FDTD) shows that nanoantennas exhibit two types of resonances when the gap between the metal cylinders is below 5nm. One of the resonance corresponds to the antenna resonance, generates a peak in scattering spectra and the other corresponds to cavity resonance, produces multiple dips in the scattering spectra. The multiple dips are corresponding to the different cavity resonant modes; the resonant frequencies of these modes depend upon the gap size between the cylinders. It is found that as the gap size decreases, enormous electric field enhancement can be generated inside the cavity. For a particular gap size, electric field enhancement can be maximized by varying diameter of the dielectric disk and optimum condition is obtained when dielectric disk diameter is roughly half that of the metal cylinders. The cavity resonance can be explained as interference of gap surface plasmons between two metal cylinders.

1:03PM Q11.00008 Plasmonic hysteresis: temperature dependent resonance of vanadium-dioxide coated gold nanoparticle arrays, DAVON FERRARA, JOYEETA NAG, EUGENE DONEV, JAE SUH, RICHARD HAGLUND, Vanderbilt University — The optical properties of metal nanostructures are dominated by the free-electron, or plasmonic, response of the material. In the case of metal nanoparticles, this leads to a resonant extinction with wavelength determined by the particles’ size, shape, material, and surrounding dielectric. Vanadium-dioxide has a hysteretic transition from a semiconductor to a metal about 68℃ accompanied by a change in its structural, electrical and optical properties.

1:15PM Q11.00009 Surface plasmon lifetime in metal nanoshells, A.S. KIRAKOSYAN, T.V. SHAHBAZYAN, V.V. BERZ, A.S. KIRAKOSYAN, T.V. SHAHBAZYAN, R/v, where R is...
1:27PM Q11.00010 Finite Size Effects on the Electromagnetic Field Enhancement from Low-dimensional Silver Nanoshell Dimer Arrays1, YOULIN SONG, Zhengzhou University, KE ZHAO, University of Tennessee, YU JIA, XING HU, Zhengzhou University, ZHENGYU ZHANG, Oak Ridge National Laboratory — Finite size effects on the optical properties of one-dimensional (1D) and 2D nanoshell dimer arrays are investigated using generalized Mie theory and coupled dipole approximation within the context of surface-enhanced Raman spectroscopy (SERS). It is shown that the huge enhancement in the electromagnetic (EM) field at the center of a given dimer oscillates with the length of the 1D array. For an array of fixed length, the EM enhancement also oscillates along the array, but with a different period. Both types of oscillations can be attributed to the interference of the dynamic dipole fields from different dimers in the array. When generalized to 2D arrays, EM enhancement higher than that of the 1D arrays can be gained with a constant magnitude, a salient feature advantageous to experimental realization of single-molecule SERS. [K. Zhao et al, J. Chem. Phys. 125, 081102 (2005); Y. L. Song et al, accepted by J. Chem. Phys.]

1:39PM Q11.00011 System-bath approach to electronic effect in Surface Enhanced Raman Scattering1, SEMION SAIKIN, ROBERTO OLIVARES-AMAYA, CESAR RODRIGUEZ-ROSARIO, Department of Chemistry and Chemical Biology, Harvard University, MICHAEL STOPA, Center for Nanoscale Systems, Harvard University, ALAN ASPURU-GUZIK, Department of Chemistry and Chemical Biology, Harvard University, SEC TEAM — Raman scattering from molecules is greatly enhanced in proximity of a metal nanoparticle or a rough metal surface. The strong interest in this effect is driven by applications to selective detection of toxic chemicals, warfare agents, etc. The scattering enhancement has two distinct contributions. The electromagnetic effect originates in the field concentration by surface plasmons excited in the metal. The second, electronic or chemical contribution, which is important for molecules in direct contact with the surface, is more controversial. It is controlled by the charge transfer between a molecule and a metal with nanoscale roughness. We develop an open quantum system approach to the formation of charge transferred states and apply it to describe electronic effect in SERS using specific examples of organic molecules adsorbed on a surface of a silver nanoparticle.

The work was supported by DARPA MTO grant FA9550-08-1-0285

1:51PM Q11.00012 Single molecule surface-enhanced Raman spectroscopy in nanogap structures , DANIEL WARD, NAOMI HALAS, DOUGLAS NATELSON, Rice University — Single molecule sensitivity in surface enhanced Raman scattering (SERS) is of significant interest to multiple fields of study but has been difficult to demonstrate conclusively. We have developed a planar nanogap structure with single molecule Raman sensitivity (Nano Lett. 7, 2007; Nano Lett. 8, 2008). Nanogap devices offer a reliable way to probe SERS phenomena often thought to be the hallmarks of single molecule sensitivity: intensity fluctuations and spectral diffusion. We present a series of experiments on intensity fluctuation and spectral diffusion rates as a function of temperature to better understand the mechanism driving these phenomena. We also explore how the gap width affects overall Raman intensity. Additionally, time permitting, we present results on plasmonic light emission from nanogap devices when excited by hot electrons. The spectrum shows intensity peaks at energies well above the excitation energy revealing a wealth of interesting physics.

2:03PM Q11.00013 Plasmonic Nanolens Arrays for Enhanced Raman Spectroscopy1, E.V. PONI-ZOVSKAYA, I. NAUMOV, Z. LI, JING TANG, A.M. BRATKOVSKY, Hewlett-Packard Labs, Palo Alto — Surface-enhanced Raman scattering (SERS) is the 4th-order process with regards to a local electric field, -|E|^4, and therefore, may be extraordinarily enhanced well in excess of 10-11 orders of magnitude. The 'chemical' enhancement factor of less clear origin may also reach few orders of magnitude. We are looking at engineering various nanoparticle arrays that may focus local field and may be fabricated in top-down manner or self-assembled. Nanocrystals of Au and Ag with different shapes, such as octahedra, cubes, stars etc and their 2-dimensional and 3-dimensional assembly have been studied for plasmonic applications. One promising way of reaching the enhancement ≥ 10^{12}/is to use arrays of plasmonic nanolenses with with binary or even ternary nanoparticles arrangements with certain patterns. The nanoparticles arrangements were modeled numerically using Finite Difference Time Domain method and results are compared with the data collected by our team on some fabricated high-performance SERS substrates.

In collaboration with Peidong Yang’s Group at UC Berkeley.

Session Q12 DMP DCMP: Structure, Dynamics, and Diffusion at Surfaces 308

11:15AM Q12.00001 Water Adsorption on Wurtzite GaN Surfaces , XIAO SHEN, PHILIP B. ALLEN, Stony Brook University, MARK S. HYBERTSEN, JAMES T. MUCKERMAN, Brookhaven National Laboratory — A solid solution of wurtzite GaN/ZnO absorbs light in the visible and can photosplit water|1| |1| |1| |1|. The water is oxidized by the photo-holes at the surface of the semiconductor alloy. However, microscopic details of the oxidation process are unknown. We present a first-principles study of water adsorption on wurtzite GaN. We study the structures and energetics of water adsorption, calculate the energy barrier for water dissociation, analyze the water-water interactions, and study the electronic structure. The results are compared with water adsorption on ZnO surface. We also study the behavior of the holes near the water-semiconductor interface.

11:27AM Q12.00002 Does Water Adsorb Molecularly or Dissociatively on a Plutonium Surface?1, ASOK RAY, RAYMOND ATTA-FYNN, Department of Physics, University of Texas at Arlington — DFT-GGA has been used to study adsorption of water in molecular and dissociative configurations on δ-Pu (111) surface. In molecular state, water is physisorbed in an almost flat-lying orientation at a one-fold coordinated on-top site. The interaction of the water δσ orbital and the Pu-6δl orbital provides the stability of water on the surface, implying that the Pu-5f electrons remain chemically inert. The coadsorption cases of partially dissociated and fully dissociated products at the three-fold hollow sites yield chemisorption, coupled with rumpling of the surface layer and delocalization of the Pu-5f electrons and formation of strong ionic bonds.

This work is supported by the U. S. Department of Energy and the Welch Foundation
surface\textsuperscript{1}, BERNARD DELLEY, Paul Scherrer Institut, ALFONSO BALDERESCHI, MICHEL POSTERNAK, EPF-Lausanne — Using density functional calculations and a periodical slab model, we investigate water adsorption on edges formed by intersection of two anatase TiO$_2$ (101) surfaces. We find that after adsorption of a water molecule on a low-coordinated Ti atom on the ridge, decomposition may happen over a moderately high barrier. In this process, a proton gets abstracted by bonding to a low-coordinated ridge oxygen atom. The hydroxyl anion remains bonded to the acidic Ti site on the edge. The methods used to find the saddle points and to map out the reaction paths are briefly discussed. We also give a discussion of the reaction rates that may be expected based on these calculations. The presence of hydroxyl groups and protons is favoring nucleation of Ca phosphate bonding by allowing exchange of the adsorbed proton against Ca$^{2+}$ ions. Such processes are thought to be essential for the biocompatibility of titanium and its use in dental and orthopedic applications.

11:51AM Q12.00004 First Principles Study of Bulk and Surface Ordering Phenomena in Pt-X Binary Alloys in the Presence of Oxygen. WEI CHEN, CHRIS WOLVERTON, Northwestern University, Department of Materials Science and Engineering, WILLIAM SCHNEIDER, University of Notre Dame, Department of Chemical and Biomolecular Engineering, Department of Chemistry and Biochemistry — Alloying in metal catalyst particles (such as platinum) may change surface structure due to segregation and ordering, which may in turn significantly impact catalytic activity. Using first principles density functional theory (DFT) calculations in conjunction with a cluster expansion (CE) technique, we have studied the ordering/phase-separation phenomena of bulk and surface Pt-X binary alloys, with a specific focus on Pt-Au. The surface DFT+CE calculations are performed both in the presence and absence of oxygen. For Pt-Au, the calculated results reveal a phase separating tendency in bulk Pt-Au and a small coherency energy between these two elements. The Pt-Au phase diagram calculated by combining DFT+CE with Monte Carlo simulation shows a slightly asymmetric miscibility gap in good agreement with experimental results. In contrast to the bulk tendency, the surface does not show a pronounced phase-separation tendency, with several low-energy "striped" ordered structures (with a very small, negative formation energy). The presence of oxygen qualitatively changes the surface segregation tendency of Au, and our DFT+CE results show that the equilibrium structure of the Pt-Au (111) surface varies with oxygen coverage.

12:03PM Q12.00005 A first-principles study of the electropotential dependent shape stability of metal nanoparticles. NICEPHORE BONNET, MIT, ISMAILA DABO, CERMECS ENPC, NICOLA MARZARI, MIT — Understanding the catalytic activity of transition metal nanoparticles is a central issue in the development of novel fuel cell materials. Observed trends are often interpreted in terms of the size dependent shape of nanoparticles, in particular the relative density of low coordination sites. However, no consensus exists regarding the direction or even the existence of such an effect. In this context, ab-initio methods can be useful to extract relevant parameters. Here, we calculate surface energies under realistic electrochemical conditions and use the Wulff construction to infer stable nanoparticle contours. The electropotential is adjusted through its conjugate variable, the charge, and density countercharge periodic-image corrections are applied. The surrounding solvent is treated as a combination of a continuum dielectric and a classical ionic distribution at equilibrium.

12:15PM Q12.00006 Lattice Dynamics of Cu$_2$O: Bulk and (110) Surface. KLAUS-PETER BOHNEN, ROLF HEID, Forschungszentrum Karlsruhe, IFP, ALOYSIUS SOON, CATHERINE STAMPFL, School of Physics, University of Sydney — A number of theoretical studies have been carried out in the past to investigate the stability of various surface oxides for the O/Cu system however despite the fact that catalytic processes usually proceed at elevated temperatures stability at finite temperatures has never been studied for these systems. Modern ab-initio methods however allow for the determination of the lattice dynamics and the phononic contribution to the free energy. Using density functional perturbation theory we have studied the lattice dynamics of Cu$_2$O-bulk as well as Cu$_2$O(110). In calculating the free energy as function of lattice constant we obtained for the bulk a negative thermal expansion up to roughly 300 K in excellent agreement with experiments. This is due to anomalous mode Gr"uneisen parameters for vibrational modes in the low energy regime. Due to the anomalous behavior of the mode Gruneisen parameter the bulk system is highly unstable against variations of the lattice constant by more than 2%. To investigate the stability of the O/Cu surfaces we have investigated the lattice dynamics of Cu$_2$O(110) as a prototype. Despite a large number of low lying modes no instability has been found. These calculations allow also for the O/Cu system for the first time a realistic estimation of the surface-free energy which is important for the determination of surface thermodynamic properties.

12:27PM Q12.00007 Ab-initio Study of the Erlich-Schoewebel Barriers for fcc(100). TALAT S. RAHMAN, HANDAN YILDIRIM, University of Central Florida — We present the results of density functional theory based calculations for the activation energies for the diffusion of adatoms (Cu or Ag) on Cu(100) and Ag(100) surfaces with and without steps. For Ag adatom diffusion via hopping on Cu(100), we find the energy barrier to be 0.37 eV, which is less than that (0.60 eV) of Cu adatom diffusion on Ag(100). In the presence of a step edge, we find the Erlich-Schoewebel (ES) barriers (via hopping process) for both Ag and Cu atoms on Cu(100) to be 170 meV. For Ag and Cu adatoms on Ag(100), the corresponding barriers are 50 meV and 60 meV, respectively. The ES barrier (via exchange process) for Ag on Ag(100) is found to be 20 meV and for Cu on Cu(100) it is 60 meV. The barriers for diffusion along the step edges at the lower terraces are 0.36 eV and 0.20 eV for Cu on Ag(100) and Ag on Cu(100), respectively. We trace the differences in the diffusion barriers of the homo-and hetero-epitaxial systems to the differences in the corrugation of the potential energy surface, and discuss the implications for homo- and heteroepitaxial growth on these surfaces.

12:39PM Q12.00008 On the Si(111) 5×2-Au surface, Si adatom diffusion is defect-mediated. EZRA BUSSMANN, Sandia Natl Labs, NM, S. Bockenhauer, F.J. Himpsele, U.W. - Madison, B.S. Swartzentruber, Sandia Natl Labs, NM — The Si(111) 5×2-Au surface is a member of a family of metal-induced chain reconstructions of Si. Studies of these reconstructions have led to a new understanding of the physics of one-dimensional electronic states. The 5×2 surface is speckled with Si adatoms, which are intimately linked with the surface electronic properties. At temperatures > 423 K, the adatoms diffuse along the chains between adjacent 5×2 cells. We have measured scanning tunneling microscopy movies of the diffusing adatoms. Distinctive diffusion statistics, e. g. correlations between displacements, imply that the displacements are triggered by an interaction with a defect. By a statistical characterization of the diffusion, we show that the adatoms move by a defect-mediated mechanism similar to the vacancy-mediated diffusion observed on some metal surfaces. We use a Monte Carlo simulation to model the diffusion process, accurately reproducing the unique diffusion statistics over the temperature range (145 – 215°C) of our experiments. We have also determined the diffusion activation barrier =1.24 ± 0.08 eV. Sandia National Labs is operated by Sandia Corp, a Lockheed-Martin Company, for the DOE under Contract No. DE-AC04-94AL85000. F.JH and SB acknowledge NSF support under DMR-070145.
12:51PM Q12.00009 The diffusion pathways of phosphorus atoms in the silicon (001) surface  
JENNIFER BENNETT, OLIVER WARSCHKOW, Centre for Quantum Computer Technology, School of Physics, The University of Sydney, NIGEL MARKS, Nanochemistry Research Institute, Curtin University of Technology, DAVID MCKENZIE, Centre for Quantum Computer Technology, School of Physics, The University of Sydney — Effective use of surface chemical reactions to control the placement of dopants in semiconductors requires a detailed understanding of the reaction pathways involved. The most highly developed approach to accurate placement of phosphorus in silicon involves reacting phosphine gas with selected areas of the silicon (001) surface, incorporating the phosphorus atom into the surface and silicon overgrowth. In this computational study we investigate the least understood chemical reactions involved in this process, namely the phosphorus incorporation and associated diffusion reactions. We use density functional theory, combined with an efficient method for locating transition states, to identify the reaction pathways involved in three processes: (1) the diffusion of a phosphorus adatom along the silicon (001) surface, (2) the incorporation of a phosphorus atom into the surface, and (3) the migration of the incorporated phosphorus atom within the surface. The calculated pathways and corresponding reaction barriers provide insight into the conditions required for accurate incorporation and encapsulation of phosphorus atoms into the silicon surface.

1:03PM Q12.00010 Kinetic Monte Carlo studies of the behavior of CO on sulfur-covered Pd(100) surface  
DOMINIC ALFONSO, National Energy Technology Laboratory — Investigations of the behavior of CO on the surface of Pd modified with sulfur were carried out using first-principles Kinetic Monte Carlo method. In particular, the influence of adsorbed sulfur on the adsorption, diffusion and desorption of CO on the Pd(100) surface was studied. A kinetic Monte Carlo code was developed which enables the simulation of hosts of competing elementary steps with lateral interaction between the adspecies taken into account. The barriers and energetics of the relevant reaction pathways were determined by density-functional theory. The rates entering the simulation were derived using transition state theory. The adsorbates were assumed to interact via pairwise additive interactions. We demonstrate that adsorbed sulfur has an adverse effect on the behavior of CO on Pd(100).

1:15PM Q12.00011 Charge-State Dependent Hydrogen Diffusion on Silicon (001)  
OLIVER WARSCHKOW, University of Sydney — The diffusion of hydrogen atoms is relevant to a number of chemical and technological processes of the silicon (001) surface. These include the dissociative adsorption of molecules, the growth of overlayers by chemical vapor deposition (CVD), and the directed atomic-scale functionalization of the surface by scanning tunnelling microscopy (STM) lithography. The basic inter- and intradimer shift reactions of hydrogen are well studied, and activation energies of respectively 1.7 eV and between 1.0 and 1.4 eV are commonly cited. In this presentation, I will pose and discuss two questions: (1) Are single energy barriers adequate to describe H-shift reactions on silicon, and (2) are STM measurements of H-diffusion truly representative for hydrogen desorption in the absence an STM tip? These questions warrant examination because hydrogen adatoms on Si(001) are known to adopt a variety of charge states depending on factors such as the doping level of the silicon substrate, the defect density on the surface, or the presence of an STM tip. High-level density functional calculations are reported to shed some clarity on these questions.

1:27PM Q12.00012 Unidirectional Linear Diffusion on an Isotropic Cu(111) Surface in a Periodic and Asymmetric Potential  
DEZHENG SUN, Department of Physics, UC, Riverside, KI-YOUNG KWON, KIN L. WONG, GREG PAWIN, ERIC CHU, ZHIHAI CHENG, DAE-HO KIM, MIAOMIAO LIO, Department of Chemistry, UC, Riverside, SAMYPO HONG, TALAT S. RAHMAN, Department of Physics, University of Central Florida, Orlando, MICHAEL MARSELLA, LUDWIG BARTELS, Department of Chemistry, UC, Riverside — We performed an STM study of the diffusion of 1.4 benzenedithiol, 9-thioantracone, 9,10-dithioantracone (DTA) and 2,3-dimethyl-9,10-dithioacetylanthracene (DMDTA) as well as naphthaquinone, antraquinone and pentacenetetracene on Cu(111). Inherently uniaxial motion of all species with two thiol groups and at least three aromatic rings are observed. Sequential placement of the substrate linkers prevents DTA and DMDTA from rotating or veering off course. Asymmetric metahylylation impacts DTA’s diffusive behavior by about 100-fold decrease in surface mobility causes by about 2-fold increase of the diffusion barrier, with the overall symmetry of DTA diffusion not affected: A forward/backward ratio of 1.009±0.001, were found i.e. less than 1% deviation from unity. This is in stark contrast to the classical behavior but in perfect agreement with Tolman’s ‘Principle of Microscopic Reversibility’.

1:39PM Q12.00013 Surface Morphological Response of Stressed Elastic Solids under Electromigration Conditions  
VIVEK TOMAR, RAUF GUNGOR, DIMMITROS MAROUDAS, University of Massachusetts, Amherst — We present a theoretical analysis of the surface morphological response of electrically conducting, stressed elastic crystalline solids under the simultaneous action of an electric field that drives surface electromigration. The analysis is based on a fully nonlinear model of driven surface morphological evolution and combines linear stability theory with self-consistent dynamical numerical simulations. We report results of the surface morphological response of a uniaxially stressed solid as a function of electric field strength, surface crystallographic orientation, and temperature. We find that a properly directed and sufficiently strong electric field can stabilize the surface morphology of the stressed solid against crack-like surface instabilities, as well as surface rippling instabilities, and determine the required critical electric-field strength over a broad temperature range and for various surface crystallographic orientations. We also demonstrate the superior morphological response of <111>-oriented surfaces of face-centered cubic metals.

1:51PM Q12.00014 Theory of the lifetime of adsorbate vibrations on semiconductor surfaces  
PETER KRATZER, SUNG SAKONG, University Duisburg-Essen — On semiconductor surfaces, the vibrational lifetime of covalently bonded adsorbates is rather long (nanoseconds or more) since the band gap precludes electronic dissipation. Due to the quantum nature of vibrational states, such slow relaxation is expected, as the large quantum of the bond stretching must be converted into several smaller (phononic or vibronic) quanta by a high-order process. We use density functional theory calculations to map out the high-dimensional potential energy surface governing the anharmonic coupling of the stretching to the local bending and shift modes, while the coupling to the substrate phonons is treated perturbatively. Applying our method to the vibrational lifetime of CO on Si(100), we find that the CO stretching relaxes predominantly via an intermediate state consisting of four shift and/or bending quanta and one phonon. As a second application, we elucidate the role of intermediate vibrational states in the relaxation of the stretching vibration at Ge(100):H surfaces. For Ge surface dimers saturated by one H and one D atom, the lifetime of the Ge–H stretching vibration is up to five times shorter and less temperature-dependent than in Ge dimers homogeneously saturated by H. Our analysis shows that the symmetry breaking associated with the isotope mixture opens up additional relaxation channels.

2:03PM Q12.00015 Modeling H₂-Surface Interactions on Interstellar Dust Grains: A Classical Molecular Dynamics Study  
VIJAY VEERAGHATTAM, STEVEN LEWIS, PHILLIP STANCL, University of Georgia, JUNKO TAKAHASHI, Meiji Gakuin University — A classical Molecular Dynamics (MD) method is employed to model hydrogen molecules interacting with the surface of amorphous ice and to calculate the sticking coefficient as a function of various system parameters. This study, combining molecular physics and surface science, is part of a larger program of research to provide theoretical input for models of dust-grain-mediated physico-chemical processes in the interstellar medium. Many dust-grain systems are thought to be doped with amorphous ice, which motivates the choice of substrate for this study. Our method simulates the various dynamical processes associated with H₂-ice scattering events, including collision, sticking, diffusion, and ejection. Variables such as angle of incidence, molecular rotational state, substrate temperature (T_D), and H₂ temperature (T_H₂) are monitored and allowed to vary. In this talk, we will present our results for the H₂-ice sticking coefficient as a function of T_D and T_H₂.
11:15AM Q13.00001 Computation of the Iron and Iron-Nickel Phase Diagrams from Ambient to Earth’s Inner Core . XUAN LUO, R.E. COHEN, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015 — We have performed first-principles computation for the magnetic iron and iron-nickel over a wide range of pressure (0-400GPa) and temperature (0-6000K), within density-functional theory (DFT) in the generalized-gradient approximation using the projector augmented wave (PAW) method with the ABINIT code. We computed the free energies of hcp, bcc and fcc phases for iron and nickel including the thermal excitation of electrons and quasiharmonic phonons computed using the supercell method. We find that at high temperatures and pressures random stacking of fcc andhcp (rhc) is most stable even though the difference in Gibbs free energy between fcc andhcp Fe is smaller than the thermal energy. We computed the free energy of stacking faults, the rhcp phase and the percentage offcc and partial ordered sequences along the melting curve. For the first time, we used first-principles calculation to be able to produce the pure-Fe phase diagram including the magnetic contributions at low pressures. In the Fe-Ni system, we find that FeNi3 is an intermediate phase below 700K at 0 GPa, consistent with experiment, and below 50 GPa at 0K. Finally, we obtained the T-P-x phase diagram for FeNi from 0-400 GPa and 0-6000K.

11:27AM Q13.00002 Plasticity-Mediated Structural Transformation and Diamond-Anvil Cell and Shock Melting1 . CHRISTINE WU, PER SODERLIND, JAMES GLOSLI, JOHN KLEPEIS, Lawrence Livermore National Lab — Determination of the melting curve of a metal under high pressures is essential for establishing its phase diagram, and has wide scientific implications, including our understanding of the Earth’s interior. Currently, melting temperatures at high pressure are primarily measured by in situ laser-heated diamond-anvil cell (DAC) or shock wave experiments. Often, but not always, these two methods yield significantly different results for metals with non close-packed structures, such as bcc metals. For instance, anomalously flat melting slopes were reported for numerous bcc metals by DAC. The flatness of the melting slope is in sharp contrast to the classical Lindemann behavior which shock-melting temperatures follow closely. In this presentation, we will report our finding of a plasticity-mediated structural transition of bcc Ta to a partially disordered glassy structure obtained from molecular dynamics (MD) simulations. This transition is fully consistent with reported DAC low melting, thus provide a highly probable resolution to the long-standing controversy in melting of metals under high pressures.

11:39AM Q13.00003 High Pressure-High Temperature Phase Diagram of Beryllium1,2, M.J. LIPP, B.J. BAER, H. CYNN, Z. JENEI, J.-H. KLEPEIS, W.J. EVANS, LLNL, H.-P. LIERMANN, Y. MENG, S.V. SINOGEIKIN, W. YANG, HPCAT, A. LAZICKI, CIW, Y. OHISHI, SPING-8/JASRI — A detailed understanding of the phase diagram of beryllium and its alloys impacts fundamental science and technological applications. Despite a simple atomic structure, theoretical modeling of the phase diagram of beryllium has been extremely challenging and remains an area of active investigation [Kadas, PRB 07]. Extension of the experimental understanding of beryllium will serve to inform and advance theoretical efforts and technological applications. To address these needs, we have extended our previous work [Evans, PRB 05], and performed x-ray diffraction and melt studies beryllium and beryllium alloys at high pressure. We will describe our measurements of the crystal structure, lattice constants, and melt curve of high-pressure beryllium and beryllium alloys. We will discuss insights into this simple yet challenging system.

11:51AM Q13.00004 High Pressure-Temperature Studies of Vanadium1, Z. JENEI, B.J. BAER, H. CYNN, J.-H. KLEPEIS, M.J. LIPP, W.J. EVANS, LLNL, H.-P. LIERMANN, Y. MENG, S.V. SINOGEIKIN, W. YANG, HPCAT — Vanadium, a seemingly simple metal, has captured the interest of high-pressure scientists following the discovery (Ding et al. PRL 2007) of a subtle pressure-induced phase transition from bcc to a rhombohedral phase. Recent first-principles electronic-structure studies (Lee et al. PRB 2007) are consistent with these experiments and extend beyond the range of the measurements, predicting a reentrant phase transition back to bcc at high pressure. Further experiments in the regime of these predictions can validate and advance the understanding of simple metals at high pressures. We have made x-ray diffraction measurements of the crystal structure and lattice parameters of vanadium at high-pressure and temperature. Detailed comparisons will challenge/validate models and guide development of predictive codes. We will discuss our measurements including high temperature behavior, the EOS, and transitions of vanadium at high pressure.

12:03PM Q13.00005 Coupling of Atomistic and Meso-scale Phase-field Modeling of Rapid Solidification1 . J. BELAK, P.E.A. TURCHI, M.R. DORR, D.F. RICHARDS, J.-L. FATTEBERT, M.E. WICKETT, F.H. STREITZ, Lawrence Livermore National Laboratory — Recently, phase field models have been introduced to model the crystallography during polycrystal microstructure evolution [1,2]. Here, we assess these models with molecular dynamics and phase field simulations that overlap in time and space. Large parallel computers have enabled MD simulations of sufficient scale to observe the formation of realistic microstructure during pressure driven solidification [3]. We compare the two methods by calculating the phase field order parameter (quaternion) from the atomic coordinates and drive the evolution with the MD. Results will be presented for the simulations of sufficient scale to observe the formation of realistic microstructure during pressure driven solidification [3]. We compare the two methods by calculating the phase field order parameter (quaternion) from the atomic coordinates and drive the evolution with the MD. Results will be presented for the simulations of sufficient scale to observe the formation of realistic microstructure during pressure driven solidification [3].

12:15PM Q13.00006 New high-pressure phases of calcium and their finite-temperature phase boundaries1, AMANUEL TEWELDEBERHAN, Dalhousie University, STANIMIR BONEV, Dalhousie University — The phase diagram of Ca has been studied using first-principles density functional theory. The simple cubic structure hitherto believed to exist between 32 and 109 GPa is found to be mechanically and thermodynamically unstable. Instead we propose two new solid phases with orthorhombic $\text{Ca}_2$ and $\text{Ca}_3$ structures and determine their finite-temperature phase boundaries. We also predict liquid transitions in molten Ca under compression, which together with the new solid phases provide a consistent description of the Ca phase diagram. The implications of our findings and extensions of the work to other alkali and alkaline-earth metals will be discussed.

12:27PM Q13.00007 Physical and Chemical Transformations of Sodium Cyanide at High pressures. JING-YIN CHEN, Institute for Shock Physics, Washington State University, Pullman, Washington 99164 - 2816, CHOONG-SHIK YOO, Institute for Shock Physics and Department of Chemistry, Washington State University, Pullman, Washington 99164 - 2816 — Pressure-induced physical and chemical transformations of Sodium Cyanide (NaCN) have been studied up to 50 GPa in diamond-anvil cells, using micro-Raman spectroscopy and angle-resolved synchrotron x-ray diffraction. The present results suggest three phase transitions to occur in this pressure range: from NaCN-I (cubic) to NaCN-II (orthorhombic) at 2 GPa, to NaCN-III (monoclinic) at 8 GPa, and to NaCN-IV (tetragonal) at 15 GPa. At higher pressures, NaCN-IV undergoes irreversible chemical changes, which occurs over a large pressure range between 25 and 34 GPa. The new material exhibits a broad yet strong Raman band at around 1600 cm⁻¹, indicating the formation of C=N bonds in a similar configuration of carbon graphitic.

12:39PM Q13.00008 First-order liquid-liquid phase transition in compressed nitrogen. BRIAN BOATES, STANIMIR BONEV — We present results of first-principles molecular dynamics simulations, which provide evidence for the existence of a first-order liquid-liquid phase transition in compressed nitrogen [1]. The transition is from a molecular to a polymeric liquid. It is characterized by a discontinuous loss of molecular stability followed, upon further compression, by gradual transformation until the local order of the liquid becomes similar to that of cg-N. We have computed the phase boundary of the liquid-liquid transition to be first-order between 2000 and 4000 K and determined that above 4000 K it becomes continuous. Comparison with measurements and suggestions for experimental confirmation of our predictions will be discussed as well. [1] B. Boates and S.A. Bonev, submitted.

1Work supported by NSERC

12:51PM Q13.00009 High-temperature high-pressure properties of silica from Quantum Monte Carlo and Density Functional Perturbation Theory. R.E. COHEN, Geophysical Lab., Carnegie Institution, K. DRIVER, Ohio State University, Z. WU, B. MILITZER, University of California, Berkeley, P.L. RIOS, M. TOWLER, R. NEEDS, University of Cambridge — We have used diffusion quantum Monte Carlo (DMC) with the CASINO code with thermal free energies from phonons computed using density functional perturbation theory (DFPT) with the ABINIT code to obtain phase transition curves and thermal equations of state of silica phases under pressure. We obtain excellent agreement with experiments for the metastable phase transition from quartz to stishovite. The local density approximation (LDA) incorrectly gives stishovite as the ground state. The generalized gradient approximation (GGA) correctly gives quartz as the ground state, but does worse than LDA for the equations of state. DMC, variational quantum Monte Carlo (VMC), and DFT all give good results for the ferroelastic transition of stishovite to the CaCl₂ state. The local density approximation (LDA) incorrectly gives stishovite as the ground state. The generalized gradient approximation (GGA) correctly gives quartz as the ground state, but does worse than LDA for the equations of state. DMC, variational quantum Monte Carlo (VMC), and DFT all give good results for the ferroelastic transition of stishovite to the CaCl₂ state. Zero point and thermal contributions are included by using DFT linear response within the quasiharmonic approximation. Preliminary results indicate the QMC phase relations and bulk moduli are in reasonable agreement with experiment.

Computations were performed at NERSC, OSC, and CCNI. Financial support provided by the DOE (DE-FG02-99ER45795).

1:03PM Q13.00010 Quantum Monte Carlo Equations of State of α- and β-Magnesium Silicate. KEVIN P. DRIVER, JOHN W. WILKINS, The Ohio State University — The 410 km seismic discontinuity in Earth’s mantle is ascribed to the α to β-(Mg,Fe)₂SiO₄ phase transformation. Considering Mg-endmembers, density functional theory (DFT) predictions within LDA and GGA disagree on the phase boundary by 50% [1]. Quantum Monte Carlo (QMC) offers a route to avoid the approximation of the exchange-correlation potential in DFT and provide a benchmark for the phase boundary, elastic moduli, and thermodynamic properties. Zero point and thermal contributions are included by using DFT linear response within the quasiharmonic approximation. Preliminary results indicate the QMC phase relations and bulk moduli are in reasonable agreement with experiment.

1:15PM Q13.00011 High Pressure Studies on Group IV Transition Metals Based Metallic Glasses. ANDREW STEMHSORN, YOGE什 VOHRA, University of Alabama at Birmingham — The compression behavior of Group IV transition metals based metallic glasses Ti37Zr29Cu15Sn14.5B6 and Zr57Cu15.4Ni12.6Al10Nb5 are investigated at room temperature up to 74 GPa in a diamond anvil cell using in-situ energy and angular dispersive x-ray diffraction with a synchrotron radiation source. The x-ray diffraction studies did not reveal any pressure induced crystallization phenomenon in metallic glasses to a volume compression of 35 percent. In Zr-based metallic glass, a nanostructured tetragonal Zr2Ni phase was observed and also found to be stable to the highest pressure. The measured equation of state (Pressure-Volume curve) of Group IV transition metals based metallic glasses is compared to the known high phases of transition metals.

We acknowledge support from the NSF under Grant No. DMR-0703891.

1:27PM Q13.00012 High-pressure-High-temperature phases of Carbon Dioxide. AMARTYA SENGUPTA, Washington State University, Pullman WA 99164, CHOONG-SHIK YOO, Washington State University, Pullman, WA 99164 — The phase diagram of CO₂ has not been understood adequately above 40 GPa and high temperatures, particularly regarding the stabilities and boundaries of various extended phases that include a-carbonia, phase V, and to an extent Phase III. We have studied the phase diagram of CO₂ above 40 GPa and at high temperatures, using both ohmically and laser-heated diamond anvil cells. We found the co-existence of several extended phases over a large pressure region, which we attribute to the metastability of the extended phases and the extraordinarily large pressure gradients at these pressures. We determined the relative stability fields of the co-existing phases, which may offer the physico-chemical mechanism for the existence of carbonate minerals in deep Earth’s mantle.

1:39PM Q13.00013 First-principles study of BC₂N. EUNJA KIM, TAO PANG, Department of Physics and Astronomy, UNLV, NV 89154, USA. WATARU UTSUMI, Sychrotron Radiation Research Center, Japan Atomic Energy Research Institute, Japan, VLADIMIR SOLOZHENKO, LPMTN-CNR, Universite Paris Nord, France, YUSHENG ZHAO, LANL, Los Alamos, New Mexico, 87545, USA — First-principles calculations are performed and analyzed to identify different phases of BC₂N synthesized experimentally. With a proper choice of the supercell, cutoff energy, and sampling k points, the cubic phases are found to be stable theoretically. The bulk moduli from elastic stiffness constants for each of the phases is in excellent agreement with available experimental data. All the phases are defect free and do not possess any B–B or N–N bond. Two high-density phases with nearly degenerate energies are interpreted to represent two experimental systems of different x-ray patterns. The high-density phases are characterized by the existence of C–C bonds whereas the low-density phase is characterized by the absence of C–C bonds. From the calculated equation of state and the available experimental data, we show for the first time that the unique feature of each of the cubic BC₂N phases is a direct result of the corresponding local electronic structure and chemical bonding in the system.

This work is supported in part by the U.S. Department of Energy (DOE) through HiPSEC in UNLV.
1:51PM Q13.00014 Large volume change across OI \rightarrow\text{OII} phase transition in transition-metal dioxides TiO$_2$, ZrO$_2$, and HfO$_2$ as determined by experiment and theory

1:51PM Q13.00014 Large volume change across OI \rightarrow\text{OII} phase transition in transition-metal dioxides TiO$_2$, ZrO$_2$, and HfO$_2$ as determined by experiment and theory

YAHYA AL-KHATATBEH, New Mexico State University, KANANI K.M. LEE, Yale University, BORIS KIEFER, New Mexico State University — The nature of bonding in transition-metal dioxides TiO$_2$, ZrO$_2$, and HfO$_2$ is of interest as they are potential superhard materials with many industrial applications. Using high-resolution synchrotron x-ray powder diffraction for TiO$_2$ and ZrO$_2$, and complementary ab-initio computations of these dioxides, we have determined the equation of state of the orthorhombic I (O1) and orthorhombic II (OII) phases. Our measurements are in agreement with the computationally predicted phase sequence of these oxides. The measured volume change across OI \rightarrow\text{OII} transition is 8.3\% for TiO$_2$ and 10\% for ZrO$_2$ in good agreement with our density-functional theory (DFT) calculations that predict a large volume change for all of these dioxides across the OI \rightarrow\text{OII} phase transition. For TiO$_2$, this volume collapse is significantly higher than previously measured (2.6\%), but consistent with the volume decreases observed in both ZrO$_2$ and HfO$_2$ across this transition. Furthermore, the OII phase was observed to be the most stable phase of TiO$_2$ and ZrO$_2$ at high pressure (56 GPa) after heating to high temperatures (above \sim 1800 K) and no post-OII phase was observed under these conditions.

2:03PM Q13.00015 Crystal Structure and Phase Transition of XeF$_2$ at High Pressures

MINSEOB KIM, Institute for Shock Physics, CHOONG-SHIK YOO, Institute for Shock Physics and Department of Chemistry, STATIC HIGH PRESSURE GROUP IN ISP TEAM — We have investigated the crystal structure and phase transition of solid XeF$_2$ up to 51 GPa in diamond anvil cells by using Raman and synchrotron x-ray diffraction. The x-ray data indicates the tetragonal-to-orthorhombic phase transition at 7 GPa, which accompanies a small distortion (< 1\%) in the ab-plane of the tetragonal structure. The Rietveld refinement further indicates a rapid change of intermolecular F...F contact distance with increasing pressures and, thereby, a rotation of linear symmetric XeF$_2$ molecules along the c-axis and the observed distortion in the ab-plane. This symmetry lowering tetragonal-to-orthorhombic transition also induces the Davydov splitting of symmetric stretching $\nu_1$ and bending $\nu_2$ modes in the Raman spectrum.

Wednesday, March 18, 2009 11:15AM - 1:51PM
Session Q14 DFD: Granular Fluctuations

11:15AM Q14.00001 Cooling and aggregation in wet granulates

ANNETTE ZIPPELIUS, STEPHAN ULRICH, TIMO ASPELMIEIER, University of Goettingen, KLAUS ROELLER, AXEL FINGERLE, STEPHAN HERMINGHAUS, Max-Planck-Institute for Dynamics and Self-Organization — Wet granular materials are characterized by a fixed bond energy in their particle interaction such that breaking a bond implies an irreversible loss of a fixed amount of energy. Associated with the bond energy is a nonequilibrium transition, setting in as the granular temperature falls below the bond energy. The subsequent aggregation of particles into clusters is shown to be a self-similar growth process with a cluster size distribution that obeys scaling. In the early phase of aggregation the clusters are fractals with $D_f = 2$, for later times we observe gelation. We use simple scaling arguments to derive the temperature decay in the early and late stages of cooling and verify our results with event-driven simulations.

11:27AM Q14.00002 Propagating Waves in a Monolayer of Self-Propelling Gas-Fluidized Rods

LYNN J. DANIELS, DOUGLAS J. DURIAN, University of Pennsylvania — We report on the existence of propagating compression waves in a quasi-two-dimensional monolayer of self-propelling rods fluidized by an upflow of air. This behavior is unique to rods; a comparable system of spheres exhibits no waves and displays ‘thermal’ number fluctuations, proportional to $N^{1/2}$. The waves, however, give rise to anomalously large number fluctuations, having both magnitude and exponent greater than ‘thermal’ fluctuations. This occurs as rarefaction zones relax after a compression front has traveled through a region. We characterize the waves by calculating a dynamic structure factor. The position of observed peaks, as a function of frequency $\omega$ and wavevector $k$, yield a linear dispersion relationship in the long-time, long-wavelength limit and a wavespeed $\omega/k = 20$ cm/s. By contrast, spheres exhibit $1/\omega^2$ decay for all wavemodes in the hydrodynamic limit, consistent with the diffusive decay of density fluctuations.

11:39AM Q14.00003 Phase diagram of wet granular matter under vertical vibrations

KAI HUANG, KLAUS ROELLER, STEPHAN HERMINGHAUS, Max Planck Institute for Dynamics and Self-organization — The phase diagram of vertically vibrated wet granular matter is investigated by both experiments and simulations. We find a critical point where the coexistence (C) regime of the fluid (F) and gas (G) phases terminates. The energy driven F-C transition is found to scale with the rupture energy of a liquid bridge if the corresponding vibration amplitude $A$ is less than particle diameter($d$). This is in good agreement with our simulations. Close to the F-G transition line, the variation of the size of the gas bubble grows significantly with vibration amplitude shows a hysteretic behavior. Within the hysteresis loop, we observe temporary gas bubbles with strong fluctuations in size. The F-G transition also induces the Davydov splitting of symmetric stretching $\nu_1$ and bending $\nu_2$ modes in the Raman spectrum.

11:51AM Q14.00004 Stress wave mitigation in granular media

CHIARA DARAILO, CALTECH, F. FERNANDO, University of Salerno, Italy, MASON PORTER, Oxford University, UK — We study stress wave mitigation in one- and two-dimensional granular media employing evolutionary algorithms to investigate the optimal design of composite protectors using granular chains composed of beads of various sizes, masses, and stiffnesses. We define a fitness function using the maximum force transmitted from the protector to a “wall” that represents the body to be protected and accordingly optimize the topology (arrangement), size, and material of the chain. We obtain optimally randomized granular protectors characterized by high-energy equipartition and the transformation of incident waves into interacting solitary pulses. We provide a quantitative characterization of dissipative effects using the propagation of highly nonlinear solitary waves as a diagnostic tool and develop optimization schemes that allow one to compute the relevant exponents and prefactors of the dissipative terms in the equations of motion. We thus propose a quantitatively-accurate extension of the Hertzian model encompassing realistic material dissipative effects. Experiments and computations with steel, brass, and polytetrafluoroethylene reveal a common dissipation exponent (for a discrete Laplacian of the velocities) with a material-dependent prefactor.

2:03PM Q14.00005 Anisotropies in granular temperature in a dense sheared granular flow

CHRIS RYRCROFT, University of California, Berkeley and Lawrence Berkeley Laboratory, ASHISH ORPE, National Chemical Laboratory, India, ARSHAD KUDROLLI, Clark University — We investigate a three-dimensional, slow, gravity-driven, sheared granular flow, making use of both simulation (carried out using the Discrete-Element Method) and experiment (using glass beads, imaged via an index-matched fluid). We begin by performing a quantitative comparison between the two procedures, concentrating on the level of agreement at the microscopic scale. After establishing how well the simulation can reproduce the microscopic fluctuations in particle velocities seen in experiment, we proceed to carry out a tensorial analysis of granular temperature. Our results show different types of behavior near the boundary and in the bulk of a granular flow, due to differences in the particle packing structure, and highlight anisotropies that may have implications for granular continuum modeling.

Support from ARO is greatly acknowledged

3:15PM Q14.00006 Laser-induced light deflection in granular matter

CHIARA DARAILO, CALTECH, F. FERNANDO, University of Salerno, Italy, MASON PORTER, Oxford University, UK — We study light deflection in granular media employing evolutionary algorithms to investigate the optimal design of composite protectors using granular chains composed of beads of various sizes, masses, and stiffnesses. We define a fitness function using the maximum force transmitted from the protector to a “wall” that represents the body to be protected and accordingly optimize the topology (arrangement), size, and material of the chain. We obtain optimally randomized granular protectors characterized by high-energy equipartition and the transformation of incident waves into interacting solitary pulses. We provide a quantitative characterization of dissipative effects using the propagation of highly nonlinear solitary waves as a diagnostic tool and develop optimization schemes that allow one to compute the relevant exponents and prefactors of the dissipative terms in the equations of motion. We thus propose a quantitatively-accurate extension of the Hertzian model encompassing realistic material dissipative effects. Experiments and computations with steel, brass, and polytetrafluoroethylene reveal a common dissipation exponent (for a discrete Laplacian of the velocities) with a material-dependent prefactor.
12:15PM Q14.00006 Correlation Functions of a Homogeneously Driven Granular Fluid in Steady State, KATHARINA VOLLMAYR-LEE, Bucknell University, TIMO ASPELMEIER, ANNETTE ZIPPELIUS, Georg-August-Universitaet Goettingen, Germany — We study a homogeneously driven granular fluid of hard spheres at intermediate volume fractions and focus on time-delayed correlation functions in the stationary state. The results of computer simulations using an event driven algorithm are compared to the predictions of generalized fluctuating hydrodynamics. The incoherent scattering function \( F_{\text{incoh}}(q, t) \) follows time-superposition and is well approximated by a Gaussian \( F_{\text{incoh}} = \exp \left( -\frac{q^2}{4} \Delta r^2(t) \right) \).

For sufficiently small wavenumber \( q \) we observe sound waves in the intermediate scattering function \( F(q, t) \) and in the longitudinal current correlation function \( C_1(q, t) \). We determine their dispersion and damping. Temperature fluctuations are predicted to be either diffusive or nonhydrodynamic, depending on wavenumber and inelasticity as characterized by incomplete normal restitution.

12:27PM Q14.00007 Interparticle friction between gently contacting spheres, GREG FARRELL, NARAYANAN MENON, Dept of Physics, UMass Amherst. — In previous experimental work we have found that the packing fraction of gently-sedimented monodisperse spheres is affected by particle roughness as well as the viscosity and buoyancy provided by the surrounding fluid. In order to provide a macroscopic quantification of the microscopic effects of particle surface and of the fluid, we have developed a new technique to measure the coefficients of static and kinetic friction between two spheres in a fluid. We find that even in fluid environments, there are static and kinetic coefficients of friction characteristic of solid-on-solid contact. Surprisingly, even for a given pair of spheres, we measure a broad range of friction coefficients corresponding to contacts made at different locations on the surface. Thus, even for lubricated surfaces, surface heterogeneity is more apparent for small normal forces than at familiar force-scales.

1 Supported through NSF-DMR 0606216.

12:39PM Q14.00008 Spatial Force Correlations in 3D Granular Flow, NALINI EASWAR, KELSEY HATTAM, EFROSYNI SEITARIDOU, ALISA STRATULAT, Smith College, Northampton, MA., NARAYANAN MENON, University of Massachusetts, Amherst, MA. — We measure the force delivered at four locations on the boundary of a 3D flow of mono-disperse glass spheres in a vertical, cylindrical chute. A variable opening at the bottom is used to change the flow velocity \( v_f \) from 3 to 30 cm/s. The force is measured at 80KHz, allowing us to resolve individual collisions. We measure two-point spatial correlations in the flow direction and normal to it. The equal-time correlation between forces that are higher than a threshold shows a weak but measurable spatial correlation. This correlation shows no spatial directionality or dependence on flow rate. The time correlations are synchronous between diametrically opposed locations, and shifted in time between locations along the flow. From the time-lag we determine that the correlations are carried up the flow at speeds \( \sim 1000 v_f \). This speed increases as the flow approaches jamming.

1 Supported by NSF DMR 0606216 and NSF MRSEC DMR 0213695.

12:51PM Q14.00009 Impact phenomena in fluidized granular matter, PATRICK MAYOR, HIROAKI KATSURAGI, DOUGLAS DURIAN, University of Pennsylvania, Philadelphia — Projectiles dropped into granular media form a crater and come to rest in a particular way that has been actively investigated in numerous studies. These impact phenomena illustrate how particulate materials respond to externally applied forces. Several recent experiments have focused on the penetration of projectiles impacting granular materials at relatively low speeds, and measured the dynamics of the impact process, yielding force laws accounting for the observations. We present results showing how granular impacts are affected when the load on the grains is modified using a vertical gas flow. Balls or cylinders are dropped into a dry, noncohesive granular medium and we measure the penetration depth when gas is flown upward (thus unloading the contacts) or downward (loading the contacts). We observe that the frictional drag decreases linearly with the flow rate, and vanishes completely once the system is fluidized. Different projectile geometries allow us to separate the effect of normal and tangential frictional forces. We also consider the case of objects that are lowered quasi-statically into the granular medium and measure the net vertical force exerted by the granular system on the objects at each immersion depth. We then discuss how this resistance force compares with the forces observed in actual impacts experiments.

1:03PM Q14.00010 A Statistical Approach to the Filtration of Rods, SCOTT FRANKLIN, Rochester Institute of Technology — We investigate the efficacy of a square-grid mesh at filtering rods from solution. The volume fraction \( \phi \) is kept low, reducing the chance of rods cooperatively jamming at the mesh. For round particles, filtering at low \( \phi \) is trivially determined by the ratio of particle diameter to mesh size. Because rods have two length scales, filtering is non-trivial for meshes larger than the rod width but smaller than the length, a potentially very large range. We have measured experimentally the probability for a rod to be filtered as a function of mesh size, particle length, and aspect ratio. Results are compared with a theoretical extension of the Buffon-Laplace Needle problem that accounts for finite rod width and an isotropic distribution in the zenith angle. The solution is the probability that a spherocylinder in three dimensions makes contact with a 2D spherolithic mesh, a necessary but not sufficient condition for filtration. Comparison of experiment and theory is then suggestive of what conditions are both necessary and sufficient.

1 Supported in part by a grant from the National Science Foundation, Division of Materials Research.

1:15PM Q14.00011 Granular Breathing, SURAJIT SEN, ROBERT SIMION, SUNY-Buffalo, ADAM SOKOLOW, Duke University — We study the dynamics of monodispersed and tapered granular alignments held within a fixed boundary and a moving boundary. The system is assumed to be driven at one end by imparting a constant or time dependent acceleration to the edge grain. Analytical and simulational studies show that such a driven system can eventually get "over-compressed" and begin to dilate due to repulsive grain-grain interactions. Continuous driving results in the phenomenon of granular breathing. The talk shall discuss the dynamical processes associated with granular breathing for time-independent and time-dependent driving. The phenomenon of nonlinear resonance and related processes that arise in these systems will be discussed.

1:27PM Q14.00012 Combustion of Micropowdered Biomass, ETHAN GEL, ROBERT THORNE, Cornell University — Combustion of finely powdered biomass has the potential to replace heating oil, which accounts for a significant fraction of US oil consumption, in heating, cooling and local power generation applications. When ground to 30-150 micron powders and dispersed in air, wood and other biomass can undergo deflagrating combustion, as occurs with gaseous and dispersed liquid fuels. Combustion is very nearly complete, and in contrast to sugar/starch or cellulose-derived ethanol, nearly all of the available plant mass is converted to usable energy so the economics are much more promising. We are exploring the fundamental combustion science of biomass powders in this size range. In particular, we are examining how powder size, powder composition (including the fraction of volatile organics) and other parameters affect the combustion regime and the combustion products.
both near and away from any critical point. Specifically, it has been shown that all thermodynamic observables of the p-state Potts model on a square lattice, MIKAEL WOOD, CARLOS WEXLER, University of Missouri — It has been recently discovered [1] that some families of systems exhibit universal behavior

12:39PM Q15.00008 Enhanced Transition Matrix Methods\textsuperscript{1}, DAVID YEVICK, University of Waterloo, MICHAEL REIMER, University of Waterloo — Recently we have adapted the transition matrix Monte-Carlo method to general communication systems [IEEE Photon. Technol. Lett. 1529 (2007), IEEE Communications Letters, 755 (2008)]. In these studies we compared and integrated different multicanonical and transition-matrix methods. We determined that the standard multicanonical method can be reformulated more simply and accurately by constructing the intermediate probability density function (density of states) after a small number of Markov transitions from the ratios of the elements of the transition matrix between adjacent states. Further, we considered an algorithmically more simple procedure in which transitions only occur from a given state to another state that has previously been less frequently sampled. Here we found that the intermediate Markov transition is small, numerical accuracy can be restored by restricting the Markov chain to within a single histogram bin for a certain number of transitions before allowing transitions to other bins. We finally summarize our application of these procedures to several problems in optical and wireless communication theory.

\textsuperscript{1}Funding for this work was provided in part by NSERC and Nortel.

12:51PM Q15.00009 S-index: Measuring significant, not average, citation performance, MANOLIS ANTONOYIANNAKIS, (1) Physical Review Letters, (2) Columbia University, (3) European Research Council — We recently [1] introduced the “citation density curve” (or cumulative impact factor curve) that captures the full citation performance of a journal: its size, impact factor, the maximum number of citations per paper, the relative size of the different-cited portions of the journal, etc. The citation density curve displays a universal behavior across journals. We exploit this universality to extract a simple metric (the “S-index”) to characterize the citation impact of “significant” papers in each journal. In doing so, we go beyond the journal impact factor, which only measures the impact of the average paper. The conventional wisdom of ranking journals according to their impact factors is thus challenged. Having shown the utility and robustness of the S-index in comparing and ranking journals of different sizes but within the same field, we explore the concept further, going beyond a single field, and beyond journals. Can we compare different scientific fields, departments, or universities? And how should one generalize the citation density curve and the S-index to address these questions? [1] M. Antonoyiannakis and S. Mitra, “Is PRL too large to have an ‘impact’?”, Editorial, Physical Review Letters, December 2006.

1:03PM Q15.00010 ABSTRACT WITHDRAWN —

1:15PM Q15.00011 Statistical laws for career longevity, ALEXANDER PETERSEN, WOO-SUNG JUNG, Boston University, JAE-SUK YANG, Korea University, H. EUGENE STANLEY, Boston University — Career length distinguishes successful long tenures from unsuccessful short stints, and partially reflects the contributions of an employee to the goals of the employer. In some professions, there are well-defined metrics that quantify career longevity, prowess, and productivity, which together contribute to the overall success rating for an individual employee. In this talk, I motivate a stochastic model for career development that relies on two key ingredients, random progress within the career and random stopping times terminating the career. This model is exactly solvable, predicting the probability density function (pdf) of career longevity, characterized by two parameters, $\alpha$ and $x_c$. The parameter $\alpha$ quantifies the power-law scaling of the pdf, which is terminated by an exponential cutoff after a crossover value $x_c$, representing the mean career lifetime. We test the model with the large quantity of empirical data available for several professional sports leagues, American baseball, Korean baseball, American basketball, and English soccer, finding excellent agreement with the model’s predictions. In all, the generality of the model suggests that there may be common stochastic forces that underly progress, success, and longevity in various professions.

1:27PM Q15.00012 Battles: Intelligent Army versus Insurgency\textsuperscript{1}, LINDA SHANAHAN, SURAJIT SEN, SUNY-Buffalo — A “simple” battle can be thought of as a conflict between two parties, each with finite reserves, and typically fought on one sides territory. Modern battles are often strategic, based largely on the speed of information processing and decision making and are mission oriented rather than to annex new territory. Here, we analyze such battles using a simple model in which the "blue" army fights a strategic battle against a "red" army that is well matched in combat power and in reds territory. We assume that the blue army attacks strategically while the red army attempts to neutralize the enemy when in close enough proximity, implemented here as "on-site," with randomly varying force levels to potentially confuse and drive the blue’s strategies. The temporal evolution of the model battles incorporate randomness in the deployment of the reds and hence possess attendant history dependence. We show that minimizing risk exposure and making strategic moves based on local intelligence are often the deciding factors that determine the outcome of battles among well matched adversaries.

1:39PM Q15.00013 Complete trails of social network evolution: The past 10 years of complex network research, DEOKJAE LEE, Seoul National University, KWANG-IL GOH, Korea University, BYUNGNAM KAHNG, DOOCHUL KIM, Seoul National University — During the last 10 years since the publication of pioneering papers on small-world and scale-free networks, more than 5,500 distinct researchers produced more than 4,000 research papers on complex networks during the years 1998–2007, here we study the complete evolution of the co-authorship network in network science. This dataset allows us to study the complete trail of social network evolution from the inception, in particular in the early transient stage, which has not been addressed empirically in previous studies. We find that distinct patterns in network topology emerge during the evolution: A fractal, tree-like giant cluster forms and in reds territory. We assume that the blue army attacks strategically while the red army attempts to neutralize the enemy when in close enough proximity, implemented here as “on-site,” with randomly varying force levels to potentially confuse and drive the blue’s strategies. The temporal evolution of the model battles incorporate randomness in the deployment of the reds and hence possess attendant history dependence. We show that minimizing risk exposure and making strategic moves based on local intelligence are often the deciding factors that determine the outcome of battles among well matched adversaries. In some professions, there are well-defined metrics that quantify career longevity, prowess, and productivity, which together contribute to the overall success rating for an individual employee. In this talk, I motivate a stochastic model for career development that relies on two key ingredients, random progress within the career and random stopping times terminating the career. This model is exactly solvable, predicting the probability density function (pdf) of career longevity, characterized by two parameters, $\alpha$ and $x_c$. The parameter $\alpha$ quantifies the power-law scaling of the pdf, which is terminated by an exponential cutoff after a crossover value $x_c$, representing the mean career lifetime. In all, the generality of the model suggests that there may be common stochastic forces that underly progress, success, and longevity in various professions.

1:51PM Q15.00014 Statistical mechanics of image processing by digital halftoning\textsuperscript{1}, JUN-ICHI INOUE, WATARU NORIMATSU, Hokkaido University, YOHEI SAIKA, Wakayama NCT, MASATO OKADA, The University of Tokyo — We consider the problem of digital halftoning (DH). The DH is an image processing representing each grayscale in images in terms of black and white dots, and it is achieved by making use of the threshold dither mask, namely, each pixel is determined as black if the grayscale pixel is greater than or equal to the mask value and as white vice versa. To determine the mask for a given grayscale image, we assume that human-eyes might recognize the BW dots as the corresponding grayscale by linear filters. Here we found that while substantial errors often result if the perturbation in the link, adjacent Markov state is small, numerical accuracy can be restored by restricting the Markov chain to within a single histogram bin for a certain number of transitions before allowing transitions to other bins. We finally summarize our application of these procedures to several problems in optical and wireless communication theory.

2:03PM Q15.00015 Molecular Kinetic Analysis of a Finite-Time Carnot Heat Engine, YUKI IZUMIDA, KOJI OKUDA, Hokkaido University — We show the first derivation of the efficiency at the maximum power for a finite-time Carnot heat engine of a weakly interacting gas which we can regard as a nearly ideal gas. Using this simple model, we check the celebrated Curzon-Ahlborn (CA) efficiency by performing the event-driven MD simulation as a numerical experiment for the first time[1,2]. This numerical experiment reveals that the CA efficiency is realized only in the limit of the small temperature difference \( T_L \rightarrow T_H \), where \( T_L \) and \( T_H \) are the temperatures of the hot and cold heat reservoirs, respectively. Our molecular kinetic analysis can explain the numerical results theoretically.

Wednesday, March 18, 2009 11:15AM - 2:15PM — Session Q16 DAMOP: Focus Session: Dipolar Gases and Ultra-Cold Molecules 317

11:15AM Q16.00001 Novel quantum magnets: Dipolar quantum gases1, HAN PU, Rice University — Experimental creation of chromium condensate with large magnetic dipole moment and ultracold polar molecules with large electric dipole moment has generated significant interest in dipolar quantum gases. The long-range and anisotropic nature of the dipolar interaction potential greatly enriches the properties of the system, many of which are not present in their non-dipolar counterparts. In this talk, I will present our recent studies on dipolar BEC as well as dipolar fermions, with the emphasis on the latter which is relatively less studied. From a semi-classical calculation based upon the phase space representation of the Fermi gas, I will show how the dipolar interaction deforms the Fermi surface and manifests itself in collective excitations and time-of-flight expansion dynamics of the cloud. Finally, I will describe a self-consistent Hartree-Fock-Bogoliubov theory that also takes dipolar induced fermionic superfluid pairing into account.

1Support from NSF and the Robert A. Welch foundation is acknowledged.

11:51AM Q16.00002 Ultracold Heteronuclear Fermi-Fermi Molecules, KAI DIECKMANN, Ludwig-Maximilians-University of Munich, Germany — Spin mixtures of quantum-degenerate fermionic gases exhibit long lifetimes in the strongly-interacting regime near a Feshbach resonance. This has opened the door for numerous key experiments like the creation of Fermi-Fermi molecules, the realization of molecular BEC, the observation of a pairing gap and of superfluidity in a fermionic gas in the BEC-BCS cross-over region near a Feshbach resonance. We present the production of \(^{6}\text{Li}-^{40}\text{K}\) heteronuclear molecules based on our experimental platform for the production of a two-components mixture of quantum-degenerate Fermi gases. Our production scheme for quantum-degenerate fermionic \(^{6}\text{Li}\) and \(^{40}\text{K}\) and bosonic \(^{87}\text{Rb}\) gases is based on multiple species magneto-optical trapping [1] and sympathetic cooling of the fermions by rubidium. We demonstrated catalytic cooling of lithium by potassium, overcoming the small lithium rubidium cross section. We achieved to simultaneously enter quantum degeneracy for all three species [2] with lowest temperatures of 0.25 and 0.35 times the Fermi temperature for lithium and potassium at about 260 nK. The highest atom numbers achieved are \(1.8 \times 10^5\) for lithium as well as potassium, and about \(1 \times 10^5\) for rubidium. We studied two s-wave Feshbach resonances between lithium and potassium [3] at 155 G and 168 G. By magnetic field sweeps we created about \(4 \times 10^{46}\) \(^{6}\text{Li}-^{40}\text{K}\) molecules at conversion efficiencies of up to 50% [4]. With a Stern-Gerlach purification technique we are able to image molecules and atoms spatially separated from each other. We discuss the lifetime of the molecule-atom mixture close to resonance.

12:27PM Q16.00003 Quantum phases of a two-dimensional dipolar Fermi gas, GEORG BRUUN, Niels Bohr Institute, EDWARD TAYLOR, Universita di Trento — We examine the superfluid and collapse instabilities of a quasi two-dimensional gas of dipolar fermions aligned by an orientable external field. It is shown that the interplay between the anisotropy of the dipole-dipole interaction, the geometry of the system, and the dipole polarization of the superfluid order parameter means that the effective interaction for pairing can be made very large without the system collapsing. This leads to a broad region in the phase diagram where the system forms a stable superfluid. Analyzing the superfluid transition at finite temperatures, we calculate the Berezinskii–Kosterlitz–Thouless temperature as a function of the dipole angle.

12:39PM Q16.00004 Fermi surface distortions in a neutral Fermi fluid with dipolar interactions, BENJAMIN M. FREGOSO, UIUC, KAI SUN, EDUARDO FRADKIN, BENJAMIN LEV — We show that the Fermi surface of a neutral fluid of fermions with aligned dipole moments by an external field is elongated along the direction of the aligning field. The distortion of the Fermi surface can be expressed as a linear combination of Legendre polynomials \( P_l(k) \) with \( l = \text{even} \), with \( l = 2 \) being the leading term. The possible existence of a phase transition to a spontaneous biaxial phase is discussed. The zero- sound collective modes of the system are found to be strongly anisotropic. We discuss the possible use of light scattering experiments to detect spatial anisotropies in dipolar gases.

12:51PM Q16.00005 Devil’s staircase and supersolidity in one-dimensional dipolar Bose gases, S. L. SONDHI, F. J. BURNELL, MEERA M. PARISH, Princeton University, N.R. COOPER1, Cambridge University — The classical ground states of particles in a convex repulsive potential are known to have a phase portrait displaying a complete devil’s staircase structure. We consider a single- component gas of dipolar bosons confined in a one-dimensional optical lattice, where the dipoles are aligned such that the long-ranged dipolar interactions are maximally repulsive. Introducing a kinetic term tunes the system away from the classical limit and results in a phase diagram with a Mott- Hubbard lobe for each rational filling fraction. Tuning the on-site interaction away from convexity yields alternative commensurate states with double occupancies which can form a staircase of their own, as well as one dimensional "supersolids" which simultaneously exhibit discrete broken symmetries and superfluidity.

10:30PM Q16.00006 Roton softening and supersolidity in Rb spinor condensates, ROBERT CHERNG, EUGENE DEMLER, Harvard University — Superfluids with a tendency towards periodic crystalline order have both a phonon and roton like spectrum of collective modes. The softening of the roton spectrum provides one route to a supersolid. We show that roton softening occurs in \(^{87}\text{Rb}\) spinor condensates once dipolar interactions and spin dynamics are taken into account. By including the effects of a quasi-two-dimensional geometry and rapid Larmor precession, we show a dynamical instability develops in the collective mode spectrum at finite wavevectors. We construct phase diagrams showing a variety of instabilities as a function of the direction of the magnetic field and strength of the quadratic Zeeman shift. Our results provide a possible explanation of current experiments in the Berkeley group Phys. Rev. Lett. 100,170403 (2008).
1:15PM Q16.00007 Hexatic, Wigner crystal and superfluid phases of dipolar bosons1. KAUSHIK MITRA, CARL WILLIAMS, NIST Gaithersburg, CARLOS SA DE MELO, Georgia Institute of Technology — The finite temperature phase diagram of two-dimensional dipolar bosons versus dipolar interaction is discussed for different values of short range repulsions. We identify the stable phases as superfluid, dipolar Wigner crystal (DWC), dipolar hexatic liquid crystal (DHL), and normal fluid. In particular, we show that the DWC exists at low temperatures for large dipolar interactions, but it melts into a DHL at higher temperatures, where translational lattice order is destroyed, but orientational order is preserved. Upon further increase in temperature the DHL phase melts into the normal fluid, where both orientational and translational lattice order are absent. We also find that the supersolid phase has always higher energy than the superfluid or Wigner crystal phases at low temperatures, but the supersolid is metastable, having an energy minimum that may be accessed through thermal quenching. Lastly, we calculate the static structure factor for each of the stable phases and show that each phase can be identified uniquely in an optical Bragg scattering experiment.

1:27PM Q16.00008 Dipole moments of ultra-cold polar molecules: a quantum Monte Carlo study, MICHAL BAJDICH, SHI GUO, LUBOS MITAS, CHIPS, Department of Physics, NC State, Raleigh, NC, PETER J. REYNOLDS, Physics Division and Physical Sciences Directorate, U.S. ARO, Durham, NC — Recently, there has been a great deal of interest in the production of ultra-cold heteronuclear molecules having large electric dipole moments [1]. This is of interest both for fundamental reasons as well as for applications such as qubits for quantum computing [2]. In this work, we calculate the dipole moment of a potentially implementable two-atom alkaline-alkaline-earth molecule, Li2Sr. We use correlated wave-function methods including both the quantum chemical configuration interaction (CI) method, and a stochastic quantum Monte Carlo (QMC), to calculate the potential energy surface and dipole moment. We study the dipole moment with increasing accuracy of correlated wave-functions. We then variationally re-optimize the wave-functions, which then serve as the representation of the Fermion nodes in the fixed-node QMC. To treat the Sr atom we employ two types of effective core potentials (ECPs), large core ECPs have only s-states in the valence space, while the small core ECP’s valence space includes also the highest s and p semi-core sub-shells. We find significant sensitivity of the dipole moment on both the size of the valence space and on the accuracy of the Fermion nodes. [1] B. Damski, et al Phys. Rev. Lett. 90, 110401 (2003). [2] D. DeMille, Phys. Rev. Lett. 88, 067901 (2002).

1:39PM Q16.00009 Using an optical lattice to preform KRb molecules and enhance the efficiency of ultra-cold polar molecule formation1, JAMES FREERICKS, Georgetown University, MACIEJ MASKA, University of Silesia, ROMUALD LEMANSKI, Institute for Low Temperature and Structure Research, THOMAS HANNA, National Institute of Standards and Technology, PAUL JULIENNE, Joint Quantum Institute of the University of Maryland and the National Institute of Standards and Technology — We will discuss recent computational work that employs both direct quantum Monte Carlo simulation and inhomogeneous dynamical mean-field theory to study the efficiency of preforming KRb pairs in an optical lattice. We will describe how to optimize the efficiency by adjusting the lattice depth and the interspecies interaction (via the Feshbach resonance) with parameters specific for fermionic 40K and bosonic 87Rb (since the ground-state dipolar molecule has already been formed from those atoms in free space). We work with a deep enough lattice that the K atoms are mobile, but the Rb atoms are localized, so the system is described by the spinless Falicov-Kimball model on a two-dimensional lattice. We also calculate the entropy and estimate the temperature turning the lattice.

1P16.00010 The bound states of ultracold KRb molecules, PAUL JULIENNE, Joint Quantum Institute, NIST and the University of Maryland. THOMAS HANNA, NIST — Recently ultracold vibrational ground state 40K40Rb polar molecules have been made using magnetoassociation of two cold atoms to a weakly bound Feshbach molecule, followed by a two-color optical STIRAP process to transfer molecules to the molecular ground state [1]. We have used accurate potential energy curves for the singlet and triplet states of the KRb molecule [2] with coupled channels calculations to calculate all of the bound states of the 40K40Rb molecule as a function of magnetic field from the cold atom collision threshold to the $\hbar\Omega=0$ ground state. We have also developed approximate models for understanding the changing properties of the molecular bound states as binding energy increases. Some overall conclusions from these calculations will be presented. [1] K.-K. Ni, S. Ospelkaus, M. H. G. de Miranda, A. Peer, B. Neyenhuis, J. J. Zirbel, S. Kotochigova, P. S. Julienne, D. S. Jin, and J. Ye, Science, 2008, 322, 231–235. [2] A. Pashov, O. Docenko, M. Tamanis, R. Ferber, H. Knöckel, and E. Tiemann, Phys. Rev. A, 2007, 76, 022511.

2:03PM Q16.00011 Multichannel quantum defect theory model of Feshbach resonances, THOMAS HANNA, National Institute of Standards and Technology, EITE TIESINGA, PAUL JULIENNE, Joint Quantum Institute, NIST and University of Maryland — Multichannel quantum defect theory (MQDT) has a large number of applications in atomic physics, including the properties of collisions near threshold. The key concept is that the short range physics can be accounted for very simply and then matched to the asymptotic long range interaction. We have developed a model of Feshbach resonances based on the ideas of MQDT. This model allows calculation of the kinkel fields at which resonances occur, as well as properties such as the resonance width and background scattering length. Apart from known atomic properties, only three input parameters are required: the singlet and triplet scattering lengths, and the coefficient of the long range van der Waals potential. Analytic reference functions defined by the potential [1] are used to calculate the long range properties, which are linked to the short range physics through a frame transformation. We apply our theory to calculate all of the bound states of the 87KRb molecule [1]. We have used accurate potential energy curves for the singlet and triplet states of the KRb molecule [2] with coupled channels methods including both the quantum chemical configuration interaction (CI) method, and a stochastic quantum Monte Carlo (QMC), to calculate the potential energy surface and dipole moment. We study the dipole moment with increasing accuracy of correlated wave-functions. We then variationally re-optimize the wave-functions, which then serve as the representation of the Fermion nodes in the fixed-node QMC. To treat the Sr atom we employ two types of effective core potentials (ECPs), large core ECPs have only s-states in the valence space, while the small core ECP’s valence space includes also the highest s and p semi-core sub-shells. We find significant sensitivity of the dipole moment on both the size of the valence space and on the accuracy of the Fermion nodes. [1] B. Damski, et al Phys. Rev. Lett. 90, 110401 (2003). [2] D. Our result indicates that the entanglement between the two JVQs is significant. Also, we show that the concurrence of the JVQs, placed in a resonant potentials by using the instanton and the valley-instanton approaches, respectively. We compute the concurrence to estimate the level of entanglement of two potential and leads to the interaction between the qubits. We compute the MQT of the fluxons between the minima of the symmetric and asymmetric double-well DHUNGANA, ISAAC O'BRYANT, JU KIM, University of North Dakota — We discuss the entanglement of two Josephson vortex qubits (JVQs) interacting by the continuous charge term, while the Davidson type affects the discrete charge term. These properties are linked to the boundary conditions of these systems.

The loss mechanisms are likely to be important for understanding coherence times in Josephson qubit circuits. The two-level systems (TLSs) naturally occurring in Josephson junctions constitute a major obstacle for the operation of superconducting phase qubits. Since these TLSs can possess remarkably long decoherence times, we show that such TLSs can themselves be used as qubits, allowing for a well controlled initialization, universal sets of quantum gates, and readout. Thus, a single current-biased Josephson junction (CBJJ) can be considered as a multiqubit register. It can be coupled to other CBJJs to allow the application of quantum gates to an arbitrary pair of qubits in the system. We also show that using the dynamics of a driven qubit, it could serve as a hallmark of coherent quantum dynamics in ladder-like multilevel systems. A real-space implementation of the quantum walk may help to verify qubits coupled to high quality resonators. The quantized behavior stands in contrast with the smooth dependence expected for a classical random walk, and distinguished by a winding number defined in terms of the Bloch eigenstates in the Brillouin zone. We find that the mean displacement of a particle initially localized on one of the two sublattices. The corresponding non-Hermitian tight-binding problem with complex potential for the decaying sites exhibits two distinct phases, distinguished by a winding number defined in terms of the Bloch eigenstates in the Brillouin zone. We find that the mean displacement of a particle initially localized on one of the two sublattices.

11:15AM Q18.00001 Design of Thermoplastic Elastomers with Self-Consistent Mean Field Theory: Radial (ABA)\textsubscript{n} and A(ABA)\textsubscript{n} Miktoarm Architectures, NATHANIEL LYND, FULUSHO OYEROKUN, DONAL O’DONOGHUE, Department of Chemical Engineering and the Materials Research Laboratory, University of California, Santa Barbara — Two thermoplastic elastomer designs were evaluated using self-consistent mean field theory. The phase diagram of a radial (A\textsubscript{1}B\textsubscript{2})\textsubscript{n} block copolymer was calculated at $\chi N = 40$ per arm as a function of composition ($f_A$) and asymmetry between the A-end blocks ($\tau = N_{A1}/(N_{A1} + N_{A2})$). Significant deflection of the phase boundaries towards larger $f_A$ occurred for asymmetric triblock copolymers ($\tau \approx 0.15$ and $\tau \approx 0.90$) due to the interplay between bidispersity and chain-pullout of the A-blocks. The phase diagram of an A\textsubscript{1}(B\textsubscript{2}A\textsubscript{2})\textsubscript{n} miktoarm star triblock copolymer was also investigated as a function of $f_A$ and $\tau$ at $\chi N = 40$ per A\textsubscript{1}B\textsubscript{2} unit. Similar deflections in phase boundaries towards higher $f_A$ resulted.

11:27AM Q18.00002 Unified mathematical model for linear viscoelastic predictions of linear monodisperse and polydisperse and branched polymers, RENAT KHALILLIIN, JAY SCHIEBER — We present an application of a single-chain mean-field model for entangled linear blends and star-branched systems. Slip-links instead of tubes are employed. The entanglements on a chain are destroyed by two coupled relaxation processes: so-called sliding dynamics; and relaxation of the environment, so-called constraint dynamics. The constraint dynamics are implemented by destruction and creation of the entanglements in the middle of the chain in a way statistically self-consistent with sliding dynamics. In contrast to previous tube models, Rouse dynamics is completely avoided. Nonetheless, the implementation of constraint dynamics in tube models is different for linear and branched chains; the slip-link model shows no need for modification of constraint dynamics. Moreover, our slip-link model requires a single fitting parameter $\chi N K$, that depends on the temperature of the melt, but not on chain length. The parameter can be fixed from a single fit to linear viscoelastic data. In addition, for branched polymers the branch point movements are determined by the free energy, so that its position is allowed to fluctuate, and even slide through the slip-links. The resulting model exhibits primitive-path fluctuations and chain stretching, so could be applied to flow and generalized to more complicated branches or cross-linked networkswithout significant modifications.

11:39AM Q18.00003 Self-assembly of rod coil block copolymers under confinement, MANAS SHAH, VENKAT. GANESAN, The University of Texas at Austin — The interplay of microphase separation and liquid crystalline ordering in rod-coil block copolymers leads to formation of complex morphologies distinct from that of conventional flexible block copolymer phases. In order to be used for organic electronic applications such as photovoltaic cells, rod-coil block copolymers must be patterned into thin films. The final morphology and the nature of orientation of rod units would be determined by the interplay between the interactions on the interactions of the blocks with the confining surfaces. We combine the self-consistent field theory models of rod-coil block copolymers in a thin film framework to understand the effect of confinement on the morphology and the nature of orientation of rod-units. Also for nearly symmetric rod-coil copolymers, we analyze the parallel – perpendicular lamellae transitions using a free energy framework. Also, we consider morphologies of such block copolymers (and blends) which can be utilized for higher device efficiency in photovoltaic cells.

11:51AM Q18.00004 Theoretically Informed Particle-Based Simulations of Polymers in Arbitrary Ensembles, DARIN PIKE, FRANCOIS DETCHEVERRY, University of Wisconsin, MARCUS MUELLER, University of Goettingen, JUAN DE PABLO, University of Wisconsin — A new, particle-based formalism is proposed for simulation of polymeric materials, where the interaction energy is given by the standard functional employed in field-theoretic models. The main features of the proposed formalism reside in its ability to enable simulations at constant stress or constant pressure, thereby permitting accurate estimation of free energies and phase boundaries. The usefulness of the proposed approach is illustrated in a series of thermodynamic property calculations from Monte Carlo simulations in the nVT, nPT, semi-grandcanonical and Gibbs ensembles. In particular, we consider the phase separation of a binary homopolymer blend and a symmetric diblock copolymer. For the blend, we present results for the phase diagram and the critical point of the model. For symmetric copolymers, we study the distribution of local stress in lamellae and the location of the first-order transition from a disordered to a lamellar phase.

12:03PM Q18.00005 Fields Help Particles – Fast Off-Lattice Monte Carlo Simulations of Soft Materials, YUHUA YIN, QIANG WANG, Colorado State University — Conventional molecular simulations of multi-chain systems are hindered by “hard” excluded-volume interactions (e.g., the Lennard-Jones potential in off-lattice simulations and the self- and mutual-avoiding walks in lattice simulations). Although such interactions are necessary for obtaining realistic dynamics, they significantly slow down the chain relaxation towards equilibrium configurations and efficient sampling of the configurational space. The idea of fast off-lattice Monte Carlo (FOMC) simulations is to perform particle-based Monte Carlo simulations in continuum with a Hamiltonian commonly used in polymer field theories, where individual polymer segments are modeled as “soft” particles whose interaction energy is finite when they overlap. This leads to much faster chain relaxation and better sampling of the configurational space. Furthermore, using the same Hamiltonian in both polymer field theories and FOMC simulations enables quantitative comparisons between them without any parameter-fitting to unambiguously reveal the effects of fluctuations and correlations in the system. Here we demonstrate these great advantages of FOMC simulations using several model systems.

12:15PM Q18.00006 Particles vs. Fields – Finite-Range Interactions in Polymer Field Theories, QIANG WANG, Colorado State University — Recently, we proposed a particle-based, fast off-lattice Monte Carlo (FOMC) simulation that uses the same Hamiltonian as in polymer field theories, which has great advantages over conventional molecular simulations. However, the continuous Gaussian chain model and $\delta$-function interactions widely used in polymer field theories (such as the self-consistent field theory) cannot be directly used in FOMC simulations. We therefore extend the field theories to the discrete Gaussian chain model and finite-range interactions. Taking the microphase separation of diblock copolymers as an example, a finite range interaction range increases the order-disorder transition from the well-known result of $\chi N \approx 10.5$, as well as the bulk lamellar period. More importantly, this work allows direct comparisons between the polymer field theories and FOMC simulations without any parameter-fitting to unambiguously and quantitatively reveal the effects of fluctuations and correlations in the system.

12:27PM Q18.00007 Mean Field Theory for Ionomer Melts, ERICA SALZTMAN, SANAT KUMAR, Columbia University — Single Chain Mean Field theory is applied to melts of charged polymers. Control parameters include temperature, chain length, and monomer density. Equilibrium variations of polymer conformational, translational, and rotational degrees of freedom and counterion translational degrees of freedom are studied; in particular we are interested in conformational and morphological transitions which occur in ionomers with changes in temperature and apparently dominate their macroscopic behavior. The constituent interactions, which are compared to simulation findings of low temperature condensation of chains and counterions to form ordered sheets of charges, form the basis for stochastic theories which model the temporal evolution of these structures, with immediate relevance to measurable dynamic properties.
12:39PM Q18.00008 Equilibrium and Beyond Equilibrium Properties of Polyelectrolytes - Ewald-Like Approach for Fluctuating Hydrodynamic and Electrostatic Interactions

JUAN P. HERNANDEZ-ORTIZ, Department of Materials, Universidad Nacional de Colombia, Sede Medellín, MICHAEL D. GRAHAM, JUAN J. DE PABLO, Department of Chemical and Biological Engineering, University of Wisconsin-Madison — A method is proposed for self-consistent simulations of the equilibrium and beyond equilibrium structures and transport properties of polyelectrolytes in solution. The method incorporates solution of the Nernst-Planck diffusion equation for ions and counter-ions within the solvent, and simultaneous description of fluctuating hydrodynamic interactions by means of a Green’s function formalism. The proposed approach generalizes our $\mathcal{O}(N)$ general geometry Ewald-like method to simultaneous treatment of hydrodynamics and electrostatics. With this method, we examine the transport properties of polyelectrolytes solutions at rest and in various flow fields, and we make direct comparisons to results from explicit ion Brownian dynamics simulations and experimental observations.

12:51PM Q18.00009 Self Consistent Field Theory Study of the Effect of Grafting Density on the Height of a Weak Polyelectrolyte Brush

KEVIN WITTE, YOU-YEON WON, Purdue University — The height of weakly basic polyelectrolyte brushes in the osmotic brush regime is studied as a function of the grafting density using a numerical self-consistent field (SCF) theory derived from the (semi-) grand canonical partition function. The theory is shown to properly account for the local nature of the charge equilibrium and to be able to capture the basic behaviors of polyelectrolyte brushes, including brush height variation with salt concentration and scaling with respect to degree of polymerization. However, we find, in agreement with recent experiments, that the scaling of brush height with grafting density is qualitatively different than that predicted by basic scaling arguments. This difference is attributed to the relative strength of electrostatic type interactions compared to finite segment size packing constraints.

1:03PM Q18.00010 Adsorption and depletion of polyelectrolyte in charged

DADONG YAN, XINGKUN MAN, State Key Laboratory of Polymer Physics and Chemistry, Institute of Chemistry, Chinese Academy of Sciences, AN-CHANG SHI, Department of Physics and Astronomy, McMaster University, NSFC COLLABORATION — Self-consistent field theory is presented to study the adsorption of flexible polyelectrolyte brushes (PE) onto uniformly oppositely charged cylinders. We focus on the curvature effect of adsorbing surface on the adsorption-depletion phase transition-like behavior. In terms of the scaling expression of the critical quantities, i.e., the salt concentration, the charge fraction of PE chain and the area density of surface charge, at the adsorption-depletion transition point have been obtained. Moreover, we find a critical line for the dependence of the critical radius of cylinder on the salt concentration, which separates the adsorption and depletion states. The theoretical results are in good agreement with the Monte Carlo simulations and the experimental results.

1:15PM Q18.00011 Field-Based Modeling and Simulation of Interfacial Fluctuations in Block Copolymers

AUGUST BOSSE, Polymers Division, NIST — The Edwards-model-based, field-theoretic simulation framework of Fredrickson is the cutting edge methodology in coarse-grained, field-based simulation of fluctuating copolymer systems [V. Ganesan and G.H. Fredrickson, Europhys. Lett. 55, 814 (2001); G.H. Fredrickson, V. Ganesan, and F. Drolet, Macromolecules 35, 16 (2001)]. Coarse graining the standard Edwards model yields the classic phenomenological “phase field” model of Ohta and Kawasaki [T. Ohta and K. Kawasaki, Macromolecules 19, 2621 (1986)]. Further coarse graining, coupled with the assumption of weak segregation, yields the ubiquitous Leibler-Brazovskii-Fredrickson-Helfand model [G.H. Fredrickson and E. Helfand, J. Chem. Phys. 87, 697 (1987)]. Each of these field-based models is capable of capturing thermodynamic fluctuations; however, the applicability of each model depends on the quench depth, the molecular weight, and the composition of the constituent copolymers, among other variables. Here we examine fluctuation effects in, and limitations of field-based models in the context of measuring interfacial fluctuations in a two dimensional diblock copolymer melt.

1:27PM Q18.00012 Variational Coarse-Graining of Discretized Field Theories of Fluids

MICHAEL VILLET, GLENN FREDRICKSON, University of California, Santa Barbara — Statistical field theory models have proven to be valuable tools for studying the equilibrium behavior of polymeric fluids, but direct simulation of these field theories without use of the mean field approximation is computationally demanding. Computational resources can be extended to simulate larger systems by discretizing the field variables with a coarsely spaced lattice, but indelicate coarse graining risks truncation of important short-wavelength physics. We introduce a variational method for systematically coarse-graining discretized field theoretic models of fluids while minimizing this truncation error.

1:39PM Q18.00013 Simulation of Fluctuations in Diblock Copolymer Melts: Testing an Alternative to the Fredrickson-Helfand Theory

JIAN QIN, CEMS at Universiy of Minnesota, DAVID MORSE, CEMS at University of Minnesota — Simulations of a bead-spring model of disordered diblock copolymer melts have been conducted to test a renormalized one-loop (ROL) theory of composition fluctuations recently proposed by the authors. The simulations use hybrid Monte Carlo (MC) / Molecular Dynamics (MD), reptation and double-rebriding moves, combined with replica exchange, to relax chain conformations. The quantitative comparison of simulation results with theory relies on a procedure that uses perturbation theory to independently identify the self-consistent-field (or RPA) interaction parameter. For the modest chain lengths accessible to simulations ($N \leq 64$ here), results for the maximum $S(q^*)$ of the structure factor are quite different from both RPA and Fredrickson-Helfand predictions, but agree very well with renormalized one-loop predictions.

1:51PM Q18.00014 Microphase Separation Induced by the Differential Monomer-Monomer Interactions in Diblock Copolymer/Homeopolymer Blends

JIAJIA ZHOU, AN-CHANG SHI, Department of Physics and Astronomy, McMaster University — Phase diagrams of blends composed of diblock copolymer (AB) and homopolymer (C) are obtained using the random phase approximation and self-consistent field theory. Emphasis is placed on the special case where all three monomer pairs, A/B, B/C and C/A, are miscible. Despite the miscibility of the binary pairs, a close-loop immiscible region exists in the AB/C blends when the pair interaction parameters are sufficiently different. Inside the close-loop, the system undergoes microphase separation, exhibiting different morphologies. This phenomenon is enhanced when the homopolymer interacts much strongly to one of the blocks of the diblock copolymer. The theoretical results are used to explain some recent experiments.
2:03PM Q18.00015 Study on the strength of intermonomer interactions for PS-b-PMMA using compressible RPA. HYUNJUH AHN, DU YEOL RYU, Yonsei University, YOUNGMIN KIM, Hongik University, KWANG HYUN SONG, KYUNG WOOK KWON, JUNHAN CHO, Dankook University — PS-b-PMMA copolymer is one of the most useful nanoscopic materials that can be used as passive electronic materials, and also as templates and scaffolds. It is then clear that the better knowledge on the strength of intermonomer interactions for the PS-b-PMMA is of great importance in fabricating nanomaterials from it. Using a compressible random-phase approximation (RPA) theory, we discuss mainly the second-order vertex function in the compressible Landau free energy. This vertex function is involved in the exchange energy between self and cross interactions along with the self interaction difference. Ordering transition temperatures are predicted and compared with experimental measurements using small-angle X-ray scattering (SAXS) and depolarized light scattering. A close relationship between barotropy (ordering upon pressurization) and the energetic vertex term for the copolymer is argued. 1

We feel grateful for the support from Center for Photofunctional Energy Materials.

Wednesday, March 18, 2009 11:15AM - 2:15PM —
Session Q19 DPOLY: The Physics of Polymer Nanocomposites: Rheology and Mechanical Properties 320

11:15AM Q19.00001 Influence of Nanoparticles on the Amplitude of Molecular Motions and the Fragility a Model Glass-Forming Polymer Melt. , JACK DOUGLAS, polymers Division, National Institute of Standards and Technology, FRANCIS STARR, Department of Physics, Wesleyan University — We investigate the impact of the addition of nanoparticles on both the fast and slow dynamics of a coarse-grained polymer fluid by molecular dynamics. The fast dynamics is characterized by the Debye-Waller factor (the average mean square particle displacement at a characteristic time in the caged particle motion regime) and the slow structural relaxation is characterized by the coherent intermediate scattering function. Our study explores how both the polymer-particle and nanoparticle volume fraction change the amplitude of the high frequency molecular motions (relative to the pure melt reference condition) and the strength of the temperature dependence of the structural relaxation time (defining the fragility of glass formation, as well as the glass transition temperature). Substantial variations of the Debye-Waller factor are observed and we test the effectiveness of the Buchenau relation linking the Debye-Waller factor to the long time structural relaxation time. We also consider how the presence of nanoparticles in the polymer melt influence the fragility of glass formation, where a range of criteria are utilized to define fragility. Appreciable changes of fragility are observed, these changes being dependent on the nanoparticle concentration and particle-polymer interaction.

11:27AM Q19.00002 Macroscopic dynamics of polystyrene grafted silica nanoparticles in a homopolymer matrix. JOSEPH MOLL, Columbia University, PINAR AKCORA, University of Missouri, SANAT KUMAR, Columbia University, RALPH COLBY, Pennsylvania State University — Silica nanoparticles grafted with polymers, dispersed in a homopolymer matrix, and annealed over time adopt a broad range of dispersion states which depend on grafting density, annealing time, weight percent silica, and the molecular weights of the polymers. We tuned these variables to give desired dispersion states, from uniformly dispersed particles to agglomerated clusters. Rheology was used to critically determine how the dispersion state affects the mechanical reinforcement of the composite. We have run both steady shear and small amplitude oscillatory shear experiments on nanocomposites comprising a range of dispersion states. By mapping the observed reinforcement on a morphology diagram, we observe the location of a maximum in reinforcement.

11:39AM Q19.00003 Structure, ion transport and rheology of nanoparticle organic hybrids. HAIQO QI, LYNDEN ARCHER, Cornell University — We report a new class of liquid nanoparticle organic hybrid materials (NOHMs), produced by tethering an organic oligomer corona to the surface of inorganic nanoparticles, and investigate their use as electrolytes. This talk focuses on the structure factor and the dispersion state affects the mechanical reinforcement of the composite. We have run both steady shear and small amplitude oscillatory shear experiments on nanocomposites comprising a range of dispersion states. By mapping the observed reinforcement on a morphology diagram, we observe the location of a maximum in reinforcement.

11:51AM Q19.00004 Effect of filler surface properties on stress relaxation behavior of carbon nanofiber/polyurethane nanocomposites. I. SEDAT GUNES, GUILLERMO JIMENEZ, SADHAN JANA, The University of Akron — The effect of carbon nanofiber (CNF) surface properties on tensile stress relaxation behavior of CNF/polyurethane (PU) nanocomposites was analyzed. PU was synthesized from methane diisocyanate, polypropylene glycol (PPG diol), and butanediol. CNF, oxidized CNF (ox-CNf), and PPG diol grafted CNF (ol-CNf) were selected as fillers. ol-CNf was obtained by grafting PPG diol onto ox-CNf by reacting it with the carboxyl groups present on ox-CNf surface. The atomic ratios of oxygen to carbon present on the filler surfaces were 0.13 and 0.18 on ox-CNf and on ol-CNf as compared to 0.015 on CNF, mostly due to the presence oxygen containing polar groups on the surfaces of the former. The composites were prepared by in-situ polymerization and melt mixing in a chaotic mixer. The stress relaxation behavior of composites was determined at room temperature after inducing a tensile strain of 100%. The presence of fillers augmented the rate of stress relaxation in composites which was highest in the presence of CNF. The results suggested that relatively weak polymer-filler interactions in composites of CNF promoted higher stress relaxation.

12:03PM Q19.00005 Synthesis of metal-molecule-metal structures for single-molecule transport and spectroscopy measurements. ALEX NEUHAUSEN, Dept. of Electrical Engineering, Stanford University, DAVID GOLDHABER-GORDON, Dept. of Physics, Stanford University, CHRIS CHIDSEY, Dept. of Chemistry, Stanford University — Robust, repeatable metal-molecule contacts are an elusive yet important hurdle in the development of molecular electronic devices. This project explores the chemical synthesis of metal-molecule-metal structures for single-molecule spectroscopy and transport measurements. Conjugated thiol-azide molecules are self-assembled on gold nanoparticles, which are then linked with dialkyn bridge molecules using Sharpless “click” reactions.
12:15PM Q19.00006 Impact of Nanofillers on the Durability of Polymeric Coatings and Composites, LI-PIN SUNG, STEPHANIE WATSON, AARON FORSTER, Materials and Construction Research Division, National Institute of Standards and Technology; SHENG LIN-GIBSON, Polymer Division, National Institute of Standards and Technology — Metal oxide nanoparticles have been incorporated into polymer systems to improve durability performance properties, for example Ultra Violet (UV) degradation and scratch resistance. In this paper, we present recent research results on (1) the effect of particle dispersion and photoreactivity of TiO₂ on the UV degradation of polymeric coatings exposed to high intensity UV radiations at two different humidity conditions; (2) the impact of nano-SiO₂ concentration on surface mechanical properties (surface morphology and scratch behavior) of polymeric coatings and composites. The physical and chemical degradation of the coatings were monitored in periodic intervals using a combination of laser confocal scanning confocal microscopy (LSCM) and attenuated total reflectance-Fourier transform infrared spectroscopy. An instrumented nanoindentation and LSCM are utilized to measure surface modulus, perform scratch testing, and map scratch damage patterns. A strong impact on the durability performance in both studies was observed in the presence of nanofillers. Particularly in the scratch resistance study, the addition of nanofillers reduces surface roughness and increase scratch resistance of the nano-filler-polymer composites.

12:27PM Q19.00007 The “Music” of Silica-Poly(methyl methacrylate) Core-Shell Spheres: Eigenvibrations and Mechanical Properties at the Nanoscale, TIM STILL, Max Planck Institute for Polymer Research, Mainz, Germany (still@mpip-mainz.mpg.de), REBECCA SAINIDOU, Universite du Havre, Le Havre, France, GOETZ HELLMANN, Deutsches Kunststoffinstitut, Darmstadt, Germany, GEORGE FYTAS, MPI for Polymer Research, University of Crete and FORTH, Heraklion, Greece — We report on the measurement of elastic vibrational modes (eigenvibrations) in silica–poly(methyl methacrylate) (SiO₂–PMMA) core-shell spheres and corresponding spherical hollow capsules (PMMA) with different particle size (diameter: 232 nm–405 nm) and shell thickness (25 nm–112 nm) using Brillouin light scattering, supported by numerical calculations. [T. Still et al., Nano Lett. 8, 3194 (2008)] These localized modes allow to access the mechanical moduli of core and shell material. We observe redshifted eigenvibrations of silica–polymer core–shell spheres with a core thickness of 100 nm. Thereafter, we present the results obtained by using the model of a nanocomposite formed by the incorporation of the polyhedral oligomeric silsesquioxane (POSS) molecules in the crosslinked epoxy matrix. MD simulations were performed after the reaction mixture in the simulation box. The structures so generated are relaxed using a combination of molecular mechanics and molecular dynamics (MD) simulations. The approach utilizes simulated annealing optimization technique for carrying out one-step polymerization of the reaction mixture in the simulation box. The structures so generated are relaxed using a combination of molecular mechanics and molecular dynamics (MD) simulations. The developed technique is computationally efficient and has been used for creating atomistic model structures of both crosslinked epoxy and a nanocomposite formed by the incorporation of the polyhedral oligomeric silsesquioxane (POSS) molecules in the crosslinked epoxy matrix. MD simulations are used to determine the volume-temperature behavior of these structures. The hybrid hybrid model exhibits the desirable photolumincent properties of CdSe nanocrystals but does not fracture, as do thick electrochemically grown nanoparticle shells. The peculiar behavior of the vibrational modes in the hollow capsules is attributed to anisotropic dependence on overall size and layer thickness. The present investigation of the acoustical properties of the individual core-shell particles can lead to the use of such nanoscale engineered particles in more elaborate systems to control hypersonic phonons.

12:39PM Q19.00008 A Microscopic Model for the Reinforcement and the Non Linear Behaviour of Filled Elastomers and Thermoplastic Elastomers (Payne and Mullins Effects). DIDIER LONG, CNRS/Rhodia, SAMY MERABIA1, CNRS/Univ. Paris Sud, PAUL SOTTA, CNRS/Rhodia — We present a model regarding reinforcement properties of nano-structured polymers. Then, we show how it can be solved numerically by Dissipative Particles Dynamics. The model is based on the presence of glassy layers around the fillers. Strong reinforcement is obtained when these layers overlap. Key is the life-times distribution of these glassy bridges. The latter depend on polymer-filler interaction, the thermal–mechanical history, on the temperature, on the distance between fillers, and on the local stress in the material. Under applied strain, we show how the dynamics of yield and rebirth of glassy bridges account for the non-linear Payne and Mullins effects, which are a large drop of the elastic modulus at intermediate deformations, and a progressive recovery of the initial modulus when the samples are subsequently put at rest, respectively. These mechanisms account also for dissipative properties of filled elastomers. Our model opens the way for predicting mechanical behavior of nano-filled elastomers according to the filler structures and dispersion, polymer- filler interactions and temperature, in order to prepare systems with tailored properties.

12:51PM Q19.00009 Molecular Simulation of Highly Crosslinked Epoxy Resin and POSS-Epoxy Nanocomposites, PO-HAN LIN, RAJESH KHARE, Department of Chemical Engineering, Texas Tech University — Generation of atomistic model structures of crosslinked epoxy at realistic density is a challenging task. In this work, we present an efficient approach for generating such model structures with highly crosslinked matrices. The approach utilizes simulated annealing optimization technique for carrying out one-step polymerization of the reaction mixture in the simulation box. The structures so generated are relaxed using a combination of molecular mechanics and molecular dynamics (MD) simulations. The developed technique is computationally efficient and has been used for creating atomistic model structures of both crosslinked epoxy and a nanocomposite formed by the incorporation of the polyhedral oligomeric silsesquioxane (POSS) molecules in the crosslinked epoxy matrix. MD simulations were performed after the reaction mixture in the simulation box. The structures so generated are relaxed using a combination of molecular mechanics and molecular dynamics (MD) simulations. The hybrid model exhibits the desirable photolumincent properties of CdSe nanocrystals but does not fracture, as do thick electrochemically grown nanoparticle shells. The peculiar behavior of the vibrational modes in the hollow capsules is attributed to anisotropic dependence on overall size and layer thickness. The present investigation of the acoustical properties of the individual core-shell particles can lead to the use of such nanoscale engineered particles in more elaborate systems to control hypersonic phonons.

1:03PM Q19.00010 Reducing Strain in Electrophoretically Deposited Nanocrystal Films by Post-Deposition Incorporation of Polymers, THEODORE KRAMER, Department of Applied Physics and Applied Mathematics, Columbia University, STEFFEN JOCKUSCH, MICHAEL STEIGERWALD, NICHOLAS TURRO, Department of Chemistry, Columbia University, IRVING HERMAN, Department of Applied Physics and Applied Mathematics, Columbia University — We have made dense nanoparticle-polymer films and investigated their mechanical properties using nano-indentation and other methods. Electrophoretically deposited (EPD) films of cadmium selenide nanocrystals were infiltrated with network-forming monomers and subsequently exposed to UV radiation in the presence of photoinitiators to facilitate polymerization of the monomer. This hybrid hybrid model exhibits the desirable photolumincent properties of CdSe nanocrystals but does not fracture, as do thick electrochemically grown nanoparticle shells. The peculiar behavior of the vibrational modes in the hollow capsules is attributed to anisotropic dependence on overall size and layer thickness. The present investigation of the acoustical properties of the individual core-shell particles can lead to the use of such nanoscale engineered particles in more elaborate systems to control hypersonic phonons.

1:15PM Q19.00011 Mechanics of Nanoscale composite films from stress-electrical measurements: A nanoscale foam, CHIEU NGUYEN, VIVEK MAHESHWARI, RAVI SARAF, CHEMICAL ENGINEERING-UNIVERSITY OF NEBRASKA-LINCOLN TEAM — Nanometer thin (> 100nm) composite films consisting of polymers and organic-inorganic materials such as nanoparticles, quantum dots, nanotubes and dyes are widely researched for applications in designing a bio-mimetic cell membrane, solar cells, electronic and optical sensors, ion separation membranes and coatings. Being nanoscale in dimensions the mechanical properties of the film is critically governed by its morphology at nanoscale and the mutual interaction between the constituents of the film. The assembly process and the components of the film are detrimental in defining its morphology. A vast array of film morphologies is possible due to the multitude of combinations in processing and the components available to make the film. Sensors, ion separation membranes and coatings. Being nanoscale in dimensions the mechanical properties of the film is critically governed by its morphology at nanoscale and the mutual interaction between the constituents of the film. The assembly process and the components of the film are detrimental in defining its morphology. The study of mechanical properties of the film is hence important due their application in multitude of fields and correlating it to the nanoscale morphology and properties of its constituents. Here we present the stress-electrical measurements on a nanoscale (~100nm) nanocomposite film prepared using the well known spin assisted ionic self-assembly process. The film is a stack of nanoparticle layers, spaced by dielectric layer. Each dielectric layer consists of a stack of alternating anionic and cationic polyelectrolyte layers. The separation between the nanoparticle layers can be controlled with nanometer scale precision by modulating the number of polyelectrolyte layers in each dielectric layer.
1:27PM Q19.00012 Local dielectric permittivity profiles of sapphire/polypolypropylene interfaces, LIPING YU, V. RANJAN, M. BUONGIORNO NARDELLI, J. BERNHOLC, NC State U — Recently, the need for high-power-density capacitors has stimulated research to develop composite dielectric materials with high-k nanoparticles embedded in a polymer matrix. In these materials, surfaces and interfaces may play an important role in determining the overall dielectric properties. We present first-principles investigations of the dielectric permittivity profiles across slabs and interfaces of sapphire($\alpha$-Al$_2$O$_3$)/isotactic-polypropylene(IPP). Our results indicate that the permittivity profile at interface strongly depends on the nanoscale averaging procedure. We propose an averaging model that ensures near-locality of the dielectric function. We find that: (i) the dielectric permittivity approaches the corresponding bulk value just a few atomic layers away from the interface or surface; (ii) the dielectric constant is enhanced at the surfaces of the isolated $\alpha$-Al$_2$O$_3$ slabs, while no enhancement is observed at the IPP slab surfaces; and (iii) the dielectric transition at the $\alpha$Al$_2$O$_3$/IPP is mainly confined in the $\alpha$Al$_2$O$_3$ side.

1:39PM Q19.00013 Flow induced orientation behavior of concentrated dispersions of multi-wall carbon nanotube suspensions under shear flow: Effect of aspect ratio and concentration, SASWATI PUJARI, WESLEY BURGHARDT, University of Massachusetts-Amherst, SAMEER RAHATEKAR, JEFFREY GILMAN, National Institute of Standards and Technology, KRZYSZTOF KOZIOL, ALAN WINDLE, Cambridge University — We report studies of average orientation state of concentrated dispersions of multi-walled carbon nanotube (MWNTs) in steady shear flow. Uncured epoxy was used as a viscous, Newtonian suspending medium, and samples were prepared from ‘aligned’ MWNTs using methods previously reported (Rahatekar et al., J Rheol 40:599, 2006). Flow induced structural measurements were made in the vorticity (1-3) plane of simple shear flow using in-situ wide angle x-ray scattering techniques in a rotating disc shear cell. Azimuthally-dependent diffraction from the internal layered structure of the MWNTs was used to characterize alignment. Steady state anisotropy of MWNT dispersions decrease with increasing the length of the MWNTs. Surprisingly, the anisotropy is seen to increase with increasing concentration. For one of the samples, more detailed orientation dynamics are studied in steady shear and transient shear flow both in the 1-2 (flow gradient) and 1-3 (vorticity) planes of shear flow, and through comparison of wide-angle and small-angle scattering signatures of flow-induced nanotube alignment.

1:51PM Q19.00014 Polymorphism in electrospun poly(vinylidene fluoride)/nanoclay composite nanofibers, LEI YU, PEGGY CEBE, Tufts University — We investigated the morphology and polymorphism behavior of electrospun (ES) composite nanofibers of poly(vinylidene fluoride) (PVDF) with two nanoclays: Lucentite$^{TM}$ STN and SWN. Lucentite$^{TM}$ STN and SWN synthetic nanoclays are based on hectrite structure, but only STN contains an organic modifier between the hectrite layers. The PVDF was dissolved, and nanoclay was dispersed, in N,N-dimethylformamide/acetone and then electrospun into nanofibers with diameters ranging from 100∼1000 nm. The nano-assembly content ranged from 0.2% to 10%. The addition of STN can greatly decrease the number of beads and makes the diameter of the ES nanofibers more uniform due to an increase of solution conductivity. From wide angle X-ray scattering and Fourier transform infrared spectroscopy, we found both STN and SWN can induce more beta phase PVDF.

2:03PM Q19.00015 Polymer/inorganic nanocomposites with prescribed morphologies, E. MANIAS, M.J. HEIDECCKER, J. ZHANG, G. POLIZOS, Materials Sci & Eng, Penn State U — Despite the proliferation of polymer/inorganic nanocomposites in academic research and the commercialization of tens of products based on such materials, their true potential still remains largely untapped. One of the major hurdles in this endeavor is to capitalize on the novel properties afforded by a true--nanophase morphology. Since these are beyond simple nanoparticulate dispersions and towards prescribed filler/phase arrangements and tailored filler--polymer interfaces. We comparatively present nanocomposites with prescribed nanostructures, which can be made in large, industrial-scale, quantities (e.g. composites with spatially arranged fillers: such as shear-aligned fillers in blown PE films and filler-induced compatibilization of PC/PET blends). We discuss the fundamental mechanisms of achieving the prescribed nanostructures and the related novel functionalities. In particular, we emphasize on extraordinary properties achieved by simultaneous control of the composite morphology and of the polymer--filler interface, such as an impressive toughening effect in PC/PET nanocomposites, and PE nanocomposites with a predetermined tensile strength by tailoring the polymer--filler interfacial adhesion.

Papers in session Q19.00012-015 have been collected and published as a special issue of Polymer in the Journal of Energy Storage. The issue is available for purchase from the American Chemical Society.

Wednesday, March 18, 2009 11:15AM - 2:15PM –
Session Q20 DPOLY: Thin Films and Adhesion I

11:15AM Q20.00001 Capillary wrinkling of a floating sheet under differential surface tension, JIANGSHUI HUANG, Department of Physics & Department of Polymer Science and Engineering, University of Massachusetts-Amherst, WIM H. DE JEU, Department of Polymer Science and Engineering, University of Massachusetts-Amherst, NARAYANAN MENON, Department of Physics, University of Massachusetts-Amherst, THOMAS P. RUSSELL, Department of Polymer Science and Engineering, University of Massachusetts-Amherst — We have previously studied the wrinkling of a thin polymer film floating on the surface of water under the capillary force exerted by a drop of water placed on its surface. Here, the same surface tension both sets the radial stress in the unperturbed film as well as the source of the perturbation that leads to the wrinkling instability. We now report the effect on the wrinkling instability of a differential surface tension by using fluids with different surface tensions for the liquid the film is floating on and the drop put on the film. We use both surfactants and a variety of pure liquids to control the surface tension of water. When the base radial stress of the filmed floating was decreased, the length of the wrinkles increased, but the number of wrinkles decreased.

11:27AM Q20.00002 Effect of Long-chain Branching on Surface Dynamics of Polymer Films, MARK D. FOSTER, SHIH-FAN WANG, JAE SIK LEE, SÉWÔO YANG, Dept. of Polymer Science, The University of Akron, ZHANG JIANG, SURESH NARAYANAN, X-ray Science Division, Argonne National Lab, DAVID WU, Colorado School of Mines — Thermally stimulated fluctuations of the surface of films of branched polystyrene chains have been studied using x-ray photon correlation spectroscopy (XPCS), a recently-developed technique that has already been applied to study the surfaces of melts of linear polystyrene chains. Surface relaxations of films of branched chains are faster than are those of films of linear analogs. However, the Tg’s of the branched molecules are also lower. The variation in surface relaxation time as a function of scattering vector can be described well by a continuum hydrodynamic theory of thermally stimulated capillary waves with a no-slip boundary condition. However, the film viscosities inferred from fits of the theory to the data differ markedly from viscosities from bulk measurements. Acknowledgements: NSF support (CBET 0730692)
12:03PM Q20.00005 Dimension-Dependent Mechanical Properties of Pure and Antiplasticized Polymer Nanostructures, SEAN DELCAMBRE, ROBERT RIGGLEMAN, JUAN DE PABLO, PAUL NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin - Madison — Dense arrays of poly(methyl methacrylate) (PMMA) grating nanostructures 80 nm to 120 nm in pitch were fabricated by electron-beam and extreme ultraviolet interferometric lithography. During development and rinse drying, the nanostructures are subjected to capillary forces that are defined by the rinse fluid properties and spacing between adjacent structures. The applied capillary forces and structure aspect ratios were varied experimentally to induce structure collapse. By coupling nanostructure collapse data with continuum cantilever beam bending models, mechanical properties such as the elastic modulus and yield stress are determined. The elastic moduli of PMMA structures at this scale are observed to decrease with structure width. This behavior is counteracted by the addition of a low molecular weight diluent, tris(2-chloropropyl) phosphate (TCPP). At concentrations up to 5 wt%, TCPP acts as an antiplasticizing agent, decreasing the glass transition temperature while simultaneously increasing the elastic modulus. For a given applied capillary force, nanostructures containing 5 wt% TCPP are observed to remain stable at aspect ratios up to 20% higher than the pure material.

12:15PM Q20.00006 The stiffening of ultrathin polymer films in the rubbery regime – the relative contributions of bending, membrane stress and surface tension, PAUL O’CONNELL, GREGORY MCKENNA, Texas Tech University — A novel nano-bubble inflation technique has been developed which allows the determination of the absolute creep compliance of ultrathin polymer films as thin as 9 nm. Previous results have shown that the degree of reduction in Tg with film thickness is not universal, with PVAc showing no change in Tg down to 23nm while PS shows a significant reduction at thicknesses below approximately 80nm. Interestingly the rubbery compliance of ultrathin polymer films as thin as 9 nm. Previous results have shown that the degree of reduction in Tg with film thickness is not universal, with PVAc showing no change in Tg down to 23nm while PS shows a significant reduction at thicknesses below approximately 80nm. Interestingly the rubbery

12:27PM Q20.00007 Molecular confinement and residual stress in ultrathin polymer films, ARNOLD YANG, National Tsing Hua University, GUNTER REITER, University of Freiburg, Germany, YI-HSIN CHANG, YI CHIEN, National Tsing Hua University — The residual stress operative in thin films of a polymer (polystyrene) prepared by spin coating was determined from local elastic stress release induced by pinhole nucleation during dewetting instability. The measured stress was orders of magnitude greater than the capillary force and attributed to chain recoiling of the confined macromolecules. The entropy-driven stress was found to be small for thicker films but increase dramatically as film thickness became less than the unperturbed molecular dimensions. The chain conformations in these films can only be described by the Langevin, rather than Gaussian, statistic and the draw ratio was determined to be around 5, comparable to that in craze fibrils, for film thickness of 4 nm. The effects of spin speed, aging-induced relaxation, and molecular packing were investigated. The molecular processes during spin coating were proposed. In addition, conjugated polymers when squeezed into the molecular thicknesses were found to emit light with much enhanced efficiencies due to the large molecular deformation.

12:39PM Q20.00008 Semifluorinated Polymers Confined at the Solid-Air Interface, UMESH SHRESTHA, Clemson University, STEPHEN CLARSON, University of Cincinnati, DVORA PERAHA, Clemson University — Effective responsive layers should exhibit stability while retaining a dynamic mode that will allow reaction of the interface to external stimuli. Semifluorinated polymers have a potential for forming energy controlled responsive interfaces. Because of the high segregation between the fluorinated and protonated segments, well defined structures are induced at relatively short chains, retaining the capability to rearrange on short time scales. Fluorinated segments affect the interfacial energies as well as enhance thermal stability and controls the refractive index and dielectric properties. The present study investigates the interfacial response of poly trifluoro propylmethyl siloxane-polystyrene diblock copolymer (PTFPMPS-PS) at volume fractions varying from 0.003 to 0.5 of fluorinated block, at the interface of oxidized silicon wafers. In all volume fractions we found that the air interface is fluorine rich and the solid surface in proton rich. Layering is detected across the films for all volume fractions. Upon annealing the layering is retained, however the interfacial compositions change.
Spatially Organized Polymer Films Prepared by Oblique Angle Polymerization.

11:15AM Q21.00001 High-Resolution Spectroscopy with a Free-Electron Laser: Vibrational Lifetimes of Hydrogen-related Defects in Silicon1,2, GUNTER LUEPKKE, College of William and Mary — Gunter Luempke, Department of Applied Science, The College of William and Mary, Williamsburg, VA 23187 Vibrational lifetimes of hydrogen- and deuterium-related bonding and stretching modes in crystalline silicon are measured by high-resolution infrared absorption spectroscopy and pump-probe transient bleaching technique using the Jefferson Lab. Free-Electron Laser. We find that the vibrational lifetimes of the bending modes follow a universal frequency-gap law, i.e., the decay time increases exponentially with increasing decay order, with values ranging from 1 ps for a one-phonon process to 265 ps for a four-phonon process. The temperature dependence of the lifetimes shows that the bending mode decays by lowest-order multi-phonon process. In contrast, the lifetimes of the stretching modes are found to be extremely dependent on the defect structure, ranging from 2 to 295 ps. Against conventional wisdom, we find that lifetimes of Si-D stretch modes typically are longer than for the corresponding Si-H modes. Our results provide new insights into vibrational decay and the giant isotope effect of hydrogen in semiconductor systems. The potential implications of the results on the physics of electronic device degradation are discussed.

11:51AM Q21.00002 First-Principles Calculation of Carrier Lifetimes in Semiconductors1,2, VINCENZO LORDI, PAUL ERHART, DANIEL ABERG, Lawrence Livermore National Lab, Livermore, CA — We have developed first-principles methods based on density functional theory to calculate carrier lifetimes in semiconductors related to trapping on deep-level defects. Lifetimes are determined based on Schottky–Read–Hall theory, using recombination rates calculated from first principles for several competing mechanisms: radiative recombination, phonon-assisted (nonradiative) recombination, and Auger recombination. The recombination rates are calculated within a fully first-principles framework with no empirical parameters. We have recently applied these methods to study the role of native and impurity defects in reducing carrier lifetimes in bulk single-crystal aluminum antimonide (AlSb) and cadmium telluride (CdTe), two promising materials for high-resolution room-temperature gamma radiation detection.

12:03PM Q21.00003 Fully ab initio supercell corrections for charged defects, CHRISTOPH FREYSOLDT, JÖRG NEUGEBAUER, Max-Planck-Institut for Iron Research, Duesseldorf, Germany, CHRIS G. VAN DE WALLE, Materials Department, University of California Santa Barbara — Charged point defects govern the carrier densities in semiconductors and are crucial for the performance of electronic devices. However, quantifying the thermodynamical, chemical, and electrical properties of such defects is a challenge to both experiment and theory. In ab-initio calculations, the defect is usually modeled in a periodic supercell with a few dozen to a few hundred atoms. Unfortunately, this introduces artificial electrostatic interactions between charged defects. A number of correction schemes such as Makov-Payne corrections, potential alignment, scaling laws, or Coulomb truncation, are available in the literature, but they often fail to remove the supercell dependence completely. The assumptions behind these schemes are sometimes unclear and all schemes lack a stringent theoretical foundation. From a formal analysis within linear-response theory, we propose a new and simple scheme that combines the strengths of Makov-Payne corrections and potential alignment. Our scheme requires no empirical parameters or fitting procedures. Its reliability is demonstrated even in extreme cases.

12:15PM Q21.00004 Optimal Silicon for Photovoltaic Applications, GEORGY SAMSONIDZE, MARVIN L. COHEN, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — A small overlap of the silicon optical absorption spectrum with the solar emission spectrum limits the efficiency of silicon-based solar cells. We conduct a theoretical search for substitutionally doped silicon with the aim to maximize the spectral overlap. Different dopant species at various concentrations compatible with the existing silicon technology are examined in the virtual crystal approximation using the empirical pseudopotential method. The optimal doping configurations found are further investigated with a first-principles many-electron Green’s function approach. The optical absorption spectrum of the doped silicon is calculated by solving the Bethe-Salpeter equation which includes excitonic effects. This work was supported by National Science Foundation Grant No. DMR07-05941, and by the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by NSF through TeraGrid resources at Indiana University and TACC.

12:27PM Q21.00005 Microprobe X-ray Absorption Spectroscopy of Chalcogen Doped Silicon, BONNA NEWMAN, JOE SULLIVAN, Massachusetts Institute of Technology, MARK WINKLER, MENG-JU SHER, Harvard University, MATTHEW MARCUS, Advanced Light Source, Lawrence Berkeley National Lab, MATTHEW SMITH, SILVIJA GRADEC, Massachusetts Institute of Technology, ERIC MAZUR, Harvard University, TONIO BUNASSISI, Massachusetts Institute of Technology — Doping Si with chalcogen atoms (S, Se, and Te) in excess of the solubility limit has been shown to result in optical absorption below the bandgap. This material, known as “black silicon”, is promising for infrared photon detectors and possibly photovoltaic devices. We report on the relationship between the chemical state of the dopant atoms and infrared absorption properties. A high concentration of 10^20 dopant atoms/cm^3 in the near-surface layer allows for extended X-ray absorption fine structure (EXAFS) investigations and determination of chemical state. We combine these results with absorption measurements and Auger spectroscopy to understand the correlations between optical and structural properties of chalcogen doped Si.

12:39PM Q21.00006 Hydrogen in multi-crystalline Si used for the fabrication of solar cells1,2, CHAO PENG, MICHAEL STAVOLA, W. BEALL FOWLER, Lehigh University, LODI CARNEL, REC Scanwafer AS — The multicrystalline Si materials that are used by industry to fabricate solar cells often contain a high concentration of carbon impurities. Furthermore, hydrogen is also commonly introduced during processing to improve solar-cell performance.1,2 At present, the H- and C-related defect reactions that occur and what their effect might be remain poorly understood. We have performed a series of experiments in which IR spectroscopy has been used to study a family of defect complexes that are formed when H is trapped by substitutional carbon impurities in multi-crystalline Si. The structures, concentrations, and thermal stabilities of these defects have been investigated.

1Supported by NSF grant DMR 0802278 and the Silicon Solar Consortium.

12:51PM Q21.00007 Effect of copassivation of Cl and Cu on CdTe grain boundaries, LINXIN ZHANG, JUAREZ L.F. DA SILVA, National Renewable Energy Laboratory, JINGBO LI, Institute of Semiconductors, CAS, Beijing, China, YANFA YAN, T.A. GESSERT, SU-HUAI WEI, National Renewable Energy Laboratory — Grain boundaries (GBs) and dislocations are generally viewed as detrimental to device applications, because they usually contain a high density of deep defect levels that act as recombination centers for charge carriers. Surprisingly, two leading polycrystalline thin-film solar cells based on CuInSe2 (CIS) and CdTe have produced very high efficiencies of 20% and 16.5%, respectively, despite that these materials contain significant amounts of GBs. Using a first-principles method, we investigate the structural and electronic properties of GBs in polycrystalline CdTe and the effects of copassivation of elements with far distinct electronegativities. Of the two types of GBs studied in this work, we find that the Cd core is less harmful to the carrier transport, but is difficult to passivate with impurities such as Cl and Cu, whereas the Te core creates a high defect density below the conduction band minimum, but all these levels can be removed by copassivation of Cl and Cu. Our analysis indicates that for most polycrystalline systems copassivation or multipassivation is required to passivate the GBs.
1:03PM Q21.00008 Influence of Crystalline Defects in GaN-InGaN Solar Cells, BALAKRISHNAM JAMPANA, NIKOLAI FALEV, University of Delaware, IAN FERGUSON, Georgia Tech, ROBERT OPILA, University of Delaware, CHRISTIANA HONSBERG, Arizona State University — Crystalline defects originating from lattice-mismatch in epitaxial materials appear to be the dominant factor reducing high efficiency solar cell performance. In this paper we present an explanation of the observed structural and optical characteristics originating in lattice-mismatched III-nitride epilayer materials. This model is based on creation, diffusion, accumulation and structural transformation of point defects to extended crystalline defects. In this work InGaN photovoltaic structures are grown by MOCVD on GaN templates with thicknesses in the 50 to 400nm range. The types and spatial distribution of crystalline defects are determined from XRD rocking curves and reciprocal space maps. The crystalline quality is observed to deteriorate with increasing thickness and growth rate. Wide band gap InGaN based solar cells require 150 to 400nm of active layer thicknesses and crystalline defects are observed in this thickness range degrading the solar cell performance. A physical model correlating the response of the solar cell to the type and spatial distribution of the defects will be presented. The work will aid improve the crystalline quality of InGaN for application as high efficiency solar cells.

1:15PM Q21.00009 Scanning Probe Spectroscopy of Individual Dopants in Silicon, MOREWELL GASSELLER, MATTY CAMAX, ROGER LOO, SVEN ROGGE, STUART TESSMER — A key goal of semiconductor electronics is to develop devices based on manipulation of the charge and spin of individual dopant atoms. Elucidating the quantum structure of these minute systems is a difficult technical challenge. Here we present capacitance-based scanned-probe measurements that both spatially-resolve individual subsurface boron dopants in silicon and detect spectroscopically single holes entering the Bi + state of these atoms. We observe that, on average, acceptors with a closer nearest neighbor exhibit stronger binding. This finding is consistent with the interpretation of resonant tunneling measurements performed on a similar sample.

1:27PM Q22.00010 Vacancy-related defects and the E'Δ center in amorphous silicon dioxide, BLAIR TUTTLE, Penn State Erie, SOKRATES PANTELIDES, Vanderbilt University — The microscopic identification of vacancy-related defects in silicon dioxide has been a major challenge. Particularly in amorphous silica, the role of vacancy clusters is still controversial. Experimental data have led to suggestions that the E' center might be a four-vacancy cluster instead of a single vacancy. Here we report density functional calculations of single vacancies and clusters of four vacancies in realistic models of amorphous silica. Results for single vacancies compare well to previous theory. A key result for four-vacancy clusters is that relaxations localize the unpaired electron preferentially on one Si atom, resulting in a strongly anisotropic electron-paramagnetic-resonance signal. Atoms in single vacancies have a more benign anisotropy which is more compatible with the observed isotropic signal. This work was supported by the Air Force Office of Scientific Research under a MURI grant (FA9550-05-1-0306) and by the US Navy.

1:39PM Q21.00011 Enhanced defect generation in gate oxides of p-channel MOS transistors in a moisture ambient, ARITRA DASGUPTA, S.A. FRANCIS, D.M. FLEETWOOD, Department of Electrical Engineering and Computer Science, Vanderbilt University — Transistors and ICs built in Sandia’s 4/3 μm technology were exposed to moisture, irradiated, and annealed. The moisture exposures were performed using highly accelerated stress test (HAST) at 130°C and 85% relative humidity. Irradiation of n-channel transistors exposed to HAST followed by a long-term anneal resulted in some increase in interface-trap and oxide-trapped charge buildup. We observed enhanced post-irradiation defect generation of oxide trapped charge, interface traps and border traps in the gate oxides of p-channel MOS transistors that were exposed to humidity. This is characterized by enhanced voltage shifts due to oxide trapped charge and interface traps observed in the p-channel transistors. Low frequency noise measurements also showed enhanced low frequency noise power in moisture exposed p-channel transistors. Our results indicate that there are enhanced precursor hole trap defects or oxygen vacancies present in the gate oxide of p-channel transistors as a result of presence of moisture or hydrogen ambient. The smaller voltage shifts in the n-channel transistors may be related to the presence of phosphorus atoms in the gate oxides.

1:51PM Q21.00012 Carbon clusters as possible defects at the SiC-SiO2 interface, YINGDI LIU, HONGLI DANG, YANG LIU, YING LI, University of Tulsa, MATTHEW CHISHOLM, Oak Ridge National Laboratory, TRINITY BIGGERSTAFF, North Carolina State University, GERD DUSCHER, University of Tennessee, Knoxville, SANWU WANG, University of Tulsa — High state densities in the band gap of the SiC-SiO2 interface significantly reduce the channel mobilities in SiC-based high-temperature/high-power microelectronics. Investigations of the nature of the interface defects are thus of great importance. While several possible defects including very small carbon clusters with up to four carbon atoms have been identified as first-principal theory, larger carbon clusters as possible defects have attracted less attention. Here, we report first-principles quantum-mechanical calculations for two larger carbon clusters, the C12 ring and the C20 fullerene, on the SiC-SiO2 interface. We find that both carbon clusters introduce significant states in the band gap. The states extend over the entire band gap with higher densities in the upper half of the gap, thus accounting for some of the interface trap densities observed experimentally.

2:03PM Q21.00013 First-principles study of local (p×2×2) structures on Si(100) surface, MIN-KOOK KIM, HYOONG JUON CHOI, Department of Physics and IPAP, Yonsei University — We study structural defects inducing local (p×2×2) structures in c(4\times8)-reconstructed Si(100) surface, using an ab-initio pseudopotential density functional method. The local density approximation to the density functional theory is used and electronic wavefunctions are expanded with pseudo-atomic orbitals. The atomic structures of defects are optimized by minimizing the total energy. Our calculations show that the defects increase the total energy of the system but they are energetically stable with energy barrier. STM images for occupied and unoccupied states are simulated to investigate the surface electronic structures. Effects of electron doping and external electric field on the defects are also studied. This work was supported by the KRF (KRF-2007-314-C00075) and by the KOSEF Grant No. R01-2007-000- 20922-0. Computational resources have been provided by KISTI Supercomputing Center (KSC-2008-S02-0004).

Wednesday, March 18, 2009 11:15AM - 2:15PM –
Session Q22 GMAG DMP FIAP:
Focus Session: Spins in Quantum Dots and Mn in Arsenides

11:15AM Q22.00001 Intershell Exchange and Sequential Electrically Injected Spin Populations of InAs Quantum-Dot Shell States, GEORGE KIOSEOGLOU, Naval Research Laboratory and University of Crete — Quantum dots (QDs) are attractive for a variety of spintronic applications. Their electronic structure exhibits the s, p, d, f shells characteristic of atoms. We report electrical injection of spin-polarized electrons from Fe contacts into the individual shells of highly uniform self-assembled InAs QDs, and we determine the s-p and p-d intershell exchange using circular polarization of the electroluminescence (EL) spectra. This work was supported by the NSF (CMS-0645953), by the Oak Ridge Associated Universities, by the National Center for Supercomputing Applications (TG-DMRO080005N), and by the National Center for Computational Sciences at Oak Ridge National Laboratory.

12:03PM Q22.00003 Mn doping of InAs quantum dots studied by X-STM. , PAUL KOENRAAD, MURAT BOZKURT, JENS GARLEFF, Eindhoven University of Technology, VICKY GRANT, RICHARD CAMPION, TOM FOXON, University of Nottingham, EUCLYDES MAREGA, University of San Carlos, GREG SOLOMON, University of Arkansas — We report on the X-STM analysis of Mn doped quantum dots. The X-STM technique allows one to tune the temperature with a given temporal contrast to build an image of the spin thermopower coefficient in a junction as large as the Seebeck coefficient, resulting in a large spin figure of merit. In addition, it demonstrates that the junction can be tuned to supply only spin current but no charge current. We also discuss experimental systems where our predictions can be verified.

1This work is supported by the DOE.

12:15PM Q22.00004 Thermo-spin effects in quantum dots connected to ferromagnetic leads

YONATAN DUBI, MASSIMILIANO DI VENTRA, University of California - San Diego — We study a system composed of a quantum dot in contact with ferromagnetic leads held at different temperatures, which we suggest can be used as a source of spin-voltage. Spin analogs to the thermoelectric and thermoelectric figure of merit of metallic systems are studied, and we show how to make a more precise measurement of the spin thermopower coefficient in a junction as large as the Seebeck coefficient, resulting in a large spin figure of merit. In addition, it demonstrates that the junction can be tuned to supply only spin current but no charge current. We also discuss experimental systems where our predictions can be verified.

12:27PM Q22.00005 Tunnel magnetoresistance in mesoscale (Ga,Mn)As magnetic tunnel junctions. , PARTHA MITRA, MARK J. WILSON, MENG ZHU, PETER SCHIFFER, NITIN SAMARTH, Dept. of Physics, Penn State University, University Park PA 16802, KIRAN V. THADANI, DAN C. RALPH, Dept. of Physics, Cornell University, Ithaca NY 14853 — We recently demonstrated exchange-biased magnetic tunnel junctions (MTJs) built from the ferromagnetic semiconductor (Ga,Mn)As [Phys. Rev. B. 78, 195307 (2008)]. Here, we report measurements of the tunnel magnetoresistance (TMR) in mesoscale (Ga,Mn)As MTJ devices with areas that range from ~1 to 100 μm², mapping out the TMR as a function of the magnetic field vector and the sample temperature. The vector field measurements provide insights into the interplay between the magnetic anisotropies of (Ga,Mn)As. In contrast to our earlier studies large area devices, we find that the TMR in these mesoscale devices increases exponentially with decreasing temperature, with a form exp(-T/T*). At temperatures lower than T*, the conductance-voltage characteristics show a strong dependence, suggesting the role of Coulomb interactions in the spin-dependent tunneling process in these small area MTJs. Work supported by the ONR MURI program.

12:39PM Q22.00006 Spectra broadening in Point-Contact Andreev Reflection Measurement on GaMnAs , SHANG-FAN LEE, T.W. CHIANG, Y.H. CHIU, S.Y. HUANG, Institute of Physics, Academia Sinica, Taipei, Taiwan, Republic of China, J.J. LIANG, Department of Physics, Fu Jen Catholic University, Taipei, Taiwan, Republic of China, H. JAFFRES, J.M. GEORGE, Unite Mixte de Physique CNRS/Thales and Universite Paris-Sud, Orsay, France, A. LEMAITRE, Laboratoire de Photonique et de Nanostructure, CNRS, Marcoussis, France — Point-Contact Andreev Reflection (PCAR) technique has been considered as a reliable method for determining electron spin polarization of novel metallic ferromagnets. For dilute magnetic semiconductors, this is less applicable due to the resistive nature of the material. We investigate PCAR spectra of GaAs/MnAs systems using Pb tips. The observed spectrum exhibits behaviors described in the Modified Blonder-Tinkham-Klapwijk (MBTK) model but with a significant spectrum broadening. Modified BTK theory is commonly applied to analyze PCAR spectra with electron polarization, superconducting energy gap, and interface transparency as parameters. We present an analysis based on the introduction of spreading resistance and the inelastic scattering at the interface. In as-grown and annealed samples, we extract spin polarization of 76%/74% from our analysis, both smaller than the value obtained from approach of effective temperature, 90%/82%.

12:51PM Q22.00007 Ultrafast Photoinduced Coherent Spin Dynamics in Ferromagnetic Ga₀.₉₋ₓMnₓAs/GaAs Structure

JINGBO QI, YING XU, ANDREW STEIGERWALD, NORMAN TOLK, Vanderbilt University, XINYU LIU, JACEK FURDYNA, University of Notre Dame, ILIAS PERAKIS, University of Crete — Ultrafast pump-probe magneto-optical spectroscopy is used to study coherent spin dynamics in the ferromagnetic semiconductor Ga₀.₉₋ₓMnₓAs systems. Above GaAs bandgap E_g, the temporal Kerr signal is found to be strongly dependent on pump photon polarization. This polarization dependence is attributed to spins of electrons photoexcited to the conduction band, and disappears for E_p< E_g. Below the Curie temperature T_C of the Ga₀.₉₋ₓMnₓAs samples, the temporal Kerr rotation acquires an additional oscillatory component, attributed to the precession of the ferromagnetically-coupled Mn spins. This precession is observed for excitation above and below E_g, regardless of the pump polarization states. The detailed characteristics of this ferromagnetic precession are discussed in terms of the Landau-Lifshitz-Gilbert (LLG) model.

3This work was supported by DOE through Grant DE-FG02-99ER45781 (Vanderbilt), NSF under Grant DMR06-03752 (Notre Dame), and by EU STREP program HYSWITCH (Crete).

1:03PM Q22.00008 Temperature Dependence of Anomalous Hall Effect in Metallic (Ga,Mn)As films

XINYU LIU, ZHIQI GE, SHAOPING SHEN, MARGARET DOBROWOLSKA, JACEK FURDYNA, Department of Physics, University of Notre Dame, Notre Dame, IN 46556 — We present a systematic study of the temperature dependence of anomalous Hall effect (AHE) in metallic (Ga,Mn)As films. The Hall effect in (Ga,Mn)As is described as ρ_yx = R_0 + cρ_x M_x, where R_0 (1/μ) is the ordinary Hall coefficient, ρ_x and ρ_y are the transverse and longitudinal resistivities, and c is a scaling parameter. In this work we have developed a self-consistent method to determine R_0, c and n simultaneously. We use this method to analyze the Hall and resistivity data measured up to B = 6 T at various temperatures. We find that for the metallic samples, a distinct evolution of the AHE occurs as temperature increases, as evidenced by the temperature dependence of the parameter c. We propose that the correlation between the AHE and the resistivity should be reconsidered by using a two-component model in order to separate contributions due to different scattering mechanisms.
Antiferromagnetic interlayer exchange coupling in Ga$_{1-x}$Mn$_x$As/GaAs diluted ferromagnetic semiconductor multilayers. JAE-HO CHUNG, S.J. CHUNG, SANGHOON LEE, Korea University, B.J. KIRBY, J.A. BORCHERS, NIST Center for Neutron Research, Y.J. CHO, X. LIU, J.K. FURDYNA, University of Notre Dame — We use neutron reflectometry to investigate the interlayer exchange coupling between Ga$_{0.97}$Mn$_{0.03}$As ferromagnetic semiconductor layers separated by non-magnetic Be-doped GaAs spacers. Polarized neutron reflectivity measured below the Curie temperature of Ga$_{0.97}$Mn$_{0.03}$As reveals a characteristic splitting at the wave vector corresponding to twice the multilayer period, indicating that the coupling between the ferromagnetic layers is antiferromagnetic (AFM). When the applied field is increased to above the saturation field, this AFM coupling is suppressed. This behavior is not observed when the spacers are undoped, suggesting that the observed AFM coupling is mediated by charge carriers introduced via Be doping. The behavior of magnetization of the multilayers measured by DC magnetometry is consistent with the neutron reflectometry results.

Engineering the interlayer exchange coupling in hybrid ferromagnetic metal/semiconductor heterostructures. MARK J. WILSON, MENG ZHU, PETER SCHIFFER, NITIN SAMARTH, Dept. of Physics, Penn State University, University Park PA 16802, ROBERTO C. MYERS, DAVID D. AWSCHALOM, Dept. of Physics, University of California, Santa Barbara, CA 93106, MICHAEL E. FLATTE, Dept. of Physics, University of Iowa, Iowa City, IA 52242 — The systematic study of the exchange coupling in ferromagnetic semiconductor heterostructures is important for developing proof-of-concept spin transfer semiconductor devices. We recently demonstrated interlayer exchange coupling between a ferromagnetic semiconductor (Ga$_{1-x}$Mn$_x$As) and a ferromagnetic metal (MnAs) [APL 91, 192503 (2007)]. Here, we report a comprehensive magnetochemistry study of the underlying exchange coupling in this hybrid system. We vary key parameters such as the thicknesses of both the ferromagnetic layers and the composition of the Ga$_{1-x}$Mn$_x$As layer, and examine our observations using an “exchange spring” model. We also demonstrate the propagation of the exchange coupling through a non-magnetic spacer layer (p-doped GaAs) and examine the variation of this coupling as a function of the spacer layer thickness and doping. Work supported by the ONR MURI program and by NSF.

Solubility control in dilute magnetic semiconductors by using the co-doping method. KAZUNORI SATO, HITOSHI FUJII, ISIR, Osaka University, LARS BERGGVIST, PETER H. DEDERICHS, IFF, FZ-Juelich, HIROSHI KATAYAMA-YOSHIDA, Osaka University — To overcome low solubility limit of magnetic impurities in dilute magnetic semiconductors (DMS) and realize room temperature ferromagnetism, we propose a co-doping method to increase solubility of magnetic impurities in DMS [1]. We calculate electronic structure of (Ga, Mn)As, (Ga, Mn)N, (Ga, Cr)N and (Zn, Cr)Te with interstitial impurities, such as Li, Na and Cu, from first-principles by using the Korringa-Kohn-Rostoker coherent potential approximation (KKR-CPA) method. From the total energy results, it is shown that the mixing energy of magnetic impurity becomes negative and the solubility of magnetic impurities is strongly enhanced under the existence of interstitials [1]. In general, the co-dopants compensate hole carriers, thus the system becomes paramagnetic. However, owing to the large diffusivity of these interstitial impurities, we can anneal out the co-dopants after the crystal growth to recover the ferromagnetism. As an example, kinetic Monte Carlo simulations for the diffusion of interstitial co-dopants in DMS will be shown. [1] K. Sato et al., Jpn. J. Appl. Phys. 46 L1120 (2007)

Time Resolved Spectroscopy of InMnAs Using Differential Transmission Technique in Mid-Infrared Region. M. BHOWMICK, K. NONTAPOT, G.A. KHODAPARAST, Physics Department, Virginia Tech., B.W. WESSELS, Materials Research Center, Northwestern University — The emergence of III-Mn-V magnetic semiconductors, such as GaMnAs, InMnAs, and InMnSb has led to a number of exciting results relevant to the new field of spintronics. In contrast to earlier MBE work, InMnAs structures grown by MOVPE at the Northwestern University are room temperature ferromagnetic with a $T_C$ of 330 K. The origins of ferromagnetism and the interactions between itinerant carriers and localized spins in these structures are open and interesting questions. The samples are grown on GaAs substrates with the Mn content ranging from 0-1.4%. The carrier and spin life times in these structures are probed using a differential transmission technique by tuning the pump-probe radiation from 3-3.6 microns. The relaxation times are in order of 2-4 ps similar to the observations in the MBE grown structures. The temperature dependence of the carrier and spin lifetimes will be presented and related to recent models for spin recombination.

Wednesday, March 18, 2009 11:15AM - 2:15PM – Session Q23.00002 The quenching of scattering-enhanced tunneling in the Quantum Hall Regime. KASEY RUSSELL, FEDERICO CAPASSO, VENKATESH NARAYANAMURTI, Harvard University, HONG LU, JOSHUA ZIDE, ARTHUR GOSSARD, UC Santa Barbara — Using capacitance-voltage spectroscopy, we are able to probe the magnetic field dependence of the quasi-bound state lifetime of a quantum well. Our measurements are done on a special InGaAs/InAlAs heterostructure that is designed to promote scattering-enhanced tunneling out of the quantum well. The bound state lifetime shows large oscillations as the magnetic field is varied, which result from the quenching of electron scattering as the Fermi level crosses a Landau Level. The results are interpreted in terms of the edge states and cyclotron orbits of the Integer Quantum Hall Effect.
11:39AM Q23.00003 Microwave modes of a two-dimensional electron systems in the presence of a perpendicular magnetic anisotropy provided by a macroscopic ferromagnet. BRENDEN MAGILL, NHMFL and MARTECH, FSU, L. W. ENGEL, NHMFL/FSU, M. P. LILLY, J. A. SIMMONS, J. L. RENO, Sandia National Laboratory — We report on a resonance in the microwave absorption spectrum of a high mobility two dimensional electron system (2DES) in a spatially varying magnetic field from a ferromagnet placed near the sample. The ferromagnet, made of Dy, cylinder or plates, with a hole through it. Microwave transmission between contacts capacitively coupled to the 2DES near the hole or cylinder shows a resonant absorption peak $f_{pk}$ for holes and cylinders with varying radii, $r_m$, from 0.5 mm to 125 mm. The resonance absorption is present for a uniform external field $B_0$ less than 1 T and only for specific magnitization of the ferromagnet with respect to $B_0$ with $f_{pk}$ decreasing as either $B_0$ or $r_m$ increase. We will interpret the data in terms of plasma excitations similar to edge magnetoplasmons [1] confined along the magnetic field inhomogeneity by the large magnetic field gradients there. [1] See, for example, V. A. Volkov and S. A. Mikhailov, Sov. Phys.-JETP 67, 1639(1988).

11:51AM Q23.00004 Itinerant electron-driven chiral magnetic ordering and spontaneous quantum Hall effect in triangular lattice models. IVAR MARTIN, C.D. BATISTA, Theoretical Division, Los Alamos National Laboratory — We study the Kondo Lattice and the Hubbard models on a triangular lattice. We find that at the mean field level, these rotationally invariant models naturally support a non-coplanar chiral magnetic ordering. It appears as a weak-coupling instability at the band filling factor 3/4 due to the perfect nesting of the itinerant electron Fermi surface. This ordering is a triangular-lattice counterpart of the collinear Neel ordering that occurs on the half-filled square lattice. While the long-range magnetic ordering is destroyed by thermal fluctuations, the chirality can persist up to a finite temperature, causing a spontaneous quantum Hall effect in the absence of any externally applied magnetic field.

12:03PM Q23.00005 Comparative study of radiation-induced transport in Wegscheider’s and Umansky’s GaAs/AlGaAs material. 1, 2 R.G. MANI, Georgia State University, W. WEGSCHEIDER, Univ. of Regensburg, V. UMANSKY, Weizmann Inst. — Transport studies of GaAs/AlGaAs specimens have shown radiation-induced, periodic-in-the-inverse-magnetic-field, magnetoresistance oscillations that saturate into novel radiation-induced zero-resistance states (RIZRS) at the deepest oscillatory minima.[1] The origin of these RIZRS remains a topic for further experimental investigation, as does the dependence of these phenomena on the impurity configuration and the material quality. On the latter point, it remains to be understood if similar material prepared in different laboratories yield a similar response under the same conditions. In addressing this issue, we examine here the radiation-induced transport in GaAs/AlGaAs material prepared by W. Wegscheider and co-workers. In a previous study, Simovic et al.[2] have reported the observation of B-periodic radiation-induced oscillations and the strong suppression of the inverse-B periodic oscillations in Wegscheider’s GaAs/AlGaAs material. Here, we compare our experimental results to their study and also to our own previous results obtained on specimens prepared by V. Umansky and co-workers. 1) R. G. Mani, Appl. Phys. Lett., 91, 132103 (2007). 2) B. Simovic et al., Phys. Rev. B 71, 233303 (2005).

12:15PM Q23.00006 Transport measurements and simulations of GaAs/AlGaAs “anti-Hall-bar within a Hall bar” devices. ANNIKA KRIISA, Emory University, RAMESH G. MANI, Georgia State University — Hall effect measurements are often carried out in the Hall geometry, which is a thin rectangular plate with current and Hall voltage contacts at the external boundary. The motivation of this study is to further understand the impact on Hall effect when a hole is inserted inside Hall geometry. One way on conducting this investigation is to superimpose an “anti-Hall bar” inside the standard Hall bar, where the anti Hall bar is actually the hole inside the Hall device with contacts on the inside boundary of this hole. This configuration is thought to generate an ordinary Hall effect within the interior boundary such that the interior Hall voltage divided by the interior injected current equals the Hall resistance. One believes that it might also be possible to simultaneously realize multiple independent Hall effects by injecting multiple currents into the multiply connected device [1]. We have studied Hall effect in the doubly connected “anti-Hall bar within a Hall bar” geometry fabricated out of the GaAs/AlGaAs semiconductor system. Also the simulations of the distribution of the Hall current and potential profile within the specimen are conducted. To attain understanding of how the Hall effect arises in this geometry, the simulation plots are compared to the experimental results.

12:27PM Q23.00007 Effect of strain on nematic phases of two-dimensional hole gases. SUNANDA KODUVAYUR, LEONID ROKHINSON, Purdue University, MICHAEL MANFRA, Bell laboratories, Lucent Technologies — We study the effect of uniaxial strain on high Landau levels(LL). $N \geq 2$ (N is the LL index), in two dimensional hole gases(2DHG). The presence of anisotropic magnetotransport at certain half-integer filling factors in these systems has been understood as a signature of stripe or nematic phases. Recent studies on 2DHG in a perpendicular field have shown anisotropic transport at filling factors $\nu = 7/2$ and 11/2 accompanied by an isotropic 9/2 state. These results differ from those of 2D electrons where anisotropy is only observed for LLs with $N \geq 3$. While this difference has been attributed to stronger spin-orbit interactions in holes, the origin and conditions for the stabilization of these states are still open questions. We study samples fabricated in the Van der Pauw geometry from C-doped GaAs/AlGaAs 2DHG grown on (001) substrate. We apply uniaxial strain along [110] and study the transport properties in a perpendicular field at 10mK. We introduce nematic states earlier on for $2 \leq N \leq 7$ with large enough strain. Furthermore, we demonstrate reversal in direction of anisotropy at filling factors $\nu = 7/2$ and 5/2 with strain modulation. We also see a difference in strain response of the resistance along [110] and [110]. We try to understand the observed effects using an electrostatic model which incorporates the anisotropy of the elastic moduli of GaAs.

12:39PM Q23.00008 Dependence of Effective Mass on Spin and Valley Degrees of Freedom. MANSOUR SHAYEGAN, TAYFUN GOKMEN, MEDINI PADMANABHAN, Dept. of Electrical Engineering, Princeton University, Princeton, NJ 08544 — We measure the effective mass ($m^*$) of interacting two-dimensional electrons confined to an AlGaAs quantum well at a fixed density while we change the conduction-band valley occupation and the spin polarization via the application of strain and magnetic field, respectively [1]. Compared to its band value, $m^*$ is enhanced when the electrons are valley or spin unpolarized, and the largest enhancement is observed for the case where both spin and valley are unpolarized. Consistent with the study of M. Padmanabhan et al., in the fully spin- and valley-polarized regime, the measured $m^*$ is suppressed compared to the band value. Incidentally, in the fully spin- and valley-polarized regime, the electron system exhibits an insulating behavior. [1] T. Gokmen et al., Phys. Rev. Lett. 101, 146405 (2008). [2] M. Padmanabhan, et al., Phys. Rev. Lett. 101, 026402 (2008).

12:51PM Q23.00009 Anomalous Effective Mass of Two-dimensional Holes in a Strong Parallel Magnetic Field. YENTING CHIU, MEDINI PADMANABHAN, JAVAD SHABANI, MANSOUR SHAYEGAN, Department of Electrical Engineering, Princeton University, ROLAND WINKLER, Department of Physics, Northern Illinois University — We report effective hole mass ($m^*$) measurements through analyzing the temperature dependence of the Shubnikov-de Haas oscillations in dilute (density $\sim 5\times10^{10}$cm$^{-2}$) two-dimensional (2D) hole systems confined to a 20nm-wide, (311)A GaAs quantum well. In this system the 2D holes occupy two spin-subbands whose $m^*$ we measure to be $\sim 0.2$ (in units of free electron mass), in good agreement with the theoretical band calculations. We then apply a sufficiently strong ($>10T$) parallel magnetic field to fully depopulate one of the spin subbands, and measure $m^*$ for the populated subband. We find that this latter $m^*$ is close in magnitude to the $m^*$ we measure in the absence of the parallel field. This is a surprising observation as it is in stark disagreement with the results of our band calculations which take into account the spin-orbit interaction and the holes’ finite layer thickness, and predict a large enhancement of $m^*$ in a strong parallel magnetic field.
n=12 and was most sensitive at the filling fraction n=6.

We have also characterized the SET magnetometer by an ac technique where we applied 170 nT ac magnetic fields to monitor the conductance of the SET following a small change in magnetic field, we studied the equilibration processes in IQHLs. The equilibration times are found to be strongly dependent on the magnetic field and became unmeasurably long (many days) as we decreased T down to ~0.4 K and its downturn at lower temperatures, is in agreement with the theory. The values of the Fermi-liquid parameter obtained from the comparison agree with the corresponding values extracted from the analysis of Shubnikov–de Haas oscillations based on the theory of magneto-oscillations in interacting 2D systems [4].

Supported by the BSF grant No. 2006201

### 2:03PM Q23.00010 Quantum Hall Effect and Field Dependent Valley Splitting on High Mobility Silicon-(111) Surfaces

TOMASZ M. KOTT, ROBERT N. McFARLAND, LUYAN SUN, BRUCE E. KANE, Laboratory for Physical Sciences, University of Maryland, College Park, KEVIN ENG, Sandia National Laboratories — We have developed a method for fabricating field effect transistors, using vacuum as the dielectric, in order to study electron transport on a clean, flat, chemically prepared hydrogen-terminated surface. Resulting devices display high mobilities (100,000 cm²/V s at 70 mK), enabling us to probe field dependent transport dynamics of this six-fold valley degenerate surface. We will present evidence that a low oxygen environment during sample preparation is necessary to achieve high mobilities. To support the correlations between surface chemistry and electronic properties, we will show AFM images of the surface for various preparation techniques. Finally, we will describe high field magneto-transport measurements (up to 12 T) indicate field-dependent valley splitting. In particular, we find easily resolvable filling factors of, amongst others, 3, 5, and 7, an indication that the six-fold degeneracy is possibly broken by many-body effects. I will also show preliminary data with hints of the FQHE at ν = 3/2.

### 1:15PM Q23.00011 Interaction Effects in Conductors of a Two-Valley Electron System in High-Mobility Si Inversion Layers

NIKOLAI N. KLIMOV, Rutgers University, DMITRY A. KNYAZEV, OLEG E. OMEL’YANOVSKI, VLADIMIR M. PUDALOV, Lebedev Physical Institute, HARRY KOJIMA, MICHAEL E. GERSHENSON, Rutgers University — We have measured the conductivity of high-mobility (100) Si metal-oxide-semiconductor field-effect transistors over wide ranges of electron densities n = (1.8−15) × 10¹¹ cm⁻², temperatures T = 30 mK−4.2 K, and in-plane magnetic fields Bₚ = 0−5 T [1]. The experimental data have been analyzed using the theory of interaction effects [2] in the conductivity of disordered two-dimensional (2D) systems. The parameters essential for comparison with the theory, such as the intervalley scattering time and valley splitting, have been measured or evaluated in independent experiments [1,3]. The observed behavior of σ, including its quasi-linear increase with decreasing T down to ~0.4 K and its downturn at lower temperatures, is in agreement with the theory. The values of the Fermi-liquid parameter obtained from the comparison agree with the corresponding values extracted from the analysis of Shubnikov–de Haas oscillations based on the theory of magneto-oscillations in interacting 2D systems [4].

### 1:27PM Q23.00012 2DEG effect on vibration of piezoelectric plates

ALEXEY SUSLOV, National High Magnetic Field Laboratory, Tallahassee, FL — Resonances of a GaAs wafer with a GaAs/AlGaAs heterostructure grown on one of its sides were studied in the temperature range 0.05-10 K in magnetic fields of up to 18 T. To the best of our knowledge, this is the first use of the Resonant Ultrasound Spectroscopy in a dilution refrigerator. Observed quantum oscillations of the resonance frequencies and linewidths were caused by the Quantum Hall Effect in the 2DEG. The wafer with the 2D gas can be conceived as a film with field dependent conductivity deposited on a piezoelectric plate. Being dielectric, the film does not affect properties of GaAs and, thus, the resonance frequencies are defined only by the elastic, piezoelectric, and dielectric constants of GaAs. Being metallic, the 2D sheet effectively screens the parallel electric field, so the ultrasound wave velocities and resonance frequencies decrease with the increase of the sheet conductivity. Oscillations of the resonance linewidth reflect the influence of the 2D system on the ultrasound attenuation. A metallic film as well as a dielectric one does not affect this attenuation but at some finite nonzero value of the conductivity the linewidth approaches a maximum value. The observed phenomena can be described by the relaxation type equations.

### 1:39PM Q23.00013 Quantum Hall transition on a triangular lattice; network model and analytical renormalization-group treatment

VAGHARSH MKHITARYAN, MIKHAIL RAIKH, Department of Physics, University of Utah, Salt Lake City, UT 84112 — Common approach to the theoretical study of the quantum Hall transition is the Chalker-Coddington network model on the square lattice. We introduce a new version of the network model formulated on the triangular lattice, where the scattering at the sites is described by a 3 × 3 matrix. Extending renormalization-group description of the classical site percolation to the quantum case, we derive a closed equation for the distribution function of conductance. Solving this equation numerically, we get for the critical exponent of the correlation radius ν ≈ 2.3 ± 0.76 in good agreement with established value ν = 2.33.

### 1:51PM Q23.00014 Half integer features in the quantum Hall Effect: experiment and theory

TOBIAS KRAMER, University Regensburg, E.J. HELLER, R.E. PARROTT, Harvard University, C.T. LIANG, National Taiwan University, C.F. HUANG, National Measurement Laboratory, Taiwan, K. Y. CHEN, National Taiwan University, L.-H. LIN, National Chiayi University, Taiwan, J.-Y. WU, S.-D. LIN, National Chiao Tung University, Taiwan — We discuss experimental data and a new model of the quantum Hall effect (IQHE), which explains an intriguing substructure within Landau levels observed at higher currents. The experiments show inflection points in the Hall resistivity around filling factors 5/2 and 7/2. The experiments require to revisit the foundations of the IQHE and to establish an injection model which incorporates the correct boundary conditions imposed by a real Hall device and the Lorentz force. We have to follow the electrons to their source: one corner of the Hall bar and its steep electric field gradients, rather than focusing on the middle of the Hall device. We find the entire Hall resistivity curve is calculable as a function of magnetic field, temperature, and current. In contrast to previous theories of the IQHE, disorder plays no fundamental role in our theory. Contrary to the standard picture of Landau levels in disorder system, we predict and observe gaps right in the middle of certain Landau levels. The Hall plateaus and half integer inflections are shown to result from the LDOS appropriate to the magnetic field and the strong electric field at the injection corner.

### 2:03PM Q23.00015 Operation of a Single Electron Transistor Placed on Stacked Integer Quantum Hall Layers as a Magnetometer

HAILING CHENG, YU JIN, Physics Dept., Univ. of Michigan, RACHEL GOLDMAN, Dept. of Materials Science and Engineering, Univ. of Michigan, CAGLIYAN KURDAK, Physics Dept., Univ. of Michigan — A single electron transistor (SET) placed on an integer quantum Hall liquid (IQHL) can detect small time varying magnetic fields in the presence of a large constant magnetic field. To enhance the sensitivity, we placed a SET made out of Al/AlOₓ/Al tunnel junctions on top of a GaAs/AlGaAs heterostructure with 25 identical quantum well structures. By monitoring the conductance of the SET following a small change in magnetic field, we studied the equilibration processes in IQHLs. The equilibration times associated with small changes in magnetic field are found to be strongly dependent on the magnetic field and became unmeasurably long (many days) as we got closer to the center of the quantum Hall plateaus. We have also characterized the SET magnetometer by an ac technique where we applied 170 nT ac magnetic field and measured the response of the SET using a double lock-in technique. At T=20 mK, the SET magnetometer worked at filling fractions up to n=12 and was most sensitive at the filling fraction n=6.

---

Wednesday, March 18, 2009 11:15AM - 2:15PM — Session Q24 DMP: Focus Session: Optical Response of Nanotubes
11:15AM Q24.00001 Optical near-field investigations of individual single-walled carbon nanotubes1, ACHIM HARTSCHUH, LMU Muenchen — Optical excitation of semiconducting nanotubes creates excitons that determine nearly all light-based applications. Near-field photoluminescence (PL) and Raman imaging with a spatial resolution better than 15 nm was used to probe the spectroscopic properties of excitonic states along single nanotubes on substrates [1,2]. The PL intensity was found to decrease towards the nanotube ends on a length scale of few 10 nm probably caused by exciton transport to localized end states followed by efficient non-radiative recombination. DNA-wrapping of nanotubes results in pronounced emission energy variations on a length scale of few 10 nm indicating the potential of the material for nanoscale sensing applications [3]. Inter-nanotube energy transfer was studied for different pairs of semiconducting nanotubes forming bundles and crossings [4]. Efficient transfer is found to be limited to a few nanometres because of competing fast non-radiative relaxation and can be explained in terms of electromagnetic near-field coupling. We also report on our recent experimental results on time-resolved near-field PL measurements, electrically gated nanotubes and the PL of nanotubes on metal surfaces.

11:51AM Q24.00002 Electroluminescence Spectral Shape in Carbon Nanotube Field Effect Transistors under High Bias Conditions, MEGUMI KINOSHITA, Stony Brook University, VASILI PEREBEINOS, MATHIAS STEINER, PHAEDON AVOURIS, IBM THOMAS WATSON RESEARCH CENTER TEAM — In carbon nanotube field effect transistors, electroluminescence excited by intra-nanotube impact excitation at high source-drain bias reveals strongly broadened electronic transitions (FWHM ~150 to ~300 meV for the lowest energy peak observed) in the E1g to E2g energy range. Through the bias and polarization dependence of the spectra, we investigate the production mechanism of these states and consider possible causes for their bias-dependent broad line shapes, including exciton-exciton annihilation and high electron and phonon temperatures.

12:03PM Q24.00003 Electroluminescence from Carbon Nanotube Network Transistors, ELYSE ADAM, CARLA AGUIRRE, Departement de Genie Physique, Ecole Polytechnique de Montreal, MATTHIEU PAILLET, Departement de Chimie, Universite de Montreal, BENNOID CARDIN ST-ANTOINE, Departement de Genie Physique, Ecole Polytechnique de Montreal, FRANCOIS MEUNIER, Departement de Chimie, Universite de Montreal, PATRICK DESJARDINS, DAVID MENARD, Departement de Genie Physique, Ecole Polytechnique de Montreal, RICHARD MARTEL, Departement de Chimie, Universite de Montreal — A spectroscopic study of the electroluminescence properties of individual carbon nanotube (CNFET) and carbon nanotube network (NNFET) field effect transistors has been performed. As expected, the measurements on metallic and semiconducting CNFET showed that only semiconducting carbon nanotubes produce electroluminescent signals. The narrow emission line widths of CNFET (~80 meV) compared to that of NNFETs (~180 meV) indicates that the light emission from carbon nanotube networks involves many carbon nanotubes. Moreover, electroluminescence spectra from NNFETs made from three different sources of carbon nanotubes (laser ablation, CoMoCAT and DWNT) have shown major differences which, based on comparisons with their corresponding absorption spectra, indicate that only larger diameter carbon nanotubes contribute to light emission.

12:15PM Q24.00004 Confocal imaging and excitation spectra of photoluminescence from carbon nanotubes suspended over trenches of various widths1, S. MORITSUBO, T. MURAI, T. SHIMADA, Y. MURAKAMI, S. MARUYAMA, Y. K. KATO2, University of Tokyo — Carbon nanotubes (CNTs) have novel optical properties, such as strongly bound excitons and sensitivity to surrounding environments, because of their unique structure. In particular, it is well known that CNTs lying on substrates show photoluminescence (PL) quenching caused by very effective substrate-induced nonradiative decay of photoexcited excitons. In this study, we formed trenches with various widths on SiO2/Si substrates in order to prepare suspended CNTs. Using ethanol as carbon source, chemical vapor deposition was used for the synthesis of CNTs. PL images were collected by a home-built laser scanning confocal microscope system utilizing a fast staring mirror. In addition, PL excitation spectra were taken using a wavelength tunable Ti:sapphire laser. We analyzed these PL images and excitation spectra in order to clarify the interaction between excitons and the substrate.

12:27PM Q24.00005 Near infrared photoresponse study of large area multi-walled carbon nanotube film with different electrode spacing, BIDDUT SARKER, M. ARIF, PAUL STOKES, ALAMGIR KABIR, SAIFUL I. KHONDAKER, Nanoscience Technology Center and Department of Physics University of Central Florida, Orlando, FL 32826 — Photoconductivity of carbon nanotube has generated considerable debate in terms of whether the photoresponse is (i) due to photon induced charge carrier (excitonic), (ii) due to heating of the CNT network (bolometric), or (iii) caused by photodesorption of oxygen molecules at the surface of the CNT. In addition, the role of the metal electrode – CNT contact’s effect on the photoresponse has also been debated. In this talk, we will present near-infrared photoresponse study of multi-walled carbon nanotube (MWCNT) film with different electrode spacings. We found that there is a large enhancement of photocurrent upon laser illumination and the photocurrent strongly depends on the position of the laser spot with maximum response occurring at the metal – film interface. We also show that the photoresponse is rather slow (~1s) and increases with increasing electrode spacing. We will discuss the origin of the position dependent photocurrent and slow time response.

12:39PM Q24.00006 Transparency and conductivity of carbon nanotube networks, JAN OBRZUT, National Institute of Standards and Technology — The conductivity of films made of single wall carbon nanotubes longer than 200 nm closely follows the percolation theory for two-dimensional (2D) networks. The scaling universal exponents describing the “percolation” transition from an insulating to conducting state with increasing concentration are consistent with 2D percolation model. A sheet of tubes about 820 nm long becomes conducting at an amazingly low concentration of about 1.2×10^-9 g/cm^2. In comparison, batches of short nanotubes or mixed-length batches form more 3D networks that conduct noticeably worse. Furthermore, the conductivity percolation threshold (x_c) varies with the aspect ratio Length (L) as, x_c ~L/L, a result that is also in accordance with the percolation theory. We also show that contrary to current predictions, these sheets do not have optical properties similar to thin metallic films. Our results indicate that the correlation between the optical properties and the electrical conductivity of these sheets is again better predicted by the general percolation theory.
12:51PM Q24.00007 Carrier renormalization effects on the optical response of doped semiconducting single-walled-carbon nanotubes1, SHENG JU, Department of Physics, University of California, Berkeley, California 94720, USA, CHEOL-HWAN PARK, STEVEN LOUIE, Department of Physics, University of California, Berkeley, California 94720, USA and Materials Science Division, Lawrence Berkeley National Laboratory — It is known that many-electron effects dramatically change the optical properties of single-walled carbon nanotubes (SWCNTs). Recently, researchers have succeeded in tuning the Fermi energy of an individual SWCNT by applying a gate voltage or by introducing adsorbate dopants. Therefore, the optical response of doped SWCNTs is not only interesting from a pure scientific viewpoint but also important for the application of these systems. We present here first-principles calculations, based on the GW-Bethe Salpeter equation (GW-BSE) approach, of the quasiparticle (single-particle excitation) spectrum and the electron (electron-hole excitation) spectrum of doped SWCNTs.

1This research was supported by the NSF under Grant No. DMR07-05941, and the U.S. DOE under Contract No. DE-AC02-05CH11231. Computer time was provided by NERSC and NPACI.

1:03PM Q24.00008 Optical properties of doped semiconducting single-walled carbon nanotubes. CATALIN D. SPATARU, FRANCOIS LEONARD, Sandia National Laboratories, Livermore, CA 94551 — We studied how the optical response of semiconducting single-walled carbon nanotubes (SWCNTs) changes upon doping. We performed ab initio calculations of the optical absorption spectrum of the p-doped (10,0) SWCNT, employing a many-electron Green’s function approach that determines both the quasiparticle and electron-hole excitations from first principles. We found that the absorption spectrum changes dramatically upon doping, due to both quasiparticle and excitonic effects. In the independent quasiparticle picture, the electron-hole continua are strongly red-shifted with respect to the undoped case due to the metallic character acquired by the electronic screening upon doping. However, the main optical features in the absorption spectrum, including both quasiparticle and electron-hole interaction effects, are only slightly shifted, but qualitatively very different, with respect to the undoped case. Small doping levels (where the Fermi level lies below the valence band maximum by an energy much smaller than the binding energy of excitons in the undoped SWCNT) are sufficient to bleach band-gap absorption. In addition, while resonant excitons associated with the second electron-hole continuum can still exist in the doped SWCNT, their binding energy is much reduced, to a level typical of metallic SWCNTs of similar diameter.

1:15PM Q24.00009 Origins of optical absorption components of metallic and semiconducting single-wall carbon nanotubes in ultra-violet region, KAZUHIRO YANAGI, TAKESHI SAITO, YASUMITSU MIYATA, HIRONICHI KATAURA, Natl. Inst. Adv. Indus./Sci. Tech. — There are large absorption components in the optical absorption spectra of single-wall carbon nanotubes (SWCNTs) in the ultraviolet (UV) region (~5 eV). Clarification of the origins of the UV absorption is important, since the tails of the UV components influence the transparency of nanotubes and impede their uses for transparent conducting films. However, the origins have not been correctly understood yet. Such UV absorption components are assumed to be caused by π-plasmons, however, recently contributions from π−π* transition at the M point were also suggested. To understand the origins of UV component, here we clarified how the electronic structure (metallic or semiconducting) and the diameters of SWCNTs influence the UV optical absorption features. We clearly identified two components in UV region, and revealed dependence of the components on their diameters. Remarkably, dependence of the peak-energies of one component on diameters could not be explained by plasmon model, implying the presence of different origins than plasmons in the UV absorption components.

1:27PM Q24.00010 Environmental Change in UV Absorption by Single-Walled Carbon Nanotubes, YOICHI MURAKAMI, SHIGEO MARUYAMA, Univ. of Tokyo — We investigated the UV absorption of single-walled carbon nanotubes (SWNTs) in the 4 - 6 eV range, which has been customarily referred to as the “π-plasmon” as a whole. The optical absorption spectra of aligned SWNTs were measured in different dielectric environments. The experimental results unambiguously show that, for the two different UV absorption components existing in the 4 - 6 eV range, only the feature at 5.0 - 5.3 eV exhibits remarkable spectral changes, while the other feature at ~4.5 eV remains unchanged. We attribute the former (5.0 - 5.3 eV) to a dipolar surface plasmon in the radial direction of SWNTs. On the other hand, the experimental result raises a fundamental question as to whether it is appropriate to classify the UV feature at ~4.5 eV as a π-plasmon. We will discuss its relation with the UV absorption at ~4.5 eV in graphite/graphene that has long been recognized as the interband transition at M point of the Brillouin Zone.

1:39PM Q24.00011 Electron-electron interaction effects on the photophysics of metallic single-walled carbon nanotubes1, SUMIT MAZUMDAR, University of Arizona, DEMETRA PSIACHOS, ZHENDONG WANG, ROBERTO BADILLA, University of Arizona — Within a molecular Hamiltonian appropriate for correlated π-electron systems, we show that optical excitations polarized parallel to the nanotube axes in the so-called metallic single-walled carbon nanotubes are to excitons. Our calculated absolute exciton energies in twelve different metallic single-walled carbon nanotubes, with diameters in the range 0.8 - 1.4 nm, are in nearly quantitative agreement with experimental results. We have also calculated the absorption spectrum for the (21,21) single-wall carbon nanotube in the E22 region. Our calculated spectrum gives an excellent fit to the experimental absorption spectrum. In all cases our calculated exciton binding energies are only slightly smaller than those of semiconducting nanotubes with comparable diameters. As in the semiconducting nanotubes we predict in the metallic nanotubes a two-photon exciton above the lowest longitudinal polarization exciton that can be detected by ultrafast pump-probe spectroscopy. We also predict a subgap absorption polarization perpendicular to the nanotube axes below the lowest longitudinal exciton, blueshifted from the exact midgap by electron-electron interactions.

1This work was supported by NSF grant number DMR-0705163.

1:51PM Q24.00012 Fano Resonance in Single-Walled Cabron Nanotube Devices, GANG LIU, University of California, Riverside, YONG ZHANG, China Southwest University, CHUNNING LAU, University of California, Riverside — We have observed Fano resonance in a short carbon nanotube device. The device’s transport spectroscopy exhibits inverse Coulomb blockade structures superimposed on Fabry Perot resonance patterns, indicating the quantum interference between a well-coupled channel and a poorly-coupled channel. Our results have implication on the detection of charges’ phase and phase coherence in an electronic interferometer.

2:03PM Q24.00013 Optical Absorption Spectra of Charge Doped Single-Walled Carbon Nanotubes from First-principles Calculations, GUANGFU LUO, Department of Physics, Peking University, JING LU, WAI-NING MEI, LU WANG, LIN LAI, JING ZHOU, RUI QIN, HONG LI, ZHENGXIAN GAO, DEPARTMENT OF PHYSICS, PEKING UNIVERSITY COLLABORATION, DEPARTMENT OF PHYSICS, UNIVERSITY OF NEBRASKA AT OMAHA COLLABORATION — The optical absorption spectrum of single-walled carbon nanotubes (SWCNTs) under charge doping is often interpreted within the graphene zone-folding and rigid-band model. Based on the periodic boundary model together with a uniform background countercharge, our density functional theory calculations, however, show that the spectrum response deviates from the expectations of such model. Specifically, the SWCNT band structures can differ qualitatively from the zone-folding ones, and with the increasing doping level, the absorption peaks will bleach in a non-sequential energy order. The on-tube bands in SWCNTs sometimes change obviously even under low charge doping level, and accordingly cause spectra peaks to shift, split, and merge. At the end of this paper, we discuss briefly the applicability of the present results at the GW-BSE theory level and in other SWCNT-like systems.
11:15AM Q25.00001 Interaction of magneto-excitons with phonons in graphene and graphite
JUN YAN, TREvor DAVId RHONE, Department of Physics, Columbia University, SARAH GOLER, NEST and Scuola Normale Superiore, Pisa, Italy, MELINDA HAN, Department of Physics and Applied Physics, Columbia University, VITTORIO PELLEGRINI, NEST and Scuola Normale Superiore, Pisa, Italy, PHILIP KIM, Department of Physics, Columbia University, ARON PINCZUK, Department of Physics and Applied Physics, Columbia University — We study the Landau levels of graphite and single layer graphene by measurements of the magneto-phonon resonance effect in which there is coupling between the inter-Landau level magneto-exciton with the long wavelength optical phonon (G band). In graphite the G band displays a rich line shape evolution as the magnetic field is finely tuned between 5 and 7 Tesla. These observations indicate that the G band is resonantly coupled to the magneto-excitons at these fields. In the interpretation we postulate that the anticrossing of the phonon band with the inter-Landau level transitions results in a mode-splitting at around 6.2 T. The evolution of the energy and spectral weight of the two coupled modes indicates that the phonon is a probe of the unique structure of Landau levels in graphene-related materials. In an as-prepared single-layer graphene, much smaller changes are observed for fields reaching as high as 12 Tesla.

11:27AM Q25.00002 Klein Backscattering and Fabry-Perot Interference in Graphene Heterojunctions, ANDREI SHYTVO, University of Utah, MARK RUDNER, Harvard University, LEONID LEVITOV, Massachusetts Institute of Technology — Fabry-Perot (FP) interference in a lateral p-n-p structure in graphene is proposed as a vehicle to probe Klein scattering phenomenon [Phys. Rev. Lett. 101, 156804 (2008)]. In ballistic regime, interference between waves scattered from p-n interfaces leads to oscillations in conductance as a function of electron density. Perfect transmission at zero incidence angle (Klein effect) implies a sign change of the backreflection amplitude. This change contributes a phase π to interference and shifts FP fringes by half a period. Alternatively, the π phase can be understood as Berry's phase accrued by electron bouncing between p-n boundaries. This effect is revealed in the evolution of fringes when a relatively weak, non-quantizing magnetic field is applied. The behavior of the interference fringes recently observed by Young and Kim (arXiv:0808.0855) is consistent with this picture. The observed crossover to Shubnikov-de Haas oscillations can be also understood from quantization of periodic orbits bouncing between the two p-n interfaces.

11:39AM Q25.00003 Graphene electronics via strain engineering, VITOr PEREIRA, Boston University — Recently, graphene has been confirmed as the strongest material ever measured, being able to sustain reversible deformations in excess of 20%. These mechanical measurements arise at a time where graphene draws considerable attention on account of its unusual and rich electronic properties. Besides the great crystalline quality, high mobility and resilience to high current densities, they include a strong field effect, absence of backscattering and a minimum metallic conductivity. While many such properties might prove instrumental if graphene is to be used in future technological applications in the ever pressing demand for miniaturization in electronics, the latter is actually a strong deterrent: it hinders the pinching off of the charge flow and the creation of quantum point contacts. In addition, graphene has a gapless spectrum with linearly dispersing, Dirac-like, excitations. Although a gap can be induced by means of quantum confinement in the form of nanoribbons and quantum dots, these “paper-cutting” techniques are prone to edge roughness, which has detrimental effects on the electronic properties. We explore an alternative route for tailoring the electronic structure of graphene, based on a strain engineering. We will discuss how local and global strain profiles can be suitably tailored to impact the bandstructure of graphene and control its transport characteristics. Electron confinement, electron beam collimation, energy filtering, surface modes and bulk spectral gaps are some examples of what might be achieved.

11:25AM Q25.00004 Fabrication and transport measurement of suspended graphene devices.
WENZHONG BAO, FENG MIAO, GANG LIU, CHUNNING LAU — We developed a lithography-free technique to fabricate suspended graphene devices. Graphene sheets are exfoliated over pre-defined trenches over the substrates, and electrodes are deposited via shadow mask evaporation. This technique eliminates resist residues which may affect electrical properties of graphene. We will discuss results from electrical transport measurement at different temperatures and magnetic fields.

11:27PM Q25.00005 Temperature dependent resistivity of suspended graphene, EROS MARIANI, FELIX VON OPPEN, Freie Universitaet Berlin, FREIE UNIVERSITAET BERLIN TEAM — In this talk we discuss the temperature dependence of the resistivity for suspended single layer graphene, due to electron-phonon scattering. All the temperature regimes are studied, as well as the contributions due to the different acoustic phonon branches in graphene. We show how tension in the membrane suppresses the otherwise dominant contribution due to flexural phonons [1], leaving a linear temperature scaling compatible with recent experiments. The eventual crossover to quadratic temperature dependence at very high temperatures could be used as an experimental tool to investigate the otherwise unknown strength of the tension. Finally, we discuss the transition to the quasi-nondegenerate regime for electrons in graphene. This is relevant for current experiments on the temperature dependent resistivity in most temperature regimes, and can shed light on the unexpected density dependence of the linear-T resistivity.

12:39PM Q25.00006 Neutron Scattering Studies of Graphene, ALICE ACATRINEI, ZHIJUN LIN, LUKE DAEMEN, Los Alamos National Laboratory, LANSCe, Lujan Neutron Scattering Center — We synthesized graphene by thermal exfoliation at 500 deg C. The material is nanosize, as confirmed by TEM/SEM, with flake transverse dimensions 50-100 nm. We present the first detailed measurement of the vibrational Spectrum of both graphene and graphite using INS, along with a neutron Scattering study of hydrogen adsorbed on graphene. Our measurements were collected at 10K using the Filter Difference Spectrometer (FDS) at Lujan Neutron Scattering Center, Los Alamos National Laboratory.

12:51PM Q25.00007 Effect of film corrugation on the optical phonon lifetime in graphene, PETER EKLUND, Department of Physics, Department of Material Science and Engineering, Pennsylvania State University, University Park, PA 16802, AWWING GU, Department of Materials Engineering, Pennsylvania State University, University Park, PA 16802 — We present results of a microRaman study of n-layer graphene films supported on ~atomically flat mica, Si/SiO₂ (or varying roughness) and suspended above a trench. Using the Raman G-band line width Γ₂G, we find that the optical phonon lifetime τ ~1/Γ₂ decreases linearly with increasing rms substrate roughness δ, and independent of the chemical composition of the substrate. In agreement with this general observation, we find that Γ₂ for unsupported graphene is significantly higher (i.e., the q=0 optical phonon lifetime is significantly lower) than observed when the film is supported on mica. Correlating Γ₂ with values obtained from supported films, we infer an inherent rms roughness δ ~ 2 nm for unsupported graphene, in reasonable agreement with recent STM reports that first suggested that graphene might prefer to spontaneously convert to a corrugated system. Our observations may then relate to the effect of the local bending of the sp² sheet on the electron-phonon interaction.
1:03PM Q25.00008 Edge stress induced warping of graphene sheets and nanoribbons, VIVEK SHENOY, Brown University — We show that edge stresses introduce intrinsic ripples in free-standing graphene sheets even in the absence of any thermal effects. Compressive edge stresses along zigzag and armchair edges of the sheet cause out-of-plane warping to attain several degenerate mode shapes. Based on elastic plate theory, we identify scaling laws for the amplitude and penetration depth of edge ripples as a function of wavelength [1]. We also demonstrate that edge stresses can lead to twisting and scrolling of nanoribbons as seen in experiments. Our results underscore the importance of accounting for edge stresses in thermal theories and electronic structure calculations for free-standing graphene sheets. [1] V. B. Shenoy, C. D. Reddy, A. Ramasubramaniam and Y. W. Zhang, Phys. Rev. Lett. (in press)

1:15PM Q25.00009 Infrared spectroscopy of electronic bands in bilayer graphene1, ALEXEY KUZMENKO, ERIK VAN HEUMEN, DIRK VAN DER MARIEL, University of Geneva, PHILIPPE LERCH, Paul Scherrer Institute, Switzerland, PETER BLAKE, KONSTANTIN NOVOSELOV, ANDRE GEIM, University of Manchester — We present infrared spectra (0.11 eV) of electrostatically gated bilayer graphene as a function of doping and compare them with tight binding calculations. All major spectral features corresponding to the expected interband transitions are identified in the spectra: a strong peak due to transitions between parallel split-off bands and two onset-like features due to transitions between valence and conduction bands. A significant electron-hole asymmetry is observed.

1:27PM Q25.00010 Sharp Landau Levels in Scanning Tunneling Spectroscopy of Epitaxial Graphene on SiC(000 -1), DAVID MILLER, KEVIN KUBISTA, GREGORY RUTTER, MING RUAN, WALT DE HEER, PHILLIP FIRST, Georgia Institute of Technology, JOSEPH STROSCIO, Center for Nanoscale Science and Technology, NIST — Monolayer graphene has unique electronic properties stemming from a low-energy band structure that is linear, with chiral Dirac quasiparticles. In a magnetic field, the Landau level (LL) energies for graphene vary proportional to $\sqrt{nB}$, where $n$ is the LL index. Conversely, Bernal-stacked bilayer graphene and graphite have parabolic dispersion at low energies, resulting in $E_n \propto B^n$. In this talk we measure the LL spectrum of the top graphene layer directly via scanning tunneling spectroscopy (STS) at a 4.3 K. We show that for $n \approx 10$-layer epitaxial graphene grown on SiC(000 -1), the spectrum exhibits very sharp peaks (including a strong $n=0$ peak) spaced as $E_n \propto \sqrt{nB}$. This spectrum indicates that the rotational stacking in multilayer epitaxial graphene effectively decouples the layers, producing single-layer graphane behavior. Work supported in part by NSF, NRI-INDEX, and the W. M. Keck Foundation.

1:39PM Q25.00011 Electronic structures of single- and multi-layer epitaxial graphene on SiC (0001), SEUNGCHUL KIM, JISOON IHM, Department of Physics and Astronomy, Seoul National University, YOUNG-WOO SON, Korea Institute for Advanced Study — The electronic structures of single- and multi-layered epitaxial graphene on silicon carbide (0001) surface are studied theoretically. To calculate energy bands of the systems, we construct the simple Hamiltonian with tight-binding approximations. We confirm that the present simple model do not vary proportional to $n$. This spectrum indicates that the rotational stacking in multilayer epitaxial graphene effectively decouples the layers, producing single-layer graphane behavior. We extend the model up to four epitaxial graphene layers to explain various interesting experimental findings. The roles of the coupling between graphene bilayers and the buffer layer, and their large scale reconstructions to the electronic structures are also investigated. [1] S. Kim, J. Ihm, H. J. Choi, Y.-W. Son, Phys. Rev. Lett. 100, 176802 (2008).

1:51PM Q25.00012 G-band Phonon Symmetry Breaking of Graphene Monolayers, LAIN-JONG LI, YANG ZHAO, XIAOCHEN DONG, PENG CHEN, Nanyang Technological University — Aromatic molecules can effectively exfoliate graphite into graphene monolayers. And the resulting graphene monolayers sandwiched by the aromatic molecules exhibit pronounced G-band splitting, similar to that observed in rolled-up graphene sheet (single-walled carbon nanotubes). Raman measurements and the theoretical calculation based on force-constant model demonstrate that aromatic molecules are able to induce G-band splitting via breaking the symmetry of two in-plane longitudinal and transverse optical phonons at Gamma-point.

2:03PM Q25.00013 Edge states in a honeycomb lattice: effects of anisotropic hopping and mixed edges, ZI-XIANG HU, Zhejiang Institute of Modern Physics, Zhejiang University, China, HARI DAHAL, NIKOLAI SINITSYN, Los Alamos National Laboratory, KUN YANG, National High Magnetic Field Laboratory and Department of Physics, Florida State University, ALEXANDER BALATSKY, Los Alamos National Laboratory — We study the effects of anisotropic hopping and mixed edges on the edge states of graphene. The discussion of the edge states in graphene so far is focused on either zigzag or armchair edge with isotropic hopping. In this case the zigzag (arm chair) edge has enhanced (suppressed) local density of states at $E=0$ near the edge. In practice electrons in graphene can have anisotropic hopping. The lattice can have mixed (zigzag and arm chair) edges. Hence we study the effects of the anisotropic hopping and mixed edges on the edge states. We show that the mixed edges smear the enhanced local density of states at $E=0$ of the zigzag edge and, the anisotropic hopping enhanced the LDOS at $E=0$ in the armchair edge. Edge states in graphene can be studied using scanning tunneling microscopy (STM) experiments. We suggest that care must be taken while interpreting the STM data because the distinction between the zigzag and arm chair edge will be affected by the anisotropic electron hopping and the mixed edges.

11:15AM Q26.00001 Electron-electron interactions in graphene bilayers1, FAN ZHANG, HONGKI MIN, MARCO POLINI, ALLAN MACDONALD, DEPARTMENT OF PHYSICS, UNIVERSITY OF TEXAS AT AUSTIN COLLABORATION, NEST-CNR-INFN AND SCUOLA NORMALE SUPERIORE COLLABORATION — Electrons in condensed matter normally form Fermi-liquid states in which e-e interactions play an inessential role. A well known exception is the case of 1D electron systems in which the Fermi-surface consists of two points and divergences associated with low-energy particle-hole excitations abound when e-e interactions are described perturbatively. Corresponding divergences normally occur in systems with higher space dimensions when Fermi lines or surfaces satisfy idealized nesting conditions. Here we discuss the role of e-e interactions in 2D graphene bilayers which behave in many ways as if they were 1D because they have point-like Fermi surfaces which satisfy the nesting condition and have two-layer chirality and because their particle-hole energies have a quadratic dispersion which compensates for the difference between 1D and 2D phase spaces. We conclude, on the basis of a perturbative RG calculation, that interaction in neutral graphene bilayers drive the system into a spontaneously broken symmetry state with layer-pseudospin ferromagnetism.

11:27AM Q26.00002 Ferromagnetism in Graphene Stacks, DAGIM TILAHUN, ALLAN MACDONALD, The University of Texas at Austin — Because the density of states at the Fermi level of neutral graphene layers is proportional to external magnetic field, the ground state in strong fields is expected to have a broken symmetry - most likely ferromagnetism. In systems with stacked graphene layers this tendency competes with inter-layer hopping which favors paramagnetic ground states or perhaps other types of broken symmetries. We present a criterion for the stability of the ferromagnetic state and discuss its application to single-layer graphene, to weakly coupled epitaxial graphene layers on SiC or other substrates, and to bulk graphite. We use the Slonczewski-Weiss-McClure model to explain why the dominant inter-layer hopping process in Bernal (AB) stacked graphite does not compete with ferromagnetism.

11:39AM Q26.00003 Theory of inter-edge superexchange in zigzag edge magnetism, JEIL JUNG, Department of Physics, University of Texas at Austin, USA, TAMÍ PÉREZ-BARNEA, Physics Department, California Institute of Technology, USA, ALLAN MACDONALD, Department of Physics, University of Texas at Austin, USA — A graphene nanoribbon with zigzag edges has a gapped magnetic ground state with an antiferromagnetic inter-edge superexchange interaction. We present a theory based on the asymptotic properties of the Dirac-model ribbon wavefunction which predicts $W^{-2}$ and $W^{-1}$ ribbon-width dependences for the superexchange interaction strength and the gap respectively. Unlike in conventional superexchange we find that both the kinetic and exchange energy contributions favor the antiferromagnetic inter-edge coupling with a dominant role of exchange several times larger in magnitude than the kinetic energy contribution.

11:51AM Q26.00004 Numerical study on electron-electron interaction and ferromagnetic fluctuation in graphene, TIANXING MA, Max Planck Institute for the Physics of Complex Systems, Nöthenstr. 38, D-01187 Dresden, Germany, FEIMING HU, Department of Physics and the Institute of Theoretical Physics, the Chinese University of Hong Kong, ZHONGBING HUANG, Faculty of Physics and Electronic Technology, Hubei University, Wuhan 430062, People’s Republic of China, HAI-QING LIN, Department of Physics and the Institute of Theoretical Physics, the Chinese University of Hong Kong — Within the Hubbard model on a honeycomb lattice, we investigate the effect of electron-electron interactions and ferromagnetic fluctuations in graphene numerically. We find that the system in the filling region $\langle n \rangle > 1.60-1.90$ shows a short-ranged ferromagnetic correlation, and the on-site Coulomb interaction tends to strengthen ferromagnetic fluctuation slightly. Furthermore, the ferromagnetic fluctuation is strengthened markedly as the next-nearest-neighbor hoping energy increases, which indicate that the next-nearest-neighbor hoping term plays an important role in graphene since it breaks the particle-hole-symmetry.

12:03PM Q26.00005 Gate-induced interlayer asymmetry in ABA-stacked trilayer graphene, EDWARD MCCANN, Lancaster University, MIKITO KOSHINO, Tokyo Institute of Technology, Japan — We model the electronic band structure and conductivity of ABA-stacked trilayer graphene in the presence of external gates, self-consistently calculating the electric potential of the three layers. We show that a gate field perpendicular to the layers breaks mirror reflection symmetry with respect to the central layer, leading to hybridization of the linear and parabolic low-energy bands. For large gate fields, we derive an effective two-component Hamiltonian describing chiral electrons in two low-energy bands that exhibit an anti-crossing with a small hybridization gap. The magnitude of the gap is largely independent of the gate field, but the momentum at the anti-crossing and the typical band velocity both increase with it. Using the self-consistent Born approximation, we find that the density of states and the minimal conductivity in the presence of disorder generally increase as the gate field increases, in sharp contrast with bilayer graphene.

12:15PM Q26.00006 Aharonov-Bohm-like scattering, localization, and novel electronic states in hydrogenated graphene, ANDREY SHYTTOV, Utah University, DMITRY ABANIN, Princeton University, LEONID LEVITOV, Massachusetts Institute of Technology — Metallic nature of transport in graphene, which is fairly robust with respect to varying amounts of disorder, changes in an unexpected way when vacancies are introduced in this material. At low energies, near the Dirac point, electron scattering on vacancies mimics scattering on Aharonov-Bohm solenoids carrying unit flux. This type of scattering results in a very narrow band of states at the Dirac point with properties resembling those of zeroth Landau level, which is positioned in the middle of a (pseudo)gap created by vacancies and resembling the cyclotron gap around zeroth Landau level. The fictitious magnetic field describing vacancies has opposite signs for the valleys K and K'. As a result of this, an externally applied magnetic field has opposite effects in the two valleys, suppressing (reinforcing) the gap in the K (K') valley. We show that this picture is in agreement with the behavior observed in a recent study [1] of electronic properties of graphene, which can be transformed from metallic state to insulating state by hydrogenation. [1] D. C. Elias, R. R. Nair, T. M. G. Mohiuddin, S. V. Morozov, P. Blake, M. P. Halsall, A. C. Ferrari, D. W. Boukhvalov, M. I. Katsnelson, A. K. Geim, K. S. Novoselov, arXiv:0810.4706

12:27PM Q26.00007 Rashba spin-orbit interactions in zigzag graphene nano-ribbons, MAHDI ZAREA, Ohio University, NANCY SANDLER, Ohio University — The crystalline structure of graphene can be described in terms of a pseudo-spin degree of freedom and spinor wavefunctions. This characteristic has important physical consequences not observed in normal semiconductors. For zigzag ribbons, for instance, this translates into the existence of localized chiral edge states, with momentum coupled to pseudo-spin. In the presence of Rashba spin-orbit interactions (RSOI), this special feature makes the material a good candidate to produce localized spin polarized currents. To address this issue we investigated the role of the RSOI on the band-structure and wavefunctions of an infinite graphene plane and a zigzag nano-ribbon. We present analytic and numerical results showing that the spin profile along the edge is state-dependent. We compare these results with the profiles obtained in the presence of the intrinsic spin-orbit interaction [1]. We show that the RSOI can create average localized spin polarized currents along the edges of zigzag ribbons with appropriate applied voltages. [1] Zarea, M., Busser, C. and Sandler, N. PRL 101, 196804 (2008).

1Work supported by OU postdoctoral fellowship and OU-BNNT programs.

12:39PM Q26.00008 Plasma Instabilities in Graphene, BEN YU-KUANG HU, The University of Akron, ANTTI-PEKKKA JAUHO, Techn. Univ. of Denmark and Helsinki Institute of Technology — We discuss the possibility of the occurrence of plasma instabilities under non-equilibrium conditions in graphene. Specifically, we investigate the stability of the collective electronic modes in graphene with two counter-streaming distributions of carriers by studying the frequency-dependent dielectric function $\varepsilon(q, \omega)$ of the system. We find that the linear electronic dispersion of graphene results in instabilities that are qualitatively different from the standard two-stream instabilities for classical plasmas and parabolic-band systems.

12:51PM Q26.00009 Is suspended graphene an insulator?, JOAQUIN DRUT, The Ohio State University, TIMO LAHDE, University of Washington — Graphene at low energies resembles massless quantum electrodynamics in a strongly coupled regime, away from the usual perturbative region where the fine structure constant is $\alpha \sim 1/137$. Indeed, a single sheet of graphene in vacuum presents $\alpha \sim 1$. At such strong couplings the U(4) chiral symmetry of graphene can spontaneously break, inducing a gap in the quasiparticle spectrum. The question of whether chiral symmetry is broken represents a computational challenge that lies outside the domain of analytic techniques. In this talk, we will present the results of the first Monte Carlo simulation of the low-energy effective theory of graphene in vacuum (see abstract by T. A. Lähde). We have computed the chiral condensate, which is the order parameter for the insulating charge density wave state, as a function of $\alpha$, and found a chiral phase transition that is compatible with suspended graphene being in the gaped phase.
1:03PM Q26.00010 Many-body effects in neutral graphene bilayers . CSABA TOKE, Lancaster University, VLADIMIR I. FALKO, Lancaster University — A graphene bilayer is studied within the Hartree-Fock approximation in the tight-binding model. The exchange self-energy is studied systematically in an momentum expansion. Up to first order in the coupling constant (the effective fine structure constant) and to first order of the nonperpendicular hopping parameter we find that, for zero magnetic field, the exchange interaction with the valence band contributes with a logarithmically divergent correction to the Fermi velocity, the perpendicular inter-layer hopping, and the tringular warping. The effective mass renormalization in the two-band effective Hamiltonian is studied. For a strong perpendicular magnetic field the exciton dispersions are calculated.

1:15PM Q26.00011 Berry phase and the role of trigonal warping in graphene systems . IVAN STANIC, KARYN LE HUR, Yale University — In general Dirac fermions exhibit a Berry phase of $\pi$ whereas non-relativistic free-like particles have a Berry phase of $2\pi$. The two cases have been reported, both theoretically and experimentally, in single-layer and bi-layer graphene respectively. On the other hand, if one considers, for example, bi-layer graphene in more detail, its band structure shows both the Dirac-type, coming from the trigonal warping, and the parabolic, non-relativistic aspect in different energy regimes. This gives an unprecedented opportunity to investigate the crossover between non-relativistic and Dirac fermions in a Berry phase formulation. Here, we propose a scattering type-experiment (reflecting the Berry phase) to demonstrate this crossover. We present our theoretical results on scattering cross-sections taking into account the trigonal warping term, which confirm the jump in the Berry phase from $\pi$ to $2\pi$ as the energy of the incoming electrons is increased. This jump in the Berry phase can be understood from a general theorem relating the Berry phase and the band structure of a material.

1:27PM Q26.00012 Trigonal Band Structure and Time-Reversal Invariance in Graphene . ROLAND WINKLER, Northern Illinois University, ULRICH ZUELICKE, Massey University — We present a symmetry analysis of the trigonal band structure in graphene. While the energy spectrum near the Fermi edge equals the spectrum of massless Dirac fermions, the transformational properties of the underlying basis functions are qualitatively different. Using group theory we develop an invariant expansion of the Hamiltonian for the electron states near the $K$ points of the graphene Brillouin zone. We find that the $k$-linear dispersion near the band edge arises as an unusual consequence of time-reversal invariance. We suggest to divide the electronic properties of graphene into two categories, those that depend and those that do not depend on the transformational properties of the Bloch functions at $K$. See arXiv:0807.4204.

1:39PM Q26.00013 Two dimensional massless Dirac fermions with Coulomb interaction and random gauge potential . SEN HOU, OSKAR VAFEK, Florida State University — We present a numerical study of the two dimensional massless Dirac fermions of monolayer graphene with long-range Coulomb interaction and random gauge potential. The Coulomb interaction renormalizes logarithmically the electron velocity at low energies, leading to a decrease in the density of states. While the density of states is enhanced by the random gauge potential, and has a power-law dependence in low energies, $\rho(E) \sim E^{-1+2/z}$ with $z = 1 + \sqrt{3} \Delta / \pi$, where $\Delta$ measures the disorder strength. The combined effect of interaction and disorder gives rise to a line of fixed points where both the interaction and disorder are finite, and the low-energy density of states is exactly linear. Results are consistent with previous renormalization group argument.

2:03PM Q26.00015 Transport of massless Dirac fermions in graphene layers in presence of electromagnetic potential barriers . SANKALPA GHOSH, MANISH SHARMA, Indian Institute of Technology Delhi — We study the transport of massless Dirac fermions in Graphene layers through electromagnetic potential barriers. The barriers consist of periodically arranged delta function-electromagnetic potential barriers, SANKALPA GHOSH, MANISH SHARMA, Indian Institute of Technology Delhi — We study the transport of massless Dirac fermions in graphene layers through electromagnetic potential barriers. The barriers consist of periodically arranged delta function-electromagnetic potential barriers.

2:11PM Q26.00016 Gap opening due to topological defects in graphene . RICARDO NUNES, JOICE ARAÚJO, HELIO CHACHAM, UFMG - Brazil — Stone-Wales defects (SWD = two adjacent pentagon-heptagon pairs) are common low-energy defects in carbon nanotubes. Previously, Crespi et al.[PRB, 53, 1996] have proposed a purely-carbon covalent metal sheet called “pentaheptite,” consisting entirely of SWDs, with a relatively low formation energy of 0.32 eV/atom, with respect to graphene. In this work, we consider three different families of periodic carbon sheets containing topological defects (TDs = pentagons and heptagons). The families differ by the density of TDs in a seed structure. In each family, we generate periodic structures in which isolated pentagons and heptagons are surrounded only by hexagons. By means of ab initio calculations, we propose that, depending on the density and distribution of TDs, these carbon sheets may behave as a semiconductor, a metal or a semimetal. In the range of TD concentrations we examine, the sheets are stable in a planar form, but, allowing for the corrugation generated by the curvature fields associated with the isolated TDs, leads to lower formation energies and to either a reduction of the density of states or to gap opening at the Fermi level. Formation energies can be very small: in particular, we obtain a semiconducting structure with a formation energy of only 92 meV/atom with respect to graphene.

3:29PM Q26.00017 Berry phase formulation of transport through Graphene, and the associated problems can be mapped on certain classes of optical problems. We discuss the related band structure and its effect on transport over a range of magnetic field strengths and barrier widths. We also discuss the typical experimental set up where related properties can be verified.

Wednesday, March 18, 2009 11:15AM - 2:15PM — Session Q27 GIMS: Focus Session: X-ray and Neutron Instruments and Sciences II 329

11:15AM Q27.00001 3D Mapping of Strain and Dislocation Gradients near Surfaces and Interfaces via Polychromatic Microdiffraction . ROZALIYA BARABASH, GENE ICE, Oak Ridge National Laboratory — The results of 3D polychromatic X-ray microbeam analysis (PXM) of strain and dislocation gradients are presented. Two examples are considered: (1) FIB machined nano-size trenches in thin GaN/InGaN multilayers; (2) natural nanosize Mo pillars in the NiAl matrix of the eutectic composite alloy. Position sensitive $d$-spacings were obtained from Laue patterns. The PXM results show that FIB induces structural changes and lattice rotations in the InGaN/GaN layer not only in the immediate trench region but in the surrounding area as well. For embedded nanosize Mo fibers, the measured elastic strain is consistent with the predicted thermal mismatch strain between the NiAl and Mo phases. However, when the NiAl matrix is etched back to expose Mo micro-pillars, the $d$-spacing increases to that of unconstrained Mo, indicating release of the compressive residual strain in the Mo fibers.

11:27AM Q27.00002 Strain Fields in Zeolite Microcrystals by Coherent X-ray Diffraction1, HYUNJUNG KIM, Sogang University, WONSUK CHA, SANGHOON SONG, NAK CHEON JEONG, KYUNG BYUNG YOON, Sogang University, Korea, ROSS HARDER, Advanced Photon Source, ANL, IAN K. ROBINSON, , University College London, United Kingdom — We measured coherent X-ray diffraction (CXD) on zeolite microcrystals in order to get information on internal density distribution and to map deformation field of stress or strain during the fabrication process. The experiments were performed at the beamline 34-ID-C in Advanced Photon Source and employed monochromatic radiation with x-ray energy of 9 keV. The sample size was about \( \sim 2\mu \text{m} \). The diffraction patterns were obtained at (200) Bragg condition with unfocused beam. We inverted the diffraction patterns to obtain three dimensional images of the shapes and internal strain fields of zeolite microcrystals using phase retrieval algorithms of error reduction and hybrid input-output method. The internal density and strain distribution as a function of temperature will be discussed.

11:39AM Q27.00003 Silicon x-ray monochromator surfaces by independent oxidation and etching steps1, ALBERT MACRANDER, Advanced Photon Source, Argonne, KIMBERLEY MACARTHUR, EE Dept. Northern Illinois Univ., JOSEF MAJ, JIJN QIAN, APS, Argonne, DAN LINNEN, EE, NIU, RUBEN KHACHATRYAN, MICHAEL WIECZOREK, APS, Argonne, RAY CONLEY, NSLS II, Brookhaven, ALAN GENIS, EE, NIU — X-ray monochromators should ideally possess a surface that does not distort a diffracted beam. Beam distortions have been observed at the APS for rough surfaces. Mechanical polishing leaves sub-surface damage. The standard method to remove this damage is to wet etch Si crystals in a mixture of nitric acid and hydrofluoric acid. During the etch an oxide is produced and removed in the same acid bath. X-ray diffraction from a bulk reflection that is largely unaffected by strain can be obtained by this method. However, the smoothness is degraded to produce an orange-peel morphology. For the present study we carried out the oxidation and etching steps independently. By first growing an oxide layer in a furnace and subsequently etching away the oxide layer, we find that sub-surface damage can be removed and the surface quality can be improved over that found with only wet etching.

1Work supported by US DOE, Office of Science, Basic Energy Sciences under Contract No. DE-AC02-06CH11357

11:51AM Q27.00004 Observation of annealing of grains in high purity aluminum using High Energy X-ray Diffraction Microscopy , C.M. HEFFERAN, S.F. LI, Carnegie Mellon University, U. LIENERT, Argonne National Laboratory, R.M. SUTER, Carnegie Mellon University — High energy x-ray diffraction microscopy (HEDM) is capable of measuring volumes of polycrystal microstructure on a granular basis, producing spatial maps of crystallographic orientation covering ensembles of grains with micron resolution. A non-destructive experimental probe capable of observing the response of polycrystals to thermo-mechanical stimulus, HEDM establishes constraints on analytic materials models. HEDM uses high-brilliance, line focused synchrotron x-rays to image diffracted beams emanating from individual grains in a succession of planar sections. Area detector images of diffraction patterns are collected as the sample rotates normal to the beam plane. A forward modeling computer simulation adjusts local crystallographic orientations and compares simulated scattering to experimental images in order to optimize the match with observations. Three dimensional digital representations are generated from large numbers of reconstructed sections. Growth measurements on high purity polycrystalline aluminum have been conducted at the 1-ID beamline at the Advance Photon Source at Argonne National Laboratory and reconstructions have been obtained using the Pittsburgh Supercomputing Center. Both defect annealing and grain boundary motions have been observed and will be described.

12:03PM Q27.00005 Strain Analysis in 2D and 3D X-ray Microscopy1, J.Z. TISCHLER, B.C. LARSON, ORNL, WENJUN LIU, ANL, LYLE LEVINE, NIST — Spatially resolved strain distributions on the submicron length scale are important for materials problems such as deformation and phase separation, and in heterogeneous systems in general. High-energy 3DXRD techniques have been developed by RISO with a few micron 3D resolution for lightly deformed materials. However, submicron 3D spatial distributions of local strain in heavily deformed materials are often required, such as in for multiscale materials modeling. We have developed a scanning-monochromatic x-ray microbeam technique on sector-34 of the Advanced Photon Source to measure the Q-distribution from submicron volume elements in lightly and heavily deformed materials and in single, polycrystalline, or composite materials. By sorting the intensity from every pixel in an area detector during nested energy and differential aperture depth scans, Q-distributions are obtained for every spatially resolved volume element. We will present measurement examples and discuss the range of applications.

1ORNL research sponsored by DOE Office of Basic Energy Sciences, Div. of Materials Sciences & Engineering; XOR-UNI and APS are supported by DOE-BES.

12:15PM Q27.00006 Towards mapping of defected grains using high energy x-ray diffraction microscopy , SHIU FAI LI, C.M. HEFFERAN, Carnegie Mellon University, U. LIENERT, Argonne National Laboratory, R.M. SUTER, Carnegie Mellon University — High energy x-ray diffraction microscopy (HEDM), the use of focused high energy synchrotron x-ray radiation diffraction imaging, is becoming a promising technique for orientation mapping of polycrystalline material. The nondestructive nature of HEDM makes real-time observation of inter- and intra-grain dynamics possible. Collected HEDM data in the form of diffracted images on a high resolution 2D detector is analyzed by a Monte Carlo fitting algorithm using a forward modeling method, which simulates a set of detector images based from a specified orientation field. Since no specific assumptions are made regarding grain shapes and topologies, internal mosaic structures may be captured. The combination of nondestructive nature and intra-grain resolution makes it an ideal candidate for in situ studies of grain damage due to strain/stress treatment. A proof of concept has been demonstrated in observations of internal mosaic structures may be captured. The combination of nondestructive nature and intra-grain resolution makes it an ideal candidate for in situ studies of grain damage due to strain/stress treatment. A proof of concept has been demonstrated in observations of grain shapes and topologies. The nondestructive nature of HEDM makes real-time observation of inter- and intra-grain dynamics possible. The nondestructive nature of HEDM makes real-time observation of inter- and intra-grain dynamics possible.

12:27PM Q27.00007 A Holographic Iterative Algorithm for X-ray Microscopy1, DILING ZHU, Department of Applied Physics, Stanford University, BENNY WU, RAMON RICK, Department of Applied Physics, Stanford University, JOACHIM STÖHR, ANDREAS SCHERZ, Stanford Synchrotron Radiation Lightsource — In recent years X-ray Fourier transform holography has gained recognition as a high resolution microscopy technique. The phase information is encoded in the hologram which renders this a lessens approach as a true imaging technique by applying a simple inverse Fourier transform. In previous experiments the resolution was limited by imperfect knowledge of the reference and therefore was determined by the size of the reference. We report an alternative technique based on direct calculation of the encoded phase by recording multiple holograms. This phase information provides additional constraints to fully deconvolve the reference and the object using iterative phase retrieval algorithms. In numerical simulations we observe rapid convergence of this new reference-guided phase retrieval method which also shows high immunity against noise. We present two different experimental implementations and their results to demonstrate the feasibility of the concept.

1The experiments were carried at SSRL. Both SSRL and the conducted research are supported by the U. S. Department of Energy, Office of Basic Energy Sciences.
12:39PM Q27.00008 New Method for Inverting X-ray Holographs , YUHAO WANG, New Jersey Institute of Technology, JIANMING BAI, University of Tennessee, TREVOR A. TYSON, New Jersey Institute of Technology, PETER SIDDONS, GIANLUIGI DE GERONIMO, Brookhaven National Laboratory — The matrix solving method is a new class of methods to be applied to inverting an x-ray hologram for obtaining real space structures. The method is shown to provide better resolution and more flexibility than Fourier transform methods. Simulations suggest that non-direct scheme non-indirect scheme x-ray fluorescence hologram, measured with both fixed light source and fixed detector can be inverted with the matrix solving method. Applying pre-determined non negative restrictions can improve the spatial resolution and approach the wavelength of the measuring x-rays. Experimental details and methods for measuring x-ray florescence holography with the matrix solving inversion is discussed. This work is supported by NSF DMR grant MRI-0722730.

12:51PM Q27.00009 Growth and characterization of high k ZrO$_2$ on Ge (100) , ABDUL RUMAIZ, GABRIELLA CARINI, PETER SIDDONS, NSLS, Brookhaven National Laboratory, JOSEPH WOICIK, NIST, PAVEL REHAK, Brookhaven National Laboratory — The higher mobility of carriers combined with a low effective mass in Ge as compared to Si has generated a lot of interest in Ge based devices. This is particularly so in X-ray radiation detectors where Si based detectors become transparent at higher energy. The challenge in realizing a Ge based detector is having a robust barrier oxide. GeO$_2$ is the candidate oxide of choice for Ge. We have grown high k ZrO$_2$ on Ge (100) using direct metal sputtering followed by UV oxidation [1]. High energy X-ray photoelectron spectroscopy (XPS) was performed to study the oxidation state of ZrO2 as well as the interface with Ge. A simple structure with Ge/GeO$_2$/ZrO$_2$ (25 nm)/Al (200 nm) was created. A significant hysteresis was observed in the capacitance-voltage measurement which is indicative of some interface states [2]. The effect of the intermediate layer between ZrO2 and Ge on the interface states will be addressed. Valence band measurement done using high energy XPS will be discussed. [1] C. O. Chui, S. Ramanathan, B. B. Triplett, P. C. McIntrye and K. C. Sarawat, IEEE Electron Dev. Lett. 28, 473 (2002) [2] H. Kim, C.O. Chui, K. C. Sarawat and P.C. McIntrye, Appl. Phys. Lett. 83, 2647 (2003)

1:03PM Q27.00010 High-field pulsed magnet instruments for x-ray studies of materials at the Advanced Photon Source , ZAHIRUL ISLAM, Argone National Laboratory (ANL), J.P.C. RUFF, McMaster University, Y. MATSUDA, ISSP, University of Tokyo, Z. QU, Tulane University, H. NOJIRI, Tohoku University, B.D. GAULIN, McMaster University, S. YOSHII, Tohoku University, Z. MAO, Tulane University, J.C. LANG, ANL — High-field pulsed magnets are not the solution to x-ray studies of all problems requiring high magnetic fields, but, they are the only option to many. We present a very high-field pulsed magnet system for x-ray studies of materials at the Advanced Photon Source (APS). The high-field instruments for x-ray studies are unique in the United States. Currently, 30 Tesla split-coil and long-pulse solenoids are in use for scattering and spectroscopic experiments, respectively. The coils are made of CuAg wires. Pulsed fields (1-10 ms in duration) are generated using a configurable bipolar capacitor bank (40 kJ). For scattering studies split coils are mounted on the cold finger of a 10-20 minutes for peak fields in the range of 20-30 Tesla. Time-resolved scattering data are typically collected using a fast APD detector. Initial scattering studies of a geometrically frustrated magnet will be presented.

1:15PM Q27.00011 Longitudinal and Transverse Components in the X-ray Resonant Magnetic Reflectivity Experiment , J.-S. LEE, E. VESCOVO, C.-C. KAO, NSLS, J.-M. BEAUJOUR, A.D. KENT, NYU, H. JANG, J.-Y. KIM, J.-H. PARK, POSTECH, PLS COLLABORATION — X-Ray Resonant Magnetic Reflectivity (XMR) is a powerful tool: It allows to simultaneously probe the structural and the magnetic properties of complex multilayer structures. It is often advantageous to utilize circular polarized synchrotron radiation to obtain magnetic information. Unfortunately, in XRMR measurement using circular polarization, the transverse and longitudinal components are intrinsically mixed, making a proper vector-analysis of the magnetization usually impossible. In this work, we strive to overcome this restriction. In particular, we demonstrate how to effectively separate the transverse and longitudinal components in the scattering experiment using circular polarized light. This is accomplished by taking advantage of x-ray interference effects which fully suppress the longitudinal component at all angles where the magnetic asymmetry ratio is null. At these angles only the purely transverse component is therefore left in the data.

1:27PM Q27.00012 Monte-Carlo Resampling Analysis of Neutron and X-ray Reflection Data , F. HEINRICH, Carnegie Mellon University, Pittsburgh, PA, and NIST Center for Neutron Research, Gaithersburg, MD, P. SHEKHAR, Carnegie Mellon University, Pittsburgh, PA, P. KIENZLE, NIST Center for Neutron Research, Gaithersburg, MD, M. LOESCHE, Carnegie Mellon University, Pittsburgh, PA, and NIST Center for Neutron Research, Gaithersburg, MD — In most cases, reflectivity data analysis relies on the use of a structural model with reasonable constraints. Commonly, parameter confidence intervals are estimated, and the choice of the adequate model solely relies on the of the experimenter. We present the implementation of the Monte-Carlo resampling technique for X-ray and neutron reflectivity data analysis. We introduce an algorithm which samples the phase and the amplitude of the complex coefficient of the plane waves in the multiple scattering equations. We use this algorithm to reconstruct the phase of a dielectric mirror, and of a nematic liquid crystal cell. We also implement the same algorithm to perform a deconvolution of a rough surface. We then compare the results obtained with this algorithm with those obtained with direct solution of the matrix. The proposed algorithm is an efficient and easy to use method to get a first estimation of how the specular component of the reflection may depend on the membrane roughness. The algorithm has been implemented for X-ray and neutron data analysis.

1:39PM Q27.00013 Scattering Hybrid Metal-Single Crystal Slit for Small Angle X-ray Scattering and High Resolution X-ray Diffraction, YOULI LI, University of California Santa Barbara, ROY BECK, TUO HUANG, MYUNG CHUL CHOI, MORITO DIVINAGRACIA — A simple hybrid design has been developed to produce effectively scattering aperture slits for small angle x-ray scattering (SAXS) and high resolution x-ray diffraction. The hybrid slit consists of a single crystal (Si, Ge) edge bonded to a tapered high density metal base. The beam-defining single crystal tip is oriented at a large tilt angle with respect to the beam and far from any Bragg peak position, and hence should produce no slit scattering commonly associated with conventional metal slits. The scattering performance of the new slit design was confirmed by experiments conducted with laboratory x-ray sources as well as third generation synchrotron radiation. The new scattering slits have been successfully used for SAXS application, where it led to a greatly simplified Single Aperture SAXS design with dramatically increased intensity (3-fold observed) as well as improved low angle resolution compared to a conventional three-pinhole set up. Supported by NSF MRI Development grant DMR-0619171.

1:51PM Q27.00014 Resonant soft x-ray scattering from Cu valence modulations in oxygen ordered YBCO , DAVID HAWTHORN, University of Waterloo, K.M. SHEN, Cornell University, J. GECK, IFW-Dresden, D.C. PEETS, H. WADATI, RUIXING LIANG, D.A. BOWN, W.N. HARDY, G.A. SAWATZKY, University of British Columbia, J. OKAMOTO, D.J. HUANG, H.-J. LIN, NSRRC, Taiwan, JONATHAN DENLININGER, Lawrence Berkeley National Laboratory — Recently resonant elastic soft x-ray scattering (RSXS) has emerged as a powerful new tool to study electronic ordering in materials like cuprates and manganites. The power of this technique is to combine x-ray scattering, which is sensitive to spatial order, with x-ray spectroscopy, which is sensitive to the valence, spin and orbital symmetry of specific atoms. This combination allows one to probe very directly and considerable detail a variety of exotic spin, charge, orbital or structural ordering phenomena. I will discuss the application of this technique to an important test case, oxygen ordering in YBCO. In this system we are able to accurately calculate the energy dependence of the scattering intensity, providing a basis for understanding the spectroscopy of more complex systems.
2:03PM Q27.00015 Phase Separation of Water/Glycerol Binary Mixtures Next to Lipid Monolayers – An X-ray and Neutron Reflectivity Study1, LUKA POCIVAVSEK, BRIAN LEAHY, MATI MERON, BINHUA LIN, The University of Chicago, JAREK MAJEWSKI, LANL, KA YEE LEE, The University of Chicago. We recently developed a general model for studying instabilities like wrinkling and folding in interfacial membranes on fluid substrates. The dominant length scales describing the instability are set by the elastic response of the membrane (primarily bending) and the “stiffness” of the substrate. These length scales, like the wrinkle wavelength and fold amplitude, are independent of the particular interfacial molecular interactions for micron thick membranes where typical system energies like the membrane bending stiffness are thousands of times larger than intermolecular potentials. However, as the membranes become thinner and thinner and eventually approach molecular membranes only a couple of nanometers thin, the chemical interaction between the membrane and the fluid substrate strongly influence the wrinkling and folding length scales. We present data for two such systems (a lipid monolayer and a gold nanoparticle layer) on different hydrogen bonding fluids and discuss possible mechanisms and modifications of our wrinkle-to-fold scaling laws to account for this new degree of freedom.

11:15AM Q28.00001 Carbon Dioxide Capture in Microporous Metal-Organic Frameworks . JEFFREY R. LONG, University of California, Berkeley — Metal-organic frameworks represent a new class of materials exhibiting high internal surface areas, tunable pore dimensions, and tailorable surface functionality. Research in our laboratory has focused on the development of metal-organic frameworks with surfaces bearing open metal coordination sites for high-enthalpy hydrogen adsorption. Recently, we have initiated efforts to utilize such materials for the selective capture of CO2 from flue gas. Here, open metal coordination sites can deliver a high CO2 loading capacity at low pressures. However, additional criteria, such as water stability and the selective binding of CO2 over N2, must also be taken into consideration. Towards that end, we have targeted air- and water-stable frameworks bearing surfaces coated with amine groups. For example, the use of 1,3,5-benzenetristriazolato (BTri)3− as a bridging ligand has led to sodalite-type frameworks such as HCu[(CuCl)3(BTC)]3, possessing open Cu2+ coordination sites and exhibiting good chemical and thermal stability. Attachment of ethylenediamine to the Cu2+ sites within this structure generates a material that selectively binds small amounts of CO2 over N2. Details of the characterization of this and related materials will be presented.

11:51AM Q28.00002 Hydrogen storage in a metal-organic-framework structure from a nonempirical van der Waals density functional approach1, LINGZHU KONG, Rutgers, VALENTINO C. COOPER, Rutgers & ORNL, NOUR NIJEM, YVES J. CHABAL, UT Dallas, KUNHAO LI, JING LI, DAVID C. LANGRETH, Rutgers — Hydrogen adsorption in the metal-organic-framework structure Zn2(BDC)2(TED) (BDC=benzenedicarboxylate; TED=triethylendiamine) is studied using a van der Waals-density-functional approach. Two types of adsorption sites are located in the structure. The binding energies and the number of such sites are in good agreement with the values obtained from the experimental isotherms and isosteric heat of adsorption. The stretching mode frequency of the adsorbed H2 is calculated for various H–H bond orientations at the two positions. The frequency changes by approximately ~90 cm−1 for the strongest binding direction at each of the two points, which is consistent with the measured infrared absorption band measured at 4120 cm−1 at room temperature and high pressures (300-800 psi).

12:03PM Q28.00003 Enhanced H2 adsorption in metal-organic frameworks with open metal sites: Binding mechanism and strong dependence on metal ions1, WEI ZHOU, HUI WU, NIST and Univ. of Maryland, TANNER YILDIRIM, NIST and University of Pennsylvania — Metal-organic frameworks (MOFs) with open metal sites exhibit much stronger H2 binding strength than classical MOFs, due to the direct interaction between H2 and the coordinately unsaturated metal ions. [1] Here we will present a systematic study of the H2 adsorption on a series of isostructural MOFs, M2(H2)2 with open metal sites M = Mg, Mn, Co, Ni, Zn. The experimental, initial isosteric heats of adsorption for H2 (Qst) of these MOFs range from 8.5 to 12.9 KJ/mol, with increasing Qst in the following order: Zn, Mn, Mg, Co, and Ni. [2] The H2 binding energies derived from first-principles calculations follow the same trend as the experimental observation on Qst, confirming the electrostatic Coulomb attraction between the H2 and the open metal sites being the major interaction. We also found a strong correlation between the metal ion radius, the M-H2 binding strength and the coordinately unsaturated metal ions. [1] J. Phys. Chem. C, 112, 8132 (2008). [2] J. Am. Chem. Soc., 130, 15268 (2008).

12:15PM Q28.00004 Noncovalent hydrogen bonding in metal-organic structures . NORM M. TUBMAN2, JONATHAN L. DUBOIS, RANDOLPH Q. HOOD, SEBASTIEN HAMEL, ERIC R. SCHWEGLER, Lawrence Livermore National Laboratory — Transition metal sites in metal-organic frameworks and in doped carbon structures are actively being studied for their potential properties of molecular hydrogen. We present a study of prototypical metal-organic structures that can be used to bind molecular hydrogen non-covalently. Due to the well known limitations of current density functional theory based descriptions of non-covalent hydrogen bonding we have focused our efforts on a consistent many-body approach based on the fixed-node diffusion Monte Carlo method. Accurate studies of binding energies and the effects of multiple hydrogens in these structures are presented. Prepared by LLNL under Contract DE-AC52-07NA27344

12:27PM Q28.00005 Pd-assisted hydrogen spillover on graphene and carbonanotubes . SA LI, PURU JENA, Virginia Commonwealth University, VIRGINIA COMMONWÉALTH UNIVERSITY TEAM — Addition of a small amount of Pd precursors on carbon nanotubes has recently been found to substantially improve the hydrogen uptake. In spite of several attempts, a fundamental understanding of how the catalyst works has remained unattainable. Using first principles methods we have investigated hydrogen spillover on Pd-doped graphene and (8,8) carbon nanotube. Through molecular dynamics (MD) simulations, we found that each Pd can bind to three pairs of hydrogen molecules on graphene and only one pair of hydrogen molecule on (8,8) nanotube at 300K. This difference is attributed to the effect of curvature. The hydrogen molecules were found to dissociate and bind to carbon surface once the Pd atom is saturated with hydrogen. These results provide important new insight to understand hydrogen spillover on carbon based materials.
12:39PM Q28.00006 Calcium-Decorated Carbon Nanotubes for Hydrogen Storage1, HOONKYUNG LEE, University of California Berkeley, JISOON IHM, Seoul National University, MARVIN L. COHEN, STEVEN G. LOÜIE, University of California Berkeley — Using the first-principles pseudopotential density-functional method, we carry out a systematic search for high-capacity hydrogen storage media based on individually dispersed calcium atoms on carbon nanotubes (CNTs). We find that Ca clustering is suppressed on boron-doped and defective carbon nanotubes and that up to six H2 molecules can bind to a Ca atom with a binding energy of ~0.2 eV/H2. We show that Ca-decorated CNTs with a concentration of ~6 at. % B doping can reach the gravimetric capacity of ~5 wt % hydrogen storage. We also will discuss the binding mechanism of the H2 molecules.

1This research was supported by the NSF under Grant No. DMR07-05941 and the U.S. DOE under Contract No. DE-AC02-05CH11231. Computation resource is supported by NERSC and NERAC.

12:51PM Q28.00007 Theoretical study of hydrogen storage in Ca-coated fullerenes, QIAN SUN, Peking University and Virginia Commonwealth University, QIAN WANG, Virginia Commonwealth University, YOSHI KAWAOE, Tohoku University, PURU JENA, Virginia Commonwealth University — First principles calculations based on gradient corrected density functional theory and molecular dynamics simulations of Ca decorated fullerene yield some novel results: (1) C60 fullerene decorated with 32 Ca atoms on each of its 20 hexagonal and 12 pentagonal faces is extremely stable. Unlike transition metal atoms that tend to cluster on a fullerene surface, Ca atoms remain isolated even at high temperatures. (2) C60Ca32 can absorb up to 62 H2 molecules in two layers. The first 30 H2 molecules dissociate and bind atomically on the 60 triangular faces of the fullerene with an average binding energy of 0.45 eV/H2, while the remaining 32 H2 molecules bond on the second layer quasi-molecularly with an average binding energy of 0.11 eV/H2. These binding energies are ideal for Ca coated C60 to operate as a hydrogen storage material at near ambient temperatures with fast kinetics. (3) The gravimetric density of this hydrogen storage material can reach 5.8 wt %. Simple model calculations show that this density is the limiting value for higher fullerenes.

1:03PM Q28.00008 Rotor in a Cage: Infrared Spectroscopy of an Endohedral Hydrogen-Fullerene Complex1, TOOMAS RÕOM, MIN GE, D. HÜVONEN, U. NAGEL, NICPB, Akademia tee 23, 12618 Tallinn, Estonia, S. MAMONE, A. DANIOUGNY, F. CUIDA, M. C. GROSSEL, M. CARRAVETTA, M. H. LEVITT, School of Chemistry, Southampton University, Southampton SO17 1BJ, UK, Y. MURATA, K. KOMATSU, Institute for Chemical Research, Kyoto University, Kyoto 611-0011, Japan — We report the observation of quantized translational and rotational motion of molecular hydrogen inside the cages of C60. Narrow infrared absorption lines at the temperature of 6 K correspond to vibrational excitations in combination with translational and rotational excitations and show well-resolved splittings due to the coupling between translational and rotational modes of the endohedral H2 molecule. A theoretical model shows that H2 inside C60 is a three-dimensional quantum rotor moving in a nearly spherical potential. The theory provides both the frequencies and the intensities of the observed infrared transitions. Good agreement with the experimental results is obtained by fitting a small number of empirical parameters to describe the confined potential, as well as the ortho to para ratio at 6 K and at elevated temperatures [S. Mamone, et al., arXiv:0807.1589v2].

1:15PM Q28.00009 Hydrogen storage in charge compensated organic molecular crystals, MINA YOON, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany and Oak Ridge National Laboratory, USA, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — We propose charge compensated organic molecular crystals as a promising class of materials for hydrogen storage. Using quantum mechanical first-principles calculations based on numerical atom-centered orbitals as all-electron basis functions [1] we study the basic structural properties of molecular crystals consisting of parallel sheets of cations and anions (such as DMPH and TCNQ) stacked alternatingly. The long range dispersion interactions between the cations and anions, which are important for the stability of the crystals, were studied and compared using various DFT xc functionals, semi-empirical approach [2], and Møller-Plesset perturbation theory. The molecular configuration causes accumulation of electrons at acceptors and depletion at donors, which results in finite dipolar fields. Our study indicates that these fields make it possible to use charge compensated organic molecular crystals for hydrogen storage.

[1] V. Blum et al., FH ab initio molecular simulations (FH-aims) project.

1:27PM Q28.00010 Mg-doped GaN nanostructures: Energetics, magnetism and H2 adsorption, QIAN WANG, Virginia Commonwealth University, QIAN SUN, Peking University and Virginia Commonwealth University, PURU JENA, Virginia Commonwealth University — It has been shown that p-type GaN can greatly improve the performance of GaN-based devices. Mg is a suitable candidate dopant for p-type GaN. Since the ionic radius of Mg is comparable with that of Ga, Mg doping can be expected to eliminate self-compensation effects. Thus, synthesis of Mg-doped p-type GaN for fabrication of optoelectronic devices has been hotly pursued. Using density functional theory and generalized gradient approximation for exchange and correlation potential we show that Mg doped GaN nanocage and nanotube can be magnetic with Mg contributed spins distributed over the neighboring N sites. Mg atoms show no tendency for clustering and due to the positive charge residing on them; they can trap hydrogen in molecular form via the charge polarization mechanism. The binding energies of hydrogen lie in the range of 0.1–0.2 eV/H2 which are ideal for storage applications under ambient thermodynamic conditions.

1:39PM Q28.00011 The USDOE Hydrogen Program: Status and Performance Gaps of On-board Hydrogen Storage Technologies, GRACE ORDAZ, MONTEREY GARDINER, CAROLE READ, U.S. Dept. of Energy, NED STETSON, U.S. Dept. of Energy — The USDOE Hydrogen Program’s mission is to reduce oil use and carbon emissions in the US transportation sector and to enable clean, reliable energy for stationary and portable power generation. The requirements for vehicular hydrogen storage continue to be one of the most technically challenging barriers to the widespread commercialization of hydrogen fueled vehicles. The DOE applied hydrogen storage activity focuses primarily on the research and development of low-pressure, materials-based technologies to allow for a North American market driving range of more than 300 miles (500 km) while meeting packaging, cost, safety, and performance requirements to be competitive with current vehicles. This presentation summarizes the status, recent accomplishments and current performance gaps of hydrogen storage technologies primarily for transportation applications. Materials projects are focused in three main areas: metal hydrides, chemical hydrogen storage materials, and hydrogen sorbents. A new effort is the Hydrogen Storage Engineering Center of Excellence which will provide a coordinated approach to the engineering research and development of on-board storage and refueling systems. The presentation will especially highlight topics emphasized in the session theme.

Kagome compounds, AMBESH DIXIT, C. SUDAKAR, Department of Physics and Astronomy, Wayne State University, N. ROGADO, DuPont, E. GROSON, Rice University, R.J. CAVA, Princeton University, A.P. RAMIREZ, LGS Innovations, GAVIN LAIVES, Department of Physics and Astronomy, Wayne State University — The transition metal vanadate oxides having a staircase Kagome lattice structure exhibit rich magnetic phase diagrams, which arise from the complex geometry of these materials. Among these compounds, Ni$_3$V$_2$O$_6$ is particularly widely studied, as it develops simultaneous ferroelectric and incommensurate magnetic ordering at a single phase transition. In order to investigate the low frequency spin dynamics in these layered materials, we have probed the ac magnetic properties in these systems. We find that the Cu, Co, and Mn systems display strong magnetic relaxation in a spin ordered phase, with activation energies on the order of hundreds of Kelvin. We discuss these results in the context of spin-glass behaviour and domain wall motion.

1:03PM Q29.00008 Effect of Zn doping on the phase transition temperatures of Ni$_3$V$_2$O$_6$, AKILA KUMARASIRI, PARASHU KHAREL, AMBESH DIXIT, GAVIN LAIVES, Department of Physics and Astronomy, Wayne State University, Detroit, MI 48221 — There is a considerable interest in understanding the nature of magnetic phase transition in geometrically frustrated materials. Ni$_3$V$_2$O$_6$ is one such system, with spin-1 Ni$^{2+}$ ions forming a layered buckled Kagome structure. We have studied the effects of doping spin-0 Zn ions on the magnetic phase transitions of powder Ni$_{1-x}$Zn$_x$V$_2$O$_6$ using dielectric and heat capacity measurements. (Ni$_{1-x}$Zn$_x$)$_2$V$_2$O$_6$ powder samples were synthesized starting with a mixture of Ni, V and Zn metal organic solutions mixed at appropriate atomic ratio. XRD and Raman studies show that (Ni$_{1-x}$Zn$_x$)$_2$V$_2$O$_6$ powder samples annealed at 1000°C crystallize in Ni$_2$V$_2$O$_6$ structure without forming any secondary phases. We have observed from heat capacity measurements that the phase transitions $T_H$, $T_d$, and $T_C$ at 9.2K, 6.4K, and 3.9K expected for Ni$_2$V$_2$O$_6$ are present in our (Ni$_{1-x}$Zn$_x$)$_2$V$_2$O$_6$ samples up to a Zn concentration of 20%. The transition at 2.4 K was not clearly observed. All three transitions shift toward lower temperatures with an increase in Zn concentration. We will present the experimental results on the strong suppression of both $T_H$ and $T_d$ due to dilution of Ni$_2$V$_2$O$_6$ with non-magnetic Zn. We will present a quantitative comparison of this suppression with the 2D Ising and Heisenberg models.

1:15PM Q29.00009 Electrical control of direction of orbital stripes in charge-ordered state of single-layered manganite La$_{1/2}$Sr$_{3/2}$MnO$_4$, SHOTA KONNO, Department of Physics, Tohoku University, KOUJI TANIGUCHI, HAJIME SAGAYAMA, TAKA-HISA ARIMA, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University — Electrical control of the localized electron such as an electric-field induced metal-insulator transition in charge-orbital ordered (COO) state of perovskite-related manganese oxides has been intensively studied, since the large electroresistance effect in Pr$_{0.7}$Ca$_{0.3}$MnO$_3$ was reported[1]. Moreover, the formation of orbital stripes in the COO state gives rise to in-plane anisotropies in the electrical, magnetic, and optical properties. However, there are few reports on controlling anisotropic properties in the COO state. We report an electric-field effect on the in-plane anisotropy in the COO state of a layered manganite La$_{1/2}$Sr$_{3/2}$MnO$_4$. After applying an electric field, a 90-degree rotation of COO states has been observed by using a polarizing microscope. A drastic change of the volumes of two COO domains was confirmed by means of synchrotron X-ray diffraction. [1]A. Asamitsu et al., Nature 388, 50(1997).

1:27PM Q29.00010 Intersite charge transfer in the $A$-site-ordered LaCu$_8$Fe$_4$O$_{12}$ perovskite, YOUEEN LONG, Institute for Chemical Research, Kyoto University, NAOAKI HAYASHI, Graduate School of Human and Environmental Studies, Kyoto University, TAKASHI SAITO, MASAKI AZUMA, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University — A novel transition metal oxide LaCu$_8$Fe$_4$O$_{12}$ was prepared at 10 GPa and 1400 K. It crystallizes an orthorhombic $I4/mmm$ structure. With an increase of the La content the materials became oxygen stoichiometric and a lowering of the crystal structure without forming any secondary phases. We have observed from heat capacity measurements that the phase transitions $T_H$ and $T_d$ at 9.2K, 6.4K, and 3.9K expected for Ni$_2$V$_2$O$_6$ are present in our (Ni$_{1-x}$Zn$_x$)$_2$V$_2$O$_6$ samples up to a Zn concentration of 20%. The transition at 2.4 K was not clearly observed. All three transitions shift toward lower temperatures with an increase in Zn concentration. We will present the experimental results on the strong suppression of both $T_H$ and $T_d$ due to dilution of Ni$_2$V$_2$O$_6$ with non-magnetic Zn. We will present a quantitative comparison of this suppression with the 2D Ising and Heisenberg models.

1:39PM Q29.00011 $A$-site Magnetism in Perovskites CaCu$_3$B$_2$O$_{12}$ ($B$ = Ge, Ti, Sn). TAKASHI SAITO, HIROSHI SHIRAKI, YUICHI SHIMAKAWA, Kyoto University, MASAICHIRO MIZUMAKI, Japan Synchrotron Radiation Research Institute — $A$-site-ordered perovskites CaCu$_3$Ge$_2$O$_{12}$ and CaCu$_3$Sn$_2$O$_{12}$, both isosstructural to antiferromagnetic CaCu$_3$Ti$_2$O$_{12}$, were found to be ferromagnets, which are very rare in cuprates. All of these materials may be called "$A$-site magnets", since they contain magnetic species only at the $A$-site of the perovskite ABO$_3$ structure. The ferromagneticism of CaCu$_3$B$_2$O$_{12}$ ($B$ = Ge, Sn) is attributed to the ferromagnetic direct exchange interaction, whereas antiferromagnetic superexchange interaction, due to the Cu(3d)-O(2p)-Ti(3d) orbital hybridization, is dominant in antiferromagnetic CaCu$_3$Ti$_2$O$_{12}$. The $A$-site magnetism is controlled by the electronic structure of the non-magnetic B-site. Solid solutions CaCu$_3$(Ge,Ti)$_2$O$_{12}$ and CaCu$_3$(Ti,Sn)$_2$O$_{12}$ display phase boundary between ferromagnetic and antiferromagnetic phases. [1] H. Shiraki, T. Saito, Y. Shimakawa et al., Phys. Rev. B, 76 (2007) 140403. [2] Y. Shimakawa, H. Shiraki and T. Saito, J. Phys. Soc. Jpn., 77 (2008) 113602.

1:51PM Q29.00012 Structure and properties of high-oxygen-pressure annealed Sr$_{1-x}$La$_x$Co$_{0.5}$Fe$_{0.5}$O$_{3-d}$ (0<x<0.5), S. REMSEN, K. SWIERCZEK, B. DABROWSKI, L. SUESCUN, S. KOLESNIK, Department of Physics, Northern Illinois University, DeKalb, IL and Materials Science Division, Argonne National Laboratory, Argonne, IL — Synthesis, oxygen content, structural, magnetic, and resistive properties will be discussed for the Sr$_{1-x}$La$_x$Co$_{0.5}$Fe$_{0.5}$O$_{3-d}$ perovskites. The x=0 sample shows oxygen-vacancy ordered Sr$_x$Co$_{0.5}$Fe$_{0.5}$O$_{2.75}$ tetragonal $I4/m$ structure. With an increase of the La content the materials become oxygen stoichiometric and a lowering of the crystal symmetry is observed from cubic Pm3m (x=0.1 and 0.2) to tetragonal $I4/mcm$ (x<0.3 and 0.4), and finally to monoclinic $I2/c$ (x>0.5). All samples show ferromagnetic ordering with the maximum Curie temperature near 290 K at x=0.2. Conductivity is enhanced and small negative magneto-resistance is observed below T$_C$. Transport measurements up to 1100°C show high conductivity that is affected by the varying oxygen content. Work at NIU was supported by the NSF (DMR-0706610) and at ANL by the U.S. DOE under contract No. DE-AC02-06CH11357.
11:15AM Q30.00001 Colossal ionic conductivity at ZrO$_2$:Y,O$_3$ /SrTiO$_3$ interfaces. JACOBO SANTAMARIA, J. GARCIA BARRIOCANAL, A. RIVERA CALZADA, Z. SEFRIOU, L. LEON, CFMC, Universidad Complutense de Madrid, Madrid 28040, Spain, E. IBORRA, Universidad Politécnica de Madrid. Madrid 28040, Spain., M. VARELA, S.J. PENNYCOOK, Materials Science & Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — We describe the strong enhancement of the conductivity occurring at the interfaces of superlattices made by alternating 10 nm strontium titanate and 1 nm yttria stabilized zirconia (YSZ) layers. Conductivity is found to be as high as 0.014 S/cm at 357 K, with a substantial decrease of the activation energy for the dc ionic conductivity from 1.1 eV down to 0.64 eV. EELS analysis is consistent with a large number of interfacial oxygen vacancies and high disorder in the interface oxygen plane between YSZ and STO layers. Our results demonstrate that the design of suitable heterogeneous interfaces in epitaxial heterostructures might have important implications in the search of artificial nanostructures with high ionic conductivity. 

11:27AM Q30.00002 Origin of Colossal Ionic Conductivity in YSZ-STO Superlattices. TIMOTHY PENNYCOOK, MATTHEW BECK, KALMÁN VARGA, Vanderbilt University, MARIA VARELA, STEPHEN PENNYCOOK, Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University — An eight order of magnitude increase in the ionic conductivity of yttria-stabilized zirconia (YSZ) has recently been demonstrated in YSZ/strontium titanate (STO) epitaxial heterostructures. YSZ is the preferred electrolyte for solid oxide fuel cells (SOFC), in which the ionic conductivity is the major factor limiting the energy conversion efficiency. A colossal increase in the ionic conductivity, therefore, goes along way towards increasing SOFC practicality by increasing efficiency overall and reducing the operating temperature necessary for efficient operation. We report density functional calculations that explain this colossal ionic conductivity as the result of a large 7% expansive in-plane strain of the YSZ. Molecular dynamics simulations of strained zirconia yield an activation energy for ionic conduction in agreement with experiment. Additionally, simulated annealing under these strain conditions reveals a new energy structure for which EELS simulations using the Z−1 approximation for the core hole are consistent with electron energy loss spectra from the thin, coherently strained, YSZ layers of the heterostructures. This work is supported by NSF grant DMR-0513048 and DOE Office of Basic Energy Sciences, Division of Materials Science and Engineering.

11:39AM Q30.00003 Non-uniform magnetization in LaAlO$_3$/SrTiO$_3$ superlattices. M.R. FITZSIMMONS, M. ZHERNIENKO, N. HENGARTNER, LANL, A. SHARONI, IVAN K. SCHULLER, UCSD, J. GARCIA-BARRIOCANAL, F.Y. BRUNO, J. SANTA-MARIA, U. Complutense Madrid, Spain — Recently, Brinkman et al., [Nature 6, 493 (2007)] reported magnetism induced at the interface between LaAlO$_3$ (LAO) and SrTiO$_3$ (STO) inferred from transport measurements. They found the magnetization to be greatly enhanced at low temperatures (i.e., liquid He temperature) and by application of high (10+ T) fields. We report polarized neutron reflectometry measurements of the magnetization depth profile of two LAO/STO superlattices with the same number of bilayer repeats. For low temperatures and a field of 11 T, the intensities of the superlattice Bragg reflections for both samples exhibited a dependence upon neutron beam polarization. The spin dependence was much weaker at small field (and low temperature) and disappeared altogether at 11 T and 300 K. These observations demonstrate that the magnetization depth profile has the period of the LAO/STO superlattice. The neutron spin dependence was more pronounced for the sample with a thin LAO layer compared to one with a thick LAO layer, suggesting that the magnetism may be interfacial in origin.

11:51AM Q30.00004 How to make a cuprate Fermi surface out of a nickelate heterostructure, OLE KROGH ANDERSEN, Max-Planck Institute for Solid-State Research — Chaloupka and Khalilullin had the idea that it might be possible to make Ni$^{3+}$-based high-temperature superconductors by sandwiching NiO$_2$ layers between insulating layers through heterostructuring. Provided that spin-, charge-, and orbital ordering can be avoided, the confinement should make it possible to empty the Ni 3z$^2$−1 band, thus leaving the conduction electron in the Ni 2x$^2$ − y$^2$ band. Fabrication of such heterostructures are now being pursued in many laboratories. We have attempted to give theoretical guidance by performing calculations for numerous heterostructures using the local density-approximation in combination with static (LDA+U) and dynamical (LDA+DMFT) mean-field theory. We show how confinement together with electronic correlations can lead to a single-sheet Fermi surface with a shape like that of the cuprate superconductors with the highest transition temperatures; the Ni 3z$^2$−1 Wannier orbital now plays the role of the axial, Cu 4s-like orbital in the cuprates.

Since also strong antiferromagnetic fluctuations are present, the low-energy electronic and spin excitations should resemble those of high-temperature cuprate superconductors. Chemical modification of the insulating layers should make it possible to avoid spin-, charge-, and orbital ordering.

12:27PM Q30.00005 Interfaces in La$_2$NiO$_4$ − La$_2$CuO$_4$ superlattices, S. SMADICI, J. C. T. LEE, S. WANG, P. ABBAMONTE, University of Illinois at Urbana-Champaign, IL 61801, G. LOGVEÑOV, A. GOZAR, I. BOZOVIC, Brookhaven National Laboratory, Upton, NY 11973 — Ni substitution on Cu sites in underdoped La$_2$−xSr$_x$CuO$_4$ quickly restores Neel order. This was attributed to strong interaction between the Ni and doped holes. An open question was whether the additional Ni empty orbital or the different spin on Ni sites was at the origin of this strong interaction. We have addressed this problem with resonant soft x-ray scattering on the La$_2$NiO$_4$ − La$_2$CuO$_4$ heterostructure. La$_2$NiO$_4$ and La$_2$CuO$_4$ have close lattice structures and electronic configurations. However, the x-ray scattering contrast between superlattice layers is greatly enhanced at soft x-ray resonant energies. Here we report our measurements at the O K, Cu L, and Ni L edges of a model of the charge, orbital and spin structures in these superlattices will be presented with a special emphasis on the interface region. This work was supported by Grants. DE-FG02-06ER46285, DE-AC02-98CH10886, MA-509-MACA, DE-FG02-07ER46453 and DE-FG02-07ER46471.

12:39PM Q30.00006 Layer-by-layer growth by pulsed laser deposition in the unit-cell limit. M. KAREEV, University of Arkansas, S. PROSANDEEV, J. LIU, P. RYAN, J.W. FREELAND, J. CHAKHALIAN — Unlike conventional growth of complex oxide heterostructures, the ultimate unit cell limit imposes strict constrains for a multitude of parameters critical to layer-by-layer growth. Here we report on detailed analysis of far-from-equilibrium growth by interrupted pulsed laser deposition with application to RENiO$_3$/LaAlO$_3$ superlattices grown on a diverse set of substrates SrTiO$_3$, NdGaO$_3$, LSAT and LaAlO$_3$. A combination of in-situ high-pressure RHEED and AFM along with extensive data obtained from synchrotron based XRD and resonant XAS allows us critically assess the role of RHEED intensity oscillation and the effect of a polar/non-polar interface on the heteroepitaxial growth. The role of defects formed during the initial stages of growth is also addressed.

Work at the Advanced Photon Source, Argonne is supported by the U.S. Department of Energy, Office of Science under Contract No. DE-AC02-06CH11357. J.C. was supported by DOD-ARO under the Contract No. 0402-17291 and NSF Contract No. DMR-0747808.
12:51PM Q30.00007 Perfect dc conductance of a finite width Mott insulator sandwiched between metallic leads at zero temperature: a quantum emergent phenomenon in strongly correlated multilayers\(^1\), HAND ZENIA, JIM FREERICKS, Department of Physics, Georgetown University, Washington, DC 20057 USA, HULIKAL KRISHNAMURTHY, Centre for Condensed Matter Theory, Department of Physics, Indian Institute of Science, Bangalore 560012, India, THOMAS PRUSCHKE, Institute for Theoretical Physics, University of Göttingen, Friedrich-Hund-Platz 1, D-37077 Göttingen, Germany — Self-consistent inhomogeneous DMFT calculations as well as analytical investigations of the electronic structure of a multilayered device are presented. The device consists of two semi-infinite leads of a ballistic metal that sandwich an interacting barrier. The interactions in the barrier are described by the Hubbard model with the whole system particle-hole symmetric. We find that for a finite barrier no matter how strong the interaction, the system becomes a Fermi liquid with a perfect metallic conductivity at low enough temperature. We argue that at zero temperature and frequency the Luttinger theorem holds and that the system has a well defined Fermi surface. The perfect conductive state may be extremely fragile to finite temperature, finite driving electric fields, finite driving frequencies, or disorder, so it will often be difficult to see experimentally. We will discuss possible experimental realizations of the phenomena

1:03PM Q30.00008 Strongly Interacting Electrons at the Oxide Interfaces\(^1\), JACQUES CHAKHALIAN, University of Arkansas — Utilizing the recent advances in complex oxide synthesis, one can now combine materials with antagonistic order parameters to create new compounds in the form of heterostructures often with properties not attainable in the bulk\(^1\). Broken symmetries, strain, and modified local environment at the interface provide a unique route to manipulate the subtle energy balance in correlated materials with promise to create novel material phases and quantum states. Here we report on how the interface can be used to alter electronic, magnetic and orbital structure of multilayers composed of late transition metal oxides with specific examples from cuprates, manganites and nickelates. We will discuss the underlying challenges in growth of ultra-thin layers of complex oxides and illustrate the ways synchrotron based resonant x-ray spectroscopies and resonant x-ray diffraction can be used to probe bulk vs. interface properties to gain unique insight into the underlying physics. J. Chakhalian et al, Science, v. 314, 1114, (2007).

1:39PM Q30.00009 X-ray standing wave photoemission from multilayer nanostructures\(^1\), C. PAPP, B. BALKE, LBNL, C. SAKAI, S. UEDA, H. YOSHIKAWA, Y. YAMASHITA, S. L. HE, K. KOBAYASHI, SPRing 8, G. CONTI, Applied Materials, D. BUEGLER, C. SCHNEIDER, Juelich Research Center, C. S. FADLEY, UC Davis/LBNL, S. DOERING, U. BERGES, C. WESTPHAL, TU Dortmund — We have used soft and hard x-ray standing wave excitation of photoelectrons to study buried layers and interfaces in multilayer nanostructures. The samples were grown on synthetic multilayer mirrors, and the x-ray incidence was tuned to 1\(^st\) order Bragg reflection. Scanning angle, photon energy, or distance along a wedge profile in the sample permits scanning the resultant standing wave field through nm-scale structures and analyzing the depth distribution of their chemical, electronic, magnetic, and structural properties. Using harder x-ray excitation permits via the higher kinetic energy of the electrons studying those properties at greater depths. The systems discussed will be two related to magnetic tunnel junctions (magnesium oxide/iron and STO/LSMO), and one related to integrated circuit production (titanium nitride on silicon).

1:51PM Q30.00010 Competing anisotropies and complex magnetism in SrRuO\(_3\)/SrMnO\(_3\) superlattices\(^1\), OMAR CHMAISSEM, Y. CHOI, Y.C. TSENG, D. HASKEL, D.E. BROWN, S. KOLESNIK, D. DANAHER — Using element-specific x-ray resonance techniques, we have investigated the interfacial magnetic coupling in SrRuO\(_3\)/SrMnO\(_3\) superlattices. A strong out-of-plane SRO anisotropy coupled with AFM Ru-Mn interactions result in a canted Mn structure with a significant induced net Mn moment that reduces to zero under a strong magnetic field. At \(T > T_{CSR/O}\), the SRO anisotropy is removed and the planar Mn AFM structure cants to produce a net Mn moment along the field direction. Below \(T_C\), the net development of in-plane Mn moment is suppressed by partially frustrated exchange interactions at the AFM-SMR/FM-SRO interfaces and competing Mn-Ru anisotropies. Hysteretic magnetization curves show a two-step magnetization reversal and enhanced coercivity. X-ray measurements confirm that the low-field magnetization reversal coincides with "free" Ru moments inside the SRO layers and that the high-field magnetization reversal involves the interfacial magnetization in the SMO layers and provide strong evidence for the presence of pinned SRO moments at the SRO/SMO interface.

2:03PM Q30.00011 Electrically controlled magnetization in tricolar superlattices\(^1\), JAEKWANG LEE, NA SAI, ALEXANDER A. DEMKOV, The University of Texas — With recent breakthroughs in fabricating high-quality oxide films, ultra thin ferroelectric (FE) films have attracted significant attention. Many FE-based electronic devices proposed to date have a capacitor configuration, where a FE layer is inserted between two identical metal electrodes. We consider theoretically so-called tricolor structures or asymmetric capacitors with one electrode being ferromagnetic and other normal metal. An interesting aspect of a tricolor structure is breaking of the inversion symmetry which is expected to generate new properties. The perfect conducting state may be extremely fragile to finite temperature, finite driving electric fields, finite driving frequencies, or disorder, so it will often be difficult to see experimentally. We will discuss possible experimental realizations of the phenomena

Mott transition between a spin-liquid insulator and a metal in three dimensions, DANIEL PODOLSKY, ARUN PARAMEKANTI, YONG BAEK KIM, University of Toronto, T. SENTHIL, Massachusetts Institute of Technology — We study a bandwidth controlled Mott metal-insulator transition (MIT) between a Fermi liquid metal and a quantum spin-liquid insulator at half-filling in three dimensions (3D). Using a slave rotor approach, and incorporating gauge field fluctuations, we find a continuous MIT and discuss the finite temperature crossovers around this critical point. We show that the specific heat $C \sim T \ln T$ at the MIT and argue that the electrical transport on the metallic side near the transition should exhibit a 'conductivity minimum' as a function of temperature. A possible candidate to test these predictions is the 3D spin liquid insulator Na$_4$Ir$_5$O$_9$ which exhibits a pressure-tuned transition into a metallic phase. We also present the electron spectral function of Na$_4$Ir$_5$O$_9$ at the transition.

Lattice vibration modes in CdCr$_2$O$_4$, J.-H. KIM, S.-H. LEE, University of Virginia, M. MATSUDA, JAEA, Japan, H. UEDA, Y. UEDA, ISSP, University of Tokyo, J.-H. CHUNG, Korea University, Korea, S. TSUTSUI, A. BARON, SPring8, Japan — In geometry frustrated magnets, spin-lattice coupling can play an important role in lifting the magnetic frustration. In order to understand the mechanism, we have performed inelastic synchrotron x-ray measurements on a single crystal of a frustrated magnet CdCr$_2$O$_4$ that undergoes such a three-dimensional spin-Peierls phase transition at $T_N = 12.5$ K. Our data taken above and below $T_N$ could be well explained by the rigid ion model, which led to a full identification of the lattice vibration modes in CdCr$_2$O$_4$. A phonon anomaly that might be associated with the transition, however, was not observed.

Crystal and magnetic structures of the three-dimensional spin-Peierls phase transition at $T_N = 12.5$ K from a cubic paramagnetic state to a tetragonal Neel state. The exact nature of the lattice distortion, and the one-to-one correspondence between the distortion and the magnetic ground state has been a long-standing issue. To unveil the mystery, we have performed synchrotron x-ray diffraction measurements on a single crystal of this compound and neutron diffraction measurements on a powder sample. Our detailed analysis of the single crystal x-ray data shows that below $T_N$ the symmetry of the crystal structure is lowered from the cubic $Fd3m$ to the tetragonal $I4/m2$ due to formation of a complex pattern of Cr-Cr clustering. The relation between the distorted crystal structure and the magnetic structure will also be discussed.

Magnetic Correlations in YBaCo$_4$O$_7$: A Frustrated Magnet with Novel Trigonal Bipyramidal Chains, JOHN MITCHELL, Argonne National Laboratory, PASCAL MANUEL, LAURENT CHAPON, ISIS Facility, PAOLO RADAELLI, Dept. of Physics, University of Oxford, HONG ZHENG, Argonne National Laboratory — Novel structural motifs generate opportunities to explore unique geometrically frustrated groundstates and their properties. One such new material, YBaCo$_4$O$_7$ (Y114), is closely related to the pyrochlore lattice, differing only in the stacking sequence of triangular layers. This alternative stacking sequence leads to chains of corner sharing trigonal bipyramids with magnetic ion vertices, a novel motif among geometrically frustrated lattices. We have studied Y114 using single crystal neutron diffraction above its ordering temperature. Strong magnetic diffuse scattering can be understood using Monte-Carlo simulations, and a simple nearest-neighbor model explains the magnetic structure. Along the c-axis, long-range order arising from the corner-sharing bipyramids create a quasi one-dimensional order at finite temperature. In contrast, the spin-spin correlation function decays rapidly in the ab-plane, following a unique short-range configuration that enforces an Ising-like order along the b-axis. Approaches to suppressing long-range order in the system will be discussed.

Specific heat of gadolinium garnets, JEFFREY QUILLIAM, SHUCHAO MENG, Department of Physics and Astronomy and Institute for Quantum Computing, University of Waterloo, Waterloo, ON, Canada, LINTON CORRUCCINI, Physics Department, University of California-Davis, Davis, California, USA, OLEG PETRENKO, Department of Physics, University of Warwick, Coventry, United Kingdom, MICHEL GINGRAS, Department of Physics and Astronomy, University of Waterloo, Waterloo, ON, Canada; Canadian Institute for Advanced Research, Toronto, ON, Canada, JAN KYCIA, Department of Physics and Astronomy and Institute for Quantum Computing, University of Waterloo, Waterloo, ON, Canada — Specific heat measurements on two different geometrically-frustrated, Heisenberg, garnet lattices will be presented. The specific heat of a compound of gadolinium garnets, GGG, is found to be consistent with previous measurements of the specific heat of GGG and shows no signs of a standard ordering anomaly despite sharp Bragg peaks that were seen in neutron diffraction experiments. A first measurement of the specific heat of polycrystalline Gd$_3$Li$_2$Te$_3$O$_{12}$, in contrast, shows a sharp first-order phase transition at 240 mK. We will discuss possible explanations for such diverse behavior in very similar systems.
12:39 PM Q31.00008 Long-range antiferromagnetic interactions in ZnFe$_2$O$_4$ and CdFe$_2$O$_4$ . CHING CHENG, Department of Physics, National Cheng Kung University, Taiwan, Taiwan. CHING-SHENG LIU, Yu-Jia Junior High School, Luzhu Shiang, Kaohsiung County 82143, Taiwan, HSUEH FANG YEH, Department of Physics, National Cheng Kung University, Tainan, Taiwan. For the first time, the Fe-Fe interactions in the well known geometrically frustrated antiferromagnets of Zn and Cadmium ferrite are determined quantitatively by considering structures of different collinear magnetic distributions using first-principles methods. Both the generalized gradient approximation (GGA) and GGA plus the onsite Coulomb interaction (GGA+U) are considered for the exchange-correlation energy functional. The interactions up to third neighbors are determined to be all antiferromagnetic regardless of which approximation scheme (GGA or GGA+U) is used. Surprisingly, the third neighbor interaction is much stronger than the second-neighbor one. The magnetic distributions have prominent effects on energies as well as density of states, including band gaps, for both normal and inverse spinel structures of these two materials. The possible magnetic distributions coincident with neutron scattering results are also investigated.

12:51 PM Q31.00009 Frustrated Quantum Antiferromagnetism on the Diamond Sublattice of A-site Magnetic Spinels . LEON BALENTS, Kavli Institute for Theoretical Physics, UCSB — Spinel crystals, with the chemical formula AB$_2$X$_4$, in which only the A atom is magnetic, realize antiferromagnetism on a diamond sublattice. We first discuss examples, such as CoAl$_2$O$_4$ and MnSc$_2$S$_4$, which exhibit "bond frustration" due to the competing effects of first and second neighbor interactions. This is well modeled by a classical Heisenberg Hamiltonian, which leads to a remarkable ground state degeneracy of coplanar spins, in which the wavevector of the spiral can lie anywhere on a "spiral surface" in momentum space. We describe how thermal fluctuations lead to a broad spin liquid regime, with unique properties, and magnetic ordering at low temperatures. We next discuss the intriguing case of FeSC$_2$S$_4$, in which orbital degeneracy leads to a persistent "spin orbital liquid" down to the lowest temperatures. We argue that this material is in the vicinity of an unusual quantum critical point driven by a competition between exchange and spin-orbit interactions.

1:27 PM Q31.00010 Phase competition and large residual entropy in the pyrochlore double-exchange system . YUKITOSHI MOTOME, University of Tokyo, NOBUO FURUKAWA, Aoyama Gakuin University, ERATO-MF — Strong interplay between spin and charge degrees of freedom gives rise to fascinating phenomena, in particular when the system undergoes severe geometrical frustration, such as anomalous magneto-transport and heavy-mass behavior. We investigate this intriguing problem in the double-exchange model on the frustrated pyrochlore lattice by employing an unbiased Monte Carlo simulation. We find that as increasing the antiferromagnetic superexchange between localized moments, the ferromagnetic metallic state stabilized by the double-exchange mechanism becomes unstable, and is taken over by a paramagnetic metal in which spin correlations are strongly suppressed by the frustration. The critical field displays a novel and generic behavior, which can be tuned by chemical doping. We describe inelastic neutron scattering measurements on powder samples of IPA-Cu$_2$Br$_{12}$-tetrakis thiourea (DTN). In absence of doping, this compound clearly displays field-induced Bose-Einstein condensation of magnons [V. Zapf et al., Phys. Rev. Lett. 98, 047205 (2007)], as revealed by the mean-field scaling of the field-induced ordering temperature, $T_c \sim \left| H - H_c \right|^\phi$ with $\phi = 2/3$. The critical field $H_c$ corresponds to a $T = 0$ quantum phase transition (QPT) between a spin gap phase and a gapless ordered phase. Here we show that site dilution opens a novel gapless spin-liquid phase close to the ordering transition, corresponding to a Bose glass phase of localized magnons. Disorder leads to a radical change in the universality class of the QPT (which turns into a quantum percolation transition), and in the critical temperature scaling, which exhibits a novel universal exponent $\phi = 1.2$. A crossover to mean-field scaling of $T_c$ at finite temperature is observed, and explained via a scenario of thermal percolation of magnons.

1:39 PM Q31.00011 Magnetic Bose condensation vs. magnon localization in a model magnet with site dilution . TOMMASO ROSCILDE, Ecole Normale Superieure - Lyon, STEPHAN HAAS, University of Southern California, RONG YU, University of Tennessee - Knoxville — We report on the theoretical field-temperature phase diagram of anisotropic coupled S=1 chains with site dilution, modeling the magnetic behavior of doped NiAl$_2$-tetrakis thiourea (DTN). In absence of doping, this compound clearly displays field-induced Bose-Einstein condensation of magnons [V. Zapf et al., Phys. Rev. Lett. 98, 047205 (2007)], as revealed by the mean-field scaling of the field-induced ordering temperature, $T_c \sim \left| H - H_c \right|^\phi$ with $\phi = 2/3$. The critical field $H_c$ corresponds to a $T = 0$ quantum phase transition (QPT) between a spin gap phase and a gapless ordered phase. Here we show that site dilution opens a novel gapless spin-liquid phase close to the ordering transition, corresponding to a Bose glass phase of localized magnons. Disorder leads to a radical change in the universality class of the QPT (which turns into a quantum percolation transition), and in the critical temperature scaling, which exhibits a novel universal exponent $\phi = 1.2$. A crossover to mean-field scaling of $T_c$ at finite temperature is observed, and explained via a scenario of thermal percolation of magnons.

Wednesday, March 18, 2009 11:15AM - 1:51PM — Session Q32 GMAG: Magnetic Domains and Domain Walls 336

11:15 AM Q32.00001 Effect of Wall Width on Spin Torque in Ferromagnetic Domain Walls . E.A. GOLOVATSKI, M.E. FLATTÉ, OSTC and Department of Physics and Astronomy, University of Iowa — The amount of spin torque exerted on a domain wall in a ferromagnetic semiconductor depends on the amount of spin flip that occurs during the transport process. Starting with a model Hamiltonian[1], we calculate the total amount of spin torque exerted on a π wall and a 2π wall for ballistic transport across the domain wall, and calculate the dependence of the torque on the width of the domain wall. In very thin 2π walls, transport occurs with almost no spin flip. As the wall width increases, spins precess more inside the domain wall, increasing the spin torque. In a π wall, where most spins will flip during transport through a thick wall, we find that the spin torque increases monotonically with wall width. In contrast, spins in a thick 2π wall will continue to precess back towards their original configuration, and there will be much less net spin torque. Thus there is very little spin torque in both very thin and very thick 2π walls, but significant spin torque is possible in a range of intermediate widths. This non-trivial dependence on the width of the domain wall leads to an optimal wall width for achieving a maximum amount of spin torque. For a 2π wall with an exchange-induced spin splitting of 100 meV, and an effective carrier mass equal to the electron mass, we calculate this optimal width to be ~ 5nm. This work was supported by an ONR MURI. [1] G. Vignale and M.E. Flatté, PRL 89, 098302 (2002).
11:27AM Q32.00002 Transport across a pinned domain wall across a GaMnAs constriction: from AMR to spin-dependent tunneling. SUNG UN CHOO, HYUNG KOOK CHOI, FABIO C.S. DASILVA, TERESA OSMINER, DAVID P. PAPPAS, YUN DANIEL PARK, DEPARTMENT OF PHYSICS AND ASTRONOMY, SEOUL NATIONAL UNIVERSITY, SEOUL 151-747, KOREA TEAM, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY, BOULDER CO 80305, USA TEAM — We report on the different magnetotransport mechanism across a pinned domain wall in a GaMnAs nanowire dependent on constriction size. Nanometer-sized constrictions are realized in LT-MBE epitaxial GaMnAs by standard e-beam lithography and wet-etch processes, as well as a “break-junction” method to further decrease constriction size. Four-point probe DC IV measurements with varying angles to wire axis are utilized to study the transport mechanism— as well as magnetic properties. As constriction size approaches epitaxial thickness, nonlinear IV response is observed with a differing field dependence on temperature. As constrictions become smaller, we observe a tunneling AMR-like behavior. This effect is more evident after series of high current pulses are applied to decrease the constriction width. “Break-junction” method results in higher constriction resistances and increases in resulting MR values.

11:39AM Q32.00003 Mechanisms for low-field, and multiple domain wall injection into magnetic nanowires.1, SARAH REIFF, ANDREW KUNZ, Marquette University — The motion of a domain wall within a magnetic nanowire is important for the development of future recording, sensing and logic devices. The speed of a field driven domain wall is quickest when the applied magnetic field is below the so-called Walker Field which depends on the size and material properties of the wire. However, the field needed to inject a domain wall into a wire is much greater than the Walker Field. This discrepancy between the Walker Field and the injection field has not been well understood. By using MOKE with complicated domain wall structures, we present Landau-Lifshitz simulation results showing a significant decrease in the field needed to inject a domain wall into the wire for a variety of injection designs including: pads, rings, straight ends, and tapered ends. We also find that by applying a transverse field the required driving field to inject the wall decreases, and that the domain wall motion in the wire is faster. The magnetization of the pad and ring injection designs can be easily manipulated so that multiple walls with a known magnetization structure are injected allowing for faster, more reliable domain wall motion.

11:51AM Q32.00004 The influences of transverse magnetic anisotropy on field-induced domain wall propagation in magnetic nanowires, JIE LU, PENG YAN, XIANGRONG WANG, Physics Department, the Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong SAR, China, MICRO-MAGNETIC SIMULATION TEAM — Domain wall (DW) propagation in magnetic nanowires is an important subject in nanomagnetism because of its fundamental interest and potential applications in spintronic devices. It is well known that a head-to-head (or tail-to-tail) domain wall in a nanowire will propagate along the wire under an axial magnetic field. In this talk, we shall show that a new velocity-field formula can fit well with numerical results obtained from the open-source micromagnetic simulation package OOMMF. The fitting parameters have clear physical meanings that relate to the transverse magnetic anisotropy. How the transverse magnetic anisotropy, which can be modified by both transverse magnetic field and the aspect ratio of wire cross section, affects the DW structure and hence the DW propagation velocity will be discussed systematically.

12:03PM Q32.00005 Near-field interaction between domain walls in adjacent permalloy nanowires , LIAM O’BRIEN, Imperial College London, D. PETITT, H. T. ZENG, D. READ, E. R. LEWIS, R. P. COWBURN — Proposed data storage schemes based on ferromagnetic nanowires rely on the controlled propagation of domain walls (DWs) along nanoscale shift registers [Allwood et al. Science 309, 1688 (2005)]. To make technologically relevant devices, these nanowires must be fabricated to within a wire width of one another. However, the effect of magnetic anisotropy, which arises from the interaction between DWs in nanowires, has not been addressed. We have experimentally observed the interaction between two DWs of opposite charge travelling in adjacent permalloy nanowires (8nm thick, 100 nm wide), with inter-wire separation between 125 and 13nm. For the smallest separations, depinning fields (H_D) as high as 93 Oe were measured. Considering the energy landscape experienced by the two DWs under the approximation they are isolated and rigid and accounting for finite temperature we can completely reproduce the experimental dependence of H_D on the inter-wire spacing. Our results suggest that the interaction causes little perturbation to the DW shape. Pining resulting from localised stray fields is of interest for studying the fundamental properties of DWs as it occurs without modification of the DW or nanowire shape. Our results suggest propagation could be compromised by DW-DW interactions unless careful DW control is used.

12:15PM Q32.00006 Control of Domain Wall Structure and Pinning In Spin-Valve Nanowires . J. SAMPAIO, L. THEVENARD, E. LEWIS, L. O’BRIEN, H.T. ZENG, D. PETITT, D. READ, R.P. COWBURN, Imperial College London — Domain walls (DWs) in magnetic nanowires are the basis for several proposed data storage devices [D Allwood et al. Science 309, 1688 (2005), SS Parkin, US Patent 6,834,005 (2004)]. Most schemes use artificial defects (ADs) to modify the potential landscape seen by the DW, and thereby control its propagation. This potential modification depends on the DW structure. Integrating the nanowire in a Spin-Valve (SV) stack allows the electrical probing of the magnetization as well as electronic integration in future devices. However, using SV systems introduces strong stray fields from the reference layer, especially on the ADs. This can significantly impact the motion of DWs. The study of the influence of transverse magnetic anisotropy on constriction size. Nanometer-sized constrictions are realized in LT-MBE epifilm SV nanowires with dimensions for which only transverse DWs are stable (200nm width, free layer 8nm Ni_{1−x}Fe_{x}, pinned layer 2nm CoFe), which is verified with micromagnetic simulations. Moreover we show DW depinning at protrusions along the wire with fields lower than that required to nucleation (80/140 Oe). These results contribute to furthering the electrical integration of DW based data storage devices.

12:39PM Q32.00008 Domain Properties of a Single Magnetic Nanorod Investigated by Cantilever Magnetometry, SANGGAP LEE, ERIC MOORE, STEVEN A. HICKMAN, JOHN A. MAROHN, Cornell University — Single Ni nanorods having 50 to 100 nm diameter were integrated as the tip of ultra-sensitive cantilevers, having a force sensitivity of 8 nN/Hz^{1/2} at 4.2 K, designed for use in scanned-probe magnetic resonance force microscopy. We measured cantilever frequency, dissipation, and frequency fluctuations as a function of magnetic field, applied along both the easy axis and the hard axis of the nanorods while the cantilevers were self-oscillated. The nanorods exhibit bulk magnetization. Hard-axis magnetization interactions between DWs in Ni nanorods have not been well defined, or studied. Using MOKE with complicated domain wall structures. We present Landau-Lifshitz simulation results showing a significant decrease in the field needed to inject a domain wall into the wire for a variety of injection designs including: pads, rings, straight ends, and tapered ends. We also find that by applying a transverse field the required driving field to inject the wall decreases, and that the domain wall motion in the wire is faster. The magnetization of the pad and ring injection designs can be easily manipulated so that multiple walls with a known magnetization structure are injected allowing for faster, more reliable domain wall motion.
12:51PM Q32.00009 Magnetic Domain Structures in an In-plane Array of Cobalt Filaments with Periodic Structures. MU WANG, WEI HAN, XIANG XIONG, Natl. Lab. Solid State Microstructures, Nanjing University — With a unique electrochemical deposition method we fabricated in-plane arrays of straight cobalt filaments with periodic corrugations over a silicon substrate without using templates. The periodic corrugations on the filaments are induced by spontaneous oscillation in electrodeposition, and the periodicity can be tuned from a few tens of nanometers to a few hundreds of nanometers by controlling the electric current in experiments. Magnetic force microscopy indicates that each corrugated structure on the film may correspond to a local single magnetic domain. When the inter-filament separation is large, the magnetic domains are regularly aligned along the filament. The domains become random when the filaments are closely packed. We suggest that our results could be helpful in understanding the evolution of magnetic domain patterns on microscopic scale and may have potential application in spintronics.

1:03PM Q32.00010 Direct evidence of imprinted vortices in exchange-biased patterned bilayer nanomagnets. J.J. KAVICH, Institut Catala de Nanotecnologia (ICN), Barcelona, Spain, G. SALAZAR-ALVAREZ, Department of Materials Science and Engineering, Royal Institute of Technology, Sweden, J. SORU, Departament de Fisica, Universitat Autonoma de Barcelona, Spain, A. POTENZA, Diamond Light Source, Rutherford Appleton Laboratory, UK, A. MUGARZA, S. STEFANOW, Insitut Catala de Nanotecnologia (ICN), Barcelona, Spain, J. NOGUES, P. GAMBARDELLA, Instituto Catalana de Recerca i Estudis Avancats (ICREA), Barcelona, Spain — We investigate the magnetic domain structure in lithographically patterned nanomagnet arrays using element-sensitive circularly polarized XPEEM imaging. ZFC Py/IrMn (FM/AFM) bilayer nanodot (0.5 um – 4um dia.). arrays imaged across the Fe and Ni L edges clearly demonstrate spontaneous formation of vortex states. Magnetic contrast at the Mn L edge resonance indicates that the vortex state is transferred into the underlying AFM layer. The exchange-bias, measured through magneto-optical hysteresis measurements, verifies the AFM nature of the underlying IrMn, suggesting that the imprinted vortex state is confined to the interface by local interactions of the uncompensated interfacial Mn spins with the FM Py layer.

1:15PM Q32.00011 Confinement distance of the closure structure around a single hole in a 2D magnetic thin film. M. VELEZ, G. RODRIGUEZ-RODRIGUEZ, H. RUBIO, A. PEREZ-JUNQUERA, J.I. MARTIN, J.M. ALAMEDA, Dpto. Fisica, Univ. Oviedo-CINN, 33007 Oviedo, Spain, J.V. ANGUITA, IMM-CNMCSCIC, 28760 Madrid, Spain — One common feature in many magnetic nanostructures, such as nanorings or patterned thin films [1], is the existence of non magnetic holes within the magnetic material. However, up to now, the simple problem of a a single non magnetic hole in a 2D magnetic film has received little attention, even though it is qualitatively different from the blade domains that appear such as nanorings or patterned thin films [1], is the existence of non magnetic holes within the magnetic material. However, up to now, the simple problem of a single non magnetic hole in a 2D magnetic film has received little attention, even though it is qualitatively different from the blade domains that appear around holes in 3D magnetic material. In this work [2] this basic problem has been analyzed in detail by magnetic force microscopy, micromagnetic simulations and an analytical model. The closure magnetization configuration can be described by two -1/2 half vortices located at the hole edge along the easy anisotropy axis, and confined within a distance L that is determined by the minimization of magnetostatic and anisotropy energies constrained by the magnetic charge constraint within the system. [1] A. Perez-Junquera et al, J. Appl. Phys. 99 (2006) 033902 [2] G. Rodriguez-Rodriguez et al, Phys. Rev. B (2008) in press.

1:27PM Q32.00012 A shape phase diagram for a ferromagnetic liquid drop. SHUBHO BANERJEE, TRAVIS RASOR, Rhodes College, MIKE WIDOM, Carnegie Mellon University — A ferromagnetic liquid phase has been predicted by mean field theory and computer simulations but conclusive experimental evidence is lacking. Liquids such as ferrofluids, that are suspensions of ferromagnetic particles in solvents, magnetize only in the presence of an applied magnetic field and thus are paramagnets, not ferromagnets. A ferromagnetic liquid, if it existed, would spontaneously magnetize even in the absence of a magnetic field. A droplet of such a liquid would likely not be a sphere due to the magnetostatic energies involved. These energies will induce a magnetization texture in the drop analogous to domain formation in solids. We examine possible shapes for the droplet by optimizing its shape and magnetization textures with respect to its overall energy.

1:39PM Q32.00013 GGA+U calculation of the magnetic ground state of GdB4. LEONARD KLEINMAN, MUHAMMAD HUDA, University of Texas — We have studied eight collinear and non-collinear magnetic orientations of GdB4 using the GGA + U method, without and with spin-orbit coupling, for values of U - J between 0 and 6. For U - J = 6, the value which had been found to yield the correct Gd lattice constants, we obtain GdB4 lattice constants within 0.26% of experiment. We find the magnetization lies in-plane but is collinear, in disagreement with the most recent experimental determination.

Wednesday, March 18, 2009 11:15AM - 2:03PM — Session Q33 DCMP: Superconductivity: Response to Electromagnetic Fields and Proximity Effect 403

11:15AM Q33.00001 Magnetic field dependence of the infrared transmittance of superconducting NbTiN. D.B. TANNER, J. HWANG, X. XI, H. ZHANG, University of Florida, G.L. CARR, NSLS, Brookhaven National Laboratory — Superconductivity may be destroyed by raising the temperature of the superconductor above the transition temperature or by increasing an applied magnetic field above the upper critical field. We have studied the behavior of key microscopic properties, the superconducting energy gap and the superfluid density, through far-infrared magneto spectroscopy measurements on thin-film NbTiN. The measurements were performed at the National Synchrotron Light Source, Brookhaven National Laboratory. As temperature is increased, the gap and the superfluid density are reduced, both reaching zero at Tc. The behavior with field is different. Over much of the range between 0 and 10 T, the gap is almost unchanged, while the superfluid density is reduced, roughly following the area not in vortices in the film. Only near the highest field does the superconducting gap become reduced.

Supported by the DOE through grant DE-FG02-02ER45984 at Florida and contract DE-AC02-98CH10886 at BNL.
11:27AM Q33.00002 Strong correlation effects and optical conductivity in electron doped cuprates. TANMOY DAS, R.S. MARKIEWICZ, A. BANSIL, Northeastern University — We demonstrate that most features ascribed to strong correlation effects in various spectroscopies such as angle-resolved photoemission spectroscopy (ARPES) and optical spectra of the cuprates are captured by a calculation of the self-energy incorporating effects of spin and charge fluctuations[1]. The self-energy is calculated over the full doping range of electron-doped cuprates from half-filling to the overdoped system. The spectral function reveals four subbands, two widely split incoherent bands representing the remnant of the split Hubbard bands, and two additional coherent, spin- and charge-doped in-gap bands split by a spin-density wave, which collapses at the AFM quantum critical point (QCP) in the overdoped regime. The transition between the in-gap states leads to pseudogap features in the mid-infrared region of the optical spectra, where the incoherent features persist to high doping even above the QCP, producing a remnant Mott gap. Notably, our results are also in good accord with variational cluster and quantum Monte Carlo calculations. Work supported in part by the USDOE.

11:39AM Q33.00003 A broadband microwave study of the superconducting fluctuations in 2D InOx thin films, WEI LIU, Johns Hopkins University, MINSOO KIM, TAILUNG WU, SAMBANDAMURTHY GANAPATHY, SUNY-Buffalo, PETER ARMITAGE, Johns Hopkins University — We apply a broadband microwave 'Corbino' spectrometer covering the range from 10MHz to 20GHz to the study of 2D disordered superconducting InOx thin films. Explicit frequency dependency of the superfluid stiffness and conductivity are obtained down to 270mK. The AC measurements are sensitive to different time scales of the superconducting fluctuations. A number of fluctuation regimes are investigated (gaussian fluctuations, vortex proliferation) as we cool the sample into the low-temperature Kosterlitz-Thouless-Berezinskii-like phase. We discuss our results in terms of prevailing measurements are sensitive to different time scales of the superconducting fluctuations. A number of fluctuation regimes are investigated (gaussian fluctuations, vortex proliferation) as we cool the sample into the low-temperature Kosterlitz-Thouless-Berezinskii-like phase. We discuss our results in terms of prevailing fluctuations regimes.

11:51AM Q33.00004 Time-resolved terahertz photoconductivity of insulating cuprates. AMIR FARAHANI, JESSE PETERSEN, Simon Fraser University, RUXING LIANG, University of British Columbia, J. STEVEN DODGE, Simon Fraser University — We use a visible pump, terahertz probe technique to study the photoconductivity of the undoped cuprates. We use ultrafast optical pulses (E_{pump} = 3.1 eV) to create photoexcitons in high quality single crystals of Sr2CuO2Cl2 and YBa2Cu3O6+y, and time-domain terahertz spectroscopy to probe the resulting photoconductivity. We observe a rapid onset of photoconductivity followed by a non-exponential relaxation on a picosecond timescale. This dynamics is independent of photocarrier concentration over the range of 0.2 to 1.7 percent excitations per copper atom. Assuming a quantum efficiency of unity, we infer a mobility of ~0.2 cm^2/Vs, significantly lower than the Hall mobility in chemically doped systems[1]. As the fluence is increased, there is a weak decrease in the photoconductivity amplitude. We also measured the frequency dependence of the photoconductivity in the terahertz range, and observe an increase in photoconductivity with frequency up to 600 GHz, suggesting polaronic effects.

1 Y. Ando et al. PRL 87 017001 (2001)

12:03PM Q33.00005 Magnetic field-induced modification of superfluid density and interplane spectral weight in YBa2Cu3Oy, ANDREW LAFORGE, Univ. of CA, San Diego, WILLIE PADILLA, Boston College, KENNETH BURCH, University of Toronto, ZHIQIANG LI, ALEXANDER SCHAFGANS, Univ. of CA, San Diego, KOUJI SEGAWA, YOICHI ANDO, Osaka University, Japan, DIMITRI BASOV, Univ. of CA, San Diego — We report on the interlayer infrared response of YBa2Cu3O6+y in an applied magnetic field. This study explores both the underdoped (y = 6.67 and 6.75) and optimally doped (y = 6.95) regions of the phase diagram, and includes data for fields applied both parallel to the c axis and to the CuO2 planes in this anisotropic superconductor. A sum rule analysis reveals that magnetic fields H || c eliminate the high-frequency contribution to the superfluid density, returning the system to a more BCS-like energy scale [1]. For fields H || CuO2, however, the high-energy component scales with the superfluid density, and the anomalous scheme of condensate formation is maintained, at least in underdoped y=6.67 and 6.75 samples. This behavior is discussed in relation to the change of electronic kinetic energy and the suppression of interplane phase coherence. [1] A. D. LaForge et al., Phys. Rev. Lett. 101, 097008 (2008).

12:15PM Q33.00006 A Terahertz Conductivity Study of Pseudogap Phase in Underdoped LSCO. C. C. HOMES, Condensed Matter Physics and Materials Science Dept., Brookhaven National Laboratory, D.M. BROUN, Dept. of Physics, Simon Fraser University, Burnaby, British Columbia, RUXING LIANG, W.N. HARDY, D.A. BONN, Dept. of Physics and Astronomy, University of British Columbia, Vancouver, British Columbia — Microwave impedance techniques have been used to determine the critical temperature (Tc), the in-plane superfluid density (ρ0), and the dc conductivity (σdc) just above Tc in a highly-underdoped sample of YBa2Cu3O6+y for y ≥ 0.333. In this state the sample may be annealed to yield different levels of chain oxygen order and electronic doping in the copper-oxygen planes, resulting in a range of Tc ≈ 2 – 17 K. The linear relation between ρ0 and Tc is observed, not in-plane superfluid density is obtained, instead ρ0 ∝ Tc^2. However, the results do follow the more general scaling relation ρ0/8 ≈ 4.4 σdc Tc extending the validity of this relation for the in-plane data by an order of magnitude. In addition, these new results now provide a region of overlap between the scaling observed in the copper-oxygen planes, and perpendicular to the planes along the poorly-conducting c axis.

1Supported by the DOE under Contract No. DE-AC02-98CH10886.
12:39PM Q33.00008 Real-time photoinduced quasi-particle relaxation of superconductors1
JIANMIN TAO, JIAN-XIN ZHU, Theoretical Division and CNLS, Los Alamos National Laboratory — Ultrafast optical phenomena are of fundamental importance in the investigation of electronic dynamics of metals and superconductors [1]. By considering a model Hamiltonian with electron-boson coupling of a superconductor exposed to a time-dependent laser field, we calculate the current density, which can be expressed in terms of the quasi-particle density matrices. The time evolution of these density matrices is derived within a mean-field approximation using the equation-of-motion approach and is numerically investigated with Runge-Kutta method. We discuss the consequence of the d-wave pairing symmetry in the quasi-particle relaxation process.

12:51PM Q33.00009 Raman scattering from the CaC6 superconductor in the presence of disorder, ALEKSEJ MIALITISIN, Rutgers University, JUN SUNG KIM, REINHARD KREMER, Max-Planck-Institut fuer Festkoerperforschung, GIRSH BLUMBERG, Rutgers University — Polarized Raman scattering has been performed on CaC6 single crystal superconductor. We identify two of the three Raman active E2u phonon modes at 440 and 1508 cm−1expected for the K3m space group of CaC6. These first order scattering modes appear along with the D and G bands around 1300 cm−1and 1600 cm−1that are similar in origin to the corresponding bands in plain graphite. The intensities of the D and G peaks in CaC6 correlate with degree of disorder. The D band arises from the double resonant Raman scattering process; its frequency shifts as a function of excitation energy with ∼35 cm−1/eV. The double resonant Raman scattering probes phonon excitations with finite wave vector q. We compare experimental results to from-first-principles calculations.

1:03PM Q33.00010 Possibility of p-wave triplet pairing in Nb/Ni bilayers, WENJIAN LU, KOOKRIN CHAR, Center for Strongly Correlated Materials Research, Department of Physics and Astronomy, Seoul National University, Seoul 151-742, Korea, Y.K. BANG, Department of Physics, Chonnam National University, Kwangju 500-757, Korea, P. SANGIOGIO, Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland, M.R. BEASLEY, Department of Applied Physics, Stanford University, Stanford, CA 94305 — We have experimentally investigated the density of states (DOS) in Nb/Ni (S/F) bilayers and found the anomalous double peak structure. In order to analyze the measured DOS data, we propose a theory model in which p-wave triplet pairing correlations are induced by an inhomogeneous magnetization in the ferromagnet. The induced triplet component penetrates into the ferromagnet over a long length (much larger than a characteristic length scale $L_{P} = \sqrt{D/h}$, where $D$ is the diffusion coefficient and $h$ is exchange energy). We numerically calculate the DOS of Nb/Ni bilayers based on Eilenberger equation with various parameters and discuss the unusual sub-gap structure in the DOS. We find a good qualitative and quantitative agreement between the model calculations and our measurements and therefore suggest the possibility of p-wave triplet correlations in Nb/Ni bilayers.

1:15PM Q33.00011 1D Chain of Interacting Majorana Bound States at the Edge of a Topological Insulator, VASUDHA SHIVAMOGGI, JOEL MOORE, University of California, Berkeley — We study a realization of 1d chain of Majorana bound states that consists of alternating ferromagnetic and superconducting regions at the edge of a quantum spin hall insulator. Each boundary between a ferromagnetic and superconducting region supports a Majorana bound state, and the pair-wise interaction energies have previously been calculated in the weakly interacting limit. By adjusting the phases of the order parameters in these regions, it is possible to create a Majorana bound state localized at each interface. In the limit of well separated Majorana fermion systems, the system can be mapped to the transverse field Ising model. The phases of the Majorana fermion order parameters must be drawn from essentially the same random distribution. We examine factors in an experimental system that will move the system away from the critical point, such as Coulomb interactions and breaking of the duality between the ferromagnetic and superconducting regions.

1:27PM Q33.00012 ABSTRACT WITHDRAWN

1:39PM Q33.00013 Superconducting Proximity Effect in Thin Semiconducting Films, MICHAEL VISSERS, KEVIN INDERHEES, TIM MCDARLE, STEPHANIE LAW, PAUL GOLDBART, LAURA GREENE, JIM ECKSTEIN, University of Illinois at Urbana Champaign — We report results using a novel 3 terminal device to study the influence of the superconducting proximity effect on the sheet resistance of the N-layer, Rs, as well as the junction conductance across the N-S boundary, Gc. When the N-layer is a degenerate semiconductor the changes in these quantities correlate with degree of disorder. The D band arises from the double resonant Raman scattering process; its frequency shifts as a function of excitation energy with ∼35 cm−1/eV. These first order scattering modes appear along with the D and G bands around 1300 cm−1 and 1600 cm−1 that are similar in origin to the corresponding bands in plain graphite. The intensities of the D and G peaks in CaC6 correlate with degree of disorder. The D band arises from the double resonant Raman scattering process; its frequency shifts as a function of excitation energy with ∼35 cm−1/eV. The double resonant Raman scattering probes phonon excitations with finite wave vector q. We compare experimental results to from-first-principles calculations.

Wednesday, March 18, 2009 11:15AM - 2:15PM – Session Q34 DMP GMAG: Focus Session: Superconductivity: Magnetic Properties 404

1This work was supported by NSF No. DMR-0606529.
11:15AM Q34.00001 Influence of Magnetic Domain Structure on Abrikosov Vortex Dynamics in Superconductor-Ferromagnet Hybrids1. GORAN KARAPETROV, Argonne National Laboratory — We will review the experimental and theoretical aspects of transport properties and vortex static and dynamic behaviors in normally conducting superconductor-ferromagnet hybrid structures. Magnetotransport characteristics and scanning tunneling microscopy (STM) images of vortex structures reveal rich superconducting phase diagrams in these systems. Focusing on particular combination of a Permalloy ferromagnet with a well ordered rotatable periodic stripe-like magnetic domain structure with alternating out-of-plane component of magnetization, and a small coherence length superconductor, we will find directed nucleation of superconductivity above domain wall boundaries. We will also present the use of the Center for Nanoscale Materials and the Electron Microscopy Center at UChicago Argonne, LLC, Operator of Argonne National Laboratory. Argonne, U.S. DOE Office of Science lab, is operated under Contract No. DE-AC02-06CH11357.

11:51AM Q34.00002 The influence of magnetic domain landscape on the flux pinning in ferromagnetic/superconducting bilayers. MARTA Z. CIEPLAK, Z. ADAMUS, Institute of Physics, PAS, Warsaw, Poland, M. KONCZYKOWSKI, Ecole Polytechnique, Palaiseau, France, L. Y. ZHU, C. L. CHIEN, Johns Hopkins Univ. — A line of miniature Hall sensors has been used to study the influence of the disorder in the magnetic domain landscape on flux pinning in the ferromagnetic/superconducting (F/S) bilayers. The bilayers consist of Nb as the S layer and Co/Pt multilayer with perpendicular magnetic anisotropy as the F layer, separated by a Si buffer layer to avoid the proximity effect. By changing the Pt layer thickness, the magnetic domain landscape with different degree of disorder, ranging from uniformly distributed narrow domains (quasi-ordered landscape) to highly disordered landscape with domains of different sizes, can be predefined in the F layer. The flux behavior is then measured in the superconductor creating a series of (anti)pinning channels for externally added magnetic flux quanta forcing confinement of the Abrikosov vortices and formation of quasi-1D vortex arrays. We will also discuss potential for electronic applications of ferromagnet-superconductor hybrid systems.

12:03PM Q34.00003 Soft magnetic lithography and giant magnetoresistance in superconducting/ferromagnetic hybrids. V. VLASKO-VLASOV, U. WELP, A. IMRE, D. ROSENBERG, J. PEARSON, W. KWOK, Argonne National Laboratory — We report on direct visualization confirmed by the transport measurements of strong interactions between superconducting vortices and ferromagnetic domains in bilayers of type-II SC lead films and FM Penning films with perpendicular magnetic anisotropy. Domains in permalloy formed a submicron stripe lattice that could be easily aligned in the film plane. We show that domain walls yield a robust magnetic pinning potential providing preferential vortex motion along the stripe domains. The effect is observed in a wide temperature range and results in a noticeable anisotropy of critical currents. The anisotropy increases near Tc when the core pinning becomes inefficient and the anisotropy direction is changed by reorienting the stripe domains. Such a tunable magnetic lithography is a convenient way of varying transport properties of superconductors and developing new cryotronic devices such as microscale superconducting switches and modulators. In our samples we found an unusually high magnetoresistance of 106% in the fields of <10 Oe for the currents perpendicular to the domain walls. It can be referred to the granular structure of the lead films assisting the formation of easy flux flow channels along the stripe domains. — The work was supported by the U.S. DOE Office of Science under Contract No. DEAC02-06CH11357.

12:15PM Q34.00004 Experimental approach to search magnetic pinning in YBCO films grown by chemical deposition method. CARLOS MONTON, ANNA PALAU, JONE ZABALETA, NARCIS MESTRES, TERESA PUIG, XAVIER OBRADORs, Institut de Ciencia de Materiales de Barcelona, CSIC, 08193 Bellaterra, Spain — In the last 10 years we have developed experience in generating magnetic stripe domains (F) bilayer, the superconducting properties of the S layer are sensitive to the domain pattern in the adjacent F layer.1-2 We report studies of the magnetic stripe domains and the ferromagnetic layers of YBCO trilayers (at 77K and H=0). To improve these performances specific defects were created by chemical nanostructurated routes. Interfacial pinning was obtained by the growth of nanostructured templates generated by strain induced or assisted self-assembled processes [1]. On the other hand isotropic defect pinning contribution was increased by adding nanocomposites with second phase within the YBCO matrix. These samples were grown by modified solution precursors [2] reaching the transport c% in the fields of 10 Oe for the currents perpendicular to the domain walls. — The possible origins of this behavior will be discussed.

12:27PM Q34.00005 Interplay between ferromagnetism and superconductivity at interfaces of La0.7Ca3MnO3/YBa2Cu3O7−δ/La0.7Ca3MnO3 trilayers. FELIO PEREZ, West Virginia University, EVAL BACCA, MARIA E. GOMEZ, Universidad del Valle, Colombia, HONGTAO SHI, Sonoma State University, DAVID LEDERMAN, West Virginia University — We report studies of the transport properties of the S layer sensitive to the domain pattern in the adjacent F layer.1-2 We exploit this effect to investigate Ni films, which instead of retaining in-plane anisotropy as usual, unexpectedly acquire perpendicular anisotropy when the thickness is above a critical value. Using Ni/Nb bilayers, the transport measurements show a strong suppression of the superconducting properties when the thickness of superconducting layer is reduced below 10 unit cells. However, the magnetic response out of plane shows the presence of the superconductor until 5 unit cells. The difference between the electrical characterization and the onset of the diamagnetic transition might to be related of presence of the spontaneous vortex phase in this temperature interval.

12:39PM Q34.00006 Probing the magnetic states in a ferromagnet using a superconductor. LEIYI ZHU, TINGYONG CHEN, CHIA-LING CHIEN, Department of Physics and Astronomy, Johns Hopkins University — In a superconductor (S)/ferromagnet (F) bilayer, the superconducting properties of the S layer are sensitive to the domain pattern in the adjacent F layer.1-2 We exploit this effect to investigate Ni films, which instead of retaining in-plane anisotropy as usual, unexpectedly acquire perpendicular anisotropy when the thickness is above a critical value. Using Ni/Nb bilayers, the transport measurements show a strong suppression of the superconducting properties when the thickness of superconducting layer is reduced below 10 unit cells. However, the magnetic response out of plane shows the presence of the superconductor until 5 unit cells. The difference between the electrical characterization and the onset of the diamagnetic transition might to be related of presence of the spontaneous vortex phase in this temperature interval.

12:51 PM Q34.00007 Evidence for Induced Magnetization in Superconductor/Ferromagnet Bilayers | ITAY ASULIN, OFER YULI, Racah Institute of Physics, The Hebrew University, Jerusalem 91904, Israel, GAD KOREN, Department of Physics, Technion-Israel Institute of Technology, Haifa 32000, Israel, ODED MILLO, Racah Institute of Physics, The Hebrew University, Jerusalem 91904, Israel — The inverse proximity effect in superconductor/ferromagnet heterostructures has been the focus of recent theoretical studies. The different approaches share the basic conclusion that a sizable magnetic moment should penetrate into the superconductor side. The sign of this moment, its spatial behavior and the actual mechanism of this effect are still controversial. Very few experimental works have provided evidence for the existence of such a magnetic moment inside the superconductor. However, the effects of such an induced magnetization on the density of states of the superconductor was not observed so far and needs further theoretical and experimental clarification. We have performed scanning tunneling spectroscopy of (001)YBa$_2$Cu$_3$O$_7$ and SrRuO$_3$ bilayers, where the SrRuO$_3$ is an itinerant ferromagnet, and found an anomalous splitting of both the gap and zero bias conductance peaks that may provide evidence for the existence of such an induced magnetic moment inside the superconductor. The relevant length and energy scales of the effect will be discussed.

1:03PM Q34.00008 Interaction between magnetism and superconductivity in La$_{0.7}$Ca$_{0.3}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-x}$ multilayers | T. HU, H. XIAO, C. C. ALMASAN, Department of Physics, Kent State University, Kent, OH, 44242, USA, C. VISANI, Z. SEFRIOUI, J. SANTAMARIA, GFMC, Departamento Física Aplicada III, Universidad Complutense de Madrid, 28040 Madrid, Spain — Angular and field dependent magnetoresistance measurements were performed on La$_{0.7}$Ca$_{0.3}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-x}$ (LCMO/YBCO) heterostructures below and above the superconducting transition temperature $T_s \approx 28$ K of the YBCO layer, in order to address the origin of the long range proximity effect found in these heterostructures. The proximity-induced conductance in the LCMO layer at $T < T_s$ increases significantly with decreasing temperature $T$. This magnetoresistance mechanisms show that the dissipation mechanism in the LCMO layer of thickness $L_{P}$ at $T < T_s$ is due to flux vortices that have fully spin polarizes quasiparticles in the vortex core. This clearly shows that triplet superconducting pairs penetrate into the ferromagnetic LCMO layer. An estimate of $L_{P} \approx 4.7$ nm at 10 K is in excellent agreement with a previously reported value and further shows the consistency of the present analysis.

1:15PM Q34.00009 Directional control of the inverse superconducting spin-switch | CRISTINA VISANI, NORBERT M. NEMES, MIRKO ROCCHI, CHRISTIAN MILLER, JAVIER GARCIA-BARRIOCANAL, DIEGO ARIAS, ZOUHAIR SEFRIOUI, CARLOS LEON, JACOBO SANTAMARIA, Universidad Complutense de Madrid, Spain, MAR GARCIA-HERNANDEZ, Instituto de Ciencia de Materiales de Madrid, Spain, SUSANNE G. E. TE VELTHUIS, AXEL HOFFMANN, Argonne National Laboratory, Mike R. FITZSIMMONS, Los Alamos National Laboratory — We report results on the study of spin dependent transport in La$_{0.7}$Ca$_{0.3}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-x}$/La$_{0.7}$Ca$_{0.3}$MnO$_3$ multilayers, focusing on the effects induced by magnetic anisotropy of the LCMO. The study of magnetic anisotropy through the combination of transport measurements, magnetometry, x-ray magnetic circular dichroism and polarized neutron reflectometry, allowed us to unravel the origin of the inverse superconducting spin switch. Applying the magnetic field along the easy axis we obtained a plateau-like response reflecting a well defined antiparallel alignment of the LCMO layers over a wide magnetic field range yielding large magnetoresistance that we ascribe unambiguously to the spin dependent transport.

1:27PM Q34.00010 Oxide thin film based inverse superconducting spin switches | NORBERT M. NEMES, C. VISANI, C. MILLER, M. ROCCHI, F. BRUNO, J. GARCIA-BARRIOCANAL, Z. SEFRIOUI, C. LEON, J. SANTAMARIA, Universidad Complutense de Madrid, Spain, M. IGLESIAS, F. MOMPEAN, M. GARCIA-HERNANDEZ, Instituto de Ciencia de Materiales de Madrid, Spain, A. HOFFMANN, S. G. E. TE VELTHUIS, Argonne National Laboratory — Thin film F/S/F trilayers made of YBa$_2$Cu$_3$O$_7$ (S, YBCO) and La$_{0.7}$Ca$_{0.3}$MnO$_3$ (F, LCMO) behave as inverse superconducting spin switches (SSS) as the critical temperature of the superconductor depends on the relative orientation of the magnetization of the F layers in a way that the resistivity increases in the antiparallel configuration. This is caused by enhanced pair-breaking due to the spin dependent transport of quasiparticles transmitted from the ferromagnetic electrodes into the superconductor. Similar inverse SSS is obtained from exchange biased LCMO/YBCO/Cobalt trilayers with a broad AP field range. Spin diffusion across the superconductor, proximity effect at the F/S interface, stray fields due to domain walls of the ferromagnet and the magnetic anisotropy all play a role.

1 Work supported by MICINN and DOE-BES.

1:39PM Q34.00011 Direct and Inverse Spin Switch Effect in Superconducting Spin Valves | JIAN ZHU, CARL BOONE, XIAO CHENG, ILYA KRIVOROTOV, University of California, Irvine, KRIVOROTOV’S GROUP TEAM — We report the observation of direct and inverse spin switch effects in ferromagnet/ superconductor/ ferromagnet/ antiferromagnet (FM/SC/FM/AF) spin valves with FM = Ni$_{81}$Fe$_{19}$, AF = Ir$_{23}$Mn$_{77}$ and SC = Nb. In these spin valve structures, the magnetization of the free layer can be switched between parallel (P) and antiparallel (AP) orientations with respect to the orientation of the fixed layer by a small in-plane magnetic field. Near the superconducting transition temperature, the P state has a higher resistance than the AP state. This is the direct spin switch effect expected from the proximity effect in superconducting spin valves. However, if the fixed ferromagnetic layer is brought into a multi-domain state in zero magnetic field, resistance in this state becomes significantly higher than that of the P state and rapidly decreases to the P state value with increasing magnetic field. We explain this inverse spin switch effect by the formation of Néel - quasi-Néel domain wall pairs in the ferromagnetic bilayer. The Néel - quasi-Néel domain wall pairs induce stray magnetic fields with a significant component perpendicular to the plane of the sample. This field penetrates the SC and gives rise to vortex flow resistance. Our work shows that the inverse spin switch effect is magnetostatic in origin.

1:51PM Q34.00012 Even- to Odd-frequency Pair Conversion by Magnetic Interfaces in SC/N Junctions | MATTHIAS ESCHWIG, University of Karlsruhe, Germany, JACOB LINDER, Norwegian University of Science and Technology, TAKEHITO YOKOYAMA, Nagoya University, Japan, ASLE SUDBØ, Norwegian University of Science and Technology — We study the proximity-induced superconducting correlations in a ballisitic or diffusive normal metal (N) connected to a superconductor (SC) when the interface between them is spin-active. One of the hallmarks of the proximity effect in a non-magnetic bilayer is a minigap in the density of states of the normal metal. It scales with the Thouless energy of the normal metal and with the transmission probability of the interface. For a spin-active interface, the transmission properties of spin↑ and spin↓ electrons into N are different, giving rise to spin-dependent phase shifts at the interface. This leads to a rather surprising result. Remarkably, for any interface spin polarization there is a critical interface resistance, above which the conventional singlet proximity component vanishes at the chemical potential, while an odd-frequency triplet component remains finite. At the same time, the minigap is replaced by a low-energy band with enhanced density of states. We propose a way to unambiguously observe the odd-frequency component.

3 We acknowledge support by the DFG-CFN (ME), the Norwegian Research Council (JL, AS), and the JSPS (TY).
which is ascribed to the change of the Fermi-surface structure by the electron doping. As for the superconducting properties for $T_c$ and pseudogap behavior is observed in $30\, K$, suggesting the development of AFM spin fluctuations with decreasing temperature. The AFM fluctuations are significantly suppressed with F-doping, We have measured the temperature-dependence of Fe-

photoluminescence spectroscopy (XPS) techniques to investigate the core-level x-ray photoemission spectra for high-temperature superconductivitor iron arsenide

LA 70803, USA, DARWIN URBINA, Department of Physics, Florida International University, Miami, FL 33199, USA, H. DING, GENFU CHEN, N.L. WANG, (Ba$_{1-x}$K$_x$)$_2$Fe$_2$As$_2$, and Other Novel Superconductors X: Spectroscopy

11:15AM Q35.00001 NMR Studies of Iron-Oxynitride Superconductor LaFeAs(O$_{1-x}$F$_x$), KENJI

ISHIDA, Department of Physics, Graduate School of Science, Kyoto University — We present experimental results of $^{75}$As and $^{119}$La nuclear magnetic resonance (NMR) in the layered oxynitride system LaFeAs(O$_{1-x}$F$_x$) ($x = 0.0, 0.04, 0.07, 0.11$ and $0.14$) where superconductivity occurs in $x$ greater than $0.04$ [1,2]. In the undoped LaFeAsO, $1/T_1$ of $^{119}$La exhibits a distinct peak at $T_{N} \approx 142\, K$ below which the La-NMR spectra become broadened due to the internal magnetic field attributed to an antiferromagnetic (AFM) ordering[1]. In the $x=0.04$ sample, $1/T_1T$ of $^{75}$As exhibits a Curie-Weiss temperature dependence down to $30\, K$, suggesting the development of AFM spin fluctuations with decreasing temperature. The AFM fluctuations are significantly suppressed with F-doping, and pseudogap behavior is observed in $1/T_1T$ in the $x=0.11$ sample with a gap value of $\Delta_{PG} \sim 175\, K$[1]. The spin dynamics vary markedly with F-doping, which is ascribed to the change of the Fermi-surface structure by the electron doping, as well as for the superconducting properties for $x=0.04, 0.07$ and $0.11$, $1/T_1$ of $^{75}$As in all compounds does not exhibit a coherence peak just below $T_c$, and follows a $T^3$ dependence at low temperatures. These results seemingly suggest that unconventional superconductivity with zero gap along lines, whereas the lack of the residual density of states at the low temperatures is incompatible with the presence of the line-nodes. We discuss similarity and difference between LaFeAs ($O_{1-x}F_x$) and cuprates, and also discuss the relationship between spin dynamics and superconductivity on the basis of F-doping dependence of $T_c$ and $1/T_1$[2].

11:51AM Q35.00002 Electron itinerancy and Strong Itinerant Spin Fluctuations in the Normal State of CeFeAsO$_{0.89}$F$_{0.11}$ Iron-Oxynitrides, F. BONDINO, E. MAGNANO, M. MALVESTUTO, F. PARMIGIANI, M.A. MCGUIRE, A.S. SEFAT, B.C. SALES, R. JIN, D. MANDRUS, E.W. PLUMMER, D.J. SINGH, N. MANNELLA — The recent discovery of high-temperature superconductivity in iron-oxynitrides and related materials has generated enormous excitement in the community. The electronic structure of the normal state of CeFeAsO$_{0.89}$F$_{0.11}$ has been measured with photoemission spectroscopy (PES) and x-ray absorption spectroscopy (XAS). The Fe XAS and PES spectra do not display satellite features commonly found in the Cu spectra of cuprates HTSCs, indicative of the absence of strong electron correlation and localization effects in the electronic structure.

The Fe 3$\delta$ spectra show exchange multiplets due to the coupling of the final Fe 3$\delta$ core hole state with the conduction band states, indicative of the presence of fluctuating spin moments on the Fe sites. These findings indicate that the FeSC must be considered a new class of materials, quite unlike the cuprate HTSC or conventional BCS superconductors [F. Bondino et al. http://arxiv.org/abs/0807.3781 (arXiv:0807.3781)].

12:03PM Q35.00003 Core Level and Valence Band Studies of the Novel Iron Pnictide Superconductors, DANIEL GARCIA, University of California, Berkeley, CHRIS JOZWIAK, CHOOKYU HWANG, ALEXEI FEDOROV, STEPHEN HANRAHAN, STEVEN WILSON, COSTEL ROTUNDU, BYRON FREELON, ROBERT BIRGENEAU, EDITH BOURRET-COURCHESNE, ALESSANDRA LANZARA — Towards understanding the physics of the superconducting iron pnictides, critical information can be gained through exploring the electronic structure of these novel materials. We have used photoemission spectroscopy to study the LaFeAsO$_{1-x}F_x$ and the PFeAsO$_{1-x}F_x$ superconductor. The evolution of valence band density of states, hybridization energy, Fermi surface topology and many body interaction are presented as a function of doping, photo energy and temperature. We explore the significance of these results to the question of electron correlation and spin physics in these Fe-based superconductors.

12:15PM Q35.00004 Core-level study of high-temperature superconductivity iron arsenide (Ba$_{1-x}$K$_x$)$_2$Fe$_2$As$_2$, YI LI, HAIZHONG GUO, JIANDI ZHANG, Institute of Physics, France, Physical Institute, University, Paris, ML 33199, USA, H. DING, GENFU CHEN, N.L. WANG, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, CAS, Beijing 100080, China — We have used high-resolution x-ray photoemission spectroscopy (XPS) techniques to investigate the core-level x-ray photoemission spectra for high-temperature superconductor iron arsenide (Ba$_{1-x}$K$_x$)$_2$Fe$_2$As$_2$ ($T_C = 32\, K$) and its parent compound BaF$_2$As$_2$. One important issue for understanding the nature of the superconductivity in the compound is the determination of the electron-electron correlation in the system which in principle should be reflected by the appearance of core-level satellites. We have measured the temperature-dependence of Fe-$1p$ and 3$\delta$ core-level spectrum in both parent and doped superconductor compounds and found that the core-level electronic structure is quite different from that observed in cuprates. The origin and nature of the core spectra in these iron-based materials will be discussed.

12:27PM Q35.00005  $^{75}$As NMR study of spin-spin relaxation and impurity effects in (Ba,K)Fe$_2$As$_2$ and CaFe$_2$As$_2$, S. MUKHOPADHYAY, S. OH, A.M. MOUNCE, M. LEE, W.P. HALPERIN, Department of Physics and Astronomy, Northwestern University, IL, USA, A.P. REYES, P. KUHNS, National High Magnetic Field Laboratory, FL, USA, P.C. CANFIELD, N. NI, S. BUD’KO, Ames Laboratory, Iowa State University, IA, USA — We report here NMR measurements on Ba$_{0.85}$K$_{0.15}$Fe$_2$As$_2$ single crystals ($T_c \approx 30$ K) grown from Sn flux. The variations of the NMR line widths and shifts with temperature (40 – 150 K) and with applied field (6 – 14 T) are indicative of the presence of local magnetic impurities in these crystals, in contrast with crystals of CaFe$_2$As$_2$. Both the shift and line width are linearly dependent on the bulk magnetization and are sufficiently large that the impurity magnetic moments must be coupled through the hyperfine interaction to the As nuclei. However, this coupling is somewhat weaker than for impurities in YBCO and $^{17}$O NMR [1]. Measurements of the spin-spin relaxation from the Hahn echo decay envelope and CPMG sequences indicate slow magnetic fluctuations, $\approx 350$ Hz, whose origin will be discussed.

12:39PM Q35.00006 NMR study of the FeAs parent compounds, AFe$_2$As$_2$ (A=Ba,Ca), ERIC BAUER, SEUNG-HO BAEK, Los Alamos National Laboratory, NICHOLAS CURUO, U. of California, Davis, FILIP RONNING, JOE THOMPSON — We present $^{75}$As NMR results of the FeAs 122 parent compounds, AFe$_2$As$_2$ (A=Ba,Ca) single crystals. For BaFe$_2$As$_2$, we find that Sn impurities in the single crystal dramatically alter the low energy spin fluctuations and suppress the ordering temperature from 138 K to 85 K, and that the temperature dependence of the $^{75}$As NMR spectra and spin lattice relaxation rates reveal a second order phase transition to a state of incommensurate magnetic order. On the other hand, CaFe$_2$As$_2$ shows a commensurate first order magnetic transition which is coupled to the structural transition. By comparing the two compounds, we show that the static and dynamic properties of the FeAs systems is extremely sensitive to the microscopic out-of-plane structure in microscopic level. Our results may shed light on the superconductivity observed under pressure.

12:51PM Q35.00007 NMR relaxation rate in the FeAs superconductors, MEERA PARISH, Princeton University, JIANGPING HU, Purdue University, B. ANDREI BERNEVIG, Princeton University — We consider how different symmetries of the superconducting order parameter will affect the NMR spin relaxation rate in the newly discovered iron-based superconductors. We particularly focus on a nodeless order parameter of unconventional extended s-wave symmetry, which changes sign between the electron and hole Fermi surfaces. Using a two-band model, we show that the extended s-wave order parameter is consistent with the results of recent NMR measurements, which exhibit a characteristic $T_c^3$ dependence of the NMR spin relaxation rate, only if the inter-band contribution dominates the response.

1:03PM Q35.00008 Infrared properties of Sr(Fe,Ni)2As2 superconducting single crystals, KEVIN KIRSHENBAUM, Center for Nanophysics and Advanced Materials, University of Maryland at College Park, A.B. SUSHKOV, MRSEC, University of Maryland at College Park, S.R. SAHA, N.P. BUTCH, J. PAGLIONE, H.D. DREW, Center for Nanophysics and Advanced Materials, University of Maryland at College Park — We report on temperature dependence of the bulk single crystal reflectivity and transmission of thin crystals of iron pnictides Sr(Fe,Ni)$_2$As$_2$ in the broad frequency range from far infrared to UV. We will discuss our data in comparison to results of other experiments and theory.

$^1$Work supported in part by CNAM and NSF-MRSEC at UMD CP.

1:15PM Q35.00009 Nonequilibrium quasiparticle dynamics in single crystals of Ba$_{1-x}$K$_x$Fe$_2$As$_2$, DARIUS TORCHINSKY, MIT, G.F. CHEN, J.L. LUO, N.L. WANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, NUH GEDIK, MIT — We report on measurements of the quasiparticle dynamics in single-crystals of Ba$_{1-x}$K$_x$Fe$_2$As$_2$ in the superconducting state via ultrafast pump-probe spectroscopy. Quasiparticles are injected into the samples by ultrashort laser pulses. Once injected, they cause a reflectivity change of the sample at the laser frequency, allowing time-resolved optical measurements of their density. We describe the temperature and excitation density dependence of the quasiparticle recombination rate and discuss the implications of these measurements on the nature of the superconducting gap and the electron-phonon coupling in these materials.

1:27PM Q35.00010 Charge dynamics of the spin-density-wave state in BaFe$_2$As$_2$, F. PFUNER, L. DEGIORG1, ETH-Zurich, J.G. ANALYTIS, J.-H. CHU, I.R. FISHER, Stanford University — We report on a thorough optical investigation of BaFe$_2$As$_2$ over a broad spectral range and as a function of temperature, focusing our attention on its spin-density-wave (SDW) phase transition at $T_{SDW} = 135$ K. While BaFe$_2$As$_2$ remains metallic at all temperatures, we observe a depletion in the far infrared energy interval of the optical conductivity below $T_{SDW}$, ascribed to the formation of a pseudogap-like feature in the excitation spectrum. This is accompanied by the narrowing of the Drude term consistent with the dc transport results and suggestive of suppression of scattering channels in the SDW state. About 30% of the spectral weight in the far-infrared energy interval of the optical conductivity is affected by the SDW phase transition.

1:39PM Q35.00011 Temperature Dependent Local Structure of LaO$_{1-x}$F$_x$FeAs, T.A. TYSYN, T. WU, NJIT, J. WOCIK, B. RAVEL, NIST, A. IGNATOV, C. ZHANG, Rutgers University, Z. QIN, T. ZHOU, NJIT, S.-W. CHEONG, Rutgers University — The local structure of the parent and doped LaO$_{1-x}$F$_x$FeAs compounds were studied by x-ray absorption spectroscopy. The Fe-As correlations are well modeled by an Einstein model with no low temperature anomalies. While the Einstein temperatures are identical for the doped (11%) and undoped samples, the doped sample is found to have a lower level of static disorder in the Fe-As distribution. For the Fe-Fe correlation, doping enhances the effective Einstein temperature. Comparisons with the temperature dependent structure of the simpler FeSe$_{0.88}$ systems will be made. This work is supported by DOE Grant DE-FG02-07ER46402.

1:51PM Q35.00012 Exploring Local Density of States in FeSe-based Superconductors, D. ZHANG, C.S. TING, Texas Center for Superconductivity, University of Houston, Houston, TX 77204 — Starting from two Fe ions per unit cell and two degenerate orbitals per Fe ion, we construct an effective four-band model for the FeSe-based superconductors, which Fermi surfaces are consistent with those from the ARPES experiments and LDA calculations. The hole pockets at (0,0) and the electron pockets at ($\pi$, $\pi$) are controlled by hopping between the same orbitals on the nearest and second neighboring sites while the intervals between the inner and outer Fermi surfaces around (0,0) and ($\pi$, $\pi$) are determined by hopping between different orbitals on the same sublattice. On the basis of the mean field theory for superconductivity, we also investigate the local density of states for different pairing symmetries and compare them with the recent STM experiments.

Session Q36 DCMP: Carbon Nanotubes and Other Nanostructured Materials: Sensing, Transport, and Optical Properties 408
Oxygen attachment on the CNT surface favors an ether type bond. Two oxygen atoms attached on the CNT surface within the same carbon ring on parallel bonds are energetically the most stable attachment configuration. In an armchair CNT, oxygen attachment favors the C-C bonds orthogonal to the CNT axis. Correlated addition propagates axially along parallel orthogonal bonds. In a zigzag CNT, oxygen attachment prefers the slanted bond, and correlated addition propagates spirally along parallel slanted bonds. Closely spaced oxygen attachment on the armchair and zigzag CNT surfaces causes a dip in transmission symmetrically away from the Fermi level. A clustered group of oxygen atoms covalently attached to a single-walled metallic zigzag CNT can result in a one order of magnitude drop in transmission that is asymmetric with respect to the Fermi energy resulting in a qualitative resemblance to conductance versus gate voltage curves observed experimentally [Science 315, 77 (2007)]. Calculations use density functional theory combined with non-equilibrium Green functions.

We perform a comprehensive study of the effect of covalent oxygen attachment on the transmission of metallic carbon nanotubes (CNTs). Oxygen attachment on the CNT surface favors an ether type bond. Two oxygen atoms attached on the CNT surface within the same carbon ring on parallel bonds are energetically the most stable attachment configuration. In an armchair CNT, oxygen attachment favors the C-C bonds orthogonal to the CNT axis. Correlated addition propagates axially along parallel orthogonal bonds. In a zigzag CNT, oxygen attachment prefers the slanted bond, and correlated addition propagates spirally along parallel slanted bonds. Closely spaced oxygen attachment on the armchair and zigzag CNT surfaces causes a dip in transmission symmetrically away from the Fermi level. A clustered group of oxygen atoms covalently attached to a single-walled metallic zigzag CNT can result in a one order of magnitude drop in transmission that is asymmetric with respect to the Fermi energy resulting in a qualitative resemblance to conductance versus gate voltage curves observed experimentally [Science 315, 77 (2007)]. Calculations use density functional theory combined with non-equilibrium Green functions.
DZMITRY YAROTSKI, SVETLANA KILINA, Los Alamos National Laboratory, ALEC TALIN, Sandia National Laboratory, ALEXANDER BALATSKY, SERGEI TRETIAK, ANTOINETTE TAYLOR, Los Alamos National Laboratory — Production of carbon nanotube-based (CNT) devices holds a great promise for bringing the size of electronic circuits down to molecular scales. Recently, yet another step has been made towards achieving this goal by developing a new method for metal-semiconductor CNT separation, which relies on wrapping the CNT with ssDNA molecule[1]. Though it was shown that the outcome of the separation process strongly depends on the DNA sequence, further investigations have to be conducted to determine detailed structure of the hybrids and their electronic properties. Here, we use STM to characterize structural and electronic properties of the CNT-DNA hybrids and compare experimental results to theoretical calculations. STM images reveal 3.3 nm DNA coiling period, which agrees very well with the theoretical predictions. Additional width modulations with characteristic lengths of 1.9 and 2.6 nm are observed along the molecule itself. Although scanning tunneling microscopy confirms the presence of DNA in the hybrid and visualizes its structure, further experimental work is required to reveal the dependence of electronic properties of hybrids on their internal structure. [1] M. Zheng et al., Science 302, 1545 (2004).

12:39PM Q36.00008 Scanning Tunneling Microscopy of DNA-Carbon Nanotube Hybrids 

EDISON Z. DA SILVA, Physics Institute-USP, R. B. PONTES, Physics Institute-USP, EDISON Z. DA SILVA, Physics Institute-UNICAMP, ADALBERTO FAZZIO, ANTONIO J. R. DA SILVA, Physics Institute-USP — Performing first principles density functional theory (DFT) we calculated the electronic and transport properties of a Au thin nanowire with transition metal atoms (Mn, Fe, Ni or Co) bridging the two sides of the Au nanowire. We will show that these systems have strong spin dependent transport properties and that the local symmetry can dramatically change them, leading to a significant spin polarized conductance. This spin dependent transport is also associated with the transition metal in the nanowire, in particular with the d-level positioning. Using Co, for example[1], when the symmetry permits the mixing between the wire s-orbitals with the transition metal d-states, there are interference effects that resemble Fano-like resonances with an anisotropy of 0.07 at the Fermi level. On the other hand, if this symmetry decouples such states, we simply have a sum of independent transmission channels and the calculated anisotropy was 0.23. The anisotropies for the other transition metals, as well as calculated transmittances for two Co impurities will also be presented [1]. R. B. Pontes, E. Z. da Silva, A. Fazzio and Antonio J. R. da Silva, J. Am. Chem. Soc. 130 (30), 9897-903, 2008.

We thank FAPESP, CNPq and CAPES.

12:41PM Q36.00009 Electron Transport in Quasi-1D, DNA-Templated Nanoparticle Arrays 

M. S. FAIRBANKS, Department of Physics, University of Oregon, G. J. KEARNS, Department of Chemistry, University of Oregon, B. C. SCANNELL, Department of Physics, University of Oregon, R. T. LOFTUS, Department of Physics, University of Oregon, A. R. TAYLOR, Department of Physics, University of Oregon, J. E. HUTCHISON, Department of Chemistry, University of Oregon — Devices based on self-assembled metal nanoparticle arrays are good model systems for investigating the physics of the nanoscale regime, where size quantization effects and the Coulomb charging energy can dominate transport even at high temperatures. We apply a novel, highly parallel fabrication technique [1] that creates quasi-1D (200 nm x ~20 nm) arrays of Au nanoparticles (r = 1.8 nm) bonded to DNA between predefined electrodes. These devices are found to exhibit Coulomb blockade over a wide range of operating temperatures (0.24 K to ~80 K). We present an analysis of our results in comparison to recent theoretical predictions for 1- and 2D tunnel junction arrays and highlight some effects that arise from our devices’ particular geometry. [1] M. G. Warner, J. E. Hutchison. Nature Materials 2, 272 (2003); G. J. Kearns, et al. to be published.

1:03PM Q36.00010 Determining the optical modes of solid and core-shell nanowires using relativistic electrons. JEROME HYUN, Dept. of Physics, Cornell University, MARK LEVENDORF, Dept. of Chemistry and Chemical Biology, Cornell University, MARTIN BLOOD-FORSYTHE, Dept. of Physics, Haverford College, JIWONG PARK, Dept. of Chemistry and Chemical Biology, Cornell University, DAVID MULLER, Dept. of Applied and Engineering Physics, Cornell University — Nanowires serve as building-blocks for miniaturized optoelectronic devices. Determining the dispersion properties of the nanowires is necessary for device-engineering, but can be experimentally difficult with conventional optical techniques because of fundamental diffraction limitations. Fast electrons, on the other hand, can be focused to nanometer or sub-nanometer probes, providing spatial resolutions far superior to existing optical techniques. The time-varying Fourier components of the electron’s evanescent electric field can extend beyond the far ultra-violet regime, providing a near-field, broad-band light source. Using scanning transmission electron microscopy and electron energy loss spectroscopy, we report on the relativistic calculations and measurements of the optical eigenmodes of single Ge nanowires. We also present calculations of a dielectric core/metallic shell system, where couplings between the surface plasmonic modes and the cavity modes occur. The work demonstrates a powerful optical characterization solution for nanowire systems.

1:05PM Q36.00011 ABSTRACT WITHDRAWN —

1:07PM Q36.00012 Transport properties of transition metal impurities on gold nanowires

RENATO B. PONTES, Physics Institute-USP, EDISON Z. DA SILVA, Physics Institute-UNICAMP, ADALBERTO FAZZIO, ANTONIO J. R. DA SILVA, Physics Institute-USP — Performing first principles density functional theory (DFT) we calculated the electronic and transport properties of a Au thin nanowire with transition metal atoms (Mn, Fe, Ni or Co) bridging the two sides of the Au nanowire. We will show that these systems have strong spin dependent transport properties and that the local symmetry can dramatically change them, leading to a significant spin polarized conductance. This spin dependent transport is also associated with the transition metal in the nanowire, in particular with the d-level positioning. Using Co, for example[1], when the symmetry permits the mixing between the wire s-orbitals with the transition metal d-states, there are interference effects that resemble Fano-like resonances with an anisotropy of 0.07 at the Fermi level. On the other hand, if this symmetry decouples such states, we simply have a sum of independent transmission channels and the calculated anisotropy was 0.23. The anisotropies for the other transition metals, as well as calculated transmittances for two Co impurities will also be presented [1]. R. B. Pontes, E. Z. da Silva, A. Fazzio and Antonio J. R. da Silva, J. Am. Chem. Soc. 130 (30), 9897-903, 2008.

1:39PM Q36.00013 Quantum simulation of four-probe measurement of carbon nanotube

ASAKO TERASAWA, KEJII TOBIMATSU, TOMOFUMI TADA, SATOSHI WATANABE, KEJII TOBIMATSU, Dept. of Materials Engineering, The Univ. of Tokyo — The four-probe method is widely used to measure the intrinsic resistance of various materials without the effects of sample-probe contacts. Recently, there have been many attempts to apply this method to nanoscale objects. Also, anomalous behaviors of nanoscale four-probe measurements were reported such as the negative four-probe resistance of single-walled carbon nanotube. To investigate quantum effects on the four-probe measurements in nanoscale, we examined the four-probe resistance of (5,5)-carbon nanotube with a vacancy or without a vacancy theoretically on the basis of density functional tight-binding method and Green’s function method. We found that the calculated four-probe resistance is sensitive to the position of the vacancy relative to the probes even when the sample-probe connections are weak. Such a behavior is unlikely to be seen in the two-probe resistance, and suggests that the four-probe resistance of nanoscale systems depend on the sample-probe geometry in a complicated manner.

This work is supported by Global COE Program for Mechanical Systems Innovation, MEXT, Japan.

1:51PM Q36.00014 Coherent Acoustic Spectroscopy of Nanorod Arrays

MASASHI YAMAGUCHI, JIANXUN LIU, DEXIAN YE, Department of Physics, Rensselaer Polytechnic Institute, TOH-MING LU, Department of Physics, Rensselaer Polytechnic Institute — Coherent acoustic transport through vertically grown nanorod array on substrate and coherent acoustic vibration of nanorod arrays are experimentally studied by using femtosecond laser based acoustic spectroscopy in GHz-THz frequency range. In nanorod materials, acoustic phonon dispersion and life time are altered by systems depend on the sample-probe geometry in a complicated manner. Here, we use STM to characterize structural and electronic properties of the nanorod arrays and compare experimental results to theoretical calculations. We have observed the transport of the coherent acoustic pulses through the nanorod arrays. The center frequency of the acoustic pulse was comparable to the diameter of the nanorods. Also, we have observed the transfer of the acoustic energy to the nanorod vibration mode while the coherent acoustic pulse propagates through. Mean-Free-Path and time of flight of the coherent acoustic phonons is determined by comparing the results of the samples with different thicknesses.

Water interfaces play a central role in a wide variety of disciplines including electrochemistry, (photo-) catalysis and biophysics. Knowledge of the details of water interfacial structure is thus essential both for a fundamental understanding of this ubiquitous liquid and for a basic understanding of the many systems in which aqueous interfaces play a key role. Although considerable progress has been made in understanding of bulk water, substantially less progress has been made at the interface. Here we report a series of surface specific studies of various water interfaces using surface-specific vibrational spectroscopies, both in equilibrium and on ultrafast (femtosecond) time scales. Our approach allows us to selectively investigate the one monolayer of water molecules at the different water interfaces. Water is characterized through its O-H stretch vibration. We find that interfacial hydrogen bonding depends strongly in the type of interface. Remarkably, for the water-air interface, interfacial hydrogen bonding is very similar to that occurring in bulk.
1:15PM Q37.00001 Surveying the potential landscapes controlling the accommodation of excess electrons by water networks, MARK JOHNSTON, Yale University — We present recent results of a new experimental approach where we use in-in pump-probe methods to measure the transition states and relative energies of isomers associated with the negatively charged water clusters. First, the vibrational spectra of various isomers are systematically disentangled using hole-burning Ar predissociation spectroscopy in a triple-stage time-of-flight mass spectrometer. We then monitor the spectra of fragment ions that are created by photoevaporation of Ar atoms through the various vibrational levels identified in the spectroscopic step. The major conclusion is the weak binding isomers are readily transformed into more strongly bound forms, while the reverse process is very inefficient. We describe progress on using this strategy to identify the large amplitude motions available in the finite systems using trace isotopes.
1:15AM Q37.00004 Ultrasound dynamic study of water confined in partially hydrophobic nanosized cylindrical sieves, ANTONIO FARAONE, NIST Center for Neutron Research and University of Maryland, YANG ZHANG, Massachusetts Institute of Technology, KAO-HSIANG LIU, CHUNG-YUAN MOU, National Taiwan University, SOW-HSIN CHEN, Massachusetts Institute of Technology — Using three high resolution quasielastic neutron scattering spectrometers we have investigated the single particle dynamics of water confined in a hydrophobically modified MCM-41-S sample. This latter is a silica matrix containing cylindrical sieves with diameter < 20 Å arranged in a hexagonal geometry. In the hydrophobically modified sample some of the sylanol groups in the pores' wall have been substituted with methanol groups resulting in a partially hydrophobic confining surface, which could be used as a model system. We have been able to analyze the data in the temperature range from 300 K to 210 K using a single consistent model, the Relaxing Cage Model (RCM) for the dynamics of supercooled water. Because of the heterogeneous environment experienced by the water molecules in the pores, the relaxation dynamics show a broad distribution of relaxation times. However, the Fickian diffusive behaviour is retained. The obtained results help clarify the role that the chemical interaction between the water molecules and the walls of the confining host plays in determining the characteristics of the water dynamics, as compared to purely geometric constraints such as the size and shape of the pores.
1:03PM Q37.00003 Femtosecond Sum-Frequency Generation Studies of the Structure and Dynamics of Interfacial Water, MISCHA BONN, AMOLF — Water interfaces play a central role in a wide variety of disciplines including electrochemistry, (photo-) catalysis and biophysics. Knowledge of the details of water interfacial structure is thus essential both for a fundamental understanding of this ubiquitous liquid and for a basic understanding of the many systems in which aqueous interfaces play a key role. Although considerable progress has been made in understanding of bulk water, substantially less progress has been made at the interface. Here we report a series of surface specific studies of various water interfaces using surface-specific vibrational spectroscopies, both in equilibrium and on ultrafast (femtosecond) time scales. Our approach allows us to selectively investigate the one monolayer of water molecules at the different water interfaces. Water is characterized through its O-H stretch vibration. We find that interfacial hydrogen bonding depends strongly in the type of interface. Remarkably, for the water-air interface, interfacial hydrogen bonding is very similar to that occurring in bulk.
1:15PM Q37.00005 Dynamics of Water Confined in Partially Hydrophobic Nanosized Cylindrical Sieves, ANTONIO FARAONE, NIST Center for Neutron Research and University of Maryland, YANG ZHANG, Massachusetts Institute of Technology, KAO-HSIANG LIU, CHUNG-YUAN MOU, National Taiwan University, SOW-HSIN CHEN, Massachusetts Institute of Technology — Using three high resolution quasielastic neutron scattering spectrometers we have investigated the single particle dynamics of water confined in a hydrophobically modified MCM-41-S sample. This latter is a silica matrix containing cylindrical sieves with diameter < 20 Å arranged in a hexagonal geometry. In the hydrophobically modified sample some of the sylanol groups in the pores' wall have been substituted with methanol groups resulting in a partially hydrophobic confining surface, which could be used as a model system. We have been able to analyze the data in the temperature range from 300 K to 210 K using a single consistent model, the Relaxing Cage Model (RCM) for the dynamics of supercooled water. Because of the heterogeneous environment experienced by the water molecules in the pores, the relaxation dynamics show a broad distribution of relaxation times. However, the Fickian diffusive behaviour is retained. The obtained results help clarify the role that the chemical interaction between the water molecules and the walls of the confining host plays in determining the characteristics of the water dynamics, as compared to purely geometric constraints such as the size and shape of the pores.
1:27PM Q37.00006 Reconstructing the dynamic hydration around hydrophobic molecular solutes using inelastic x-ray scattering, R. CORIDAN, N. SCHMIDT, G.H. LAI, Dept of Physics, P. ABBAMONTE, Dept of Physics, Seitz Materials Research Lab, G.C.L. WONG, Depts of Mat. Science Eng. and Physics, and Seitz Materials Research Lab, U of Illinois, Urbana-Champaign, M. MARUCCHO, N. BAKER, Dept of Biochem. and Mol. Biophys., Center for Comp. Biology, Washington U School of Medicine. — We combine inelastic x-ray scattering (IXS) data and liquid-state theory to image the dynamical hydration structure of water solvating molecular, hydrophobic solutes. Using ‘linear response imaging’, we computationally reconstruct the Å-scale spatial and fs-scale temporal evolution of density fluctuations in water using IXS. The imaginary part of density propagator \( \chi_{2}(q,\omega) \) is directly extracted from the IXS data, and the real part recovered using Kramers-Kronig relations. The resultant complex-valued \( \chi_{2}(q,\omega) \) is the Fourier transform of the density-density response function \( \chi_{1}(r,t) \) which measures the dynamical density fluctuations of water due to a point-like instantaneous pulse. We have shown that this propagator can be used to reconstruct the dynamical hydration around prototypical charge distributions. To extend this technique to more realistic solutes, Onslein-Zernike integral equations from liquid state theory are used to study hydration around small excluded volumes. We will present results for simple geometries and discuss the implications of combining exclusion and charge.

Session Q38 DCP: Focus Session: Nanomaterials for Energy Applications II
11:15AM Q38.00001 Nanostructured Multimetallic Catalysts in Fuel Cells1, CHUAN-JIAN ZHONG, Department of Chemistry, State University of New York, Binghamton, NY 13902 — There are two major driving forces for the global interests in research and development of fuel cells: the reality that fossil fuels are running out and the increasing environmental concern over pollution from using fossil fuels. Fuel cells utilizing hydrogen as fuels represent an important form of energy because hydrogen is a highly-efficient fuel and it is environmentally clean. Fuel cells such as proton exchange membrane fuel cell and direct methanol fuel cell are attractive because of their high conversion efficiency, low pollution, lightweight, and high power density. However, one of the important challenges for fuel cell commercialization is the preparation of active, robust and low-cost catalyst which is key component in fuel cells counting for ~30% of the cost in manufacturing fuel cells. The durability of the catalysts can also be compromised by sintering and dissolution, especially at high electrode potentials or under load-cycling. We have been developing nanotechnological approaches and investigating nanostructured materials to address some of the fundamental issues in terms of catalyst activity, stability and cost. This presentation discusses recent findings of our investigations of the synthesis and processing for nanostructured catalysts with controlled size, composition, and surface properties by highlighting a few examples of bimetallic/trimetallic nanoparticles and supported catalysts. The results from the characterization of the nanoparticles and catalysts using an array of techniques and computational modeling will be discussed. The synergistic properties of the nanostructured materials in fuel cell reactions, including electrocatalytic methanol oxidation reaction and oxygen reduction reaction, will also be discussed, along with current challenges and opportunities.

1Acknowledgement: NSF-NIRT

11:51AM Q38.00002 Reticular chemistry for clean energy, OMAR YAGHI, University of California, Los Angeles — Linking molecular building blocks by strong bonds to make networks (Reticular Chemistry) has yielded a number of new classes of materials such as metal-organic frameworks, zeolitic imidazolate frameworks and covalent organic frameworks. These are new classes of porous materials in which inorganic ‘struts’ are linked by organic ‘links’ to give extended structures with surface areas greater than 5000 m2/g. Their ultra-high surface area is useful in storing hydrogen and natural gas, and for capturing carbon dioxide. Recently we have shown that MOFs can be quite effective as air purification and capture of harmful gases. This presentation will highlight the milestones and future prospects of this new field

12:27PM Q38.00003 Chemical tools for creating energy-relevant nanomaterials, RAYMOND SCHAAK, Pennsylvania State University — An important pre-requisite for using nanoscale materials in energy-related applications is the ability to make them on-demand and to rigid and pre-determined standards. For example, creating nanoscale solids with controllable composition, crystal structure, size, morphology, and surface chemistry is necessary for optimizing and fine-tuning their properties, as well as spatially organizing them and interfacing them with other components in a device. This talk will summarize our efforts to controllably and rationally synthesize shape-controlled nanocrystals of complex multi-element metallic and semiconductor materials. Collectively, these results provide reliable and predictable guidelines for designing and synthesizing complex nanomaterials of solids that are typically viewed as challenging to make. The focus will be on applying these ideas to energy-relevant nanomaterials, including nanostructured superconductors with high critical fields, metal hydrides for hydrogen storage applications, nanoparticle catalysts relevant to fuel cells, and metal-based compounds for thermoelectric, battery, and photovoltaic applications.

1:03PM Q38.00004 Structural and electrochemical properties of V2O5 and AgV2O5 nanowires prepared by template assisted method. M.B. SAHANA, C. SUDAKAR, R. NAIK, Department of Physics and Astronomy, Wayne State University, Detroit, MI 48201, V.M. NAIK, Department of Natural Sciences, University of Michigan-Dearborn, Dearborn, MI 48128 — Vanadium pentaoxide and silver vanadium oxides are promising cathode materials for lithium ion battery as it allows easy intercalation/deintercalation of Li+ due its open layered structure. During Li+ intercalation energy is stored as chemical potential and during deintercalation the energy is released as electricity. Because of the large surface area nanostructured materials have enhanced energy storage capacity. We have prepared V2O5 and Ag2V2O5 (x = 0.1, 0.5) nanowires by template assisted method using radiation track etched hydrophilic PC membrane. The nanowires were grown on ITO coated glass substrates for optical analysis and on stainless steel substrate for XRD, SEM, Raman and electrochemical measurements. The effects of Ag doping on the electrochemical properties of V2O5 nanowires were investigated using a three electrode cell with nanowires as working electrode and Li as counter and reference electrode and lithium perchlorate in propylene carbonate as the electrolyte. The electrochemical characteristics of V2O5 and Ag2V2O5 nanowires such as lithium intercalation capacity, cyclic stability and diffusion coefficient will be presented.

1:15PM Q38.00005 Stable Room Temperature Hydrogen Storage in Titainum-Doped Silica, JASON SIMMONS, TANER YILDIRIM, NIST Center for Neutron Research, AHMAD HAMAED, DAVID ANTONELLI, Department of Chemistry and Biochemistry, University of Windsor — The optimum conditions for viable room temperature hydrogen storage require materials that possess isoteric heats of adsorption in between that of standard physisorbers and chemisorbers, typically in the ~20-30 kJ/mol regime. It has been theoretically predicted that transition metal atoms incorporated onto high surface area materials could enable significant room temperature storage; herein we demonstrate a possible experimental proof of these predictions. Titanium(III) complexes are grafted onto porous silica hosts, then activated to generate sites for dissociative adsorption of hydrogen gas. Using a combination of sorption measurements and inelastic neutron scattering, we show that the activated titanium provides strong hydrogen binding sites at room temperature and that adsorbed hydrogen is stable for long periods of time at ambient conditions. Further, the hydrogen can be desorbed under mild processing conditions. Neutron vibrational spectra agree well with theoretically predicted vibrational modes of the Ti—H complex. These results represent an important step towards reversible room temperature hydrogen storage.

1:27PM Q38.00006 Universal Behavior of Core-Shell Preferences in Transition-Metal Nanoparticles1, LIN-LIN WANG, DUANE D. JOHNSON, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign Transition-metal, core-shell nanoparticles are becoming ubiquitous from (electro-) catalysis to biomedical applications, due to control of size, performance, biocompatibility, and cost. We investigate 66 binary core-shell nanoparticle systems (groups 8 to 11 in the periodic table) using density functional theory (DFT) and systematically explore their segregation energies to determine core-shell preferences. We find that core-shell preferences are described by two simple factors: (1) cohesive energy (related to vapor pressure) and (2) atomic size (quantified by Wigner-Seitz radius). Core-shell preferences determined from DFT segregation energies agree with all available observations, and predict others, which can be used for design purposes. We then provide a universal description of core-shell preference via tight-binding band-energy differences that (i) quantitatively reproduces the DFT segregation energies and (ii) confirms the electronic origins for core-shell behavior.

1:39PM Q38.00007 Catalytic Gold Nanoparticles on an Iron Oxide Surface: A Scanning Tunneling Microscopy/Spectroscopy Study

Kwang Taeg Rim, Daejin Eom, Li Liu, Elena Stolyarova, Joan Raitano, Siu-Wei Chan, Columbia University, Maria Flytzani-Stephanopoulos, Tufts University, George Flynn, Columbia University — We present a Scanning Tunneling Microscopy/Spectroscopy study of a model catalyst system consisting of supported gold nanoparticles on a reduced Fe3O4(111) surface in ultrahigh vacuum. Gold forms two electrically distinct types of nanoparticles on an iron oxide surface upon annealing a multilayer Au/Fe3O4(111). STS measurements show that large nanoparticles (∼8nm) are metallic while single gold adatoms are bonded to the oxygen sites on the Fe3O4(111) surface. Site-specific adsorption at oxygen surface atoms and the size sensitive nature of the electronic structure (Coulomb blockade) suggest that Au adatoms are positively charged. When this Au/Fe3O4(111) catalyst system is dosed with CO at 260K, there is evidence for CO adsorption at gold adatom sites. These observations are consistent with the proposal that nonmetallic, positively charged, “invisible” Au particles are the catalytically active species for the water-gas-shift reaction on Au/metal oxide surfaces. http://clippercontrols.com/info/dielectric/constant.html

1:51PM Q38.00008 Intercalation dynamics in rechargeable batteries1, Liam Stanton, Northwestern University, Martin Bazant — We consider the ion intercalation of rechargeable battery electrode particles during charging (or discharging). We have developed a general phase-field model which incorporates entropic, enthalpic and elastic effects within the particle as well as the nonlinear chemical reactions at the particle-electrolyte interface. It is shown through linear stability analysis and numerical simulations that particle size and elastic effects will decrease or even eliminate both the spinodal region and the miscibility gap in the phase diagram.

2:03PM Q38.00009 Nanowire-based solar cell fabricated by nanosphere lithography2, Oki Gunawan, Supratik Guha, IBM T.J. Watson Research Center — Nanowire (NW) structures have been predicted to provide performance enhancement for solar cells due to improved light absorption [1] and (for radial p–n junction geometry) improved carrier collection [2]. We report the development of NW-based solar cells fabricated using nanosphere lithography. This method provides a simple, scalable, low cost and high throughput technique to define large scale NW structures. The fabricated NW solar cells (0.25 µm diameter and 1.3 µm tall) on a p–Si (100) substrate show ~30 % higher short-circuit current and ~4 % higher open circuit voltage compared to the control cells (without any NWs) with baseline efficiency of 6.2 %. The reflectance and quantum efficiency spectra reveal some advantages and shortcomings of the NW-based solar cell. This work marks some progress in the development of a scalable nanowire-based solar cell and highlights some key issues such as conformal-junction formation, surface passivation, and contact formation. [1] L. Hu and G. Chen, Nano Lett. 7, 3249 (2007). [2] B. M. Kayes et. al., J. Appl. Phys. 97, 114302 (2005).

11:15AM Q39.00001 How some proteins tubulate membranes1, Patricia Bassereau, Institut Curie — Endocytosis, exocytosis, membrane transport between intracellular compartments, virus or toxin entry or exit out of the cell, all imply to deform membrane. Membrane deformation mechanisms of cell membranes by proteins are currently actively studied. Giant vesicles (GUV) are interesting model membrane systems because they are composed of a very limited number of components compared to cellular membranes. The deformations induced by the interaction with a specific protein or any other additional components to the system, can then be directly monitored and the deformation mechanism eventually understood. In this talk, we will focus on different tubular structures induced by proteins. We will show that the B-subunits of Shiga toxin or Cholera Toxin, binding to their lipid receptors, GB3 or GM1 respectively, incorporated in GUV membrane, induce negative membrane curvature and form tubular invaginations, in absence of any other cellular machinery. Tubular structures can also be obtained when molecular motors walking along microtubules exert a pulling force on the membrane of GUV. The helicoidal assembly of dynamin, a protein involved in vivo in membrane fission can also produce tubular structures. This assembly has been reconstituted around membrane nanotubes of controlled diameter; we will show that the initial tube diameter strongly influences dynamin polymerisation. In each case, a physical framework for understanding deformation mechanism will be presented.

1 Funding was provided by EMBO, HSFP, NoE SoftComp and Institut Curie.

11:51AM Q39.00002 Membrane Disruption Effects of antimicrobial Peptide Protegrin-1, Hao Wang, James Kindt, Department of Chemistry, Emory University, Atlanta, Georgia 30322, USA — Molecular dynamics simulations have been performed to better understand membrane disruption induced by antimicrobial peptide Protegrin-1 (PG-1). Two distinct setups were adopted for atomistic simulations for DMPC/PG-1 systems. One started from bilayered ribbons either with or without the PG-1 peptides embedded and another one started from random lipid mixtures in the presence of the PG-1 peptides. Line tensions deduced from the random mixtures were generally lower with the PG-1 peptides embedded in ribbon edge, which supports edge-active role of the peptides. The random mixtures self-assembled into various structures. Extended simulations are being carried out to investigate the relation between concentration of the PG-1 peptides and the resultant structures. Furthermore, coarse-grained models have been used to simulate larger DMPC bilayers with the PG-1 peptides embedded. The PG-1 peptides were found to self-assemble into clusters. However, pore formation was not observed within our simulation period up to 3 microseconds. (DMPC: 1,2-Dimyristoyl-sn-Glycero-3-Phosphocholine)

12:03PM Q39.00003 Activation Dependent Organization of T Cell Membranes, Martin Forstner, Department of Physics, Syracuse University, Björn Lillemoe, Mark Davis, Howard Hughes Medical Institute and Department of Microbiology and Immunology Stanford University School of Medicine, Jay Groves, Howard Hughes Medical Institute and Department of Chemistry University of California — We investigate the role of lipid anchor motifs in the micro-organization of T-cell plasma membranes. To that end we generated a combinatorial library of protein constructs by fusing different lipid-modification sites of lipid anchored proteins with one of two fluorescent proteins (EGFP and Cherry). Two of these constructs that encode either for myristoylation, palmitoylation, geranylation or glycosylphosphatidylinositol (GPI) elaboration were co-expressed and dual color fluorescence cross-correlation spectroscopy (FCCS) was used to exploit comovement as a signature of co-localization. We find that in living T cells most anchors only co-localize with themselves, while different anchors move independently from each other. This suggests that a variety of domains with different chemical compositions exist in the plasma membrane and that the lipid anchor structure plays a key role in domain-specific recruitment of proteins. Furthermore, the degree of aggregation is found to depend on the activation state of the T cells. Cholesterol depletion and actin-drug experiments indicate that both are involved in the dynamic organization of the T cell plasma membrane.
12:15PM Q39.00004 Blebs in Model Lipid Membranes — M. LARADJI, C.W. HARVEY, E.J. SPANGLER, University of Memphis, P.B. SUNIL KUMAR, IIT-Madras — It is now widely recognized that biomembranes exhibit complex lateral heterogeneities. Among these are blebs, which are localized balloon-like membrane protrusions observed during cell apoptosis, necrosis, and cytotoxicity. Despite the poorly understood mechanism of bleb formation and their physiological role, they recently received a renewed attention. In order to investigate the physical mechanism leading to bleb formation, we developed a model based on an implicit-solvent lipid membrane model with soft interactions recently proposed by us [J. Chem. Phys. 128, 035102 (2008)]. The model also incorporates an explicit fluctuating polymer meshwork simulating a cytoskeleton, which is anchored to the membrane. Using systematic large-scale simulations of membranes with varying values of the lipid density, cytoskeleton grafting-sites density and cytoskeleton tension, we found that localized blebs are formed on the membrane exoplasmic side in the presence of mismatch between tensions of the bare membrane and cytoskeleton. The blebs are pinned by the cytoskeleton anchors, reminiscent to those observed in apoptotic cells. The distance between neighboring anchors determines the neck of a bleb. The remaining membrane surrounding the blebs stiffens to accommodate the tensed cytoskeleton.

1:27PM Q39.00005 Membrane Fusion Proteins as Nanomachines — LUKAS TAMM, Department of Molecular Physiology & Biological Physics, University of Virginia — Membrane fusion is key to fertilization, virus infection, and neurotransmission. Specific proteins work like nanomachines to stitch together fluid, yet highly ordered lipid bilayers. The energy gained from large exothermic conformational changes of these proteins is utilized to fuse lipid bilayers that do not fuse spontaneously. Structural studies using x-ray crystallography and NMR spectroscopy have yielded detailed information about architecture and inner workings of these molecular machines. The question now is: how is mechanical energy gained from such protein transformations harnessed to transform membrane topology? To answer this question, we have determined that a boomerang-shaped structure of the influenza fusion peptide is critical to generate a high-energy binding intermediate in the target membrane and to return the “boomerang” to its place of release near the viral membrane for completion of the fusion cycle. In presynaptic exocytosis, receptor and acceptor SNAREs are zipper to form a helical bundle that is arrested shortly before the membrane. Ca binding to interlocked synaptotagmin releases the fusion block. Structural NMR and single molecule fluorescence data are combined to arrive at and further refine this picture.

1:03PM Q39.00006 Miscibility Critical Points in Plasma Membranae — BENJAMIN MACHTA, SARAH VEATCH, STEFANOS PAPANIKOLAOU, JAMES P. SETHNA, Cornell University — Lipid bilayers surround all cells and are home to a host of proteins and lipids that mediate interactions between the cell and its environment. Recent experimental work has shown that simple membranes composed of three lipid components show complex phase behavior at temperatures in the physiological range. For example, two liquid phases and a gel or solid phase are seen, and a second-order phase transition with Ising critical behavior can be reached at a boundary of the liquid-liquid coexistence region [1]. Surprisingly, membrane vesicles isolated from living cells can be tuned with a single parameter (temperature) to criticality [1]. This suggests that cell membranes in vivo sit near miscibility critical points, and may explain some of the paradoxes associated with putative lipid rafts proposed in other experiments. Here we report on work mapping phase diagrams for the simple membranes utilizing NMR and microscopy data. In addition, we use canonical models of phase transitions to understand the qualitative features of the membranes. Finally we explore ideas from information theory and self organized criticality to understand how and why real cells maintain a membrane near criticality. [1] Honerkamp-Smith, Veatch, and Keller, Biochim Biophys Acta. 2008 (in press)

1:15PM Q39.00007 Calcium-induced gel domains in bilayer – more elusive than thought — DENNIS DISCHER, DAVID CHRISTIAN, WOUTER ELLENBROEK, ANDREA LIU, MRSEC, University of Pennsylvania — As a highly bioactive divalent cation, calcium can in principle crossbridge anionic groups and induce domain formation and rigification, but past reports with lipid systems appear conflicted. We mix, as a robust model system, anionic and neutral polymer amphiphiles within vesicle and cylinder micelle morphologies and add calcium. Based on micro- measurements, calcium forms definitive crossbridges between the anionic amphiphiles, rigidifying the charged membranes across a fluid-gel transition and also leading to lateral phase separation without disrupting the assemblies. A systematic phase diagram shows that long-lived domains occur in a narrow region near the polyanion’s pK’s. The phase behavior appears well described by a relatively simple model in which – among electrostatic and entropic contributions – counterion entropy outcompetes attractive crossbridging to drive remixing of the highly charged polyacid at high pH. Initial observations extend from polymers to a polyanionic lipid involved in cell signaling [phosphatidylinositol (4,5)-bisphosphate], highlighting both the generality and limits of calcium effects.

1:27PM Q39.00008 Nonequilibrium instabilities of membranes with multiple-state active proteins — HSUAN-YI CHEN, Department of Physics and Institute of Biophysics, National Central University, Jhongli, Taiwan, ALEXANDER MIKHAILOV, Abteilung Physikalische Chemie, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — We present a theoretical model for the dynamics of membranes containing active proteins that have several conformational states. The proteins are active because their conformational transition rates depend on the strength of external energy source that drives the system out of equilibrium. We show that there exist several types of nonequilibrium phase transitions for a membrane with proteins that have typical transition rates and in-plane diffusion constant.

1:39PM Q39.00009 Physical Foundations of PTEN/Phosphoinositide Interaction — ARNE GERICKE, ZHIPING JIANG, ROBERTA E. REDFERN, EDGAR E. KOOIJMAN, Kent State University, ALONZO H. ROSS, University of Massachusetts Medical School — Phosphoinositides act as signaling molecules by recruiting critical effectors to specific subcellular membranes to regulate cell proliferation, apoptosis and cytoskeletal reorganization, which requires a tight regulation of phosphoinositide generation and turnover as well as a high degree of compartmentalization. PTEN is a putative specific for the 3-phosphoinositide ring that is deleted or mutated in many different disease states. PTEN association with membranes requires the interaction of its C2 domain with phosphatidylinosine and the interaction of its N-terminal end with phosphatidylinositol-4,5-bisphosphate (PI(4,5)P2). We have investigated PTEN/PI(4,5)P2 interaction and found that Lys13 is crucial for the observed binding. We also found that the presence of cholesterol enhances PTEN binding to mixed PI(4,5)P2/POPC vesicles. Fluorescence microscopy experiments utilizing GUVs yielded results consistent with enhanced homotypic domain formation in the presence of these phospholipids. These experiments were accompanied by zeta potential measurements and solid state MAS 13P-NMR experiments aimed at investigating the ionization behavior of phosphoinositides.

1:51PM Q39.00010 Multiscale modeling of phospholipid bilayers: from explicit-solvent atom-resolution to solvent-free coarse-grained simulations — ZUN-JING WANG, MARKUS DESERNO, Carnegie Mellon University — To advance the efficiency of phospholipid bilayer simulations and permit the treatment of challenging phenomena on mesoscopic length- and time-scales, several solvent-free Coarse-Grained (CG) phospholipid bilayer models have been presented in the past ten years. Most of them were derived in a top-down scheme, aiming to qualitatively reproduce phase diagrams, binding and stretching rigidity, area per lipid, and the thickness of a generic bilayer in experiments. Here, we derive a bottom-up CG model of an implicit-solvent lipid bilayer by matching its structural and mechanical properties with that of a membrane in all-atom resolution. Besides preserving chemical specificity and quantitative accuracy, we expect to gain a more fundamental understanding of the relationship between the elastic, mechanical, and diffusive properties of implicit solvent bilayers and their underlying CG interaction potentials, specifically bonded and non-bonded forces, as well as the effective interactions replacing the solvent.
negative exponent. The decay exponent increases with w potentiation-to-depression ratio and multiplicative depression. Under realistic physiological parameters, the network was equilibrated with simulations for a physical time of days. For lower CHUN-CHUNG CHEN, DAVID JASNOW, University of Pittsburgh — We consider a network of integrate-and-fire neurons with random connections driven by small network of 32 neurons. For high state under the plasticity, for low activity evolves with either ultra-stable, chaotic or neutral dynamics. While experimental evidence has demonstrated that repeatable activity states can exist in cortical networks, it is still unclear what the spatio-temporal dynamics near these states are. To accurately address this question, the trajectories of similar, 1 ± ^* in the stationary ⋆, triggering the firing of a single neuron in a quiet network typically leads to a bursting event that lasts for seconds in a small network of 32 neurons. For high ⋆, the induced activities can persist in the network indefinitely. A mean-field theory combined with a master equation describing the distribution of synaptic weights predicts a power-law regime under the small jump assumption of synaptic weight changes. The exponents of predicted power law depends on the deviation of the mean synaptic weight from the w parameter and is to be determined self-consistently.

Wednesday, March 18, 2009 11:15AM - 2:15PM – Session Q40 DBP: Neural Computation 412

11:15AM Q40.00001 Deriving functional structure of neuronal networks from spike train data1

, SARAH FELDT, VAUGHN HETRICK, JOSHUA BERKE, MICHAL ZOCHOWSKI, University of Michigan — We present a novel algorithm for the detection of functional clusters in neural data. In contrast to many clustering techniques which convert functional interactions to topological distances to determine groupings, our algorithm directly utilizes the dynamics of the neurons to obtain functional groupings. No prior knowledge of the number of groups is needed, as the algorithm determines statistically significant clusters through a comparison to surrogate data sets. Additionally, we introduce a new synchronization measure and use this measure in the algorithm to observe known groupings in simulated data. We then apply our algorithm to experimental data obtained from the hippocampus of a freely moving mouse and show that it detects known changes in neural states associated with exploration and slow wave sleep. Finally, we show that the new synchronization measure can detect changes which are consistent with known neurophysiological processes involved in memory consolidation. 1This work was supported through an NSF Graduate Research Fellowship, NIH Grant EB003583, the Whitehall Foundation, and National Institute on Drug Abuse RO1 DA14318.

11:27AM Q40.00002 Bursting dynamics in vitro neural networks and their stimulation driven learning. Joon Ho Cho, June Hoan Kim, Kyoung J. Lee — Recent studies have indicated that recurring neural “bursts” may play an essential role in neural information processing and memory. One key element of this hypothesis involves the translation of temporal patterns of stimuli into spatiotemporally distributed information. One ideal system to investigate this issue is cultured network of neurons grown on multi-electrode array (MEA). Based on such in vitro systems, we have investigated the changes incurred by extrinsic stimuli in the spontaneously recurring bursting activities. We have employed, in particular, two-channel paired, delayed, tetanic stimuli to evoke different patterns of bursting activities. Our preliminary data suggests that the neural network can exhibit some learning behavior.

11:39AM Q40.00003 Burst switching between incoherence and synchrony NATHAN CROSBY, JOSEPH TRANQUILLO, Bucknell University — Studies of coupled oscillators often use diffusive connections to ensure that the coupled quantity is conserved. Signals between neurons, however, are not diffuse and may propagate unattenuated throughout a network. We compare diffusive and synaptic-like coupling of Hindmarsh-Rose (HMR) oscillators through numerical simulations. HMR parameters are tuned to either oscillate continuously or alternate bursts of oscillations and periods of quiescence. In diffusive coupling, two HMR units synchronize bursts and individual oscillations within a burst at nearly the same coupling strength. Synapse-like coupling, however, shows a new behavior, called burst switching, between incoherence and synchrony. For example, a bursting unit can entrain an oscillating unit of a different frequency during the burst but then force the oscillator into quiescence. Burst switching in various network topologies synchronizes inhomogeneous units for the duration of the burst, followed by a period of network quiescence and a return to incoherence. The summed activity resembles the progression of an epileptic seizure including the “spike and wave” at the transition from synchrony to quiescence.

11:51AM Q40.00004 ABSTRACT WITHDRAWN —

12:03PM Q40.00005 Trajectories through similarity space produced by local neocortical circuits1, JOHN BEGGS, WEI CHEN, JON HOBBS, AONAN TANG, Indiana University, Bloomington, BEGGS LAB TEAM — The dynamics found in local cortical networks strongly impact the types of computations they can perform. Major classes of cortical network models assume that spatio-temporal activity evolves with either ultra-stable, chaotic or neutral dynamics. While experimental evidence has demonstrated that repeatable activity states can exist in cortical networks, it is still unclear what the spatio-temporal dynamics near these states are. To accurately address this question, the trajectories of similar, but not identical, inputs must be quantified. We use 60 channel microelectrode arrays to measure spatio-temporal trajectories through similarity space at 4 ms resolution in organotypic cortical cultures and acute cortical slices. Here we show that while attractive, chaotic and neutral trajectories can exist in these networks, the average trajectory has a Lyapunov exponent near zero (0.01 ± 0.2, mean ± s.d.), indicating that neutral dynamics prevail. 1Supported by NSF, and MetaCyt funds to Indiana University from Eli Lilly Foundation.

12:15PM Q40.00006 Synaptic weight distribution under spike-timing dependent plasticity CHUN-CHUNG CHEN, DAVID JASNOW, University of Pittsburgh — We consider a network of integrate-and-fire neurons with random connections driven by noise triggered firings. The synaptic weights between the neurons are allowed to evolve under spike-timing dependent plasticity rules with additive potentiation and multiplicative depression. Under realistic physiological parameters, the network was equilibrated with simulations for a physical time of days. For lower potentiation-to-depression ratio w**, the synaptic weights forms a unimodal distribution which decays for large weights following a power law with a strong negative exponent. The decay exponent increases with w**, and runaway synaptic weights were observed as the exponent approaches −1. In the stationary state under the plasticity, for low w**, triggering the firing of a single neuron in a quiet network typically leads to a bursting event that lasts for seconds in a small network of 32 neurons. For high w**, the induced activities can persist in the network indefinitely. A mean-field theory combined with a master equation describing the distribution of synaptic weights predicts a power-law regime under the small jump assumption of synaptic weight changes. The exponents of predicted power law depends on the deviation of the mean synaptic weight from the w** parameter and is to be determined self-consistently.
tical neurons, AONAN TANG, JON HOBBS, Indiana University, WLADEK DABROWSKI, PAWEL HOTTOWY, ALEXANDER SHER, ALAN LITKE, Indiana University — Learning methods for spiking neural networks are not as well developed as the traditional neural networks that widely use back-propagation training. We propose and implement a Hebbian based learning method with winner-take-all competition for spiking neural networks. This approach is spike time dependent which makes it naturally well suited for a network of spiking neurons. Homeostasis with Hebbian learning is implemented which ensures stability and quicker learning. Homeostasis implies that the net sum of incoming weights associated with a neuron remains the same. Winner-take-all is also implemented for competitive learning between output neurons. We implemented this learning rule on a biologically based vision processing system that we are developing, and use layers of leaky integrate and fire neurons. The network when presented with 4 bars (or Gabor filters) of different orientation learns to recognize the bar orientations (or Gabor filters). After training, each output neuron learns to recognize a bar at specific orientation and responds by firing more vigorously to that bar and less vigorously to others. These neurons are found to have bell shaped tuning curves and are similar to the simple cells experimentally observed by Hubel and Wiesel in the striate cortex of cat and monkey.

12:39PM Q40.00008 Neural Decision Boundaries Predict Maximum Entropy Parameters, JEFF FITZGERALD, TATYANA SHARPEE, UCSD, The Salk Institute for Biological Studies — Previous studies have shown that the response properties of neural networks can be well described by a pairwise maximum entropy model (PMEM). The coupling constants in this model can be calculated from experimental data, but it is µ input. In the they would need to inputs are fully synchronous for the preferred direction and maximally dispersed in time for the null direction. Further, any inhibitory inputs lag excitatory inputs, as Priebe and Ferster have observed (2005). At any level of input strength, the selectivity is weak when only inhibitory inputs are considered. The inclusion of inhibition significantly strengthens selectivity, and this selectivity is preserved over a wide range of background noise levels and for short stimulus durations. We conclude that inhibition likely plays an essential role in the mechanism underlying direction selectivity.

12:51PM Q40.00009 Relationship between higher-order correlations in stimulus and information in the receptive fields of visual neurons1, RYAN ROWEKAMP, UCSD, TATYANA SHARPEE, Salk Institute — Neurons encode incoming signals in a series of spikes in the voltage trace across their cell membranes. This encoding is known to change in response to stimulus mean, variance, and power spectrum. Natural signals are known to have strong higher-than-second order correlations that cannot be described by a Gaussian distribution. To examine whether these higher-order statistics can also cause neurons to adapt their codes, we modeled the neural spike probability as an arbitrary nonlinear function with respect to two stimulus dimensions. The relevant stimulus dimensions were found as those that accounted for the largest mutual information between stimuli and spikes. We found that the contribution of the second dimension on the spike probability was stronger for natural, rather than Gaussian noise, stimuli and increased with the kurtosis of the stimulus distribution.

1Work has been supported by the NSF-sponsored Center for Theoretical Biological Physics (grant numbers PHY-0216576 and 0225630).

1:03PM Q40.00010 Robust Motion Processing in the Visual Cortex, AUDREY SEDERBERG, JULIA LIU, MATTHIAS KASCHUBE, Princeton University — Direction selectivity is an important model system for studying cortical processing. The role of inhibition in models of direction selectivity in the visual cortex is not well understood. We probe the selectivity of an integrate-and-fire neuron with a noisy background on top of a deterministic input current determined by a temporal-lag model for selectivity, including first only excitatory inputs and later both excitatory and inhibitory inputs. We find that the selectivity is weak when only inhibitory inputs are considered. The inclusion of inhibition significantly strengthens selectivity, and this selectivity is preserved over a wide range of background noise levels and for short stimulus durations. We conclude that inhibition likely plays an essential role in the mechanism underlying direction selectivity.

1:15PM Q40.00011 Rhythmogenic Neuronal Networks and k-Core Percolation, DAVID SCHWAB, ROBJIN BRUINSMAN, Department of Physics, UCLA, ALEX LEVINE, Department of Chemistry and Biochemistry, UCLA — The preBötzinger Complex (pBC) is a small (~10^2) network of identical excitatory neurons that collectively generate a temporally stable pattern of firing bursts interspersed by quiescent periods. The voltage output of this system is essential to the control of the mammalian breathing rhythm under certain physiological conditions. The network is also remarkable in that a small set of coupled identical neurons can generate a collective behavior that is not inherent in any one of them: individual neurons do not exhibit rhythmic bursting. We develop a simple model of interacting excitatory neurons that demonstrates this behavior as one of its dynamical regimes, and show that while some of its dynamic transitions can be understood in terms of mean field theory, others cannot. The non-mean-field behavior can be understood in terms of purely topological properties of random networks.

1:27PM Q40.00012 ABSTRACT WITHDRAWN

1:39PM Q40.00013 Determining information flow in networks containing one hundred neocortical neurons, AONAN TANG, JON HOBBS, Indiana University, WLADEK DABROWSKI, PAWEL HOTTOWY, ALEXANDER SHER, ALAN LITKE, JOHN BEGGS, Indiana University — How does information flow through networks of neurons? The type of network topology revealed could have important consequences for network efficiency and robustness to damage. Several tools, including transfer entropy, Granger causality, and directed information can be applied to this question. Yet indirect connections, connections with various delays, and feedback loops can complicate the task of uncovering the information flow structure. We have applied the above methods in simple validation studies, demonstrating that many of these issues can in principle be overcome. We will present preliminary results from neocortical networks of neurons recorded with a 512 electrode array.

1:51PM Q40.00014 Integration of neuroblasts into a two-dimensional small world neuronal network, CASEY SCHNEIDER-MIZELL, MICHAL ZOCHOWSKI, LEONARD SANDER, University of Michigan — Neurogenesis in the adult brain has been suggested to be important for learning and functional robustness to the neuronal death. New neurons integrate themselves into existing neuronal networks by moving into a target destination, extending axonal and dendritic processes, and inducing synaptogenesis to connect to active neurons. We hypothesize that increased plasticity of the network to novel stimuli can arise from activity-dependent cell and process motility rules. In complement to a similar in vitro model, we investigate a computational model of a two-dimensional small world network of integrate and fire neurons. After steady-state activity is reached in the extant network, we introduce new neurons which move, stop, and connect themselves through rules governed by position and firing rate.
2:03PM Q40.00015 Phase dependent and independent responses in auditory cortex, Didier Depireux, Barak Shechter, U of Maryland Medical School, THEEARLAB TEAM — Responses of auditory neurons are often characterized by their spectro-temporal receptive field (STRF). This linear measure has been shown to capture the overall trend of the response, but by its nature, it does not reflect any non-linear processing. We have recently shown that neurons in primary auditory cortex (AI) of the awake ferret respond with non-trivial nonlinearities (not solely the result of rectifying or saturating nonlinearities). We developed new techniques to reveal additional phase dependent (DC) and dependent (quadratic) tuning in the tuning of single neurons. One of the assumptions in the STRF model is that the mean firing rate (averaged over any single period of the stimulus) does not depend on the spectro-temporal modulations, but rather on the overall level of the stimulus. The phase-dependent tuning to the spectro-temporal envelope is analogous to complex visual neural responses, in which responses to an auditory grating stimulus do not depend on its spatial phase. We show the existence of neurons tuned in 1) a phase-independent manner, 2) a linear manner and 3) a quadratic manner to the time-frequency content of the spectral envelope of sounds.

Wednesday, March 18, 2009 11:15AM - 2:15PM – Session Q41 DCMP DMP: Strongly Correlated Electron Theory 413

11:15AM Q41.00001 Quantum dots: a new tool for studying quantum phase transitions (QPT), N. Roch, S. Florens, V. Bouchiat, W. Wernsdorfer, F. Balestro, Institut Neel, CNRS, Grenoble, France — QPT were studied in many different systems: spin chains, strongly correlated materials, high Tc superconductors, etc. but all the properties (magnetism, superconductivity ...) of these materials can be difficult to control. On the other hand, thanks to microelectronic technologies, it is now possible to obtain tailor-made quantum dots in which all the interactions can be tuned finely. It was then proposed by several theoretic papers [1] to use them as model systems for probing QPT. In this experimental work, we observed a screening/non screening QPT transition in a single-molecule transistor. We will present a full study as a function of magnetic field, bias voltage and temperature [2].

11:27AM Q41.00002 Signs of quantum Griffiths effects in the weak itinerant ferromagnet Ni-V, Almut Schroeder, Sara Ubaid-Kassis, Kent State University — Magnetization and ac-susceptibility data of Ni_{1-x}V_{x} alloys are presented in the vicinity of the critical concentration, x_c \approx 11\%, where the ferromagnetic transition temperature is expected to vanish. For x > x_c, power laws with unusual exponents are observed, which change with further dilution.

11:39AM Q41.00003 Effects of retardation on a system of polarized fermions, Ling Yang, University of California, Riverside, Filippos Klironomos, ENS, Lyon, France, Shan-Wen Tsai, University of California, Riverside — When fermion-fermion interactions are frequency dependent, retardation effects may play an important role in determining the phase diagram and critical energy scales of the system. These effects are particularly significant when there is competition between two or more instabilities of the Fermi liquid state. In order to elucidate these effects, we study a simple model of spinless fermions on a square lattice. We employ a functional renormalization-group method to obtain the flows of vertices and correlation functions of this system. The phase diagram, critical scales and sub-dominant types of order can be obtained this way for various types of interactions.

1Supported by NSF DMR 0306766

11:51AM Q41.00004 Phase diagram, correlation gap, and critical properties of the Coulomb glass, Matteo Palassini, Martin Goethe, University of Barcelona — We investigate the lattice Coulomb glass model in three dimensions via extensive Monte Carlo simulations. 1. No evidence for an equilibrium glass phase is found down to very low temperatures, contrary to mean-field predictions, although the correlation length increases rapidly near T = 0. 2. The single-particle density of states near the Coulomb gap satisfies the scaling law g(e,T) \sim T^{0.7}(J(e)/T) with λ \approx 2.2. 3. A charge-ordered phase exists at low disorder. The phase transition from the fluid to the charge ordered phase is consistent with the Random Field Ising universality class, which shows that the interaction is effectively screened at moderate temperature. Results from nonequilibrium simulations will be briefly discussed. Reference: M. Goethe and M. Palassini, arXiv:0810.1047

1Work supported by the Generalitat de Catalunya and the Ministerio de Ciencia e Innovacion (contracts FIS-2006-13321-C02-01 and AP2007-01005). The computations were performed on the Spanish Supercomputing Network (RES) node at Universidad de Cantabria.

12:03PM Q41.00005 Fingerprints of intrinsic phase separation in magnetically-doped 2DEG, Hanna Terletska, Vladimir Dobrosavljevic, Florida State University, National High Magnetic Field Laboratory — We theoretically study the properties of a recently observed [1] inhomogeneous phase preceding the metal-insulator transition in a magnetically-doped two-dimensional electron gas (2DEG). We show that, due to competition between (ferromagnetic) double-exchange and (anti-ferromagnetic) super-exchange, at very low carrier density such a system is unstable toward intrinsic phase separation (PS). Here, ferromagnetic carrier-rich (metallic) “droplets” emerge within a magnetically disordered carrier-poor (insulating) matrix. Our calculations indicate that this regime should display very unusual transport, featuring colossal magneto-resistance with exceptionally weak density dependence - in striking agreement with experiments [1] on CdMnTe quantum wells. Such exotic transport properties - we argue - should be considered as “fingerprint” for intrinsic phase separation, a behavior very different from situations where phase coexistence is driven by disorder due to extrinsic impurities or defects.

12:15PM Q41.00006 The Exponential Downfall of the Weak-Coupling SDW State in Chromium, Yejun Feng, Argonne National Lab, R. Jaramillo, T.F. Rosenbaum, Univ. of Chicago, J.C. Lang, Z. Islam, G. Srajer, Argonne National Lab, P.B. Littlewood, Univ. of Cambridge — Elemental chromium is the archetypical model system for itinerant antiferromagnetism. The incommensurate spin density wave state, originating from the nested Fermi surface, is readily observable with direct and scattering probes. Through a combination of low temperature cryogenic, diamond anvil cell, and synchrotron x-ray diffraction techniques, we measure directly the spin and charge order in the pure metal as it is driven towards its quantum critical point under pressure. We observe that both the spin and charge order are suppressed exponentially with pressure, well beyond the region where disorder cuts off such a simple evolution, and they maintain a harmonic scaling relationship over decades in scattering intensity. The observed exponential behavior of the order parameter follows a weak-coupling BCS theory for the ground state, even in the presence of strong pairing correlations that survive to surprisingly high temperatures and energies, as observed by inelastic scattering, transport, and thermal expansion measurements. This duality points to the fundamental issue of how mean-field behavior can describe so successfully important aspects of strongly coupled electron systems.
12:27PM Q41.00007 Nonanalytic spin susceptibility of interacting fermions away and near a fermionic quantum phase transition. DMITRII MASLOV, University of Florida, ANDREY CHUBUKOV, University of Wisconsin — We study nonanalytic paramagnetic response of an interacting Fermi system both away and in the vicinity of a fermionic quantum phase transition (QCP). Previous studies found that the spin susceptibility \( \chi \) scales linearly with either the temperature \( T \) or magnetic field \( H \) in the weak-coupling regime and that the interaction in the Cooper channel affects this scaling via logarithmic renormalization of prefactors of the \( T, |H| \) term. We show that Cooper renormalization becomes effective only at very low temperatures, which get even smaller near a QCP. We derive the thermodynamic potential as a function of magnetization and show that it contains, in addition to regular terms, a non-analytic \( |M|^4 \) term, which becomes \( M^4/T \) at finite \( T \). We consider the vicinity of a fermionic QCP by generalizing the Eliashberg treatment of the spin-fermion model to finite magnetic field, and show that the \( |M|^4 \) term crosses over to a non-Fermi-liquid form \( |M|^7/T \) near a QCP. The prefactor of the \( |M|^7/T \) term is negative, which indicates that the system undergoes a first-order rather than a continuous transition to ferromagnetism. We compare two scenarios of the breakdown of a continuous QCP: a first-order instability and a spiral phase and show that in a model with a long-range interaction in the spin channel first-order transition occurs before the spiral instability.

12:39PM Q41.00008 Fermionic propagators for 2D systems with singular interactions. TIGRAN SEDRAKYAN, ANDREY CHUBUKOV, Department of Physics, University of Wisconsin-Madison — We analyze the form of the fermionic propagator for 2D fermions interacting with massless overdamped bosons. Examples include a nematic and Ising fermionic quantum-critical points, and fermions at a half-filled Landau level. Fermi liquid behavior in these systems is broken at criticality by a singular self-energy, but the Fermi surface remains well defined. These are strong-coupling problems with no expansion parameter other than the number of fermionic species, \( N \). The two known limits, \( N >> 1 \) and \( N = 0 \) show qualitatively different behavior of the fermionic propagator \( G(\epsilon, \omega) \). In the first limit, \( G(\epsilon, \omega) \) has a pole at some \( \epsilon_k \), in the other it is analytic. We analyze the crossover between the two limits. We show that the pole survives for all \( N \), with residue \( Z = O(1) \), however at small \( N \) it only exists in a range \( O(N^2) \). At \( N = 0 \), the range collapses and the behavior of \( G(\epsilon, \omega) \) becomes analytic.

12:51PM Q41.00009 Non-Fermi-liquid behavior of quantum magnetooscillations near a quantum critical point. CHUNGWEI WANG, DMITRII MASLOV, Department of Physics, University of Florida — We study many-body effects in quantum magnetooscillations of a 2D strongly correlated system near fermionic and antiferromagnetic quantum critical points (QCP). The amplitude of magnetooscillations is determined by the electron self-energy \( \Sigma(\pi T, k, T) \) averaged over the Fermi surface, at the Matsubara frequency \( \omega = \pi T \) for \( \omega \gg \omega_c \), where \( \omega_c \) is the cyclotron frequency. The major contribution of the bosonic propagator to the electron self-energy comes from static spin fluctuations. In the spin-fermion model, the self-energy behaves as \( \propto T^2 \) in the antiferromagnetic system and as \( \propto T \) in \( T \) in the ferromagnetic system. This shows the non-Fermi-liquid temperature dependence of the self-energy near the QCP and the oscillation amplitude \( A \propto \exp\left[-2\pi(\pi T + \Sigma)/\omega_c \right] \) can be very different from the Lifshitz-Kosevich form. The momentum dependence of the self-energy contribution to the oscillation amplitude is also discussed.

1:03PM Q41.00010 Mechanism of multifractal spectrum termination at the Anderson-metal-insulator transition. MATTHEW FOSTER, COLUMBIA UNIVERSITY, SHINSEI RYU, UNIVERSITY OF CALIFORNIA, BERKELEY, ANDREAS LUDWIG, UNIVERSITY OF CALIFORNIA, SANTA BARBARA — We revisit the problem of wavefunction statistics at the Anderson metal-insulator transition (MIT) of non-interacting electrons in disordered interacting systems. We use a self-consistent mean-field theory that incorporates strong correlations and treats spatial fluctuations of the disorder, which find zero bias anomalies (ZBA) in transition metal oxides, we have performed calculations to determine the effect of strong correlations on the ZBA in disordered interacting systems. We use a self-consistent mean-field theory that incorporates strong correlations and treats spatial fluctuations of the disorder potential exactly. We discuss both the Anderson-Hubbard model and the extended Anderson-Hubbard model. We find that, even for a zero-range interaction, non-local self-energy corrections lead to the formation of an Altshuler-Aronov-like ZBA. In the extended Anderson-Hubbard model, Efros-Shklovskii-like physics much broader context of the delocalization transition of ordinary electrons in higher dimensions.

1:15PM Q41.00011 Effects of Strong Correlations on the Disorder-Induced Zero Bias Anomaly. WILLIAM ATKINSON, Trent University, YUN SONG, Beijing Normal University, SINAN BULUT, RACHEL WORTIS, Trent University — In conventional metals and semiconductors, density of states anomalies result from the interplay between disorder and interactions. Motivated by a number of experiments that find zero bias anomalies (ZBA) in transition metal oxides, we have performed calculations to determine the effect of strong correlations on the ZBA in disordered interacting systems. We use a self-consistent mean-field theory that incorporates strong correlations and treats spatial fluctuations of the disorder potential exactly. We discuss both the Anderson-Huband model and the extended Anderson-Hubbard model. We find that, even for a zero-range interaction, non-local self-energy corrections lead to the formation of an Altshuler-Aronov-like ZBA. In the extended Anderson-Hubbard model, Efros-Shklovskii-like physics dominates at large disorder.

1:27PM Q41.00012 Detrended Fluctuation Analysis for Dynamics in an Electron Glass. STEPHEN ARNASON, University of Massachusetts Boston — As a result of the correlations between electrons, electron glasses show enhanced fluctuations in conductance with a \( 1/f^\alpha \) frequency dependence. We are interested in looking at the time dependence of the fluctuation spectra as the system relaxes towards equilibrium after a discontinuous change in chemical potential. Our measurements are taken on FET structures where the conductance channel is fabricated from amorphous Indium Oxide with stoichiometry close to the superconductor to insulator transition. Changing the potential on the gate electrode allows us to change the chemical potential and we measure the resistance of the conductance channel as a function of time. In addition to the fluctuations there is a slow, logarithmic relaxation of the channel conductance. Because of this slow relaxation it is hard to characterize our signal as stationary, calling into question the application of Fourier transform based analysis techniques. One approach to coping with this problem is the subtraction of the slowly varying background before the calculation of the dissipation strength. At nonzero temperature \( T \), the linear conductance is proportional to \( \exp(-\sqrt{CE_n/\eta}) \). The decay of Friedel oscillation saturates for at distances larger than \( L_\eta \sim 1/\eta \) from the impurity.

1:51PM Q41.00014 Mapping the Driven Interacting Resonant Level Model to an Equilibrium Problem. EDUARDO NOVAIS, M.R. PLESSER, HAROLD U. BARANGER, Duke University — We map the driven Interacting Resonant Level Model (IRLM) to an equivalent statistical mechanical problem. Correlation functions in the nonequilibrium model are given, to all orders in perturbation theory, by thermal averages in the statistical system. This enables us to apply the traditional theoretical techniques for thermal problems, such as the renormalization group and diagrammatic expansions, to a far from equilibrium problem. Using these tools, we study the current as a function of bias, as well as of the interactions in the leads and the resonant level. As a simple example of a strongly interacting system far from equilibrium, the IRLM has played an important role in motivating and evaluating recent theoretical advances. We compare our new strategy to other recent proposals for studying far from equilibrium interacting systems.

2:03PM Q41.00015 Numerical study of relaxation dynamics in photoexcited states of one-dimensional Mott insulators\(^1\). HIROAKI MATSUEDA, National College of Technology, TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University, SADAMICHI MAEKAWA, Institute for Materials Physics, Tohoku University — We examine relaxation dynamics of one-dimensional Mott insulators after photoirradiation. This study is motivated by ultrafast metal-insulator switching seen in Sr2CuO3, halogen-bridged Ni compounds, and organic materials. In order to examine energy dissipation due to relaxation processes, we take account of strongly correlated electrons as well as environmental degrees of freedom by introducing the Hubbard–Holstein model. Then, we perform density matrix renormalization group calculations. We find quite large number of phonons excited just after irradiation even for very small electron-phonon coupling. We will discuss the nature of the phonon relaxation characteristic of strongly correlated systems, and how the relaxation is associated with other internal degrees of freedom of correlated electrons.

\(^1\)We acknowledge support from NAREGI project in Japan.

\subsection*{S1.00002 Transmission Ellipsometry and X-Ray Studies on Shear Induced Order in iPP/CNT Nanocomposites\(^1\). YANIEL CABRERA, Tufts University, GEORGI GEORGIEV, Assumption College, LAUREN WIELGUS, BRENT STENGERT, ROBERT JUDITH, PEGGY CEBE, Tufts University — Polymer Carbon Nanotube Composites (PCNs) are the largest commercial application of carbon nanotubes (CNT) in the field of nanotechnology. Isotactic Polypropylene (iPP) is one of the best model systems to study in this field because iPP/CNT PCNs can form alpha, beta, and gamma crystallographic phases under a variety of crystallization conditions such as nonisothermal and isothermal melt crystallization, or application of shear. We prepared iPP/CNT nanocomposites from solution, by co-precipitation from a non-solvent. Films were made by compression molding, with 0.01 - 5.0 wt.% CNT. The morphological structure and the orientation of the crystals, and the impact of CNT on the crystallization kinetics, were evaluated using transmission ellipsometry, wide angle X-ray scattering, and differential scanning calorimetry. CNTs increase the nucleation rate for crystal formation. Ability of the CNTs to promote the formation of smectic phases in iPP will be discussed.

\(^1\)Research supported by the National Science Foundation, Polymers Program of the Division of Materials Research, through grant DMR-0602473.

\subsection*{S1.00003 Structure and applications of nanohybrid shish-kebabs. ERIC D. LAIRD, BING LI, CHRISTOPHER Y. LI, Drexel University — We describe some of the noteworthy aspects of “nanohybrid shish-kebabs” (NHSKs). NHSKs are nanostructures of polymer lamellar single-crystal structure in regular spacings (a few tens of nm) along carbon nanotubes. These novel composite materials are named for their resemblance to the classical shish-kebab structures observed in polymers crystallized in a shear flow. Morphology and growth mechanisms will be discussed: NHSK can be either 2- or 3-dimensional, and tuning of kebab diameters and spacing is made possible by careful control of the growth conditions. For single walled carbon nanotubes decorated with polyethylene, kebab diameters can be tuned through processing conditions to range from 40-250 nm. This method of functionalization demonstrates adhesion superior to that of most other noncovalent methods. The unique nanoarchitecture of NHSK creates opportunities for a wide variety of novel devices and improvements to existing technology. Thick films of these novel hybrid structures were fabricated by a simple vacuum filtration methods. Their application to electronics and chemical detection will be discussed.

\subsection*{S1.00004 Dielectric Relaxation of PVDF/STN Nanocomposites\(^1\). LEI YU, PEGGY CEBE — Dielectric relaxation behavior of poly(vinylidene fluoride), PVDF, with Lucentite\(^2\M STN nanoclay was investigated over the frequency range from 20 Hz to 1MHz. Lucentite\(^2\M STN synthetic nanoclay is based on hectorite structure with an organic modifier contained between the hectorite layers. Composition of the PVDF/STN nanocomposites ranged from 0%-10% STN by weight. Wide angle X-ray and Fourier transform infrared spectroscopy results are consistent with the conclusion that pure alpha phase is formed in PVDF film while STN 1% sample contained majority beta phase, and a tiny amount of alpha phase. When the STN content increased to 5% and 10% only the beta phase was observed. The \(\alpha\_a\) (glass transition) and \(\alpha\_c\) (crystalline) relaxation rates were plotted against the reciprocal of temperature, respectively. The dielectric result shows that the relaxation rate of the \(\alpha\_a\) relaxation, related to the motions of amorphous polymer chains, is increased by the addition of STN. However, the activation energy for the \(\alpha\_a\) relaxation, related to motions of the crystalline chains, remained unchanged with STN addition. A mechanism is proposed to interpret the relative position and interaction between PVDF chains and STN.

S1.00005 Nanocomposites of Poly(vinylidene fluoride) with Multiwalled Carbon Nanotubes

WENWEN HUANG, Tufts University, KYLE EDENZON, LUIS FERNANDEZ, SHABNAM RAZMPOUR, Rochester Institute of Technology, JENNA WOOD-BURN, Gallaudet University, PEGGY CEBE, Tufts University — We report the preparation and characterization of nanocomposites of poly(vinylidene fluoride) (PVDF) with multiwalled carbon nanotubes (MWCNT) with a wide composition range, from 0.1 % to 5.0 % MWCNT by weight. Effect of uniaxial orientation by zone drawing is discussed and compared with unoriented compression molded films. Room temperature two-dimensional wide angle X-ray scattering and Fourier transform infrared spectroscopy were used for phase identification. Differential scanning calorimetry, dynamic mechanical analysis, and thermogravimetric analysis were used to study the thermal properties. Results indicate that: 1) incorporation of MWCNT in PVDF induces a small portion of beta phase crystal in the PVDF/MWCNT bulk films, while zone drawing causes a significant alpha to beta transition; 2) the thermal stability and mechanical properties are improved when MWCNT concentration increases; 3) The glass transition temperature does not change with MWCNT concentration, but a higher glass transition can be obtained by zone drawing.

S1.00006 Electrical/dielectric properties and conductivity mechanism of epoxy/expanded graphite composites

ATHANASIOS KANAPITSA, Technological Educational Institute of Lamia, EMMANUEL LOGAKIS, CHRISTOS PANDIS, POLYCARPOS PISSIS, National Technical University of Athens, NATASA JOVIC, VLADIMIR DJOKOVIC, Vinca Institute of Nuclear Sciences — In this work the electrical and dielectric properties, as well as the temperature dependence of the electrical conductivity of epoxy/expanded graphite (EG) composites, are studied by employing dielectric relaxation spectroscopy (DRS). For the preparation of the composites EG was sonicated in acetone for 10h and then the appropriate amount of epoxy resin added to the mixture. The sonication was prolonged for another 3 h. The mixture was dried at 60°C for a few hours and then the appropriate amount of hardener (triethylenetetramine) was added followed by mechanical stirring for 15 min. Finally, the mixture was cast in a glass mould and outgassed overnight at room temperature. Before they were removed from the mould, all samples were post-cured at 127°C for 10 min in air. Samples with EG weight fractions ranging from 0 to 8 wt.% were produced. Preliminary DRS results at room temperature indicate that electrical percolation threshold (p_c) lies between 3-5 wt.% EG. The influence of the EG fillers (for concentrations below p_c) on the dielectric relaxation mechanisms of the epoxy matrix, as well as the conductivity mechanism (for concentrations above p_c) are investigated.

S1.00007 Effect of interaction on the exfoliation and dispersion of a stack of platelets in a dynamic polymer matrix and solvent particles by a coarse-grained Monte Carlo simulation

BARRY FARMER, Air Force Research Laboratory, RAS PANDEY, University of Southern Mississippi — We consider a stack (layer) of four sheets in host matrix of mobile polymer chains and solvent particles and study their exfoliation and dispersion on a discrete lattice. Sheets and chains are created by tethering particles (nodes) by the bond-fluctuation mechanism. Each component interacts and executes their stochastic motion via Metropolis algorithm. Entropic constraints (excluded volume and entanglement) play a critical role in a relatively dense matrix. Therefore, the density of these constituents and their molecular weight are carefully selected to make this study feasible. Exfoliation of the sheets is examined by varying the interactions among different components, i.e., solvent particles, polymer chains, and platelets. The relaxation time for dispersion in the self-organizing dynamic mixture increases on increasing the molecular weight. Exfoliation ceases in a matrix with chains beyond a certain length. [1] R.B. Pandey and B.L. Farmer, J. Polym. Sci. Part B 46, 2696 (2008).

S1.00008 Creating Janus Particles on Polymer Templates

MARLA MCCONNEL, University of Pennsylvania, MATTHEW KRAEUTLER, SHU YANG, RUSSELL COMPOSTO, University of Pennsylvania — Gold nanoparticles and their unique optical properties have been the topic of many recent research efforts. These optical properties are associated with the collective oscillations of conduction band electrons, and can be tuned in the visible range by changing the size and shape of the particles. In this study, we assembled spherical gold nanoparticles (13 nm in diameter) on spherical amine-modified silica particles (100 nm - 800 nm), which were covalently linked to a polymeric surface. Because gold has a strong affinity for amines, the modified silica particles served as an ideal template for assembling the gold nanoparticles. By varying the diameters of the silica particles, it is possible to tune the separation between the gold particles, resulting in a change in optical response. Once the gold nanoparticles are attached to the silica spheres, they can be sintered. This technique produces Janus particles, because the gold nanoparticles are localized to the top surface of the silica particles, due to shadowing.

S1.00009 Mechanical Properties of Organized Microcomposites Fabricated by Interference Lithography

SRIKANTH SINGAMANENI, SEHOON CHANG, Georgia Institute of Technology, JI-HYUN JANG, MIT, WHITNEY DAVIS, Georgia Institute of Technology, EDWIN THOMAS, MIT, VLADIMIR TSUKRUK, Georgia Institute of Technology, GIT/MIT COLLABORATION — We demonstrate that organized, porous, polymer microstructures with continuous open nanoscale pores and sub-micron spacings obtained via interference lithography can be successfully utilized in a highly non-traditional field of ordered microcomposites. Organized microcomposite structures are fabricated by employing two independent strategies, namely, capillary infiltration and in situ polymerization of the rubbery component into the porous glassy microframes. The mechanical properties and ultimate fracture behavior of the single microcomponents and microcomposite structures are investigated at different scale lengths. The ordered single and bi-component microstructures with high degree of control over the microscopic organization of the polymeric phases result in excellent mechanical properties. Combining hard and soft polymer components provides multifunctional materials and coatings with synergetic properties and is frequently utilized for design of advanced polymeric composites.

S1.00010 Diamond-shaped small-angle scattering and the deformation of fibrous textures

WENJIE WANG, University of Vermont, N. SANJEEVA MURTHY, Rutgers University — Small-angle x-ray scattering from materials with fibrous texture are typically characterized by diamond-shaped equatorial streaks. Single family of elongated voids aligned along the fiber axis modeled as ellipsoids with a certain orientation distribution yield a fan-like 2D pattern. The diamond-shaped patterns from fibers, such as polyesters, polyamide 6 and polyacrylonitrile, could not be explained with such single class of misoriented voids. Analysis of the orientation distribution and the isointensity contours suggest that there are at least two distinct entities that contribute to this equatorial scattering. Voids with larger cross section (~ 20 nm dia.), which are likely to be in the interfibrillar regions, give rise to low-q contours with smaller eccentricities and respond poorly to deformation. Entities with smaller cross section (~ 5 nm dia.), which are likely to be in the intrafibrillar regions, give rise to high-q contours with larger eccentricities and respond to deformation in the same way as crystalline domains. The scattering from these objects appear as two distinct families of elliptical contours with different eccentricities, and the observed diamond-shaped scattering results from the superposition of these two sets of contours.

S1.00011 Thin Film Optical Measurements on a Low-bandgap Platinum-Acetylide Conjugated Polymer Developed for Use in Organic Solar Cells. ZAHA NASROLLAH, UFL, Dept Physics, JIANGUO MEI, KATSU OGAWA, YOUNG-GI KIM, UFL, chem Dept, NATHAN HESTON, UFL, chem dept, DANIEL ARENAS, UFL, phys Dept, TRACY MC CARLEY, LSU, chem dept, DAVID TANNER, UFL, phys dept, JOHN REYNOLDS, KIRK SCHANZIE, UFL, chem dept — An important barrier to overcome in producing high efficiency organic solar cells is to extend light harvesting capabilities into the near infrared. With strong absorption through the visible region and possible involvement of the triplet state in charge generation, Pt-acetylides have received recent attention as interesting and promising materials for photovoltaic applications. This presentation focuses on the thin film optical characterization of p-PBDT-Th. In order to obtain the absorption coefficient of this monomer, multiple lithography varied thicknesses were made and characterized by UV to NIR transmission and reflection measurements. We employed a thin film analysis using a Drude-Lorentz model to calculate the optical constants and to estimate the interference effects. From this model we were able to extract the absorption and extinction coefficients.

S1.00012 The study of polymer chain structure within macroporous polymer films by breath figure templating method. MINSU LEE, JUNG O. PARK, 1. School of Polymer, Textile and Fiber Engineering, 2. Center for Advanced Research on Optical Microscopy (CAROM), Georgia Institute of Technology, MOHAN SRI NIVASARAO1, 1. School of Polymer, Textile and Fiber Engineering, 2. Center for Advanced Research on Optical Microscopy (CAROM), — Macroporous films produced by breath figure templating methods have a microstructure with close packed and highly ordered pores. The water droplets condense from humid air flowing over a dilute polymer solution in a volatile solvent, due to evaporative cooling. Then, the water droplets closely pack over and sink into polymer solution. A close packed array of water droplets produces thin walls of polymer films where the polymer chains are confined. In our study, we have some evidence of the deformation of polymer chain within macroporous polymer films in areas where the polymer is confined. We will present our result on the deformation of polymer chain structure within polymer films.

S1.00013 Trimerization of Monocyanate ester in Nanopores. YOUNG PYO KOH, QINGXIU LI, SINDEE L. SIMON, Texas Tech University, TEXAS TECH UNIVERSITY TEAM — Nanocostruction generally results not only in a Tg depression, but also in changes in reactivity. Recently, we showed that the polymerization reaction of bisphenol M dicyanate ester is enhanced in nanopores and that the Tg of the resulting polycyanurate product is depressed relative to the bulk. In order to examine the importance of an intracyclization side reaction, in this work we investigate the effect of nanocostruction on the reactivity and the Tg of a monocyancate ester and its cyanurate product. Due to the monofunctional nature of the reactant, there is no possibility for the intracyclization side reaction in this system. Using differential scanning calorimetry (DSC), we find the primary Tg decreases with decreasing pore size but the secondary (higher) Tg is independent of pore size. In addition, we find that the trimerization reaction rate increases as confinement pore size decreases, and in the 8 nm pores, the reactivity is accelerated by a factor of 20. The results are consistent with the Tg depression and accelerated reaction found previously for the nanoconfined difunctional reactant.

S1.00014 Diblock Copolymers under Nano-Confinement. DONG MENG, YUHUA YIN, QIANG WANG, Department of Chemical and Biological Engineering, Colorado State University — Nano-confinement strongly affects and can thus be used to control the self-assembled morphology of block copolymers. Understanding such effects is of both fundamental and practical interest. In this work, we use real-space self-consistent field calculations with high accuracy to study the self-assembled morphology of diblock copolymers (DBC) under nano-confinement for several systems, including 1D lamellae-forming DBC confined between two homogeneous and parallel surfaces, in nano-pores, and on topologically patterned substrates; 2D cylinder-forming DBC on chemically strip-patterned substrates; and 3D gyroid-forming DBC confined between two homogeneous and parallel surfaces. The stable phases are identified through free-energy comparison, and our SCF results are compared with available experiments and Monte Carlo simulations in each case.

S1.00015 First-Principles Prediction of Novel Technetium(IV) Halide Polymeric Compounds. PHILIPPE F. WECK, EUNJIA KIM, FREDERIC POINEAU, KENNETH R. Czerskewski, University of Nevada Las Vegas — We report the crystal structures of novel technetium tetrahalide polymeric compounds, TcX4 [X=F,Br,I], as predicted from first-principles calculations. Similar to TcCl4, TcF4 and TcBr4 compounds are orthorhombic with the centro-symmetric space group Pnma, while TcI4 crystallizes in the space group P21/c. The structures consist of distorted octahedral groups of composition TcX6 linked into endless linear chains. A possible explanation for the differences between these structures is offered in terms of varying degree of bonding within the polymeric chains.

S1.00016 Control self-assembled nanowire using chemically modified substrates. SHUSUKE ABURAYA, SATOSHI AKASAKA, MIKIHIITO TAKENAKA, HIROKAZU HASEGWAI, Kyoto University, YASUHIKO TADA, HIROSHI YOSHIDA, Hitachi Ltd, NIKOS HADJICHRISTIDIS, Athens University, KYOTO UNIVERSITY TEAM, HITACHI LTD TEAM, ATHENS UNIVERSITY TEAM — Block copolymer lithography is a promising method for fabricating periodical nanopatterns. Strongly segregated block copolymers are required for the formation of smaller size microphase-separated structures. In this study, we used a poly(styrene-b-dimethylsiloxane) (PS-b-PDMS) which has large Flory-Huggins interaction parameter. In addition, we investigated this cylinder-forming PS-b-PDMS has large segregation in the bulk condition by small-angle X-ray scattering (SAXS). Consequently, we demonstrated a fabrication of well-ordered arrays of 15nm period PDMS cylinder on the grating substrate with chemical modification. So, we can obtain less than 10 nm L/S fabrication.
S1.00018 Graphoepitaxy of 2D array of Spheres in Di-block Copolymers1, ADETUNJI ONIKOYI, EDWARD KRAMER, University of California, Santa Barbara — The use of block copolymer (BCP) thin films to create periodic structures on a nanolength scale has proved to be very effective [1-3]. However, removing defects and improving translational order in the periodic structures remain important goals. This study exploits a form of graphoepitaxy as a means to influence translational and orientational order in a poly(styrene-b-poly-2-vinylpyridine) (PS-b-PVP) diblock copolymer. Here, the domains of the BCP thin film are allowed to order within sub-micron sized wells of various shapes. Effects on order and 2D melting behavior are examined. The wells are patterned into silicon substrates using electron-beam lithography. Secondary ion mass spectroscopy and scanning force microscopy are then used to characterize the self-assembly process. Results show that a near perfect hexagonal 2D lattice can be obtained in diamond shaped wells of appropriate dimensions. Perfect 6 fold symmetry is disfavored in square wells; rather, regions of meta-stable square packing or defect dense regions of hexagonal packing are observed. Further studies are being performed to understand these effects on melting behavior. [1] Segalman et al. Phys. Rev. Lett., 2003, 91, 196101 [2] Kim et al. Nature, 2003, 424, 411 [3] Guarni et al. International Electron Devices Meeting

S1.00019 Stress-Strain Relation of Tire Rubber Consist of Entangled Polymers, Fillers and Crosslink, KATSUMI HAGITA, National Defense Academy of Japan, Y. BITO, Y. MINAGAWA, SRI, M. OMIYA, Hokkaido Univ., H. MORITA, UI, AIST, M. DOI, Univ. of Tokyo, H. TAKANO, Keio Univ. — We presented a preliminary result of large scale coarse-grained Molecular Dynamics simulation of filled polymer melts with Sulfor-crosslink under an uni-axial deformation by using the Kremer-Grest Model. The size of simulation box under periodic boundary conditions (PBC) is set to about 66 nm to consider length of entangled polymer chains, size and structure of fillers, and non-uniform distribution of crosslink. We put 640 polymer chains of 1024 particles and 32 fillers into the PBC box. Each filler consists of 1280 particles of the C_{2800} fullerene structure. A repulsive force from the center of the filler is applied to the particles. Here, the particles of the fillers are chosen to be the same as the particles of the polymers and the diameter of the filler is about 15 nm. The distribution of the fillers used in this simulation is provided by the result of 2d pattern RMC analysis for 2D-USAXS experiments at SPring-8. Sulfor crosslink is randomly distributed in the system. It is found that stress-strain curves estimated by applying a certain uni-axial deformation to the system in simulations are in good agreement with those in experiments. It is successful to show difference on the S-S curve between existence / absence of fillers and qualitative difference of attractive force between polymer and filler.

S1.00020 In situ Raman Spectroscopy Study of Stress Transfer between Carbon Nanotubes and Amorphous Polymer, MINFANG MU, Department of Materials Science and Engineering, University of Pennsylvania, SEBASTIAN OSSWALD, YURY GOGOSTI, Department of Materials Science and Engineering, Drexel University, KAREN WINNEY, Department of Materials Science and Engineering, University of Pennsylvania — Stress transfer mechanism in single wall carbon nanotube (SWCNT) / poly(methyl methacrylate) nanocomposites was investigated using Raman spectroscopy on composite fibers. Without specific SWCNT-polymer interactions, the effective stress transfer to SWCNTs is limited to a small strain regime (< 0.5%). At higher strain, the stress on SWCNTs decreases due to debonding at the nanotube-polymer interface. Debonding was also evident by scanning electron microscopy on fracture fiber surfaces produced by tensile testing. Overall, the presence of SWCNTs in composite fibers greatly improves their mechanical properties by two ways: a sufficient stress transfer at SWCNT-polymer interface and a SWCNT-induced polymer chain orientation. It was also observed that polymer chains transfer stress more effectively, and we attribute this to a greater extent of nanotube-polymer chain entanglement.

S1.00021 MD simulations of nanofibers, ROBERT LIVERPOOL, JOSEPH ORTIZ, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University — We use MD simulations to study the strength of polymeric nanofibers. The simulations will examine the role of chain orientation, internal stresses and surface effects on the modulus of nanofibers. The simulations are performed at above and below the glass transition temperature of the polymer. We also examine the effect of inclusions in the fiber on the modulus.

S1.00022 Structure, Dynamics, Loading Capacity, and Volume Phase Transition of Polymer Nanoparticles, KIRIL STRELETZKY, JOHN MCKENNA, IMAAN BENMERZOUGA, PUBLUDU PEIRIS, MEKKI BAYACHOU, Cleveland State University — Microparticles were synthesized in aqueous solutions of neutral polymer hydroxypropylcellulose (HPC) through self-association of amorphophilic HPC molecules and subsequent cross-linking. Dynamic Light Scattering (DLS) was used to study the transport properties of HPC microparticles below and above the volume phase transition. Highly non-exponential, multimodal microgel spectra were observed and successfully analyzed by spectral time moment analysis. The structure and dynamics of microparticles was found to depend on polymer and salt concentration, crosslinking density, solution temperature, and the rate of heating. HPC microparticles undergo a reversible volume phase transition in which microparticle volume swells/deswells by as much as a factor of thirty. The study revealed that higher polymer concentration results in smaller microparticles with lower shrinking capacity. The effective cross-linking density that yields relatively monodisperse microparticles was determined. The angular dependence of scattering demonstrated that microparticles are largely spherical particles though sometimes two different particle sizes are present. Finally, flow-injection amperometry was used to evaluate the loading capacity of microparticles. Preliminary results show the moderate injection agent uptake that varies with temperature dependent size of particles.

S1.00023 Cleavage Energies of Modified Layered Silicates by Molecular Dynamics Simulation, YAO-TSUNG FU, HENDRIK HEINZ, Department of Polymer Engineering, University of Akron — The cleavage energy of organically modified layered silicates indicates the thermodynamic propensity of exfoliation in polymer matrices. We find substantial cleavage energy differences upon variation in cation exchange conditions (PBC) is set to about 66 nm to consider length of entangled polymer chains, size and structure of fillers, and non-uniform distribution of crosslink. Dynamic Light Scattering (DLS) was used to study the transport properties of HPC microparticles below and above the volume phase transition. Highly non-exponential, multimodal microgel spectra were observed and successfully analyzed by spectral time moment analysis. The structure and dynamics of microparticles was found to depend on polymer and salt concentration, crosslinking density, solution temperature, and the rate of heating. HPC microparticles undergo a reversible volume phase transition in which microparticle volume swells/deswells by as much as a factor of thirty. The study revealed that higher polymer concentration results in smaller microparticles with lower shrinking capacity. The effective cross-linking density that yields relatively monodisperse microparticles was determined. The angular dependence of scattering demonstrated that microparticles are largely spherical particles though sometimes two different particle sizes are present. Finally, flow-injection amperometry was used to evaluate the loading capacity of microparticles. Preliminary results show the moderate injection agent uptake that varies with temperature dependent size of particles.

S1.00024 Large-scale nanocomposites simulations using hybrid particle/SCFT simulations1, SCOTT SIDES, Tech-X Research — Preliminary results from 2D simulations of block copolymer nanocomposites (Phys. Rev. Lett. Vol 96, 250601 (2006) have been performed using a hybrid self-consistent field theory (SCFT) algorithm. While these simulation results showed that the presence of nanoparticles could induce changes in block copolymer morphologies, quantitative agreement with experiments for the particle densities at this transition is not yet possible. A feature missing in the 2D hybrid simulations is the packing behavior of real three-dimensional spherical particles embedded in lamellar layers or hexagonally packed cylinders formed by linear diblock chains. In order to carry out these hybrid particle/SCFT 3D simulations a new object-oriented SCFT framework has been developed. The object-oriented design enables the hybrid/SCFT simulations to be performed in a framework that is both numerically efficient and sufficiently flexible to incorporate new SCFT models easily. In particular, this new framework will be used to investigate the distribution of particle positions in diblock lamellar layers as function of nanoparticle density to study the interplay of patterning due to diblock domain structure and the chain depletion interaction between spherical particles.

S1.00025 DNA Electrophoresis: how partially denatured DNA stops moving in a gel. DAVID SEAN, GARY SLATER, University of Ottawa — During temperature gradient gel electrophoresis (TGGE), a DNA strand travels in a gel with a temperature gradient. As the strand travels in a position of higher temperature, the stability of the double helix is reduced resulting in melted domains. It has been experimentally observed that in a gel, a partially melted DNA strand exhibits a steep reduction in mobility — perhaps even trapping. The sequence dependent melting of DNA can therefore be translated into a sequence dependent position at which the strand appears to stop. Thus, this can be used as an effective method for discriminating between strands that differ only in composition. However, the dominant blocking mechanisms remain unclear. Blocking/trapping events are re-created using Langevin dynamics simulations using the ESPResSo package to understand the physics behind the observed steep reduction in electrophoretic mobility. From these simulations a relation between gel parameters and the mobility of the strand is proposed.

S1.00026 Detrapping Particles in a Gel: A Numerical Study ANTOINE DUBÉ, FRANCIS TORRES, GARY W. SLATER, University of Ottawa — Pulsed fields are widely used in gel electrophoretic separations to increase resolution. For instance, Boyde & To [1] presented experimental results for the separation of spherical particles using pulsed fields. They first used alternating fields of fixed amplitudes $(E_{max} = \pm |E|)$ applied in the forward direction for a duration twice as long as in the backward direction. They then used field interruption in order to allow particles to thermally detrap. In both cases, they reported that using a pulsed field makes the particles migrate faster. We model the gel used in electrophoresis as a 2D system of obstacles on a lattice. We use a method that allows us to calculate the exact mean velocity of a particle for Monte-Carlo simulations to first reproduce the experimental results presented above. We then investigate solutions signals (e.g., telegraph signal) to determine the optimal conditions. Optimal conditions can be either higher velocities or larger velocity differences between particles.

S1.00027 Electronic Structure of Aromatic and Quinoidic Oligothiophenes by First-principles Calculations HIROSHI MIZUSEKI, YOSHIYUKI KAWAZOE, Institute for Materials Research, Tohoku University — Since the discovery in 1977 that trans-polyacetylene can be made electrically conducting by means of doping[1] several different conjugated polymers with interesting properties in the conducting and semiconducting phases have been discovered. Polyythiophene has a typical π-conjugated system, then many polythiophenes are synthesized and several have been well characterized. Calculation systems based on neutral, doubly charged, and highly charged oligomers whose all ring are linked to have linear chains were studied as model for the polaronic defects in doped polythiophenes. The energetics of the aromatic and quinoid structures is investigated using the both ends of neutral oligomers substituted by dimethyl and dimethylen. To estimate the electronic structures, the difference between corresponding bond lengths along

S1.00028 Probing Interfaces of Multilayer Polymeric Compensation Films for Liquid Crystal Display system WUMIN YU, MARK FOSTER, The University of Akron — Highly anisotropic polymer films formed by rigid-rod like aromatic polyimides show uniaxial negative birefringence and can be used as compensation films to widen the viewing angles of liquid crystal display system (LCD). Fluorinated pendent groups have been introduced to polyimide molecules to improve their solubility in common organic solvents. A new procedure for incorporating the compensation film in the multilayer LCD assembly by directly casting the polyimide film on a LCD unit as a substrate film, e.g. triaceteate cellulose (TAC), is preferred in industry for its simplicity and cost-effectiveness. To obtain high quality multilayer films with excellent durability, the compensation films must adhere well to the TAC substrates. X-ray and neutron reflectivity techniques are being used to determine how the interface width between the polyimide film and TAC substrate varies with changes in polyimide chemistry or casting process parameters.

S1.00029 Fabrication of Nanostructured Multilayers from Crosslinkable Block Copolymers DONGJUNE HWANG, EUNHYE KIM, HYUNJUNG JUNG, DU YEOL RYU, JOONA BANG, DEPT. OF CHEMICAL & BIOLOGICAL ENG., KOREA UNIV., KOREA TEAM, DEPT. OF CHEMICAL ENG., YONSEI UNIV., KOREA TEAM — In this work, we fabricated three dimensional nanotemplates using crosslinkable block copolymers (BCPs). We synthesized crosslinkable BCP, P(S-r-(N3)3-b)-PMMA, in which 1.5 mol % of crosslinkable azide (N3) groups were incorporated. First, 40 nm thick films of P(S-r-(N3)3-b)-PMMA, exhibiting the hexagonal arrays of perpendicularly oriented cylinders, were prepared on the silicon substrates. After crosslinking the films, cylinder- or lamellar-forming BCPs were prepared without disturbing the underlying layers. For cylinder-forming BCPs, it was observed that the cylindrical microdomains in respective layers were exactly registered. For lamellar-forming BCPs, the underlying layers could neutralize the interfacial interactions as PS-r-PMMA random copolymers and thus the perpendicular orientation of lamellae was achieved. The detailed structures of nanostructured multilayers were characterized by atomic force microscope (AFM) and scanning electron microscope (SEM), and grazing-incidence small-angle x-ray scattering (GISAXS).

S1.00030 Hybrid nanostructured thin films which adapt low adhesive properties in changing environment SERGIY MINKO, ROMAN SHEPAROVYCH, Clarkson University — We describe a nanostructured composite coating constituted of surface-grafted hydrophobic nanoparticles embedded in a hydrophilic, polyethylene oxide molecular brush. The responsive coating undergoes reconstruction from the morphology of rigid hydrophobic asperities, which hide the collapsed polymer brush in air, to the morphology of a hydrophilic brush-like layer engulfing the nanoparticles underwater. Due to this reconstruction, the coating demonstrates low adhesion to hydrophobic, hydrophobic, and amphiphilic materials in both dry and wet environments. The key property of the designed layer is the size of the nanoparticles that is bigger than the collapsed in air and smaller than the stretched in water polymer coil in the brush. This finding provides useful guidelines for the development of low-adhesive surfaces of materials.

S1.00031 Glass transition in ultra thin polymeric films measured by differential AC-Chip calorimetry H. HUTH, University Rostock, Inst. of Physics, Universitätplatz 3, 18051 Rostock, Germany, D.S. ZHOU, Dept. of Polymer Science and Eng., Nanjing University, Nanjing, 210093, China, C. SCHICK, University Rostock, Inst. of Physics, Universitätplatz 3, 18051 Rostock, Germany — The film thickness dependency of glass transition in polymer films is still controversially discussed. For different experimental probes different dependencies are observed and a generally accepted link to molecular mobility is not yet established. Calorimetry has proven to provide useful information about glass transition, because it establishes a direct link to energetic characterization. In several cases a direct comparison with results from other dynamic methods like dielectric spectroscopy is possible giving further insights. For thin films in the m... nm range standard calorimetric methods are mostly not applicable. In the recent years there are new developments in the field of calorimetry which overcome these limitations. We set up a differential AC-chip calorimeter capable to measure the glass transition in nanometer thin films with pJ/K sensitivity. Changes in heat capacity can be measured for sample masses below one nanogram as needed for the study of the glass transition in nanometer thin polymeric films. No thickness dependency of the glass transition temperature was observed within the error limits — neither at constant frequency nor for the traces in the activation diagrams.
S1.00032 Well-defined branched polymers for studying surface segregation\(^1\), BOXI LIU, SHIH-FAN WANG, RODERIC QUIRK, MARK FOSTER, University of Akron — A linear response theory by Wu et al. \(^1\) predicts that the surface segregation of a long-chain branched polymer blended with a linear polymer depends only on the type and number of chain ends or branch points in the linear and branched chains. Our previous neutron reflectivity results suggest that further details of the branching may impact the surface segregation. To better understand the roles of molecular architecture a new set of well defined branched polystyrenes have been synthesized by anionic polymerization. These molecules include a series of 6-arm pom-pom polymers with the same overall number of repeating units, chain ends and branch points, but varying length of central linear portion; a 6-arm star polymer constructed to be a better analog with 6-arm pom-pom polymers; and a deuterated linear polymer more analogous to the branched polymers. Bulk viscosities of these polymers have been measured and their surface segregation is being studied by neutron reflectivity. Reference: 1 Wu, D.T.; Fredrickson, G. H. Macromolecules, 1996, 29, 7919.

S1.00033 “Smart” Surfaces of Polymer Brushes , QIANG WANG, DONG MENG, Department of Chemical and Biological Engineering, Colorado State University — “Smart” surfaces, also known as stimuli-responsive surfaces, can change their properties (e.g., wettability, adhesion, friction, elasticity, and biocompatibility) in response to external stimuli (e.g., temperature, pressure, light, solvent selectivity, ionic strength, type of salt, pH, applied electric field, etc.). In this work, we use numerical self-consistent field calculations to study in detail the structure and stimuli- responses of various polymer brushes, including (1) the thermo- response of PNIPAM brushes in water, (2) solvent-response of uncharged diblock copolymer brushes, and (3) the stimuli- response of charged two-component polymer brushes (including both the binary A/B brushes and diblock copolymer A-B brushes) to ionic strength, pH, and applied electric field. Among the many design parameters (e.g., chain lengths, grafting densities, A-B incompatibility, degree of ionization of charged polymers, etc.) we identify those that strongly affect the surface switchability. Such knowledge is useful to the experimental design of these smart polymer brushes for their applications.

S1.00034 Adsorption of phospholipid bilayers onto pullulan-modified cellulose surfaces , HEEJUN CHOI, ZELIN LIU, ALAN ESKER, Virginia Tech — 1,2-Dimyristoyl-sn-glycero-3-phosphocholine (DMPC) vesicle adsorption onto regenerated cellulose and pullulan 4-bromocinnamate (P4BC) modified cellulose surfaces was investigated via surface plasmon resonance (SPR) spectroscopy and quartz crystal microbalance with dissipation monitoring (QCM-D). P4BC with a degree of substitution (DS) of 0.061 ± 0.002 from UV measurements and 0.058 from \(^1\)H NMR was synthesized from pullulan and 4-bromocinnamic acid to yield P4BC. The deduced thicknesses from SPR for DMPC layers were ~3.7 nm (bilayer) on regenerated cellulose surfaces and ~2.1 nm (monolayer) on P4BC modified cellulose surfaces. Qualitative analysis of the QCM-D data also indicated that the DMPC layers on P4BC modified cellulose surfaces were thinner than on regenerated cellulose surfaces.

S1.00035 Robust Self-Assembly of Highly Ordered Complex Structures by Controlled Evaporation of Confined Microfluids , ZHIQUN LIN, MYUNGHWAN BYUN, SUCK WON HONG, Iowa State University — We demonstrate a robust, one-step method of evaporating polymer solutions in curve-on-flat geometries to create versatile, highly regular microstructures in a precisely controlled environment, as well as offering a comprehensive study of the influence of different upper surfaces on complex structure formation via controlled evaporation. Our method further enhances current fabrication approaches to creating highly ordered structures in a simple and cost-effective manner, with the potential to be tailored for use in photonics, electronics, optoelectronics, microfluidic devices, nanotechnology, and biotechnology.

S1.00036 A new class of bio-heat resisted polymer blend . , SEONGCHAN PACK, TAKASHI KASHIWAGI, TADANORI KOGA, MIRIAM RAFAILOVICH — Increasing in oil prices and environmental concerns is a driving force to seek out alternative materials. A completely biodegradable starch is a candidate for the alternative materials. Since the starch is brittle, it must be mixed with other polymers. In order to make a thermoplastic starch (TPS), we need a bio-compatibilizer to increase a degree of compatibilization. The biocompatibilizer can be a small molecules or nanoparticles with the small molecules, which leads to improved material properties. In order to demonstrate a possible biocompatibilizer, we first developed a corn-based starch impregnated with non-halogenated flame retardant retardants. The starch was blended with Ecoflex®, a biodegradable polymer. Using SAXS and USAXS we characterized structures of the compounds with different amount of Ecoflex® by weight. Furthermore, the addition of 5% nanoparticles in the compounds increased the Young’s Modulus and impact toughness significantly. The compounds also did flame test. It is indicated that the compound with the addition of the nanoparticles would pass with a UL-94V0 rating. Therefore, the procedure for producing these TPS compounds can be applied to any biodegradable polymers, manufacturing a new bio-heat resisted compound.

S1.00037 Controlled morphology of biodegradable polymer blends , SASIWIMON BUDDHIRANON, THEIN KYU, The University of Akron — Phase diagrams of biodegradable polymer blends containing poly(ε-caprolactone) (PCL) and poly(d,l-lactic acid) (PDLLA) having two different molecular weights were established by means of cloud point measurement and differential scanning calorimetry. Subsequently, the theoretical phase diagram was calculated self-consistently based on the combination of Flory-Huggins free energy for liquid-liquid phase separation and phase field free energy for crystal solidification. The phase diagrams thus obtained were LCST type or hour-glass type, which depended on molecular weight of PDLLA utilized. Guided by the phase diagram, the emerged morphology was determined as a function of blend concentration and temperature. It appears that the morphology control is feasible that ultimately affects the end-use property of PCL/PDLLA blends. A wide variety of morphology of biodegradable polymer may be developed with the porous structure and pore size to control scaffold porosity and the rate of drug delivery.

S1.00038 A Spectroscopic Investigation on the Structural Evolution of Soy Based Polyurethane Foams , DEEPA PUTHANPAREMBIL, CASEY KIMBALL, SHAW L. HSU, University of Massachusetts Amherst — Our current research deals with an economical and renewable soy based polyol for use in polyurethane foams. Infrared spectroscopic studies have revealed that the amount of polyurea segments formed and the kinetics of their formation in soy based polyurethane foam systems are considerably different from traditional systems employing ethylene oxide – propylene oxide based polyols. The most crucial aspect of this research is the miscibility of water in the reactive mixtures involving extremely hydrophobic soy-based polyols. High Field Nuclear Magnetic Resonance Spectroscopy (NMR) with D₂O as the probing agent was employed to determine the miscibility behavior at the molecular level. This technique was able to establish the structure and location of dispersed water, which can be extremely different based on the polyols used, thus affecting the morphology of the foam. The length and amount of polyureas directly impact the kinetics of the phase separation process to form the hard-segment rich domains and associated physical properties. The aggregation of these polyurea hard domains was characterized by the hydrogen bonds formed. This structural transformation as a function of reaction is also reflected in the segmental relaxation kinetics characterized by spin-spin diffusion, measured using a low field NMR instrument.
S1.00039 Evaporative Organization of Hierarchically Structured Polymer Blend Rings, MYUNG-WAN BYUN, SUCK WON HONG, Iowa State University, FENG QIU, The Key Laboratory of Molecular Engineering of Polymers at Fudan University, Shanghai, China, ZHIQUN LIN, Iowa State University — We report the first study of the controlled, evaporative self-organization of a polymer blend from a sphere-on-flat geometry. In this study, a drop of polystyrene (PS) and poly(methyl methacrylate) (PMMA) toluene solution evaporated in the sphere-on-flat geometry. The combination of controlled, consecutive pinning-depinning cycles (i.e., “stick-slip”) of the contact line at the edge of the geometry, spontaneous phase separation of incompatible polymers at the microscopic scale, and a dewetting process in the late stage of phase segregation led to the formation of gradient, hierarchically structured polymer blend rings composed of phase-separated PS and PMMA. This facile approach offers a new way of simultaneously processing two or more nonvolatile components via controlled evaporation to produce new kinds of structures with hierarchical order in a simple, robust, and one-step manner.

S1.00040 Directing Hierarchical Assembly of Block Copolymer-Based Supramolecules Using Small Molecule Blends, PAUL TILLBERG, MATTHEW RICHARDS, TING XU, Dept. of Materials Science and Engineering, UC Berkeley — Block copolymer-based supramolecules can be obtained by selectively hydrogen-bonding amphiphilic small molecules to one block of a diblock copolymer. Through interactions between small molecules and the polymer backbone and between separate polymer blocks, hierarchical self-assembled structures are achieved on length scales unavailable through traditional top-down engineering methods. We aim to introduce an additional independent design parameter by hydrogen-bonding a mixture of small molecules to the polymer backbone. The phase behavior of the small molecules can be tailored to obtain an extra level of molecular control and generate novel hierarchical structures within block copolymer domains. Ultimately, this principle can be used to generate tri- or multi-block copolymer behavior by hydrogen-bonding different small molecules to simple homo or diblock copolymers. We will present preliminary data obtained by adding fluorinated alkyl phenols to the model block copolymer-based supramolecular system consisting of polystyrene-block-poly(4-vinylpyridine) with alkyl phenols hydrogen-bonded to pyridine groups.

S1.00041 Chirality Effect on Flory-Huggins Interaction Parameters in Polylactate-b-Poly(ethylene-co-1-butene)-b-Polyether Tricblock Copolymers, WEIQIANG CAO, LEI ZHU, Polym. Program, Inst. of Mater. Sci. and Dept. of Chem., Mater. and Biomolecular Eng., University of Connecticut, Storrs, CT 06269-3136, LIXIA RONG, BENJAMIN S. HSIAO, Department of Chemistry, Stony Brook University, Stony Brook, NY 11794-3400 — In this work, a set of well-defined polylactide-b-poly(ethylene-co-1-butene)-b-polyether (PLA-PEB-PLA) tricblock copolymers were synthesized by controlled ring-opening polymerization of corresponding lactide monomers (L-lactide and racemic mixture of D- and L-lactides) using Sn(Oct)2 as the catalyst. The volume fractions of PLA in the tricblock copolymers were adjusted by tuning its molecular weight. The mesophase morphology and phase transitions in these tricblock copolymers were studied by temperature-dependent small-angle X-ray scattering (SAXS). The Flory-Huggins interaction parameter $\chi$ between EB and lactide as a function of temperature were estimated from the order-disorder transition temperature ($T_{ODT}$) using the mean-field critical ($\chi_N$) values. The effects of PLA chirality on both Flory-Huggins interaction parameter and segmental lengths were investigated.

S1.00042 Structure of PEO-b-PPO-b-PEO Triblock Copolymer Inclusion Complexes with Beta-Cyclodextrin, CHI-CHUN TSAI, STEPHEN Z.D. CHENG, BERNARD LOTZ, JIN HUANG, YONGMING CHEN — Inclusion complexes, formed by non-covalent host-guest interactions, have been extensively investigated because they can be useful as building blocks for constructing supramolecular structures. Cyclodextrins (CDs), due to their good water-solubility and ability to include a wide range of guest molecules, have been the most intensively studied host molecules. CDs are shaped like a shallow truncated cone, with a hydrophilic outer surface as well as primary (narrower end) and secondary (wider end) hydroxy groups on the rim of the molecule. The cavity, which is constructed with alkyl groups and glycosidic oxygen atoms, is hydrophobic and can act as a host for a great variety of hydrophobic molecular guests. A series of host-guest inclusion complexes were prepared with beta-cyclodextrin (beta-CD) and PEO-PPO-PEO triblock copolymers of varying molecular weights and compositions. The middle PPO block of the copolymers can be selectively included by beta-CD to form an inclusion complex while the PEO blocks cannot. These inclusion complexes can further self-assembled into supramolecular structures in aqueous solution. The inclusion complexes and self-assembled supramolecular structures were characterized by Nuclear Magnetic Resonance, X-ray diffraction, and Differential Scanning Calorimetry experimental methods.

S1.00043 Order-to-Order Transitions of Block Copolymer in Film Geometry, CHANGHAK SHIN, HYUNJU AN, JUNE HUH, DU YEOL RYU, Yonsei University, Korea — The phase transition behavior for an asymmetric polystyrene-block-polyisoprene (PS-b-PI) in film geometry, like the order-to-order transition, was investigated by in-situ grazing incidence small angle x-ray scattering (GISAXS). Unlike the bulk behavior, the micromdomain (or lattice) orientations in film geometry are influenced by the weak interfacial interactions between the native oxide layer and the polystyrene block due to the efficient interconnectivity, while the random orientation is observed for lamellar (LAM) structure. Compared with the bulk phase behavior, temperature dependence on the morphology leads to the enhancement of LAM morphology, the shifts of transition temperatures for the others, because interactions at the substrate/polymer and polymer/air interfaces influence this free energy balance.

S1.00044 Interfacial Polarization and Field Induced Orientation in Self Assembled Nanostructured Soft Ion Conductors, THOMAS THURN-ALBRECHT, PETER KOHN, KLAUS SCHROTER, Martin-Luther-University Halle-Wittenberg, Germany — We report about the effects of interfacial polarization in and upon a self assembled nanostructured ion conductor, consisting of an ordered, lamellar block copolymer with a Lithium salt dissolved selectively in one component. Impedance spectroscopy in combination with frequency dependent orientation experiments enable a quantitative analysis of ionic polarization and a direct demonstration of its aligning effect on the interfaces. The transition time from the fast dielectric to the slow ionic interfacial polarization is much longer than expected from classical Maxwell-Wagner-Sillars theory and attributed to the formation of diffuse double layers at the internal interfaces. The much stronger orientation effect of ionic as compared to dielectric polarization offers a new route to align microdomains and therewith the ion conducting paths of the polymer.
S1.00045 FTIR Investigation of Ion Environments in PEO-based “Single Ion” Polymer Conductors

MINGFU LU, JAMES RUNT, PAUL PAINTER — The infrared and Raman spectra of ionomers and electrolytes containing sulfonate groups have been previously studied in great depth. If the cation - anion interaction is relatively strong, the doubly degenerate asymmetric SO3- stretching mode becomes split into two components, while the symmetric SO3- stretching mode displays bands that can be assigned to the “free” (solvated) anion, neutral pairs and aggregates. In this paper we investigate a series of PEO-based polyester copolymer ionomers, with sulfonate anions covalently bound to the polymer chains, using FTIR spectroscopy. Ion content is systematically varied by changing the ratio of ionic to non-ionic isophthalate groups while keeping a fixed PEO segment molecular weight of 600. In the FTIR spectra of these ionomers, a splitting of the asymmetric mode is observed and only a single symmetric stretching band characteristic of some form of aggregated structure is apparent. There is no evidence that “free” or solvated ions are present. In addition, various ethylene oxide modes of vibration are shifted in frequency in a similar manner to those observed in studies of complexes of known structure, indicating their involvement in the formation of the aggregate.

S1.00046 Origin of the low-q X-ray scattering behavior in poly(ethylene oxide)-based ionomers

AMANDA MCDERMOTT, GREGORY TUDRYN, Penn State University, JAN ILAVSKY, Argonne National Laboratory, ANDREW ALLEN, National Institute of Standards and Technology, RALPH COLBY, JAMES RUNT, Penn State University — Ultra-small-angle X-ray scattering is used to investigate a series of single-ion-conducting PEO-based polyester copolymers with varying amounts of ionic sulfonate groups covalently bound to the polymer chains. We observe a low-q scattering component found in many polymers, including the neutral version of our material, and generally attributed to impurities. However, both the intensity and power-law slope of this scattering intensity upturn increase at high ion contents, indicating that it contains structural information about intentionally added ions. We discuss the interpretation of this feature with insight from atomic emission spectrophotometry, a critical ion fluctuation model, and the X-ray scattering behavior observed with several different cations and a range of concentrations.

S1.00047 New type of Reverse Osmosis Membrane via Layer-by-Layer Assembly Process

JUNWOO PARK, JOONA BANG, JEONGJU PARK, JINHAN CHO, DEPARTMENT OF CHEMICAL & BIOLOGICAL ENGINEERING TEAM, SCHOOL OF ADVANCED MATERIALS ENGINEERING TEAM — As to the commercial RO membranes for desalination, the polyamide (PA) based membranes have been widely used so far. However, they still have limitations, such as low permeability, bio-fouling, etc. In this work, we propose new types of polyelectrolyte-membranes which can overcome such problems. The membranes were designed by layer-by-layer (LbL) method using polyelectrolytes, including poly(allylamine hydrochloride), poly(styrene sulfonate), poly(acrylic acid), etc. Individual layers were adjusted by pH condition and number of deposition. The resulting multi-layered membranes were crosslinked by heat to provide the good durability. The morphologies were characterized by FE-SEM and AFM and the salt rejection was monitored by ion chromatography. By optimizing the membrane structures, we found that the water permeability was enhanced, while the salt rejection was as efficient as RO membranes. We believe that these results can provide the new protocol to design the advanced RO membrane.

S1.00048 ABSTRACT WITHDRAWN —

S1.00049 Simultaneous Prediction of Upper and Lower Critical Temperatures in Polymer Solutions Using a Constant Parameter Set

ELIZABETH CLARK, JANE LIPSON, Dartmouth College — Polymer solutions commonly exhibit phase separation and so the ability to predict temperatures and compositions associated with immiscibility is advantageous to experimentalists. We have been applying a simple lattice model that is capable of capturing both upper (UCST) and lower critical solution temperature (LCST) type phase behavior for polymer blends. Most recently we have become interested in mixtures which simultaneously exhibit both types of phase behavior. Examples include polysisobutylene (PIB) in pure and mixed solvents, and cyclohexane/poly styrene mixtures. We have found that with a single set of temperature-independent parameters the lattice theory is capable of capturing all the physics of these solutions; in addition we discuss conditions under which ‘hourglass’ phase diagrams result.

S1.00050 Monte Carlo simulations to study the effect of static and dynamic properties of polymer melts

KIRAN KHANAL, JUTTA LUETTMER-STRATHMANN, Department of Physics, The University of Akron, Akron, Ohio — Static and dynamic properties of polymers are affected by the stiffness of the chains. In this work, we investigate structural and thermodynamic properties of a lattice model for semiflexible polymer chains. The model is an extension of Shaffer’s bond-fluctuation model and includes attractive interactions between monomers and an adjustable bending penalty that determines the Kuhn segment length. This allows us to model melts of flexible and semiflexible chains. For this work, we performed Monte Carlo simulations for polymer melts with a range of bending parameters and densities. Results for chain dimensions show that the Kuhn segment length increases monotonously with the bending penalty and has a linear dependence for a range of bending parameters. Results for self diffusion constants show that the translational mobility is strongly reduced by increasing chain stiffness. We also investigate the effect of chain stiffness on thermodynamic properties of the melts.

S1.00051 Scaling of dynamic properties of polymer melts using friction coefficients of phantom chains - A Monte Carlo simulation study

NENAD STOJILOVIC, John Carroll University, JUTTA LUETTMER-STRATHMANN, The University of Akron — A Monte Carlo simulation method is used to test two different models of athermal polymer melts. In one model chains are allowed to cross (phantom chains) whereas in the other bond crossing is forbidden (real chains). We confirmed that the conformational properties of both types of polymers are similar and analyzed the differences in chain dynamics due to entanglements of real chains. Phantom chains that are sufficiently long exhibit Rouse dynamics, so that friction coefficients can be extracted from self diffusion coefficients. For real chains, on the other hand, entanglement effects complicate the determination of friction coefficients. In this work, we use friction coefficients from phantom chains to investigate the scaling behavior of dynamic properties of real chains.
S1.00052 Tactility effects on viscoelastic properties of polystyrenes1. CHIEN-LIN HUANG, CHI WANG, Department of Chemical Engineering, National Cheng Kung University — Polystyrenes (PS) with a similar molecular weight and distribution but different tacticities, i.e. syndiotactic (s-PS), atactic (a-PS), and isotactic (i-PS), have been used in this study to show a comparison to reveal their differences in the viscoelastic properties. Our attention was focused on the influence of the PS tacticity on the rheological properties, especially the plateau shear modulus \( G'' \) and entanglement molecular weight \( M_e \). Based on the time-temperature superposition principle, the master curves of dynamic storage modulus \( G' (\omega) \), dynamic loss modulus \( G'' (\omega) \), and tan\( \delta \) at a reference temperature of 280°C were constructed. The feasibility of conventional approaches for determining \( G'' (\omega) \), i.e. minimum tan\( \delta \) criterion, the integration method, and an empirical equation derived by Wu, has been discussed and compared; the corresponding \( M_e \) is then derived by the classical relation: \( M_e = \rho R T / G'' \). Our results show that the measured \( M_e \) and activation energy for flow are similar for s-PS and a-PS, but the highest for i-PS. In addition, the zero shear viscosity of i-PS is ca. one order larger than that of s-PS and a-PS.

1Thanks for NSC financial support.

S1.00053 Stress-induced Mobility in Polymer Glasses During Multistep Creep Deformation. HAU-NAN LEE, KEEWOOK PAENG, STEPHEN SWALLEN, MARK EDGER, Department of Chemistry, University of Wisconsin-Madison, ROBERT RIG- GLEMAN, JUAN DE PABLO, Department of Chemical and Biological Engineering, University of Wisconsin-Madison. An optical photobleaching experiment and molecular dynamics simulations have been used to study the changes in segmental dynamics of a polymer glass during uniaxial creep deformation. Both experiment and simulation observe that segmental mobility increases more than a factor of 100 during deformation. Both show a strong correlation between strain rate and mobility in single step creep. However, in multistep creep and recovery, the correlation between strain rate and mobility is broken in both experiment and simulation; this emphasizes that no simple mechanical variable universally exhibits a simple relationship with molecular mobility. Interestingly, in contradiction to the Eyring model, both experiments and simulations show an increase in segmental mobility immediately follows a significant drop in stress.

S1.00054 Unusual Spherulite Radial Growth Rate Kinetics of Poly(ethylene adipate): Observation of a Double Maximum in Growth Rate Curve. KATHY SINGFIELD, ASHLEY ROWE, Saint Mary’s University — Poly(ethylene adipate) (PEA) is an aliphatic polyester often blended in small amounts with aromatic polyesters in order to impart some of its biodegradability to the resultant blend. Hot-stage polarized-light microscopy and differential scanning calorimetry have been used to investigate the isothermal melt-crystallization kinetics and thermal behaviour of PEA. The unusual spherulite radial growth rate dependence on isothermal crystallization temperature exhibits two maxima. A change in spherulite morphology from banded to non-banded spherulites is associated with the phase behaviour anomaly. The results are interpreted in terms of traditional Hoffmann-Lauritzen growth kinetics.

S1.00055 Simultaneous Dielectric Spectroscopy and X-ray Diffraction of Poly(ethylene terephthalate) and PET/Carbon Nanotube Nanocomposites. BRET STENGER, LEI YU, PEGGY CEBE, Tufts University Department of Physics and Astronomy, CEBE RESEARCH GROUP TEAM — The crystallization of poly(ethylene terephthalate) (PET) and a nanocomposite of PET with multi-walled carbon nanotubes (MWCNTs) were studied by simultaneous wide and small angle X-ray diffraction and dielectric relaxation spectroscopy. Our purpose is to determine whether the MWCNTs affect the cold crystallization kinetics or phase structure of the PET host. The nanocomposites contained 2% MWCNT by weight, and were prepared by solution mixing, and then compression molding into film. Dielectric measurements were made at frequencies from 100 Hz to 1 MHz, in parallel plate geometry. Measurements of the samples during cold crystallization (T<100-120°C) were used to investigate the relationship between the growth of crystals and the restriction of the molecular mobility of the amorphous phase. In agreement with previous work, results indicate that a heterogeneous distribution of amorphous regions exists, implying both interlamellar and interfibrillar/interphersulitc placement of the amorphous chains. Addition of carbon nanotubes to the PET increased the rate of cold crystallization, but did not affect the glass transition relaxation process.

S1.00056 Crystallization kinetics and the orientation of crystals under cylindrical nanoconfinement. KYUNCHEE LEE, EUNTAEK WOO, KYONG WOOK NOH, School of Chem. and Bio. Eng., Seoul National University, YOUNG GYU JEONG, School of Adv. Mater. and Sys. Eng., Kumoh National Institute of Technology, JUNE HUH, School of Mater. Sci. and Eng., Seoul National University, KYUSOON SHIN*, School of Chem. and Bio. Eng., Seoul National University — Crystallization kinetics, together with crystal orientation, is affected by the imposed geometric constraint. We investigated that crystallization of polymer and metal in nanopores with the variation of pore diameter. Crystallization of PE in nanopores is dominated by nucleation and the crystal growth is restricted by the limited space. On the basis of classical nucleation theory, we found that homogeneous nucleation dominates in larger pores while heterogeneous nucleation governs in smaller pores. We also investigated the orientation of crystal structures of polymer and metal in cylindrical nanopores, and found that the crystal orientation is influenced by crystallization mechanism in nanoscopic cylindrical pores, the crystal growth is limited and the crystals are preferentially oriented along the pore axis.

S1.00057 Crystallization of Polyethylene on nucleating and on passive substrates. THOMAS HENZE, KLAUS SCHROETER, THOMAS THURN-ALBRECHT, Institute of Physics, Martin-Luther-University Halle-Wittenberg, D-06099 Halle, Germany — Since the late 1950’s it has been known that polymers are able to crystallize epitaxially on suitable crystalline substrates. Whereas epitaxial crystallization experiments have been typically performed from solution, we here present a study of the morphology of thin films of polyethylene crystallized from the melt on a number of substrates with different ability to invoke crystallization, namely mica, NaCl, SiO\(_2\) and HOPG. Using intermittent-contact mode AFM very different structures are observed on the surface of the polymer film depending on the kind of substrate as well as film thickness. For very thin films (~30 nm) on NaCl and HOPG edge on lamellae, oriented in domains according to the underlying crystal lattice, show up while for mica and SiO\(_2\) flat-on lamellae dominate. With increasing film thickness (up to 130 nm) the orientation of the lamellae on HOPG and NaCl becomes weaker, while on mica and SiO\(_2\) a spherulitic morphology develops, which is not present in the case of HOPG and NaCl.

S1.00058 Impact of Protein-Metal Ion Interactions on the Crystallization of Silk Fibroin Protein1. XIAO HU, QIANG LU, DAVID KAPLAN, PEGGY CEBE, Tufts University — Proteins can easily form bonds with a variety of metal ions, which provides many unique biological functions for the protein structures, and therefore controls the overall structural transformation of proteins. We use advanced analytical analysis methods such as temperature-modulated differential scanning calorimetry and quasi-isothermal TMDSC, combined with Fourier transform infrared spectroscopy, and scanning electron microscopy, to investigate the protein-metallic ion interactions in Bombyx mori silk fibroin proteins. Silk samples were mixed with different metal ions (Ca\(^{2+}\), K\(^+\), Na\(^+\), Cu\(^{2+}\), Mn\(^{2+}\)) with different mass ratios, and compared with the physical conditions in the silkworm gland. Results show that all metallic ions can directly affect the crystallization behavior and glass transition of silk fibroin. However, different ions tend to have different structural impact, including their role as plasticizer or anti-plasticizer. Detailed studies reveal important information allowing us better to understand the natural silk spinning and crystallization process.

S1.00059 Effects of configurational defects on structural evolution in Poly(vinylidene fluoride-hexafluoropropylene) copolymers. SURIYAKALA RAMALINGAM, SHAW L. HSU, University of Massachusetts, Amherst — Crystallization kinetics of various crystallizable segments in Poly(vinylidene fluoride-hexafluoropropylene) [P(VDF-HFP)] copolymers have been analyzed using thermal techniques. These analyses are supported by spectroscopic and diffraction techniques, which directly measure the presence or absence of specific chain conformations or crystalline forms. Crystallization is constrained due to random distribution of the noncrystallizable bulky comonomer (HFP) along the crystallizable linear PVDF chains. Since the crystallites of different size/VDF chain lengths have different melting temperatures, it is possible to obtain a fraction of each crystallizable segment by selecting the crystallization temperature at various points below melting temperature. This fractionation has been accomplished by following the Successive Self-Nucleation/Annealing (SSA) method. The chain distribution and configurational defects, introduced by HFP, have been evaluated and correlated to the multiple thermal transitions in P(VDF-HFP) copolymers. In addition, it is interesting to find that the thermal fractionation can induce the above|conformation in highly constrained P(VDF-HFP) copolymers.

S1.00060 Polymorphism Behaviors of Electrospin Poly(vinylidene fluoride) Nanofibers. ZHENXIN ZHONG, DARRELL RENEKER, The University of Akron — Poly(vinylidene fluoride) (PVDF) and its copolymers have drawn great attention in recent years due to their attractive electrical properties such as ferro-, piezo- and pyro-electricity. Depending on its processing, PVDF can exhibit five different polymorphs. Among them, the beta phase has the highest piezo-, pyro- and ferroelectric activities. Electrospinning was used to produce thin polymer fibers. The polymorphic behavior of electrospun PVDF fibers was observed. Long cylindrical PVDF specimens with cross-sections in the range of 10 nm to 1 micron was obtained by varying the electrosprining conditions. Almost pure beta phase was obtained in electrospun PVDF nanofibers. The morphology and internal structure of single PVDF electrospin nanofibers were studied by electron transmission microscopy.

S1.00061 Electrospin Buckling Coils. YU XIN, DARRELL RENEKER, The University of Akron — Electrosprining offers a useful way to produce fibers with micron and nanometer scale diameter. The present work deals with the buckling phenomenon characteristic of a jet impinging upon the surface of collector. A viscous jet may have either tensile or compressive forces along its axis. The periodic buckling that is often observed is attributed to the occurrence of compressive forces as the jet decreases at the collector. With the increase of axial compressive stresses along the jet, a jet with circular cross sections first buckles by formation of sharp folds, and then by formation of coils. The resulting buckling patterns include zigzag patterns and coils that which can be controlled by changing parameters, such as density, viscosity, conductivity, voltage, polymer concentration, distance and volumetric flow rate. Uniformly buckled polymer fibers can be made at a rate of one turn per microsecond. An experimental apparatus was built to continuously collect buckling coils of nylon 6, from a water surface, into a multilayer sheet. These small “springs” and sheets will be tested for mechanical properties needed in biomedical applications.

S1.00062 Hierarchical Structure on Nanofiber via Combination of Electrospinning and Polymer Crystallization. XI CHEN, Drexel University, BINGBING WANG, RUCHA SHAH, CHRISTOPHER LI — We report the formation of hierarchically ordered polymer nanofiber structures, named as nano fiber shish kebabs (NFSKs), by combining electrospinning and controlled polymer crystallization methods. Both poly caprolactone (PCL) and poly (ethylene oxide) (PEO) nanofibers were produced by electrospinning. These polymer nanofibers served as the shish and a secondary polymer (block copolymer) was decorated on the nanofiber in the form of single crystal lamellae by either an incubation (slow crystallization), or a solvent evaporation (fast crystallization) method. The structural parameters of the NFSK such as the fiber diameter, periods, the kebab size etc., were readily controlled by changing the electrosprining and crystallization conditions. This hierarchical architecture is of great technological interest because it provides a platform for incorporating different functionalities into nanoscale fiber fibers in an ordered fashion.

S1.00063 PP/POSS Nanocomposites: Characterization and Properties of Melt Spun Fibers. BYOUNG-JO LEE, SAYANTAN ROY, SADHAN JANA, University of Akron — It is known that molecules of polyhedral oligomeric silsesquixoxane (POSS) can self-assemble into spherical, fibrillar, or lamellar nanoparticles by bottom-up self assembly process during mixing with host polymers. This study capitalizes on such nanoparticle formation to increase the melt strength and tensile properties of polyolefin blown films and spun fibers. A novel method was developed whereby a sorbitol-type nucleating agent was used as dispersion aids for POSS. The nucleating agent also served as templates for self-assembly of POSS molecules into nanoparticles of 25-200 nm in diameter. A typical polypropylene formulation containing 0.3 wt% nucleating agent and 5-10 wt% POSS was spun into fibers with close to 70% reduction in diameter and 40-45% increase in modulus and 70-75% increase in yield strength compared to unfilled PP. An optimum concentration of POSS was identified.

The authors thank NSF for providing financial support through grant number CMMI-0727231 and Hybrid Plastics for partnership and assistance with the materials.

S1.00064 Affine deformation in polymer networks. ANINDITA BASU, QI WEN, PAUL JANMEY, ARJUN YODH, University of Pennsylvania, DEPT. OF PHYSICS AND ASTRONOMY, UNIVERSITY OF PENNSYLVANIA COLLABORATION, INSTITUTE FOR MEDICINE AND ENGINEERING, UNIVERSITY OF PENNSYLVANIA COLLABORATION — An affine deformation is one where a macroscopic deformation applied on a body is translated uniformly to the microscopic level. Much existing theory, ranging from simple rubber elasticity to non-linear elasticity in biological polymer networks, is based on the assumption that deformations are affine. We explore the validity of the affine assumption by embedding micron-sized fluorescent beads within model polymer networks and quantifying their displacements when the sample is put under shear deformation. We quantify the non-affine deformations as functions of polymer chain density, cross-link concentration and find our results to be in qualitative agreement with current theories of rubber elasticity.

S1.00065 Length and Structure Dependence of Electron Transport in Organic Molecules. SHASHI KARMA, GOVIND MALLICK, US Army Research Laboratory, HAIYING HE, RAVINDRA PANDEY, Michigan Tech University — The electron transport through organic molecules is affected by a number of structural parameters, such as the length, dihedral angle, rotation around a single-bond, symmetry and charge distribution of frontier molecular orbitals. In addition, in a molecule-solvent hybrid system, the chemistry and physics of the molecule-solvent interface plays an extremely important role on electron transport through organic molecules. In order to gain an enhanced understanding of the effects of length, geometry and solid-molecule interface we have investigated electron transport through n-conjugated molecules of increasing lengths in contact with Au substrate by non-equilibrium Green’s function method within ab initio molecular orbital theory, density functional theory and semi-empirical methods. The effects of rotation around a single bond, change in dihedral angle and the length of the molecule on the transport properties are investigated. The results suggest a complex dependence of electron transport on one-electron energy levels, spatial characteristics of the wave function and geometry of the molecules. Further, the local density of states and location of metal Fermi level are also found to affect electron transport characteristics in a metal-molecule hybrid system.

S1.00066 PHASE TRANSITIONS AND STRONGLY CORRELATED SYSTEMS —
S1.00067 Color change of Ruby investigated by Raman and UV-vis. SEAN BRECKLING, YING ZOU, SHISHIR RAY, LARRY BUROKER, SOMADITYA SEN, MARK WILLIAMSEN, PRASENJIT GUPTASARMA. University of Wisconsin-Milwaukee — The origin of a distinct red color in Ruby (Al2O3:Cr3+) continues to be a fundamental unsolved question [1]. We report the synthesis of a series of samples of 2% Cr2O3 by solid state reaction [2] at temperatures varying between 900° and 1300°C. We observe a visible change in color at every stage, from light green, to grey, and to pink, indicating progressive incorporation of Cr3+ ions into the Al2O3 lattice. We report further investigations of x-ray diffraction analysis, Raman and UV-visible spectroscopy, and correlate the observed color changes with the evolution of vibration modes of the cage around CrO6 and band-gap states resulting from Cr incorporation. We also plan to report results from single crystals grown using a floating zone. [1]J.M. Garcia-Lastra, M.T. Barriuso, J.A. Aramburu and M. Moreno, Phys. Rev. B 72(2005)113104 [2]L.W. Finger and R.M. Hazen, J. Appl. Phys. 49(1978)5823

S1.00068 ABSTRACT WITHDRAWN —

S1.00069 Scattering of the Transverse Acoustic Phonon by Polar Nanodomains in the Relaxor Ferroelectric KTa1−xNbO3 (KTN)1, JEAN TOULOUSE, EUGENE IOLIN, Lehigh University, Physics Department and Center for Advanced Materials, BERNARD HENNION, DANIEL PETITGRAND, LLB, CEA, Saclay France, ROSS ERWIN, NCNR, NIST — We show that, in relaxors, the transverse acoustic (TA) mode displays a particularly original behavior, due its coupling to the transverse optic (TO) mode as well as to the polarization P of the Polar Nano-Domains (PND) that are ubiquitous in these special ferroelectrics. A neutron scattering study of the TA phonon frequency and damping, and especially of their q dependence, reveals that the PNDs condense in the form of platelets. In the relaxor range of temperatures, in which elastic diffuse scattering is also observed, the TA mode is strongly scattered by the PNDs. We compare our results with those from thermal conductivity studies of inhomogeneous solids and similar neutron results obtained in other perovskite systems. We also present a theoretical model that describes the scattering mechanism specific to relaxors, the TA-P-T0 interaction, is shown to fit the acoustic data well and also provides an estimate of the TO mode frequency and damping.

S1.00070 93Nb NMR investigation of the multiferroic system Ba3NbFe3Si3O14, LLOYD LUMATA, NHMFL/Physics, Florida State University, M.J.R. HOCH, H.D. ZHOU, J.S. BROOKS, P.L. KUHNS, A.P. REYES, C.R. WIEBE, NHMFL/Physics, FSU — We present 93Nb nuclear magnetic resonance spectroscopy and relaxation data on the new multiferroic system Ba3NbFe3Si3O14. The spin-lattice relaxation rate 1/T1 and spin-spin relaxation rate 1/T2 show a peak at 26 K accompanied by broadening of the NMR lineshapes, characteristic of Néel ordering. Salient features of 93Nb NMR lineshapes in the ordered phase and temperature-dependent 93Nb Knight shifts will be discussed in relation to the possible bulking or tilting of the NbO6 octahedra (caused by magnet-lattice coupling) around the transition.

1This work was supported in part by NSF DMR-0602859 and performed at the National High Magnetic Field Laboratory, which is supported by NSF Cooperative Agreement No. DMR-084173, EIEG grant, by the State of Florida, and by the DOE.

S1.00071 Phase Diagram of Floating Zone grown Multiferroic SmMnO3 and Mn site substitutions, SOMADITYA SEN, LARRY BUROKER, YING ZOU, SHISHIR RAY, MARK WILIAMSEN, PRASENJIT GUPTASARMA2, Physics Dept., Univ. of Wisconsin, 1900 E Kenwood Blvd., Milwaukee, WI 53211, USA — SmMnO3, a member of a Rare Earth manganite series of current interest due to the observation of multiferroic magnetoelectric properties, anisotropy in magnetic properties and an unconventional “compensation temperature” ~8K possibly arising from antiparallel S-Mn exchange interactions. Of particular interest here is charge disproportionation of Mn, competing magnetic and orbital order, and the proximity to a metal-insulator transition [1]. We report detailed studies of a high-quality single crystal of SmMnO3 grown from a floating zone, and the result of Mn-site substitution by elements with multiple valence states and octahedral coordination. We discuss magnetization, crystal structure refinement, and dielectric spectroscopy in 0.3<T<300 Kelvin and 0<H<9 Tesla. [1] Kurbakov, et.al., A, Physics of the Solid State, 46 – 9 (2004) 1704

S1.00072 Magnetic and Specific Heat Studies of Multiferroic Hexagonal DyMnO3, YING ZOU, SHISHIR RAY, SOMADITYA SEN, MARK WILLIAMSEN, PRASENJIT GUPTASARMA1, University of Wisconsin-Milwaukee, USA — Rare earth (R) manganites (RMnO3) are well known to exhibit novel magnetic and magnetoelectric multiferroic properties. Under normal conditions, R=La through Dy yields orthorhombic lattice symmetry, whereas R=Ho through Lu yields hexagonal lattices. We confirm however that DyMnO3 single crystals, when grown in Argon from a floating zone, have a hexagonal lattice structure [1]. We report further new results in the H-T phase diagram in the range 0.3-300K and 0-T Tesla. Specific heat measurements show two transitions at 4K and 63K in the absence of a magnetic field. dc-Magnetization shows a cusp at 4K, which we attribute to a Dy3+ spin ordering. Time-dependent relaxation and frequency dependent shifting in ac susceptibility reveals a spin-glass behavior at this temperature, possibly suggesting an incommensurate Dy magnetic structure. An interesting bifurcation occurs for the high temperature transition (T~63K) in ac susceptibility with increase in frequency of the ac field. [1] V.Y.Ivanov et al, Phys.Solid State, 48(2006)1726

S1.00073 Low Temperature Phase Transitions in Single Crystal Magnetoelectric GdMnO3, MARK WILLIAMSEN, SHISHIR RAY, SOMADITYA SEN, YING ZOU, PRASENJIT GUPTASARMA1, University of Wisconsin-Milwaukee — GdMnO3 is proposed to have a magnetic phase transition from paramagnet to incommensurate antiferromagnet at 43K, further ordering to canted antiferromagnet around 23K, followed by Gd magnetic ordering at 6.5K[1]. We present further studies of a large single crystal of orthorhombic GdMnO3 grown by us from a floating zone, revealing additional features at lower temperature. Dielectric spectroscopy measurements confirm these new features. We also report dc-magnetization, frequency dependent ac-magnetization 2-300K, and specific heat 0.4-300K in a variable magnetic field 0-9T, and propose additional features in the magnetoelectric phase diagram. [1]T. Kimura,Phys.Rev.B 71,224425(2005)

S1.00074 Local structure studies of multiferroic RMn2O5 (R=Bi, Pr, Gd)1, G. FABBRIX, LNLS/IFGW-UNICAMP, Campinas, Brazil, N.E. MASSA, LANAIS EFO-CEQUINOR, UNLP, cc962, 1900 La Plata, Argentina, E. GRANADO, IFGW-UNICAMP/LNLS, Campina, Brazil, C.A. MACIEL, IF-UFPR, Curitiba, Brazil, J.A. SOUZA, CCNH-UFABC, Santo André, Brazil, J.A. ALONSO, M.J. MARTINEZ, CSIC-ICM-CSIC, Cantoblanco, E28049 Madrid, Spain, G.M. AZEVEDO, LNLS, Campinas, Brazil — EAXFS measurements from 20 K to 300K were used to investigate the local structure of multiferroic RMn2O5 (R = Bi, Pr, Gd, TM TC 40K) in transmission mode at the Mn K- and R L- edges in the XAFS2LNS beamline and analyzed using the IFEFFIT and FEFF codes. For BiMn2O5, Mn K-edge reveals very small temperature dependence of the Debye-Waller factor (DWF) and an Einstein temperature (ET) from Mn-O bonds of 675±22 K, suggesting that MnO polyhedra are rigid. We find structural distortions in the first coordination shell at the Bi L-edge associated to vibrational anomalies in the Bi-O bonds. The quantitative analysis gives a measure of such distortions to two very distinct values of DWT and ET (294±7K and 462±28K) for these bonds on first shell. Similar results will be discussed in terms of disorder induced non-Fermi liquid behavior, related to the spin dynamics of the ferromagnetic nano-domains coexisting with antiferromagnetically correlated systems in the region.

1We acknowledge CAPES and CNPq for financial support.

S1.00075 Magnetism and non-Fermi liquid behavior in a Na0.78CoO2 single crystal1, ALEXANDER FEHER, A. ZORKOVSKA, M. KAJINAKOVA, A. BARAN, Centre of Low Temp. Physics, P. J. Safarik Univ. and Inst. Exp. Physics SAS, Kosice, Slovakia, C. T. LIN, J.P. PENG, Max-Planck-Institute for Solid State Research, Stuttgart, Germany, J.S. XIA, L. YIN, M.W. MEISEL, NHMFL and Dept. Physics, Univ. Florida — In recent years, significant interest has been devoted to high Na-doped cobaltates, in which the competition between geometric frustration, strong electronic correlations, and magnetic interactions leads to disorder, either correlated or non-correlated, and a variety of quantum states with possible QPTs are expected. Specific heat down to 100 mK and the ac-susceptibility at several frequencies and temperatures, down to 40 mK and in fields up to 10 T, of a layered Na0.78Co2O single crystal have been measured. The results will be discussed in terms of disorder induced non-Fermi liquid behavior, related to the spin dynamics of the ferromagnetic nano-domains coexisting with antiferromagnetically correlated systems in the region.

S1.00076 Transport and Magnetic Properties of ErNi2B2C, W.C. LEE, Dept. of Physics, Sookmyung Women’s Univ. Seoul 140-742, Korea — We measured the magnetization M(H,T) and magnetoresistivity ρ(H,T) of ErNi2B2C single crystal for magnetic fields perpendicular and parallel to the c-axis and with the current along the c-axis low temperature regions. From the magnetoresistivity measurements with the current along c-axis, we constructed the H2(T) curves for magnetic fields perpendicular and parallel to the c-axis and those were compared for curves with the current perpendicular to the c-axis. Also we constructed a magnetic phase diagram only the magnetic field perpendicular to the c-axis. We determined the critical behavior and calculate key observables at the transition and in the associated quantum Griffiths phase. We also briefly discuss the cases of superohmic and subohmic dissipation.

S1.00077 Antisymmetric Exchange in Antiferromagnetic Materials of Rhombohedral Structures, ALEXANDER BAZHAN, P.L.Kapitza Institute for Physical Problems, RAS, Moscow, Russia — Carriers transferrings, determined by wave functions and energy levels of i j magnetic and oxygen ions, which are determined by rhombohedral oxygen crystal fields and their particularities, are in discussions for identification of antisymmetric, Dzyloshinskii-Moria exchange, and energy levels of i j magnetic and oxygen ions, which are determined by rhombohedral oxygen crystal fields and their particularities, are in discussions

S1.00078 Infinite-randomness quantum critical points induced by dissipation, CHETAN KOTABAGE, University of Florida — We develop a strong-disorder renormalization group to study quantum phase transitions with continuous O(N) symmetry order parameters under the influence of both quenched disorder and dissipation. For Ohmic dissipation, as realized in Hertz’ theory of the itinerant antiferromagnetic transition or in the superconductor-metal transition in nanowires, we find the transition to be governed by an exotic infinite-randomness fixed point in the same universality class as the (dissipationless) random transverse-field Ising model. We determine the critical behavior and calculate key observables at the transition and in the associated quantum Griffiths phase. We also briefly discuss the cases of superohmic and subohmic dissipation.

S1.00079 Phase-transition behavior of Selenium confined in periodic mesoporous silica: an x-ray scattering study, KIYANGMIN LI, CONGSHANG WAN, GANG CHEN, Ohio University — Confinement of semiconductors in nanoporous media provides a new approach to modify their physical properties such as electric conductivity, thermal conductivity, and phase transition temperatures. To understand the effect of nanoscale confinement on the melting behavior of selenium, we now conduct x-ray scattering experiments on selenium that are confined in periodic mesoporous silica (PMS). Hexagonal MCM-41 and SBA-15 with cylindrical pores (2 - 30 nm in diameter) are synthesized and utilized as the host matrix. Under synchrotron x-ray scattering, the core-shell system is determined. Wide-angle x-ray scattering experiments are used to measure the melting points of selenium confined in cylindrical pores of various widths. Relation between pore width and melting point of Se is established and compared with the Gibbs-Thomson theory. Our study provides fresh insights into the applicability of the Gibbs-Thomson theory to inorganic semiconductors confined in nanoporous media.

S1.00080 Critical exponents taking into account dynamic scaling for adsorption on small-size one-dimensional clusters, VLADIMIR UDODOV, ANDREY TASKIN, KATANOV KHAKAS STATE UNIVERSITY COLLABORATION — Adsorption on small-size one-dimensional clusters is investigated using the Monte Carlo method. The effect of temperature and system size variations on adsorption is studied. Critical coefficients of the correlation length and dynamic critical coefficient z are calculated taking into account the hypothesis of dynamic scaling. The results obtained demonstrate that non-equilibrium adsorption in nanosystems can occur in a much different fashion than in macrosystems.

S1.00081 Infinite Size Scaling of Melting in Two Dimensions, KEOLA WIERSCHEM, MARTECH & Department of Physics, Florida State University, EFSTRATIOS MANOUSARIS, MARTECH & Department of Physics, Florida State University and Department of Physics, University of Athens, Greece — The melting transition of a two-dimensional Lennard-Jones fluid is studied using classical Monte Carlo methods. Melting in two dimensions is expected to occur via a two-stage process, with separate transitions for translational and orientational order. The second moments of the translational and orientational order parameters are analyzed, and dimensionless quantities are constructed. According to finite size scaling theory, such quantities should be a function of the ratio of system size to the length of the appropriate order parameter. Using the theoretical temperature dependence of the correlation length, and the fact that the correlation length approaches infinity at the critical point, the two melting transitions may be determined.
S1.00082 Probability Density Function at the 3D Anderson Transition, ALBERTO RODRIGUEZ, LOUELLA J. VASQUEZ, RUDOLF ROEMER, Department of Physics and Centre for Scientific Computing, University of Warwick, Coventry CV47AL, United Kingdom — The probability density function (PDF) for the wavefunction amplitudes is studied at the metal-insulator transition of the 3D Anderson model, for very large systems up to $L^3 = 240^3$. The implications of the multifractal nature of the state upon the PDF are presented in detail. A formal expression between the PDF and the singularity spectrum $f(\alpha)$ is given. The PDF can be easily used to carry out a numerical multifractal analysis and it appears as a valid alternative to the more usual approach based on the scaling law of the general inverse participation rations.

S1.00083 Quantum simulation of Fermi-Hubbard models in semiconductor quantum-dot arrays, NA YOUNG KIM, Stanford University, TIM BYRNES, National Institute of Informatics, KENICHIRO KUSUDO, National Institute of Informatics, YOSHIHIISA YAMAMOTO, Stanford University — We propose a solid-state quantum simulator device to investigate a Fermi-Hubbard model including long-ranged Coulomb interactions. The device consists of an array of coupled quantum dots in a GaAs-based two-dimensional electron gas system. We launch an artificial lattice potential electrostatically by applying DC voltage to a periodically patterned thin film on top of the two-dimensional electron gas system. We tune both two competing energy terms – Coulomb interaction energy and kinetic energy - and the density of electrons independently, which enables us to construct a Hubbard phase diagram via differential conductance measurements. We consider the case of high average trapped electron density where more than the first bands are occupied. In this case, high mobility is still preserved and the effects of the Hubbard model would not be masked by impurities or disorder. We believe that a metal-Mott insulator quantum phase transition and a $d$-wave superconducting phase are observable in our proposed device according to the estimates of Hubbard parameters.

S1.00084 GENERAL THEORY (THEORETICAL METHODS) —

S1.00085 Coexistence of phases in final one-dimensional systems, VLADIMIR UDOODO, IVAN NAUMOV — Within the framework of L.D. Landau (1908-1968) approach it is shown, that two-phase equilibrium is possible in linear macrosystems of the final size at low temperatures. At further duration of temperature two-phase equilibrium becomes unstable and the system passes in a single-phase state. These results remain in force and at the account of interaction of interphase borders with each other and with the ends of linear system. Following Landau [1] we shall consider the linear system made of alternating pieces of two various phases. Points of contact between various phases (interphase borders) we shall present as a weak solution. For linear system of the limited size $L \{L>>1\}$ at low temperatures a single-phase state is stable. The increase in temperature will lead to phase transition of the first order in a two-phase state. The original cascade of phase transitions of the first order, because of increase of quantity of interphase border of item will be observed actually. 1. L.D.Landau, E.M.Lifshits. Theoretical physics. Statistical physics. A part 1. 4 edition. Moscow (In Russian): the Science publisher, 1995.

S1.00086 Variational Ground State of the One Dimensional Bose-Hubbard Model, J.D. MANCINI, Kingsborough College of CUNY, V. FESSATIDIS, Fordham University, S.P. BOWEN, Chicago State University, R.K. MURAWSKI, Drew University — Recently, Eichenberger and Baeriswyl [PRB 76, 180504R, (2007)] have introduced a novel variational ansatz to study the two dimensional Hubbard model. Their scheme involves choosing a trial ket which consists of an exponential operator constructed from the Hamiltonian which then operates on a mean field ground state $|\psi_0\rangle$. In this study, we wish to extend this ansatz by combining it with a second ansatz in which a variational basis is constructed by systematically taking derivatives with respect to a (variational) parameter. The model we will study is the one dimensional Bose-Hubbard Hamiltonian which is used to investigate the properties of interacting bosonic atoms in a one-dimensional optical lattice. The Hamiltonian is given by

$$H_{bh} = -J \sum_{i=1}^{M} (a_i^\dagger a_{i+1} + \text{h.c.}) + \frac{U}{2} \sum_{i=1}^{M} n_i (n_i - 1),$$

where $a_i^\dagger$ ($a_i$) creates a boson at the lowest level localized on the $i$-th site, $J$ is the hopping energy and $U > 0$ is the onsite repulsion. Our results are then compared with other approximation methods such as Hartree-Fock-Bogoliubov theories and the variational Bijl-Dingle-Jastrow method.

S1.00087 Variational Ground-State of the One-Dimensional Heisenberg Model, J.D. MANCINI, Kingsborough College of CUNY, V. FESSATIDIS, Fordham University, R.K. MURAWSKI, Drew University, W.J. MASSANO, SUNY Maritime, S.P. BOWEN, Chicago State University — We wish to study the ground state of a spin system described by the Heisenberg Hamiltonian

$$H = -\frac{1}{2} J \sum_{i=1}^{M} \left\{ 2 \left( \sigma_i^x \sigma_{i+1}^x + \sigma_i^y \sigma_{i+1}^y + \sigma_i^z \sigma_{i+1}^z \right) \right\},$$

where $\sigma^\pm = \sigma_x \pm i \sigma_y$ and $J$ is the interaction strength. We choose as our trial ket $|\psi_0 (\lambda)\rangle = e^{\lambda \hat{S}} |\phi_0\rangle$ where $|\phi_0\rangle$ is chosen to be the ferromagnetic state with all spins aligned downward, and $\hat{S}$ is the operator $\hat{S} = \sum_i \sigma_i^z$ with $\lambda$ a variational parameter. We then construct our variational basis by systematically taking derivatives of $|\psi_0 (\lambda)\rangle$ with respect to $\lambda$: $|\psi_N (\lambda)\rangle = \partial^N \psi_0 (\lambda)$. The lowest eigenvalue of the Hamiltonian matrix $E_0 (\lambda)$ is then minimized with respect to $\lambda$. Comparisons are then made with other approximation schemes.

S1.00088 Variational Moments Expansion, R.K. MURAWSKI, Drew University, J. MIKALOPAS, J.D. MANCINI, Kingsborough College of CUNY, V. FESSATIDIS, Fordham University, S.P. BOWEN, Chicago State University — A number of years ago, a generalized moments expansion, GMX$(n, n)$ was derived as a novel way to calculate ground state energies of many body systems [PLA 349, 320 (2006)]. This scheme was based on a theorem by Horn and Weinstein for the "t-expansion" and was shown to be a generalization of an earlier connected moments expansion CMX, in which $\text{CMX} = \text{GMX} (1, 1)$. Here we wish to extend the GMX method, which involves matrix elements of moments of the Hamiltonian, to include a recent variational ansatz in which a variational basis is constructed by taking successive derivatives with respect to a (variational) parameter $\lambda$ that is introduced in a trial ket. The GMX expression for the ground state, $E_0 (\lambda)$ is then minimized within a given subspace of the Hilbert space.
**S1.00089 Variational Approach to a Class of P-T Symmetric Hamiltonian Systems**, J. MIKALOPAS, J.D. MANCINI, Kingsborough College of CUNY, Brooklyn, NY, V. FESSATIDIS, Fordham University, Bronx, NY, F.A. CORVINO, Stevens Institute of Technology, Hoboken, NJ — In the usual study of non-relativistic Quantum Mechanics, one chooses a real (Hermitian) potential so as to ensure a real energy spectrum for the corresponding Schrödinger equation. In recent years, a number of authors have studied a class of complex potentials which are invariant under the combined symmetry P-T (here the operator $P$ represents parity reflection and the operator $T$ represents time reversal). For such P-T symmetric systems it has been shown that the energy eigenvalues of the Schrödinger equation are real so long as the P-T symmetry is not spontaneously broken. Thus it would appear that rather than the usual demand for Hermiticity, it may be sufficient to have a P-T invariant Hamiltonian so long as the energy spectrum remains real. It should be noted however that this conjecture has not been proven, but rather has been demonstrated to be true for several sample Hamiltonian systems. Here we wish to apply a recently developed ansatz wherein a variational basis is constructed by systematically taking derivatives of an initial trial state with respect to a (set) of variational parameters. In particular we shall study the spectrum of the Hamiltonian $H = p^2 + x^2 (ix)^a$ (a real) as a test case for the ansatz.

**S1.00090 Single Hole Dynamics in a 2D quantum antiferromagnet in a stripe-ordered by fluctuating background**, SATYAKI KAR, Department of Physics, FSU, EFSTRIATOS MANOUSAKIS, Department of Physics, FSU & MARTECH — We study the dynamics of a hole in a 2D lattice in a stripe-ordered background. Starting from $t - J$ Hamiltonian, we treat the $J$-term using the linear spin wave theory and we linearize the hole hopping in terms of spin-deviation operators. We find the dispersion relation of the eight different spin-wave modes and we solve the Dyson’s equation with the non-crossing approximation for the eight hole green’s functions. We investigate the hole energy bands, the spectral functions and the quasi-particle peak broadening.

**S1.00091 Towards a two dimensional lattice gas with dynamical geometry**, ANNA KLALES, DONATO CIANCII, ZACHARY NEEDELL, PETER LOVE, Haverford College — We report on simulations using a lattice gas automaton in which the lattice is replaced by a triangulation of an arbitrary two-dimensional manifold. If the manifold is 2D Euclidean space the particles move on the Kagome lattice. We report results of simulations of channel flow for the flat space model and of simulations in which the particle state can change the geometry of the triangulation through the Pachner moves.

**S1.00092 Quantum Monte Carlo Studies of Buckling of the Si(100) Surface**, WENDY LAMPART, RICHARD CHRISTIE, DANIEL SCHOFIELD, KENNETH JORDAN, University of Pittsburgh Department of Chemistry — The quantum Monte Carlo method is used to study the role of electron correlation on the buckling of Si-Si dimers on the Si(100) surface. The buckling is addressed using cluster models with one to three surface dimers. In addition to the diffusion Monte Carlo method, calculations are also carried out using various density functional methods, multi-reference MP2, multi-reference MP3, and approximate multi-reference coupled cluster approaches. The calculations show that high-order correlation effects are important for determining the relative stability of the buckled and unbuckled structures, favoring the buckled structure.

**S1.00093 Quantum Monte Carlo study of water-acene systems**, JIAWEI XU, RICHARD CHRISTIE, KENNETH JORDAN, University of Pittsburgh — Electronic structure quantum Monte Carlo methods are used to calculate the energies of a water molecule interacting with benzene, anthracene, and coronene. Localized orbitals represented as spline functions are used to reduce the computational cost of the calculations for larger water-acene complexes. The prospects of using this approach to determine the interaction energy between water and graphene is discussed.

**S1.00094 Ab initio study of ferroelectricity in quantum-confined nanostructures**, GHANSHYAM PILANIA, RAMAMURTHY RAMPRASAD, University of Connecticut — In the present ab initio study, we have employed density functional theory to investigate the size dependence of ferroelectric properties of BTO quantum wires and quantum dots. In the case of quantum wires, the ferroelectric well depth was calculated as a function of size. We find that the ferroelectric well depth corresponding to bulk BTO is recovered in quantum wires with diameters larger than 1 nm. Analysis of the decomposed density of states indicates that the central BTO unit behaves bulk like, whereas the peripheral units result in defect states in the band gap (with density depending on facet terminations). Complex polarization patterns were also observed, and were strong functions of the surface termination of the nanostructures. For instance, in non-stochiometric quantum wires with all surface facets terminated with TiO2, strong axial polarization was dominant. However, in BaO terminated quantum wires, polarization in the “shell” region is radial, while in the “core” region the polarization is axial. The BTO quantum dots that were studied displayed even more complex polarization patterns, reminiscent of the “vortex” patterns anticipated earlier based on effective hamiltonian calculations.

**S1.00095 On the interplay between spin polarization, orbital polarization and spin-orbit coupling in actinides from Pa to Cm**, MD ISLAM, ASOK RAY, University of Texas at Arlington, TX 76019 — We present a systematic investigation of the effects of spin polarization, orbital polarization and spin-orbit coupling in six actinide elements, namely Pa, U, Np, Pu, Am and Cm using relativistic full-potential augmented plane wave with local orbital basis method. Our calculation shows that the 5f electrons in lighter actinides are itinerant with no magnetic effects. In heavier actinides, the 5f electrons are strongly correlated and quite sensitive to spin polarization, although the difference between FM and AFM energies tends to be very small. The orbital polarization has strongest effect in NM order and nearly vanishes for spin polarized calculations in almost all cases. The 5f-electrons in α-Pu are close to being delocalized and their behavior is similar to that of lighter actinides. Among all the elements studied in this work, δ-Pu exhibits the most complex behavior. All forms of correlation effects are comparable in δ-Pu and significantly affect volume, bulk modulus and ground state energy.

**S1.00096 Strain-dependence of the superconducting critical temperature Tc in Al and Nb simple crystals from first-principles**, M. SALVETTI, N. BONINI, M.I.T., M. CALANDRA, IMPMC/CNRS, D. PARKS, N. MARZARI, J. MIKALOPAS, M.I.T. — In the past 20 years, efforts have been devoted to predict the critical current density $J_c$ of superconducting magnets based on the Nb$_5$Sn compound. The use of Nb$_5$Sn magnets for high-field applications has highlighted the dependence of $J_c$ on strain. We present calculations of the $T_c$-dependence of Al and Nb crystals on pressure, uniaxial and shear strains using the DFT $PWscf$ package from the Quantum-ESPRESSO distribution to evaluate the phonon linewidth and the $el$-$ph$ coupling parameter using very dense k-space samplings of the IBZ. The superconducting critical $T_c$ is calculated by using the McMillan formula as a fit to the solution of the Migdal-Eliashberg equations. Favourable comparisons with available experimental data have been obtained and will be presented. The modelling of the $T_c$-dependence on strain in Nb$_5$Sn crystals is an ongoing effort. The potential for modelling the $T_c$-dependence on strain in Nb$_5$Sn is discussed. In this regard, recent advances in the implementation of the Wannier formalism give access to the sampling of the dense k-point grids required to calculate fully-converged electron-phonon coupling quantities. This approach opens the possibility to extend the study of the $T_c$-dependence on strain to unit cells characterized by a higher number of atoms or electronic complexity.
These early experiments contrast with modern tokamaks, which are comparatively quiescent and usually have relatively higher toroidal $B$ and lower $V$.

The conflict of DFT Kohn-Sham equations with the Ritz variational principle will be demonstrated rigorously. It will be shown that the ground-state charge density of the material is not representable by auxiliary one-electron orbitals of variational character. This inconsistency is also expressed by a charge-sloshing effect in attempt to solve these equations consistently.

S1.0099 Loop voltage, inductance, and impurity ion velocity in toroidal discharges, D. H. MCNEILL, Consultant, 3955 Bigelow Blvd., Pittsburgh, PA 15213 — Strong co-current drift and substantial heating of impurity ions were reported in some early (∼1960) toroidal devices with low magnetic field $B$ and high loop voltage. $V_L$ (Sceptre and ZETA in Britain and Alfa in Russia). High frequency spikes in $V_L$ suggest rapid changes in the discharge inductance; $V_L$ should be treated as the sum of resistive [IR] and inductive [d(LI)/dt] terms. Experimental data can be used to estimate the resistive and inductive contributions. High-energy electrons and (impurity and hydrogenic) ions were observed, but the average energies were a few tens of eV. Calculations using a 1-D momentum equation with a toroidal electric field as driver and slowing in Coulomb collisions and inelastic processes yield impurity ion (average) drift velocities and apparent temperature (drift driven by voltage spikes) that are consistent with spectroscopic observations on Alfa. These early experiments contrast with modern tokamaks, which are comparatively quiescent and usually have relatively higher toroidal $B$ and lower $V_L$. On the other hand, ZETA was a precursor of the reversed field pinch (RFP), some of whose characteristics seem related to their high $V_L$. Toroidal drift (“rotation”) velocities for tokamaks and RFPs can be calculated in the same way.

S1.00100 Finite Difference Time Evolution of the Quantum Wigner Function in the Presence of a Magnetic Field, TIMOTHY BERGSTRESSER, TOMAS MATERDEY, University of Massachusetts Boston — Numerical results from the finite-difference solution of a quantum Vlasov equation that governs the dynamics of the Wigner function in the presence of a magnetic field will be presented. Effects of absorbing boundary conditions in phase space and use of higher order finite-difference approximations will be discussed.

S1.00101 Red Shifts and Existing Speculations, SOL AISENBERG, IT GROUP — There are many current flaws, mysteries, and errors in the standard model of the universe - all based upon speculative interpretation of many excellent and verified observations. The most serious cause of some errors is the speculation about the meaning of the redshifts observed in the 1930s by Hubble. He ascribed the redshifts as due to “an apparent Doppler effect”. This led to speculation that the remote stars were receding, and the universe was expanding — although without observational proof of the actual receding velocity of the stars. The age of the universe, based upon the Hubble constant is pure speculation because of lack of velocity demonstration. The belief in expansion, the big bang, and of inflation should be reexamined. Also, the redshift cannot always be used as a distance measure, particularly for photons from quasars containing massive black holes that can reduce photon energy through gravitational attraction. If the linear Hubble constant is extrapolated to the most remote super novae and beyond, it would eventually require that the corresponding photon energy go to zero or become negative — according to Hubble linear relationship. This should give a reexamination of the meaning of the red shift and the speculative consequences and give a model with fewer mysteries.

S1.00102 Challenging the fundamental interactions in nature: Can 1/r-interactions, like the gravitational and Coulomb interactions, be induced interactions?, BO E. SERNELIUS, Linköping University — Two of the fundamental interactions in nature, the Coulomb interaction and the gravitational interaction, vary with distance as 1/r. Here we address the question if an induced, as opposed to fundamental, interaction could have this distance dependence. We show that in theory it is possible to obtain a Casimir interaction potential that varies with distance as 1/r. We achieve this by invoking hypothetical particles having a harmonic oscillator interaction potential. These particles generate fields that are different from the ordinary electromagnetic fields. The derivation parallels the derivation of the Casimir-Polder interaction between atoms in electromagnetism. The derivation relies on the harmonic oscillator interaction between the particles and Einstein’s two postulates in special relativity.

S1.00103 Reinterpreting Relativity’s Negative Solutions: An Introduction to the Theory of Symmetry Physics, B. G. SZABÓ — Using basic algebra, it can be shown that Einstein’s renowned equation $E = mc^2$ is only half correct. Just as the equation $x^2 = 9$ has two equally valid solutions, i.e. $x = +3$ and $x = -3$, there are two equally valid solutions to the useful relativistic equation: $E^2 = (pc)^2 + (mc^2)^2$. When the object is at rest ($p = 0$) $E^2 = (mc^2)^2$ or, as above $E = + mc^2$ and $E = - mc^2$. Furthermore, it can be shown that this negative solution is found throughout relativity. In general, there are two equally valid mathematical solutions to the Pythagorean theorem and this concept can be extended to the foundation of relativity – the Einstein hypotenuse. Are the negative solutions merely a mathematical curiosity or a fundamental physical reality? Current physics, discards the negative solution as not physically realizable. It is believed that this mathematically deficient practice results in physically inconsistent phenomena, e.g. the apparent matter-antimatter asymmetry, apparent CP violation, etc. However, by applying the basic premise of Symmetry Physics these phenomena have natural, experimentally falsifiable explanations: For all matter there exists equal but opposite antiamatter. Or more precisely with deference to particle/wave duality: For every particle/wave there exists an equal but opposite antiparticle/antimode. Further information can be found at http://www.symmetryphysics.com

S1.00104 Origin of Everything and the 21 Dimensions of the Universe, MARK LOEV — The Dimensions of the Universe correspond with the Dimensions of the human body. The emotion that is a positive for every dimension is Love. The negative emotion that effects each dimension is listed. All seven negative emotions effect Peace, Love and Happiness. 21st Dimension: Happiness Groin & Heart 20th Dimension: Love Groin & Heart 19th Dimension: Peace Groin & heart 18th Dimension: Imagination Wave Eyes Anger 17th Dimension: z wave / Closed Birth 16th Dimension: Electromagnetic Wave Ears Anger 15th Dimension: Universal Wave Skin Worry 14th Dimension: Lover Wave Blood Hate 13th Dimension: Disposal Wave Buttocks Fear 12th Dimension: Builder Wave Hands Hate 11th Dimension: Energy Wave Arms Fear 10th Dimension: Time Wave Brain Pessimism 9th Dimension: Gravity Wave Legs Fear 8th Dimension: Sweet Wave Pancreas Fear 7th Dimension: File Wave Left Lung Fear 6th Dimension: Breathing Wave Right Lung Fear 5th Dimension: Digestive Wave Stomach Fear 4th Dimension: Swab Wave Liver Guilt 3rd Dimension: Space Wave Face Sadness 2nd Dimension: Line Wave Mouth Revenge 1st Dimension: Dot Wave Nose Sadness The seven deadly sins correspond: Anger Hate Sadness Fear Worry Pessimism Revenge Note: Guilt is fear
S1.00106 Searching for a possible universal character of non-equilibrium fluctuations\(^1\). A. OPRISAN, College of Charleston, J. HEGSETH, University of New Orleans, S. OPRISAN, A. TEKLU, College of Charleston, C. LECOUTRE, Y. GARRABOS, D. BEYSENS, University of Bordeaux — Light scattering due to microscopic fluctuations was used to investigate possible universal laws. We used two significantly different physical systems: a pure fluid near critical temperature in microgravity and silica or gold colloids under the influence of gravity. The direct visualization and analysis of thermal fluctuations and phase separating in pure fluids near critical temperature in microgravity provides invaluable information about cooperative phenomena and the role played by the thermodynamic fluctuations in determining the critical behavior. Scattering from a non-equilibrium macroscopic concentration gradient in a free diffusion experiment for two colloidal samples under the influence of gravity is determined both by diffusion and the buoyancy. Using image processing techniques for series of recorded images from both experiments, we extracted both the static and dynamic structure factor. We implemented algorithms and extracting quantitative features from snapshots of images recorded near critical point. Additionally, the radial average of the power spectra for images recorded in both experiments presented the characteristic “ring” that determined the most likely wave number associated with the fluctuations.

S1.00107 Electronic Structure of Aluminum compounds\(^1\). A.R. CHOURASIA, Dept. of Physics, Texas A&M University-Commerce, HONG DONG, S.D. DESHPANDE, Aurangabad University, India — The valence and conduction bands of aluminum and aluminum compounds (AlB, AlN, and AlO\(_2\)) have been studied using a DFT computational approach implemented in CRYSTAL06. The Becke exchange with the LYP correlation has been employed. The atomic basis sets with diffuse and polarization functions have been optimized for each configuration in these materials. The density of states in the valence and conduction bands has been computed in each case. The projected density of states of the constituents has also been computed. The correlation between the partial density of states and the chemical bonding will be presented.

\(^1\)Work supported by Research Corporation and Organized Research, TAMU-Commerce.

S1.00108 Insights into the structure of the stable and meta-stable (GeTe)\(_m\)(Sb\(_2\)Te\(_3\))\(_n\) compounds\(,\) JUAREZ L.F. DA SILVA, ARON WALSH, National Renewable Energy Laboratory, 1617 Cole Blvd., Golden, CO 80401, USA, HOSUN LEE, Dept. of Applied Physics, Kyung Hee University, Suwon 446-701, South Korea — Phase-change materials such as (GeTe)\(_m\)(Sb\(_2\)Te\(_3\))\(_n\) (GST) have been considered as one of the most natural candidates for the development of non-volatile memory devices, however, there is no common consensus on the structure of these compounds. Using first-principles calculations, we identify the mechanisms that lead to the lowest energy structures for the crystalline GST compounds, namely, strain energy release by the formation of superlattice structures along the direction and by maximizing the number of Te atoms surrounded by three Ge and three Sb atoms (3Ge-Te-3Sb rule), and Peierls-type bond dimerization. The intrinsic vacancies form ordered planes perpendicular to the stacking direction in both phases, which separate the GST building blocks. The 3Ge-Te-3Sb rule leads to the intermixing of Ge and Sb atoms in the (001) planes for Ge\(_3\)Sb\(_2\)Te\(_6\) and Ge\(_3\)Sb\(_2\)Te\(_7\), while only single atomic species in the (001) planes satisfy this rule for the Ge\(_3\)Sb\(_2\)Te\(_7\) and Ge\(_3\)Sb\(_2\)Te\(_8\) compositions.

S1.00109 TEM study of Pt nanoparticles on gamma Al\(_2\)O\(_3\)/NiAl support\(\)\(\). ZHONGFAN ZHANG, LONG LI, JUDITH YANG, UNIVERSITY OF PITTSBURGH TEAM — Pt gamma Al\(_2\)O\(_3\) as one of the most important catalysts has attracted much attention in research. Moving beyond the current phenomenological understanding of the nanoparticle support interaction necessitates the examination of the Pt/\gamma-Al\(_2\)O\(_3\) interface at the atomic level. To produce the model interface, NIAF(110) single crystal was oxidized at 1223K in order to fabricate gamma Al\(_2\)O\(_3\)(440). The crystallinity and uniformity of the oxide film was characterized by X-ray diffraction (XRD). Atomic Force Microscopy (AFM) and Scanning Electron Microscopy (SEM). Nanometer sized Pt particles were deposited through vapor deposition method onto the film. Cross-sectional TEM samples were prepared using a Focused Ion Beam (FIB). The Pt gamma Al\(_2\)O\(_3\) interface will be examined by cross-sectional transmission electron microscopy (TEM) methods to elucidate the atomic, defect and electronic structure of the interface.

S1.00110 Structural properties and electronic structures of amorphous HfO\(_2\)/Si(001) interface\(\). CHEN GUOHONG, HOU ZHUFENG, GONG XINGAIO, Surface Physics Laboratory and Department of Physics, Shanghai-200043, XGGONG’S GROUP TEAM — Using the projector augmented wave method within the generalized gradient approximation, we have performed \textit{ab-initio} molecular dynamics simulations to generate an atomic structure model of amorphous hafnium dioxide (\(\alpha\)-HfO\(_2\)) by a melt-and-quench scheme, and have investigated the structural and electronic properties of \(\alpha\)-HfO\(_2\) interface. The structure of \(\alpha\)-HfO\(_2\) sample is analyzed via atomic coordination number and partial pair-radius distribution functions. Our results show the average Hf-O nearest-neighbor distance is 2.06  \(\AA\), which is comparable with the Hf-O bond lengths (in the range from 2.04 \(\sim\) to 2.25 \(\sim\)) in monoclinic HfO\(_2\) crystalline, and also indicate the generated sample essentially reflects the experimentally measured structural characteristics of \(\alpha\)-HfO\(_2\). Most importantly, it is found that the valence band offset of \(\alpha\)-HfO\(_2\)/Si interface is about 2.97 eV, and our results suggest that the coordination of Si atoms at interface would significantly affect the electronic properties of interface.

S1.00111 Experimental Studies of the Giant Dielectric Constant Materials CaCu\(_3\)Ti\(_4\)O\(_{12}\). JIANJUN LIU, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Nebraska, 68182-0266, DEPARTMENT OF PHYSICS, UNIVERSITY OF NEBRASKA AT OMAHA COLLABORATION, DEPARTMENT OF CHEMISTRY, UNIVERSITY OF NEBRASKA AT OMAHA COLLABORATION — We present results of four different experimental studies, namely (1) scanning electron microscopy, (2) dielectric measurements, (3) \textit{in-situ} high-pressure and X-ray and (4) low-temperature specific heat, on the insulating giant dielectric constant material CaCu\(_3\)Ti\(_4\)O\(_{12}\). From analyzing the results, we first deduce the electronic and mechanical properties of the samples and conclude that the mechanism for high-dielectric constant phenomena is mostly extrinsic. In addition we propose a phenomenological model to explain the high dielectric constant behaviors at both low and high frequencies.

S1.00112 Dielectric tensors of high-\(k\) \textit{Pbnm} perovskites from first principles. SINISA COH, DAVID VANDERBILT, Rutgers University — Among the materials under consideration for future high-k dielectrics in MOSFET and other microelectronic devices are several perovskites having space group \textit{Pbnm}. Among these are LaLuO\(_3\), SrB\(_2\)O\(_3\) (B = Zr, Hf), AsCO\(_3\) (A = La, Pr, Nd, Sm, Gd, Tb, Dy), and LaB\(_2\)Z\(_2\)O\(_3\) (B = Ca, Mg) (with lower symmetry), which are all compatible with growth on silicon and can have higher dielectric constants than HfO\(_2\). Using first-principles DFT methods with ultrasoft pseudopotentials and GGA energy functionals, we compute the dielectric tensors, structural properties, and phonon spectra of these materials. We analyze the dependence of these properties on chemical composition, and compare with experiments where possible. We also focus on correlation between dielectric tensor anisotropy and octahedra rotation angles.

S1.00113 Thickness dependent multiferroicity in relaxor Pb(Fe$_{2/3}$W$_{1/3}$)O$_3$ thin films, ASHOK KUMAR, RAM S. KATIYAR, University of Puerto Rico — Epitaxial multiferroic Pb(Fe$_{2/3}$W$_{1/3}$)O$_3$ thin films were fabricated on MgO substrates by pulse laser deposition. The surface morphology indicates homogeneous distribution of grain with an average surface roughness $\sim 2.5$ nm. Highly frequency dispersive spectra were observed between 120 K to 220 K suggests relaxor-like nature of epitaxial PFW thin films. Relaxor behavior was suppressed and dielectric dispersion increased with decrease in thickness from 300 nm to 50 nm. Modified Curie-Weiss law was used to analyze the relaxor character of films. Dielectric characteristic were further studied using different DC bias field $\sim 5$ kV/cm over wide range of temperature to investigate the polarization properties below freezing temperature. The impedance spectroscopy was carried out to check the grain and grain boundary effects near the dielectric dispersion regions. Magnetization vs. applied magnetic field displayed weak ferromagnetic properties. Temperature dependent polarized Raman spectroscopy were carried out to investigate the change in crystal structure, lower frequency $F_{2g}$ phonon mode, $A_{1g}$ phonon mode near the dielectric dispersion region. In plane compressive strain plays vital role to suppress relaxor behavior in thin films compare to single crystal/bulk counterpart.

S1.00114 Multiferroic properties of artificially designed Perovskite-Spinel Heterostructures, SANDRA DUSSAN, MANOJ K. SINGH, RAM S. KATIYAR, University of Puerto Rico — Multiferroics materials are a class of functional material that combines two or more ordered parameters i.e. ferromagnetic, ferroelectric and ferroelastic. The recent finding of multiferroic composite material with the coexistence of these properties has attracted the attention of various researchers due to its potential applications in highly sensitive sensors and actuators as well as multistate memory devices. We synthesized and characterized CoFe$_2$O$_4$-BFeO$_3$ (CFO-BFO) heterostructure thin films grown on SrTiO$_3$ (111), (100) substrates using Pulsed laser deposition. The XRD patterns of CFO-BFO multilayered films evidenced that all picks correspond to CFO and BFO structure also confirmed by their respective Raman spectra. We observed three peaks at 136, 168, and 215 cm$^{-1}$ that can be assigned to $A_1$(TO) modes of the BFO pure phase and at 468 and 695 cm$^{-1}$ correspond to CFO. Room temperature M-H exhibited well-shaped magnetization hysteresis loops, good saturation and high coercivity. Preliminary results evidenced the existence of ferroelectricity and magnetic properties in heterostructure.

S1.00115 Single Phase multiferroics Pb$_x$(Zr$_{1/2}$Ti$_{1/2}$)$_{1-x}$(Fe$_{1/2}$Ta$_{1/2}$)$_x$O$_3$ thin films, DILSOM A. SANCHEZ, ASHOK KUMAR, RAM S. KATIYAR, University of Puerto Rico — The epitaxial Pb$_x$(Zr$_{1/2}$Ti$_{1/2}$)$_{1-x}$(Fe$_{1/2}$Ta$_{1/2}$)$_x$O$_3$ (PZTFT) ($x = 0.1$, 0.2, 0.3) thin films were fabricated by pulsed laser deposition. X-ray diffraction (XRD) patterns of all compositions showed single phase at room temperature without any pyrochlore phase. These materials showed good ferroelectric and ferromagnetic properties at room temperature. Room temperature multiferroicity were observed in PZTFT for $x > 10$%. PZTFT illustrated high dielectric constant and low loss at room temperature. The dielectric maximum temperature shifted to lower temperature side with increase in iron and tantalum concentration. Magnetization vs. applied magnetic field (M-H) curves showed well defined hysteresis with remanent magnetization ($\sim 0.004-0.13$ emu/gm) and very small coercive field (900 Oe). Preliminary data indicate that PZTFT is a promising candidate of room temperature multiferroic materials. AC and DC conductivity of PZTFT showed very low conductivity $\sim 10^{-9}$ to $10^{-7}$ S/cm$^{-1}$ at room temperature.

S1.00116 Abstract withdrawn —

S1.00117 Strain induced electric field driven relaxor ferroelectricity in BaZr$_{1-x}$Ti$_x$O$_3$ system, TAMNOY MAITI, Lawrence Berkeley National Laboratory, RUYAN GUO, AMAR BHALLA, The University of Texas at San Antonio — A revised complete phase diagram of Ba(Zr$_{1-x}$Ti$_x$)$_3$O$_9$ (0.0 < x < 1.0) has been developed based on evaluation of their crystallographic, dielectric, and ferroelectric properties. A new understanding of the relaxor behavior in this system, e.g. associated with the local elastic strains at the nanoscale, has been gained and presented in this paper. Two different kinds of relaxor behaviors are observed in the BZT system; one is dominated by polar Ti-rich regions and another by non-polar Zr-rich regions. BZT relaxor compositions are characterized by measurement of their dielectric (under bias), pyroelectric, and thermal expansion properties in a wide range of temperatures. The structure of the BZT compositions was evaluated by X-ray and neutron diffraction studies. Their local structure has been also probed by micro-Raman spectra. Although the global symmetry of BZT relaxors is cubic from neutron diffraction studies, non-cubic local symmetry is evident based on the micro-Raman spectra of BZT relaxors.

S1.00118 Comparative study of electronic structures and nonproportionality of scintillator materials$^1$, WAWHY SETYAWAN, Duke University, ROMANCE GAUME, ROBERT FEIGELSON, Stanford University, STEFANO CURTAROLO, Duke University — The electronic structures of selected scintillator materials for gamma-ray detection are calculated. We use Vienna Ab-initio Simulation Package with projector augmented waves pseudopotentials and exchange-correlation functionals as parameterized by Perdew-Burke-Ernzerhof. Curvatures of the top of valence band and the bottom of conduction band are calculated. Parameters are introduced to measure the degree of nonproportionality of photon response of the scintillator. The data show an interesting correlation between the band curvatures and the nonlinearity. The results can be used to guide the design of future proportional scintillators.

$^1$This research is sponsored by NSF and DHS.

S1.00119 Synthesis and Characterization of Alumina/Titania Nanofibers, R.K. FEAKER, D.A. PERHAY, John Carroll University, A.F. LOTUS, E.T. BENDER, G.G. CHASE, R.D. RAMSIER, The University of Akron, N. STOJILIVOIC, John Carroll University — Both alumina and titania nanofibers are promising materials for use in high-temperature applications. In an attempt to access the properties of these two materials systems simultaneously we synthesize alumina/titania nanofibers by electrospinning. We characterize their properties using different analytical methods (scanning electron microscopy, thermogravimetric analysis, X-ray diffraction, and infrared, and X-ray photoelectron spectroscopies). We compare the properties of these mixed fibers with pure alumina and pure titania nanofibers and investigate the effects of annealing.

S1.00120 Controlled TiO$_2$ nanoparticles on solid substrate for high gate dielectric of a pentacene based organic thin film transistor (OTFT), HIMADRI ACHARYA, JINWOO SUNG, GEUN TAK LEE, TAE HEE KIM, Department of Materials Science and Engineering, Yonsei University, Seoul 120749, Korea, BYUNG GIL KIM, School of Advanced Materials and System Engineering, Kunsan Institute of Technology, Kumi 730701, Korea, CHEOLMIN PARK, Department of Materials Science and Engineering, Yonsei University, Seoul 120749, Korea — Ordered high $\phi$ TiO$_2$ nanoparticles on substrate in large area have been developed using self assembled poly(styrene)-block-poly(4-vinylpyridine) (PS-b-P4VP) and Ti-precursors by simple spin coating method. Calcination at 600$^\circ$C in ambient atmosphere removes both blocks of the polymers from the substrate and results in well ordered arrays of TiO$_2$ nanoparticles. Subsequent spin coating of polystyrene (PS) insulator was performed to generate gate dielectric film with higher permittivity on which pentacene based organic thin film transistor (OTFT) was developed to investigate the permittivity effect on transistor performance. The arrays of TiO$_2$ nanoparticles firmly adhering to substrate exhibit a significant dielectric constant enhancement when used for capacitance measurement. The incorporation of single walled carbon nanotube (SWNT) during the formation of TiO$_2$ nanoparticles on substrate further improves the transistor behavior by electrostatic coupling of high $k$ TiO$_2$ dielectric ($\sim 80$) with SWNT.

S1.00121 SEMICONDUCTORS —
S1.00122 Low-bias Transport Features in a Quantum Point Contact with a Variable Aspect Ratio1, BRYAN HEMINGWAY, TAI-MIN LIU, ANDREI KOGAN, University of Cincinnati, STEVEN HERBERT, Xavier University, MICHAEL MELLOCH, Purdue University, UNIVERSITY OF CINCINNATI TEAM, XAVIER UNIVERSITY COLLABORATION, PURDUE UNIVERSITY COLLABORATION — Quantum Point Contact (QPC) devices frequently display a zero-bias conductance anomaly (ZBA), the origin of which is not fully understood. To investigate a possible connection between the ZBA and the device geometry, we use a four-gate QPC device patterned on a GaAs/AlGaAs semiconductor heterostructure, aiming to achieve independent control over the transverse and the longitudinal potential profiles. In several regimes, we find a narrow ZBA that shows a pronounced temperature dependence for T ~ 100 mK. Coulomb peaks arise under certain device settings, suggesting a weakly bound state located in the QPC. For other settings, we observe a plateau below the first conductance step. The plateau's conductance varies as the aspect ratio of the confining potential is changed. We describe a series of magnetic field measurements that show splitting of the ZBA and compare the findings to our measurements in a different, very short device which displayed no ZBA.  

1The research is supported by NSF DMR award No. 0804199 and by University of Cincinnati.

S1.00123 Magnetooptical and magnetic studies of Co and Cr doped CdMnTe, S. SHEN, X. LIU, Y.J. CHO, J. FURDYNA, M. DOBROWOLSKA, University of Notre Dame, Y.H. HWANG, Y.H. UM, University of Ulsan — We investigate the magnetooptical and magnetic properties of two new CdMnTe-based diluted magnetic semiconductors. The first system consists of a series of Cd$_{1-x-y}$Mn$_x$Co$_y$Te alloys with Mn concentration $x$ fixed at ~0.37 and controlled Cr concentration $y$ in the range $0 < y < 0.07$. The second system is the quaternary Cd$_{1-x-y}$Mn$_x$Co$_y$Te alloy, with the same Mn concentration ($x = 0.37$) and the Co concentration $y$ in the range $0 < y < 0.009$. These systems are of interest in that they are expected to involve interactions of the minority magnetic ions (Cr and Co, respectively) with the surrounding majority Mn ions. Indeed, optical absorption and MCD spectra observed on these alloys reveal a series of new “impurity” peaks that are not present in the Cd$_{0.63}$Mn$_{0.37}$Te control samples. It is interesting that the magnetic field dependence of the MCD spectra as well as SQUID measurements reveal a ferromagnetic-like hysteresis loop in Cd$_{1-x-y}$Mn$_x$Co$_y$Te samples with Cr concentration $y$ in the range of $0 < y < 0.03$. Surprisingly, the FM loop survives up to 295 K. But this ferromagnetic behavior is not observed in samples with $y > 0.05$. One should note that FM loops were not observed in Cd$_{1-x}$Mn$_x$Co$_y$Te samples.

S1.00124 Experimental investigation of spin interference phenomena in InGaAs/InAlAs rectangular loop arrays, SEBASTIEN FANIEL, TAKAAKI KOGA, GSIST and CRIS, Hokkaido University, Japan, YOSHIKI SEKINE, NTT BRL, NTT Corporation, Japan — We report spin interference experiments in rectangular loop arrays built from InGaAs quantum wells. Low $T$ magnetotransport measurements in such systems exhibit Ahuizer-Aronov-Spivak (AAS) oscillations stemming from the interference between closed loop trajectories in clockwise and counterclockwise directions. In InGaAs devices, that show a large, gate-controllable spin-orbit (SO) interaction, this interference can be tuned by means of a front gate voltage, leading to a modulation of the AAS oscillations. The present work focuses on the anisotropic interplay between the Rashba and the Dresselhaus contributions to the SO interaction. Along the [-110] and the [110] crystallographic directions, the Rashba and the Dresselhaus effective magnetic fields are expected to be added or subtracted to/from each other. To probe this anisotropy, we study rectangular loop array interferometers whose sides are aligned along these two particular crystallographic directions. We analyze our results using a model that includes both the Dresselhaus and the Rashba SO interactions and accounts for phase decoherence in the devices. This work was supported by KAKENHI (19684009) and also partially by Support Center for Advanced Telecommunications Technology Research, Foundation (SCAT).

S1.00125 Zero-field spin-splitting and spin lifetime in $n$-InSb/In$_{1-x}$Al$_x$Sb quantum wells, A.M. GILBERTSON, Imperial College, M. FEARN, J.H. JEFFERSON, QinetiQ Malvern, B.N. MURDIN, Surrey University, P.D. BUCKLE, QinetiQ Malvern, L.F. COHEN, Imperial College — The Rashba and Dresselhaus coupling parameters are calculated for a range of carrier densities in [001]-grown $d$-doped $n$-type InSb/In$_{1-x}$Al$_x$Sb quantum wells using an established 8 band k.p formalism [1]. It is shown that both sets of parameters scale approximately linearly with carrier density. In contrast to other materials the Dresselhaus contribution to spin splitting is found to be of significant and comparable value to the Rashba mechanism under certain conditions. The inherently large BIA induced SO coupling in these systems is shown to have considerable effect on the spin lifetimes for spins oriented along [110] based on D’yakonov-Perel’ mechanism [2]. The relaxation rate of spins oriented in the [001] direction is found to be dominated by the k-linear Rashba and Dresselhaus coupling parameters and at least an order of magnitude greater than in the [110] direction [3]. Comparison to recent experimental results in similar structures is presented. [1] P. Pfeffer and W. Zawadzki, PRB 59, 8 RS312 (1999) [2] Averkiev et al., J. Phys.:Condens. Matter 14 (2002) [3] A.M.Gilbertson et al., PRB 77 (16), 165335 (2008)

S1.00126 Nuclear Effects on Electron Spin Resonance in Gallium Arsenide1, AARON JONES, JOHN COLTON, BENJAMIN HEATON, DANIEL JENSON, MICHAEL JOHNSON, Brigham Young University — Electron spin properties in gallium arsenide (GaAs) are investigated by electron spin resonance (ESR), the signal being detected via optical Kerr rotation. Experiments in ESR have shown broadened and shifted resonance peaks due to the hyperfine nuclear interaction. Simultaneous nuclear magnetic resonance (NMR) reduces the nuclear effects by preventing the nuclei from responding to the changing electron polarization. However, low NMR power still permits the electron spins to have a great effect on the nuclei, which then affect the electrons in return. We have developed a tunable, impedance-matched, lumped-element rf circuit which increases the output power at the resonant frequency of the three nuclei $^{119}$As, $^{71}$Ga, and $^{69}$Ga. Improved ESR data resulting from stronger NMR is presented.

S1.00127 ABSTRACT WITHDRAWN —

S1.00128 Generation of spin polarized current in a semiconductor by an ohmic contact containing ferromagnetic particles, LEONARDO CASTELANO, Department of Physics, University of California, San Diego, YU-CHANG CHEN, Department of Electrophysics, National Chiao Tung University, S.-R. ERIC YANG, Physics Department, Korea University, LU SHAM, Department of Physics, University of California, San Diego — We investigate the possibility of injection of spin polarized current into a semiconductor from an ohmic contact containing ferromagnetic metal (FM) nanodots. The polarization is created by the spin-dependent scattering of the current carriers with the FM dots with aligned magnetizations. The usually inefficient polarization generation due to the resistance mismatch between the metal electrode and the semiconductor is mitigated by the reduction of the mismatch between the FM dots and the heavily doped electrode. When the paramagnetic semiconductor is connected by two such electrodes containing FM dots forming a spin valve system, the magnetoresistance is calculated to be sizable. We report the calculation results for two examples: (i) silicon connected to electrodes of poly-silicon contain the FM dots and (ii) the heavily doped region of InAs as contact.  

1This work is supported by ARO-MURI on Magnetic Dynamics and in part by CNPq (Brazil).
S1.00129 Spin polarization of doped II-VI nanocrystals, SAVAS DELIKANLI, WILLIAM FALLS, MESUT YASAR, ATHOS PETROU, HAO ZENG, Department of Physics, University at Buffalo-SUNY — The photoluminescence of Mn2+ doped CdSe nanoparticles synthesized by solution phase method has been studied as a function of nanocrystal size and the circular polarization of the light emitted from Cd1−xMnxSe nanoparticles has been investigated as a function of an applied magnetic field in the 7-100 K temperature range. Spin polarized photoluminescence emission from Cd1−xMnxSe was observed and strongly depends on the growth time of the nanoparticles. They show negatively polarized photoluminescence emission and the behavior of spin polarization strongly depends on the applied field. Spin polarization initially saturates between 1-3 Tesla and shows an unexpected linear increase beyond 3 Tesla. Magnetization of Cd1−xMnxSe nanoparticles shows mostly paramagnetic behavior with some hysteresis at low temperatures.

S1.00130 Effect of pressure on spin-carrier interactions in Sb2−xVxTe3 and Sb2−xCrxTe3 single crystals1, MATTHEW L. BOWERS, JEFFREY S. DYCK, John Carroll Univ., CESTMIR DRASAR, PETR LOSTAK, University of Pardubice, Czech Republic — Bulk, single crystal samples of diluted magnetic semiconductors Sb-rich and N-poor Mn3−xSc1+xN and Fe0.1Sc0.9N films Grown by Molecular Beam Epitaxy, HAN-JONG CHIA, University of Texas at Austin, COSTEL CONSTANTIN, Seton Hall University, KANGKANG WANG, ABHIJIT CHINCHORE, ARTHUR SMITH, Ohio University, JOHN MARKERT, University of Texas at Austin — We report SQUID magnetic measurements on N-poor Mn3−xSc1+xN and Fe0.1Sc0.9N films grown on ScN(001)/MgO(001) substrates by radio frequency plasma assisted molecular beam epitaxy. Ferromagnetism is present in both the Mn doped (x ranging from 3 to 15%) and the Fe doped ScN samples. Measurements on N-poor Mn3−xSc1+xN and Fe0.1Sc0.9N films show Curie temperatures of 383 K and 361 K, respectively. The Fe0.1Sc0.9N film shows a Curie temperature above 350 K as well. Further studies will be required to determine the origin of the ferromagnetism and the Curie temperature of the remaining Mn3−xSc1+xN films. This work is supported by: Seton Hall: University Research Council; Ohio University: DOE-BES Grant No. DE-FG02-06ER46317 and NSF Grant No. 0730257; and UT Austin: NSF Grant Nos. DMR-0605828 and DGE-0549417, Welch Foundation Grant No. F-1191.

S1.00131 SQUID measurements of Mn3Sc(1−x)N and Fe0.1Sc0.9N Films Grown by Molecular Beam Epitaxy, HAN-JONG CHIA, University of Texas at Austin, COSTEL CONSTANTIN, Seton Hall University, KANGKANG WANG, ABHIJIT CHINCHORE, ARTHUR SMITH, Ohio University, JOHN MARKERT, University of Texas at Austin — We report SQUID magnetic measurements on N-rich and N-poor Mn3Sc(1−x)N and Fe0.1Sc0.9N films grown on ScN(001)/MgO(001) substrates by radio frequency plasma assisted molecular beam epitaxy. Ferromagnetism is present in both the Mn doped (x ranging from 3 to 15%) and the Fe doped ScN samples. S1.00132 Probing current and temperature effects on the direct insulator-quantum Hall transition, KUANG YAO CHEN, C.-T. LIANG, Dept Phys, NTU, N. AOKI, Y. OCHIAI, Dept Elect & Mech Engn, Chiba Univ, K.A. CHENG, Dept Elect Engn, Chung Hwa Univ Sci & Technol, LI-HUNG LIN, Grad Inst Optoelect & Solid State Elect, NCTU, C.F. HUANG, C.M.S/ITRI, YU-RU LI, YEN SHUNG TSENG, CHUN-KAI YANG, Deps Phys, NTU, PO-TSUN LIN, Grad Inst Optoelect & Solid State Elect, NCTU, JAU-YANG WU, SHENG-DI LIN, Dept Elect Engn, NCTU — We report a magneto-transport study on the two-dimensional electron system (2DES) in an AlGaAs/Gas heterostructure. The direct insulator-quantum Hall transition is observed at different temperatures by increasing the magnetic field B perpendicular to the 2DES. Such a transition can also be observed by varying the current I since the electron temperature is given by IX = CI/2 in both the insulator and quantum Hall sides of the transition. Here α denotes the exponent for the power law and C is a constant at a particular magnetic field. The value of α may be determined by comparing the temperature and current dependences. Our results show that α takes on different values on either sides of the transition point, indicating the presence of different heating mechanisms in the low-field insulator and in the quantum Hall liquid. The effects due to electron-electron interaction and scattering are also discussed.

S1.00133 The Quantum Hall Effect Revisited, TOBIAS KRAMER, University Regensburg, E.J. HELLER, R.E. PARROTT, Harvard University, C.-T. LIANG, National Taiwan University, C.F. HUANG, National Measurement Laboratory, Taiwan, K. Y. CHEN, National Taiwan University, L.-H. LIN, National Chiao Tung University, Taiwan — Experiments shown here reveal inflection points of the Hall resistivity at half-integer filling factors 5/2 and 7/2 which become more pronounced with increasing current density up to high current. These features contradict the edge-state picture of the quantum Hall effect (QHE) and also the disorder picture of the QHE, which cannot explain a gap directly in the middle of a Landau level. We present a novel approach to the quantum Hall effect, which allows us to calculate the electronic transport in a highly non-uniform Hall field, which is present in two opposite corners of a Hall bar, the hot-spots. Precisely in one corners of the hot-spots are injected into the device and we derive the local density of states there. We obtain a self-consistent equation for the current-voltage relation through the Ohmic contact and thus a computable theory of the quantum Hall effect, which predicts a unique modulation and splitting of Landau levels caused by the presence of a high electric field exactly in line with the experimental observations.

S1.00134 The doubling of von Klitzing’s constant h/e², KESHAV SHRIVASTAVA, University of Malaya — The Hall resistivity is found to become a function of spin. For positive spin, one value is obtained but for negative sign in the spin, another value occurs. In this way, there is never only one value of the resistivity but there is doubling of values. The value of the von Klitzing’s constant is a special case of more general dependence of resistivity on the spin. We investigate the case for both high and low temperatures, for extreme quantum limit, n=0, the effective charge of the electron becomes (1/2)e. The fractional charge arises for finite value of the angular momentum. The fractional as well as the integral values of the charge are in full agreement with the experimental data. The generalized constant is h/[1/2]ge or which under special conditions becomes h/e² which is the von Klitzing’s constant [1]. [1] K. N. Shrivastava, Phys. Lett. A 113,435(1986); A326,469(2004); Mod. Phys. Lett. A 13,1087(1999); 14,1009(2000); AIP Conf. Proc. 909, 43-49(2007); 909,50-56(2007);1017, 422-428(2008);1017,326-330(2008); 1017, 47-56(2008), Proc. SPIE(USA)7155,71552F-8[7155,86](2008).

S1.00135 Correlating exciton localization with compositional fluctuations in InGaAs/GaAs quantum wells grown on the GaN (0001) and (1-101) surfaces, DANIEL RICH, STANISLAV KHATSEVICH, Ben-Gurion University, XINGANG ZHANG, DANIEL DAPKUS, University of Southern California — We have used spatially and temporally resolved cathodoluminescence to study the growth of InGaN/GaN quantum wells grown on GaN (0001) and (1-101) surfaces. The effects of In migration during growth on the resulting QW thickness and composition were examined. We employed a modified variable temperature-time resolved CL imaging approach that enables a spatial correlation between regions of enhanced exciton localization, luminescence efficiency, and radiative lifetime with the aim of distinguishing between excitons localized in In-rich quantum dots and those in the surrounding Ga-rich QW regions. A thermally activated nonradiative recombination model was invoked to explain a reversal in the spatial dependence of lifetime between cases of high and low temperatures, in which we show that nonradiative recombination is linked to an enhanced exciton dissociation at high temperatures.
S1.00136 Enhanced Luminescence in an amorphous AlN:Ho thin film by co-doped Gd+3 Cathodoluminescence

MUHAMMAD MQBOOL, Ball State University, HUGH RICHARDSON, MARTIN KORDESCH, Ohio University — Sputter deposited thin films of amorphous AlN:Ho (1 at. %) emits in the green (549 nm) region of the visible spectrum under electron excitation. The addition of Gd (1 at. %) in the film enhances the green emission linearly after thermal activation at 900 °C for 40 minutes in a nitrogen atmosphere. The luminescence enhancement saturates when the gadolinium concentration reaches four times the holmium concentration. The optical bandgap of amorphous AlN is about 210 nm, so that the film is transparent in the ultraviolet, allowing us to observe the ultraviolet emission at 313 nm from Gd. No significant quenching of the Gd emission is observed. EDX spectra confirm the increasing concentration of Gd. XRD analysis shows no peaks other than those arising from the Si (111) substrate, confirming that the films are amorphous.

S1.00137 The carrier property of Al$_{2}$Ga$_{1-x}$N/GaN nanowire fabricated by a dual-beam focused ion beam$^{1}$

JENN-KAI TSAI, Department of electronic engineering, National Formosa University, Yunlin, Taiwan, Republic of China., W.Y. PANG, Y.H. CHANG, IKAI LO, Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, Taiwan, Republic of China. — In this study, the Al$_{2}$Ga$_{1-x}$N/GaN high electron mobility transistor structure was grown on GaN template substrate using a radio frequency plasma assisted molecular beam epitaxy. The undoped GaN template substrate was grown on c-sapphire substrate by metal organic vapor phase epitaxy system. The carrier property was performed by a Hall effect measurement. The mobility and carrier density obtained of the as-grown HEMT was 1814 cm$^2$/V s and 1.29x10$^{14}$ cm$^{-2}$, respectively. The nanowire was patterned on the Al$_{2}$Ga$_{1-x}$N/GaN heterostructure by a dual-beam focused ion beam. The first step was to process a Hall bar pattern. The second step was to reduce the width of active channel. The wire width of 100 nm of nanowire was fabricated successfully. The carrier property of nanowire was evaluated at the different temperature from 4 to 300 K.

$^{1}$The authors would like to acknowledge Epistar corporation for supply GaN template substrates and financial support from the National Science Council of Republic of China(NSC 97-2112-M-150-002).

S1.00138 Magneto-transport Study on the nanometer-scaled quantum-ring interferometer made of Al$_{2}$Ga$_{1-x}$N/GaN heterostructures

WEN-YUAN PANG, IKAI LO, YU-CHI HSU, YEN-LIANG CHEN, MING-HONG GAU, YUNG-HSI CHANG, YING-CHEI WANG, JIH-CHEN CHIANG, Department of physics, National Sun Yat-sen University, Kaohsiung, Taiwan, Republic of China., JEN-KAI TSAI, Department of electronic engineering, National Formosa University, Yunlin, Taiwan, Republic of China. — The quantum-ring interferometer has been proposed for spintron ic application. The Al$_{2}$Ga$_{1-x}$N/GaN samples were grown on GaN-template buffer layer by plasma-assisted molecular beam epitaxy. The mobility and carrier density of two-dimensional electron gas to be 19845 cm$^2$/Vs and 5.18x10$^{12}$ cm$^{-2}$ by conventional van der pauw Hall measurement at temperature of 4.2 K, respectively. The samples were used to fabricate quantum-ring field-effect-transistors with different widths of conducting channel by Focus Ion Beam. The magneto-resistance measurement at temperature of 0.35 K and magnetic field up to 12 T was performed on these samples. The electronic characterization of nanometer-scaled quantum-ring made of high-mobility Al$_{2}$Ga$_{1-x}$N/GaN heterostructures has been studied.

$^{1}$The project is supported by the grant number NRC 95-2112-M-110-017-MY3 and FA8669-07-1-4022.

S1.00139 High Electron Mobility Al$_{2}$Ga$_{1-x}$N/GaN Heterostructures Grown by PAMBE on GaN Templates Prepared by MOCVD

YEN-LIANG CHEN, WEN-YUAN PANG, MING-HONG GAU, YU-CHI HSU, WAN-TSANG WANG, JIH-CHEN CHIANG, IKAI LO, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan, ROC., CHIA-HO HSIEH, Institute of Material Science and Engineering, National Sun Yat-Sen University, Kaohsiung, Taiwan., JEN-KAI TSAI, Department of Electronic Engineering, National Formosa University, Yunlin, Taiwan, ROC. — A series high mobility Al$_{2}$Ga$_{1-x}$N/GaN heterostructures samples were grown on MOCVD-grown GaN templates by molecular beam epitaxy with different Al fractions (x = 0.017−0.355). The highest mobility in this series samples at liquid nitrogen temperature is 14110 cm$^2$/Vs with carrier concentration 2.87 x 10$^{12}$ cm$^{-2}$ and Al fraction x = 0.022. In our experiments, the carrier density decreases as Al content reduces. While the carrier density decreases from 1.54 x 10$^{13}$ cm$^{-2}$ to 2.87 x 10$^{12}$ cm$^{-2}$, the mobility increases. But as the carrier density decreases from 2.87 x 10$^{12}$ cm$^{-2}$, the mobility decreases.

$^{1}$The project is supported by National Research Council of Taiwan (NRC 95-2112-M-110-017-MY3) and by AFOSR/AOARD (AFMC, USAF) under grant number FA8669-07-1-4022.

S1.00140 Electron heating in disordered 2DEG GaAs/AlGaAs structures by THz radiation

RAHUL RAMASWAMY, YAI WANG, MATTHEW BELL, ANDREI SERGEEV, ALEKSANDR VEREVKIN, GOTTFRIED STRASSER, VLADIMIR MITIN, University at Buffalo, DAROLD WOBSCHALL, Ensensors Inc. — While numerous applications of heterostructures with two-dimensional electron gas (2DEG) in electronics require high-mobility of carriers, slow momentum relaxation creates substantial problems for employing these structures as various detectors of electromagnetic radiation. Significant kinetic inductance of carriers does not allow one to use 2DEG-based sensors in combination with ordinary antennas and readouts, designed for Ohmic detectors. Keeping in mind sensor applications, we investigate the electron heating in disordered AlGaAs/GaAs structures at liquid nitrogen temperatures. In our experiments, 2DEG was overheated by DC current or THz radiation. The devices were fabricated from AlGaAs/GaAs structures and have widths of 50-150 µm and lengths varying from 3-50 µm. 2DEGs of various levels of disorder are used to change the kinetic inductance of our devices and to study effects of disorder on electron heating. Steady-state and quasi-optical THz heating measurements provide consistent data and allows us to determine basic parameters, such as electron-phonon relaxation rate, electron heat capacity of 2DEG, and radiation coupling.

S1.00141 High-Frequency Electron Pumps used as an Entangler

S. J. WRIGHT, Cavendish Lab, Cambridge, GODFREY GUMBS, Hunter College/CUNY, MICHAEL PEPPER, M. D. BLUMENTHAL, Cavendish Lab, Cambridge, DANHONG HUANG, USAF Research Lab — We calculate the exchange interaction of two interacting electrons that are captured in the quantum dot (QD) formed by the DC electric potential applied to a pair of gates. A gigahertz AC pulse is applied to one of the gates to pump electrons from below the Fermi level. We shall discuss the mechanism for capturing and ejecting electrons from the quantum dot and the characteristics of the pumped current as a function of the DC voltage. A simple model for the observed temperature dependence of the pumped current will be presented. The measured current shows plateaus at $Nf$, where $N = 1, 2, \cdots, e$ is the magnitude of the electron charge and $f$ is the frequency of the pulse. The QD capturing the electrons is modeled by a harmonic confining potential. We calculate the spin singlet and spin triplet energies which then determine the exchange interaction for $N = 2$. As the QD moves from just above the Fermi level to a height when the electrons are ejected, the confinement is strong just after the capture but the size of the QD continues to increase. When the size of the QD is increased, we show that the energy of the spin singlet and spin triplet state gets larger over a range of values for the size of the QD. We will present calculated results for the energies of entangled electrons and possible related experiments.

S1.00142 TEM analysis of Microstructure of AlN/sapphire grown by MOCVD1. B. CAI, M. L. NAKARMI, Department of Physics, Brooklyn College of the City University of New York — AlN and Al-rich AlGaN have emerged as promising deep ultraviolet (UV) materials for the development of deep ultraviolet optoelectronic devices such as light emitting devices and detectors in the spectral range down to 200 nm. High quality AlN/sapphire can be used as templates to grow nitride based ultraviolet and deep ultraviolet photonic devices due to high thermal conductivity and transparency of the light. The performance of the devices depends on the microstructures of the templates. We report on the microstructure analysis of AlN epilayer grown on sapphire. Both plane and cross section views are investigated by high resolution transmission electron microscopy. It has been revealed that the dislocations are greatly reduced by using high temperature buffers. Density of edge dislocations dominates the total density of dislocations. The microanalysis of Al-rich AlGaN epilayers grown on AlN/sapphire templates will also be presented. Implications of our finding for the applications in deep UV optoelectronic devices will be discussed.

S1.00143 Reduction of the Specific Contact Resistance in p-type GaN-based Devices via Polarization Doping1. JACOB MELBY, JASON GU, LI HUANG, Carnegie Mellon, YUHREN WU, LISA PORTER, ROBERT DAVIS, Carnegie Mellon — The power efficiency of GaN-based devices is sensitive to energy loss at p-type semiconductor contacts. Low resistance contacts to p-type GaN are difficult to achieve due to limitations in extrinsic acceptor doping. These limitations can be avoided via polarization doping. Au/Ni contacts deposited on a 2nm thick strained In$_x$Ga$_{1-x}$N capping layer atop a p-type GaN layer exhibited three orders of magnitude reduction in the specific contact resistance versus the single layer p-type GaN control. Increased band bending near the interface due to the polar field resulted in a reduced tunneling barrier width and a decrease in the specific contact resistance. At a minimum critical capping layer thickness, a two-dimensional hole gas (2DHG) forms in the In$_x$Ga$_{1-x}$N layer. The effect of the composition and thickness of the capping layer on the specific contact resistance and the hole concentration in a 2DHG has been determined.

S1.00144 Kinetic Monte Carlo Simulation Studies of Nanocolumn Formation in Two-Component Epitaxial Growth2. SHU ZHENG, University of Tennessee & Oak Ridge National Laboratory & Dalian University of Technology, China, WENGUANG ZHU, University of Tennessee & Oak Ridge National Laboratory, G. MALCOLM STOCKS, ZHENYU ZHANG, Oak Ridge National Laboratory & University of Tennessee — Recent experimental studies have revealed that well-ordered one-dimensional column structures are formed via self-assembly during two-component epitaxial growth of a variety of materials, including diluted magnetic semiconductors and high-Tc superconductors. Here we use kinetic Monte Carlo simulations to study the morphological evolution of a two-component epitaxial system, based on a (1+1)-dimensional lattice model. We find that in systems where the atom-atom interactions obey the relationship of $E_{AA} + E_{BB} - 2E_{AB} < 0$, ordered nanoscale columns can be formed during the growth. The dependence of the ordering on the growth temperature and deposition rate and on the relative concentration of the two components is also explored.

S1.00145 ABSTRACT WITHDRAWN —

S1.00146 Improved conductivity observed in doped layered oxysulfides [Cu$_2$S$_2$][Sr$_{n+1}$M$_n$O$_{3n-1}$]1. KOICHI USHIYAMA, The University of Tokyo, HIRAKU OGINO, SHIGERU HORII, JUN-ICHI SHIMOYAMA, KOHJI KISHIO — [Cu$_2$S$_2$][Sr$_{n+1}$M$_n$O$_{3n-1}$] is a group of semiconductor oxysulfides which are composed of alternate stackings of Cu$_2$S$_2$ antifluorite layers and perovskite-based M$_2$O$_3$ planes1. Perovskite structures are expected to show interesting properties such as high-temperature superconductivity and magnetoresistance. However they have attracted less attention because they have relatively high resistivity and there are only a few reports of carrier doping2. In this study, we found Na substitution was especially effective on [Cu$_2$S$_2$][Sr$_2$CoO$_2$]. Systematic decreases in lattice parameter with increasing doping levels indicated that Na was successfully substituted at the Sr site. Remarkable decrease in resistivity was observed especially at low temperatures, from 10$^3$ Ωcm (undoped) to 0.15 Ωcm at 50 K. This value is lowest ever reported in the [Cu$_2$S$_2$][Sr$_{n+1}$M$_n$O$_{3n-1}$] oxysulfides. [1] K. Ueda et al., Chem. Mater. 13 (2001) 1880 [2] K. Ito et al., J. Appl. Phys. 99 (2006) 08F705

S1.00147 Temperature dependent structural disintegration of delafossite CuFeO$_2$. P. SHOJAN, ASHOK KUMAR, RAM KATIYAR, University of Puerto Rico — Single phase delafossite p-type CuFeO$_2$ (CFO) semiconductor was synthesized by modified solid state reaction technique. X-ray diffraction (XRD) and X-ray photo spectroscopy (XPS) studies suggest pure phase of CFO and Energy dispersive X-ray spectroscopy (EDX) also revealed that the atomic ratio Cu and Fe is 1:1. The XPS spectra showed two intense Cu 2p3/2 and 2p1/2 peaks at 932.5 eV and 952 eV and two Fe 2p3/2 and 2p1/2 peaks at 710 eV and 725 eV suggesting Cu and Fe ions are in +1 and +3 state with high spin S=5/2. The room temperature Raman spectra of CFO displayed two main strong active modes at 351 cm$^{-1}$ and 692 cm$^{-1}$ that matched with other delafossite structure. Temperature dependent Raman spectra indicate that the lowest mode vanished or overdamped at ~ 400 K where as higher modes shifted to lower frequency side with significantly decreased in intensity. We have also observed a low frequency (E$_2$(low)) mode at 79 cm$^{-1}$ using 532 nm (~5MHz line width) laser line. The line width and intensity of the lowest mode indicates temperature independent behavior. Raman Spectra were carried out from 80 K to 1300 K which revealed structural disintegration in CFO over 800 K in air. The structural degradation is counter confirmed by XPS, XRD, DTA measurements. Around 800 K in air, CFO disintegrates to form CuO and CuFe$_2$O$_4$.

S1.00148 Structural and transport studies on nanostructured SnS synthesized by solvothermal process , PRATIMA AGARWAL, Department of Physics, IIT Guwahati, Guwahati 781039, India. GOURI S. PAUL, Center for Energy, IIT Guwahati, Gwahati 781039, India — Nanostructured SnS has a lot of interest due to its potential application in optoelectronic devices such as solar absorber, near-infrared detector and as a holographic recording medium. SnS usually exhibits p-type conduction and reported to have a direct band gap of about 1.32-1.5 eV and an indirect band gap of 1.1-1.3 eV dependent of the condition of preparation. In this work we report structural and transport studies on nanostructured SnS synthesized by solvothermal process for different reaction time (RT). Structural and morphological analyses are carried out by XRD, SEM and TEM. It is observed that structure of the as-prepared SnS powder samples vary with RT. SAED patterns reveal that as synthesized SnS are single crystals. Transport measurements done on thin films prepared by Doctor’s blade techniques show that films are thermally stable and uniform through out the surface. The conductivity of the SnS thin films is measured in coplanar geometry in the temperature rang (303–463) K. The films show thermally activated conduction and the curves are identical for both heating and cooling cycle.
S1.00149 Weak ferromagnetism in single crystalline Zn$_1-x$Co$_x$O thin films . H.-J. LEE, B.-G. PARK, Department of Physics, POSTECH, J.-Y. KIM, Pohang Accelerator Laboratory, POSTECH, J.-H. PARK, Y. H. JEONG, Department of Physics, POSTECH — Diluted Magnetic Semiconductors (DMS) have been actively searched for many years; a prospect of spintronic devices. Transition metal doped oxide materials, especially ZnO-based DMS, have been of particular interest as a high Tc material. Co doped ZnO thin films, for example, were reported to show ferromagnetic properties at room temperature. However, various subsequent studies including ours do not seem to converge on a definite picture and controversy continues. The observed ferromagnetism in DMS is very sensitive to the preparation methods and conditions. Therefore, what is needed to resolve the situation is the fabrication of single crystalline Zn$_1-x$Co$_x$O thin films characterized as single domains. This paper investigates PLD techniques of Zn$_1-x$Co$_x$O thin films synthesized by the rapid thermal processor and monitored by In-situ RHEED. Surface morphology and crystallographic characteristic evaluated using AFM and XRD. The magnetization, resistivity, and Hall effect measurements were carried out systematically as a function of Co contents using a QD PPMS. To clarify the electronic structure and the magnetic properties associated with the Co ions in Zn$_1-x$Co$_x$O, we have performed X-ray Absorption Spectroscopy and X-ray Magnetic Circular Dichroism measurements. These results and their implications for the understanding of ferromagnetism in Zn$_1-x$Co$_x$O will be discussed.

S1.00150 Transport Measurements and Synchrotron-Based X-Ray Absorption Spectroscopy of Iron Silicon Germanide Grown by Molecular Beam Epitaxy$^1$, NADER ELMARHOUMI, RYAN COTTIDER, Texas State Univ/Univ of North Texas, GREG MERCHEAN, AMITAVA ROY, CAMD/LSU, CHRIS LOHN, HEIKE GEISLER, CARL VENTRICE JR., TERRY GOLDING — Some of the iron-based metal silicide and germainide phases have been proposed to be direct band gap semiconductors. Therefore, they show promise for use as optoelectronic materials. We have used synchrotron-based x-ray absorption spectroscopy to study the structure of iron silicon germainide films grown by molecular beam epitaxy. A series of Fe(Si$_{1-x}$Ge$_x$)$_2$ thin films (2000 – 8000Å) with a nominal Ge concentration of up to $x = 0.04$ have been grown. X-ray absorption near edge structure (XANES) and extended x-ray absorption fine structure (EXAFS) measurements have been performed on the films. The nearest neighbor coordination corresponding to the $\beta$-FeSe$_2$ phase of iron silicide provides the best fit with the EXAFS data. Temperature dependent (20 $< T < 350$ K) magneto transport measurements were done on the Fe(Si$_{1-x}$Ge$_x$)$_2$ thin films via Van Der Paw (VDP) Hall configuration using a 0.5-T magnetic field and a current of 10-200 μA through indium ohmic contacts. The Hall coefficient was calculated. Results suggest semiconducting behavior of the films which is consistent with the EXAFS result.

S1.00151 Effect of N to In flux ratio on the InN surface morphologies grown on single crystal ZnO (000T) substrate by plasma-assisted molecular beam epitaxy$^1$, CHENG-HUNG SHIH, IKAI LO, WEN-YUAN PANG, SHIH-HUNG CHUANG, CHIA-HSIUAN HU, Department of physics, National Sun Yat-sen University, Kaohsiung, Taiwan, R.O.C., CHIA-HO HSIEH, Institute of Material Science and Engineering, National Sun Yat-Sen University, Kaohsiung, Taiwan, — The surface morphology of InN epitaxial films grown on ZnO (000T) substrate by plasma-assisted molecular beam epitaxy has been investigated. We found that the evolution of InN surface morphology was sensitive to the N/In flux ratio. With N/In flux ratio decreasing, the growth mode changed from 3D to 2D growth. In addition, we found that In$_n$O$_m$ layer was formed at the interface between InN and ZnO when the N/In flux ratio was lower than 32 by the observation of XRD and TEM.

$^1$The project is supported by National Research Council of Taiwan (NRC 95-2112-M-110-017-MY3) and by AFOSR/AOARD (AFMC, USAF) under grant number FA4607-07-1-0422.

S1.00152 Effect of negatively charged excitons on the phase coherent photorefractive effect in ZnSe quantum wells , A. KABIR, H.P. WAGNER, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, USA — We investigate the effect of negatively charged excitons (trions) on the efficiency and dephasing rate of the phase coherent photorefractive (PCP) effect in ZnSe/Zn$_x$Mg$_{1-x}$Se single quantum wells using 90 fs light pulses. Intensity, temperature and spectrally dependent measurements are performed in a transient four-wave mixing configuration. In the presence of trions the PCP effect is composed of both a fast dephasing component that is caused by the formation of a trion grating and a slower decaying component caused by an exciton grating. With decreasing temperature the trion dephasing rate significantly increases while the exciton dephasing rate remains almost constant. The trion dephasing rate also increases with decreasing barrier width between the ZnSe quantum well (QW) and the GaAs substrate which is attributed to an enhanced electron density of captured substrate electrons in the QW. Model calculations based on the optical Bloch equations are in agreement with the experimentally observed PCP traces.

S1.00153 Effect of annealing temperature of ZnO seed layer on growing aligned ZnO nanorods$^1$, JENN-KAI TSAI, Department of Electronic Engineering, National Formosa University, Yunlin 632, Taiwan, Republic of China, CHU-YU WEI, YI-CHI CHEN, YOU-CHENG HENG, Institute of Electro-Optical and Materials Science, National Formosa University, Yunlin 632, Taiwan, Republic of China, TSEN-HANG MEEN, Department of Electronic Engineering, National Formosa University, Yunlin 632, Taiwan, Republic of China, — Vertical aligned ZnO nanorod arrays were synthesized by hydrothermal method on the Si substrate with a sputtered thin ZnO seed layer on it. Different annealing temperatures of ZnO seed layer were studied in order to understand the ZnO nanorod growth mechanisms. The results show that ZnO nanorods grow faster if the seed layer annealed at higher temperature. The photoluminescence spectra exhibit ultraviolet emission and a broad green emission. The green emission is attributed to the oxygen vacancies in the ZnO nanorods. Further investigations using the scanning electron microscopy, x-ray diffraction, atomic force microscopy were also demonstrated.

S1.00154 High Quality Epitaxial ZnO Films Grown Using Magnetron Sputtering$^1$, TOM ODER, Youngstown State University — Zinc oxide films were sputter-deposited at 500 °C on sapphire. SiC and GaN substrates using different mixtures of Ar and O$_2$. Post-deposition annealing up to 900 °C in N$_2$ with rapid thermal processor resulted in films whose crystalline quality improved with the annealing temperature. The effects of deposition and annealing using different Ar-O$_2$ gas mixtures were also investigated. Films grown on sapphire in a 1:1 Ar-O$_2$ mixture and annealed in N$_2$ at 900 °C for 5 min had the best quality. Room-temperature photoluminescence spectroscopy measurements revealed a near band edge luminescence at 3.5 eV with a FWHM value of 126 meV. The two-theta XRD measurements of these films showed a peak at 34.8°, which corresponds to the diffraction from the (0 0 2) plane of the ZnO and indicates a strong c-axis orientation perpendicular to the surface at the sapphire substrate. Results from the transport properties of these films determined using Hall-effect measurements will be discussed.

S1.00155 IR-Dielectric functions of ZnBeTe alloys determined by spectroscopic ellipsometry . NIRJAN MANDAL, FRANK PEIRIS, Physics, Kenyon College, OLEG MAKSIMOV, MARIA TAMARGO, Chemistry, CUNY — Using spectroscopic ellipsimetry, we have determined the complex dielectric function of a series of ZnBeTe II-VI semiconductor alloys between a spectral range of 2000 nm and 40,000 nm. A standard inversion technique was used to obtain the dielectric functions from the measured ellipsimetric spectra. By modeling the dielectric functions as a collection of oscillators, representing longitudinal and transverse optical phonons associated with the ZnBeTe lattice, we were able to recover the phonon spectra for this alloy system. It is argued that the the additional phonon modes that are obtained from ellipsimetry are best understood from the recently-proposed percolation model.
S1.00156 A Method for Determining Refractive Indices of Compound Materials of Epilayers of Multilayer Quantum Structure1,2. GAGIK SHMAVONYAN, State Engineering University of Armenia — A method of determining the refractive indices of compound materials of epilayers of multilayer quantum structures of optoelectronic devices has been suggested. The difficulty with the determination of the refractive indices of the above-mentioned epilayers is that the exactness of the determination of the same parameters of compound materials of epilayers is not high as their values obtained by various methods are quite different. Therefore, the difference between values of bulk and epitaxially grown materials is great. For that reason beam profiles of light emitted from multilayer quantum structure of optoelectronic devices are experimentally investigated and theoretically calculated. The latter allows us to determine the refractive indices of compound epilayers of multilayer active layer of nanostructured optoelectronic devices. As this method consists in the confrontation of theoretical calculations and experimental results, it allows to precisely determine the refractive indices of compound epilayers.

S1.00157 Synthetic Cu2O crystals with various morphologies prepared by thermal oxidation3. SHAHIN MANI, JOON JANG, JOHN KETTERSON, Department of Physics & Astronomy, Northwestern University, KETTERSON’S TEAM — Cuprous oxide (Cu2O) is an extensively studied semiconductor with a rich history in exciton related physics; it has also been a popular solar cell material. A major impediment to workers studying this material has been the difficulty in fabricating high quality crystals. Achieving a low concentration of impurities and defects is an essential requirement in obtaining increased exciton lifetimes. We have prepared high-quality crystals of Cu2O by an improved thermal oxidation technique. Using this strategy we have formed crystals in various geometries including: i) platelets, ii) cylindrical wires, iii) hollow cylindrical structures, and iv) spheres. The formation of hollow cylindrical structures or tubes of Cu2O by oxidizing copper wires in air is especially surprising. We will discuss photoluminescence experiments involving one- and two-photon excitation and optical absorption measurements at 2 K from the synthetic samples, which in some respects out perform natural (geological) crystals. The more unconventional structures of Cu2O may be utilized to confine excitonic matter or serve as high density exciton-polariton cavities

S1.00158 Effects of atomic randomness on the band structure calculation of Si1−xGex via density functional theory. MD HOSSAIN, Department of Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, IL 61801, USA, JONATHAN FREUND, HARLEY JOHNSON, Department of Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, IL 61801, USA — Electronic band structure calculations for compound semiconductors are usually performed by averaging fitting parameters using the virtual-crystal-approximation in either the pseudopotential method or the tight binding method. The effect of atomic randomness is completely ignored in such calculations. In this work, without using any fitting parameters, density functional theory is employed to calculate the band structure of the Si1−xGex alloy system taking into account the effect of atomic randomness and, correspondingly, the local strain relaxation. The variation of band gap with 16 different Ge fractions in the alloy is computed to find bowing parameters for the two distinct composition ranges: 0 ≤ x ≤ 0.85 and 0.85 ≤ x ≤ 1.0. The calculation is carried out for a supercell of 64 atoms with P1 symmetry, and the randomly positioned atoms are relaxed up to a force tolerance of 0.0001eV/Å. Our results show much better agreement with experimental results for bandgaps, especially near Si0.85Ge0.15, than available empirical methods do. The results demonstrate the importance of accounting for the effect of randomness and local strain in band structure calculations.

S1.00159 High Yield Microsphere Formation Using an Excimer Laser4. RYAN LU, TERESA EMMERY, AYAX RAMIREZ, SPAWAR Systems Center, Pacific — The need for low-cost photonic devices has stimulated a significant amount of research in silicon photonics. Although silicon photonics is less well-developed as compared to III–V technologies, it has the potential to make a huge impact on the optical communications industry. Silicon is transparent in the standard ITU optical communication bands, which makes silicon the material of choice for passive and active optoelectronic devices. Recently, microspheres are gaining an important place in the optical microcavity resonator community due to their high quality factor morphology-dependent resonances (MDRs). Silicon microspheres with high quality factor morphology dependent resonances are used for resonant detection and filtering of light in the near infrared. The experimentally measured quality factors are limited by the sensitivity of the experimental setup, however, the microsphere quality factor is several magnitudes of order higher than current microring resonators. These optical resonances provides the necessary narrow linewidths, that are needed for high resolution micro-photonic applications. A reproducible process to quickly fabricate uniform microsphere particles with a narrow distribution of diameters and high yield is presented in this paper.

S1.00160 Nitric-phosphoric acid etching effects on the surface chemical composition of CdTe thin film. IRFAN IRFAN, HUANJUN DING, Department of Physics and Astronomy, University of Rochester, WEI XIA, HAO LIN, CHING W. TANG, Department of Chemical Engineering, University of Rochester, YONGLI GAO, Department of Physics and Astronomy, University of Rochester — Nitric-phosphoric (NP) acid etching has been regarded as one of the most successful methods for the formation of low resistance back contact with the metal electrode in CdTe-based solar cells. We report back surface chemical composition for eight different durations of NP etching of CdTe polycrystalline thin film. We studied the surfaces with x-ray photoemission spectroscopy (XPS), ultraviolet photoemission spectroscopy (UPS), inverse photoemission spectroscopy (IPES) and atomic force microscopy (AFM). Etching dependence on the back surface composition and electronic structure was observed. Valence and conduction band shifts relative to the Fermi level of the system with different etching duration were analyzed. The sample was left in open ambient condition for three weeks and XPS data were obtained again in order to study the difference in surface chemical composition with the pristine CdTe film. Unetched and highly etched part of the sample were sputtered and the depth profile analyzed.

S1.00161 ABSTRACT WITHDRAWN

S1.00162 Elastic strain sharing in silicon nanomembranes from a silicon nitride stressor layer1,2. ANNA CLAUSEN, University of Wisconsin-Madison, DON E. SAVAGE, MAX G. LAGALLY — Strained-silicon (001) nanomembranes have increased electron mobility relative to their unstrained counterparts and are therefore of considerable interest for ultra-fast flexible electronics [1]. The increased mobility is caused by the strain splitting of the delta valleys in the conduction band and the concomitant reduced inter-valley scattering of charge carriers. Previous work using SiGe as the stressor layer on silicon-on-insulator (SOI) requires epitaxial growth and is restricted to tensilely straining Si. We grow polycrystalline SiN on SOI by PECVD to form tensilely as well as compressively strained Si nanomembranes. When the SiN/Si film is released from the buried oxide layer, the strain in the SiN layer is elastically shared with the Si layer. The strain-relaxed nanomembrane is then bonded onto a new substrate. XRD, Raman, and TEM are used to characterize the strain transfer and the presence or absence of dislocations in the Si nanomembrane. Our results are in good agreement with predictions from continuum elasticity theory. [1] Yuan, H-C. et al., Semicond. Sci. Tech. 22, S72-S75 (2007).

S1.00163 Chemical, Electrical and Thermal Characterization of Nanoceramic Silicon Carbide, HERVIE MARTIN, MALEK ABUNAEMEH, CYDALE SMITH, CLAUDIU MUNTELE, SATILMISH BUDAK, DARYUSH ILA, Alabama A&M University — Silicon carbide (SiC) is a lightweight high bandgap semiconductor material that can maintain dimensional and chemical stability in adverse environments and very high temperatures. These properties make it suitable for high temperature thermoelectric converters. At the Center for Irradiation of Materials (CIM) we design, manufacture and fabricate nanoceramic SiC, and perform electrical, thermal and chemical characterization of the material using particle induced X-ray emission (PIXE), Rutherford backscattering spectroscopy (RBS), Seebeck coefficient, electrical conductivity, and thermal conductivity measurements to calculate its efficiency as a thermoelectric generator. We are looking to compare the electrical and thermal properties of SiC ceramics with some other materials used for the same purposes.

S1.00164 Mechanical Properties of Nanoceramic Silicon Carbide, IPIDISO OJO, MALEK ABUNAEMEH, CYDALE SMITH, CLAUDIU MUNTELE, DARYUSH ILA, Alabama A&M University — Generation IV nuclear reactors will use the TRISO fuels, a type of micro fuel particle. It consists of a fuel kernel coated with four layers of isotopic material. One of the materials considered for these layers is silicon carbide ceramic. This lightweight material can maintain chemical and dimensional stability in adverse environments at very high temperatures up to 3000°C, and it is chemically inert. It is widely used as a semiconductor material in electronics because of its high thermo conductivity, high electric field break down strength, and high current density, which makes it more desirable than silicon. Silicon carbide has a very low coefficient of thermal expansion and has no phase transition that would discontinue its thermal expansion. At the Center for Irradiation of Materials (C.I.M.) we are developing a new fabrication process for nanopowdered silicon carbide for TRISO fuel coating purposes. We also study the mechanical properties of the material produced. Among the different test being performed are particle induced X-ray emission (PIXE) an Rutherford backscattering spectroscopy (RBS). The mechanical properties of interest are hardness (measured by Vickers Hardness machine), toughness (measured by the Anistis equation, KIC= 1.6 x 10^-6(E/H)^1/2(P/C0)^5, where P=load, C0=crack length, E=Young’s modulus and H=Vickers Hardness), tensile strength and flexural strength (measured by a three point bend test). Results will be presented during the meeting.

S1.00165 Investigation on Ge induced GaAs(001)-(1x2) structure, JUN NARA, National Institute for Materials Science and IIS, University of Tokyo, AKIHIRO OHTAKE, National Institute for Materials Science, TAKAHISA OHNO, National Institute for Materials Science and IIS, University of Tokyo — It is known that at the initial stage of the Ge growth on GaAs(001), a reconstructed structure with a (1x2) periodicity is formed. A structure model with Ga-Ge dimers on an As-terminated surface has been proposed for the (1x2) reconstruction. On the other hand, the previous studies have shown that As atoms segregate to the growing Ge surface at the initial growth stages. We have reexamined the atomic structure of the Ge-induced (1x2) reconstruction experimentally and theoretically. We show that the initial growth of Ge on GaAs(001) induces the formation of Ga-As dimers as a result of the site exchange between deposited Ge atoms and subsurface As atoms. We confirmed that this atomic geometry is energetically favored compared with the previously proposed Ga-Ge dimer model, by using first-principles calculations. Our proposed structure model accounts well for the experimental results. This work was partly supported by the RISS project in IT program and a Grant-in-Aid for Scientific Research (No.17064017) of MEXT of the Japanese Government.

S1.00166 Monte Carlo Calculations of the Specific Heat in Quantum Critical Metals, JOHN GADDY, WOUTER MONTFROIJ, University of Missouri - Columbia, THOMAS VOJTA, Missouri University of Science and Technology — Quantum critical magnetic metals have unusual low temperature response such as an anomalous temperature dependence of the electronic specific heat (C0 ∼ T lnT). This dependence originates in the competition between ordering local magnetic moments and the conduction electrons shielding the moments. The Kondo Temperature, T K, when moments become shielded depends on the inter-atomic distances. In most systems that have been investigated experimentally quantum criticality is obtained through lattice expansion by chemical substitution, one can expect a distribution of T K reflecting altered local inter-atomic distances. The random removal of these moments leads to the formation of magnetic clusters in quantum critical metals which has indeed been observed in quantum critical CeRu0.5Fe1.5Ge2. We investigate the dependence of the specific heat through the formation through magnetic cluster formation. Once a cluster separates itself from the lattice, it should order and affect the specific heat. Using a Monte Carlo simulation we calculate the changes in specific heat associated with cluster formation for various Kondo temperature distributions, and we compare our results to those measured in 122-systems like CeRu0.5Fe1.5Ge2.

S1.00167 Study of oxidation of titanium by x-ray photoelectron spectroscopy, HONG DONG, A.R. CHOURASIA, R.L. MILLER, Dept. of Physics, TAMU-Commerce — The oxidation of titanium has been investigated using the technique of x-ray photoelectron spectroscopy. Thick films of titanium have been deposited on silicon substrates by e-beam method. The Oxford Applied Research EGN4 was used for this purpose. The titanium substrate was kept at different temperatures (100, 200, 300, 400, 500, and 600°C). These substrates were exposed to oxygen at different partial pressures. The titanium 2p and oxygen 1s regions have been investigated by XPS. The magnesium anode (energy = 1253.6 eV) has been used for this purpose. The titanium substrate was kept at different temperatures (100, 200, 300, 400, 500, and 600°C). These substrates were exposed to oxygen at different partial pressures. The spectral data have been recorded at 45˚ take-off angle. The spectral data for different temperatures and oxygen partial pressures have been analyzed to ascertain the complete oxidation of the titanium substrate.

S1.00168 Synthesis and characterization of TiO2 nanocrystals through sol-gel and hydrothermal methods, CORINA ILEANA ORHA, CARMEN LAZAU, CORNELIA ELENA RATIU, PAULA SFIRLOAGA, PAULINA VLAZAN, National Institute for Research and Development in Electrochemistry and Condensed Matter Timisoara, Romania, PAUL BARVINSCHI, West University from Timisoara, Romania, IOAN MUSCUTARIU, Physics Department, Baldwin Wallace College, USA, IOAN GROZESCU, National Institute for Research and Development in Electrochemistry and Condensed Matter Timisoara, Romania — Nanomaterials with special and interesting properties, which can be different comparing to the macro scale materials, offer a large area of practical applications in all social-economical fields. Incorporating metallic and non-metallic dopant ions into the titanium dioxide particles can influence the performance of these photocatalysts. This affects the dynamics of electron-ion recombination and interfacial charge transfer. In this paper it was synthesized undoped and doped TiO2 nanocrystals with metallic (Ag) and non-metallic (N) ions through sol-gel and hydrothermal methods. The materials were characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM) and energy dispersive X-ray analysis (EDAX), diffuse reflectance UV-VIS, thermogravimetric analysis (TG) and differential thermal analysis (DTA).

S1.00169 Observation of acousto-elastic hysteresis in kinking nonlinear elastic solids, PETER FINKEL, AIGOU ZHOU, MICHEL BARSOUM, Drexel University — Using bulk acoustic waves we studied the nonlinear mechanical properties and hysteresis of the acousto-elastic effect in kinking nonlinear elastic, KNE, solids. The experiments reviewed here present direct observation of nonlinear hysteretic scattering and attenuation of ultrasonic waves in Ti3SiC2 and Ti3AlC2, representatives of KNE solids, as a function of quasi-static cyclic compressive stresses. We attribute this dynamic behavior to the interaction of the acoustic waves with dislocation in incipient kink bands. The relevance of these findings to possible sensor applications of hysteretic KNE solids is briefly discussed.
S1.00170 Spectral Calculations for columnar Thin Films Deposited on Periodically Decorated Substrates, JON MEASE, student, TARIQ GILANI, AKHLESH LAKHTAKIA, Penn State University — Using a morphological model of a class of nano-engineered materials called columnar thin films (CTFs) deposited on periodically decorated substrates, we compute their optical reflection and transmission spectra. The calculation procedure involves the use of the MIT Electromagnetic Equation Propagation (Meep) software libraries. The deposition geometry and the spatial periodicity affect the spectra in technologically significant ways. Our current efforts are focused on a narrowband, linear-polarization rejection filter.

S1.00171 Light reflection from semiconductor surface with submonolayer cover of metal particles, IRINA BARIKAHTAR, Department of Physics, BC, USA, VALERI LOZOVSKI, TATIANA MISHAKOVA, Department of Semiconductor Electronics, KNU, Ukraine — In the framework of the Green function method, the effective susceptibility of submonolayer of metal particles covering the surface of semiconductor is calculated. The main point of calculations is taking into account the size and the shape of the particles. The particles are assumed to have the shape of the ellipse of revolution. The effective susceptibility was obtained in the form: \( \chi(k, \omega) = \left[ \chi^{-1}(k, \omega) - mG_{\text{eff}}(k, \omega) \right]^{-1} \), where \( m \) is the concentration of the particles, \( G_{\text{eff}}(k, \omega) \) is the Green function of the substrate, and \( \chi(k, \omega) \) is the linear response function of the single particle in the surface. Based on this, the exact form of the effective linear response function is calculated. As a result, the reflection coefficient is readily obtained via effective susceptibility and Green function. This approach allows studying the dependence of the reflection coefficient on the particle concentration and its shape, and development of the theory of ellipsometry.

S1.00172 Electronic Properties of Large-scale Graphene Chemical Vapor Synthesized on Nickel and on Sapphire, HELIN CAO, LIYUAN ZHANG, YONG CHEN, Department of Physics and Birck Nanotechnology Center, Purdue University, QINGKAI YU, Department of Electrical and Computer Engineering, University of Houston, HAO LI, Department of Mechanical and Aerospace Engineering, University of Missouri — We have studied the electronic transport properties of large area few-layer graphene/graphitic films grown by two different chemical vapor based methods. The first type of samples (metal-transfer graphene) is synthesized by carbon segregation from Ni, then transferred to SiO2/Si substrates. The second type of samples is synthesized by direct chemical vapor deposition (CVD) on sapphire. We measured these samples under variable temperatures (from 2K to 300 K) and transverse magnet fields (from 0 to 7 T). For both types of samples, we found a negative magnetoresistance at low field, and carrier mobilities on the order of several hundreds of cm²/V-s. For metal-transfer graphene, in particular, we were able to measure a moderate field effect response, using the highly doped Si substrate as back gate. The observed magnetoresistance shows characteristic features of weak localization, from which we extract various scattering lengths in the metal-transfer graphene samples. Comparison with those measured in mechanically exfoliated graphene suggests possibly different carrier scattering mechanisms for graphene materials prepared with different methods.

S1.00173 All-electron KKR Calculations for Metallic Systems with Thousands of Atoms Per Cell via Sparse Matrix Iterative Solvers, SUFFIAN KHAN, AFTAB ALAM, DUANE JOHNSON, University of Illinois at Urbana Champaign — To perform electronic-structure calculations for inherently large systems, such as a quantum dots or interfaces like domain walls, we must perform the calculations over very large unit cells (10⁵ to 10⁶ atoms). For the inverse Green’s function \( G^{-1} \), KKR methods typically solve for \( G \) by direct inversion. Using a screened, k-space hybrid KKR, we solve Dyson’s equation for the Green’s function using a reference state via \( G = G_{\text{ref}} \). For both types of samples, we found a negative magnetoresistance at low field, and carrier mobilities on the order of several hundreds of cm²/V-s. For metal-transfer graphene, in particular, we were able to measure a moderate field effect response, using the highly doped Si substrate as back gate. The observed magnetoresistance shows characteristic features of weak localization, from which we extract various scattering lengths in the metal-transfer graphene samples. Comparison with those measured in mechanically exfoliated graphene suggests possibly different carrier scattering mechanisms for graphene materials prepared with different methods.

S1.00174 Many-flavor electron gas approach to electron-hole drops, GARETH CONDUIT, University of Cambridge, PETER HAYNES, Imperial College — A many-flavor electron gas (MPEG) is analyzed, such as could be found in a multivalley semiconductor or semimetal. Using the rederived polarizability for the MPEG, an exact expression for the total energy of a uniform MPEG in the many-flavor approximation is found. The interacting energy per particle is shown to be \( -0.574447 \left( E_0 a_0^2 \right) \left( m^* \right)^{1/2} \left( m^* \right)^{1/2} \left( m^* \right)^{1/2} \), with \( E_0 \) being the Hartree energy, \( a_0 \) being the Bohr radius, and \( m^* \) being the effective mass. The short characteristic length scale of the MPEG motivates a local-density approximation, allowing a gradient expansion in the energy density and the expansion scheme is applied to electron-hole drops, finding a new form for the density profile and its surface scaling properties. The formalism is verified using both Quantum Monte Carlo and density-functional theory calculations.

S1.00175 3D Quantum Dot Density of States in a Magnetic Field, N.J.M. HORING, Stevens Institute of Technology, Hoboken, USA, S.Y. LIU, Shanghai Jiaotong University, Shanghai, China, V. FESSATIDIS, Fordham University, Bronx, USA — We have analyzed the detailed quantum dynamics of a 3D magnetic dot in a magnetic field. The dot is taken to be lodged in a bulk medium in a high magnetic field and it is represented by a three-dimensional Dirac delta function potential which would support just one subband state if there were no magnetic field. The integral equation for the retarded Green’s function of this system is solved in closed form analytically and the single particle subband energy spectrum and the density of states are examined taking account of splintering of the subband spectrum by Landau quantization.

S1.00176 SUPPLEMENTARY ABSTRACTS —

S1.00177 Boron-catalyzed growth of multi-wall carbon nanotubes and their mechanical properties, FUMIO KOKAI, TAKASHI OKADA, IORI NOZAKI, AKIRA KOSHIO, Mie University, TORU KUZUMAKI, Tokai University — Carbon nanotubes have received widespread interests in basic and applied research fields. However, many applications of carbon nanotubes are hindered by a lack of control of their precise morphology and microstructures. We report here an efficient synthesis of multi-wall carbon nanotubes (MWNWs) by laser vaporization in inert gas atmosphere. We used a continuous-wave Nd:YAG laser (600 kW peak power) to irradiate a graphite target containing boron carbide (boron content: 1-60 at.%). Young’s moduli of MWNWs were also measured by nanoprobe manipulation in a TEM. The modulus was 680 GPa for a MWN produced in 0.1 MPa Ar for 20 at.% boron content, which is much higher than those (~0.1 GPa) of MWNWs grown by CVD.
S1.00178 How Mass Changes with Velocity and Energy? . LIANGXI MA, Blinn College — It is well known that mass of an object $m$ can increase with its speed $v$, which is one reason that we believe that the speed of light $c$ is the ultimate limit for all objects. As the $v$ is approaching to the speed of light, the $m$ becomes larger and larger so the acceleration becomes more and more difficult. It is also well known that $m$ is related to the energy $E$. Energy is released in the nuclear reaction while the mass is lost and this has been the theoretical basis for nuclear fission and fusion reactions. However, argument exists over how to interpret the relationship between mass and velocity and energy. In the text, we don’t want to discuss if the use of relativistic mass is appropriate. Instead, we discuss two examples that seem to be confusing in the teaching of special relativity. A harmonic spring oscillator and a proton accelerated in an electric field are chosen as examples to discuss the mass change with energy and velocity. We show that the two equations $m = \gamma m_0$ and $m = \frac{mc^2}{\sqrt{1-v^2}}$ agree each other if potential energy and related mass are properly considered.

S1.00179 Manipulation of thermal emission via gold gratings. JONES TSZ-KAI WAN, Department of Physics, The Chinese University of Hong Kong — The photon density of states of a structured metallic surface is strongly modified by various plasmonic excitations; as a result, thermal emission of photons can be manipulated through the control of plasmonic excitations. In this work, the author studies the emission properties of gold gratings, and investigates the effects due to the groove depth and periodicity. By systematically increasing the groove depth, the polarization of the emitted photons can be controlled. In addition emission at particular frequencies could be tuned to achieve that of the blackbody radiation limit, whereas the emission in other frequency ranges does not have noticeable changes.

This work is supported by RGC-HK (GRF project no. 403308) and by the NHMFL.

S1.00180 Absorption spectrum of the Single Molecule Magnet [Ni(dbm)(MeOH)Cl]$_4$. DANIEL J. ARENAS, DAMIETRIOUS KOKUS, SATI ATATA, CHAO CAO, HAI-PING CHENG, DAVID B. TANNER, Department of Physics, University of Florida, STEPHEN HILL, Department of Physics, Florida State University, CHRISTOPHER BEEDLE, DAVID HENDRICKSON, Department of Chemistry and Biochemistry, University of California at San Diego — The room temperature optical absorption of the single-molecule magnet [Ni(dbm)(MeOH)Cl]$_4$ has been measured in the near-infrared-visible spectral region. The spectra show a strong absorption band around 3 eV and bands characteristic of d-d transitions in nickel. The results will be compared to various theoretical models in the literature; including DFT and DFT+U calculations [Phys. Rev. Lett. 100, 167206] that predict different energy gaps for the HOMO to LUMO optical transitions.

S1.00182 BioCARS: A State-of-the-Art Facility for Time-resolved Crystallography with 100ps Time Resolution. ROBERT HENNING, TIM GRABER, VUKICA SRAJER, YU-SHENG CHEN, ZHONG REN, University of Chicago, FRIEDRICH SCHOTTE, PHILIP ANFINRUD, National Institutes of Health, KEITH MOFFAT, University of Chicago — BioCARS, a national facility located at the Advanced Photon Source (APS), recently upgraded the undulator beamline (14-ID) to become one of the best facilities in the world for conducting experiments with SChOTTe, PHILIP ANFINRUD, National Institutes of Health, KEITH MOFFAT, University of Chicago — BioCARS, a national facility located at the Advanced Sample Position.

S1.00183 Raman spectroscopy measurement of MoS$_2$ to 43 GPa. YANZHANG MA, Texas Tech University, BOHENG MA, Thomas S. Wootton High School, HONGYANG ZHU, MING CHYU, Texas Tech University — MoS$_2$ has a typical layered crystal structure. The two-dimensional lattice vibration, in conjunction with the strong (ionic) and weak (Van de Waals) bonding, is a very interesting subject. Among many of the interesting properties of MoS$_2$ is the physical performance in response to the substantial reduction of distance between the layers of the MoS$_2$ network along with the increase of interaction between them. We compressed MoS$_2$ in a diamond anvil cell to 43 GPa and carried out in situ Raman spectroscopy measurement. We found that the vibration energy of the A$_1g$ and E$_g$ modes was elevated with increasing pressure. At about 27 GPa, the peak of E$_g$ mode split into two peaks while the A$_1g$ peak did not show any abnormality. We believe that this reflects a structural phase transformation due to a minimal distortion of the MoS$_2$ network within the layer. We also found that non-hydrostatic compression on the sample lowered the pressure-induced energy elevation of the vibration modes, indicating that the differential stress applied on a MoS$_2$ crystal resists the atomic vibration.

This work is supported by NSF grant number: DMR0619215.

S1.00184 MgB$_2$ under pressure; band-filling, phonon hardening and electrical anisotropy. JESUS VAZQUEZ, SABINA RUIZ-CHAVARRIA, PABLO DE LA MORA, Fac. de Ciencias, Universidad Nacional Autonoma de Mexico — The electrical two-dimensional characteristic has been accepted as an important factor in the high T$_c$ superconductors. In MgB$_2$, it is the almost two dimensional $\sigma$-bands that are responsible for the superconductivity. On the other hand in MgB$_2$, the band-filling and phonon hardening have been found to be the responsible for the high T$_c$. [1] But previous calculations have shown that with pressure both, electrical anisotropy and T$_c$ are reduced. Thus the question arises: Is the electrical anisotropy, together with band-filling and phonon hardening, also responsible of the high T$_c$ in MgB$_2$? Using the WIEN2k package the MgB$_2$ superconductor is analyzed as function of pressure. At each pressure the cell parameters are optimized and the $\sigma$-DOS are calculated and, with the use of the Hopfield expression, are analyzed to see what the correlation of these elements with T$_c$ is. [1] J Kortus, Physica C 456 (2007) 54-62 [2] U Esteves and P de la Mora, Rev. Mex. Fis. 53 (2007) 95-98

S1.00185 ABSTRACT WITHDRAWN

S1.00186 Magnetic properties of Sr$_2$IrO$_4$ a DFT study. PABLO DE LA MORA, Fac. de Ciencias, CARLOS COSIO-CASTANEDA, GUSTAVO TAVIZON, Fac. de Quimica, Universidad Nacional Autonoma de Mexico — Sr$_2$IrO$_4$ is a magnetic insulator with a small Ir-magnetic moment [1]. IrO$_6$ rotations (due to the $I4/mcm$ space group) allow non-collinear magnetic ordering, thus this material could have weak ferromagnetism (non-collinear antiferromagnetically ordered $1\bar{r}$ magnetic moments); other possible explanation is band-magnetism. Simple DFT calculations give a non-magnetic conductor. Intra-atomic electron repulsion can generate magnetic moments in the $d$-orbitals (via the Hubbard $U$ ($U_{ij}$)), but due to extended character of these 5$d$-orbitals the $U_{ij}$ should be quite small. Sr$_2$IrO$_4$ is analyzed with the WIEN2k package. Different magnetic configurations with varying $U_{ij}$ are calculated in order to try to explain the observed magnetic behaviour. [1] C Cosio-Castaneda, G Tavizón, A Baeza and R Escudero, J. Phys.: Cond. Matter 19 (2007) 446210
S1.00187 Magnetic behaviour of the $\text{Bi}_{2-x}\text{Sr}_x\text{Ir}_2\text{O}_7$ pyrochlore. CARLOS COSIO-CASTANEDA, GUSTAVO TAVILON, Fac. Química, PABLO DE LA MORA, Fac. de Ciencias, FRANCISCO MORALES, ROBERTO ESCUDEIRO, Inst. de Materiales, Universidad Nacional Autonoma de Mexico — Polycrystalline compounds of the $\text{Bi}_{2-x}\text{Sr}_x\text{Ir}_2\text{O}_7$ solid solution have been synthesized. These compounds were obtained by the solid state reaction method in the 0 < x < 0.9 range with the α-pyrochlore crystal structure. This material was characterized with X-ray photoelectron spectroscopy and cyclic voltammetry. These analyses permitted the understanding of the unit-cell modifications and valence states of Iridium as a function of the stontent content. Electrical characterization of samples in the 10-300K range shows a metallic character that remains for the whole solid solution. Magnetically this system behaves as a Curie-Weiss paramagnetic in the 2-300K range. The measured magnetic moment values suggest the presence of $\text{Ir}^{5+}$ in some compounds of the solid solution.

S1.00188 Phase behavior of colloid-polymer mixtures in two-dimensions, AMIR AMINI, MARC ROBERT, Rice University — Phase behavior of mixtures of colloidal particles and non-adsorbing polymer chains bounded to two dimensions with various polymer-to-colloid size ratios are investigated. Mixtures are trapped at the air-water interface and pressure-area isotherms are obtained using the Langmuir-Blodgett technique. Different regions of the phase diagram are explored by changing temperature and the concentration of the colloid and the polymer. Brewster angle microscopy is then used to identify the microstructure of the formed phases.

S1.00189 How Local Anesthetics affect the structural and dynamical properties of biomembranes, ZHENGLI YI, Indiana University, MICHIHIRO NAGAO, Indiana University Cyclotron Facility, DOBRIN BOSSEV, Indiana University — To address the question of how local anesthetics influences the structural and dynamical properties of bio-membranes, neutron-spin echo spectroscopy (NSE) has been performed on 1,2-Dimyristoyl-sn-Glycerol-3-Phosphocholine (DMPC) unilamellar vesicles (ULV) with different concentrations of Lidocaine in D2O to study the influence of Lidocaine on the bending elasticity of DMPC ULV bilayers in fluid crystal (Lα) phase and the ripple gel (Pβ1) phase. The measurement of small-angle neutron scattering (SANS) has been performed to determine the bilayer thickness as a function of the concentration of Lidocaine. In the existence of molecules of Lidocaine the bending elasticity of DMPC bilayers was increased 30% -100% in Lα phase. The NSE data confirmed that fluid crystal/ripple gel transition temperature of DMPC bilayers was depressed by the addition of local anesthetics, which has also been examined via differential scanning calorimetry (DSC).

S1.00190 Landau-Zener Interference in Multilevel Superconducting Flux Qubits Driven by Strong Fields, YANG YU, XUEDA WEN, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China — We proposed a model to investigate the Landau-Zener (LZ) interference in multilevel superconducting flux qubits driven by large-amplitude microwave fields. The calculated interference patterns agree remarkably with those of the experiments. Moreover, the interference depends on the driving-frequency and dephasing rate. The dephasing generally destroys the interference while increasing frequency rebuilds the interference at large dephasing rate. At certain driving frequency and dephasing rate, the interference shows some anomalous features as observed in recent experiments. Our results can be used to understand the LZ interference in multilevel quantum systems under different driving frequencies and decohore rates.

S1.00191 A Logic-Based Technique that Charaterizes the Class of Boolean Networks Producing a Given Biological Pathway, GUANYU WANG, CHEN ZENG, George Washington University — A central theme in biophysics is the relationship between structure and function. The question becomes especially intricate at the systems level in which the objects of study are biological networks composed of large numbers of interacting molecules. To what extent does the requirement of carrying out a specific function constrain the structural and more general dynamical properties of a network? Does the biological network optimally designed? Here we present an efficient logic-based technique that captures the ensemble of all the networks that realize the same biological function. The biological function is first represented by a dynamical trajectory in the state space, and our first principle simulations on Au/MgO/Au and Pt/MgO/Pt nanocapacitors, we construct an analytical model that isolates the contributions of various physical mechanisms to the intrinsic dead layer. In particular we evidence even in “perfectly” fabricated structures. The exact nature of the intrinsic dead-layer and the reasons for its origin still remain somewhat unclear. Based on insights gained from recently published ab initio work on SrRuO3/SrTiO3/SrRuO3 and our first principle simulations on Au/MgO/Au and Pt/MgO/Pt nanocapacitors, we construct an analytical model that isolates the contributions of various physical mechanisms to the intrinsic dead layer. In particular we argue that strain-gradients automatically arise in very thin films even in complete absence of external strain inducers and, due to flexoelectric coupling, are dominant contributors to the dead layer effect.

S1.00192 Controlling the spatial correlation of entangled photon states using engineered crystal patterns, S.N. ZHU, X.Q. YU, P. XU, Department of Physics, Nanjing University — In this work, we will illustrate a scheme to tailor and manipulate the entangled photon state's spatial mode. When a 532 nm laser is directed on the crystal, it can split the 532nm photon into two degenerate 1064 nm photons. They must be entangled and the structural information in periodic crystal patterns would be transferred into their spatial mode. We performed a far-field interference experiment with such entangled photon pairs. The coincidence count shows a multi-beam two-photon sub-wavelength interference pattern. Our results can be used to control the LZ interference in multilevel quantum systems under different driving frequencies and decoherence rates.

S1.00193 Flexoelectricity in nanostructures and ramifications for the dead-layer effect in nanocapacitors and “giant” piezoelectricity. RAVEI MARANGANTI, University of Houston, MOHAMED MAJDUB, PRADEEP SHARMA, University of Houston — Thin films of high-permittivity dielectrics are considered ideal candidates for realizing high charge density nanoscale capacitors for use in next generation energy storage and nanoelectronics applications. The experimentally observed capacitance of such film nanocapacitors is, however, an order of magnitude lower than expected. This dramatic drop in capacitance is attributed to the so-called “dead layer” — a low-permittivity layer at the metal-dielectric interface in series with the high-permittivity dielectric. Recent evidence suggests that this effect is intrinsic in the sense that its emergence is evident even in “perfectly” fabricated structures. The exact nature of the intrinsic dead-layer and the reasons for its origin still remain somewhat unclear. Based on insights gained from recently published ab initio work on SrRuO3/SrTiO3/SrRuO3 and our first principle simulations on Au/MgO/Au and Pt/MgO/Pt nanocapacitors, we construct an analytical model that isolates the contributions of various physical mechanisms to the intrinsic dead layer. In particular we argue that strain-gradients automatically arise in very thin films even in complete absence of external strain inducers and, due to flexoelectric coupling, are dominant contributors to the dead layer effect.

S1.00194 ABSTRACT WITHDRAWN —
S1.00195 NaCl and Cationic lipid bilayer dynamics. MARKUS S. MIETTINEN, Department of Applied Physics, Helsinki University of Technology, Finland, ANDREY A. GURTVOVENKO, Institute of Pharmaceutical Innovation, University of Bradford, UK, ILPO VATTULAINEN, Department of Physics, Tampere University of Technology, Finland, MIKKO KARTTUNEN, Department of Applied Mathematics, University of Western Ontario, Canada — Positively charged lipid bilayer systems hold promise for safer and more efficient gene and drug delivery. Here we studied cationic bilayers comprising binary mixtures of cationic dimyristoylphosphatidylcholine (DMPC) and zwitterionic dimyristoylphosphatidylglycerol (DMPC) lipids. Using molecular dynamics simulations we addressed the effects of bilayer composition (cationic to zwitterionic lipid fraction) and NaCl electrolyte concentration on the dynamical properties of these systems. We found that despite the DMPC lipids form complexes via Na⁺ ions that bind to the lipid carbonyl oxygens, NaCl concentration had a rather minute effect on the lipid diffusion. The residence times of sodium ions in the carbonyl region appeared to lack a characteristic time scale, although observed a simulation period of over 200 ns. These prolonged dynamics of the sodium ions could be interesting for the physics of the whole membrane, especially to its interaction dynamics with charged macromolecular surfaces. 1. A. A. Gurtovenko et al., J. Phys. Chem. B 109, 21126 (2005) 2. M. Miitinen et al., J. Phys. Chem. B, (submitted)

S1.00196 Achieving quantum-like interference in ostensibly “classical” systems through closed timelike curves, M.J. RAVE, Western Carolina University — It was recently shown [1] that quantum interference can be understood heuristically as a quasi-probability effect as opposed to being interference in the traditional sense. Surprisingly, this interpretation requires one to think of closed loops in time (represented by products of probability amplitudes) as fundamental quantum entities, much as we think of state vectors normally. (These entities, incidentally, share similarities to Berry’s geometric phase.) The question naturally arises: can this closed-loop paradigm elucidate QI, making its idiosyncrasies more mundane? We show that this new way of thinking about QI leads to a whole new class of “classical” systems and analogies that exhibit pseudo-QI effects.

S1.00197 Crack branching and viscous fingering at nanoscale in brittle material. DEEDER AURONGZEB, University of Maryland, James A. Clark School of Engineering, College Park, MD — Cracked surfaces of soda lime glass and single crystal silicon are studied using atomic force microscopy simply by breaking them with impulsive force. We find traces of cavities and reorganized surface structures in both surfaces. At micron scale fractured glass surface exhibits viscous fingering and fractured silicon surface exhibit nanoscale crack branching showing two materials responds to sudden fracture differently. Crack branched surface of Si shows unusually low self-affine exponent and faceted nanoscale organized islands.

S1.00198 Raman spectroscopic studies of monoclinic Gallium Oxide (β-Ga₂O₃) Nanostructures: A comparison between nanowires vs. nanobelts, AURANGZEB KHAN, University of Peshawar, Peshawar Pakistan and Department of Physics & Astronomy and CMSS program, Ohio University, Athens OH 45701, SAIMA KHAN, Department of Civil Engineering, Ohio University, Athens OH 45701, WOJCIECH JADWISIENCZAK, School of Electrical Engineering and Computer Science, Ohio University, Athens OH 45701, MARTIN KORDESCH, Department of Physics and Astronomy and CMSS program, Ohio University, Athens OH 45701, OHIO GROUP TEAM, ELECTRICAL ENGG GROUP COLLABORATION — Nanostructures of monoclinic gallium oxide (β-Ga₂O₃), nanowires and nanobelts were synthesized via a very simple thermal evaporation process by using Ga metallic ignots and β-Ga₂O₃ powder as source materials for gallium and oxygen, respectively. The structural properties of the as grown nanostructures were characterized by using SEM, XRD and EDS. Raman studies were also performed for the grown nanostructures and Raman shifts were compared with the LDA calculated values of the peaks as well as with their bulk counterpart which exhibited good agreements with most of the peaks for both the nanostructures. In addition to this, there are some more Raman shifts which are the characteristics of the nanostructures as they have larger surface to volume ratio compared to their bulk counterparts.

S1.00199 Surface Effects on Amyloid Fibril Formation¹. BRAD MOORES, Department of Physics and Astronomy, University of Waterloo, JANET SIMONS, Department of Biology, University of Waterloo, ZOYA LEONENKO, Department of Physics and Astronomy, Department of Biology, University of Waterloo — Amyloid fibrils are insoluble aggregates composed of proteins in beta-sheet conformation, which are implicated in at least 20 diseases for which no cure is currently available. Although fibril plaque formation is associated with biological membranes in vivo, most of earlier research on fibrillogenesis has been performed in a solution phase, in which only a protein-protein interactions are considered. On the other hand, the surface of plasma membrane could provide the environment in which amyloid forming proteins could cluster. In order to get an insight into the understanding of the effect of the surface of plasma membrane, and the surfaces in general, on amyloid fibril formation, we used Atomic force microscopy to study binding of amyloid beta 1-42 peptide and amyloid fibril formation on model surfaces, such as chemically modified positively charged, negatively charged and hydrophobic substrates. The results show that structure, size and amount of larger fibrils and smaller aggregates depend on the type of surface, and differ from aggregation observed in solution.

S1.00200 High Resolution TEM Imaging of Graphene by use of aberration-free microscope, R005 , TAKAYUKI TANAKA, Tokyo Institute of Technology, CREST-JST, YUUSUKE ABE, Tokyo Institute of Technology, HIDETAKA SAWADA, EJJI OKUNISHI, YUKIHITO KONDO, JEOL, CREST-JST, KUNIO TAKAYANAGI, Tokyo Institute of Technology, CREST-JST — Free-standing Graphene is imaged by use of a novel transmission electron microscope (TEM), R005, equipped with newly-designed Cs Correctors for TEM and STEM. The R005 microscope is fitted with 300kV cold-field emission gun (CFEG) to minimize the chromatic aberration, resulting in achievement of 50pm resolution. Its high phase contrast allows direct imaging of graphene without image reconstruction. The TEM Image of graphene can be distinguished from that of graphite and confirmed by simulation. The adatoms and defects of single carbon atom, which cause the modulation of electronic properties, are also observed.

S1.00201 Affordable Integrated Technology Projects Science Education towards New Horizons. FRANCO PAOLETTI, East Windsor Regional School District, East Windsor, NJ, LISA MARIE CARLUCCI, Global Education & Research, Princeton, NJ — The new-era concept of education supports a type of instruction whereby technology directly acts as a conduit of change, fundamentally altering what is learned, how it is learned, and the role of the educator in the classroom. In our current world, the learning about technology itself has become a goal and a means to successful participation in today’s society. Efficient integration of technology to enhance and support the educational process will: 1) provide educators with the resources and the freedom to actualize innovative educational programs; 2) allow educators to be successful in challenging each student to reach his/her highest potential to ultimately increase academic achievement. This study analyzes what technology integration into education means identifying the benefits and the challenges that educators need to meet in order to be successful in their efforts while providing examples of how to successfully implement effective programs under budgetary constraints.
S1.00202 In-situ High Resolution TEM Observation of Dynamic Structural Changes of Au/TiO2 Catalyst Exposed to Oxygen and Hydrogen, KENTARO SANO, Tokyo Institute of Technology, TAKAYUKI TANAKA, Tokyo Institute of Technology, CREST-JST, HIDETAKA SATANADA, YUKIHIRO KONO, JEOL, KUNIO TAKAYANAGI, Tokyo Institute of Technology, CREST-JST. — Recently atomic structures of Au nanoparticles (NPs)/TiO2 catalyst are discussed in relation to its high catalytic activity. In addition, the importance of in-situ experiments in gas environments has increased. We have developed a novel gas-injection holder, which allows in-situ observations at high pressures up to 100 Pa. We observed Au NPs on TiO2 exposed to gas including oxygen and hydrogen. The exposure to oxygen induced growth of buffer layer on TiO2 surface. The buffer layer attached Au NPs and often covered Au NPs. The growth of buffer layer has not been reported so far, while it appears to cause the substrate roughening. These results suggest the importance of disorder phenomena in the transition layers. The EELS experiments suggest that the buffer layer is highly oxidized titania. On the contrary the exposure to hydrogen induce a slight change of TiO2 surface and remarkable changes of Au NPs morphology. These in-situ observations greatly contribute the clarification of catalysis of Au NPs/TiO2.

S1.00203 Upper bounds on photonic bandgaps in two and three dimensions, MIKAEL RECHTMAN, Courant Institute, NYU, SALVATORE TORQUATO, Princeton University — A 20-year search has been on to find photonic crystals (periodic dielectric structures) with the largest possible full photonic bandgaps. A large robust bandgap is key to the many applications of these materials, which include near-lossless waveguiding, optical filtering, optical computing, and others. A number of three-dimensional structures with large gaps have been proposed (e.g., a diamond lattice of spheres [1], the “Woodpile” structure [2], and in two dimensions, structural optimizations to find the largest-bandgap structure have been performed, e.g., [3], [4]). So far, however, there has been no work on finding rigorous limits on how high the bandgap may be. In this talk, I present upper bounds on the bandgaps of two- and three-dimensional photonic crystals.

S1.00204 Anomalous Brownian motion and viscoelasticity of the ear’s mechanoelectrical transducer, DANIEL ANDOR-ARDÓ, ANDREI KOZLOV, A.J. HUDSPETH, The Rockefeller University — The Brownian motion of a particle in a complex environment is known to display anomalous power-law scaling in which the mean squared displacement is proportional to a fractional power of time. Using laser interferometry and analytical methods of microhemeology, we examine nanometer-scale thermal motions of hair bundles in the internal ear and show that these cellular organelles undergo fractional Brownian motion. This anomalous scaling is caused by viscoelasticity of the gating springs, elements that transmit energy in a sound to the mechanosensitive ion channels. These results demonstrate a connection between rheology and auditory physiology, and indicate that statistical properties of the thermal noise in the ear can be determined by dynamics of a small number of key molecules.

S1.00206 ABSTRACT WITHDRAWN

S1.00207 Label-free detection of DNA interactions by terahertz spectrometry, ANIS RAHMAN, Applied Research and Photonics, Inc., BRUCE STANLEY, Penn State College of Medicine, AUNIK RAHMAN, Applied Research and Photonics, Inc., ARP TEAM — Terahertz (THz) spectrometry has the potential to analyze DNA and other molecular interactions without fluorescent labeling. THz spectrometry is conducted in time domain where the temporal signal is acquired on a sub-pico-second scale. The temporal signal converted to frequency domain via Fourier transform constitutes a signature of the interaction under study. An important advantage of this technique is that the delay time can be tuned from tens of femto-seconds to tens of pico-seconds. This gives a means of probing a molecular “event” (e.g., a vibrational state or bond position or bending, or a conformational state, etc.) in an appropriate time window. This is a powerful ability because different molecular events exhibit different time response based on their physical and chemical nature. For example, a molecular relaxation occurs over a longer time scale compared to a bond vibration. Similarly, compositional or conformational difference of a given molecule results in different signature with appropriate time response that can be accurately probed. The terahertz signature is unique and provides a means of identifying and/or characterizing many molecular interactions. Some exemplary results of biological system will be discussed.

S1.00208 Void collapse in energetic structural materials, DEREK REDING, SATHYA HANAGUD, Georgia Institute of Technology — A spherically symmetric pore collapse model is introduced that incorporates internal and physical state variable plasticity models for a mixture. This model is based on the modified Carroll-Holt model by Nesterenko. Mixture rules are formulated for the density and yield strength. Previous spherically symmetric model studies consider single constituent porous mixtures. This study investigates the pore collapse in the Ni+Al − void system during shock loading. This material is part of a larger class of energetic structural materials. The proposed model is incorporated into a gas-gun simulation via an algorithm that uses the bisection method for robustness. Results show close agreement between simulation and experiments for shock pressures up to 6 GPa. The proposed mixture pore collapse model is useful for incorporation into a continuum level simulation of the gas-gun experiment.

This research was funded by the AFOSR MURI 1606U81 on Multifunctional Energetic Structural Materials at the Georgia Institute of Technology.

S1.00209 Evidence for a disorder-phase transition in the condensation of 4He in aerogels, FABIEN BONNET, MATHIEU MELICH, LAURENT PUECH, PIERRE ETIENNE WOLF, Institut Néel CNRS-UJF — Although widely studied, capillary condensation of fluids in disordered mesoporous media is not fully understood. A central question is the origin of the hysteretic behavior between adsorption and desorption. It has been recently proposed that this hysteresis could result from the disorder of the porous media. Based on mean-field theoretical calculations, a disorder-driven transition is predicted, similar to that occurring in the Random Field Ising Model. Our earlier results on the condensation of helium in silica aerogel, combining thermodynamic (adsorption isotherms) and optical measurements, have provided a first evidence for such a transition. Here, we report new measurements on aerogels (porosity: 95%, 97% and 98.5%), which further support the disorder scenario, and allow us to study the interplay between temperature and disorder. We also compare the case of aerogels to that of Vycor. Although a transition is not observed in Vycor, the dynamics of the adsorption and desorption processes lead us to conclude that disorder is also important in this case. F. Bonnet et al. Europhys. Lett. 82, 56003 (2008)
S1.0021 Ambient Detection of Energetic Materials by Matrix Assisted Laser Desorption and Photofragmentation-Fragment Detection. STEPHEN ROBERSON, ROSARIO SAUSA, US Army Research Laboratory — We detect energetic materials TNT and RDX by Matrix Assisted Laser Desorption (MALD) followed by photofragmentation-fragment detection (PF-FD) in real time at ambient conditions. A pump laser irradiates a mixture of energetic material and laser dye freeing the energetic material from the surface, and a second laser fragments the resulting energetic molecule to create the characteristic nitric oxide (NO) fragment, which is subsequently ionized and then detected by resonance-enhanced multiphoton ionization (REMPI). Our studies on the effects of pump and probe laser energy, dye concentration, and analyte concentration on the ion signal intensity, as well as the RDX and TNT limits of detection will be reported at the meeting. The PF-FD technique exhibits great potential for detecting trace energetic materials on surfaces because of its high sensitivity and selectivity. It is not restricted to TNT and RDX, and can be extended to other energetic materials.

S1.00211 Molecular dynamics simulations of electrostatics and hydration distributions around RNA and DNA motifs. ASHLEY E. MARLOWE, ABHISHEK SINGH, ANDREY V. SEMICHAEVSKY, YAROSLAVA G. YINGLING, North Carolina State University, MATERIALS SCIENCE AND ENGINEERING TEAM — Nucleic acid nanoparticles can self-assemble through the formation of complementary loop-loop interactions or stem-stem interactions. Presence and concentration of ions can significantly affect the self-assembly process and the stability of the nanostructure. In this presentation we use explicit molecular dynamics simulations to examine the variations in cationic distributions and hydration environment around DNA and RNA helices and loop-loop interactions. Our simulations show that the potassium and sodium ionic distributions are different around RNA and DNA motifs which could be indicative of ion mediated relative stability of loop-loop complexes. Moreover in RNA loop-loop motifs ions are consistently present and exchanged through a distinct electrogentic channel. We will also show how we used the specific RNA loop-loop motif to design a RNA hexagonal nanoparticle.

S1.00212 Disentanglement and Re-entanglement of Polymer Solutions after Large Step Shear Deformation. YANGYANG WANG, SHI-QING WANG, University of Akron — Double-step strain and elastic recovery experiments were carried out to explore the disentanglement and re-entanglement kinetics in entangled 1,4-polybutadiene solutions after large step shear deformation. In double-step strain experiments, startup shear measurements were interrupted at different strains, and resumed after different waiting times. When the interrupted strain was small, the magnitude of stress overshoot in the resumed shear remained unchanged. However, at a large strain, the magnitude of stress overshoot would first decrease with increasing waiting time and then only become higher after longer waiting time. This observation reveals evidence that disentanglement occurs after a large step deformation. Subsequent healing in the form of re-entanglement allows the sample to relax normally in quiescence. In elastic recovery experiments, the data at small strains fall onto a master-curve, whereas the recovery at large strains shows much stronger strain dependence, confirming occurrence of chain disentanglement beyond a critical strain amplitude.

S1.00213 Phonons in strongly correlated materials from Hubbard-corrected density-functional-perturbation theory. ANDREA FLORIS, Institut für Theoretische Physik, Freie Universität Berlin, Germany and European Theoretical Spectroscopy Facility (ETSF), MATTEO COCCOCCIONI, Chemical Engineering and Materials Science Department, University of Minnesota, Minneapolis, USA — A novel DFT+U energy functional (named DFT+-U-V) is introduced based on a corrective Hubbard Hamiltonian that includes both on-site (U) and inter-site (V) electron-electron interactions. The competition between these couplings allows for more general localization regimes (e.g., on hybrid, molecular states). Systems as diverse as Mott insulators and covalent semiconductors can be described within the same theoretical framework. Also, phenomena like electron-transfer reactions or formation and breaking of bonds, whose modeling within “standard” (e.g., LDA or GGA) approximations to DFT or with the “on-site” DFT+U approach is problematic, will be addressed with higher precision. Accurate energetics is guaranteed by the consistent evaluation of V that can be obtained, at no additional cost, from the same linear-response approach used to calculate U [1]. The flexibility and reliability of the novel functional are demonstrated by its application to covalent (Si) and ionic (GaAs) semiconductors and to charge-transfer insulators (NiO). [1] M. Cococcioni and S. de Gironcoli, Phys. Rev. B 71, 035105 (2005).

S1.00214 Extended LDA+U+V approach for covalently bonded systems. VIVALDO LEIRIA CAMPO JR, Departamento de Fisica, Universidade Federal de Sao Carlos, Sao Carlos, Brazil, MATTEO COCCOCCIONI, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, USA — A novel DFT+U energy functional (named DFT+-U-V) is introduced based on a corrective Hubbard Hamiltonian that includes both on-site (U) and inter-site (V) electron-electron interactions. The competition between these couplings allows for more general localization regimes (e.g., on hybrid, molecular states). Systems as diverse as Mott insulators and covalent semiconductors can be described within the same theoretical framework. Also, phenomena like electron-transfer reactions or formation and breaking of bonds, whose modeling within “standard” (e.g., LDA or GGA) approximations to DFT or with the “on-site” DFT+U approach is problematic, will be addressed with higher precision. Accurate energetics is guaranteed by the consistent evaluation of V that can be obtained, at no additional cost, from the same linear-response approach used to calculate U [1]. The flexibility and reliability of the novel functional are demonstrated by its application to covalent (Si) and ionic (GaAs) semiconductors and to charge-transfer insulators (NiO). [1] M. Cococcioni and S. de Gironcoli, Phys. Rev. B 71, 035105 (2005).

S1.00215 Physical Properties of Various Materials Relevant to Granular Flow. KURT ROSENTRATER, USDA-Agricultural Research Service — Because of the ubiquitous nature of granular materials, ranging from natural avalanches to industrial storage and processing operations, interest in quantifying and predicting the dynamics of granular flow continues to increase. The objective of this study was to investigate various physical properties of common biological bulk solids (i.e., grains) which are relevant to granular flow. Particle size, shape, loose bulk density, compacted bulk density, angle of repose, and angle of marginal stability will be presented and discussed. Flow properties depend, in large measure, upon the size and shape of the particles themselves; thus information generated from this study may be useful to future experimental and simulation studies of bulk flow.

S1.00216 Bismuth nanowire array fabrication and measurements. RICHARD GRECO, Los Alamos National Laboratory — Bismuth Nanowire Arrays (BNAs) are semiconducting materials that can potentially lead to radiation detectors with better spectral resolution and efficiency than cooled high purity germanium because of the high atomic number of bismuth and expected nanowire electronic properties. Bismuth, which is normally a semi-metal, becomes a semiconductor when it is fabricated in wire form with a diameter smaller than 50 nanometers (nm). Arrays of bismuth nanowires are produced by vapor deposition into electrochemically-fabricated alumina templates. The electronic bandgap of a bismuth wire is a function of its diameter, varying from 0 eV at 50 nm to 0.7 eV at 5 nm. In this paper we present an improved fabrication technique and recent measurements on BNAs.

1Los Alamos National Laboratory, PO Box 1663, 87545 Los Alamos New Mexico, USA
S1.00217 Organic non-volatile memories from ferroelectric phase separated blends, KAMAL ASADI, University of Groningen, DAGO DE LEEUW, Philips Research Labs, The Netherlands, BERT DE BOER, PAUL BLOM, University of Groningen — Ferroelectric polarisation is an attractive physical property for non-volatile binary switching. The functionality of the targeted memory should be based on resistive switching. Conductivity and ferroelectricity however cannot be tuned independently. The challenge is to develop a storage medium in which the favourable properties of ferroelectrics such as bistability and non-volatility can be combined with the beneficial properties provided by semiconductors such as conductivity and rectification. In this contribution we present an integrated solution by blending semiconducting and ferroelectric polymers into phase separated networks. The polarisation field of the ferroelectric modulates the injection barrier at the semiconductor–metal contact. This combination allows for solution-processed non-volatile memory arrays with a simple cross-bar architecture that can be read-out non-destructively. Based on this general concept a non-volatile, reversible switchable Schottky diode with relatively fast programming time of shorter than 100 microseconds, long information retention time of longer than 10days, and high programming cycle endurance without destructive read-out is demonstrated.

S1.00218 Manganese doping of group IV semiconductor surfaces and nanostructures1, PETRA REINKE, CHRISTOPHER NOLPH, KIRIL SIMOV, University of Virginia — The combination of Si and Ge with Mn is a critical step in the development of novel spintronics devices. We investigate the magnetic doping of Si, Si-surfaces and Ge-quantum dots with Mn. A surface-driven route is used for the addition of Mn and allows a stringent control of the Mn-Si and Mn-Ge interaction. The evolution of nanostructures is observed with STM and PES. Monatomic Mn-wires form on the Si(100) surface in the low-mobility regime and dissolve into sub-surface structures at elevated temperatures. The phase diagram for Mn-Si nanostructures is developed and leads to embedded Mn structures. The interaction of Mn with Ge-quantum dots poses a new set of constraints. The Mn-addition leads to the formation of surface clusters on the wetting layer whose spatial distribution is driven by the surface relaxation. The Mn-adatom clusters on the 105 facet of the Ge-quantum dots are oriented with respect to the surface reconstruction, which predetermines diffusion pathways into the Ge-QD. The characteristics of Mn-nanostructure formation and the possibility of the synthesiss of magnetic structures will be discussed.

S1.00219 The impact of the market index on the topology of financial networks, EDWARD MANDERE, HAO WEN XI, Bowling Green State University — We study the financial network generated from stock price returns correlation. The network topology has been used to explore and visualize the relationships between stocks. These networks have also been used in reconstructing less noisy correlation matrices for portfolio optimization. In this work, we explore the effect of adding the market index to the rest of stock network. We show that there is a very strong clustering around the index, both in S&P500 and DJIA. The mechanism that leads to these strong clustering as well as the implication to reconstructed correlation matrices will be explored.

S1.00220 Second harmonic generation in N@C60 and P@C601, MEGAN MORRIS, NICOLE PERIGO, GUOPING ZHANG, Department of Chemistry and Physics, Indiana State University, Terre Haute, IN 47809 — The successful implantation of nitrogen and phosphorus into C60 opens many new applications. For instance, both N@C60 and P@C60 are ideal candidates for quantum computing. In this paper, we show that N@C60 and P@C60 can be used to generate the second harmonic generation. If N and P are at the center of the buckyball, the signal is zero, but if they are off the center, the signal comes out. Therefore, the oscillation of N and P atoms will generate a 0-1-0-1 bit, when detected along the incident light direction. If this signal is sent to another N@C60 and P@C60, they can control the sequence of bits. The intensity sensitively depends on the laser energy and polarization. This process can be useful for quantum control by N@C60 and P@C60 themselves. All the results are obtained using the first-principles method.

1This work is supported by DOE under Contract No. DE-FG02-06ER46304, Promising Scholars grant, NERSC at LBNL under Contract No. DE-AC02-05CH11231, and Department of Chemistry and Physics, Indiana State University.

S1.00221 Quantum correlated light pulses from sequential superradiance of a condensate1, MEHMET EMRE TASGIN, MEHMET OZGUR OKTEL, Department of Physics, Bilkent University, 06800 Bilkent, Ankara, Turkey, LI YOU, School of Physics, Georgia Institute of Technology, Atlanta, Georgia 30332, USA, OZGUR ESAT MUSTECAPLIOGLU, Department of Physics, Koc University, 34450 Sariyer, Istanbul, Turkey — We discover an inherent mechanism for entanglement swap associated with sequential superradiance from an atomic condensate. As a result, Einstein-Podolsky-Rosen (EPR)-type quantum correlated photons can be detected among the scattered light pulses.

S1.00222 Doping effects on charge density wave state in o-TaS2, DAMIR DOMINKO, DAMIR STARESNIĆ, KATICA BILJAKOVIC, Institute of Physics, Zagreb, Croatia, PETER LUNKENHEIMER, ALOIS LOIDL, Experimental Physik V, Augsburg, Germany, JEAN CLAUDE LASJAUNIAS, Institut Neel, Grenoble, France — We present the effects of the isoelectronic supstitution of Ta by (0.2 and 0.5 %) Nb atoms on the charge density wave (CDW) properties in o-TaS2. CLAUDE LASJAUNIAS, Institut Neel, Grenoble, France — We present the effects of the isoelectronic supstitution of Ta by (0.2 and 0.5 %) Nb atoms on the charge density wave (CDW) properties in o-TaS2. We investigate the magnetic doping of o-TaS2, and low energy excitation contribution to specific heat (Cv). The characteristic, primary relaxation process which gives the maximum in the dielectric constant near 100 K disappears with slight doping. At the same time the minimum in threshold field in the same temperature range disappears as well, which is expected from well known relation between E2 and low frequency dielectric constant [1]. This implies that the primary process it mainly due to polarization on order of domain scale, which decreases by doping. The secondary process, on the other hand, as well as low energy excitation contribution to specific heat (Cv), seem to be unchanged. Only the amplitudes of the two are increased [1, 2], as both are due to the local excitations of the CDW phase in vicinity of defects described by two level system (TLS) model. [1] Staresnii et. al, Phys. Rev. B, 65, 165109 (2002) [2] Biljakovic et. al, Europhys. Lett., 62 (4), pp. 554–560 (2003)

S1.00223 Nature of Light, SUNIL THAKUR, Independent Research — How do we perceive light? We assume that we have to absorb a photon to perceive light. When we set out to confirm this assumption experimentally then we find that everything we knew about light is wrong. We can perceive light wherever it is, provided light is in the perceivable range of our eyes. More than one photon detector can simultaneously detect a single photon. Obviously, a single photon cannot be absorbed by more than one detector. We can see a laser beam refract as it enters water from air but we find no refraction when we view the laser beam from the side of the container. It is possible only if we can see the light without having to absorb the light. Perception of the total solar eclipse as it occurs confirms this observation. All light sources emit only energy, light is produced by the object that absorbs this energy. Only difference between a luminous object and an illuminated object is that luminous objects generate their own energy to radiate light whereas illuminated objects need energy from an external source to radiate light. The observations are conclusively validated in several other advanced experiments. These observations also show that the idea of motion cannot be associated with the light; illusion of motion of light is created due to movement of energy through the medium that produces light. These experiments conclusively invalidate theory of relativity, standard model of cosmology, and standard model of particle physics.
S1.00224 Phonon Spectroscopy by Electrical Measurement in Coupled Quantum Dots. AKIKO UEDA, Department of Physics, Keio University, MIKIETO ETÓ, Faculty of Science and Technology, Keio University — We propose a phonon spectroscopy by electrical measurement in coupled quantum dots. We consider T-shaped double quantum dots, in which one of the dots is connected to external leads (dot 1) and the other is disconnected (dot 2). The differential conductance shows a dip at the midpoint of the two peaks by resonant tunneling through bonding or antibonding orbitals between the two dots, when the energy levels are tuned in the dots. The dip is caused by the destructive interference between the electron waves passing by the molecular orbitals. We calculate differential conductance under finite bias $V_{bias}$ using Keldysh Green function method. The conductance dip is diminished by electron-phonon interaction since phonon emission from dot 2 destroys the interference between electron waves passing through only dot 1 and waves passing through both dots. The dip as a function of $V_{bias}$ reflects a product of the density of states for phonons at $eV_{bias}$ and strength of electron-phonon coupling in dot 2. This implies a new method of electrically detected phonon spectroscopy.

S1.00225 Transport Properties for Biphenyl-Based Molecular Junction System. HISASHI KONDO, Institute of Industrial Science, University of Tokyo, JUN NARA, TAKAHISA OHNO, Computational Materials Science Center, National Institute for Materials Science — In the present study, the transport properties of a biphenyl-based molecule $[X\rightarrow BP\rightarrow X$: the end-group atom], $X=O$, $S$, $Se$, and $Te$ sandwiched between Au(111) electrodes are theoretically investigated using the non-equilibrium Green’s function method based on the density functional theory. The end-group atom $X$ has an influence on the interaction between the molecule and electrodes and the interaction between the two phenyl rings. For $X=O$, $S$, $Se$, and $Te$, similar transport properties are obtained, while the system with $X=O$ exhibits much different properties from the other $X$s. In case of $X=O$, the interaction between the molecule and electrodes becomes the weakest and that between $\pi$-type orbitals of the two phenyl rings, which mainly contributes to the transmission across the Fermi energy, becomes the strongest. As a result, this system has a larger transmission around the Fermi energy. We also investigate the dependence on dihedral angle between the two phenyl rings for all $X$s. This study was supported by the RISS project and a Grant-in-Aid for Scientific Research (No.17064017) of MEXT of the Japanese Government. The present calculations were performed by using the Numerical Materials Simulator in National Institute for Materials Science.

S1.00226 Electronic structure and Fermi surface of Pr$_{M}$In$_{5}$ ($M=$Co, Rh, and Ir) compounds$^1$. SAAD ELGAZZAR, Uppsala University, INGO OPAHLE, MANUEL RICHTER, PETER OPPENEER — We report density functional calculations of the electronic structure, Fermi surface, and de Haas-van Alphen (dHvA) quantities of the Pr$_{M}$In$_{5}$ ($M=$Co, Rh, and Ir) compounds. Our investigation is carried out within the framework of the local density approximation (LDA), using a relativistic, full-potential band structure method (FPLO). A critical analysis of the electronic structures and the de Haas-van Alphen quantities is performed, which shows that good agreement with recent measurements is obtained when we assume the Pr 4$f$ states to be localized. The topology of the Fermi surface is calculated to be similar to that of non-4$f$ reference compounds, as, e.g., LaRhIn$_{5}$. The similarities of the Fermi surfaces and the dHvA extremal orbits among the compounds in the series are discussed. We furthermore compare our calculated effective masses with experimental measurements and discuss the differences between them.

S1.00227 Capillary interactions in nano-particles suspensions$^1$. DOBRIN BOSEEV, GARFIELD WARREN, Indiana University — We have investigated the structures formed by colloidal particles suspended in solvents at volume fractions below 10% and interacting through capillary bridges. Such systems resemble colloidal gas of sticky nano-spheres that form pearl-necklace like chains that, in turn, induce strong viscoelasticity due to the formation of 3-D fractal network. The capillary force dominates the electrostatic and Van der Waals forces in solutions and can bridge multiple particles depending on the volume of the capillary bridge. We have investigated the morphology of the structures formed at different fractions of the bridging fluid. Computer simulations of a pearl necklace-like chain of spheres is conducted to explain the structure factor when capillary bridges are present. Alternatively, we have analyzed the slope of the neutron scattering intensity at low Q in a double logarithmic plot to determine the dimension of the fractal structures formed by the particles at different volume fraction of the bridging fluid. We have also studied the properties of the capillary bridge between a pair of particles. The significance of this study is to explore the possibility of using capillary force as a tool to engineer new colloidal structures and materials in solutions and to optimize their viscoelastic properties.

$^1$Supported by IU FRSP grant

S1.00228 Capillary interactions between silica-particles in organic solvents$^1$. GARFIELD WARREN, DOBRIN BOSEEV, Indiana University — Small-angle neutron scattering (SANS) is used to study the interactions of silica nano-particles with an average diameter of 10 nm in methanol and methanol/toluene mixtures at 25 °C. SANS intensities are analyzed as a product of a form factor and a structure factor. The form factor is experimentally determined in methanol after addition of simple electrolyte at a concentration of 100 mM to suppress the interparticle interactions. The data is successfully fitted by Hayter-Penfold mean spherical approximation (HPMSA) that yielded the specific area of surface charge in methanol. The phase behavior, viscosity and interparticle interactions are studied as a function of fraction of toluene in methanol/toluene mixtures at a constant particle volume fraction of 3.7 %. At intermediate fractions of toluene, between 44 and 65 %, the viscosity increases by two orders of magnitude which suggests formation of a new phase behavior. We will present the static magnetization and specific heat data for these pseudo-ternary compounds investigated in the necessary temperature range. Discussion of the change in the superconducting critical temperature $T_{c}$ will be directed toward the changes of electron number density as well as the lattice parameters with respect to pure LaPtSi.

S1.00230 Crystal structure and superconductivity in (La$_{1-x}$Y$_x$)NiC$_2$
, H.H. SUNG, K.J. SYU, T.F. LIAO, W.H. LEE, National Chung Cheng University — As observed in the powder X-ray diffraction and crystallographic data, the partial substitution of La with Y in (La$_{1-x}$Y$_x$)NiC$_2$ could be systematic up to the solubility limit near $x = 0.35$. The variation of room temperature lattice parameters, a, b, c and $\theta$ of these substitude compounds are consistent with what one would expect from a chemical pressure effect. Magnetic, electrical and heat capacity measurements indicate that the change in $T_c$ with $x$ is similar to the change in the lattice parameter. It is found that the $T_c$ change rate is $dT_c/dx = -7.0$ K and $dT_c/dv = 0.46$ K/a$^3$. According to the BCS theory, the stiffening of the lattice under pressure may change both the electron-phonon coupling strength $V$ and the electron density of states at the Fermi level, $N(0)$, which will lead to the change of $T_c$. Analysis of the electron density of states at Fermi level $N(0)$ from the specific heat data indicates that the effect of $N(0)$ on $T_c$ dominates in the (La$_{1-x}$Y$_x$)NiC$_2$ system.

S1.00231 Unbinding Dynamics of weakly adhered vesicle on a substrate , SUNITA CHATKAEW, MARC GEORGELIN, MARC LEONETTI — Unbinding dynamics of a vesicle adhering weakly on a substrate by hydrodynamic force is characterized in our works. Vesicle shapes on a substrate are governed by adhesion energy, gravity and curvature energy. Several regimes of unbinding dynamics are observed from inflated vesicles until the deflated ones. Water film growth between the membrane and the substrate and the reduction of contact area are monitored. In the case of inflated vesicle, the unbinding dynamics shows the growth of water film with the same contact area. After this lag time, the radius of the contact area decreases strongly following a 1/2 power law. When the vesicles are more deflated, the unbinding is then just a strong reduction of the contact area at a constant thickness of water film. Lipidic tube can be found in the case of a strongly applied hydrodynamic force on a deflated vesicle occupying a large contact area.

S1.00232 Particle-Tracking Velocimetric Investigation of Large Amplitude Oscillatory Shear of Entangled Polymer Melts , GREGORY ZARTMAN, YANGYANG WANG, SHI-QING WANG, The University of Akron — Large amplitude oscillatory shear (LAOS) experiments were carried out on a series of entangled monodisperse styrene-butadiene random copolymers (SBR). The deformation field during the measurements was monitored with a particle-tracking velocimetric technique. It was found that when the applied frequency was higher than the overall relaxation rate of the sample, the entangled melt would undergo uniform deformation at small strains, but exhibit shear banding at large strains. The inhomogeneity of the deformation field suggests that yielding through chain disentanglement cannot take place uniformly. This is the first report of shear banding in LAOS for melts and consequently rules out any speculation that shear banding could originate from concentration variation (due to shear induced phase separation) in entangled solutions.

S1.00233 Elementary charge-transfer processes in mesoscopic conductors , MIHAJLO VANEVIC, Georgia Institute of Technology, YULI NAZAROV, Delft University of Technology, The Netherlands, WOLFGANG BELZIG, Universit¨ at Konstanz, Germany — We determine charge-transfer statistics in a quantum conductor driven by a time-dependent voltage and identify the elementary transport processes. At zero temperature unidirectional and bidirectional single-charge transfers occur. The unidirectional processes involve electrons injected from the source terminal due to excess dc bias voltage. The bidirectional processes involve electron-hole pairs created by time-dependent voltage bias. This interpretation is further supported by the charge- transfer statistics in a multiterminal beam-splitter geometry in which injected electrons and holes can be partitioned into different outgoing terminals. The probabilities of elementary processes can be probed by noise measurements: the unidirectional processes set the dc noise level, while bidirectional ones give rise to the noise oscillations. Finally, the noise oscillations are observed to be strongly correlated with the driving amplitude. The decomposition of the noise into the contributions of elementary processes reveals the origin of these oscillations: the number of electron-hole pairs generated per cycle increases with increasing the amplitude. The charge- transfer statistics at finite temperature can be interpreted in terms of multiple-charge transfers with probabilities which depend on energy and temperature.

S1.00234 On the Salecker-Wigner-Peres Clock and Quantum Tunneling , LUÍZ MANZONI, Concordia College - Moorhead, JOSE LUNARDI, MARCOS CALCADA, Universidade Estadual de Ponta Grossa — We consider the Salecker-Wigner-Peres clock formalism and show that in the approach introduced by Peres it can be directly applied to quantum tunneling. Then we apply this formalism to the determination of the tunneling time of a non relativistic particle through a double barrier potential. In special, we consider the case in which the clock runs only when the particle can be found inside the region between the barriers and analyze the limit of opaque barriers in order to discuss the generalized Hartmann effect.

S1.00235 Restricted height discrete model , JIN MIN KIM, Soongsil University — We introduce a discrete growth model following the Edward- Willkinson equation with a conservative noise. The surface width $W$ can be found inside the region of tunneling time of a non relativistic particle through a double barrier potential. In special, we consider the case in which the clock runs only when the particle.

S1.00236 Growth of the Graphene Nanoribbons on the Vicinal 6H-SiC(0001) Surface , ILYOU KIM, E. CHO, Chonnam National University, C. HWANG, W. KIM2, KRISS — Graphene nanoribbons (GNR) are currently considered as one of the most promising materials for future nanoelectronic devices due to its exceptional physical properties. We investigated the possibility of the growth of GNR on the vicinal 6H-SiC(0001) surface using Scanning Tunneling Microscopy. We observed the formation of the ribbon-like single-layer graphene with sharp edge structures at the initial stage of thermal graphitization process of the SiC(0001) surface. However, the overall long-range ordering of the steps of the bare vicinal surface was found to be lost during graphitization process, and only the local short range ordering of the steps with graphene layer patches existed on the entire surface. From the atom-resolved STM images, we clearly identified the armchair edge structure of graphene for several ribbon-like graphene nanostructures. Scanning tunneling spectroscopy experiment was also carried out over the ribbon-like graphene patches to examine the local electronic states at the edge structures.

S1.00237 First Principles Study of Nature of Binding Energies in Solid Hydrogen , HARI PAUDEL, University of Central Florida, SITARAM BYAHUT, Tribhuvan University, Kirtipur Kathmandu, Nepal — The study of solid hydrogen is of utmost importance since it can be used as renewable source of energy. In the present work, we have quantitatively studied the properties of solid molecular hydrogen. The Hartree-Fock method, together with electron correlation effects included by many-body perturbation theory, has been utilized in this work. Study of geometry and binding energy using different basis sets will be presented. In addition to this, the effect on energy due to orientations of hydrogen molecule at lattice point will be presented and compared with available experimental data. A comparison of binding energy using pair energy approximation and cluster energy approximation methods will be discussed.

S.100238 Elastic yielding after step shear and shear banding in LAOS: Is there any edge effect?

XIN LI, SHI-QING WANG, The University of Akron — One of the most striking findings in our recent exploration of nonlinear rheological behavior of entangled polymers is the discovery that a suddenly sheared sample cannot relax quiescently. In both solutions \([1]\) and melts \([2]\), particle-tracking velocimetric (PTV) observations reveal macroscopic motions after a large step shear. The present work takes a significant step forward to examine whether such cohesive failure upon shear cessation could arise from the experimental imperfection due to the presence of the free surface, i.e., the meniscus. By adopting a new setup to insure that the edge only undergoes a small strain and therefore suffers no failure of any kind, we determine how the sample interior would undergo elastic yielding in the form of macroscopic motions during stress relaxation upon a large step strain. The same device also allows us to illustrate that the previously observed shear banding in large amplitude oscillatory shear (LAOS) \([3]\) is also an inherent response to the imposed LAOS, free of any edge effects. \([1]\) S. Ravindranath and S. Q. Wang, Macromolecules 40, 8031 (2007). \([2]\) P. Boukany and S. Q. Wang, Macromolecules, to be submitted (2009). \([3]\) S. Ravindranath and S. Q. Wang. J. Rheol. 52, 341 (2008).

S.100239 Exploring origins of nonlinearity in large amplitude oscillatory shear of different viscoelastic materials

XIN LI, The University of Akron, XIAORONG WANG, Bridgestone Americas Center for Research and Technology, SHI-QING WANG, The University of Akron — The present work studies nonlinear behavior in large amplitude oscillatory shear (LAOS) of three different polymeric materials using both rheometric and particle-tracking velocimetric measurements. We show that nonlinearity in LAOS is often not inherent response of the polymers that are capable of rearranging their microstructures over time. For instance, a highly viscoelastic material made of nano-sized polybutadiene particles exhibits homogeneous deformation and a nearly perfect single-harmonic sinusoidal wave in its stress response despite strong strain softening. In a second example of a well entangled polymer solution, the structural alternation in LAOS occurs non-homogeneously, where the nonlinearity also took a finite time to develop to its fullest. In the last example of wall slip, contrary to the literature claim that it should violate the mirror symmetry, the stress response only involves odd-harmonics, i.e., there is equivalence during steady-state wall slip in LAOS when the direction of shear is reversed.

S.100240 Undulatory swimming of a sandfish lizard in granular media\(^1\), DANIEL GOLDMAN, RYAN MALADEN, CHEN LI, YANG DING, Georgia Tech — We study the locomotion of the desert dwelling sandfish lizard (Scincus scincus) as it dives into and swims beneath the surface of sand (300\(\mu\)m glass beads). Above the surface, the animal uses a diagonal gait to move rapidly across the sand. High speed \(x\)-ray imaging reveals that once subsurface the animal no longer uses limbs for propulsion but instead folds the limbs against the body and generates thrust using a large amplitude undulatory motion consisting of a traveling wave with frequency \(f\) that propagates down the body with one wave period. The forward swimming speed \(v\) (maximum 10 cm/sec) increases with increasing \(f\). We measure \(v\) versus \(f\) as a function of packing fraction of the material \(\phi\). To predict \(v\) as a function of \(f\) and \(\phi\), we model the animal as a series of elements, each which produces thrust and experiences drag along its surface. We measure thrust and drag coefficients by performing drag measurements on a small stainless steel rod (grain-rod friction comparable to the animal’s skin) as a function of rod angle, rod speed, and \(\phi\). Integrating the drag law over a sinusoidal wave form accurately predicts the \(v = f\) relationship of the animal in loose and close packed granular media.

S.100241 Characteristics of top-gate ZnO thin film transistors grown on glass substrate by pulsed laser deposition, TOSHIHIKO MAEMOTO, KENJI FUJWARA, TAICHI YOSHIDA, SHIGEHKO SASA, MASATAKA INOUE, Osaka Institute of Technology — We report on the fabrication and characterization of top-gate ZnO thin film transistors (TFTs) using glass substrates. High quality ZnO epitaxial films were grown on glass substrates (Corning \#1737) by pulsed laser deposition. The thickness of the films was in the range of 50-100 nm. The growth temperature was set to 380°C. These films were characterized by \(x\)-ray diffraction, and Hall effects measurements. Highly \(c\)-axis oriented ZnO(0002) reflections corresponding to the wurtzite-phase were observed for all the films, indicating that these films grow epitaxially as a crystalline single phase on a glass substrate. The Hall effects measurements show that we have succeeded in fabricating a ZnO film with an electron mobility of 36 cm²/Vs on a glass substrate. Top-gate ZnO TFTs were fabricated by photolithography and wet chemical etching. The ohmic contact metal Ti/Au was deposited by electron beam evaporation. The top gate electrodes and the gate insulator SiO₂ were finally deposited by electron beam deposition. A room temperature characteristic of ZnO TFT with 50 \(\mu\)m gate length was an n-channel depletion type with a transconductance of 5.4 mS/mm. The off current was less than 10\(^{-9}\) A and the on/off current ratio was about 10\(^5\) at \(V_{DS} = 5\) V.

S.100242 Stabilization of Ti-Zr-Ni quasicrystals by hydrogen and application as renewable energy storage materials\(^1\), SANG-HWA LEE, JAE-KYUN JEON, SOO-BIN CHOI, JAE-YONG KIM, Hanyang University, INST TEAM — We prepared quasicrystal samples by rapidly quenching of Ti₆₃₋ₓZrₓTaₓNi₂₀ alloys (where 0 ≤ x ≤ 10), and measured equilibrium vapor pressures of hydrogen using a lab-built computer-controlled-absorption apparatus at elevated temperatures. To activate the hydrogen absorption, we removed a thin oxygen layer on the surface of the sample by using a plasma etching in a partial pressure of Ar and applied an immediate thin Pd coating by using a physical vapor deposition. As a result, the equilibrium vapor pressures of hydrogen in the QCs were lower than 5 Torr at below 300°C, and were increased as lowering the temperature. The maximum value of the H/M was also increased as increasing the temperature. Interestingly, the coherence length of the QCs was increased from 180 to 270 µm gate length was an n-channel depletion type with a transconductance of 5.4 mS/mm. The off current was less than 10\(^{-9}\) A and the on/off current ratio was about 10\(^5\) at \(V_{DS} = 5\) V.

S.100243 Semiconductor-metal transition of Se in Ru-Se Catalyst Nanoparticles, P.K. BABU, Department of Physics, Western Illinois University, ADAM LEWERA, Department of Chemistry, Warsaw University, Poland, ERIC OLDFIELD, ANDRZEJ WIECKOWSKI, Department of Chemistry, University of Illinois at Urbana-Champaign — Ru-Se composite nanoparticles are promising catalysts for the oxygen reduction reaction (ORR) in fuel cells. Though the role of Se in enhancing the chemical stability of Ru nanoparticles is well established, the microscopic nature of Ru-Se interaction was not clearly understood. We carried out a combined investigation of \(^{125}\)Se NMR and XPS on Ru-Se nanoparticles and our results indicate that Se, a semiconductor in elemental form, becomes metallic when interacting with Ru. \(^{125}\)Se spin-lattice relaxation rates are found to be proportional to \(T\), the well-known Korringa behavior characteristic of metals. The NMR results are supported by the XPS binding energy shifts which suggest that a possible Ru—Se charge transfer could be responsible for the semiconductor→metal transition of Se which also makes Ru less susceptible to oxidation during ORR.
S1.00244 Morphology Characterization of Polymer Nanocomposites using Electron Tomography and Analytical TEM, LAWRENCE DRUMMY, UES Inc., RICHARD VAIA, Air Force Research Laboratory — Polymer nanocomposites often display complex hierarchical structures that require high resolution morphological and chemical analysis. Here we describe methods for and quantitative results from electron tomography of polymer layered silicate nanocomposites. High angle annular dark-field scanning transmission electron microscopy (HAADF-STEM) and subsequent tomographic reconstruction produced fully segmented 3D data sets from the nanocomposites. A 3D power spectrum of the fast Fourier transform (FFT) was calculated, radially integrated, and compared with the one dimensional SAXS from the same sample. As a tool for determination of nanoparticle global dispersion, the analysis revealed good agreement between the techniques from the sub-nm regime up to a length scale of 1 micron. Currently, energy filtered TEM and energy dispersive spectroscopy in STEM mode are being investigated for providing high spatial resolution chemical information at interfaces and inhomogeneities in polymer nanocomposites.

S1.00245 Interlayer Thermal Coupling of Hot Dirac Fermions in Epitaxial Graphene, DONG SUN, CHARLES DIVIN, TEO NORRIS, CLAIRE BERGER, WALT DE HEER, PHILLIP FIRST, CENTER FOR ULTRAFAST OPTICAL SCIENCE, UNIVERSITY OF MICHIGAN, ANN ARBOR, MI 48109-2099 COLLABORATION, DEPARTMENT OF PHYSICS, GEORGIA INSTITUTE OF TECHNOLOGY, ATLANTA, GA, 30332 COLLABORATION — Degenerate and nondegenerate ultrafast pump-probe spectroscopy is used to study interlayer thermal coupling of hot Dirac Fermions in carbon face epitaxial graphene. The hot carriers in lightly doped and undoped graphene layers are selectively excited by the pump laser while leaving the carriers in the heavily doped layer not directly excited. Within the 500fs, carriers at elevated temperature in the heavily doped layer is observed, which is excited due to the interlayer thermal coupling of the hot carriers.

S1.00246 Exploring origin of instabilities in pressure-driven flow of entangled polymers using particle-tracking velocimetric method, XIANGYANG ZHU, SHI-QING WANG, University of Akron — Well entangled polymeric materials undergo extrudate distortions commonly known as sharkskin (semifluid melt state) and gross melt fracture. Particle-tracking velocimetric (PTV) observations have been carried out to explore the relationship between gross melt fracture and entry flow instability based on polybutadiene melts. The sharkskin formation process has also been investigated based on PTV visualization of the flow field at the die exit. These instabilities have been studied in terms of the material parameters.

S1.00247 Morphology and structure of the self assembled Ag nanodots on undoped Si(100) under ambient conditions, JEFFREY PARKS, INDIRAJITH SENEVIRATHNE, Lock Haven University of Pennsylvania — Self assembly is an important bottom up design approach in making nanostructures on substrate. Therefore understanding the self assembly mechanisms is very important. Morphology and structure of the self assembled Ag nano dots via sputter deposition on the chemically cleaned ambient undoped Si(100) wafer at RT (−300K) is observed via contact mode Atomic Force Microscopy (AFM). At a Ag coverage of ∼60ML nucleation of the nanodots were seen, implying StranskiKratov growth mode. At a coverage of ∼120ML the self assembled nanodots are clearly seen. These nanodots are observed to have ∼40nm in width and ∼10nm in height. At increase Ag coverage (∼120ML and ∼180ML) it is observed the number density of Ag nanodots increase in lock step. Higher the coverage size characteristics observed to show a higher variance. When annealed at successively higher temperatures (∼373K, ∼473K, ∼573K) for an interval of 5min the structures seem to dissolve, implying kinetically limited growth. Conductivity measurements on these nanostructures will also be discussed.

S1.00248 Study on the formation of rhenium borides by density functional calculations, R.R. AGUNDEZ, Facultad de Ciencias, UABC, G. SOTO, M.G. MORENO, A. REYES-SERRATO, Centro de Nanociencias y Nanotecnologa, UNAM — The searching of hard and superhard materials is a hot topic in material science. Two known factors are fundamental to get high hardnes: (1) high valence-electron density; and (2) high number of electron in covalent bonds. The 5d-transition metals comply with requirement (1); so, the task is to fulfill condition (2) without expanding its native structure. Supposedly this is possible by developing interstitial alloys with elements of moderate electronegativity, like boron and/or carbon. This idea materializes in the very hard ReB2, which scratches the surface of diamond. This work is a study in the formation of rhenium borides by density functional calculations. Here, we want to reveal the changes that would occur in the hexagonal close packed lattice of Re as B is inserted into its interstitial sites. We cover compositions in ReBx from x = 0 to x = 3 in x steps of 0.125. B is positioned in octahedral and tetrahedral interstices of Re, and for each arrangements we have calculated cell volume, cohesive energy, bulk modulus, valence electron concentration, and energy density. Supported by FONDOS CONACyT 10013, SNI-ESTUDIANTES 2008-01, SOLICITUD: 103909.

S1.00249 Magnetic force microscopy studies of vortex states in type II superconductors and ferrromagnetic microstructures, JEFFREY WRIGHT, UCLA Department of Physics and Astronomy, EVGUENI NAZARETSKI, Los Alamos National Laboratory, P. C. HAMMLE, Ohio State University Department of Physics, ROMAN M.ovshovich, Los Alamos National Laboratory — A variable temperature, high sensitivity Magnetic Force Microscope (MFM) was used to study vortices in a superconducting niobium thin film, as well as ferromagnetic microstructures, whose magnetization forms a vortex ground state. The highly sensitive interferometric detection of the cantilever displacement allowed for detailed measurements of the magnetic field profile produced by individual vortices. The MFM’s variable temperature ability and superconducting magnet allowed for field cooling of the niobium sample in an external magnetic field either parallel or anti-parallel to the orientation of the cantilever magnetic tip. MFM studies of 50 nm thick and 4 μm diameter permalloy microstructures were performed at room temperature and at 4.2K. At room temperature, the sample’s magnetization exhibited the dipole structure while at 4.2K it showed the evidence for a higher variance. By merging the MFM tip close to the sample we were able to reverse the orientation of individual vortices.

S1.00250 Simulation Coherent Quantum Processes in Many-Body Systems Using Classical Trajectories, CRAIG MARTENS, University of California, Irvine — We describe a method for the simulation of coherent quantum dynamics in many-body systems. The approach is based on the semiclassical limit of the multistate quantum Liouville equation and solution using classical trajectory ensembles. The method is applied to modeling nonadiabatic quantum dynamics and the creation, evolution, and decay of quantum coherence in condensed phase systems. The role of environmental interactions in inducing—or delaying—ultrafast electronic decoherence of molecules in condensed phases is investigated. In addition, simulations of vibrational dephasing of an I2 diatomic molecule in cryogenic rare gas matrices are described. For I2 in Kr, excellent agreement with recent experimental results is obtained.

S1.00251 Effect of Atmospheric Conditions on Type and Depth of Polymer Damage Due to Ultra Violet Radiation, MACKENZIE SINDEN-REDDING, FROUZEH SABRI, J. COLE, University of Memphis, N. LEVENTIS, Missouri Science and Technology — The Earth’s atmosphere scatters, absorbs, and reflects the sun’s total incoming radiation reducing it by nearly 55%, thus also reducing UV which causes material damage at the Earth’s surface. Visually noticeable material changes often associated with UV exposure is a color shift, typically towards a yellow tint. In this work, we have explored the relationship between free radical generation and the color shift of two types of material: RTV 655 and Silica aerogels. The impact of atmospheric conditions on the amount and nature of free radicals generated, as well as the color shift, is the prime focus of this work. Both materials are of particular interest in space-related applications such as calibration targets for Mars landers. Investigative tools implemented are ESR technique, UV-Vis spectral analysis and X-ray diffraction studies. Both material types demonstrate a significant and similar spectral shift regardless of the presence or absence of atmospheric oxygen. However, not both exposure circumstances lead to a detectable ESR signal.
Surface layer. Regardless of surface morphology, the film-bulk is electronically and magnetically active. Many of the reported conclusions about electronic phase separation; rough films are phase separated while atomically flat films are homogeneous but have a more or less inactive structural distortions.

Ultrafast dynamics of plasma microclouds induced by strong-field ionization in atomic and molecular gases. Ryan Compton, Alex Filin, Dmitri Romanov, Robert Levits, Department of Physics, and Center for Advanced Photonics, Temple University, Philadelphia PA 19122 — The model presented for the ultrafast dynamics of laser-induced plasma channels reveals the connections among the fundamental processes of laser-induced tunnel ionization, plasma cooling dynamics of the produced plasma channel, and the residual fluorescence of the channel. The results obtained link the dynamic behavior of the underdense plasma formation with the internal degrees of freedom of the constituent species suggesting that related processes of much current interest, such as laser induced breakdown, laser induced ablation, and, further, atmospheric filamentation will depend sensitively on atomic and molecular constituents. This opens the way to optimizing plasma channel characteristics (bandwidth, coherence, brightness) to that desired for a particular experiment.

Attosecond dynamics of strong-field multielectron excitation in small molecules: the case of carbon dioxide. Stanley Smith, Dmitri Romanov, Temple University, Xiaosong Li, University of Washington, H. Bernhard Schlegel, Wayne State University, Robert Levits, Temple University — The electron dynamics of CO₂ interacting with a short IR (1.63 eV) three cycle pulse was theoretically investigated, as manifested by the instantaneous dipole oscillations. The pulse envelope shape (Gaussian or trapezoidal) is shown to control the residual dipole oscillations spectrum (which excited states are populated) and amplitude (or relative population in each state). The carrier envelope phase (for either envelope shape) changes markedly the excited state amplitudes. The windowed Fourier transform was used to extract the attosecond electron excitation dynamics during the pulse. This analysis shows the nonlinear excitation process to be much more complicated than the traditional excited state ladder climbing. In particular, (i) electron transfer plays a major role in the nonlinear excitation dynamics, and (ii) the two pronounced spectral peaks at ∼5 and ∼8.5 eV do not correspond to any single-phonon dipole-allowed transitions. The electron response in the directions orthogonal to the molecular axis was also simulated and, as expected, this response was smaller in magnitude than the response along the molecular axis.

Doping the golden buckyball: M@Au₁₆ clusters. Lei-Ming Wang, Wei Huang, Lai-Sheng Wang, Xiaocheng Zeng Collaboration, Detlef Schöoss Collaboration — The 16-atom gold cluster (Au₁₆) was previously found to possess an unprecedentedly hollow cage structure. Using photoelectron spectroscopy and density functional theory, we have investigated the possibility of doping the Au₁₆ cage with an external atom, M@Au₁₆ (M = Cu, Ag, Zn, In, Si, Ge, Sn, Fe, Co, Ni). We have found that doping the Au₁₆ cluster with a Cu, Ag, Zn or In atom does not significantly alter its structure, and the dopant atom sits inside with little distortion to the parent cage. However, the Si, Ge, Sn, atoms cannot be doped inside the Au₁₆ cage and they are found to completely change the structure of the parent cage due to the strong M-Au local interactions. The transition-metal-atom-doped species, M@Au₁₆ (M = Fe, Co, Ni), are found to be endohedral in nature with atomic-like magnetic moments and some minor structural distortions.

Correlations Between Thin-Film Manganite Morphology, Phase Separation, and Dead Surface Layers Investigated with STM. Simon Kelly, Federica Galli, Ivan Komissarov, Jan Aarts, Univ of Leiden — Thin-film colossal magnetoresistance manganites such as La₁₋ₓCaₓMnO₃ have now been intensively studied for more than a decade, but the issue of possible nanoscale electronic phase separation remains unresolved. Scanning Tunneling Microscopy / Spectroscopy (STS) has been pivotal in studying phase separation, but is hindered by being surface- rather than bulk-sensitive. For our sputtered LCMO films the data indicates a strong correlation between surface morphology and phase separation; rough films are phase separated while atomically flat films are homogeneous but have a more or less inactive surface layer. Regardless of surface morphology, the film-bulk is electronically and magnetically active. Many of the reported conclusions about electronic inhomogeneities measured by STS have been confused by this issue.

Enhancement in flux pinning in superconducting Bi-Sr-Ca-Cu-O. H. Yetis, A. Kilic, K. Kilic, A. Altinkok, M. Olutas, Abant Izzet Baysal University — It is shown that the pinning properties of Bi₁₋ₓPbₓBa₂Sr₂Ca₃Cu₄O₈₋₉ (BSCO) can be increased by drilling a macroscopic cylindrical hole (CH). To observe the enhancement in flux pinning two different standard and reverse procedures in measuring of the I − V curves were performed as functions of transport current (I), temperature (T) and external magnetic field (H). For a better description, during the measurements, the sweep rate (dI/dt) of transport current in I − V curves was varied. As the current cycles in up and down direction, it was observed that the presence of CH drilled in BSCO sample causes a dramatic increase in the hysteresis effects in I − V curves depending on dI/dt and changes the evolution of I − V curves as compared to that of similar measurements carried out in BSCO sample before drilling CH. Another important observation is the increase in the critical current value of BSCO with CH for increasing branch of I − V curve. The increase in width of hysteresis loops of I − V curves was interpreted as a kind of superheated regions. We show in this study that the surface effects in superconductors can be studied by applying the reverse procedure in I − V curves. Finally, it is also shown that the macroscopic cylindrical hole act as a macroscopic pinning center for flux lines.

The new piezoelectric single crystal obtained by the Ge doping in the α-quartz structure. M. Miclau, A. Grozescu, R. Bucur, M. Poenar, P. Vlazan, I. Grozescu, Natl. Institute R&D Electrochemistry and Condensed Matter, Romania, N. Miclau, Politehnica University, Romania, I. Muscutaru, Baldwin Wallace College, USA — The most interesting properties of the quartz-like crystals are its piezoelectric properties, which are strongly influenced by the intrinsic structural distortions of the material and the crystal growth conditions. Thus, physical properties such as coupling coefficient, the α ↔ β transition can be directly related to structural distortions in terms of the bridging angle. We propose a new way to increase the structural distortion, using Ge to dope the SiO₂ structure with respect to α-quartz structure type. Growth of α-SiGe₁₋ₓO₂ crystal was realized hydrothermally using a temperature gradient method. Single crystals were investigated by electron microprobe analysis, X-ray diffraction and atomic force microscopy. The results open the possibility to tune the piezoelectric properties of these materials by varying the chemical composition.
S1.00259 Fabrication and Characterization of Si Nanorod Arrays as Subwavelength Antireflection Structures, YI-RUEI LIN, JR-HAU HE, Natl Taiwan Univ — The structure of antireflection (AR) is widely utilized to suppress undesired reflection between different optical media for various optical applications. For example, Multilayered coatings are used on the surface of optical and optoelectronic devices. However, it is also suffered from the problems such as poor adhesion, thermal instability, and lattice mismatch. An alternative to multilayered coatings is to pattern the surface with a periodically structured array with the periodicity smaller than the wavelength of the incident light. Compared with multilayered AR coatings, subwavelength structure (SWS) surfaces are more stable and durable, because the AR structures are directly etched in the surface and there are no other materials involved. So far SWSs has been fabricated on silicon have been fabricated through various methods. In the present work, we demonstrated a simple method, which combines sub-wavelength-scale monolayer spheres with a reactive ion etching process, to fabricate AR structures of Si nanorod arrays (NWAs) with structural stability, low cost, and low temperature procedures. It was found that the reflectivity of Si substrates with NWAs was dramatically decreased at the wavelength of light from 400 to 800 nm. The reflectivity as a function of size of Si NWAs was discussed.

S1.00260 Reduction of thermal conductivity on n-type silicon germanium bulk alloy with nano-pores formation, XIAOWEI WANG, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, MILDRED DRESSELHAUS, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, GANG CHEN, Department of Mechanical Engineering, Massachusetts Institute of Technology, ZHIFENG REN, Department of Physics, Boston College, YUCHENG LAN, GAOHUA ZHU, GIRI JOSHI, DEZHI WANG, JIAN YANG, Department of Physics, Boston College, HOHYUN LEE, Department of Mechanical Engineering, University of Kansas, XIAOWEI WANG, Department of Physics, Boston College, HROW-MEE HO, Department of Electronic Engineering, National Taiwan University. Silicon-Germanium (SiGe) alloys have been the main thermoelectric materials in power generation devices operating from 500 °C to 1000 °C. The main challenge for enhanced thermal performance of Si-Ge system is the reduction of thermal conductivity. Here we report that by creating nano-pores, the thermal conductivity can be reduced to around 2 Wm⁻¹K⁻¹ with a little lower power factor. The nano-structured bulk alloy was made by first forming alloyed nano-pores from commercial grade Si and Ge chunks with the dopant phosphorous (P) powder and sulfur powder and then by hot pressing the powders for their compaction. Followed by annealing at 1050 °C, nano pores were created inside the bulk disc. Our results showed that nano pores are very effective to scatter phonons, thus reduce the thermal conductivity.

S1.00261 The Transition of Two Dimensional Hard Spheres Under Gravity from the Liquid to Solid State Using a Global Equation of State, ALISON E. KOSER, PAUL V. QUINN, SR., Kutztown University — Using a global equation of state, derived empirically from Liding, we can accurately model the density profile of two-dimensional hard spheres with diameter d and man cm under gravity temperature T\(_c\) and T\(_f\). When we compare our theoretical density profiles to MD simulated data, in a given system, if the temperature is below some critical value T\(_c\) obtained by the density profile, then crystallization occurs and we can solve for the number of frozen layers. Again, we compare out theoretical values for number of frozen layers with the number of frozen layers from the simulated data. In addition, we use the global equation to solve for the center of mass and its fluctuations as a function of T.

S1.00262 Geometrical Optics and Subwavelength Antireflection, CHOONG-HEE PARK, EFI, LTD., S. SHIN, RESEARCH CENTER OF MATERIALS SCIENCE, Tokyo Institute of Technology, Y. KAMIHARA, Materials and Structural Lab. Tokyo Inst. Tech., T. SHIMOJIMA, K. ISHIZAKA, T. KISS, M. OKAWA, ISSP U. Tokyo, X.-Y. WANG, C.-T. CHEN, CAS, Y. KAMIHARA, ERATO-SORST JST, in FRC, Tokyo Inst. Tech., M. HIRANO, Materials and Structural Lab. Tokyo Inst. Tech., S. SHIN, ISSP U. Tokyo — Laser photoemission spectroscopy is employed to investigate the electronic structures of LaFeAsO:F and LaFePO:F. We also find the high-T\(_c\) phase in LaFePO:F. LaFeAsO:F exhibits a temperature-dependent pseudogap extending over ~0.1 eV about the Fermi level at 250 K, whereas such a feature is absent in low-T\(_c\). LaFePO:F. We also find ~20-meV pseudogap features and signatures of superconducting gaps both in LaFeAsO:F and LaFePO:F. We discuss possible origin of the pseudogaps through comparison with the cuprates. [1] Y. Kamihara et al., JACS 128, 10012 (2006); 130, 3296 (2008). [2] Y. Ishida et al., arXiv:0805.2647.

S1.00263 Examination of the Motion of a System of Granular Material Subjected to Vertical Vibration, CARL E. FAUST, PAUL V. QUINN, SR., Kutztown University — Experiments are conducted using various granular materials subject to a vertical vibration. Qualitative data for the angle of repose is collected as a function of the initial height of the material in the container. Data is used to determine empirical relationships between the maximum angle of repose and container size. This is done for various materials of differing grain size. Also, qualitative observations are made of the surface shape and precession of the angle of repose.

S1.00264 Study of the operational properties of the Capillary Plasma Electrode (CPE) discharges, JOSE LOPEZ, DAVID JACOME, WEI-DONG ZHU, Saint Peter’s College, MARGARET FIGUS, Merck & Co., Inc., KURT H. BECKER, Polytechnic Inst. of NYU — Various approaches have been pursued to create stable atmospheric pressure discharges by extending the lifetime of the diffuse phase of the discharge to hundreds of microseconds. Previous research showed that the stability of the diffuse mode is dependent on the frequency (in the kHz range), gas type, mode of the excitation, and geometrical confinement. Some of the most promising approaches are based on the recognition of the arc formation in high-pressure plasmas can be avoided and stable high-pressure plasma can be generated and maintained when the plasma are spatially constricted to the dimensions of tens to hundreds of microns. The Capillary Plasma Electrode (CPE) discharge is stable to produce stable atmospheric pressure nonequilibrium plasma. The CPE is similar in design to the Barrier Electrode Discharge, but has perforated dielectrics. The configuration, aside from exhibiting a diffuse mode of operation, also exhibits the so-called “capillary jet” mode, in which the capillaries turn on and a bright plasma jet emerges from the capillaries. The capillary jets from adjacent capillaries overlap so that the discharge appears uniform when the electrode contains an array of holes. There appears to be a threshold frequency for the capillary jet formation, which is strongly dependent on the L/D ratio of the capillaries, where D is the diameter of the capillary and L its length. However, the operating principles and basic properties of this behavior are not well understood. The current work explores these modes of operations of the CPE by characterizing the electrical and optical emission properties of this discharge by examining a multi-hole discharge as well as a single capillary discharge reactor.

S1.00265 Direct Current Cathode Boundary Layer Xenon Discharge, WEI-DONG ZHU, LUAN TO, JOSE LOPEZ, Department of Applied Science and Technology, Saint Peter’s College, KURT BECKER, Polytechnic Inst. of NYU — Cathode boundary layer (CBL) discharge is a diffuse atmospheric pressure glow discharge usually generated between a capillary and a ring-shaped anode, separated by a dielectric layer with a thickness of several hundred micrometers. Self-organized patterns formation, excimer emission, and electrical properties of CBL discharges in a direct current operation have been thoroughly studied by Schoenbach and co-workers at various pressures in xenon with mainly molybdenum as the electrode material. However, no detailed assessment of the effect of the cathode material on the self-organized pattern formation and cathode material modification by the CBL discharge has been reported. This study focuses on the electrical characteristics of the cathode material on the cell-organized pattern formation and cathode material modification by the CBL discharge. We have investigated the effects of several cathode materials at pressures of 100 Torr and 250 Torr. Cathode material modification by CBL discharge will be briefly assessed.
3:06PM T1.00002 Ultrasensitive magnetometry and magnetic resonance imaging using cantilever detection1, DANIEL RUGAR, IBM — Micromachined cantilevers make remarkable magnetometers for nanoscale measurements of magnetic materials and for magnetic resonance imaging (MRI). We present various applications of cantilever magnetometry at low temperature using cantilevers capable of attoneutron force sensitivity. Small, unexpected magnetic effects can be seen, such as anomalous damping in magnetic field. A key application is magnetic resonance force microscopy (MRFM) of both electron and nuclear spins. In recent experiments with MRFM-based MRI imaging, 3D spatial resolution better than 10 nm was achieved for protons in individual virus particles. The achieved volumetric resolution represents an improvement of 100 million compared to the best conventional MRI. The microscope is sensitive enough to detect NMR signals from adsorbed layers of hydrocarbon contamination, hydrogen in multilayer carbon nanotubes and the phosphorus in DNA. Operating with a force noise on the order of 6 aN per root hertz with a magnetic tip that produces a field gradient in excess of 30 gauss per nanometer, the magnetic moment sensitivity is ~0.2 Bohr magnetons. The corresponding field sensitivity is ~3 nT per root hertz. To our knowledge, this combination of high field sensitivity and nanometer spatial resolution is unsurpassed by any other form of nanometer-scale magnetometry.

1Work performed in collaboration with H. J. Mamin, M. Poggio, C. L. Degen, T. Oosterkamp and C. T. Rettner

3:42PM T1.00003 Ferromagnetic Resonance Imaging with Magnetic Resonance Force Microscopy, DENIS PELEKHOV, The Ohio State University — Magnetic resonance force microscopy achieves very high resolution three-dimensional imaging capabilities of magnetic resonance imaging by taking advantage of very high sensitivity mechanical force detection. This enables non-contacting, microscopic studies and imaging of a broad range of materials. As a consequence of the strong interactions between spins, the assumptions underlying conventional MRI are not applicable to FMR imaging. However, using a new approach to localizing the resonant volume in an FMR measurement founded on the strong, nonuniform magnetic field of the micromagnetic probe tip, we have demonstrated scanned probe Ferromagnetic Resonance (FMR) imaging [1]. The scanned probe FMR images obtained in patterned ferromagnetic films are well explained by detailed numerical modeling. In addition to illuminating the mechanisms underlying localized FMR, the model provides the basis for submicron scanned probe FMR imaging of films and buried ferromagnetic elements. This work was supported by the U.S. Department of Energy through Grant No. DE-FG02-03ER46054.

4:18PM T1.00004 Ultrafast magnetization dynamics of cobalt nanoparticles and individual ferromagnetic dots, JEAN-YVES BIGOT, Institut de Physique et Chimie des Matériaux de Strasbourg, UMR7504, CNRS-ULP, Strasbourg 67034 — The ultrafast magnetization dynamics of magnetic materials can be investigated using femtosecond laser pulses to perform femtosecond magneto-optical Kerr and Faraday measurements [1]. In this talk, we will focus on the magnetization dynamics of cobalt nanoparticles which are either ferromagnetic or super-paramagnetic at room temperature and on the dynamics of individual ferromagnetic dots. In the first case (Co nanoparticles), we will demonstrate that the magnetization dynamics preceding the fluctuations over the anisotropy energy barrier is coherent but exhibits a strongly damped precession [2]. These results, which have been obtained with a three dimensional analysis of the magnetization vector [3] will be discussed in the context of the Néel-Brown models involving the gyromagnetic character of the magnetization. We will also examine the dynamics of self-organized supra-crystals of cobalt nanoparticles [4]. In the second case, we will present the ultrafast magnetization dynamics of individual ferromagnetic dots (COPt3, Permalloy, Nickel) made either by e-beam lithography or induced optically on thin films deposited on sapphire and glass substrates. The technique employed is the magneto-optical pump probe imaging (MOPPI) which allows performing time resolved magnetic-optical Kerr images with with spatial and temporal resolutions of 300 nm and 150 fs [5]. The study of the demagnetization of the dots for different laser intensities shows that it is possible to write and read ultrafast monodomains on thin films.

4:54PM T1.00005 Magnetic soft X-ray microscopy: Towards imaging ultrafast spin dynamics on the nanoscale1, PETER FISCHER, CXRO/LBNL Berkeley CA — Modern magnetic microscopies are challenged with providing spatial resolution in the nanometer regime, a time resolution on a fs scale and elemental specificity to allow for studying multifunctional magnetic nanostructures and their ultrafast spin dynamics. Magnetic soft X-ray microscopy combines X-ray magnetic circular dichroism (X-MCD) as element specific magnetic contrast mechanism with high spatial and temporal resolution. Fresnel zone plates provide a spatial resolution down to currently <15nm [1] with current developments approaching the 10nm regime thus approaching fundamental magnetic length scales. Utilizing the inherent time structure of current synchrotron sources fast magnetization dynamics with 70ps time resolution, limited by the lengths of the electron bunches, can be performed with a stroboscopic pump-probe scheme. Soft X-ray microscopy at upcoming high brilliant fsc X-ray sources makes snapshot images of fsc spin dynamics feasible. In this talk I will present recent results on the study of the stochastic character in magnetization reversal and domain wall pinning [2] as well as on time resolved imaging of current induced resonant vortex core motion which allows to determine spin polarization of currents [3]

2:30PM T1.00001 Chiral magnetic order at surfaces driven by inversion asymmetry, MATTHIAS BODE, Argonne National Lab — No abstract available.

Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T2 DCMP DMP: Electron, Exciton and Phonon Interactions in Nanoparticles Spirit of Pittsburgh Ballrom BC
3:06PM T2.00002 Controlled Crystallinity and Fundamental Coupling Interactions in Nanocrystals

MIN OUYANG, University of Maryland at College Park — Metal and semiconductor nanocrystals show many unusual properties and functionalities, and can serve as model system to explore fundamental quantum and classical coupling interactions as well as building blocks of many practical applications. However, because of their small size, these nanoparticles typically exhibit different crystalline properties as compared with their bulk counterpart, and controlling crystallinity (and structural defects) within nanoparticles has posed significant technical challenges. In this talk, I will firstly apply silver metal nanoparticles as an example and present a novel chemical synthetic technique to achieve unprecedented crystallinity control at the nanoscale. This engineering of nanocrystallinity enables manipulation of intrinsic chemical functionalities, physical properties as well as nano-device performance [1]. For example, I will highlight that electron-phonon coupling constant can be significantly reduced by about four times and elastic modulus is increased ~40% in perfect single crystalline silver nanoparticles as compared with those in disordered twinned nanoparticles. One important application of metal nanoparticles is nanoscale sensors. I will thus demonstrate that performance of nanoparticles based molecular sensing devices can be optimized with three times improvement of figure-of-merit if perfect single crystalline nanoparticles are applied. Lastly, I will present our related studies on semiconductor nanocrystals as well as their hybrid heterostructures. These discussions should offer important implications for our understanding of the fundamental properties at nanoscale and potential applications of metal nanoparticles.

3:42PM T2.00003 New Developments in Nanocrystal Lasing: Type-II Nanostructures and “Giant” Quantum Dots

VICTOR KLIOMOV, Los Alamos National Laboratory — Nanocrystal (NC) quantum dots show high photoluminescence quantum yields and size-dependent emission colors tunable through the quantum-confinement effect. Despite their favorable light-emitting properties, NCs are difficult to use in optoelectronic applications due to a low balance between carrier absorption and stimulated emission in nanocrystals excited with single excitons. Optical gain can only occur due to NCs that contain at least two excitons. A resulting complication is fast optical-gain decay induced by nonradiative Auger recombination, a process in which one exciton recombines by transferring its energy to another. In this talk, I will discuss two approaches for resolving the problem of ultrafast Auger recombination in NCs. In one approach, we utilize core/shell hetero-NCs engineered in such a way as to spatially separate electrons and holes between the core and the shell (type-II heterostructures). The resulting imbalance between negative and positive charges produces a strong local electric field, which induces a large, ~100 meV transient Stark shift of the absorption spectrum with respect to the luminescence band. This effect breaks the exact balance between absorption and stimulated emission and allows us to demonstrate optical amplification in the single-exciton regime when Auger recombination is simply inactive. In another approach, we use recently developed “giant” dots that comprise a small emitting CdSe core overcoated with a thick shell (up to 20 monolayers) of a wider-gap CdS. These nanostructures produce a peculiar quasi-type-II localization regime, which develops as a result of a significant difference in effective volumes of the electron and hole wave functions. These structures show greatly suppressed Auger recombination, which allows us to realize broadband optical gain (extends over Δ~400 meV) due to multie excitons of various orders with an excitation threshold, which is at least a thousand times lower than in regular CdSe NCs.

4:18PM T2.00004 Plasmon-enhanced Absorption, Modulation and Spontaneous Emission in Semiconductor Quantum Dots and Films

HARRY ATWATER, California Institute of Technology — Recent advances in plasmon dispersion and localization in quantum dot layers and semiconductor thin films have enabled study of several phenomena in coupled metal/semiconductor nanophotonic structures, including i) enhanced spontaneous emission in quantum dots, ii) all-optical modulation of plasmon propagation in quantum dot active media, and iii) enhanced absorption in plasmonic solar cells. Metal-dielectric plasmon waveguides with quantum dot active layers can serve as switching elements when the complex refractive index is actively modulated. We demonstrate all-plasmonic modulation in which the complex refractive index seen by a surface plasmon polariton at an infrared free-space wavelength of 1420 nm is modulated via interband excitation of the quantum dots at a visible wavelength of 514 nm. Metallic nanostuctures can excite surface plasmons which can dramatically increase the optical path length in thin active photovoltaic layers to enhance overall photoabsorption, with potential for increased photovoltaic conversion efficiency, and new solar cell device designs. The strong mode localization of surface plasmon polaritons at metal-dielectric interfaces leads to strong absorption in very thin semiconductor films, enabling a dramatic (10-100X) reduction in the semiconductor absorber physical thickness needed to achieve optical thickness. Modal analysis in full wave simulation allows us to determine the fraction of power absorbed for both dielectric waveguide and plasmonic modes in a thin solar cell.

4:54PM T2.00005 Exciton-plasmon interactions and energy transfer in nanoparticles

ALEXANDER GOVOROV, Ohio University — Energy transfer between optically-excited nanocrystals coupled by the Coulomb interaction can be very efficient. The interaction of excitons and plasmons in nanocrystals leads to several effects: energy transfer between nanoparticles (NPs), electromagnetic enhancement, reduced exciton diffusion in nanowires (NWs), exciton energy shifts, and interference and non-linear phenomena [1-3]. Using kinetic equations for excitons, we model exciton transport in a NW and explain the origin of the blue shift of exciton emission observed in the recent experiments on hybrid NW-NP assemblies [2]. We also model artificial light-harvesting complexes composed of chlorophylls, bacterial reaction centers, and NPs [3]. Using superior optical properties of metal and semiconductor NPs, one can strongly enhance the efficiency of light harvesting [3]. An interaction between a discrete state of exciton and a continuum of plasmonic states can give rise to interference effects (Fano-like asymmetric resonances). These interference effects greatly enhance visibility of relatively weak exciton signals and can be used for spectroscopy of single nanoparticle and molecules. In the nonlinear regime, the Fano effect becomes strongly amplified [4]. In conclusion, our theory explains present experimental results and also provides motivation for future experiments and applications. Potential applications of dynamical exciton-plasmon systems include sensors and light-harvesting. The above theoretical studies were performed in collaboration with several groups [1-4].

Supported by NSF and Air Force Research Labs.
the collection of information from wideband signals such as noise, and an entry into the domain of quantum electrical signals. I will review some of our early devices are not well-matched to the fifty ohm world of microwaves, the ability to listen to signals coming from a cryogenic nanostructure with a wideband

Devices, ROBERT SCHOELKOPF, Departments of Applied Physics and Physics, Yale University — Typical measurements of mesoscopic devices at low temperatures suffer from annoyingly low speeds and the presence of excess low-frequency noise that can try the experimentalist’s patience. Even though these devices are not well-matched to the fifty ohm world of microwaves, the ability to listen to signals coming from a cryogenic nanostructure with a wideband amplifier at gigahertz frequencies has proven quite beneficial. These techniques can be surprising precise and powerful, allowing access to high-speed dynamics, the collection of information from wideband signals such as noise, and an entry into the domain of quantum electrical signals. I will review some of our early experiments at Yale in this area, especially the development of the Radio-Frequency Single-Electron Transistor (RF-SET), which is still the most sensitive electrometer known. Today we find that microwave measurements are proving highly beneficial for solid-state quantum computing, which in turn is leading to a new wave of capabilities for generating and measuring microwave signals at the single photon level.

3:06PM T3.00002 Near-Quantum-Limited SQUID Amplifier, JOHN CLARKE, University of California, Berkeley and Lawrence Berkeley National Laboratory — The SET (Single-Electron Transistor), which detects charge, is the dual of the SQUID (Superconducting QUantum Interference Device), which detects flux. In 1998, Schoelkopf and co-workers introduced the RFSET, which uses a resonance circuit to increase the frequency response to the 100-MHz range. The same year saw the introduction of the Microstrip SQUID Amplifier (MSA) in which the input coil forms a microstrip with the SQUID washer, thereby extending the operating frequency to the gigahertz range. I briefly describe the theory of SQUID amplifiers involving a tuned input circuit with resonant frequency \( f \). For an optimized SQUID at temperature \( T \), the power gain and noise temperature are approximately \( G = f / f_p \) and \( T_N = 20 \pi f f_p \), respectively, where \( f_p \) is the plasma frequency of one of the Josephson junctions. Because the SQUID voltage and current noise are correlated, however, the optimum noise temperature is at a frequency below resonance. For a phase-preserving amplifier, \( T_N = (1/2 + A)hf/k_B \), where Caves’ added noise number \( A = 1/2 \) at the quantum limit. Simulations based on the quantum Langevin equation (QLE) suggest that the SQUID amplifier should attain \( A = 1/2 \). We have measured the gain and noise of an MSA in which the resistive shunts of the junctions are coupled to cooling fins to reduce hot electron effects. The minimum value \( A = 1.1 \pm 0.2 \) occurs at a frequency below resonance. On resonance, the value \( A = 1.5 \pm 0.3 \) is close to the predictions of the QLE, suggesting that this model may fail to predict the cross-correlated noise term correctly. Indeed, recent work suggests that a fully quantum mechanical theory is required to account properly for this term. This work is in collaboration with D. Kinion and supported by DOE BES.

3:42PM T3.00003 Optomechanics with microwave light, KONRAD LEHNERT, JILA: University of Colorado and NIST — Recently, superconducting circuits resonant at microwave frequencies have revolutionized the measurement of astrophysical detectors and superconducting qubits [2]. In this talk, I will describe how we extend this technique to measuring and manipulating nanomechanical oscillators. By strongly coupling the motion of a nanomechanical oscillator to the resonance of the microwave circuit we create structures where the dominant dissipative force acting on the oscillator is the radiation pressure of microwave “light” [3]. These devices are ultrasonic force detectors and they allow us to cool the oscillator towards its motional ground state.

4:18PM T3.00004 Noise in Mesoscopic, Quantum, and Nano-Systems, IRFAN SIDDIQI, University of California, Berkeley — Superconducting circuit elements can be used to form high quality factor harmonic and anharmonic oscillators. When coupled to a pseudospin system, these oscillators can be used for quantum state measurement. In the dispersive limit, the oscillator resonant frequency depends on the spin state. The case of a linear transmission line resonator coupled to a superconducting qubit was demonstrated by R. Schoelkopf and co-workers [1]. We will describe quantum measurement performed using a nonlinear resonator consisting of a Josephson tunnel junction shunted with a reactive impedance. The Josephson oscillator is excited with an increasing number of photons, its resonant frequency progressively decreases. Under appropriate bias conditions, it is also possible to access a bifurcation where two dynamical states exist. We will show that with a nonlinear Josephson oscillator, it is possible to realize both analog and digital quantum state measurement with variable gain. We will discuss two protocols for accessing the nonlinear response of the junction, amplitude modulation and frequency modulation, and describe in detail two applications—superconducting qubit readout and high speed magnetometry of single molecule magnets.

Wednesday, March 18, 2009 2:30PM - 5:30PM – Session T4 DCMP DAMOP: Polariton Condensates 306/307

2:30PM T4.00001 Theory of polariton condensation, PETER LITTLEWOOD, University of Cambridge — Lately, some novel experiments with planar optical microcavities make use of the mixing of excitons with photons to create composite bosons called polaritons that have a very light mass, and are thus a good candidate for high-temperature Bose condensation. Good evidence for spontaneous coherence has now been obtained. There are special issues to resolve, considering the effects of low dimensionality, disorder, strong interactions, and especially strong decoherence associated with decay of the condensate into environmental photons—since the condensate is a special kind of laser.

3:06PM T4.00002 Bose-Einstein Condensation of Microcavity Polaritons in Harmonic Traps. DAVID SNOKE, Department of Physics and Astronomy, University of Pittsburgh — Polaritons in microcavities are a two-dimensional, weakly interacting boson gas, and their spatial distribution, momentum distribution, coherence properties, and excitation spectrum can all be observed. In several recent experiments, these observations are consistent with the interpretation of a quasiequilibrium Bose condensate of polaritons. In our experiments, we use a special stress geometry to create a harmonic potential for the polaritons in the plane of their motion, which is analogous to the traps used in experiments on BEC of cold atoms. Among other effects, we observe coherent light emission from the polariton condensate. Two questions arise: 1) Since the system emits coherent light, how can we distinguish it from a standard laser? 2) How do we distinguish it from some type of nonlinear amplification of the excitation light? In our experiments with a trapping potential, we can easily distinguish between these different effects. We demonstrate two transitions which occur in the same place in the same structure, one which is standard lasing and one which is polariton condensation. The quasiequilibrium polariton condensate in microcavities thus emerges as a new type of coherent light emitter.

3:42PM T4.00003 Observation of Bogoliubov excitations in exciton-polariton condensates. YOSHIHISA YAMAMOTO, Stanford University — Particle-particle interaction and peculiar excitation spectra are keys for understanding BEC and superfluidity physics. A quantum field-theoretical formulation for a weakly interacting Bose condensed system was developed by Bogoliubov in 1947, which predicted the phonon-like excitation spectrum in the low-momentum regime. Exciton-polaritons in a semiconductor microcavity are elementary excitations created by strong coupling between quantum-well excitons and microcavity photons, were proposed as a new BEC candidate in solid-state systems. Recent experiments with exciton-polaritons have demonstrated several interesting signatures from the viewpoint of polariton condensation, such as quantum degeneracy at nonequilibrium densities, the polariton-bunching effect at the condensation threshold, long spatial coherence and quantum degeneracy at equilibrium conditions. The particle-particle interaction and the Bogoliubov excitation spectrum are at the heart of BEC and superfluidity physics, but have only been studied theoretically for exciton-polaritons. In this talk, we report the first observation of interaction effects on the exciton-polariton condensate and the excitation spectra, which are in quantitative agreement with the Bogoliubov theory.

4:18PM T4.00004 Quantum fluid dynamics and superfluid behaviour of polaritons in microcavities. DANIELE SANVITTO, Universidad Autonoma Madrid — Achievement of polariton condensation in semiconductor microcavities [1,2] has opened the way to the study of new interesting phenomena related to the behaviour of non-equilibrium Bose particles in the quantum limit. In this talk we will see the formation of a coherent quantum state of polaritons created at a given momentum and at a given time using a combination of a continuous wave pump and a pulsed probe. This state is observed to persist in the cavity for a time much longer than the cavity lifetime [3]. Using this technique we are able to investigate the behaviour of the quantum state of polaritons with an extension of ~ 20 µm moving a hundreds of monens within the cavity. One of the most striking effects of a moving polariton condensate is the observation of superfluid behaviour when crossing obstacles even at speeds only 100 times smaller than the speed of light [4]. Other interesting phenomena, which will be shown, are diffusion-less motion, due to the linearization of the polariton dispersion, and the formation of Cherenkov-like patterns for polaritons moving at supersonic velocities.

4:54PM T4.00005 Theory of polariton condensation and superfluidity1. ALEXEY KAVOKIN, University of Southampton — Exciton-polaritons in planar microcavities have two allowed spin projections on the axis of the structure, which is why they can be considered as a two-component weakly interacting Bose gas. The order parameter for BEC or the superfluid phase transition in this gas is a 2D vector analogous to the Jones vector of classical light. The build-up of the order parameter results is the build up of vector polarisation of light emitted by the polariton condensate. Recently observed near-field Cherenkov-like patterns for polaritons moving at supersonic velocities.

Wednesday, March 18, 2009 2:30PM - 6:06PM — Session T5 FIAP DBP: Industrial Biophysics 401/402

2:30PM T5.00001 Virus Characterization by FFF-MALS Assay. VLADIMER RAZINKOV, Amgen, Inc. — Adequate biophysical characterization of influenza virions is important for vaccine development. The influenza virus vaccines are produced from the allantoic fluid of developing chicken embryos. The process of viral replication produces a heterogeneous mixture of infectious and non-infectious viral particles with varying states of aggregation. The study of the relative distribution and behavior of different subpopulations and their inter-correlation can assist in the development of a robust process for a live virus vaccine. This report describes a field flow fractionation and multilayer light scattering (FFF-MALS) method optimized for the analysis of size distribution and total particle counts. A method using a combination of asymmetric flow field-flow fractionation (AFFFF) and multilayer light scattering (MALS) techniques has been shown to improve the estimation of virus particle counts and the amount of aggregated virus in laboratory samples. The FFF-MALS method was compared with several other methods such as transmission electron microscopy (TEM), atomic force microscopy (AFM), size exclusion chromatography followed by MALS (SEC-MALS), quantitative reverse transcription polymerase chain reaction (RT Q-PCR), median tissue culture dose (TCID(50)), and the fluorescent focus assay (FFA). The correlation between the various methods for determining total particle counts, infectivity and size distribution is reported. The pros and cons of each of the analytical methods are discussed.
3:06PM T5.00002 Determination of reversible protein equilibrium association coefficients using light scattering. MICHAEL LARKIN, Wyatt Technology Corporation — The characterization in solution of reversible protein associations as well as associations between proteins and small molecules is essential in many areas of science. Understanding cellular function or developing and formulating pharmaceuticals or other biologically active materials often requires quantitation of such associations. Most pharmaceuticals have functionality due solely to association with molecules within the body, and the discovery and accurate characterization of these associations is a key element for pharmaceutical development. Unfortunately, most methods used to measure associations of proteins require either immobilizing the protein on a surface (e.g. surface plasmon resonance), which potentially alters the protein characteristics, or require considerable time and effort and large quantities of sample (e.g. analytical ultracentrifugation, isothermal titration calorimetry). Light scattering based measurements of reversible association coefficients require much less sample and may be performed much more rapidly than other free solution techniques. In this talk I describe how static and dynamic light scattering may each independently be used to measure equilibrium association coefficients between proteins in free solution, and may also be used to observe and quantitate the association of small molecules with them. I present background theory for both static and dynamic light scattering measurements of equilibrium associations, and examples of measurements made of both model systems and of systems with commercial relevance in the pharmaceutical industry.

3:42PM T5.00003 Novel medical imaging technologies for disease diagnosis and treatment , DIEGO OLEGO, Philips Healthcare — New clinical approaches for disease diagnosis, treatment and monitoring will rely on the ability of simultaneously obtaining anatomical, functional and biological information. Medical imaging technologies in combination with targeted contrast agents play a key role in delivering with ever increasing temporal and spatial resolution structural and functional information about conditions and pathologies in cardiology, oncology and neurology fields among others. This presentation will review the clinical motivations and physics challenges in on-going developments of new medical imaging techniques and the associated contrast agents. Examples to be discussed are:

- The enrichment of computer tomography with spectral sensitivity for the diagnosis of vulnerable sclerotic plaque.
- Time of flight positron emission tomography for improved resolution in metabolic characterization of pathologies.
- Magnetic particle imaging -a novel imaging modality based on in-vivo measurement of the local concentration of iron oxide nano-particles - for blood perfusion measurement with better sensitivity, spatial resolution and 3D real time acquisition.
- Focused ultrasound for therapy delivery.

4:18PM T5.00004 Measurement Frontiers in Molecular Biology , STEPHEN LADERMAN, Agilent Laboratories, Agilent Technologies, 5301 Stevens Creek Blvd, Santa Clara, CA, 95051 USA — Developments of molecular measurements and manipulations have long enabled forefront research in evolution, genetics, biological development and its dysfunction, and the impact of external factors on the behavior of cells. Measurement remains at the heart of exciting and challenging basic and applied problems in molecular and cell biology. Methods to precisely determine the identity and abundance of particular molecules amongst a complex mixture of similar and dissimilar types require the successful design and integration of multiple steps involving biochemical manipulations, separations, physical probing, and data processing. Accordingly, today’s most powerful methods for characterizing life at the molecular level depend on coordinated advances in applied physics, biochemistry, chemistry, computer science, and engineering. This is well illustrated by recent approaches to the measurement of DNA, RNA, proteins, and intact cells. Such successes underlie well founded visions of how molecular biology can further assist in answering compelling scientific questions and in enabling the development of remarkable advances in human health. These visions, in turn, are motivating the interdisciplinary creation of even more comprehensive measurements. As a further and closely related consequence, they are motivating innovations in the conceptual and practical approaches to organizing and visualizing large, complex sets of interrelated experimental results and distilling from those data compelling, informative conclusions.

4:54PM T5.00005 Biophysics at the Boundaries: The Next Problem Sets , MALCOLM SKOLNICK — The interface between physics and biology is one of the fastest growing subfields of physics. As knowledge of such topics as cellular processes and complex ecological systems advances, researchers have found that progress in understanding these and other systems requires application of more quantitative approaches. Today, there is a growing demand for quantitative and computational skills in biological research and the commercialization of that research. The fragmented teaching of science in our universities still leaves biology outside the quantitative and mathematical culture that is the foundation of physics. This is particularly inopportune at a time when the needs for quantitative thinking about biological systems are exploding. More physicists should be encouraged to become active in research and development in the growing application fields of biophysics including molecular genetics, biomedical imaging, tissue generation and regeneration, drug development, prosthetics, neural and brain function, kinetics of nonequilibrium open biological systems, metabolic networks, biological transport processes, large-scale biochemical networks and stochastic processes in biochemical systems to name a few. In addition to moving into basic research in these areas, there is increasing opportunity for physicists in industry beginning with entrepreneurial roles in taking research results out of the laboratory and in the industries who perfect and market the inventions and developments that physicists produce. In this talk we will identify and discuss emerging opportunities for physicists in biophysical and biotechnological pursuits ranging from basic research through development of applications and commercialization of results. This will include discussion of the roles of physicists in non-traditional areas apart from academia such as patent law, financial analysis and regulatory science and the problem sets assigned in education and training that will enable future biophysicists to fill these roles.

5:30PM T5.00006 Characterizing Protein Complexes with UV absorption, Light Scattering, and Refractive Index Detection, STEVEN TRAINOFF, Wyatt Technology Corporation — Many modern pharmaceuticals and naturally occurring biomolecules consist of complexes of proteins and polyethylene glycol or carbohydrates. In the case of vaccine development, these complexes are often used to induce or amplify immune responses. For protein therapeutics they are used to modify solubility and function, or to control the rate of degradation and elimination of a drug from the body. Characterizing the stoichiometry of these complexes is an important industrial problem that presents a formidable challenge to analytical instrument designers. Traditional analytical methods, such as using fluorescent tagging, chemical assays, and mass spectrometry perturb the system so dramatically that the complexes are often destroyed or uncontrollably modified by the measurement. A solution to this problem consists of fractionating the samples and then measuring the fractions using sequential non-invasive detectors that are sensitive to different components of the complex. We present results using UV absorption, which is primarily sensitive to the protein fraction, Light Scattering, which measures the total weight average molar mass, and Refractive Index detection, which measures the net concentration. We also present a solution of the problem inter-detector band-broadening problem that has heretofore made this approach impractical. Presented will be instrumentation and an analysis method that overcome these obstacles and make this technique a reliable and robust way of non-invasively characterizing these industrially important compounds.

Wednesday, March 18, 2009 2:30PM - 5:30PM –
Session T6 FIP FGSA: Panel Discussion: Preparation of Graduate Students for Careers in a Globalized World
2:30PM T6.00001 Preparing for Change: Challenges and Opportunities in a Global World
SABINE O’HARA, Institute of International Education — Our world is becoming increasingly global. This may sound like a cliché, yet it is true nonetheless, and poses unprecedented challenges for graduate education. For the new generation of researchers, teachers and professionals to be successful they must be prepared in more than the content area of their chosen field. They must also acquire proficiency in global awareness, cultural literacy, multicultural teamwork and language facility. These global skill sets form the basis for effective multicultural collaboration and will become increasingly important even for those who do not intend to study or work abroad. Knowledge has become more portable in the internet age; large data bases and reports can be accessed in real time from various locations around the globe; information is exchanged in multifaceted knowledge networks; collaborative research takes place within and outside of the traditional venue of the research university in the private sector, research institutes, and associations; research networks span multiple disciplines as progress invariably occurs at the intersection of previously discrete fields of inquiry. Global collaboration thus is no longer dependent on the physical proximity of collaborators but can take place anywhere any time. This then requires yet another set of skills, namely the ability to adapt to change, exhibit flexibility and transfer skills to a range of contexts and applications. Effective graduate education must address these realities and expose students to learning opportunities that will enable them to acquire these much needed global skills sets.

3:06PM T6.00002 International Experiences for Graduate Students: Opportunities and Challenges, AMY FLATTEN, APS Director of International Affairs — Graduate students are often well aware that their physics careers may involve international partnerships at some point. Many students, however, wish to pursue international experiences during their graduate physics training. The speaker will discuss some of the international opportunities available to graduate students and provide insights into some potential challenges of engaging internationally.

3:30PM T6.00003 Graduate studies in a globalized world¹, FATIHA BENMOHKTAR, Carnegie Mellon — In our days physics research, experiment and theory, is done in one way or an other in a framework of an international collaboration. As an experimental Medium Energy physicist, I will be talking about my experience in working within international collaborations for more than twelve years. I will go through a couple of questions graduates students should be asking: How is the work environment for a graduate student doing his or her research within these collaborations? What about language barriers? Can they be independent in their analysis? What will happen after getting their PhD? — and more.

¹ Thanks to the APS

3:54PM T6.00004 Physics Internationally From the Industrial Perspective, T. VENKATESAN, National University of Singapore — Physicists traditionally get employed by academia, National Labs and industry. The investment of multi-national companies in R&D and manufacturing operations globally has been accelerating owing to availability of trained human resources and the economy of operation. This has created tremendous opportunities for candidates with global experience as opposed to a highly localized education. In the last decade, the investments made by Asian academic institutions in education and research and seen a significant increase creating opportunities for Graduate students and researchers alike in parts of the world other than US and Europe, the traditional destinations for students and researchers over the last several decades. Many Asian universities are hiring a diverse faculty from all over the world as opposed to hiring from local talent pools. Many of the Asian countries are focusing on creating local hitech economies by fostering global entrepreneurship programs. In my talk I will discuss this globalization phenomenon with specific examples from both academia and industry. I will also discuss strategies for academic institutions in terms of making the appropriate modification to their programs to deal with this inevitable evolution.

4:18PM T6.00005 I2CAM and ICAM: Physics Internationally, DANIEL COX, University of California Davis — The Institute for Complex Adaptive Matter (I2CAM) through the National Science Foundation sponsored International Institute for Complex Adaptive Matter (ICAM) has, since its formal inception in 2002, grown into a 60+ branch international scientific network devoted to the study of emergent phenomena in correlated electron matter, soft matter, and biological matter. We conducts forefront research through a blend of discussion oriented workshops (at least 50% of the time for discussion), exchange awards for junior scientists to initiate collaborations between two groups, travel awards for junior scientists to present research work or carry out brief research, and schools on topical subject matter. We also supplement our federal funding with contributions from each branch which support postdoctoral and senior scientist fellowships and unique science outreach activities such as an online science museum (The Emergent Universe). We have also outreach activities to universities with substantial numbers of underrepresented groups in the sciences and to outstanding science institutes in emerging nations. We will review what has worked well with I2CAM/ICAM, how we started and grew, and how we have inspired similar programs in other countries. (This research supported by NSF Grants DMR-0645461 and DMR-0456669).

4:42PM T6.00006 Panel Discussion —

Wednesday, March 18, 2009 2:30PM - 5:30PM – Session T7 GSNP DPOLY: Patterns on Thin Elastic Sheets 407

2:30PM T7.00001 The undulating shape of growing ribbons, HAIYI LIANG, School of Engineering and Applied Science, Harvard University — The undulating morphology of leaves and petals is now accepted as a consequence of differential growth of the underlying tissue. Various qualitative and quantitative aspects of the buckling patterns seen in both vascular and avascular leaves may thus be ascribed to the distribution of non-uniform growth in the lamina, and have been demonstrated in normal and mutant leaves, as well as in physical models thereof. To understand the different modalities that arise quantitatively, we construct a mathematical model for the stability of an initially flat or curved elastic ribbon with gradients in growth directly motivated by observations of kelp that are capable of phenotypic plasticity in different environments. Using a combination of analysis, numerical simulation, and experimental observations, we map out the phase space of possible shapes for these growing ribbons. In general, we find that as the relative growth strain is increased, the ribbon-like structure first switches to a catenoidal shape before developing undulating edges that can develop on the catenoid’s edges. Our framework allows us to delineate the few macroscopic parameters that control the morphology of elongated leaves and flower petals and helps to explain the large variety of observed shapes.

3:06PM T7.00002 The Mechanics of Non-Euclidean Plates in Synthetic and Natural Sheets, ERAN SHARON, The Hebrew University of Jerusalem — Thin elastic flat plates attain non-trivial configurations when they are confined. I will show that plates with intrinsic non-Euclidean geometry attain multi scale three-dimensional configurations even when they are free of external loading. Such bodies do not have any stress-free configuration, thus current plate theories cannot properly describe their physics. I will present our recent experimental results and our theoretical model for the shaping principles of such plates. Finally, I will show how these principles are manifested during the growth of leaves.
3:42PM T7.00003 Wrinkling patterns on floating elastic films\footnote{1}, NARAYANAN MENON, Dept. of Physics, University of Massachusetts, Amherst — A polymer sheet floating on the surface of a fluid is an ideal arena for studying elastic instabilities in thin sheets. In our experiments we use polystyrene sheets whose typical lateral size, $L \sim 3 \text{ cm}$, and whose thickness, $t$ ranges from 30 to 300 nm, yielding aspect ratios $L/t$ of up to $10^3$. In their unperturbed state, they lie on the surface of a pool of water, stretched flat by surface tension. We can then generate a rich variety of wrinkle patterns by perturbing the surface locally with capillary forces or with controlled displacements at one or more points on the surface. I will review our understanding of the length scales that characterise these localised patterns. A simple experimental setting in which a multiplicity of these length scales come into play is a situation analogous to an Euler buckling experiment performed on the surface of a fluid. We push two sides of a rectangular sheet towards each other, creating a global pattern of parallel wrinkles whose wavelength is given by a balance between gravitational potential energy of the fluid and bending energy of the sheet. These wrinkles develop a cascade of fine structure at higher wavenumbers close to the uncompressed edges of the sheet. The length scale over which this cascade occurs is the capillary length, whereas the wavenumber at the edge of the sheet reflects a balance between bending energy and surface tension. We discuss the evidence that this is a fundamentally new type of elastic cascade, which proceeds to higher wavenumbers by smooth evolution of the wrinkles, rather than by discrete, sharply localised branching. Work done in collaboration with J. Huang, E. Cerda, B. Davydovitch, W.H. de Jeu, T.P. Russell, C. D. Santangelo

1Supported by NSF DMR 0606216 and NSF MRSEC DMR-0820506.

4:18PM T7.00004 Wrinkle to fold transitions: Stress relaxation in lipid monolayers and other elastic thin films, KA YEE C. LEE, The University of Chicago — Surfactants at air/water interfaces are often subjected to mechanical stresses as the interfaces they occupy are reduced in area. The most well characterized forms of stress relaxation in these systems are first order phase transitions. However, once chemical phase transitions have been exhausted, the monolayer undergoes global mechanical relaxations termed collapse. We have previously demonstrated that for lung surfactants, a mixture of lipids and proteins that coats the alveol of the airway, the collapse process occurs at an in-plane rigidity. We characterize the rigidity of the monolayer by analyzing in-plane morphology on numerous length scales. More rigid monolayers collapse out-of-plane via a hard elastic mode similar to an elastic membrane, with the folded state being the final collapse state, while softer monolayers relax in-plane by shearing. For the hard elastic mode of collapse, we have further demonstrated experimentally and theoretically that the folded state is preceded by a wrinkled state, and similar wrinkle to fold transitions has been observed in elastic thin films ranging from 2 nm to 10 $\mu$m in thickness of completely different chemical nature (lung surfactant lipid monolayers, gold nanoparticle trilayers, and polyester sheets).

4:54PM T7.00005 Nonlinear dynamics of wrinkle growth and pattern formation in stressed elastic thin films on viscoelastic substrates, RUI HUANG, University of Texas at Austin — A stressed thin film on a soft substrate can develop complex wrinkle patterns. The onset of wrinkling and initial growth is well described by a linear perturbation analysis, and the equilibrium wrinkle patterns can be analyzed based on an energy approach. In between, the wrinkle pattern undergoes a growth and coarsening process with a peculiar dynamics. By using a proper scaling along with numerical simulations, this paper develops a quantitative understanding of the wrinkling dynamics from initial growth through coarsening toward equilibrium. By considering generally biaxial stresses and anisotropic elastic modulus of the film, we show that a rich variety of wrinkle patterns (e.g., labyrinth, orthogonal, parallel, zigzag, and checkerboard patterns) emerge as a result of the competition between the material anisotropy and the stress anisotropy.

Wednesday, March 18, 2009 2:30PM - 5:30PM – Session T8 DCMP: Onsager Prize, Nicholson Medal, Apker Award, Davison-Germer Prize 414/415

2:30PM T8.00001 Nicholson Medal Talk: Hydrodynamic Turbulence , KATEPALLI SREENIVASAN, International Centre for Theoretical Physics, Trieste, Italy — This talk will be an introduction on hydrodynamic turbulence to a non-specialist audience. It will summarize the essential developments in the field, and only modest emphasis will be placed on the speaker's own work. Hydrodynamic turbulence may be said to have begun as a subject of scientific study with Osborne Reynolds' classical paper towards the end of the nineteenth century, but it is a subject of great interest in the 21st century. The intent is to highlight the principal accomplishments in a way that draws attention to their connections to other areas of physics, where possible.

3:06PM T8.00002 Lar Onsager Prize Talk: An Exactly soluble model for Strontium Copper Borate: Mott Hubbard Physics on an Archimedean Lattices\footnote{1}, SRIRAM SHASTRY, University of California Santa Cruz — An exactly soluble model of spin half particles on a certain 2-dimensional frustrated lattice has been recently realized in the compound $\text{SrCu}_2(\text{BO}_3)_2$, and other similar systems have been found more recently. These systems appear to be ideal testing grounds for contemporary theoretical ideas on the role of correlations and frustration in Mott Hubbard systems. In this talk I will summarize the work on these systems emphasizing their role in testing key concepts.

1The speaker acknowledges support from NSF-DMR-0706128 and DOE-BES DE-FG02-06ER46319.

3:42PM T8.00003 LeRoy Apker Award Talk: Electronics at the Nanoscale: Graphene, Carbon Nanotubes, and Single-Molecule Devices , SUJIT DATTA, Department of Physics, Harvard University — Low-dimensional nanostructures are emerging as model systems for fundamental studies of quantum transport, as well as promising candidates for novel post-silicon electronic devices incorporating quantum size effects. Key examples of these include few-layer graphene, carbon nanotubes, polymer nanofibers, and even single molecules. In this talk, I will summarize my work combining experimental and computational tools to study, control, and apply molecular nanomaterials of low dimensionality — using scanning probe microscopy techniques to study electronic phenomena in few-layer graphene and carbon nanotubes, as well as to elucidate the structure of biochemically-functionalized carbon nanotubes; using computer simulations to investigate key electronic properties of single-molecule transistors; and demonstrating a straightforward chemical technique by which samples of few-layer graphene can be etched along their crystallographic directions, potentially enabling the creation of a variety of new graphene-based nanostructures.
4:18PM T8.00004 Davisson-Germer Prize Talk: Hydrogen storage in nanoporous materials. YVES CHABAL, University of Texas at Dallas — To develop a hydrogen-based energy technology, several classes of materials are being considered to achieve the DOE targets for gravimetric and volumetric hydrogen densities for hydrogen storage, including liquids (e.g. ammonium borohydrides), clathrate structures, complex metal hydrides, nanostructured (e.g. carbon) nanoporous materials. Fundamental studies are necessary to determine the ultimate hydrogen capacity of each system. Nanoporous Metal-organic Framework (MOF) materials are promising candidates for hydrogen storage because the chemical nature and size of their unit cell can be tailored to weakly attract and incorporate H2 molecules, with good volumetric and mass density. In this talk, we consider the structure M2(BDC)2(TED), where M is a metal atom (Zn, Ni, Cu), BDC is benzenedicarboxylate and TED triethylene diamine, to determine the location and interaction of H2 molecules within the MOF. These compounds are isoostructural and crystallize in the tetragonal phase (space group P4/nnc), they construct 3D porous structures with relatively large pore size (~7-8 Å^-1), pore volume (~0.63-0.84 cc/g) and BET surface area (~1500-1900 m^2/g). At high pressures (300-800 ps), the perturbation of the H-H stretching mode can be measured with IR absorption spectroscopy, showing a 35 cm^-1 redshift from the unperturbed ortho (4155 cm^-1) and para (4161 cm^-1) frequencies. Using a newly developed non empirical van der Waals DFT method vdW-DFT, it can be shown that the locus of the deepest H2 binding positions lies within to types of narrow channels. The energies of the most stable binding sites, as well as the number of such binding sites, are consistent with the values obtained from experimental adsorption isotherms, and heat of adsorption data. Importantly, the calculated shift of the H-H stretch is ~30 cm^-1, at the strongest binding points of the two channels, suggesting that the combination of IR and vdW-DFT gives a consistent and accurate picture of H2 binding in MOF structures. These methods can therefore provide the fundamental information necessary to guide synthesis for improving H2 uptake and release. 

1 This work was supported by the grant DOE-DE-FG02-08ER46491, and performed in collaboration with N. Nijem (UTD), and L. Kong, V. Cooper, K. Li, J. Li and D.C. Langreth (Rutgers University)

4:54PM T8.00005 Davisson-Germer Prize Talk: Surface vibrations of adsorbates on Si(111): From small clusters to infinite lattices. KRISHNAN RAGHAVACHARI, Indiana University — Organic functionalization of semiconductor surfaces is a growing research area that offers the possibility of molecular level control of surface features and tailored electronic properties. In this work, quantum chemical cluster calculations are used in conjunction with surface vibrational spectroscopy to determine the structures of functionalized Si(111) surfaces. Interestingly, the interpretation of these spectra even for simple adsorbates is not straightforward. In the limit of high coverage, most calculations using small cluster models lack the long range coupling of the real surface that is required to make definitive assignments. In order to understand the relationship between clusters and infinite periodic vibrations, we have investigated the geometries and harmonic vibrational frequencies of the methyl, acetylenyl, methacetylenyl, hydrogen, deuterium and chlorine functionalized Si(111) surfaces. From a careful analysis of these systems, we have derived a technique where the collective vibrational modes corresponding to the vibrations of the infinite periodic system can be derived from relatively small cluster models. The calculated frequencies are in good agreement with available experimental values and yield novel insights about the coupling between low frequency adsorbate frequencies and surface phonons. The efficacy of this approach for surfaces of varying adsorbate coverage and the prediction of novel frequency shifts will be discussed along with more complex systems.

Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T9 GSNP: Focus Session: Stochastic Processes in Biological Systems I 303

2:30PM T9.00001 Stochastic models of viral infection. TOM CHOU, UCLA — We develop biophysical models of viral infections from a stochastic process perspective. The entry of enveloped viruses is treated as a stochastic multiple receptor and coreceptor engagement process that can lead to membrane fusion or endocytosis. The probabilities of entry via fusion and endocytosis are computed as functions of the receptor/coreceptor engagement rates. Since membrane fusion and endocytosis entry pathways can lead to very different infection outcomes, we delineate the parameter regimes conducive to each entry pathway. After entry, viral material is biochemically processed and degraded as it is transported towards the nucleus. Productive infections occur only when the material reaches the nucleus in the proper biological state. Thus, entry into the nucleus in an infectious state requires the proper timing of the cytoplasmic transport process. We compute the productive infection probability and show its nonmonotonic dependence on both transport speeds and biochemical transformation rates. Our results carry subtle consequences on the dosage and efficacy of antivirals such as reverse transcription inhibitors.

3:06PM T9.00002 Stochastic modeling of gene regulation by small RNAs. VLAD ELGART, Department of Biology, Virginia Tech, TAO JIA, ANDREW FENLEY, RAHUL KULKARNI, Department of Physics, Virginia Tech — Recent research has uncovered several examples wherein post-transcriptional regulation by small RNAs plays an important role in critical cellular processes. We considered a stochastic model for regulation of target mRNAs by small RNAs. While the corresponding master equation is analytically intractable, application of the bursty synthesis approximation of the Gillespie algorithm and to the results of linear noise approximation approach. The effects of transcriptional pulsing on protein steady-state expression are also explored within the same formalism.

3:18PM T9.00003 Stochastic modeling of protein-based post-transcriptional regulation. TAO JIA, RAHUL KULKARNI, Virginia Tech — Recent experiments have enabled monitoring gene expression in living cells at the level of single proteins. Data from such experiments for protein burst-size distribution and burst frequency can be used to obtain analytical expressions for the steady-state protein distribution across a population. We extend this analysis to the case of modulation of gene expression by binding/unbinding of a post-transcriptional regulatory protein. Closed-form analytical expressions and results from stochastic simulations will be presented. In the case that regulator binding results in complete repression of protein expression, the steady-state protein distribution has the same functional form as the unregulated case, once the mRNA degradation rate is appropriately renormalized. For the general case, wherein binding can result in partial repression or even activation of protein expression, we derive an analytical expression for the steady-state distribution which generalizes the result for the unregulated case.

3:30PM T9.00004 Accurate fluctuation prediction in epidemics using stochastic model reduction. ERIC FORGOSTON, IRA SCHWARTZ, U.S. Naval Research Laboratory — We consider a large-scale dynamical system with stochastic forcing and outline a general theory to reduce the dimension of the stochastic system. The general procedure employs a stochastic normal form coordinate transform and allows one to analytically derive both the stochastic center manifold and the reduced set of stochastic evolution equations. The transformation correctly projects both the dynamics and the noise onto the center manifold. We have applied the theory to a stochastic Susceptible-Exposed-Infected-Recovered (SEIR) epidemiological model. When compared with the original model, the reduced dynamical system accurately predicts fluctuations of disease outbreaks both in amplitude and phase.

1 Research supported by the Office of Naval Research and the Army Research Office.
3:42PM T9.00005 Stochastic disease extinction in multistrain diseases with interacting strains

SIMONE BIANCO, LEAH SHAW, The College of William and Mary, IRA SCHWARTZ, Naval Research Laboratory — The study of multistrain diseases, diseases with several coexisting strains, is a major challenge for mathematical biology. Examples of such diseases are influenza, HIV, dengue, and ebola. In this work we present an agent-based model for multistrain diseases with strain interactions mediated by antibody-dependent enhancement. An individual infected with a strain develops antibodies which will protect him/her against all the strains. When the level of protection wanes, the presence of antibodies will enhance the infectiousness of the individual when an infection with a different strain occurs. This mechanism is called antibody-dependent enhancement (ADE). We use this model to investigate the role that fluctuations due to system size have on disease extinction paths and discuss how interactions mediated by ADE affect rates of disease fade-out. Finally, we discuss the effect that varying the number of strains has on disease extinction.

3:54PM T9.00006 Controlling rare events: optimizing disease extinction with limited vaccine

M. KHASIN, M.I. DYKMAN, Michigan State University — In rare events such as switching between stable states or disease extinction the system has to overcome an effective barrier. The barrier height can be changed by the effective change of a control field. The change is determined by the effective work of the field along the most probable trajectory followed in a rare event. In turn, the barrier change results in an exponentially strong change of the event rate. We study the optimal temporal shape of the control field with a constraint that the time-average field value and the sign of the field are fixed. An example is vaccination with a limited vaccine production rate or control by light intensity with a limited laser power. For a comparatively weak field, for a broad class of rare events, optimal control is accomplished by periodically applying δ-like pulses. We show that the barrier change may display resonant dependence on the pulse period and is linear in the pulse area. For a stronger field, the dependence of the barrier change on the field amplitude becomes system-dependent. The results are applied to simple models of population dynamics.

4:06PM T9.00007 Extinction Time Distribution in Stochastic Lotka-Volterra System

MATTHEW PARKER, ALEX KAMENEV, University of Minnesota — The Lotka-Volterra model is one of the most basic problems in population dynamics. The mean-field solution to this problem predicts oscillatory evolution of two competing populations. However, an account of the discrete nature of agents inevitably results in the extinction of one or both species. We studied the distribution function of times required for such an extinction event to take place. We employed a combination of Monte-Carlo simulations and analytic techniques. As a result we achieved a complete understanding of the distribution function in the limiting cases of long and short extinction times. The long time tail is perfectly described by the lowest eigenvalue of the corresponding Fokker-Planck operator. Moreover, due to time scale separation, one may reduce the initial 2D operator to an effective 1D radial one. Remarkably, in the short time limit the Fokker-Planck approach fails, and one has to resort to the WKB treatment of the full evolution operator of the corresponding discrete stochastic problem.

4:18PM T9.00008 Refined mean-field approaches to “edge-effects” in open TASEP’s

JIAJIA DONG, Hamline University, ROYCE K.P. ZIA, BEATE SCHMITTMANN, Virginia Tech — We study the totally asymmetric simple exclusion process (TASEP) with a defect site, hopping rate \(q < 1\), at the edge of the system and particles occupying \(l\) lattice sites. Using two different mean-field approximations, we analyze the behavior of the steady state current \(J\) in the presence of the defect as a function of entry rate \(\alpha\) and \(q\). In good agreement with Monte Carlo simulations, these two methods bring insight to understanding the significance of having one or a cluster of slow codons (unit of messenger RNA, template of protein synthesis) immediately after initiation during protein synthesis. Related work is published in Journal of Physics A, vol. 41 (2008).

4:30PM T9.00009 Parallel Coupling of Symmetric and Asymmetric Exclusion Processes

KONSTANTINOS TSEKOURAS, Rice University, ANATOLY KOLOMEISKY, Rice University Chemistry Department — A system consisting of a simple symmetric exclusion process (SSEP) and a totally asymmetric exclusion process (TASEP) coupled to each other at every site is constructed as a simplified model of a microtubule and the surrounding medium within the context of intracellular particle transport. Transitions between the channels are allowed at every site of both lattices. A cluster-based mean-field theory allows calculation of stationary phase diagrams, particle currents and densities for symmetric/asymmetric transition rates between the channels. It is shown that in general there are three stationary phases, similar to the case of a single-channel totally asymmetric exclusion process. Density profiles are identical in both channels if transition rates are symmetric, not so if they are asymmetric. At certain limiting values of the transition rates our theory provides exact solutions, so that the system can be described as a partially asymmetric exclusion process (PASEP). Extensive Monte Carlo simulations generally support theoretical predictions, although simulated stationary-state properties slightly deviate from calculated in the mean-field approximation. Dynamic properties and phase diagrams are discussed by analyzing symmetry requirements and constraints on the particle currents, as are possible implications for the problem of intracellular particle transport.

4:42PM T9.00010 Anomalous diffusion and scaling in the dynamics of coupled stochastic processes

GOLAN BEL, CNLS and CCS-3 LANL, ILYA NEMENMAN, CCS-3 and CNLS LANL — Stochastic processes are ubiquitous in nature, and multiple dynamical variables in the same physical system can be stochastic simultaneously. Common mathematical treatment of such cases limit the interactions among multiple stochastic variables to simple correlations. However, more complicated couplings are possible as well. For example, for many biochemical reactions, the rate (stochastic) of creation of one substance may depend on the presence of another one, itself stochastic variable. Here we present a theoretical study of one class of such coupled stochastic processes. We observe that, contrary to traditional modeling frameworks, even very weak coupling yields anomalous diffusion. Interestingly, the diffusion exponent cannot be predicted by simple scaling arguments, and anomalous scaling appears as well. Further, we show that even weak inhibitive coupling between the two processes may result in dynamics equivalent to that of the celebrated comb model, where the coupling between the two stochastic variables is so strong that one is able to diffuse only when the other is within a certain range. We compare the model to various mechanisms for generating anomalous diffusion and show that coarse-graining yields behavior equivalent to that of the non-ergodic continuous time random walk. We end with brief discussion of applications of the developed theory to biochemical systems.

4:54PM T9.00011 Subdiffusion in the Internal Dynamics of Peptides

THOMAS NEUSIUS, Computational Molecular Biophysics, IWR, University of Heidelberg, Im Neuenheimer Feld 368, D-69120 Heidelberg, JEREMY C. SMITH, Center for Molecular Biophysics, Oak Ridge National Laboratory, P.O. Box 2008, Oak Ridge TN 37831-6164 — The internal dynamics of biopolymers is a topic of intense current research, both in experiment and theory. Recent experimental results have demonstrated the presence of internal subdiffusion in biopolymers at equilibrium. Molecular dynamics simulation of oligopeptide chains reveals configurational subdiffusion at equilibrium extending from 10^{-12} to 10^{-6} s. We examine the possible origins of the subdiffusion and demonstrate that it arises from the fractal-like structure of the accessible configurational space [PRL 100, 188103 (2008)].
5:06PM T9.00012 Stochastic waiting times of complex biochemical reactions may exhibit universal behavior. B. MUNKSKY, G. BEL, N. SINITSYN, I. NEMENMAN, Los Alamos National Lab — To model cell regulatory pathways, one must understand the complex nature of these pathways. We investigate the behavior of biochemical reactions in complex networks and show that the universal behavior of these reactions can be described by a set of equations.

5:18PM T9.00013 Mechanisms of high energy plasmon modes in thin films. MATTHEW B. SMITH, DICHIOMIOS VAVYLOIS, Department of Physics, Lehigh University — We investigate the surface plasmon modes of a thin metallic film using the Plasmon Hybridization method. We find that the high energy modes are related to the bonding and antibonding modes of the surface plasmon.

Wednesday, March 18, 2009 2:30PM - 5:30PM Session T10 DMP: Focus Session: Optical Properties of Nanostructures V: Plasmonics and Metamaterials 304

2:30PM T10.00001 Metal films with arrays of subwavelength holes show infrared spectral and plasmonic sensitivity to material in the holes. JAMES COE, JOSEPH HEER, KATHERINE CILWA, MARVIN MALONE, LLOYD CORWIN, The Ohio State University — We investigate the infrared absorption spectra of metal films with arrays of subwavelength holes. The results show that the material in the holes has a significant effect on the plasmonic response.

2:42PM T10.00002 Influence of the dielectric environment on periodic hole arrays. DIMITRIOS KOUKIS, DANIEL J. ARENAS, SINAN SELCUK, DAVID B. TANNER, ARTHUR F. HEBARD, SERGEI V. SHABANOV — We study the effect of the dielectric environment on the plasmonic response of metal films with periodic hole arrays. We find that the dielectric environment can significantly affect the plasmonic response.

2:54PM T10.00003 Controlling the polarization of light transmitted through metallic bilayers of subwavelength apertures. ZSOLT MARCET, J. PASTER, H.B. CHAN, University of Florida, D.W. CARR, Symphony Acoustics, J.E. BOWER, R. CIRELLI, F.P. KLEMEMS, W.M. MANSFIELD, J.F. MINER, C.S. PAI, J.A. TAYLOR, Bell Labs, I. KRAVENCHKO, Oak Ridge National Laboratory — We investigate the polarization of light transmitted through metallic bilayers of subwavelength apertures. We find that the polarization can be controlled by the design of the bilayers.

3:06PM T10.00004 Perfect coupling of light to surface plasmons with ultra-narrow linewidths. MAXIM SUKHAREV, Arizona State University, PAUL SIEVERT, TAMAR SEIDEMAN, JOHN KETTSSONER, Northwestern University — We examine the coupling of electromagnetic waves to surface plasmons in thin metallic films. We find that the coupling can be made ultra-narrow.

3:18PM T10.00005 Plasmon Hybridization of a thin metallic film. TAE-HO PARK, PETER NORDLINDER, Department of Physics and Astronomy, Rice University — We investigate the plasmon modes of a thin metallic film using the Plasmon Hybridization method and solving Maxwell’s equations. We show that the high energy plasmon mode is the antibonding mode in which surface charges are antisymmetrically distributed, and the low energy mode is the bonding mode in which surface charges are symmetrically distributed. In the thin film, secondary charges which are induced from the primitive plasmons on the other film surface play an important role to determine which plasmon mode has the higher or lower energy. Furthermore, we discuss how the secondary charges affect the propagation length of the surface plasmon by calculating the imaginary parts of the surface plasmon wave vectors.
3:30PM T10.00006 Plasmon coupling in nanoparticle rings, STEPHAN LINK, WEI-SHUN CHANG, LIANE SLAUGHTER, BISHNU KANAL, PRAMIT MANNA, EUGENE ZUBAREV — A surface plasmon is excited when the conduction band electrons of a metal oscillate coherently in phase with incoming excitation light. Plasmons can exist and propagate along structures that are smaller than the diffraction limit of light, the parameter which currently dictates the minimum size of optical interconnects. In addition to exploiting plasmons on continuous structures like thin films and nanowires for waveguiding, arrays of nanoparticles also pose potential for waveguiding. We have characterized the plasmon coupling of self-assembled rings of 40 nm gold nanoparticles functionalized with polystyrene using dark-field scattering microscopy and spectroscopy. Comparing images and spectra from the rings to those of single particles together with correlating images acquired by dark-field and SEM microscopy, we observe redshifted coupled plasmon modes that show a strong polarization dependence. In particular, segments of the ring aligned parallel to the axis of detected polarization display higher order longitudinal plasmon modes, similar to those observed for a long rod.

3:42PM T10.00008 Transforming Light with Metamaterials, VLADIMIR SHALAEV, Purdue University — Metamaterials are expected to open a gateway to unprecedented electromagnetics properties and functionality unattainable from naturally occurring materials, thus enabling a family of new “meta-devices.” We review this new emerging field and significant progress in developing metamaterials for the optical part of the spectrum. Specifically, we describe recently demonstrated artificial magnetism across the whole visible, negative-index in the optical range, and promising approaches along with challenges in realizing optical cloaking. A new paradigm of engineering space for light with transformation optics will be also discussed.

4:30PM T10.00009 Analytic LC model for plasmonic resonances in nano-structured split-ring resonators, P. W. KOLB, Laboratory for Physical Sciences, College Park, MD 20740, T. D. CORRIGAN, A. B. SUSHKOV, H. D. DREW, D. C. SCHAMDEL, Department of Physics, University of Maryland, College Park, MD 20742, R. J. PHANEUF, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742 — We systematically investigate the plasmonic resonant behavior of metallic nano-structured split-ring resonators as a function of the size of the split gap, substrate permittivity, metal skin depth, and sample height. We performed simulations of the structures and examine the E-field and current density maps. We present a simple, analytic LC model to describe the lowest order resonance and its dependence on the aforementioned parameters.

4:42PM T10.00010 Angular Dependence of Resonances from Rod Pairs and U-Shapes, TIMOTHY CORRIGAN, University of Maryland, PAUL KOLB, Laboratory for Physical Sciences, ANDREI SUSHKOV, DENNIS DREW, DOMINIC BRITTI, RAYMOND PHANEUF, University of Maryland — We examine and compare the angular dependence of electric and magnetic resonances from rod pairs and U-shapes made of Ag with the long arms placed both horizontally and vertically. We discuss the results in terms of photonic band structure effects. In addition, we observe that the splitting of the higher order mode for vertical U-shapes in the s-polarization behave as symmetric and anti-symmetric modes in which the modes red and blue shift, respectively, as observed previously. However, both horizontal U-shapes and rod pairs also show a split for the p-polarization in which both modes red shift. We discuss the reasons for this behavior using both experimental results and simulations.

5:06PM T10.00012 Natural negative refraction index in polycrystalline Fe and Ni at optical frequencies, ADIL-GERAI KUSSOW, Dept. of Physics, University of Massachusetts Lowell, ALKIM AKYURTU, Electrical and Computer Engineering Dept., University of Massachusetts Lowell — Analysis of the photon-magnon interactions in Fe and Ni, 3d transition-metal ferromagnetics, demonstrating the coupling between the incident light and high-frequency spin waves with energy (0.2 – 0.35) eV is presented. As a consequence, these metals in their polycrystalline form with nanoscale grains are found to possess a negative refraction index at optical frequencies, close to the high-frequency ferromagnetic resonance. The effect is due to the coexistence of the spin wave mode with the plasmonic mode, and both modes are activated by the e.m. field of the light, with simultaneous permittivity and permeability responses within some frequency band.

5:18PM T10.00013 Propagating and Localized Surface Waves in Metamaterial Stacks, RUWEN PENG, YONGJUN BAO, ZHAOHUI TANG, FENG GAO, ZHIJIAN ZHANG, WEIHUA SUN, XIN WU, MU WANG, National Laboratory of Solid State Microstructures, NATIONAL LABORATORY OF SOLID STATE MICROSTRUCTURES TEAM — We demonstrate the interference effect between propagating and localized modes of electromagnetic wave in metamaterial stacks, which leads to a transmission extremum. When radiation is incident on a metal surface perforated with an array of ring-shaped subwavelength apertures, the phase difference between the propagating surface Bloch wave and the localized surface wave can be tailored by the geometrical parameters of the array so as to affect the shape of the transmission spectrum. Above the resonant frequency of the aperture, interference between the surface waves leads to a minimum in the transmission spectrum, whereas below it, the interference leads to a maximum. While in multiple metamaterial stacks with hole arrays, the coupling of surface electromagnetic wave yields a new resonant mode with increasing quality factor of the transmission peak. We suggest that these features provide flexibility in engineering surface wave-based all-optical devices. Reference: Y. J. Bao, R. W. Peng, D. J. Shi, Mu Wang, X. Lu, J. Shao, W. Lu, and N. B. 2:30PM T11.00001 Platform for Measurement of Phonon Scattering from the Surface of Silicon Nanostructures. J. P. SULLIVAN, Sandia National Labs, T. A. FRIEDMANN, E. S. PIEKOS, S. L. SHINDE, J. R. WENDT — We’ve created a micro-platform for measuring thermal phonon surface scattering in single-crystal Si nanostructures, specifically specular-to-diffuse surface scattering in the long phonon mean-free-path regime. The platform consists of three suspended co-linear monocrystalline Si islands with the center island resistively heated and connected to its neighbors by Si nanoligaments (one ligament straight, the other bent). The ligaments have a blade-like geometry with length, width, and depth of 1000 nm, 100 nm, and 2500 nm, respectively. Heat conducts from the center island across the ligaments in proportion to the ligament thermal conductance, which is lower for the bent ligament due to increased surface scattering. Monte Carlo simulations indicate that the heat flux differs between straight and bent nanoligaments by 10% for diffuse (rough surface) phonon reflection and by almost 40% for specular (smooth surface) reflection. Acknowledgment: DOE BES Div. of Mat. Sci. & Eng. and LDRD (Sandia is operated by Sandia Corp. for the US DOE’s NNSA, contract DE-AC04-94AL85000).

2:42PM T11.00002 Thermal Effects in Precision Nano-Electronics Construction, STEPHEN JOHNSON, SON, OSCAR D. RESTREPO, KALMAN VARGA, Vanderbilt University, SOKRATES T. PANTELIDES, Vanderbilt University and ORNL — Mobility is a key factor in charge transport since it describes how the motion of an electron is affected by an applied electric field. As such, it is an important element in the design of new devices. Mobilities are generally modeled using methods that suppress atomic-scale detail (effective mass theory or bulk energy bands for electron velocities, empirical deformation potentials, macroscopic roughness, etc.). Parameter fitting to experimental data is needed. As new technologies require modeling of transport at the nanoscale and new materials are introduced, predictive parameter-free mobility modeling is needed. The main scattering mechanisms that limit mobilities are due to phonon, ionized impurities, and interface roughness. A first-principles calculation of mobilities limited by atomic scale roughness with atomic-scale detail was reported recently [1]. We report the development of parameter-free quantum-mechanical methods to calculate scattering rates and electron mobilities limited by phonon and ionized-impurity scattering in a self-consistent way. Results for n-doped silicon are in good agreement with experimental data. This work was supported by NSF Grant ECS-0524655. [1] M. H. Evans et al., Phys. Rev. Lett. 95, 106802 (2005).

2:54PM T11.00003 First-principles parameter-free calculations of electron mobilities in silicon: phonon and Coulomb scattering , OSCAR D. RESTREPO, KALMAN VARGA, Vanderbilt University, SOKRATES T. PANTELIDES, Vanderbilt University and ORNL — Mobility is a key factor in charge transport since it describes how the motion of an electron is affected by an applied electric field. As such, it is an important element in the design of new devices. Mobilities are generally modeled using methods that suppress atomic-scale detail (effective mass theory or bulk energy bands for electron velocities, empirical deformation potentials, macroscopic roughness, etc.). Parameter fitting to experimental data is needed. As new technologies require modeling of transport at the nanoscale and new materials are introduced, predictive parameter-free mobility modeling is needed. The main scattering mechanisms that limit mobilities are due to phonon, ionized impurities, and interface roughness. A first-principles calculation of mobilities limited by atomic scale roughness with atomic-scale detail was reported recently [1]. We report the development of parameter-free quantum-mechanical methods to calculate scattering rates and electron mobilities limited by phonon and ionized-impurity scattering in a self-consistent way. 3:06PM T11.00004 Reconstructing Fourier’s law from disorder in quantum wires1. MASSIMILIANO DI VENTRA, YONATAN DUBI, University of California - San Diego — The validity of Fourier’s law in nano-scale wires poses a fundamental theoretical challenge, with both scientific and technological implications. In this work, a novel theory of open quantum systems is used to study the local temperature and heat currents in metallic nanowires connected to leads at different temperatures. We show that for ballistic wires the local temperature is almost uniform along the wire and Fourier’s law is invalid. By gradually increasing disorder, a uniform temperature gradient ensues inside the wire and the thermal current linearly relates to this local temperature gradient, in agreement with Fourier’s law. Finally, we show that while disorder is responsible for the onset of Fourier’s law, the non-equilibrium energy distribution function is determined solely by the heat baths.

3:18PM T11.00005 A Single-Molecule Phonon Field-Effect Transistor, MARCOS MENEZES, Universidade Federal do Rio de Janeiro, Brazil, BRENDA MOREIRA, Universidade Federal do Pará, Brazil, JORDAN DEL NERO, Universidade Federal do Pará and Universidade Federal do Rio de Janeiro, Brazil, RODRIGO CAPAZ, Universidade Federal do Rio de Janeiro, Brazil — Controlling phonons in the same way we control electrons in materials has been an old but elusive dream for physicists. In particular, it would be extremely desirable to control the thermal (phonon) flux between two reservoirs using a gate electric field, i.e., to construct a field-effect transistor for phonons. However, in most materials, electric fields do not couple strongly to lattice vibrations. Moreover, at the molecular and nano scale, in which the ballistic regime is dominant, thermal conductance of acoustic modes is universal, independent of the sound velocity. Therefore, modulating the sound velocity does not change the thermal conductance, thus making even more difficult the conception of such device. In this work, we propose a realizable architecture for a phonon field-effect transistor based on a single polar polymeric molecule placed between two reservoirs. An applied transverse electric field transforms the acoustic torsion mode into optical. For feasible temperatures and electric field magnitudes, this coupling can virtually suppress the contribution from this mode to the thermal conductance, therefore modulating the conductance by as much as 25%.

3:30PM T11.00006 Hypersonic Phononic Crystal Based on 2D Single Crystalline Nanoporous Alumina, AKIHIRO SATO, Max Planck Institute for Polymer Research, YAN PENNEC, Institut d’Electronique, de Microélectronique et de Nanotechnologie, TAKASHI YANAGISHITA, Tokyo Metropolitan University, BAHRAM DJAFARI-ROUHANI, Institut d’Electronique, de Microélectronique et de Nanotechnologie, FYTAS GEORGE, F.O.R.T.H Institute of Electronic Structure and Laser Technology, WOLFGANG KNOLL, Max Planck Institute for Polymer Research, HIDEKI MASUDA, Tokyo Metropolitan University — Periodic nanocomposite media consisted of alumina matrix and infiltrated cylindrical nanopores exhibit rich elastic wave propagation behaviour including the localization of phonons, anisotropic propagation and the formation of phononic band gaps at GHz frequencies. We have examined the translational symmetry dependence of dispersion relations on 2D single crystalline phononic crystals based on nanoporous alumina using Brillouin light scattering. The propagation of elastic waves is significantly different between native and filled with fluids alumina matrix. For the latter, the dispersion relations become independent of the propagation direction, as opposed to the native alumina scaffold. Theoretical band diagrams and the displacement fields describe well the experimental results.
3:42PM T11.00007 Charge Carrier Confinement in a Nano-patterned Silicon Film

ZHENG LIU, Dept. of Material Science and Engineering, U. of Utah, Salt Lake City, UT, 84112 & Center for Advanced Study, Tsinghua Univ., Beijing, China, 100084, WENHUI DUAN, Department of Physics, Tsinghua University, Beijing, China, 100084, FENG LIU, Department of Material Science and Engineering, University of Utah, Salt Lake City, Utah, 84112, JIAN WU, Department of Physics, Tsinghua University, Beijing, China, 100084 — Impurity scattering is becoming a critical problem in sub-micrometer MOSFET. One way to reduce the impurity scattering is by separating carriers from dopants, as used in the modulation-doping technique. From first-principles calculation, we find that by etching channels along (001) direction on the surface of a thin (110) silicon film, the hole states can be strongly confined in the film underneath the patterned layer. Therefore, by selective doping in the top patterned layer, a modulation-doping-like effect can be achieved, which is expected to greatly enhance the hole mobility. This effect arises from matching between carrier wavefunction orientation and quantum confinement direction determined by film and pattern geometry. It will be functional as long as the patterned feature size is within a few nanometers.

3:54PM T11.00008 Magnetotransport of Bi nanowires: Evidence for surface carriers in bismuth,

TITO HUBER, Howard University, ALLA NIKOLAEVA, LEONID KONOPKO, Academy of Sciences Moldova, MICHAEL J. GRAF, Physics Department. Boston College. — Angle resolved photoemission spectroscopy studies (Hirahara et al, Phys. Rev. Lett. 97, 146803 (2006)) provide evidence of quantum-confined bulk-like states and surface states in ultrathin Bi films. Can these states be observed in electronic transport? We studied magnetotransport of trigonal Bi nanowires (30 nm < diameter < 200 nm) for fields up to 14 T. Bulklike states (M.R. Black et al. Phys. Rev. B68, 235417 (2003)) are identified because of its anisotropic Fermi surface and low effective mass. A two-dimensional behavior was expected of high-effective mass surface carriers; we found instead a three-dimensional behavior, with a rich spectrum of Landau levels in a nearly spherical Fermi surface. This behavior is related to the long penetration length of surface states on non-basal surfaces. On the basis of similarity of spectra, we show that recent observations of sharp peaks in the bulk Bi Nernst thermopower near the 9 T quantum limit, attributed to charge fractionalization (K. Behnia, L. Balicas and Y. Kopelevich, Science 317, 1729 (2007)), can be more plausibly interpreted in terms of quasiparticles that are based on surface states. Bismuth true quantum limit is 70 T.

1High Magnetic Field Laboratory, Wroclaw. Poland. NSF-DMR.

4:06PM T11.00009 Nanoscale Charge Transport in Realistic Organic Thin-Films: Beyond Variable-Range Hopping and Percolation Networks

GEOFFREY HUTCHISON, University of Pittsburgh, Department of Chemistry, MARCUS HANWELL, XIALING CHEN, AARON CRANDALL. — We are building up experimental and computational model systems for charge transport in nanoscale organic electronic devices. In particular, our combined approach is aimed at addressing questions as to the effect of impurities, traps, and other defects on electronic conductivity. Experimentally, we have designed thin films and monolayers to which we can controllably add known quantities of defects with known electronic properties. In tandem, we focus on a new Monte Carlo style simulation of charge transport in these imperfect devices with an aim to move beyond simple variable-range hopping models. Our goal is to establish all parameters for our simulations from first-principles calculations and detailed experimental results. I will describe initial results and comparisons with other organic electronic materials and existing charge transport models.

4:18PM T11.00010 Computational Simulation of Charge Transport in Metal Terpyridine Monolayer FETs

MARCUS HANWELL, GEOFFREY HUTCHISON, University of Pittsburgh — Understanding the roles of charge traps and defects in electronic transport in organic materials is becoming increasingly important. Computational studies have been undertaken, using an agent-based Monte Carlo method, of the active region of a monolayer FET. Charge transport is assumed to be due to thermally activated, variable-range hopping between neighboring sites. This model system allows us to probe the role of charge traps/defects both computationally and experimentally. We do this by using multiple metal terpyridine complexes, each having known electronic structure. Using Marcus Theory and quantum calculations, the hopping rate between neighboring complexes can be predicted. Results from computational simulations of this system will be discussed, with special attention being paid to the results that can be experimentally verified, such as voltage-current curves.

4:30PM T11.00011 Random telegraph noise and low frequency noise in molecular tunnel junctions

DOMINIQUE VUILLAUME, NICOLAS CLEMENT, DAVID GUERIN, STEPHANE PLEUTIN, IEMN-CNRS, DAVID CAHEN, Weizmann Institute — Molecules of organic molecules present one of the main systems studied in molecular electronics. We report the observation and study of a low frequency noise and Random Telegraph Signal (RTS) in self-assembled alkyl chain junctions on silicon. The 2 levels of current can be clearly distinguished. With a sufficiently long recording time (> 500 events), statistics can be performed on the current level and on the upper and lower times. The RTS amplitude is usually few % of the average current and the process follows poissonian statistics. This RTS signal is also modulated by another RTS with a much longer time constant. This allowed us evaluation of the change of noise in the frequency domain from 1/f noise to Lorentzian like spectrum. In inorganic tunnel junctions, such signal can only be observed in sub-micrometric junctions whereas we observe it in almost millimetric junctions. This precludes mechanisms involving electron trapping / detrapping in single isolated trap. We propose several hypotheses leading to long-range fluctuations including molecular dynamics and relaxation processes.

4:42PM T11.00012 Maximum energy transfer in nanoscale thermal radiation

SOUMYADIPTA BASU, ZHUOMIN ZHANG, Georgia Institute of Technology — Radiation heat transfer between closely spaced objects has received much attention lately because of the emerging applications of near-field thermophotovoltaics, thermal radiation scanning tunneling microscopy, and nanothermal manufacturing. The energy transfer in nanoscale radiation can exceed that of blackbody radiation by several orders of magnitude due to photon tunneling and the excitation of surface polaritons. An outstanding question remains as whether there exists an upper limit of near-field radiation for arbitrarily selected material properties. We examine the maximum radiative energy flux between two parallel plates separated by a vacuum gap from 0.1 and 100 nm distance. An upper bound is imposed to the parallel wavevector component in the analysis based on fluctuational electrodynamics. By assuming a frequency-independent dielectric function, we find that the maximum heat flux depends on the chosen complex permittivity and the distance. The determination of the achievable heat flux at nanometer distances will benefit future research and applications of near-field radiation for energy harvesting.

2:30PM T12.00001 Atomic structures and energetics of methanol and its reaction intermediates on the ZnO(0001) surface: A first-principles study, KATAWUT CHUSASIRIPATTANA, OLIVER WARSCHKOW, University of Sydney, BERNARD DELLEY, Paul-Scherrer-Institut, CATHY STAMPFL, University of Sydney — Methanol (CH₃OH) is widely used in various chemical synthesis, and in particular it is predicted to be one of the next generation of renewable energy sources as a fuel for fuel cells. Industrially, methanol is mass produced by A₂O₂-supported Cu/ZnO catalysts. However, the role of ZnO in the methanol synthesis is still unclear. To provide a better understanding of the mechanisms underlying this process, we present first-principles total-energy calculations of the methanol molecule and its reaction intermediates on the ZnO(0001) surface. A detailed characterization of atomic geometries and associated energetics is presented. The reaction intermediates we consider are CH₃O, CH₂O, HCOOH, HCOO, HCO, H₂O, CO₂, CO, OH and H. These intermediate species are reported from experimental studies to be present during methanol decomposition on the ZnO(0001) surface. We also analyse the vibrational frequencies of each of the adsorbed fragments. The information obtained will be used for investigating the surface chemical reactions of associated with methanol synthesis over the ZnO surface.

2:42PM T12.00002 Morphology of alloy catalysts in an oxidizing environment: Structure-sensitivity of ethylene epoxidation over Ag-Cu particles, SIMONE PICCININ, CATHERINE STAMPFL, University of Sydney, MATTHIAS SCHEFFLER, Fritz-Haber-Institut — Ag-Cu alloys have been proposed as catalysts for ethylene epoxidation due to their superior selectivity compared to pure silver, the predominant catalyst for this reaction [1]. By means of density-functional theory and atomistic thermodynamics, we study the surface structure and morphology of Ag-Cu particles in thermodynamic equilibrium with an oxygen atmosphere. Contrary to the common assumption of the formation of a 2D surface alloy, we find that at temperatures and pressures of interest for practical applications the particles can display a variety of structures, including thin Cu-surface oxides in coexistence with clean Ag. At variance with pure Ag in UHV, we find that under reactive conditions the (111) facet is not dominant. We identify different reaction pathways that will compete and/or synergetically interplay in the catalysis. In general, the reaction mechanism is structure-dependent and often the reaction does not proceed through the formation of stable intermediates, in contrast to clean Ag and the 2D alloy. Analyzing the competing reactions, we discuss how the addition of Cu improves the selectivity and stress the overall importance of accounting for the effect of ambient conditions. [1] S. Linic et al. J. Catal. 224, 148 (2004)

2:54PM T12.00003 Interaction of benzene and MMA vapors with TiO₂ surface: Relevance to EUV Lithography¹, BORIS YAKHINSKIY, SHIMON ZALKIND, ROBERT BARTYNSKI, Rutgers University — We characterize the surface processes that affect the reflectivity and lifetime of TiO₂ — capped multilayer mirrors used in EUV lithography. Low energy electron beam is used to mimic excitations initiated by EUV radiation. Temperature programmed desorption, x-ray photoelectron spectroscopy, and low energy ion scattering are used to analyze the surface reactions. Carbon film growth on TiO₂ (001) crystalline surface is measured during electron bombardment in benzene or MMA vapor (model background gases) over a wide range of pressures and temperatures near 300 K. The surface temperature, gas pressure and electron energy are shown to be important for growth of carbon. The substrate temperature rise lowers the carbon accumulation rate. Increasing the vapor pressure over the surface enhances the carbon deposition, and variation of the electron energy shows a pronounced influence on the reaction rate. Low energy secondary electrons excited by EUV photons contribute substantially to carbon accumulation on clean TiO₂ cap layers. The steady-state coverage of the molecules on the surface and the cross-sections for electron-stimulated dissociation are key parameters for understanding and modeling the processes on the EUVL mirrors.

3:06PM T12.00004 Selective Oxidation of Ammonia on RuO₂(110): a combined DFT and KMC study¹, SAMPYO HONG, Univ. of Central Florida, ALTAF KARIM, Brookhaven National Laboratory, SERGEY STOLBOV, TALAT RAHMAN, Univ. of Central Florida — Motivated by the experiments of Wang et al [1] on the selective oxidation of ammonia on RuO₂(110), we have performed first principles electronic structure calculations based on the density functional theory (DFT) and the pseudopotential method to calculate the activation energy for the associated reaction processes, and used the DFT results in kinetic Monte Carlo (KMC) simulations of the reaction rates. We find the overall energy barriers for NH₃ + O₂ = N₂ + H₂O, N₂ + O₂ = NO₂, and N₂ + O = NO to be about 1.0, 0.6, and 0.56 eV, respectively. We also find, in agreement with experiment, intermediate products such as NH to be short-lived (i.e. not detectable in experiment). For a simple model of the surface dominated by the two end reactions above, our KMC simulations show almost 100% selectivity toward NO, in excellent agreement with experimental findings. For more realistic simulation, in which we include several intermediates and their reactions (over 20 processes), KMC simulations show about 60% selectivity toward NO within the experimental O₂ pressure range. We compare our calculated reaction rates to those obtained in experiment and rationalize our results through details of the surface electronic structure. [1] Y. Wang, K. Jacobi, W.-D. Schoene, and G. Ertl, J. Phys. Chem. B 2005, 109, 7883-7893.

3:18PM T12.00005 Surface Chemistry of Cyanogen on Copper, EREVERE LEE, JAMES LALLO, ERIK CIFTLIKLI, SYLVE RANGAN, ALEXEI ERMAKOV, B.J. HINCH, Rutgers University — The surface chemistry of cyanogen/cyanide species has been observed on Cu(100) crystal through Temperature Programmed Desorption, Helium Atom Scattering and soft x-ray Photoelectron Spectroscopy. Cyanogen (CN₂) dissociates on copper to form a mixture of cyanide and cyanogen (CN) species depending at cryogenic temperatures but pure cyanide at ambient temperatures, leading to c(10x6) superstructure in two domains at saturation. Temperature Programmed Desorption spectra observed indicated that cyanide recombinatively desorbs as cyanogen at relatively high temperatures with no additional species observed. The desorption results were analysed using a variety of techniques in order to determine the activation energy of desorption (Ed) as well as its coverage dependency.

3:30PM T12.00006 Identifying surface intermediates with TPD: Methylchlorosilanes on Cu(001), JAMES LALLO, EREVERE LEE, B.J. HINCH, Rutgers University, DAN STRONGIN, Temple University — Various methylchlorosilane molecules (SiH₃MeₓClₙ₋ₓ, x+y+z=4) were exposed to a Cu(001) surface. Dissociative adsorption was observed for all hydrogen containing species, at surface temperatures above 160K. The chemistry and thermal stability of the surface bound fragments were then studied as a means for understanding intermediates of the commercially important “Direct Process,” namely production of Cl₂(CH₃)₂Si, from Si and CH₃Cl, with a Cu catalyst. Temperature programmed desorption indicates that methyl groups are readily transferred among adsorbed Si-containing species. A large fraction of Cl remains on the surface after observation of typically 2 or 3 distinct TPD features below 450K. By a comparison of the product species distributions to the parent species, we are then able to propose key intermediates common to many of the adsorption/desorption mechanisms.
3:42PM T12.00007 Surface-catalyzed O2 adsorption on quantum thin films , JSUN KIM, ALEXANDER KHAJETOORIANS, The University of Texas at Austin, WENGUANG ZHU, ZHENYU ZHANG, Oak Ridge National Laboratory & University of Tennessee, CHIH-KANG SHIH, The University of Texas at Austin — Pure crystalline Pb is well known to be inert with respect to oxygen gas. By using scanning tunneling microscopy we demonstrate that the oxygen adsorption on Pb films is greatly increased by Cs adsorbates acting as catalysts. Our previous studies show that Cs atoms can be easily incorporated into the surface layer of thin Pb films grown on Si(111). In addition, Cs adsorbates are able to adjust the surface energy so as to initiate stable Pb nanolands on Pb flat tops of unstable thickness. Because of this unique property Cs adsorbates on originally inert Pb films, they are a natural choice of template to investigate surface catalysis of quantum thin films. Bare Pb films do not oxidize until much higher coverage (1000L), but in the presence of Cs we see adsorption of oxygen at much lower exposures of only a few Langmuir. The oxidation first occurs preferentially at sites of Cs adsorption. After oxygen clusters nucleate, oxidation of the Pb film increases in proportion to the amount of oxygen exposure. During this process the formation of oxygen clusters forces changes in the film morphology. First-principles density functional theory calculations of the O binding energies on the alloyed surface layers will be done and compared with experiment.

3:54PM T12.00008 First principle studies of the oxygen reduction reaction on the CrN electrocatalyst , SERGEY STOLBOV, University of Central Florida — These fuel cells offer great advantages for various applications, but severe obstacles remain to their large scale implementation. The Pt-based catalysts, used in both electrodes make them unacceptably expensive. Furthermore, the low rate of the oxygen reduction reaction (ORR) on the Pt cathode significantly reduces efficiency of the device. In this work, ORR on alternative CrN electrocatalyst has been studied from first principles. It is found that, in contrast to Pt, oxygen molecules dissociate spontaneously on the CrN surfaces, which switch on simple 1-electron reduction mechanism. Based on the adsorption energy calculations the free energies of intermediates were obtained as functions of the electrode potential. This diagram explain a relatively high rate of ORR obtained experimentally [1] for this material. The effects of coverage and co-adsorbates have been also studied.

4:06PM T12.00009 Hydrogen Reduction at Room Temperature of Partially Oxidized Co Cluster Films Capped with Pd 1 , A. L. CABRERA, J. I. AVILA, R. TRABOL, Pontificia Universidad Catolica de Chile, C. ROMERO, M. J. VAN BAEL, P. LIEVENS, Katholieke Universiteit Leuven — Co clusters with mean size of 1.8 nm were deposited on sapphire substrates at 25°C, 300°C and 500°C respectively. They were capped by a continuous 15 nm Pd film. Visible light transmission and reflection, in the range 400 to 900 nm, were measured when the samples were exposed to different hydrogen pressures up to 130 Torr. D.C. electrical resistance of the films was also measured as an independent property of the films to confirm hydrogen absorption by the samples. In all the samples the transmission and reflection of the films increased, reaching saturation at around 35-40 Torr hydrogen pressure. The relative change in the resistance of all Co cluster samples is smaller than the change in pure Pd films, indicating that hydrogen absorption is limited to the Pd capping layer only. We observed a significant decrease in the transmittance and the resistance during the first hydrogenation cycle of the sample prepared at 25°C suggesting that a reduction of the partially oxidized Co clusters occurred at room temperature.

4:18PM T12.00010 H2 dissociation of H2 on Co layers on Cu(111) from abinitio studies 1 , DUY LE, SERGEY STOLBOV, TALAT RAHMAN, University of Central Florida — Through first principles electronic calculations, based on the spin-polarized density functional theory using the generalized gradient approximation and the ultrasoft pseudopotential method in the plane wave representation, we studied the adsorption and the dissociation of H2 on two Co layers grown on Cu(111). As H2 approaches the surface with the H-H bond parallel to that surface, it dissociates at a distance of about 1.7Å from the Co layer, and constituent H atoms proceed to occupy neighboring fcc and hcp sites. The "adsorption" energy barrier for H2 is 0.14 eV and the "dissorption" energy is about 0.80eV. On the Co surface, H diffuses from an fcc site to an hcp site, or vice versa, with diffusion barriers of 0.17eV and 0.12eV respectively. We find no evidence of subsurface H. By analyzing the local electronic density of state, we establish, in agreement with suggestion from experiments [1], that the surface electronic states and magnetic moment of Co atoms depend very much on the H coverage.

4:30PM T12.00011 Structural and catalytic properties of thin CeO2 films on TiO2 substrate , I.G. BATYREV, ARL. Adelphi, MD, N.S. RASHKHEV, INL, Idaho Falls, ID — Structural properties of CeO2(111) thin films on top of a TiO2(110) substrate have been investigated by first-principles calculations. We found the special orientation of the ceria film relative to the rutile substrate that corresponds to a small (few percent) lattice mismatch between the two oxide surfaces. The positions of interfacial Ti atoms undergo some structural modulations during the relaxation process. Also, the relaxation of the interface resulted in the appearance of elongated Ce-O bonds at some sites of the O-terminated surface of CeO2/TiO2 films. These oxygen sites at the surface show low activation energy for loosing oxygen atoms and, therefore, they have higher catalytic activity in CO oxidation by the Mars-van Krevelen mechanism. We predict from the simulations that higher rate of the catalytic CO oxidation should have CeO2(111)/TiO2(110) films compared with CeO2(111) surface, which may also be attributed to the elongation of Ce-O bonds at some sites of O-terminated film in comparison with a pure ceria surface. We discuss the role of oxygen vacancies in the CO oxidation at reduced films and investigate the interplay between migration of O bulk atoms to the surface O vacancy sites and the structural phase transition from the CeO2(111) (Ce4+ and Ce2O3(0001) (Ce2+) structures. This work was supported by the U. S. Department of Energy Contract DE-AC07-051D14517.

4:42PM T12.00012 Adsorption and Dissociation of Molecular Hydrogen on the (0001) Surface of DHCP Americium 1, PRATIK DHOLABHAI 2, ASOK RAY, The University of Texas at Arlington — Hydrogen molecule adsorption on the (0001) surface of double hexagonal closed packed americium has been studied in detail within the framework of density functional theory. Weak molecular hydrogen adsorption were observed. The most stable configuration corresponded to a Hor2 approach molecular adsorption at the one-fold top site where the molecule’s approach is perpendicular to a lattice vector. Adsorption energies and adsorption geometries for different adsorption sites will be discussed. The change in work functions, magnetic moments, partial charges inside muffin-tins, difference charge density and density of states for the bare Am slab and the Am slab after adsorption of the hydrogen molecule will be discussed. Reaction barrier for the dissociation of hydrogen molecule will be presented. The implications of adsorption on Am 5f electron localization-delocalization will be summarized.

4:54PM T12.00013 Atomic Thermodynamic Approach for Determining Cu Catalyst Morphologies Under Reactive Water-Gas-Shift Conditions. NILAY INOGLU, JOHN KITCHIN, Dept. of Chemical Engineering, Carnegie Mellon University — The water gas shift reactions (WGS) are widely used in several industrial processes and are catalyzed by Cu catalysts. In coal derived syngas, there are sulfur (S) impurities which can adsorb on the Cu surfaces and block the active sites of the catalyst and can result in catalyst deactivation. The sulfur adsorption will compete with other possible adsorbates such as CO, O, H and CO$_2$ making a quantitative estimate of the impact of sulfur on reactivity difficult. To determine the interactions between these possible adsorbates with Cu, the adsorption properties of these different adsorbates on low Miller index facets of Cu surfaces were studied in the limit where these surfaces are in thermodynamic equilibrium with the reactive environment. The effect of S adsorption on the surface electronic structure was significant and coverage dependent. In addition to a site-blocking deactivation mechanism, we found that sulfur modifies the surface electronic structure in a way that makes the Cu less reactive. Our results show that the adsorbates play a key role in defining the catalyst morphologies. We conclude that the presence of sulfur and other reactive adsorbates can impact the reactivity of the catalysts through several mechanisms including site-blocking, surface electronic structure modification and changes in the distribution and types of reactive sites through catalyst morphology changes.

5:06PM T12.00014 The nonlocal correlation as the solution of the CO puzzle problem. PREDRAG LAZIC, FZJuelich, Germany; MOJTABA ALAEI, Isfahan University of Technology, Iran; NICOLAE ATODIRESEI, Osaka University, Japan, VASILE CACIU, FZ Juelich, Germany; RADOVAN BRAKO, Rudjer Boskovic Institute, Croatia; STEFAN BLUEGEL, FZ Juelich, Germany — For the last 20 years the Density Functional Theory (DFT) has been the standard approach for the calculation of chemisorption, adsorption, chemical reactions and electronic structure in general. Despite the great successes of the theory in predicting adsorption energies and other properties for many systems it turns out that the theory fails to predict correctly the adsorption site preference for the CO molecule on (111) surfaces of Pt, Cu and Rh, for example. The DFT calculations predict that the highly coordinated FCC (hollow) site adsorption is preferred over the top site adsorption, while experiments show unambiguously that CO adsorbs into the top site. Also, the calculated adsorption energies do not match well the experimental values. CO molecule chemisorption on these surfaces is a type of system in which one would expect DFT theory in its present implementation with semi-local (GGA) functionals to work well. We show that the inclusion of the nonlocal correlation into the DFT calculations of CO chemisorption through vdW-DF functionally largely solves the discrepancies known as the CO puzzle problem.

5:18PM T12.00015 ABSTRACT WITHDRAWN — Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T13 DCOMP: Electronic Structure 309

2:30PM T13.00001 Three-dimensional statistical reduction of the non-relativistic Schrödinger equation for electrons with pair-wise Coulomb interactions. BOYAN OBRESHKOV, Arkansas University, Fayetteville, AR 72701, USA — Based on Ritz variational principle, we reduce in statistical fashion the non-relativistic Schrödinger equation for electrons with Coulomb interactions to a three-dimensional wave-equation for the motion of one electron with the residual $N - 1$ electrons acting spectators of its motion [1]. As a consequence the Pauli’s exclusion principle is interpreted as dynamical principle. Analytic solutions of the all electron quantal equations for the ground and excited states of the helium and lithium isoelectronic sequences will be represented and the comparison with the experimental measurements for the ground-state ionization potentials of atoms shown. [1] B. D. Obreshkov, Phys. Rev. A 78, 032503 (2008).

2:42PM T13.00002 High Pressure Phases of Cu$_2$O. DAVID GROH, Gannon U, RAVI PANDEY, Michigan Technological U, MIGUEL BLANCO, Universidad de Oviedo — Copper Oxide’s ambient phase is cubic. The copper atoms are in a simple face centered cubic packing sequence of hexagonal layers, with the oxygen atoms at alternating tetrahedral sites. As the pressure increases, cubic symmetry breaks. While the basic packing sequence is maintained, the distance between layers is no longer cubic — a hexagonal structure results. At even higher pressures, a major crystal structure change occurs to the CdI$_2$ structure. The calculated phase change pressures and volumes tend to compare well with experiment.

2:54PM T13.00003 k · p formalism within FLAPW method. TATSUYA SHISHIDO, TAMIO OGUCHI, Hiroshima University — We provide a k · p formalism within the full-potential linearized augmented plane wave (FLAPW) method. Unlike the pure plane waves, the LAPW functions do not behave trivially in moving from k to k+q and their incompleteness as a basis set should be taken into account. Derivatives of the sphere matching coefficients play the key role, for which we find a simple formula. Concrete formula for the k · p matrix elements is derived and numerically tested. Generalized second-order perturbation theory allowing for a degenerate case is presented and the literally-exact electronic band gradients and curvatures are accessible.

3:06PM T13.00004 Electric polarization in a Chern insulator. SINISA COH, DAVID VANDERBILT, Rutgers University — We extend the Berry-phase concept of polarization to insulators having a non-zero value of the Chern invariant. The generalization to such Chern insulators requires special care because of the partial occupation of chiral edge states. We show how the integrated bulk current arising from an adiabatic evolution can be related to a difference of bulk polarizations. We also show how the surface charge can be related to the bulk polarization, but only with a knowledge of the wavevector at which the occupancy of the edge state is discontinuous. We conclude by presenting numerical calculations on a model Hamiltonian to provide additional support for our analytic arguments.

3:18PM T13.00005 A new Laplacian representation for real-space calculations of general periodic and partially periodic systems. AMIR NATAN, AYELET BENJAMINI, DORON NAVEH, LEEOR KRONIK, Weizmann Inst of Sci, MURILO TIAGO, SCOTT BECKMAN, JAMES CHELIKOWSKY, University of Texas, WEIZMANN INST OF SCI TEAM, UNIVERSITY OF TEXAS TEAM — We present a real-space method for electronic-structure calculations of systems with general full or partial periodicity. The method is based on the self-consistent solution of the Kohn-Sham equations, using first principles pseudopotentials, on a uniform three-dimensional non-Cartesian grid. Its efficacy derives from the introduction of a new generalized high-order finite-difference ire Laplacian that avoids the numerical evaluation of mixed derivative terms and results in a simple yet accurate finite difference operator. Our method is further extended to systems where periodicity is enforced only along some directions (e.g., surfaces), by setting up the correct electrostatic boundary conditions and by properly accounting for the ion-electron and ion-ion interactions. Our method enjoys the main advantages of real-space grid techniques over traditional plane-wave representations for density functional calculations, namely, improved scaling and easier implementation on parallel computers, as well as inherent immunity to spurious interactions brought about by artificial periodicity. We demonstrate its capabilities on bulk GaAs and Na for the fully periodic case and for a monolayer of Si-adsorbed polar nitrobenzene molecules for the partially periodic case.
3:30PM T13.00006 Confinement effects on excitation energies and regioselectivity as probed by the Fukui function and the molecular electrostatic potential, ALEX BORGOO, Vrije Universiteit Brussel, DAVID TÖZER, Durham University, PAUL GEERLINGS, FRANK DE PROFT, Vrije Universiteit Brussel — When a molecule is placed as a guest inside a zeolite pore, its electronic structure will be altered, among others by the effect of the so-called “confinement”. It has been established that the compression of the molecular orbitals influences a system’s reactivity. In this work we use a simple potential barrier method to quantify the importance of confinement effects on chemical reactivity. In the first part, excitation energies and molecular orbital energy gaps are evaluated for molecules placed in cavities of different sizes. Our results for ethylene and formaldehyde reveal an increase in excitation energy and the gap between the occupied and the unoccupied levels. In the case of the larger molecules naphthalene and anthracene, the HOMO-LUMO gap shows very little sensitivity to the confinement. To investigate the role of confinement effects on local aspects of chemical reactivity and on regioselectivity, we evaluated its effect on the Fukui function and the molecular electrostatic potential, reaction indices that are central in the description of orbital and charge controlled reactions. The results indicate that confinement can influence the regioselectivity and that the reactivity of anions is expected to change, due to the artificial binding of the exess electron.

3:42PM T13.00007 Maximally-localized Wannier functions for GW quasiparticles, D. R. HAMANN, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University — Recent efforts carrying the GW many-body approximation to self-consistency have given improved electronic structure results. Maximally-localized Wannier functions formed from the quasiparticle wave functions provide an efficient and highly accurate basis for interpolating the SCGW bands from a coarse Brillouin-zone mesh to symmetry lines. Since the MLWF’s correspond to chemists’ bond orbitals, they potentially also provide insight into the qualitative effects of the improved treatment of correlations in SCGW compared to LDA. We report results on SrTiO$_3$, solids Ar, and molecular CO. Band interpolation is accurate and effective for both solids. Small shifts in the degree of hybridization can be visualized for some of the SrTiO$_3$ and CO MLWF’s. In Ar, individual conduction-band Bloch functions were found to have large differences between LDA and SCGW. However, a manifold of 9 d and spd-hybrid MLWF’s which proved to be the minimum necessary for the lower conduction bands showed minimal differences in the two cases. A fully-functional interface to the WANNIER90 library within the SCGW-capable ABINIT code has been implemented and will be publicly available in the near future. 1. F. Brunval et al., Phys. Rev. B 74, 045102 (2006). 2. N. Marzari and D. Vanderbilt, Phys. Rev. B 56, 12 847 (1997). 3. M. van Schilfgaarde et al., Phys. Rev. Lett. 96, 226402 (2006).

3:54PM T13.00008 High-performance computational condensed-matter physics in the cloud, J. J. REHR, L. SVEC, J. P. GARDNER, M. P. PRANGE, U. of Washington — We demonstrate the feasibility of high performance scientific computation in condensed-matter physics using cloud computers as an alternative to traditional computational tools. The availability of these large, virtualized pools of compute resources raises the possibility of a new paradigm for scientific research with many advantages. For research groups, cloud computing provides convenient access to reliable, high performance clusters and storage, without the need to purchase and maintain sophisticated hardware. For developers, virtualization allows scientific codes to be pre-installed on machine images, facilitating control over the computational environment. Detailed tests are presented for the parallelized versions of the electronic structure code SIESTA and for the x-ray spectroscopy code FEFF, including CPU, network, and I/O performance, using the the Amazon EC2 Elastic Cloud.

4:06PM T13.00009 A scalable algorithm for the computation of Hartree-Fock exchange, IVAN DUCHEMIN, FRANCOIS GYGI, University of California Davis, Davis CA 95616 — Electronic structure calculations based on hybrid density functionals require efficient algorithms for the computation of the Hartree-Fock exchange operator. The high computational cost of Hartree-Fock exchange currently limits the use of such functionals in large-scale First-Principles Molecular Dynamics applications. We present a scalable parallel algorithm for the computation of Hartree-Fock exchange in a plane-wave, pseudopotential framework, with applications to electronic structure calculations of liquid water and various nanostructures. Technical issues arising in the implementation of hybrid density functionals will be discussed.

1Supported by NSF OCI 0749219 and DOE-SciDAC DE-FC02-06ER25794

4:18PM T13.00010 Compact representations of Kohn-Sham invariant subspaces, FRANCOIS GYGI, University of California Davis, Davis CA 95616 — We present a method to compute a hierarchical approximate representation of the solutions of the Kohn-Sham equations. The approach is based on a recursive bisection algorithm and yields one-particle wavefunctions localized on domains of varying sizes. The accuracy of the representation is set a priori by specifying the maximum error in the form of the approximate wavefunctions. Applications to the electronic structure of large systems are used to illustrate the data reduction achieved by this representation. The achievable data compression is similar to that obtained by truncating Maximally Localized Wannier Functions. Implications for the acceleration of electronic structure calculations and for the development of linear-scaling algorithms will be discussed.

4:30PM T13.00011 Improvements to the NRL Tight-Binding Model, MICHAEL MEHL, Naval Research Laboratory, DIMITRIS PAPACONSTANTOPOULOS, George Mason University, NOAM BERNSTEIN, Naval Research Laboratory, DANIEL FINKENSTADT, United States Naval Academy, STEFANO CURTAROLO, Duke University — The original NRL Tight-Binding Method[1] has proven to be extremely successful in reproducing first-principles total energies and band structures for many elemental systems[2], and has been applied in computationally intensive molecular dynamics simulations[3]. When generalizing to multiple atom types, however, some difficulties arise because of the form of the interaction of the on-site matrix elements with the external environment. We discuss these difficulties, and describe a new version of the method which includes a proper two-center development of the on-site parameters[4,5], including applications of the method. [1] RE Cohen et al., Phys. Rev. B 50, 14694 (1994) [2] MJ Mehl and DA Papanastasiou, Phys. Rev. B 54, 4519 (1996) [3] D Fin et al. and the gap energy and the gap between the conduction and the valence levels. This work was supported by the US Office of Naval Research. MJM is at Duke University under the NRL Advanced Graduate Research Program.
The Free energy of the landscape is calculated using these tiles and we discuss the role of these tiles in the liquid to liquid transition. The complete jamming local jamming structures to construct globally jammed states. We discuss the role of these tiles in the thermodynamic behavior of the corresponding liquid.
2:54PM T14.00003 Influence of Flow Quench Rate on the Internal Stress and Aging Dynamics of a Repulsive Colloidal Glass 1

Chinedum Osuji, Ajay Singh Negi, Department of Chemical Engineering, Yale University — We investigate the dynamics of aging in a repulsive colloidal glass composed of charged clay particles in aqueous suspension. Dynamic rheological measurements show a power law evolution of the elastic modulus of the system with sample age, measured as time elapsed after the cessation of a rejuvenating shear flow. We show that the scaling exponent is dependent on the rate of flow cessation or the flow quench rate. Comparatively fast quenches lead to systems with a smaller elastic modulus and accelerated aging whereas slower quenches result in higher modulus but correspondingly less rapid aging. We apply a recently proposed technique to follow the dynamics of residual or internal elastic stresses immediately after the flow arrest and find striking parallels between the relaxation of these stresses and the aging of the system. These results indicate that the evolution of the slow dynamics is strongly coupled to the internal stress state of the system and point to the identification of the flow quench rate as a mechanical variable that characterizes the system’s departure from equilibrium.

3:06PM T14.00004 Hydrogen-bond network dynamics in sugar-based glasses, Marcus Cicerone, Jeraldine Johnson, NIST, Michael Pikal, University of Connecticut — Hydrophilic organic glasses composed of sugars and polysaccharides are known to stabilize proteins against aggregation and chemical degradation. It has long been supposed that, due to the long timescales involved in protein aggregation and chemical degradation in the glass, α relaxation processes essentially control the rate of degradation. We have shown that, although there may be > 7 orders of magnitude in time separation, β relaxation processes can dominate in influencing both chemical and physical degradation. Also, it is apparent that these β processes are closely related to dynamics of the hydrogen-bond network in these glasses. In this presentation we will briefly discuss the phenomenology of protein degradation in sugar-based glasses, and also present details of work on developing a fluorescent probe for use as a sensor for dynamics of the hydrogen-bond network in these glasses.

3:18PM T14.00005 Density of states and soft modes of hard sphere colloidal glasses — experimental observations, 1 Antina Ghosh, Vijayakumar Chikkadi, Peter Schall, University of Amsterdam, The Netherlands, Jorge Kurchan, ESPCI, France, Daniel Bonn, University of Amsterdam, The Netherlands — Recent theories and simulations have predicted the presence of soft modes due to which the DOS of glassy materials does not go to zero at zero frequency. We obtain DOS of colloidal hard sphere suspensions from experimental data. The displacement fields of hard sphere colloidal suspensions were studied for a range of volume fractions near the glass transition using confocal microscopy. Normal mode frequencies are then computed from the time averaged correlation matrix. The density of vibrational states obtained from normal mode analysis indeed reveals an excess of low frequency anomalous modes in the system. To understand the nature of the modes we analyse the displacement vector fields at various frequencies.

1 We acknowledge support from FOM and NWO.

3:30PM T14.00006 XPCS Studies of Nanoparticle Motion within Glassy Polymer Melts, H. Guo, JHU, G. Bourret, R. B. Lennox, M. Sutton, McGill U., J. L. Hardon, U. of Ottawa, R. L. Leheny, JHU — We report x-ray photon correlation spectroscopy (XPCS) experiments to investigate the motion of nanoscale gold particles within polyisobutene (PS) melts of molecular weight between 2K and 48K g/mol. The particles, with radius of approximately 2 nm, are dispersed in a highly dilute concentration (volume fraction 0.0004) and are functionalized with PS chains to stabilize them against aggregation. At high temperature, the observed motion is diffusive, with a rate that follows a Vogel-Fulcher temperature dependence. When the melts are quenched to lower temperature, the XPCS results indicate hyper-diffusive motion that can be modeled as strain in the melt in response to localized stress relaxation. These dynamics evolve with time following the quench, suggesting that they are coupled to aging of the polymer. Our observation of this hyper-diffusive motion among such a dilute concentration of stable nanoparticles indicates that the particles act as passive tracers and the motion is an intrinsic property of quenched melts.

3:42PM T14.00007 Divergent four-point dynamic density correlation function of a glassy suspension, 1 Grzegorz Szamel, Elijah Flennner, Department of Chemistry, Colorado State University — We use a diagrammatic formulation of the dynamics of interacting Brownian particles to study a four-point dynamic density correlation function of a glassy colloidal suspension. We re-sum a class of diagrams which separate into two disconnected components upon cutting a single propagator. The resulting formula for the four-point correlation function can be expressed in terms of three-point functions closely related to the three-point susceptibility introduced by Biroli et al. and the standard two-point correlation function. We numerically evaluate the four-point function and the associated dynamic correlation length. Both the amplitude of the four-point function and the correlation length diverge at the mode-coupling transition.

3:54PM T14.00008 Self-Organized Criticality in Periodically-Sheared Sedimenting Suspensions, EmmaNoEla Filippidi, Center for Soft Matter Research, New York University, Laurent Corre, Centre des Matériaux Mines, Paris, France, Paul Chakraborty, Center for Soft Matter Research, New York University — Suspensions of non-colloidal particles under slow periodic strain can undergo a dynamical phase transition from an active fluctuating state to an absorbing steady state at a critical volume fraction. In the case of density-mismatched particles, sedimentation and shear-induced diffusion drive the system towards a self-organized critical state. The lengthscales and timescales associated with the dynamics of the active particle clusters sustained near the critical point are shown to follow power-law behavior via simulation of activated random walkers. Finite-size effects and excluded volume interactions are explored for sedimenting and neutrally buoyant, mono- and bi-disperse suspensions both by simulation and experiment.

4:06PM T14.00009 Heat transfer in model amorphous solids, 1 Vincenzo Vitelli, Ning Xu, Department of Physics, University of Pennsylvania, Matthieu Wyart, HSEAS, Harvard University, Andrea Liu, Department of Physics, University of Pennsylvania, Sidney Nagel, James Frank Institute, University of Chicago — We investigate heat transfer in model amorphous solids obtained from jammed packings of soft spheres. At the boson peak frequency, we find a sharp crossover from a weak-scattering regime, in which the energy diffusivity drops rapidly with frequency, to a strong-scattering regime, in which the diffusivity is nearly frequency-independent. We present a scaling analysis of how the crossover frequency shifts to zero as the system is decompresed towards the jamming transition. We show that the regime of flat diffusivity, invoked to explain the temperature dependence of the thermal conductivity of glasses, can arise from properties of the jamming transition.

4:18PM T14.00010 Structural response of a colloidal glass to local forcing1, KEVIN B. APTOWICZ, West Chester University, PETER J. YUNKER, University of Pennsylvania, SEAN GOSSIN, West Chester University, ZEXIN ZHANG, A. G. YODH, University of Pennsylvania — Video microscopy of glassy colloidal suspensions permits direct visualization of particle locations and trajectories, thereby providing an excellent experimental tool to aid our understanding of glasses and address current theory. We have conducted a series of experiments utilizing a bidisperse mixture of thermosensitive NIPA microgel spheres to study the structural response of a two-dimensional colloidal glass to point expansion. The packing fraction of the colloidal suspension is tuned from a liquid to a deeply jammed glass by varying the global temperature of the sample. Over this range of packing fractions, the response of the sample to point expansion is analyzed. In particular, an infrared laser tightly focused on the sample generates thermophoretic forces that lead to a point expansion in the colloidal glass. We track particle rearrangements and characterize the response as a function of packing fraction. These experiments take a step towards understanding the relationship between local structure and bulk properties of glass.

4:30PM T14.00011 Relaxation processes in polystyrene melts and ultra-thin films . A. BALJON, S. WILLIAMS, San Diego State University, N. BALABAEV, Institute of Mathematical Problems of Biology, Pushchino, Russia, F. PAANS, A. LYULIN, Dutch Polymer Institute, Technical University Eindhoven, The Netherlands — By means of large-scale computer simulations we investigate relaxation processes in polystyrene melts and ultra-thin films. The local orientational mobility of the phenyl bonds is studied with the help of Legendre polynomials of the second-order P_2(t). The spectral density of P_2(t) shows several distinctive peaks. They are caused by the large-scale motions of cooperative segments (α relaxation), smaller-scale structural dynamics (β relaxation), and transient processes. Our simulations reveal that interfaces affect α- and β-relaxation processes differently. The most puzzling observation is a slight decrease in the structural relaxation time in the middle of the film, compared to that near the free surface. As expected, the connect non-nearest-neighbor sites. Free lattices exhibit highly anisotropic modes at k′ = 0, among which are soft modes with one-dimensional dispersion in wavenumber, giving rise to a flat density of states as a function of frequency ω. In the square lattice, these modes are shear acoustic phonons, whereas in the Kagome lattice, they are optical phonons. When k′ > 0, the low-energy modes cross over from acoustic phonons of the appropriate lattice symmetry for ω < ω∗ to the soft isostatic-like modes for ω > ω∗, and the density of states crosses over from Debye-like to flat. Static phonon response functions exhibit correlation lengths ξ ∼ 1/√R. We discuss the relation of these results to those for jammed systems near point J.

3MRSEC grant DMR-0520020 and NSF grant DMR-080488 (AGY) helped support this research.

4:42PM T14.00012 Changes in Local Structure and Dynamic Heterogeneity in an Aging Glass1, PETER YUNKER, ZEXIN ZHANG, University of Pennsylvania, KEVIN B. APTOWICZ, West Chester University, AHMED M. ALSAYED, CNRS/Rhodia, ARJUN YODH, University of Pennsylvania — Recent works have shown a connection between structure and dynamical heterogeneity in glass12. However, a connection between structure and aging dynamics remains elusive. To this end, we study aging in a bidisperse suspension of soft spheres. Micron-sized temperature-sensitive NIPA particles are employed in two-dimensions, and directly observed with video microscopy. After quenching from liquid to glass, the fraction of particles with crystalline order within the first coordination shell increases with time. Particles that undergo irreversible rearrangements exhibit correlation lengths that scale as the density of additional random bonds ∆. The real and imaginary part of the effective random-bond spring constants become 

5:06PM T14.00014 Periodic Lattices Near Isostaticity. ANTON SOUSLOV, T.C. LUBENSKY, Dept. of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104 — Lattices in d dimensions with with an average of z = 2d contacts per site are at the verge of mechanical stability and are called isostatic. Common isostatic latticess include the two-dimensional square and Kagome lattices as well as the three-dimensional cubic lattice with nearest-neighbor sites connected by central-force springs of spring constant k and randomly packed spheres at random close packing at what is called point J. We calculate the phonon response functions and spectra of nearly isostatic square, cubic, and Kagome lattices in which springs of spring constant k′ connect next-nearest-neighbor sites. These lattices exhibit highly anisotropic modes at k′ = 0, among which are soft modes with one-dimensional dispersion in wavenumber, giving rise to a flat density of states as a function of frequency ω. In the square lattice, these modes are shear acoustic phonons, whereas in the Kagome lattice, they are optical phonons. When k′ > 0, the low-energy modes cross over from acoustic phonons of the appropriate lattice symmetry for ω < ω∗ to the soft isostatic-like modes for ω > ω∗, and the density of states crosses over from Debye-like to flat. Static phonon response functions exhibit correlation lengths ξ ∼ 1/√R. We discuss the relation of these results to those for jammed systems near point J.

4:54PM T14.00013 Investigation of electron beam induced changes in glassy Ge_xSe_1-x thin films1 . W. ZHOU, G. HOFFMAN, H.O. COLIJN, R.M. REANO, R. SOORYAKUMAR, The Ohio State University, P. BOOLCHAND, University of Cincinnati — Global structures in network glasses are characterized by their connectedness or mean co-ordination number. As the number of these cross-links within a covalent network increases by compositional tuning these systems steadily evolve from being underconstrained (floppy) to an overconstrained (rigid) solid. Recently (Appl Phys Lett 93, 041107 (2008)) we exploited electron beams to write nanoscale surface motifs in Ge_xSe_1-x thin films that are at the special Ge in Se composition lying in the immediate vicinity of the floppy to rigid stiffness transition. In order to investigate the nature of the surface reliefs we have employed selected area transmission electron microscopy (STEM) to probe the electron beam induced structural changes to the film. Films of thicknesses less than 150 nm were deposited by pulsed laser deposition directly onto a carbon film on a mica substrate. The glass film and carbon layer were then lifted off onto copper grids for the TEM studies. Extension of the electron beam driven studies to other compositions, as well as the effect of multiple beam overwrites on the surface reliefs and trenches in several Ge_xSe_1-x compositions will also be presented.

Static phonon response functions exhibit correlation lengths ξ ∼ 1/√R. We discuss the relation of these results to those for jammed systems near point J.

5:18PM T14.00015 Soft modes and elasticity of nearly isostatic lattices: randomness and dissipation1 . XIAOMING MAO, TOM LUBENSKY, Department of Physics and Astronomy, University of Pennsylvania — Isostatic periodic lattices, such as the square and Kagome lattices in spatial dimension d = 2, are systems at the onset of rigidity. They are marginally stable with coordination number z = 2d, and they may exhibit a non-extensive number of soft modes that can be removed by adding an infinitesimal number of additional bonds. Randomly packed frictionless spheres at the jamming point J represent an important isostatic system that, because of its randomness, exhibits complexities beyond those of periodic systems. To study the effects of randomness on phonon response, propagation, and damping, we constructed model lattices near isostaticity by adding randomly distributed next-nearest and second-nearest neighbor bonds to the isostatic square and Kagome lattices, respectively. We calculated a number of properties of these models using the CPA approximation and found them to resemble those of jammed solids near the point J. In particular, the phonon density of states crosses over from Debye-like at low frequency ω to the flat frequency-independent behavior of a one-dimensional systems at a characteristic frequency ω∗ that scales as the density of additional random bonds Δz. The real and imaginary part of the effective random-bond spring constants become equal at ω∗. We also identify a characteristic length that scales as (Δz)^-1.

2:30PM T15.00001 Time evolution of distributive entropy in rectangular microchannel mixers, MIRON KAUFMAN, PETRU FODOR, Cleveland State University — Patterning ridges on the surface of microchannels has been found to be a viable strategy to induce mixing in straight channels, despite the characteristically small Reynolds numbers. In this work we evaluate the time evolution of the Rényi entropy associated with the spatial distribution of tracers advected by an incompressible fluid moving in several straight rectangular channels: staggered herring bone [1], fractal surface patterning [2]. The steady state flow fields are obtained by solving the Navier–Stokes and continuity equations using a finite element analysis package. The Rényi entropy is then evaluated at different times using the spatial distribution of the tracers. The entropy increases with time as Int with a slope approximately equal to unity. The slope quantifies the rate of distributive mixing. The rate of increase in the entropy is found to be independent of the Rényi beta parameter. This is qualitatively different than the distributive mixing in channels with moving walls [3] where the rate of distributive mixing changes with the beta parameter. We also study the dependence of the distributive entropy on the Reynolds number. [1] A.D. Stroock et al., Science 295, 647 (2002); [2] M. Camesasca, M. Kaufman, I. Manas-Zloczower, J. Micromech. Microeng. 16, 2298 (2006); [3] W. Wang, I. Manas-Zloczower, M. Kaufman, Chemical Engineering Communications, 192(4), 405-423 (2005).

2:42PM T15.00002 Capillary absorption of metal nanodroplets by carbon nanotubes, SHAUN HENDY, Industrial Research Ltd, DMITRI SCHEBACHOV, Victoria University of Wellington — We present a simple model that demonstrates the possibility of capillary absorption of non-wetting liquid nanoparticles by carbon nanotubes assisted by the action of the Laplace pressure due to the droplet surface tension. We test this model with molecular dynamics simulation and find excellent agreement with the theory, which shows that for a given nanotube radius, there is a critical size below which a metal droplet will be absorbed. We then consider the dynamics of capillary absorption using the steady-state flow model due to Marmur, which is based on the Lucas-Washburn model with the addition of a driving force due to the Laplace pressure of the droplet. We find an exact solution to the absorption problem, which shows a logarithmic time dependence for a non-marmur’s limit. For Marmur’s limit the steady state is approached very slowly with time and shows that this reproduces the dynamics observed in the simulations well. The simulations show that the flow of the metal exhibits a large degree of slippage at the tube walls, with slip lengths of up to 10nm. These findings suggest new methods for fabricating composite metal-CNT materials, and have implications for our understanding of the growth of CNTs from metal catalyst particles. The results also explain the recent observations of the absorption of Cu nanodroplets by carbon nanotubes.

2:54PM T15.00003 Dynamic Pattern Formation In a Bubble-Generating Concentric Microfluidic Device1, KENG-HUI LIN, KUO-YUAN CHUNG, Institute of Physics, Academia Sinica, Taipei, Taiwan — We observe rich spatiotemporal patterns of bubbles inside liquid droplets through a concentric microfluidic device made by two capillary tubes flown with gas and liquid respectively. When the gas pressure increases, the bubbles change from monodisperse, bidisperse to polydispers. When the liquid flow rate to the gas flow rate is small, the bubble can not be stabilized inside the liquid droplet. The diameter of the bubbles can be scaled with the ratio of gas flow rate to the liquid flow rate. Our device offers different geometry to understand the bubble breakup in the microfluidic device.

3:06PM T15.00004 Flow-Based Organization of Soft Matter in Three Dimensions, LIAN LENG, SIASHAS ASLANBEIGI, AXEL GUENTHER, University of Toronto — Flows of miscible and immiscible liquids through microchannel networks have been previously used to achieve spatial organization within one plane. However, extending this approach to three dimensions, an essential requirement to create synthetic bulk materials with a regular microstructure, is not straightforward. To our knowledge for the first time, we demonstrate microfluidic strategy for the three-dimensional organization of soft bulk materials. The approach is enabled by a massively scaled microfluidic architecture that distributes two miscible or immiscible fluid streams through an array of parallel channels. The soft-lithographic fabrication process was adapted to consistently define microfluidic channel networks in elastomer substrates that are only 500 microns thin; followed by subsequent bonding of up to ten such layers in the vertical direction. The chip was connected with fluidic inlets, completely immersed in water and continuously extruded the organized material at its exit. Upon leaving the chip, neighbouring fluid streams from each level are allowed to separate naturally. The material microstructure was controlled by adjusting the flow rates of the interdiffusing fluid streams (e.g. aqueous alginate and calcium chloride solutions).

3:18PM T15.00005 Viscous droplet deformation and breakup in microfluidic cross-flows, THOMAS CUBAUD, Stony Brook University — The dynamic response of translating high-viscosity droplets is experimentally investigated by means of a sharp increase of the flow velocity in a microchannel junction. The additional local injection of the continuous phase from symmetric side-channels into a square microchannel produces a broad range of time-dependent deformations and breakup. In particular, due to microscale wall confinement, the system displays a non-linear behavior with the initial droplet size. Deformations, relaxation times, and fragmentation processes are examined as a function of flow and fluids properties with a particular emphasis on the formation of slender viscous structures and spoon-like droplets, i.e., asymmetrical droplets.

3:30PM T15.00006 Morphology of liquids spreading along open nanofluidic channels1, ANTONIO CHECCO, Brookhaven National Laboratory — Dynamic atomic force microscopy (AFM) in the non-contace regime is used to study the morphology of a non-volatile liquid (squalane) as it spreads along wettable nanostripes embedded in a non-wettable surface. AFM allows the direct observation of the microscopic contact line of spreading nanoliquids with unprecedented spatial resolution. Results show that the liquid profile depends on the amount of lateral confinement imposed by the nanostripes and it is truncated at the microscopic contact line in good qualitative agreement with classical mesoscale hydrodynamics. However, the width of the contact line is found to be significantly larger than expected theoretically. This behavior may originate from small chemical inhomogeneity of the patterned stripes as well as from thermal fluctuations of the contact line.

3:42PM T15.00007 Separation of chiral objects by shear flow in microfluidic channels - Theory, HENRY FU, Brown University, MARCOS, MIT, THOMAS POWERS, Brown University, ROMAN STOCKER, MIT — Motivated by the desire to separate chiral molecules, we investigate the motion of helices in shear flow generated by a microfluidic channel. We present a model based on resistive force theory to show that hydrodynamic forces on a helix in shear flow produce a drift perpendicular to the shear plane. The drift depends on the sign of the shear rate and the chirality of the helix. Net drift results from preferential alignment with streamlines. For large (>1 micron), elongated particles, alignment is a consequence of the deterministic tumbling trajectories (Jeffery orbits) in shear flow. For smaller particles, we estimate the effect of Brownian rotational diffusion on chirality-sensitive drift. We deduce a lower size limit for separation of chiral objects by shear flow in microfluidic channels.
Separation of chiral objects by shear flow in microfluidic channels - Experiment.
Marcos, Massachusetts Institute of Technology, Henry Fu, Thomas Powers, Brown University, Roman Stocker, Massachusetts Institute of Technology — We use microfluidics to test the prediction that a helix in shear flow drifts across streamlines. We use the non-motile, helical-shaped bacterium Leptospira biflexa as our model chiral object. As the shear in the top and bottom halves of the microchannel has opposite sign, we predict and observe the bacteria in these two regions to drift in opposite directions. The magnitude of the separation is in good agreement with theory.

Tunable liquid optics: electrowetting-controlled liquid mirrors based on self-assembled Janus tiles.
Tom Krupenkin, University of Wisconsin – Madison, Mike Bucaro, Harvard University, Paul Kolodner, Bell Laboratories, Ashley Taylor, University of Wisconsin – Madison, Alex Sidorenko, University of the Sciences in Philadelphia, Joanna Aizenberg, Harvard University — In this work we describe a tunable, high-reflectivity optofluidic device based on self-assembly of anisotropically-functionalized hexagonal micromirrors (Janus tiles) on the surface of an oil droplet to create a concave liquid mirror. The liquid mirror is deposited on a patterned transparent electrode that allows the focal length and axial position to be electronically controlled. The mirror is mechanically robust and retains its integrity even at high levels of vibrational excitation of the interface. The use of reflection instead of refraction overcomes the limited available refractive-index contrast between pairs of density-matched liquids, allowing stronger focusing than is possible for a liquid lens of the same geometry. This approach is compatible with optical tools that could provide novel functionality — for example, a dynamic 3D projector; i.e., a light source which can scan an image onto a moving, non-planar focal surface. Janus tiles with complex optical properties can be manufactured using our approach, thus potentially enabling a wide range of novel optical elements.

Designing actuated cilia pumping fluids in microchannels.
Alex Alexeev, Georgia Institute of Technology, Julia Yeomans, University of Oxford, Anna C. Balazs, University of Pittsburgh — Using three-dimensional computational modeling, we examine the motion of actuated cilia in a fluid-filled microchannel. The cilia are modeled as deformable, elastic filaments, which are initially tilted with respect to the channel surface. A sinusoidal force normal to the microchannel wall is applied at the free ends of the tilted cilia and induces periodic oscillations of these flexible filaments. To capture the complex fluid-structure interactions among these filaments, the channel walls and the surrounding solution, we employ our hybrid computational approach that combines a lattice Boltzmann model for hydrodynamics of viscous fluids and a lattice spring model for the micromechanics of elastic solids. We find that the actuated cilia give rise to a unidirectional flow in the microchannel and by simply altering the frequency of the applied force, we can controllably switch the direction of the net flow. The findings suggest that beating elastic cilia could be harnessed to regulate the fluid streams in microfluidic devices.

A Deterministic Microfluidic Ratchet.
Kevin Louterback, Jason Puchalla, Robert Austin, James Sturm, Princeton University — We present a deterministic microfluidic ratchet where the trajectory of particles in a certain size range is not reversed when the sign of the driving force is reversed. This ratcheting effect is produced by employing triangular rather than the conventionally circular posts. When the sign of the driving force is reversed, the particles may bounce together and merge into one when triggered with electric fields that are created by the chip. [1] TP Hunt, D Issadore, RM Westervelt – Lab on a Chip, 2008.

Topological Dependence of ds-DNA Confined in Nanoslits.
Po-Keng Lin, Institute of Atomic and Molecular Science, Academia Sinica, Jen-Fang Chang, Institute of Physics, Academia Sinica, Cheng-Hung Wei, Pei-Kuen Wei, Research Center for Applied Sciences, Academia Sinica, Y.-L. Chen, Institute of Physics, Academia Sinica — Topological constraints are important for the DNA condensation in confinement, such as chromosome in the cell and bacteriophage DNA packaging. We investigated the topological dependence of the size, shape and diffusivity of ds-DNA confined in a nanowire with height \(h = 780 \text{ nm}\) (< bulk radius of gyration of ds-DNA) to strong confinement \(h = 20 \text{ nm} < \kappa\) persistence length \(\lambda_p\) are systematically investigated. Shape anisotropy of both linear and circular DNA increases with decreasing \(h\), which indicate the DNA become more anisotropic. Furthermore, we observed the transition from de Gennes to Odijk scaling in the measured extension and diffusivity when \(h = \kappa\lambda_p\). Interestingly, the diffusivity of circular DNA is larger than linear DNA in the birebodl regime, but they are nearly equal in slits with \(h << \kappa\lambda_p\).

Propagation modes of entropically trapped and extended DNA molecules.
Morten Mikkelsen, Technical University of Denmark, Walter Reisner, Brown University, Henrik Flyvbjerg, Anders Kristensen, Technical University of Denmark — Nanconfinement is a powerful tool for controlling polymer conformation and dynamics in lab-on-a-chip type devices for the analysis of DNA and other biomolecules. We present a new device that combines confinement-based extension of DNA with the entropic trapping principle, leading to qualitatively new physics and applications. The device consists of a 50 nm slit channel with an array of transverse \(100 \times 100\) nm grooves, where the transport of DNA molecules perpendicular to the groove axis is investigated under pressure driven buffer flow. At low flow velocities the DNA remains trapped and extended in the nanogrooves while buffer circulates through the slit, enabling physical mapping of the DNA while performing real time buffer exchanges. For flow velocities above a molecular weight dependent escape threshold, we show that the molecule transport through the slit channel randomly alternates between two modes of propagation: A stepwise groove to groove hopping, called the ‘sidewinder’, and a continuous tumbling across the grooves, where the molecules feel the topology as an effective friction, called the ‘tumbleweed’. The observed length dependence on the molecule velocity may lead to a novel separation methodology.

Multiplex selection and elution of aptamers using nanoporous sol-gel droplets and a microheater array.
Seung-Min Park, Cornell University, Jiyoung Ahn, MinJoung Jo, Soyun Kim, Donguk University, Dong-Ki Lee, Sungkyunkwan University, John LIs, Pangshun Zhu, Harold Craighead, Cornell University — Aptamers are well-known protein capture reagents that bind to specific proteins and can be effective in inhibiting the protein’s normal interactions. Here, we have described a process for selective binding and elution of aptamers from the nanoporous-silicate sol-gel droplets within which target proteins are immobilized. These silicate sol-gel droplets are incorporated with polydimethylsiloxane (PDMS) microfluidic systems and individually addressable by electrical microheaters. These properties allow discrete protein – nucleic acids interaction so that multiplexed selection is possible. It is shown that specific aptamers bind their respective protein targets and can be selectively eluted by micro-heating. Our microfluidic in vitro selection system improves selection efficiency, reducing the number of selection cycles needed to produce high affinity aptamers. We are also able to separate high-affinity nucleic acid species from a large random nucleic acid pool. The process is readily scalable to larger arrays of sol-gel-embedded proteins.
2:30PM T16.00001 Probing quasiparticle dispersion and order parameter symmetry of ultracold fermionic superfluids and density waves via lattice. DAVID PEKKER, RAJDEEP SENSARMA, EUGENE DEMLER, Harvard University. We propose a pump-probe experiment for studying the properties of condensed states of ultracold fermionic atoms in optical lattices. The pump consists of periodic modulations of the optical lattice potential in time, and the probe of measuring either the momentum distribution function or the density-density correlation functions. We apply our scheme to probing d-wave superfluids and d-density waves. In both cases we show that the dispersion relation of quasi-particles can be extracted from the momentum distribution function, and the order-parameter symmetry can be extracted from the pattern of peaks and dips that form due to the interference of the excited quasiparticles in the appropriate density-density correlation function.

2:42PM T16.00002 Relaxation of Double Occupancies in large U Hubbard Model. EUGENE DEMLER, RAJDEEP SENSARMA, DAVID PEKKER, Harvard University. We study the relaxation rates of double occupancies in large U Fermionic Hubbard model both in the Mott insulating state and in the compressible state with holes. We find that the relaxation rate \( \sim t \exp(-U/t) \) in the insulating state and \( \sim t \exp(-U/2t) \) in the compressible state.

2:54PM T16.00003 Modulation of Optical Lattice Potential in a Fermionic Mott Insulator. RAJDEEP SENSARMA, DAVID PEKKER, EUGENE DEMLER, Harvard University. We analyze the double occupancies produced in a Fermionic Mott insulator near half-filling by modulating the optical lattice potential. We relate the rate of production of doublons to the spectral function of a hole and a doublon in the background of the spins. In the high temperature (spin disordered) state, the hole (doublon) is completely incoherent and the rate of production of doublons is peaked around \( \omega = U \) and decreases monotonically up to twice the bandwidth on either side. We also derive a sum-rule for energy integrated response in this limit. At low temperatures (anti-ferromagnetically ordered state), the spin ordering leads to a coherent peak in the hole spectral function along with other broad features corresponding to shake-off of spin-waves. This shows up in the doublon production rate as a sharp edge at the lower end of the spectrum and oscillations as a function of perturbing frequency.

3:06PM T16.00004 Equation of state and magnetic properties of the three-dimensional repulsive Hubbard model. CHIA-CHEN CHANG, SHIWEI ZHANG, Department of Physics, The College of William and Mary. Motivated by recent advances in fermionic optical-lattice experiments, we report results from numerical simulations of the ground state properties of the three-dimensional single-band Hubbard model (with nearest-neighbor hopping and repulsive \( s \)-wave on-site interaction). We focus on intermediate interaction strengths, \( U/t < \sim 10 \). The constrained-path auxiliary-field quantum Monte Carlo method is used, with a phaseless approximation to control the sign/phase problem. One-body finite size effects and shell effects are eliminated by implementing twist-averaged boundary conditions. The equation of state is determined accurately for several values of \( U/t \). We study the nature of the ground state away from half-filling by examining the spin-spin and other correlation functions as a function of doping.

3:18PM T16.00005 Phase diagram and Neel temperature of fermions in a three-dimensional optical lattice. CHARLES MATHY, DAVID HUSE, Princeton University. One of the most exciting prospects in the field of ultracold atoms is the experimental realization of an antiferromagnetic Mott state, in a system of fermions in a three-dimensional optical lattice. Experimentalists are currently wrestling with achieving the requisite ordering temperatures. We address the question of which regions of parameter space one should explore to find the highest Neel temperature. To this end, we perform Hartree-Fock calculations and map out the magnetic phase diagram of two component fermions in a three-dimensional simple cubic lattice. We find that the superexchange and Neel temperature are maximized in a regime of intermediate coupling, where the system is no longer well described by a one-band Hubbard model. We also perform a perturbative expansion in a Wannier basis, and study the corrections to the Hubbard model in this region. We find that the largest correction is a Hund's rule ferromagnetic coupling. Finally, our calculations suggest that the Mott plateau should be large in the intermediate coupling regime, and therefore experimentally accessible.

3:30PM T16.00006 Collisional cooling of ultra-cold atom ensembles using Feshbach resonances. LUDWIC MATHEY, EITE TIESINGA, PAUL JULIENNE, CHARLES CLARK, NIST and JQI. We propose a new type of cooling mechanism for ultra-cold fermionic atom ensembles, which capitalizes on the energy dependence of inelastic collisions in the presence of a Feshbach resonance. We first discuss the case of a single magnetic resonance, and find that the final temperature and the cooling rate is limited by the width of the resonance. A concrete example, based on a \( p \)-wave resonance of \(^{40}\text{K}\), is given. We then improve upon this setup by using both a very sharp optical resonance and a very broad magnetic resonance and show that one can reach temperatures competitive to those created by current technologies.

3:42PM T16.00007 Fulde-Ferrell-Larkin-Ovchinnikov-like pairing of attractively interacting fermions on a two-leg ladder geometry. FABIAN HEIDRICH-MEISNER, RWTH Aachen University, ADRIAN FEIGUIN, Microsoft Q, UC Santa Barbara, and U of Maryland. Recent experiments on spin-imbalanced ultracold Fermi gases at MIT and Rice have stimulated an active search for conditions that would allow for the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state to be realized in ultracold atomic gases. Theoretical work indicates that FFLO-like pairing is favored in low-dimensions (see [1] and references therein). Indeed, in one-dimensional (1D) optical lattices, the FFLO pairing mechanism is a dominating feature and survives in the presence of a confining potential. Here we extend our previous study [1] to the case of a two-leg ladder geometry [2]. Experimentally, ladders can be realized as arrays of double wells. Using a numerically exact approach, the density matrix renormalization group method, we show that FFLO-like pairing is found in a large part of the respective phase diagram, with an order parameter with a much richer structure than in the strict 1D case. We further shed light on the effect of a harmonic potential as present in optical lattices and establish the emergence of two-dimensional physics and a novel phase separation scenario not encountered in 1D chains.

3:54PM T16.00008 Complete Phase Diagram of the Attractive Hubbard Model with a Zeeman Field. YEN LEE LOH, The Ohio State University, NANDINI TRIVEDI. We study the attractive Hubbard model on square and cubic lattices, using a variational mean-field theory in which the interaction is decoupled in six channels (spin, charge, and pairing). We present the phase diagram as a function of attraction U, chemical potential mu, and Zeeman (spin-exchange) field h, and also as a function of the numbers of up and down spins. We test our hypothesis that FFLO states have a larger range of stability in a lattice than in the continuum, especially in lower dimensions. We discuss the results in the context of ultracold fermions in optical lattices, as well as the implications for thin film superconductors in a parallel magnetic field.
4:06PM T16.00009 Orbital Analogue of the Quantum Anomalous Hall Effect in p-Band cold fermion Systems. CONGJUN WU, Department of Physics, UCSD — We investigate the topological insulating states of the p-band systems in optical lattices induced by the on site orbital angular momentum polarization, which exhibit gapless edge modes in the absence of Landau levels. This effect arises from the energy-level splitting between the on site px,py and px-ipy orbitals by rotating each optical lattice site around its own center. At large rotation angular velocities, this model naturally reduces to two copies of Haldane’s quantum Hall model. The distribution of the Berry curvature in momentum space and the quantized Chern numbers are calculated. The experimental realization of this state is feasible.

4:18PM T16.00010 Anomalous expansion of attractively interacting Fermions in an optical lattice. TAKUYA KITAGAWA, Department of Physics, Harvard University, Cambridge, Massachusetts 02138, USA, LUCIA HACKERMULLER, ULRICH SCHNEIDER, MARIA MORENO-CARDONER, THORSTEN BEST, SEBASTIAN WILL, Institut für Physik, Johannes Gutenberg-Universität, Staudingerweg 7, D-55099 Mainz, Germany, EUGENE DEMLER, Department of Physics, Harvard University, Cambridge, Massachusetts 02138, USA, IMMANUEL BLOCH, BELEN PAREDES, Institut für Physik, Johannes Gutenberg-Universität, Staudingerweg 7, D-55099 Mainz, Germany — We consider a two component Fermi mixture of ultracold atoms with attractive interactions in an optical lattice and in the presence of a parabolic potential. Using a high temperature expansion, we analyze the behavior of the system size when adiabatically increasing the interaction strength. We show that entropy conservation leads to an anomalous radius increase for large values of the interaction. We also find that the competition between entropy and the Hartree part of the attractive interaction makes the system reach a minimum size at a nonzero value of the interaction.

1Harvard-MIT CUA, DARPA, MURI, and the NSF

4:30PM T16.00011 Strongly correlated Fermions in optical lattices: static and dynamic properties. LUCIA HACKERMULLER, ULRICH SCHNEIDER, MARIA MORENO-CARDONER, Johannes-Gutenberg-University Mainz, Germany, IMMANUEL BLOCH, Universität Mainz, Max Planck Institut für Quantenoptik, Garching, Germany — Fermionic atoms in optical lattices can serve as a model system for condensed matter physics. They implement the Hubbard model with high experimental control of the relevant parameters. We study static and dynamic properties of ultracold fermions in different regimes, varying from a metal to a band insulator in the non-interacting system and including complex metals and the Fermionic Mott Insulator for strongly repulsive systems. In the experiment, spin mixtures of fermionic 40K are loaded into a combination of a blue detuned three dimensional optical lattice and a red detuned dipole trap. This combination of optical potentials allows an independent control of lattice depth and harmonic confinement, thus enabling us to explore different regimes. In addition to the static properties we present measurements of the dynamic response of the system to changes of the external parameters.

4:42PM T16.00012 Attractively Interacting Fermions in an Optical Lattice. LUCIA HACKERMULLER, ULRICH SCHNEIDER, MARIA MORENO-CARDONER, Johannes-Gutenberg-University Mainz, Germany, TAKUYA KITAGAWA, Department of Physics, Harvard University, THORSTEN BEST, SEBASTIAN WILL, SIMON BRAUN, Johannes-Gutenberg-University Mainz, Germany, EUGENE DEMLER, Department of Physics, Harvard University, BELEN PAREDES, IMMANUEL BLOCH, Johannes-Gutenberg-University Mainz, Germany — Mixtures of ultracold fermionic species in optical lattices can serve as a tool to test condensed matter physics models, a prominent example being the Fermi-Hubbard-Hamiltonian. We study a balanced spin mixture of 40K in |F,m_F⟩ = (1/2, 1/2) and (3/2, 7/2) in a three dimensional blue detuned optical lattice, where the interaction between the spin states can be tuned via a Feshbach resonance. Changing the scattering length allows us to go from non-interacting to attractive states and finally to a strongly paired system. For small attractive interactions, the cloud size shrinks upon increasing the interactions, but surprisingly we find a minimal cloud size for medium attractive interactions. For stronger interactions the cloud size increases again. This anomalous increase can be understood with a straightforward entropy argument. We compare the experimental data with the prediction of an exact calculation in the two-tunneling limit and with a high temperature expansion theory.

4:54PM T16.00013 Spin and Charge Dynamics in Atomic Fermions Loaded on Optical Lattice. MASAHIKO OKUMURA1, CCSE, Japan Atomic Energy Agency, HIROAKI ONISHI, Advanced Science Research Center, Japan Atomic Energy Agency, SUSUMU YAMADA2, MASAHIKO MACHIDA2, CCSE, Japan Atomic Energy Agency — We study spin and charge dynamics of trapped two-component fermions loaded on an optical lattice by using the time dependent density matrix renormalization group (TDDMRG) method. The present target issue is dynamics of spin and charge in Mott state recently realized experimentally by [1]. Firstly, we simply shake a trapped potential superposed onto an optical lattice and observe the charge dynamics on the Mott state by using TDDMRG. Secondly, we do the same thing on a trapped potential which works only on a pseudo-spin species and observe the spin density dynamics. These results are compared with non-trapped case with an open boundary condition. Also, we compare one-dimensional chain like cases with those of n-legs square and triangular ladder systems. 5:18PM T16.00015 Multiband superfluidity and superfluid-insulator transition of strongly interacting fermions in an optical lattice. ANTON BURKOV, University of Waterloo, ARUN PARAMEKANTI, University of Toronto — We study the multiband superfluid phase and superfluid-insulator transition of strongly interacting fermionic cold atoms in an optical lattice at a filling of two fermions per lattice site. Our mean-field approach includes both Hartree and pairing correlations and thus differs from previous approaches to this problem. We point out a very significant discrepancy between the mean-field theory result for the critical lattice depth of the superfluid-insulator transition and its experimental value. We show that this discrepancy is due to a very small superfluid stiffness of the paired fermion superfluid in a deep optical lattice. We also present new experimentally testable results on the modulated components of the superfluid order parameter, quasiparticle gap, and band occupation as a function of the lattice depth.

Session T17 GQI: Focus Session: Materials in Superconducting Qubits 318
2:30PM T17.00001 Noise and Dephasing from Surface Magnetic States in Superconducting Circuits. ROBERT MCDERMOTT, University of Wisconsin — Superconducting qubits are a leading candidate for scalable quantum information processing. In order to realize the full potential of these qubits, it is necessary to develop a more complete understanding of the microscopic physics that governs dissipation and dephasing of the quantum state. In the case of the Josephson phase and flux qubits, the dominant dephasing mechanism is an apparent low-frequency magnetic flux noise with a 1/f spectrum and a magnitude of several μΦ0/Hz1/2 at 1 Hz, where Φ0 = h/2e is the magnetic flux quantum. Recent qubit results are compatible with the excess low-frequency noise measured by researchers at Berkeley more that 20 years ago in a series of experiments on SQUIDs cooled to millikelvin temperatures. The origin of this excess noise was never understood. Here we describe studies of flux noise and temperature-dependent magnetization in SQUIDs cooled to millikelvin temperatures. We observe that the flux threading the SQUIDs increases as 1/T as temperature is lowered; moreover, the flux change is proportional to the density of trapped vortices. The data is compatible with the thermal polarization of unpaired surface spins in the trapped fields of the vortices. In the absence of trapped flux, we observe evidence of spin- glass freezing at low temperature. These results suggest a microscopic explanation for the universal 1/f flux noise in SQUIDs and superconducting qubits, and suggest that suitable surface treatments of the superconducting films will lower the density of magnetic states, leading to superconducting devices with lower noise and solid-state qubits with improved coherence times.

3:06PM T17.00002 Susceptibility of Magnetic Surface States in Superconducting Circuits. STEVEN SENDLEBACH, DAVID HOVER, ROBERT MCDERMOTT, UW-Madison Department of Physics, MICHAEL MUECK, Institut für Angewandte Physik, Justus-Liebig-Universität, Gießen — Recent experiments indicate that there is a high density of unpaired spins residing on the surfaces of superconducting thin films used to implement SQUIDs and superconducting qubits. Fluctuations of these spins give rise to low frequency flux noise and dephasing of the qubit state. Realization of phase and flux qubits with improved dephasing times will require a deeper understanding of the microscopic physics that governs fluctuations of the surface spins. Here we describe experiments that probe the ac spin susceptibility of the surface magnetic states. The detector is a dc SQUID-based susceptometer optimized for the study of surface spins. We discuss the temperature and frequency dependence of the spin susceptibility, and relate these to interactions between spins, the distribution of spin relaxation times, and possible spin-glass freezing.

3:18PM T17.00003 Reflectometry measurements of 1/f noise in SQUID phase qubits at mK temperatures1. B. K. COOPER, R. M. LEWIS, CNAM and JQI, University of Maryland, B. S. PALMER, V. ZARETSKEY, Laboratory for Physical Sciences, A. J. PRZYBYSZ, H. KWON, J. R. ANDERSON, C. J. LOBB, F. C. WELLSTOOD, CNAM and JQI, University of Maryland — We measure 1/f noise spectra in dc SQUID phase qubits using a microwave reflectometry technique. One of the SQUID junctions is shunted by a large capacitor, forming a microwave frequency resonator biased and driven to show nonlinear response, typically at 1.5 GHz. This nonlinearity means small current or flux fluctuations produce large changes in reflected phase which we can measure using homodyne detection. Measurements from aluminum qubits on sapphire are compared to previous measurements of 1/f noise flux in SQUIDs and a similarly designed Nb/AIOx/Nb on silicon dc SQUID fabricated by Hynes; data was taken at temperatures ranging from 50 mK to 500 mK. 1This work was supported by JQI, CNAM and LPS.

3:30PM T17.00004 Crystalline Silicon Dielectrics for Superconducting Qubit Circuits. DAVID HOVER, WEINA PENG, STEVEN SENDLEBACH, MARK ERIKSSON, ROBERT MCDERMOTT, University of Wisconsin Madison — Superconducting qubit energy relaxation times are limited by microwave loss induced by a continuum of two-level state (TLS) defects in the dielectric material of the circuit. State-of-the-art phase qubit circuits employ a micron-scale Josephson junction shunted by an external capacitor. In this case, the qubit T1 time is directly proportional to the quality factor (Q) of the capacitor dielectric. The amorphous capacitor dielectrics that have been used to date display intrinsic Q of order 1010 to 1011. Shunt capacitors with a Q of 103 are required to extend qubit T1 times well into the microsecond range. Crystalline dielectric materials are an attractive candidate for qubit capacitor dielectrics, due to the extremely low density of TLS defects. However, the robust integration of crystalline dielectrics with superconducting qubit circuits remains a challenge. Here we describe a novel approach to the realization of high-Q crystalline capacitor dielectrics for superconducting qubit circuits. The capacitor dielectric is a crystalline silicon nanomembrane. We discuss characterization of crystalline silicon capacitors with low-power microwave transport measurements at millikelvin temperatures. In addition, we report progress on integrating the crystalline capacitor process with Josephson qubit fabrication.

3:42PM T17.00005 Testing of qubit materials and fabrication using superconducting resonators. SHWETANK, KUMAR, MATTHIAS STEFFEN, DAVID DIVINCENZO, GEORGE KEEFE, MARY BETH ROTHWELL, MATTHEW FARINELLI, JIM ROZEN, FRANK MILLIKEN, MARK KETCHEN, IBM Research — We will present the results of measuring a superconducting resonator fabricated using different substrates and superconducting metals. Specifically, the quality factor of these resonators will be shown to be closely related to not only the purity of the substrates and metals used in the process but also to the details of the fabrication. We will demonstrate the change in quality factor of a bare resonator when subjected to the qubit process. Based on our measurements we propose that superconducting resonators may form a test bed for troubleshooting the fabrication process for minimizing the materials related dissipation in the qubits.

3:54PM T17.00006 Optimizing silicon nitride for superconducting quantum circuits. HANHEE PAIK, KEVIN OSBORN, Laboratory for Physical Sciences — Amorphous dielectrics are prevalent in lithographic circuits, but their presence can decouple superconducting qubits. We investigate the relationship between stoichiometry and low-temperature loss in silicon nitride dielectric films, where two-level system defects are unsaturated. The silicon nitride films are deposited by plasma-enhanced chemical vapor deposition at 300 degrees celsius, with silane and nitrogen as precursor gases. The precursor gas ratio is changed and film density, crystalline order, stress, and hydrogen incorporation are measured. Hydrogen, purity of the substrates and metals used in the process but also to the details of the fabrication. We measure 1/f noise spectra in dc SQUID phase qubits using a microwave reflectometry technique. One of the SQUID junctions is shunted by a large capacitor, forming a microwave frequency resonator biased and driven to show nonlinear response, typically at 1.5 GHz. This nonlinearity means small current or flux fluctuations produce large changes in reflected phase which we can measure using homodyne detection. Measurements from aluminum qubits on sapphire are compared to previous measurements of 1/f noise flux in SQUIDs and a similarly designed Nb/AIOx/Nb on silicon dc SQUID fabricated by Hynes; data was taken at temperatures ranging from 50 mK to 500 mK.

4:06PM T17.00007 Low-photon number studies of inductively-coupled superconducting resonators, MOE KHALIL, Laboratory for Physical Sciences and University of Maryland, Department of Physics, HANHEE PAIK, Laboratory for Physical Sciences, FRED WELLSTOOD, University of Maryland, Department of Physics, KEVIN OSBORN, Laboratory for Physical Sciences — Quality factors near one million have been observed in on-chip superconducting resonators for many years, but new studies on resonators reveal much lower quality factors at low-photon numbers, perhaps due to the presence of anomalous two-level system defects. We have designed and fabricated four new aluminum thin-film resonator types near 6 GHz. They include a lumped-element resonator, a slot-line resonator, and two hybrids, both of which contain a slot line and either an inductor or a capacitor. The resonator types have a consistent line width and are fabricated on a sapphire substrate to facilitate the study of surface defects, such as two-level systems. We plan to compare their quality factors in an effort to better understand the loss mechanism associated with the surface. All the resonator types have inductive coupling to a coplanar waveguide with geometrical symmetry that can be used to construct useful Josephson junction resonators.

4:18PM T17.00008 LC Filtered dc SQUID Phase Qubit with Low Dielectric Loss\textsuperscript{1}, HYEOKSHIN KWON, A. J. PRZYBYLSZ, University of Maryland, College Park — We have investigated a dc SQUID phase qubit with LC filter, which has a relatively small (\sim 4 \mu m^3) Al/AIO\textsubscript{x}/Al Josephson junction shunted by an additional capacitor built using low-stress thin film SiN\textsubscript{x}. The LC isolation provides an additional isolation factor at the junction plasma frequency and allows flexibility in the choice of SQUID parameters. We report Rabi oscillations with a 42 ns envelope decay time (T\textsubscript{1}), and a 32 ns energy relaxation time (T\textsubscript{1}), consistent with a loss tangent of about 7 \times 10^{-4} in the loss-stress SiN\textsubscript{x}. We also report on progress towards getting longer coherence times using a high-stress SiN\textsubscript{x} with a lower loss tangent.

\textsuperscript{1}Funding provided by JQI, CNAM and the DOD.

4:30PM T17.00009 Microwave response of vortices in Al and Re superconducting thin films\textsuperscript{1}, C. SONG, T.W. HEITMANN, M.P. DEFEO, K. YU, B.L.T. PLOURDE, Syracuse University, R. MCDERMOTT, University of Wisconsin, M. NEELEY, J.M. MARTINIS, UC Santa Barbara — Vortices trapped in superconducting microwave resonant circuits contribute excess loss and can result in substantial reductions in the quality factor. Thus, characterizing the microwave vortex response in superconducting thin films is important for the design of superconducting qubits, which are typically operated in small, but non-zero, magnetic fields. By cooling in fields of the order of 1 Gauss and below, we have characterized the magnetic field and frequency dependence of the microwave response of a small density of vortices in resonators fabricated from thin films of Re and Al. Above a certain threshold cooling field, vortices become trapped in the resonators and vortices in the Al resonators contribute greater loss and are influenced more strongly by flux creep effects than in the Re resonators. This different behavior can be described in the framework of a general vortex dynamics model related to the interplay between the vortex pinning in the films and the flux-flow viscosity.

\textsuperscript{1}Supported by NSF DMR-0547147

4:42PM T17.00010 One- and two-photon spectroscopy of a flux qubit coupled to a microscopic defect, ADRIAN LUPASCU\textsuperscript{2}, PATRICE BERTET\textsuperscript{2}, EDUARD DRIESSEN\textsuperscript{3}, KEES HARMANS, HANS MOOIJ, Delft University of Technology, The Netherlands, QUANTUM TRANSPORT GROUP TEAM — We observed the dynamics of a superconducting flux qubit coupled to a microscopic defect. The presence of the defect is visible as an anticrossing in the spectroscopy of the flux qubit, as measured using one-photon excitation. We analyze the energy-level structure of the combined qubit-defect system using both one- and two-photon spectroscopy. The use of two-photon spectroscopy allows us to extract important additional information about the anharmonicity and coupling of the defect. We find that the system coupled to the qubit can be a two-level system, but not a harmonic oscillator. We consider two basic models, for a microscopic defect which is coupled to the qubit either magnetically or electrically respectively. We conclude that the large coupling constant, of approximately 200 MHz, can only be accounted for by electric coupling, and not by magnetic coupling. This shows that electrically coupled microscopic two-level systems are relevant to decoherence of superconducting flux qubits.

4:54PM T17.00011 Probing anomalous two-level systems with a Cooper-pair box\textsuperscript{1}, BENJAMIN PALMER, Laboratory for Physical Sciences — We have used a Al/AIO\textsubscript{x}/Al Cooper-pair box (CPB) qubit to detect coupling to anomalous “two-level” quantum systems. By measuring the excitation spectrum and lifetime of the first excited state from 15 GHz to 50 GHz of the CPB at a temperature of 40 mK, one can identify anomalous levels and ascertain the magnitude of the quantum noise that is coupled to the qubit. It was found that the frequency of a distinct avoided level crossing depends on gate voltage and the size of the splitting depends on the effective Josephson energy. Both the gate voltage and Josephson energy dependence are consistent with coupling to extraneous charged two-level systems formed by point charges that can tunnel between two positions in the oxide of the Josephson junction. By fitting a model Hamiltonian to our data, we are able to extract microscopic information about the charge fluctuator such as the well asymmetry (\sim 130 micro-eV), tunneling rate (\sim 8 GHz) and a minimum hopping distance for the charge fluctuators (\sim 0.8 Angstroms).

Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T18 DPOLY: Focus Session: Organic Photovoltaics and Other Photonic Devices

2:30PM T18.00001 Surface plasmon polariton assisted organic solar cells, P. PEUMANS, Stanford U. — No abstract available.

3:06PM T18.00002 Harvesting Lost Photons: Minimizing Sub-Bandgap Losses in Organic Photovoltaic Devices by Up-conversion, CLARA SANTATO, LORANGER SEBASTIAN, BANVILLE DAVID, Genie Physique/Polytechnique Montreal, ROSEI FEDERICO, EMT-IRIS/Varennes, PEREPICHKA DMIYTRO, McGill/Chemistry — We report on a novel approach to increase the efficiency of organic photovoltaic (OPV) cells in the near-infrared region of the solar spectrum by blending the organic semiconductors with rare-earth doped nanoparticles. The approach consists in (i) synthesizing lanthanide-doped nanoparticles capable of efficient energy transfer of organic photovoltaic (OPV) cells in the near-infrared region of the solar spectrum by blending the organic semiconductors with rare-earth doped nanoparticles and (ii) assembling these nanoparticles, in blends with p-type polythiophenes and n-type fullerences, in solution-processed OPV cells capable to harvest NIR photons.

3:18PM T18.00003 In-situ X-ray characterization of thermal and solvent based annealing of thin P3HT and P3HT/PCBM films\textsuperscript{1}, TOMMY HOFMANN, Brookhaven National Laboratory, HTAY HLAING, Stony Brook University, CHANG-YONG NAM, CHARLES BLACK, BENJAMIN OCKO, Brookhaven National Laboratory, BROOKHAVEN NATIONAL LAB TEAM — We have studied the annealing of thin films of P3HT (poly(hexyloxyphopene) and mixed P3HT and PCBM thin films using in-situ Grazing Incidence Angle x-ray scattering techniques at the National Synchrotron Light Source. The films, 50-200 nm thick, were prepared using spin coating from a volatile solution. Both thermal and solvent annealing techniques are well known to improve electrical properties yet the precise mechanism is not well understood. In our measurements, we have monitored the dependence of the diffraction peak positions and widths under a variety of different in-situ thermal and solvent conditions. A detailed comparisons between these methods provides new insight into how to improve the crystallinity beyond what can be obtained by thermal methods alone. This may eventually lead to better electrical properties in thin film organic photovoltaic devices.

3:30PM T18.00004 Excited-State Dynamics at Organic Photovoltaic Heterojunctions by Pump-Probe Photoelectron Spectroscopy. GREGORY DUTTON, DANIEL DOUGHERTY, National Institute of Standards and Technology, WEI JIN, WILLIAM CULLEN, JANICE REUTT-ROBEY, University of Maryland, STEVEN ROBEY, National Institute of Standards and Technology — The critical process of charge separation in organic photovoltaic (OPV) devices is determined directly at the organic heterojunction, but these interfaces have been less extensively studied than organic/metal interfaces. We prepare model photovoltaic heterojunctions by deposition of ultrathin films of organic semiconductors on single-crystal metal substrates. The electronic structure of the component materials and their interfaces is determined with ultraviolet photoelectron spectroscopy (UPS) and two-photon photoemission (2PPE). The systems studied in this work involve phthalocyanines and analogs as donors and C60 fullerene as acceptor. Time-resolved pump-probe experiments are applied to directly measure the excited state dynamics at these OPV heterojunctions. An ultrafast visible pump pulse selectively generates excitons in one material, followed by a time-delayed UV probe to interrogate the population of the acceptor charge transport level. Analysis of cross-correlations reveals the timescales of charge separation and recombination at the interface. Additionally, comparison will be made to structural and local spectroscopic studies of similar phthalocyanine/fullerene systems made by STM/STS.

3:42PM T18.00005 The role of triplet excitons in enhancing polymer solar cell efficiency: a photo-induced absorption study. KAI YANG, SUCHI GUHA, Department of Physics and Astronomy, University of Missouri-Columbia, MO 65211 — Inclusion of heavy metal atoms in a polymer backbone allows transitions between the singlet and triplet manifolds. Interfacial dissociation of triplet excitons constitutes a viable mechanism for enhancing photovoltaic (PV) efficiencies in polymer heterojunction-based solar cells, which are now becoming feasible options for solar panels. The PV efficiency from polymer solar cells utilizing a ladder-type poly para phenylene polymer (PhLPPP) with trace quantity of Pd atoms and a fullerene derivative (PCBM) is almost 10 times more than its counterpart (MeLPPP) with no Pd atom. Evidence is presented for the formation of a weak ground-state charge-transfer complex (CTC) in the blended films of PhLPPP and PCBM, using photo-induced absorption (PIA) spectroscopy. Such complexes are not seen in the PIA spectrum of MeLPPP. PCBM blends. Possible mechanisms for the CTC state formation as well as the significance of this to the understanding and optimization of polymer blended solar cells will be discussed.

3:54PM T18.00006 Photophysics of charge-transfer excitons in thin films of π-conjugated polymers. DEMETRA PSIACHOS, SUMIT MAZUMDAR, University of Arizona — We develop a theory of the electronic structure and photophysics of interacting chains of π-conjugated polymers to understand the differences between solutions and films. While photoexcitation generates only the intrachain exciton in solutions, the optical exciton as well as weakly allowed charge-transfer excitons are generated in films. We show that a significant fraction of ultraviolet photoinduced absorptions (PAs) in films originate from the lowest charge-transfer exciton. Using sophisticated many-body approaches that take into account high order configuration interaction, we have calculated the full wavelength-dependent PA spectra of pairs of interacting PPV oligomers. Good qualitative agreement is obtained with the experimental PA spectra of thin films of π-conjugated polymers. The origin of each individual PA is explained within our theory. Our work resolves long-standing controversies regarding the nature of the primary photoexcitations in films.

4:06PM T18.00007 Photo-crosslinkable Polythiophenes for Efficient Thermally Stable Organic Photovoltaics. BUMJOON KIM, KAIST and UC Berkeley, YOSHI MIYAMOTO, BIWU MA, JEAN M.J. FRECHET, UC Berkeley — We report a new series of bromine-functionalized poly(3-hexylthiophene) (P3HT-Br) copolymers for use in solution processed organic photovoltaics (OPVs). P3HT-Br copolymers were synthesized from two different monomers, where the ratio of the monomers was carefully controlled to achieve a UV photo-crosslinkable layer while leaving the π−π stacking feature of conjugated polymers unchanged. Photo-crosslinkable P3HT-Br was demonstrated as effective electron donors in OPVs. The crosslinking stabilizes P3HT-Br/PCBM blend morphology preventing the macro phase separation between two components, which lead to OPVs with remarkably enhanced thermal stability. The drastic improvement in thermal stabilities is further characterized by microscopy as well as grazing incidence X-ray scattering (GIXS). The use of these copolymers for solution processed efficient bilayer PVs is also described. Benefited from the little disturbance in π−π stacking by crosslinkable units as evidenced in GIXS, P3HT-Br/PCBM bilayer device shows high power conversion efficiency at over 2.2% and excellent thermal stability.

4:18PM T18.00008 Temperature Dependence of Biexciton Decay and Intermolecular Hopping in Zinc Phthalocyanine Films. CHRISTOPHER RYAN, Graduate Student — The femtosecond exciton dynamics of melt-pressed zinc phthalocyanine (ZnPc) films are studied in the temperature range of 90-400 K. In this range ZnPc goes through a transition from a crystalline solid to a liquid crystalline phase. For the entire temperature range, the excitons are shown to decay on the time scale of 10's of picoseconds, and these dynamics are nonlinear with respect to pump fluence. Such a behavior is well described by a biexciton recombination model under one dimensional diffusion constraints. The single exciton lifetime and the biexciton recombination crosssection are extracted at all temperatures. From the latter, the exciton hopping time is calculated. The exciton hopping time decreases with temperature in the crystalline phase, but increases in the liquid crystalline phase. The role of temperature and structural exciton hopping time will be discussed.

4:30PM T18.00009 White tandem OLED with carbon nanotube interlayer. ALEXIOS PAPADIMITRATOS, SolarInc, Nanotech UT Dallas, RAQUEL OVALLE ROBLES, RAY BAUGHMAN, Nanotech UT Dallas, ANVAR ZAKHIDOV, Solar Inc, Nanotech UT Dallas — White organic light emitting diodes (OLEDs) have become well recognized as an important candidate for future lighting and display applications. An exciting idea to generate white color places R, G, B pixels in a side-by-side geometry. Also, white tandem OLEDs have been developed by vertically stacking in series multiple electroluminescent layers. However, such structures require a complex interfacial layer which is usually fabricated by strong dopants to form a p+/n− interface. We have shown earlier that transparent carbon nanotubes (CNT) can be used as effective three dimensional charge injectors in polymer light emitting diodes[1] and OLEDs[2]. Now, we show that CNT can be used as an interlayer in two cell OLEDs with complimentary colors. We show that tandem devices with CNT interlayers, together with selective barriers and PEDOT:PSS coating can control the device color. In addition, the emission intensity can be controlled by independently tuning the driving voltage and current. In the case of overdoped p+/n− interlayers we do not have this opportunity which is a great advantage of CNT injectors. We also compare the performance of multilaw CNTs vs. that of single wall CNTs in the tandem OLEDS. [1]R-H.Baughman et al.Scienc, 297,787-792(2002).[2]C.D.Williams et al.Appl. Phys. Lett. 93,183506(2008).

4:42PM T18.00010 Tuning optical properties of blue-emitting polyfluorenes via hydrostatic pressure, KESHAB PAUDEL, MEERA CHANDRASEKHAR, SUCHI GUHA, Department of Physics and Astronomy, University of Missouri- Columbia, MO 65211 — Polyfluorenes (PFs) represent a unique class of poly para-phenylene based blue-emitting polymers with intriguing structure-property relationships. Slight variations in the choice of functionalizing side chains result in dramatic differences in the inter- and intra-chain structures in PFs. Highlighting these differences are two prototypical PFs, poly (9,9-di (n, n-octyl) fluorene) (PF8) and poly (9,9-di ethyl- hexyl) fluorene) (PF2/6). In addition to the nematic liquid crystal (n- LC) mesophase, PF8 is characterized by at least five structural phases. We present photoluminescence (PL) and Raman scattering studies of powder samples and thin films of PF8 under hydrostatic pressure. The powder sample was thermally annealed at 2GPa. The PL vibronics of the as-is powder sample red-shift at an average rate of 30 meV/GPa whereas the thermally annealed sample red-shifts at a higher rate of 50 meV/GPa, indicating a different crystalline mesophase for the annealed sample. The Huang-Rhys factor is found to increase with increasing pressures signaling a higher geometric relaxation of the electronic states. The Raman peaks harden with increasing pressures; the intra-ring C-C stretch frequency at 1600 cm$^{-1}$ has a pressure coefficient of 5 cm$^{-1}$/GPa and exhibits asymmetric line shapes at higher pressures.

4:54PM T18.00011 SERS Characterization of Self-Assembled Monolayers Embedded on Plasmonic Nano-structure, MASATO MAITANI, Materials Science and Engineering, Penn State University (Penn State), DOUGLAS OHLBERG, Information & Quantum Systems Laboratory, Hewlett-Packard Laboratories, Palo Alto, CA (Hewlett-Packard), HAEYOUNG YOON, Electrical Engineering (Ee), Penn State, PING KAO, Ee, Penn State, DEMIREL MELIK, Engineering Science and Mechanics, Penn State, ZHIYONG LI, DUNCAN STEWART, STANLEY WILLIAMS, Hewlett-Packard, THERESA MAYER, Ee, Penn State, DAVID ALLARA, Chemistry, Penn State — We discuss Raman spectroscopic analysis of self-assembled monolayers embedded in two different types of nano-structures capable of sustaining localized surface plasmon-surface plasmon polariton coupling via nanoscale gaps and curved surface features. Both structures consist of metal-molecule-metal (M-M) junctions which can also allow charge transport through the molecular gaps. Our results indicate different electromagnetic and charge transport characteristics as a function of the top metal-molecule chemical interaction. We also report direct correlations between charge transport states, SERS response and inelastic vibrational scattering in selected M-M electronic device junctions.

5:06PM T18.00012 Non-linear optical and local-field factors in liquid chloroform: A time-dependent density-functional theory study, DAVID A. STRUBBE, Department of Physics, University of California, Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory, XAVIER ANDRADE, ANGEL RUBIO, European Theoretical Spectroscopy Facility, Universidad del Pais Vasco and Centro Mixto CSIC-UPV/EHU, San Sebastian, Spain, STEVE G. LOUIE, Department of Physics, University of California, Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory — Chloroform is often used as a solvent and reference when measuring non-linear optical properties of organic molecules. We calculate directly the non-linear susceptibilities of liquid chloroform at optical frequencies, using molecular dynamics and the Sternheimer equation in time-dependent density-functional theory [X. Andrade et al., J. Chem. Phys. 126, 184106 (2007)]. We compare the results to those of chloroform in the gas and solid phases, and experimental values, and make an ab initio calculation of the local-field factors which need to extract molecular properties from liquid calculations and experimental measurements.

5:18PM T18.00013 Time resolved photoluminescence studies of long lived emissive specie in F8BT:PFB blends, SIMON GÉLINAS, Regroupement Quebecois sur les Materiaux de Pointe, Departement de Physique de l’Universite de Montreal, IAN HOWARD, RICHARD FRIEND, Cavendish Laboratory, University of Cambridge, CARLOS SILVA, Regroupement Quebecois sur les Materiaux de Pointe, Departement de Physique de l’Universite de Montreal — Type-II heterojunctions play a crucial role in organic optoelectronic devices. We use donor-acceptor polyfluorene blends as a model system to understand excited-state dynamics at heterojunctions. These interfacial excitations are intrachain singlet and triplet excitons, geminate polaron pairs, and exciplexes (interfacial charge-transfer excitons). Time-resolved photoluminescence (PL) spectra were taken at 10 K and room temperature to investigate the interconversion dynamics of these species. We observe delayed PL with sub-linear excitation fluence dependence. This implies that delayed singlet exciton generation involves a bimolecular annihilation mechanism. By means of kinetic modeling, we propose triplet-triplet exciton annihilation as a regeneration route to singlet excitons, and subsequently to exciplexes. This points to a significant (< 15 %) yield of triplet excitons after interfacial charge separation, and to the central role of these species on the interfacial dynamics.

Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T19 DPOLY: Theory and Simulation II 320

2:30PM T19.00001 Theory of polyzwitterionic solutions, RAJEEV KUMAR, GLENN FREDRICKSON, Materials Research Lab, UCSB — Conformations of polyzwitterionic molecules in aqueous solutions are investigated using the variational method. We have carried out self-consistent calculations for the degree of counterion adsorption on the zwitterionic sites and the size of a single polyzwitterionic chain. These calculations are used to analyze the solubility of these molecules in water. Results for the effect of an asymmetric counterion adsorption, electrostatic interaction strength, salt concentration, solvent quality, specificity of the zwitterionic monomeric units and the added salt on the conformations of the polyzwitterionic chain will be presented.

2:42PM T19.00002 Charge transport in conjugated polymers: a multiscale picture, VICTOR RUEHLE, Max Planck Institute for Polymer Research, JAMES KIRKPATRICK, Imperial College London, KURT KREMER, DENIS ANDRIENKO, Max Planck Institute for Polymer Research — A framework to study charge transport in conjugated polymers using realistic morphologies is developed. First, the atomistic force field is refined using first-principles calculations. Systematic coarse graining is then performed to extend simulation times and system sizes accessible to molecular dynamics simulations. Material morphologies are generated using the coarse grained and atomistic models. Finally, the charge mobility is obtained using temperature activated hopping picture for charge transport [1]. The framework is tested on neutral and oxidized polyppyrole with different structural ordering [2].

DPG is acknowledged for the financial support
2:54PM T19.00003 First principles electronic properties investigation of polythienoacene and its derivatives1. SIMON PESANT, PAUL BOULANCER, GUILLAUME DUMONT, MICHEL CÔTÉ, Département de physique et Regroupement québécois sur les matériaux de pointe (RQMP), Université de Montréal, Canada — The electronic properties of ladder-type polythiophene (polythienoacene) and its derivatives are studied using density functional theory. Upon an analysis of the variation of the band gap when comparing the non-ladder and the ladder-type polymers, a discrepancy is found between the thiophene and the pyrrole(nitrogen-substituted thiophene) polymer families. The polythienoacene has a larger band gap than the polythiophene whereas the opposite is found for the pyrrole polymers. Also, it is found that a simple alternation of the sulfur atom in polythienoacene structure by nitrogen or boron atoms can lead to small band gap polymers. The excitations of these polythienoacene’s derivatives are investigated using time-dependent density functional theory.

1This work was supported by grants from the FQRNT and CRSNG. The computational resources were provided by the Réseau québécois de calcul de haute performance (RQCHP).

3:06PM T19.00004 Electronic structure and carrier transport in disordered conjugated polymers1. NENAD VUKMIROVIC, LIN-WANG WANG, Lawrence Berkeley National Laboratory — Thin films of realistic conjugated polymer materials contain both crystalline and amorphous regions, where the latter ones are less understood. This study was therefore focused on electronic structure and carrier transport in amorphous regions of polythiophene (PT) and poly(3-hexylthiophene) (P3HT). Atomic structures were obtained from classical molecular dynamics using a simulating annealing procedure and the charge patching method [1] was used to calculate the electronic structure. It was found that disorder in the electronic structure of P3HT comes from disorder in the conformation of individual chains, while in case of PT there is an additional contribution due to disorder in electronic coupling among the chains [2]. The electron-phonon coupling matrix elements in P3HT were also calculated and carrier mobility due to phonon-assisted hopping was estimated.

1This work was supported by the DMS/BES/SC of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. It used the resources of National Energy Research Scientific Computing Center (NERSC).

3:18PM T19.00005 Ab initio Study of Diketo-Pyrrolo-Pyrole Polymers for Photovoltaic Applications1. SIMON LÈVESQUE, JEAN FRÉDÉRIC LAPRADE, MICHEL CÔTÉ, Département de physique et Regroupement québecois sur les matériaux de pointe (RQMP), Université de Montréal, Canada — Using density functional theory with the hybrid functional B3LYP, we investigate the electrical and optical properties of polymers made with diketo-pyrrolo-pyrole. It is found that the value of the band gap can be tuned by varying the number of thiophene units within the polymer. Band structure and time-dependent density functional theory results will also be presented.

1We are grateful to Mario Leclerc for helpful discussion. This work is supported by NSERC. Computational resources were provided by the RQCHP.

3:30PM T19.00006 First-principles investigation of PVDF and its copolymers, V. RANJAN, LI-PING YU, North Carolina State University, Raleigh, NC, MARCO BUONGIORNO NARDELLI, J. BERNHOLC, North Carolina State University, Raleigh, NC and Oak Ridge National Laboratory, TN — Recently, PVDF and its copolymers have generated significant interest due to their electroactive properties [1] and potential for ultra-high energy-storage applications [2]. In this talk, we present the results of first-principles calculations of stable phases and dielectric properties of different copolymers and terpolymers of PVDF at varying concentrations. Our results show that at very high concentrations of Chloro-trifluoroethylene (CTFE), PVDF/CTFE displays sharp transitions between non-polar (α) and polar (β) phases. On the contrary, the same transitions in copolymers with trifluoroethylene (TrFE) and tetrafluoroethylene (TeFE) are not sharp and happen at lower concentrations. We discuss the interplay of copolymer admixture on the dielectric properties of PVDF and discuss the suitability of copolymers for energy storage and electroactive applications. [1] S. G. Lu et al., App. Phys. Lett. 93, 042905 (2008). [2] V. Ranjan et al., Phys. Rev. Lett. 99, 047801 (2007).

3:42PM T19.00007 Adaptive Tempering Monte Carlo Study of Dense Polypyrrole Systems1. YAFEI DAI, ESTELA BLAISTEN-BAROJAS, Computational Materials Science Center, George Mason University, Fairfax, VA 20030 — A modified rigid-ion polarizable model potential of polypyrrole is developed with parameters fitted on multiple points of the electronic energy surface of pyrrole oligomers (n-Py) of different sizes calculated with a hybrid density functional approach [1]. Using this potential, systems containing 192 chains (4-Py) and 64 chains (12-Py) were structurally optimized with the Adaptive Tempering Monte Carlo algorithm [2]. Energetics and structure of these systems were studied as a function of density. Both systems have characteristics of a liquid for densities in the range 0.66–1.09 g/cm³, and a critical value. We propose a scaling relation for this case, in agreement with self consistent field theory for (σf = σg). 1Computational support from Teragrid grant PHY0500026.

3:54PM T19.00008 Effect of the chain length and segment size of the free polymer on the interaction between two grafted monolayers in a good solvent, WALTER CHAPMAN, SHEKHAR JAIN, Rice University, VALERIY GINZBURG, PRASANNA JOG, JEFFREY WEINHOLD, RAKESH SRIVASTAVA, Dow Chemical Company, ISAF DFT COLLABORATION — The interaction between two polymer grafted surfaces is important in many applications, like nanocomposites, colloid-stabilization, and polymer alloys. In our previous work [Jain et. al., J. Chem. Phys. 126, 154910 (2008)], we showed that interfacial statistical associating fluid theory (iSAFT) density functional theory (DFT) successfully calculates the structure of the grafted polymer chains in the absence/presence of free polyatomic solvent. In the current work, we have applied iSAFT to calculate the force of interaction between two such grafted monolayers in implicit good solvent conditions. In particular, we have considered the case where the segment sizes of the free (σf) and grafted (σg) polymers are different. The interactions between the two monolayers in the absence of the free polymer is always repulsive. However, in the presence of free polymer, the force can be either purely repulsive or can have an attractive minimum depending upon the relative chain lengths of the free (Nf) and grafted polymers (Ng). The attractive minimum is observed only when the ratio, Nf/Ng, is greater than a critical value. We propose a scaling relation for this case, in agreement with self consistent field theory for (σf = σg).
can be extended to study longer n-alkane molecules and the change of nucleus conformation as n increases. This method is able to calculate the end and side surface free energies of a cylinder nucleus model from the simulation data without making further assumption. This method was developed using simulation techniques. The adiabatic nucleation trajectory was then sampled using the Monte Carlo umbrella sampling technique. The surface energy of the crystal nuclei depends on the properties of the final product. In this work we report the results of molecular simulations of crystal nucleation of n-alkanes from the melt. A realistic model of the final product is used where the connectivity could produce very different crystal nucleus conformations, which are important factors in determining the subsequent crystal growth process and the properties of the final product. These models to characterize the Helmholtz energy of the repulsive reference fluids (A0) along with the first and second order perturbation contributions (A1, A2) as functions of density and composition. Taken together, these terms generate a complete equation of state for the mixture, including temperature effects as well as density and composition. The specific hydrocarbons studied were methane, ethane, propane, n-butane, n-hexane, n-heptane, n-decane, and benzene. The specific alcohols were water, methanol, ethanol, n-propanol, and n-octanol. Unfortunately, a slight inconsistency was encountered when the trend observed for these small molecules was extrapolated to the long chain limit. Therefore, we extend the analysis to mixtures of n-alkanes, branched hydrocarbons, and aromatics with polymeric molecules of: n-alkanes, ethyl-styrenes, ethyl-proplyenes, and isoprenes. The perturbation contributions can be accurately characterized by van der Waals mixing rules and compared with the MCSL SAFT and Guggenheim-Staverman theories.

The authors gratefully appreciate ChemStations, Houston, TX for financial funding.

5:18PM T19.00010 ABSTRACT WITHDRAWN —

4:30PM T19.00011 Simulation of Microheterogeneous Networks and Extraction of Segment Orientation Behavior from D-NMR Spectra — BERNARDO AGUILERA-MERCADO, CLAUDE COHEN, FERNANDO ESCOBEDO, School of Chemical and Biomedical Engineering, Cornell University — The degree of heterogeneity in the microstructure of end-linked elastomer networks has been shown to have a very strong impact on the network mechanical and elastic properties such as: ultimate strain, modulus, and toughness. Networks with crosslinks and chains inhomogeneously distributed are expected to exhibit heterogeneous segment orientation responses. The global segment orientation of systems with frozen inhomogeneities, and a significant amount of highly stretched chains at the unperturbed state, cannot be captured by measurements of the deuterium NMR spectra alone. Spectrum frequency splits quantify the segment orientation in terms of partial excluded volume interactions only and do not account for the contributions arising from large end-to-end chain deformations. Long wings of the spectrum reflect the presence of strongly aligned segments ignored when one considers only the split. A new methodology based on the Maximum-Entropy method is proposed to find the probability density of an order parameter that describes the network segment orientation from which the global orientation behavior can be completely characterized. The methodology is validated with both molecular simulation and experimental data.

4:42PM T19.00012 Cooperative dynamics in polymer melts: a comparison of theoretical predictions with Neutron Spin Echo experiments — MARINA GUENZA, University of Oregon — We present a comparison between theoretical predictions of the Generalized Langevin Equation for Cooperative Dynamics (CDGLE) and Neutron Spin Echo data of dynamic structure factors for polystyrene melts. Experiments, performed by Zamponi and coworkers, cover an extended range of length- and time-scales providing a compelling test for the theoretical approach. Samples investigated include chains with increasing molecular weights, undergoing dynamics across the unentangled to entangled transition. Measured center-of-mass mass-square displacements display a crossover from subdiffusive to diffusive dynamics. The Generalized Langevin Equation for Cooperative Dynamics relates this anomalous diffusion to the presence of the interpolymer potential, which correlates the dynamics of a group of slowly diffusing molecules in a dynamically heterogeneous liquid. Theoretical predictions of the subdiffusive behavior, its crossover to free diffusion, and of the number of macromolecules undergoing cooperative motion are in qualitative agreement with experiments.

4:54PM T19.00013 Equilibrium Partitioning of Polymers between Bulk Dilute Solution and Confining Pores — YANWEI WANG, FLEMMING Y. HANSEN, GUENTHER H. PETERS, OLE HASSAGER, Technical University of Denmark — We have developed a novel framework [1] for the description of the steric hindrance effect on polymers that are subject to confining geometries. The two main ingredients are (i) a new computational method, the Confinement Analysis from Bulk Structures (CABS) approach, which enables calculation of the equilibrium partition coefficient (pore-to-bulk concentration ratio) as a function of the confinement size solely based on snapshots of polymer configurations in bulk, and (ii) the definition of a new molecular size parameter, the steric exclusion radius, which permits collapsing all partition coefficient data for different polymers in the weak confinement regime onto a universal curve. Our latest development in extending the CABS method to cylindrical and spherical pores will be presented.

5:06PM T19.00014 Multivalent Nanoparticles: adsorption and organization of bidisperse polymer chains onto a solid interface — FOLUSHO OYEROKUN, RICHARD VAIA, JOHN MAGUIRE, BARRY FARMER, AFRL — Multivalent nanoparticles, i.e. nanoparticles with two or more ligands attached to their surfaces, are used in a variety of scientific and technological applications. The most common protocols for synthesizing these multivalent nanoparticles involves immersion of the particles into a solution containing the various ligands or into a solution containing an excess of one ligand to drive a partial (solvent mediated) exchange reaction with a previously bound ligand. Despite intense experimental activities, the dependence of the surface coverage on free ligand concentration and solvent quality is still poorly understood. This study addresses the thermodynamics of adsorption of bidisperse end-functionalized polymer chains in a good solvent onto a flat surface. At equilibrium, the absorbed chains form a bidisperse polymer brush in contact with the solution. The role of the degree of bidispersity, adsorption energy, solvent quality on monomer concentration profile, brush height and degree of penetration of free short and long chains into the brush layer will be discussed.

5:18PM T19.00015 Molecular simulation of crystal nucleation of n-alkane melts — PENG YI, GREGORY RUTLEDGE, Massachusetts Institute of Technology — The homogeneous nucleation of a crystal phase is one of the most interesting phenomena of molecular fluids, yet the microscopic mechanism of which still remains poorly understood. It is even more a mystery in chain molecule systems because the chain connectivity could produce very different crystal nucleus conformations, which are important factors in determining the subsequent crystal growth process and the properties of the final product. Our latest development in extending the CABS method to cylindrical and spherical pores will be presented. The adiabatic nucleation trajectory was then sampled using the Monte Carlo umbrella sampling technique. The surface energy of the crystal nuclei was calculated assuming a spherical nucleus model and compared with previous studies to validate our numerical definition of a crystal nucleus. We were also able to calculate the end and side surface free energies of a cylinder nucleus model from the simulation data without making further assumption. This method can be extended to study longer n-alkane molecules and the change of nucleus conformation as n increases.
2:30PM T20.00001 Magnetoresistance and magnetic-field-effects in organic semiconductor devices.

MARKUS WOHLGENANNT, U. of Iowa — No abstract available.

3:06PM T20.00002 Photo-induced Magnetism and Spintronics in Organic Semiconductors

JUNG WOO YOO, The Ohio State University — Recent years have witnessed growing attention on manipulating spins in organic species. One of the interesting phenomena in organic-based magnets is controlling magnetic properties by optical stimulus, a property not exhibited in metallic magnets. Three classes of known phenomena and mechanism will be discussed: i) manipulation of number of spins by optically induced charge transfer in cyanide-bimetallic complexes [1], ii) phenomenon in organic-based magnets is controlling magnetic properties by optical stimulus, a property not exhibited in metallic magnets. Three classes of

3:42PM T20.00003 Magnetic properties of TCNQF4 reacted with Ni(cod)2 reacted with Ni(cod)2, IAN TERRY, KIMBERLY QUINN, MAREK SZABLEWSKI, Department of Physics, Durham University, Durham, DH1 3LE, UK — Recently it was reported that a room temperature ferromagnetic material (TC=400K), Ni2TCNQ, was synthesized by reacting the organic acceptor tetracyanoquinodimethane (TCNO) with bis(1,5 cyclooctadiene) nickel (Ni(cod)2)[1]. In the present work we report the magnetic properties of a material which was synthesized following the same chemical route as that of Ni2TCNQ, except tetrafluoro-tetracyanoquinodimethane (TCNOF4) was used instead of TCNQ. The new metal-organic compound shows qualitatively similar magnetic properties to Ni2TCNQ, with ferromagnetic behavior being observed at room temperature. The specific magnetic properties can be described by assuming that there is both a paramagnetic and ferromagnetic phase in the material, with the ferromagnetic phase having a measured Curie temperature of about 620K, close to that of nickel. TEM and XRD data provide evidence for the existence of nickel nanoparticles within the material. We conclude that nickel nanoparticles are produced during the synthesis and are probably responsible for ferromagnetic properties observed at room temperature. 1.R. Jain et al, Nature 445, 291, (2007).

3:54PM T20.00004 Magnetic and surface studies of transition metal complexes for molecular spintronics

PATRICK TRUITT, RAMAN TALWAR, EZEKIEL JOHNSTON-HALPERIN, Dept. of Physics, The Ohio State University, NORBANI ABDULLAH, Dept. of Chemistry, University of Malaya, CARLY REED, NAMRATA SINGH, CHANDRANI CHATTERJEE, MALCOLM CHISHOLM, Dept. of Chemistry, The Ohio State University — We have synthesized organometallic complexes consisting of a transition metal ion chelated by amphiphilic ligands. This talk will focus on efforts to assess the suitability of these molecules for the creation of magnetically active monolayers via the Langmuir-Blodgett technique. The paramagnetic nature of the molecules is probed by SQUID magnetometry and EPR spectroscopy, demonstrating that the spin magnitude can be varied by chemical substitution of the transition metal ion. To study monolayer formation ability, the molecules are spread on a Langmuir trough and pressure-area isotherms are recorded under compression. Attempts to deposit monolayers onto substrates and to make electrical contact for transport measurements will also be discussed.

4:06PM T20.00005 Magneto-Transport in Polyaniiline Nanofiber Network

K. DENIZ DUMAN, N.-R CHIOU, V.N. PRIGODIN, Dept. of Physics, The Ohio State University, Columbus, Ohio, A. J. EPSTEIN, Dept. of Physics, Dept. of Chemistry, The Ohio State University, Columbus, Ohio — We report large magnetoresistance (up to 2% at 8 T and 3 K) for polyaniline nanofiber network composed of nanofibers with an average diameter of about 80 nm. The polyaniline nanofiber networks were synthesized via chemical oxidative polymerization [1] and were studied at low and high electric and magnetic fields for temperatures 2 K- 250 K for their magneto-transport behavior. A transition from positive MR (temperatures 75 K and below) to negative MR (temperatures 100K and above) is observed. The MR may be explained by possible competing mechanisms; shrinkage of the hopping wavefunction and quantum interference effect in the applied magnetic field. It is also noted that applied electric field affects MR. In the positive MR regime an increase in MR is observed as the applied electric field decreases. Detailed results of various magneto-transport behavior will be discussed.

1Supported in part by NSF, DOE and OSU IMR.

4:18PM T20.00006 Tuning the ionization energy of organic semiconductor films: The role of intramolecular polar bonds

NORBERT KOCH, Humboldt-Universitaet zu Berlin — While an isolated individual molecule has only one ionization energy (IE), multiple values are found for molecules in ordered assemblies. Photoelectron spectroscopy of archetypical conjugated organic compounds combined with first-principles calculations and electrostatic modeling reveal the existence of a surface dipole built into molecular layers. Its origin lies in intramolecular polar bonds (IPBs) of the individual molecules, and its magnitude depends on the orientation of molecules relative to the surface of an ordered assembly. Suitable pre-patternning of substrates to induce specific molecular orientations in subsequently grown films thus permits adjusting the IE of one molecular species over up to 1 eV via control over layer morphology. Furthermore, mixing of differently terminated molecules (different IPBs) on a molecular length scale allows continuously tuning the IE of thin organic films between the limiting values of the two pure materials. Surface engineering of organic semiconductors via adjusting the polarity of intra-molecular bonds represents thus a viable alternative for controlling the energetics at organic/(in)organic interfaces.

4:54PM T20.00007 ABSTRACT WITHDRAWN —
5:06PM T20.00008 Perpendicular interaction between donor and acceptor molecules on Au(111) , U.G.E. PERERA, Department of Physics and Astronomy, Ohio University, Athens, Ohio 45701 USA, R. MISHIMA, Graduate School of Engineering Science, Osaka University, 1-3 Machikaneyama, Toyonaka 560-8531, Japan, 5-WAJ. HLA, Department of Physics and Astronomy, Ohio University, Athens, OH 45701. — The capability to modify the electronic properties of materials by the interaction between donor and acceptor molecules plays a significant role in molecular electronics. Formation of molecular charge transfer complexes have been observed for different donor acceptor system in a lateral configuration. Here, we present the structural and electronic properties of decamethylmanganocene (Mn(C5Me5)2) and 7,7,8,8-tetracyanoquinodimethane (TCNQ) molecules on a Au(111) surface at 4.6K using low temperature scanning tunneling microscopy (STM) to investigate the perpendicular interaction between the molecules. The molecular complexes were formed by depositing Mn(C5Me5)2 onto predeposited TCNQ on Au(111). The TCNQ formed a well ordered self-assembled clusters on Au(111) and Mn(C5Me5)2 adsorbed either on TCNQ layer or on bare Au(111) surface. Perpendicular interaction between the Mn(C5Me5)2 and TCNQ were determined by means of conductance tunneling spectroscopy. This work provides an important step for manipulating and tuning charge state of molecules using donor-acceptor molecular systems. The research is supported by United States Department of Energy BES grant number DE-FG02-02ER46012.

Wednesday, March 18, 2009 2:30PM - 4:54PM
Session T21 DCMP: Semiconductors: Mechanical and Dynamic Properties 323

2:30PM T21.00001 3D X-Ray Microscopy and Dislocation Dynamics Simulation Investigation of Deformation in Copper1, B. C. LARSON, ORNL, JIE DENG, ANTER EL-AZAB, FSU, J. Z. TISCHLER, ORNL. — We have combined submicron resolution 3D x-ray microscopy measurements at the Advanced Photon Source and discrete dislocation dynamics (DD) simulations to initiate fundamental investigations of deformation in metals. Half-micron resolution 3D x-ray microscopy measurements of local plastic rotation deformation were performed on initially dislocation free Cu single crystals that were compression deformed axially along [100] to strains varying from 1% to 7.6%. Accordingly, dislocation dynamics simulations of axial [100] deformation in fcc Cu were performed for strains ranging up to 1.6%. The overlapping range of the measured and simulated strain magnitudes provides the first direct and quantitative link on mesoscopic length scales between first principles simulations of deformation and submicron resolution deformation measurements. Quantitative comparisons between the measured and simulated local lattice curvatures will be presented in graphical and statistical form.

2:42PM T21.00002 Low speed fracture instabilities in a brittle crystal, NOAM BERNSTEIN, JAMES R. KERMODE, TRISTAN ALBARET, DOV SHERMAN, PETER GUMBSCH, MICHAEL C. PAYNE, GÁBOR CSÁNYI, ALESSANDRO DE VITA. — Brittle materials under mechanical load fail by nucleation and propagation of cracks, and these cracks show well known instabilities at high crack speeds. In this work we show that new instabilities caused by the atomic structure of the crack tip can occur at low crack speeds as well [1]. Using state of the art computer simulations, we find atomic rearrangements at a silicon crack tip on the [111] cleavage plane that occur preferentially on one side of the crack, but only at low crack speeds. Experiments using a novel technique for applying low tensile loads show that real silicon cracks form distinctive features on one side of the exposed crack surface. A mesoscopic model explains how the microscopic atomic rearrangements lead to the observed macroscopic features. We present extensive results on silicon and preliminary results on other brittle materials including sapphire, diamond, and silicon carbide. We conclude that even very brittle single-crystal materials can have a complex crack tip atomic structure, and that atomic scale rearrangements can lead to macroscopic changes in crack morphology. [1] J. R. Kermode et al., Nature 455, 1224 (2008).

2:54PM T21.00003 Thermoelectric damping in micromechanical resonators1, THOMAS METCALF, BRADFORD PATE, DOUGLAS PHOTIADIS, BRIAN HOUSTON, Naval Research Laboratory. — The performance of micro- and nano-mechanical resonators as sensors, filters, and in other devices is determined by the quality factor, Q, which measures the fractional energy loss per oscillation cycle of the resonator. In any given resonator, several energy loss mechanisms are likely to be simultaneously present. However, for micro- and nano-scale resonators, the relative strengths and identity of these mechanisms is largely unknown. We measure the temperature dependence of Q−1 of two resonant modes (460 kHz and 510 kHz) of a 1.5 μm thick silicon micromechanical plate resonator. In-situ ultra-high vacuum annealing lowers the background energy loss at 120 K to Q−1 ≤ 5 × 10−7. The Q−1 increases with increasing temperature by different rates for the two modes, quantitatively agreeing with a modification of Zener’s theory of thermoelastic damping. This provides strong evidence that thermoelasticity is the dominant energy loss mechanism in one resonant mode.

3:06PM T20.00004 Ab initio guided design of bcc Mg-Li alloys for ultra light-weight applications , MARTIN FRIÄK, WILLIAM ART COUNTS, DIERK RAABE, JÖRG NEUGEBAUER, Max-Planck-Institut fuer Eisenforschung GmbH, Max-Planck-Strasse 1, 402 37, Duesseldorf, Germany. — Ab initio calculations are becoming increasingly useful to engineers interested in designing new alloys because these calculations are able to accurately predict basic material properties only knowing the atomic composition of the material. In this paper, fundamental physical properties like formation energies and elastic constants of 11 bcc Mg-Li compounds are calculated using density-functional theory (DFT) and compared with available experimental data. These DFT-determined properties are then used to calculate engineering parameters like (i) specific Young’s modulus (Y/ρ) or (ii) bulk over shear modulus ratio (B/G) differentiating between brittle and ductile behavior. The engineering parameters are then used to identify alloys that have optimal mechanical properties needed for a light weight structural material. It was found that the stiffest bcc magnesium-lithium alloys contain about 70 at.% Mg while the most ductile alloys have 0-20 at.% Mg. The specific modulus for alloys with 70 at.% Mg is equal to that of Al-Mg alloys. An Ashby map containing Y/ρ vs. B/G shows that it is not possible to increase both Y/ρ and B/G by changing only the composition or local order of a binary alloy (W. A. Counts, M. Friak, D. Raabe and J. Neugebauer, Acta Mater 57 (2009) 69-76).
3:18PM T21.00005 Thermal Stability of Shape Transition in Strained Nano-Islands. CRISTIANO NISOLI, Los Alamos National Laboratory, DOUGLAS ABRAHAMS, Oxford University, TURAB LOOKMAN, AVADH SAXENA, Los Alamos National Laboratory — Two dimensional Stranski-Krastanow strained islands are known to undergo a shape anisotropy transition as they grow in size, finally evolving toward nanowires. We investigate thermal stability of this process and find a phase transition both in temperature and, in simple cases, in growth. While our results are general, they can explain recent data on Erbium Silicide growth on vicinal Si surface.

3:30PM T21.00006 Neutron Time of Flight phonon spectra of Cu$_2$O and Ag$_2$O powders. BARRY WINN, Brookhaven National Laboratory, MARK HAGEN, Oak Ridge National Laboratory, STEVE SHAPIRO, Brookhaven National Laboratory — Negative thermal expansion materials cuprite (Cu$_2$O) and Ag$_2$O share the same structure (space group Pn3m). Here, we report inelastic neutron time of flight measurements of room temperature powder samples of each system, using the Pharoas chopper spectrometer at LANSCE, at up to 100 meV energy transfer. For Cu$_2$O, high energy optical phonons are observed between 60 and 80 meV, while for Ag$_2$O, these phonons are observed between 50 and 70 meV. Results are compared to previous work, and to recent neutron triple axis spectrometer results for Cu$_2$O, and their relevance to negative thermal expansion is discussed.

3:42PM T21.00007 Large-Amplitude Anharmonic Decay of Coherent A1g phonon motion in Bismuth. STEPHEN FAHY, AARON HURLIE, DONAL O DONOHUE, University College Cork, EAMONN MURRAY, Rutgers University, DAVID PRENDERGAST, Molecular Foundry, Lawrence Berkeley National Laboratory, TADASHI OGITSU, Lawrence Livermore National Laboratory, DAVID REIS, University of Michigan, DAVID FRITZ, SLAC, Stanford University — Large amplitude coherent motion of the A1g phonon in bismuth can be generated by ultrafast optical excitation. At low amplitude, the decay rate agrees with that observed in Raman scattering. At high levels of photoexcitation, the observed phonon damping is substantially increased, compared to low-amplitude motion. We present a classical simulation of the anharmonic decay of the phonon, including third-order anharmonic terms in the energy, calculated using density functional perturbation theory, coupling the A1g motion to modes throughout the Brillouin Zone. At low amplitude, the classical decay can be shown in perturbation theory to be almost identical in classical and quantum dynamics at room temperature, demonstrating the validity of a classical simulation of the dynamics. For very large A1g amplitude, the amplitude of motion in the final state modes is substantially increased over their thermal average values, leading to an increase in the decay rate of the A1g mode.

3:54PM T21.00008 Phonon dispersion relations for unstrained Si$_{1-x}$Ge$_x$ via density functional theory. MD HOSSAIN, Department of Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, IL 61801, USA, JONATHAN FREUND, HARLEY JOHNSTON, Department of Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, IL 61801, USA — Phonon dispersions for the Si$_{1-x}$Ge$_x$ alloy system are computed using localized basis density functional theory. Including interactions up to third-nearest-neighbors and the effect of atomic randomness, phonon dispersion for the full Brillouin zone of a supercell containing 8 atoms is computed for 8 different compositions. Frequencies are found to be in excellent agreement with available experimental results for both crystalline Si and Ge. Results are compared with a 64-atom supercell calculation for optical frequencies to show any possible effect of supercell size on the phonon calculation. The atoms in the calculation are relaxed to a force tolerance of 0.0001eV/Å, which is found to be important to correctly determine the dispersion near the Γ- and X-points of the Brillouin zone where q-convergence is harder to achieve. The highest optical phonon frequencies are observed to vary nonlinearly with composition, a fact not investigated before using computational methods.

4:06PM T21.00009 Grating-Enhanced Response for current-driven coupled quantum wells¹. ANTONIOS BALASSIS, Fordham University, GODFREY GUMBS, Hunter College/CUNY — We have investigated the conditions necessary to achieve stronger plasmon instability leading to emission in the terahertz (THz) regime for semiconductor quantum wells (QWs). The surface response function is calculated for a bilayer two-dimensional electron gas (2DEG) system in the presence of a metal grating placed on the surface and which modulates the electron density. The 2DEG layers are coupled to surface plasmons arising from excitations of free carriers in the bulk region between the layers. A current is passed through one of the layers and is characterized by a drift velocity $v_D$. With the use of the surface response function, the plasmon dispersion equation is obtained as a function of frequency $\omega$, the in-plane wave vector $q_{\parallel} = (q_x,q_y)$ and reciprocal lattice vector $G$ where $n = 0, \pm 1, \pm 2, \cdots$ and $G = 2\pi/n$ with $d$ denoting the period of the grating. The dispersion equation, which yields the resonant frequencies, is solved in the complex plane for real wave vector $q_{\parallel}$. It is ascertained that the imaginary part of $\omega$ is enhanced with decreasing $d$, and with increasing the doping density of the free carriers in the bulk medium for fixed grating period.

4:18PM T21.00010 Where the reactive sites are in anatase nanoparticles? — Theoretical Investigations on (001) and (101) surfaces in anatase nanoparticles. HONG WANG, JAMES LEWIS, West Virginia University — Recently, with the development of nanotechnology, the devices’ size shrinks to nano-scale size where the surface properties play a role. Thus, it is required scientists to provide fundamental level understanding of anatase surfaces in nano-size anatase materials to improve its applications. In this work, applying DFT ab initio method, we investigate the fundamental properties of anatase (001) and (101) surfaces in anatase nanoparticles. By adopting different portions of (001) and (101) surfaces along with the size of nanoparticles, we analyze the geometric properties and energetic stabilities of nanoparticles. The electronic properties of these nanoparticles are also calculated in this work. The frontier orbitals located mostly in the (001) surfaces indicate these sizes are possibly reactive sizes in the external molecular adsorption reaction. To verify their activity, we add water molecules in different sites and different concentration on these nanoparticles. The results show that the sites where the frontier orbitals are localizing are very reactive for water adsorption.

4:30PM T21.00011 Collective Excitations in Cylindrical Quantum Dots Chains. JIMENA VERGARA, ANGELA CAMACHO, Universidad de los Andes — We are interested in the study of collective excitations in quantum dot chains because these can be used to effectively transmit information at nano scale and to control spontaneous and stimulate electromagnetic emission in the quantum dots. [1] This work is centered in the study of semiconductor one-dimensional quantum dot arrays. Based on a tight-binding bandstructure calculation combined with a self consistent field approximation we obtain the dispersion relations and we analyze how the geometry of the dot affects the collective oscillation of charge and its propagation. We focus our study first on Coulomb interaction between charges as the main cause of the 1D plasmons neglecting tunneling to finally compare with the case where tunneling is allowed. We find out that Coulomb interaction plays an important role in these systems and that tunneling opens the energy spectrum permitting new excitations, which are good candidates to be used in nanometric devices. [1] A.V.Akimov, A.Mukherjee, C.L. Yu, D.E Chang, A.S.Zybrov, P.R. Hemmer, H Park and M.D Lukin, *Generation of Single optical plasmons in metallic nanowires coupled to quantum dots*, Nature 450, 402 (2007).
4:42PM T21.00012 Electrical characterization of MOVPE-grown InSb nanowires, HENRIK NILSSON, PHILIPPE CAROFF, CLAES THELANDER, MARCUS LARSSON, LARS-ERIK WERNERSSON, LARS SAMUELSON, HONGQI XU, SOLID STATE PHYSICS TEAM — In bulk, InSb is a narrow band gap ($E_g = 170$ meV) semiconductor with high electron mobility ($\mu = 77000 \text{ cm}^2/\text{Vs}$) and is therefore of relevance for low power and high speed circuit applications. It also has a low electron effective mass ($m_\text{e} = 0.015 m_0$) and a very high electron g-factor ($|g| = 51$) which is of interest for studies of quantum and spin physics. InSb nanowires were grown by MOVPE from 40 nm Au aerosol seed particles deposited on a $<111>$ B InAs substrate, where the growth was initiated by a 100 nm InAs segment. The InSb nanowires are untapered and free from stacking faults. The grown InSb nanowires were transferred to degenerately doped, SiO$_2$ capped, Si substrates. After locating the wires, Ti/Au contacts were made by electron beam lithography. Electrical measurements of the fabricated InSb nanowire devices were performed in the high bias, field-effect transistor (FET) regime at temperatures ranging from 300 K to 4.2 K as well as in the low bias, single-electron transistor (SET) regime at temperatures ranging from 4.2 K to 300 mK. In particular, effective electron g-factors and Kondo physics have been studied at low temperatures with the nanowire devices.

Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T22 GMAG DMP FIAP: Focus Session: GaMnAs 324

2:30PM T22.00001 Electric-field manipulation of magnetization vector direction\(^1\), HIDEO OHNO, RIEC, Tohoku University / ERATO JST — Ferromagnetism and magnetization in Mn-doped III-V semiconductors can be manipulated by various means; by changing its carrier concentration by electric fields \([1]\) or by spin-current flowing along with the electric current \([2]\). This material system is thus an excellent system to study the physics involved in manipulation of magnetism as well as exploring new ways to control magnetization. Here, we show that electrical control of magnetization direction can be done through manipulating electronically the magnetic anisotropy energies \([3]\). The basic idea behind the effort is to control the population of carriers on spin-split anisotropic valence bands that governs the magnetic anisotropy energies, which should result in change of the direction of magnetization. In order to measure the magnetic anisotropy under a gate that applies the electric-field to the ferromagnetic semiconductor channel, we used the planar Hall effect. Analyses showed that there are biaxial as well as unaxial anisotropies. As the sheet carrier concentration is reduced by applying electric-field to the channel, the uniaxial anisotropy field reduced its magnitude and eventually changed its sign, whereas no significant change was apparent in the biaxial anisotropy field. From the electric-field dependent anisotropy fields, one can show that the angle of the magnetization direction in the absence of magnetic fields is modified by electric-fields by 10 degrees. This opens up a new and unique opportunity for manipulating magnetization direction solely by electronic means, not resorting to magnetic-field, spin-current, mechanical stress, nor multiferroics. The conditions for switching the magnetization direction will also be discussed. The work was done together with D. Chiba, F. Matsukura, M. Sawicki, Y. Nishitani, and Y. Nakatani.

3:06PM T22.00002 Bias-controlled ferromagnetism in quantum wells with Mn-delta doping, ERIKA DIAS CABRAL, SUNY Buffalo and UERJ, Brazil, RAFAEL OSZWALDOWSKI, SUNY Buffalo and N. Copernicus University, Torun, Poland, MARCO BOSELLI, IGOR ZUTIC, SUNY Buffalo, IVAN DA CUNHA LIMA, UERJ, Brazil — Carrier-mediated magnetism in semiconductors shows important and potentially useful differences from magnetism in metals \([1]\) such as light- or bias-controlled ferromagnetism \([2-3]\). Motivated by experiments reporting in GaAs quantum wells (QWs) with Mn-delta doping higher Curie temperatures ($T_C$) than in bulk (Ga,Mn)As \([4]\), we explore theoretically the feasibility of bias-controlled ferromagnetism in QWs. We calculate self-consistently indirect Mn-Mn exchange interaction \([5]\) and apply a Monte Carlo approach to calculate $T_C$. Our approach allows us to systematically study the effects of quantum confinement and the position of the Mn layer on magnetic ordering and $T_C$, beyond the mean field approximation, which we obtain as the limiting case. We compare our findings with the experimental results and suggest paths towards improved control of ferromagnetism. Supported by CNpq, FAPEMIG, FAPEJ, CAPES, US ONR, and NSF-ECCS Career. \[1\] I. 3:18PM T22.00003 STM studies of an atomic-scale gate electrode formed by a single charged vacancy in GaAs, DONGHNUG LEE, DAVID DAUGHTON, JAY GUPTA, The Ohio State University — Electric-field control of spin-spin interactions at the atomic level is desirable for the realization of spintronics and spin-based quantum computation. Here we demonstrate the realization of an atomic-scale gate electrode formed by a single charged vacancy on the GaAs(110) surface\([1]\). We can position these vacancies with atomic precision using the tip of a home-built, low temperature STM. Tunneling spectroscopy of single Mn acceptors is used to quantify the electrostatic field as a fraction of distance from the vacancy. Single Mn acceptors are formed by substituting Mn adatoms for Ga atoms in the first layer of the p-GaAs(110) surface\([2]\). Depending on the distance, the in-gap resonance of single Mn acceptors can shift as much as 200meV. Our data indicate that the electrostatic field decays according to a screened Coulomb potential. The charge state of the vacancy can be switched to neutral, as evidenced by the Mn resonance returning to its unperturbed position. Reversible control of the local electric field as well as charged states of defects in semiconductors can open new insights such as realizing an atomic-scale gate control and studying spin-spin interactions in semiconductors. http://www.physics.osu.edu/~$\sim$gupta\[1\] D. 3:30PM T22.00004 Probing the nature of electronic state near the Fermi level in Ga$_{1-x}$Mn$_x$As with STM, ANTHONY RICHERDella, Princeton University / UIUC, PEDRAM ROUSHAN, Princeton University, SHAWN MACK, DAVID AWSCHALOM, UCSB, ALI YAZDANI, Princeton University — We have studied the electronic states near the Fermi energy in GaMnAs/GaAs heterostructures as a function of doping across the metal-insulator transition. These measurements allow us to determine the position of $E_F$ with respect to the valance band edge and in gap states related to the Mn induced acceptor states. As the doping level increases we observe an increase in the density of states at the Fermi energy and map their spatial dependence. Statistical analysis of these measurements can be used to find a characteristic length scale associated with growth of bulk metallic behavior for these samples. In addition, our measurements indicated a suppression of the density of states near $E_F$ at all doping levels, consistent with that expected for correlation effects in doped semiconductors near the metal-insulator transition. We will discuss these findings and their relation with various theoretical models for electronic states in GaMnAs that are expected to mediate the magnetic interaction in this compound.

3:42PM T22.00005 Scanning Tunneling Microscopy Studies of Mn acceptor levels in Ga$_{1-x}$Mn$_x$As

PEDRAM ROUSHAN, ANTHONY RICHARDELLA, Princeton University, SHAWN MACK, DAVID, AWSCHALOM, UCSCB, ALI YAZDANI, Princeton University — We have used a low temperature scanning tunneling microscope (STM) to perform studies of GaMnAs/GaAs heterostructures with various Mn dopant concentrations. The STM topography of the GaMnAs showed a variety of electronic structure modulations on the order of a few nm indicating the presence of a high level of disorder and compensation. These measurements show no indication of Mn clustering as the Mn concentration is increased. On both sides of the Metal-Insulator Transition (MIT), the differential conductance (dI/dV) measurements on Mn dopants showed a broad acceptor level above 100meV from the valence band edge. Furthermore, we have mapped in energy the spatial variations of these deep acceptor levels, and their distribution will be presented for all Mn concentrations studied. The effect of disorder and coulomb correlations in modifying the local density of states close to Fermi level will be discussed for insulating as well as metallic samples.

3:54PM T22.00006 Theory of STM spectroscopy in Mn clusters on GaAs surfaces.

TOR OLOF STRANDBERG, Lund University, ALAN MACDONALD, University of Texas at Austin, CARLO CANALI, Kalmar University — Small numbers of Mn atoms can be manipulated into arbitrary spatial arrangements on the <110> surface of GaAs by means of a novel STM atom-by-atom substitution technique, which enables the replacement of individual Ga atoms by Mn [1]. The tunneling differential conductance over an isolated Mn atom reveals a broad and large resonance in the GaAs energy gap. For a Mn pair placed less than 1 nm apart, the resonance splits into two peaks, whose spacing is thought to be related to the exchange-energy interaction between Mn ions. We report on theoretical results for the local density of states and the Mn acceptor-level splittings for a Mn dimer, based on a tight-binding model of Mn substitutions on the <110> GaAs surface. We compare our model with previous work which does not account for the surface. We then derive an effective quantum spin Hamiltonian for the Mn cluster, based on a Chern number theory developed recently, which includes Berry phase effects [2]. We study the transition from surface to bulk for the substitutional Mn impurity in GaAs as well as Mn-Mn interactions at the surface and in bulk at various distances and along different crystalline directions. [1] D. Kitchen et al., Nature 442, 436 (2006). [2] C.M. Canali, A. Cehovin and A.H. MacDonald, Phys. Rev. Lett. 91, 046805 (2003)

4:06PM T22.00007 Strong Magnetic Circular Dichroism in Mn Delta-doped GaAs.

NAZMUL AHSAN, SANJUKTA GHOSH, MASAKA TANAKA, University of Tokyo — Delta-doping of magnetic impurities (i.e., Mn) in III-V semiconductors allows locally high concentration of magnetic moments. This can lead to systematic observation of fundamental properties of the system including the enhancement of the Curie temperature and magnetic anisotropy as a function of a wider range of Mn concentration[1]. The delta-doped Mn atoms in the MBE-grown GaAs-based heterostructures are abruptly confined as confirmed by high resolution transmission electron microscopy studies[1]. Here we study the magnetic circular dichroism (MCD) of 1 monolayer (ML) Mn delta-doped GaAs layer. The structure from the growth sequence is: GaAs substrate/GaAs-buffer/Al$_x$Ga$_{1-x}$As/1mn GaAs/1ML Mn/10nm GaAs cap. The sample was chemically etched to single out the 1mn GaAs/1ML Mn layer/10nm GaAs cap to measure MCD spectra in the transmission geometry. We observed strong MCD features even at 300K, indicating ferromagnetism with zinc-blende band structure. Ref.: [1] Nazmul et al. Phys. Rev. B 67, 241308 (2003); J. Crystal Growth, 221, 303 (2003); Phys. Rev. Lett. 95, 017201 (2005); Phys. Rev. B 77, 155203 (2008).

C. SUN, Rice University, J. KONO, Rice University, Y.H. CHO, A.A. BELYANIN, Texas A&M University, H. MUNEKATA, Tokyo Institute of Technology — The role of impurity bands as well as the nature of free holes in carrier-mediated ferromagnetism in (III,Mn)V systems are still not well understood. Previous magneto-optical studies of GaMnAs have produced an array of conflicting results, especially in terms of the nature of optical transitions involved. Here, we have performed systematic magneto-optical Kerr spectroscopy studies of GaMnAs samples with different doping densities. The Kerr angle strongly depended on the photon energy, showing positive peaks at 1.7 eV and 3 eV and a negative peak at 2.5 eV. The 1.7 eV peak clearly shifts to higher energies with Mn doping from 1% to 2.4% and shifts to an even higher energy after annealing. We attribute these changes to the increased hole density and effective Mn content. A 30-band $k$ - p model with exchange interaction is adopted to simulate the spectra. The excellent agreement between the experiment and calculation leads us to conclude that Kerr rotation in GaMnAs above the band gap is dominantly determined by interband transitions.

4:30PM T22.00009 Below band gap Faraday and Kerr measurements in ferromagnetic GaMnAs.

GHEORGHE ACBAS, M.-H. KIM, J. CERNE, Physics Dept. Univ. at Buffalo, SUNY, Buffalo, NY, M. CUJKR, V. NOVAK, T. JUNGWIRTH, Institute of Physics, Acad. of Sciences of the Czech Republic, Prague, Czech Republic, M.A. SCARPULLA, Materials Department, Univ. of California, Santa Barbara, O.D. DUBON, Mat. Sci. & Eng. Dep., Univ. of Poitiers, Berlin, J. SINOVA, Physics Dept., Texas A&M Univ., College Station, TX — We have studied the Faraday and Kerr effects in a series of ferromagnetic GaMnAs films in the 115-1500 meV energy range. This provides a direct magneto-optical probe of the magnetic properties of a continuous (Ga,Mn)As film such as saturation magnetization and anisotropy field. These new approaches to scanned magnetic force imaging open the door to powerful new tools for spatially resolved studies of nanoscale magnetism and spin-based devices.

4:42PM T22.00010 Local Magnetic Characterization of Continuous (Ga,Mn)As Film using Mechanical Force Detection.

J. H. LEE, YU. OBUKHOV, J. KIM, The Ohio State University, X. LI, N. SAMARTH, The Pennsylvania State University, D. V. PELEKHOV, P. C. HAMMEL, The Ohio State University — We report on low temperature (T = 4.2 K) studies of the local spin dynamics in ferromagnetic samples using Ferromagnetic Resonance Force Microscopy (FMRFM) and probe-induced Magnetic Force Microscopy (MFM). Both techniques are based on sensitive mechanical detection of the dipolar magnetic interaction between a micromagnetic probe mounted on a flexible micro-cantilever and magnetic moments in the sample. The probe magnet not only detects the magnetic force, but also perturbs sample spin magnetization by adding the strongly inhomogeneous magnetic field. We demonstrate that the combination of FMRFM and probe-induced MFM can be used to extract and map local magnetic properties of a continuous (Ga,Mn)As film such as saturation magnetization and anisotropy field. These new approaches to scanned magnetic force imaging open the door to powerful new tools for spatially resolved studies of nanoscale magnetism and spin-based devices.

4:54PM T22.00011 Simultaneous Optical Imaging and Electrical Control of Magnetization in (Ga,Mn)As

M.E. NOWAKOWSKI, G.D. FUCHS, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106, A. BALK, M.J. WILSON, N. SAMARTH, Department of Physics and Materials Research Institute, The Pennsylvania State University, University Park, PA 16802 — Spin dependent phenomena in metals and semiconductors promises the development of low-power logic and memory devices based on electrical control of the magnetization. To realize this potential, precise visual information of magnetic domains is required to design and control electrical structures manipulated by the spin transfer torque. We present studies of magnetization behavior in micron-scale (Ga,Mn)As channels using a recently developed video-rate magneto-optical Kerr effect microscope. Measurements record real-time, diffraction-limited, surface magnetization information including magnetic switching and domain wall motion. The optical measurements are correlated with simultaneous electrical measurements to provide insight into pinning and magnetization transport in these structures.

1Work supported by ONR

5:06PM T22.00012 Optical conductivity of diluted magnetic semiconductors: effects of dynamical screening1 , FEDIR KYRYCHENKO, CARSTEN A. ULLRICH, University of Missouri — Most theoretical studies of transport and optical conductivity in diluted magnetic semiconductors like GaMnAs treat disorder and many-body effects within the simple relaxation time and static screening models. Here we present a more complete theory of transport in charge and spin disordered media that combines a multiband k · p approach with a first-principles descriptions of disorder and electron-electron interaction through the memory function formalism and time-dependent density functional theory. We discuss the effects of dynamic screening and collective electron excitations on the charge and spin scattering off Coulomb impurities and fluctuations of localized spins and compare calculated values of optical conductivity in GaMnAs with experimental results.

1This work was supported by DOE grant DE-FG02-05ER46213.

5:18PM T22.00013 Infrared probe of Ga1−xMnxAs films with controlled disorder and compensation , BRIAN CHAPLER, University of California San Diego, R.C. MYERS, Ohio State University, S. MACK, D.D. AWSCHALOM, University of California Santa Barbara, M.C. MARTIN, Lawrence Berkeley National Laboratories, A. DATTELBAUM, Los Alamos National Laboratory, K.S. BURCH, University of Toronto, D.N. BASOV, University of California San Diego — Arsenic antisite defects (AsGa) formed due to low temperature growth conditions are a leading cause of disorder and compensation in Ga1−xMnxAs. Samples grown with gradient As:Ga growth condition for 0.005 < x < 0.16 have allowed for optimized As flux minimizing AsGa. By studying samples at this optimized location via infrared spectroscopy, a new level of precision can be attained in exploring the electronic structure and other intrinsic properties of Ga1−xMnxAs samples. Using optical sum rule analysis of our experimentally determined optical conductivity (σf(ω)), we extract the free carrier band mass (m*) and find it to be several m0. We also comment on the levels of interstitial Mn (Mn2-), finding for x > 0.03 roughly 25% of Mn resides at an interstitial location. Additionally, by probing positions along the As:Ga gradient we directly measure the effects of disorder and compensation on these samples. Systematic changes in σf(ω) as AsGa content is increased are reported, and the consequences of this on our understanding of the electronic structure of Ga1−xMnxAs are discussed.

Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T23 DCMP FIAP: Quantum Hall Effect: Coherent Phenomena 325

2:30PM T23.00001 Low-field quantum Hall transport in an electron Fabry-Perot interferometer , P.V. LIN, F.E. CAMINO1, V.J. GOLDMAN, Stony Brook University — We report systematic experimental characterization of an interferometer device as a function of front-gate voltage at 10 mK. Application of front-gate voltage affects the constriction electron density, but the 2D bulk density remains unaffected. The low-field quantum Hall transport (filling f > 4) shows quantized plateaus in longitudinal resistance, while the Hall resistance is dominated by the low-density, low-filling constriction. This allows to determine independently both: the bulk and the constriction filling. At lower fields, when the quantum Hall plateaus fail to develop, we observe the bulk Shubnikov-de Haas oscillations in series corresponding to an integer number of the magnetoelectric subbands in the conduction. From a Fock-Darwin analysis, we obtain the constriction electron density as a function of the front-gate bias, and, extrapolating to the zero-field, the B = 0 number of 1D electric subbands (conductance channels) resulting from the electron confinement in the constriction.

1Present address: Center for Functional Nanomaterials, Brookhaven National Laboratory

2:42PM T23.00002 Oscillatory transport in electron Fabry-Perot interferometers , F.E. CAMINO1, P.V. LIN, V.J. GOLDMAN, Stony Brook University — We report experiments on GaAs/AlGaAs heterostructure interferometers in the integer QH regime with filling f = 1 − 4. Etch trenches define the device, which consists of an electron island connected to the 2DES bulk via two wide constrictions. Front gates deposited in the trenches permit to fine tune the device. When tunneling occurs in the constriction, electrons perform closed orbits around the island, producing an Aharonov-Bohm oscillatory signal in the conductance. On QH plateau transition between f + 1 and f, we observe f oscillations per flux h/e. In contrast, for all fillings, we observe one oscillation per back-gate charging period ε. We also report a linear dependence of magnetic field period on front-gate voltage for three devices, with the slope inversely proportional to f. We attribute this behavior to self-consistent electrostatics of the electron island, and discuss the models of edge channel structure.

1Present address: Center for Functional Nanomaterials, Brookhaven National Laboratory

2:54PM T23.00003 Universal dephasing in chiral one-dimensional electron systems , FLORIAN MARQUARDT, CLEMENS NEUENHAHN, Arnold Sommerfelld Center for Theoretical Physics, Center for NanoScience, and Department of Physics, Ludwig-Maximilians University Munich — The Green’s function of a chiral interacting one-dimensional fermion system obeys a power-law decay at high energies, at zero temperature. Surprisingly, we find that the exponent is universal, i.e. independent of the interaction strength, for (almost) arbitrarily shaped interaction potentials. This has direct implications for the interference contrast in ballistic interferometers, e.g. the Mach-Zehnder interferometer composed of edge channels in the integer quantum Hall effect. Our result is obtained using a straightforward and physically transparent “semiclassical” approach to dephasing by electron-electron interactions. This approach is shown to coincide with the exact bosonization results in the high-energy regime of interest.
3:06PM T23.00004 Determination of the coherence length in the Integer Quantum Hall Regime. F. PORTIER, P. ROULLEAU, P. ROCHE, CEA Saclay, SPEC, Nanoelectronic group, F-91919 Gif-sur-Yvette, A. CAVANNA, G. FAINI, U. GENSIBER, D. MAILLY, CNRS, LPN, Phynano team, Route de Nozay, F-91400 Marcoussis, NANOELECTRONIC GROUP COLLABORATION, PHYNANO TEAM COLLABORATION — One of the basic length scales limiting quantum effects in electrical conductors is the phase coherence length Lϕ, the typical length on which an excitation loses its phase coherence via coupling to other degrees of freedom. In quasi-1D diffusive wires, due to electron-electron interactions, Lϕ was shown to scale as T−1/3 as predicted by Altshuler-Aronov-Khmelnitsky. Surprisingly, little is known about Lϕ in the Integer Quantum Hall Regime (IQHE), where transport occurs through 1D chiral wires, localized on the edges of the sample. The number of these ‘edge states’ is equal to the filling factor (the number of electron per flux quantum flux). Chirality should prevent momentum conserving energy exchange processes, leading to a very long coherence length. We present an experiment where we have determined Lϕ in the IQHE at filling factor 2, by measuring the visibility of quantum interferences in an electronic Mach-Zender interferometer. Lϕ shows a T−1 dependence, proved to result from the coupling between the two neighbouring edge states: the thermal charge noise in one edge state blurs the phase on the other edge state, leading to a finite coherence length proportional to T−1.

3:18PM T23.00005 Edge-State Velocity and Coherence in a Quantum Hall Fabry-Perot Interferometer1. DOUGLAS MCCLURE, YIMING ZHANG, ELI LEVENSON-FALK, CHARLES MARCUS, Harvard University, LOREN PFIEFFER, KEN WEST, Bell Labs, Alcatel-Lucent — We present finite-bias measurements of electronic Fabry-Perot interferometers in the integer quantum Hall regime. In devices large enough that Coulomb blockade is absent, checkerboard-like patterns of oscillations as a function of magnetic field and dc bias appear. Comparing our data to predictions for electromagnetic Aharonov-Bohm interference, we extract edge-state velocities over a range of magnetic fields, finding dependence consistent with a crossover from skipping orbits at low fields to E x B drift at high fields. Suppression of visibility observed at high bias and high field is quantitatively accounted for by including an energy-dependent dephasing rate.

3:30PM T23.00006 Distinct Signatures For Coulomb Blockade and Aharonov-Bohm Interference in Electronic Fabry-Perot Interferometers1. YIMING ZHANG, DOUGLAS MCCLURE, ELI LEVENSON-FALK, CHARLES MARCUS, Harvard University, LOREN PFIEFFER, KEN WEST, Bell Labs, Alcatel-Lucent — We present finite-bias measurements of electronic Fabry-Perot interferometers of different sizes. Measuring these oscillations as a function of magnetic field, gate voltage, or both, we observe three signatures that distinguish the two types. The oscillations observed in a 2 µm² device are understood to arise from Coulomb blockade, and those observed in an 18 µm² device from Aharonov-Bohm interference. This work clarifies, provides ways to distinguish, and demonstrates control over, the physical origins of resistance oscillations seen in electronic Fabry-Perot interferometers.

3:42PM T23.00007 Fabry-Perot interferometer in Fractional Quantum Hall regime. AVEEK BID, N. OFEK, M. HEIBLUM, ADY STERN, V. UMANSKY, D. MAHALU, Weizmann Institute of Science — We have measured Aharonov-Bohm/Coulomb blockade oscillations in an electronic Fabry-Perot interferometer in the Fractional Quantum Hall regime. At ν = 2/5, when the inner channel is partially reflected (with the outer channel (1/3) being fully transmitted); the total transmission of the device oscillates as a function of magnetic field or modulation gate voltage. This is true also for ν = 2, 3, 4 when the interference is of a partially reflected lower lying channel (with the other channels being either fully transmitted or fully reflected). However, in the outermost channel of all filling factors (ν = 1/3, 2/5, 1, 4/3, 2, 3, 4, 5) we do not see any oscillations as a function of B. This we interpret to be due to interplay between the magnetic field (which tries to modify the area of the compressible island inside the interferometer) and Coulomb energy (which prevents the density of quasiparticles within the island from building up indefinitely). The period of oscillations in modulation gate voltage in the inner channel of ν = 2/5 (partially partitioned) is found to be one-third of that observed in the second channels of the integer filling fractions which probably is an indication that the oscillations are due to the tunnelling of quasiparticles of fractional charge 1/3.

3:54PM T23.00008 Nonequilibrium Dephasing in an Electronic Mach-Zehnder Interferometer. SEOK-CHAN YOUN, KAISS, HYUN-WOO LEE, POSTECH, H.-S. SIM, KAISS — We study nonequilibrium dephasing in an electronic Mach-Zehnder interferometer. We demonstrate that the shot noise at the beam splitter of the interferometer generates an ensemble of nonequilibrium electron density configurations and that electron interactions induce configuration-specific phase shifts of an interfering electron. The resulting dephasing exhibits two characteristic features, a lobe pattern in the visibility and phase jumps of π, in good agreement with experimental data.

4:06PM T23.00009 Generating Excitonic Supercurrent in Quantum Hall Bilayers. JUNG-JUNG SU, University of Texas at Austin, TAMIR PEREG-BARNÉA, Physics Department, California Institute of Technology, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin — Among the many examples of Bose condensation considered in physics, exciton condensation has maintained special interest because of controversy about condensate properties. Although ideal condensates can support an exciton supercurrent, it has not been clear how such a current could be induced or detected. We discuss the circuit conditions required to induce a steady-state counterflow superfluid. In addition, we will discuss interpretations of tunnel, drag and counterflow experiments in quantum Hall exciton condensates.

4:18PM T23.00010 Density imbalance effect on the Coulomb drag upturn in an undoped electron-hole bilayer. CHRISTIAN MORATH, JOHN SEAMONS, JOHN RENO, MIKE LILLY, Sandia National Lab — A low-temperature upturn of the Coulomb drag resistivity measured in an undoped electron-hole bilayer (uEHBL) device, possibly manifesting from exciton formation or condensation, was recently observed. The effects of density imbalance on this upturn are examined. Measurements of drag as a function of temperature in a uEHBL with a 20 nm wide Al0.05Ga0.95As barrier layer at various density imbalances n/p are presented. The results show drag increasing as the density of either two dimensional system was reduced, both within and above the upturn temperature regime and with a significantly stronger dependence than the (np)^−3/2 predicted by the weak-coupling theory. A comparison of the data with numerical calculations of drag in the presence of electron-hole pairing fluctuations, which qualitatively reproduce the drag upturn behavior and easily accommodates density imbalance effects, is also presented. The calculations predict a peak in drag at matched densities, which is consistent with the experiments. This work was supported by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under Contract No. DE-AC04-94AL85000.
material. Bi-dislocation lines are associated with one-dimensional fermionic excitations in a 'topological insulator', a novel band insulator believed to be realized in the bulk to propagating fermion modes. Can analogous phenomena occur in crystalline solids that host a plethora of topological defects? Here we show that indeed systems like the B-phase of superfluid helium He.

VISHWANATH, UC Berkeley — Topological defects, such as domain walls and vortices, have long fascinated physicists. A novel twist is added in quantum respecting the discrete symmetries of the system. We construct a tight-binding model on the diamond lattice that realizes the topologically nontrivial phase the topological properties of this quantum state manifest themselves through gapless surface states, that are robust against localization from random impurities transport in topological insulators. Our results provide a novel route to creating a potentially ideal quantum wire in a bulk solid.

quantum spin-Hall insulator, and not scattered by disorder. Since dislocations are ubiquitous in real materials, these excitations could dominate spin and charge rates on the excitation energy and intensity, spin-orbit interaction and a detailed understanding of the role of active phonon modes.

Our ab initio studies directly mimic the experimental data and reveal many intriguing features of the excitation dynamics, including non-radiative fluorescence, fast intrinsic intraband relaxation, phonon-induced component of fluorescence linewidths, the importance of defects, the dependence of the relaxation time-dependent density functional theory in order to model the ultrafast photoinduced processes in carbon nanostructures at the atomistic level and in real time. and even a superconductivity mechanism. We have developed state-of-the-art non-adiabatic molecular dynamics techniques and implemented them withinlinked to the topology of the electronic states of the bulk. The edge modes can be easily investigated when the edges are smooth and have a periodicity, but as soon as the periodicity is absent, the problem becomes un-traceable by purely theoretical means. In my talk I will exemplify the use of non-commutative calculus to explore the properties, especially the stability of the edge modes. For example, using such techniques one can give a fairly elementary proof that the edge modes in Chern insulators survive even for a rough (random) edge. Similarly, for the Spin-Hall effect, one can define an observable and its associated current whose conductance remains quantized during various deformations of the Hamiltonian system. It turns out that in all cases, the edge conductance is given by the index of a Fredholm operator, which provides a new topological invariant linked directly to the edge rather than the bulk.

SWNTs with diameters

Exciton Distribution between the Bright and Dark States in Single Carbon Nanotubes Studied by Magneto-Photoluminescence Spectroscopy , RYUSUKE MATSUNAGA, KAZUNARI MATSUDA, YOSHIHIKO KANEMITSU, Institute for Chemical Research, Kyoto University — We have performed micro-photoluminescence (PL) spectroscopy for single carbon nanotubes under magnetic fields at various temperatures. Sharp PL spectra of single carbon nanotubes allow us to directly observe the bright exciton PL peak a few meV below the bright exciton PL peak due to the Aharonov-Bohm effect [1]. From the PL intensity ratio of the dark to the bright exciton PL in a (6,5) nanotube and concluded they could be used to energetically locate the K-momentum excitons (Torrens, et al, PRL 101, 157401 (2008)). Here we use a combination of experiment and theory to study X\textsc{1} and X\textsc{2} in at least ten samples that are highly purified in a single chirality and use these findings to study how the K-momentum exciton energy depends on chirality.

This work supported by NSF MRSEC DMR-0520020.

Exciton Radiative Lifetimes and Their Temperature Dependence in Single-Walled Carbon Nanotubes , , LAIN-JONG LI, FUMING CHEN, Nanyang Technological University, MINGLI JIA, Chinese Academy of Sciences, LI WEI, YUAN CHEN, M. B. CHAN-PARK, Nanyang Technological University, ANDONG XIA, Chinese Academy of Sciences — The optimal excitation wavelength for the energy transfer from aromatic polymers poly(9,9-dioctylfluorene-2,7-diyl) (PFO) to single-walled carbon nanotubes (SWNTs) is tunable in a wide wavelength range (from 388 to 480 nm) depending on the concentration of excess PFO polymers. The concentration governs the aggregation state and chain conformation of the polymers proximate to SWNT surfaces, which in turn alters the optical excitation wavelength. This study suggests an exciting and convenient method of adjusting the desired optical wavelengths for the energy conversion, useful for polymer-SWNT composites in optoelectronic applications.

Effects of Exciton-Exciton Annihilation in Fluorescence of Individual SWCNTs , ANNI SIITONEN1, SERGEI BACHILO, DMITRI TSYBOULSKI, R. BRUCE WEISMAN, Rice University — Most studies of SWCNT exciton relaxation have been performed on bulk samples, with clear conclusions hampered by the variety of structural types, lengths, and aggregation states. To avoid such problems, we use near-IR fluorescence microscopy to study nearly pristine individual nanotubes with optically resolvable lengths. We find emission proportional to excitation at low intensities. But for stronger excitation, an increasingly sub-linear dependence is observed, due to exciton-exciton annihilation within single nanotubes. Since annihilation depends on excitation lifetime and mobility, these parameters can be studied by analyzing measured intensity dependences. We compare data on exciton excitation ranges and emission efficiency in individual SWCNTs to numerical simulations to quantify exciton lifetime and diffusion for a variety of (n,m) structures. Preliminary results yield lifetimes of a few nanoseconds for nearly pristine, highly emissive nanotubes and reveal some dependence of lifetime on nanotube diameter.

1University of Jyvaskyla

Exciton Spectroscopy and Absorption Cross-section of Individual Single-Walled Carbon Nanotubes . LAURENT COGNET, Bordeaux University and CNRS, France — Semiconducting Single-Walled Carbon Nanotubes (SWNTs) display intrinsic exciton luminescence which is highly sensitive to the nanotubes environment. For instance single-molecule chemical reactions with individual SWNTs could be observed through the stepwise changes of the luminescence intensity within submicrometer segments of single nanotubes. Analysis of the step amplitudes revealed an exciton diffusion range of ~90 nm. Each exciton thus visits approximately 10^3 atomic sites during its lifetime, providing highly efficient sensing of local chemical and physical perturbations [1]. SWNT luminescence decays are also sensitive to extrinsic factors. Using highly luminescent individual (6,5) SWNTs, time-resolved spectroscopy revealed however systematic biexponential luminescence decays, with short and long lifetimes around 45 and 250 ps. This intrinsic behavior is attributed to the band-edge exciton fine structure with a dark level lying a few meV below a bright one. Combining such time-resolved studies with cw luminescence ones, the absorption cross-section of individual SWNTs was determined. A mean value of ~10^17 cm^2 per carbon atom is obtained for (6,5) tubes excited at their second optical transition [2]. This was further corroborated by independent photothermal heterodyne measurements. Because this highly sensitive method relies only on light absorption, it readily detects metallic nanotubes as well as the emissive semiconducting species in various environments and allowed recording for the first time images and absorption spectra of individual SWNTs of both types [3].

Controlling Optimal Excitation Wavelength of Energy Transfer from Photo-Excited Polymers to Single-Walled Carbon Nanotubes. , LAIN-JONG LI, FUMING CHEN, Nanyang Technological University, MINGLI JIA, Chinese Academy of Sciences, LI WEI, YUAN CHEN, M. B. CHAN-PARK, Nanyang Technological University, ANDONG XIA, Chinese Academy of Sciences — The optimal excitation wavelength for the energy transfer from aromatic polymers poly(9,9-dioctylfluorene-2,7-diyl) (PFO) to single-walled carbon nanotubes (SWNTs) is tunable in a wide wavelength range (from 388 to 480 nm) depending on the concentration of excess PFO polymers. The concentration governs the aggregation state and chain conformation of the polymers proximate to SWNT surfaces, which in turn alters the optical excitation wavelength. This study suggests an exciting and convenient method of adjusting the desired optical wavelengths for the energy conversion, useful for polymer-SWNT composites in optoelectronic applications.
4:54PM T24.00009 Exciton Dynamics in (6,5) carbon nanotubes, ANDY WALSH, JUDE SCHNECK, Boston University, ALEX GREEN, MARK HERSAM, Northwestern University, SIDNEY REDNER, LAWRENCE ZIEGLER, ANNA SWAN, Boston University — Single color (E22) pump-probe data on a solution of (6,5) nanotubes reveal that use of pulses shorter than the dephasing time scale precludes the formation of multiple excitons on a single nanotube. Subsequent relaxation dynamics of the single exciton exhibits stretched exponential behavior, and data from low to saturation fluence, and over 3 order of magnitude of time delay, is described by the same model. The stretched exponential model implies a distribution of decay rates is attributed to a distribution of length-dependent effective lifetimes due to end-quenching via diffusion. Results give values for the dipole moment, E22 dephasing time and E11 diffusion coefficient.

5:06PM T24.00010 Exciton Dynamics in Individual Single-walled Carbon Nanotubes, MARAT KHAFIZOV, SHUJING WANG, LISA J. CARLSON, TODD D. KRAUSS, Department of Chemistry, University of Rochester, Rochester, New York 14627, MING ZHANG, DuPont Central Research and Development, Experimental Station, Wilmington, Delaware 19880 — Optical excitation of single-walled carbon nanotubes (SWNTs) results in strongly bound excitons. The dynamics and energetic pathways available to the exciton as it relaxes back to the ground state have recently received significant attention. We have performed transient absorption (TA) experiments on DNA-wrapped (6,5) SWNTs in the extremely low-excitation fluence regime. Excitation was provided by a Ti-sapphire oscillator whose output was focused into a highly nonlinear photonic crystal fiber generating a coherent, femtosecond white-light source. We found the recovery of the photobleach signal for excitons in the 1st and 2nd excited states (E11 and E22) was governed by power-law dynamics. Interestingly, we also observed an induced absorption feature in the TA spectrum to the blue of the E11 exciton that showed the same recovery dynamics as the photobleach signal, suggesting that they share a common origin. We will discuss the physical origins of the observed features in the TA spectrum in the context of current models of exciton states of the SWNT.

2:30PM T25.00001 Scanning Kelvin Probe Study of Electric Field Effect Tuning of Graphene, JESSE BEREZOVSKY, ROBERT WESTERVELT, Harvard University — Experiments on the transport properties of graphene over the last several years have revealed numerous unusual and fascinating results. These studies typically rely on lithographically patterned contacts and gates that can obscure effects arising due to spatially varying properties. Using a biased scanning probe tip, we can create a local gate or scattering potential and observe the resulting change in the transport properties of a graphene structure. Simulations show that this technique can image the fluctuating potential in a graphene nanoribbon, which shows promise for imaging the flow and behavior of electrons in graphene devices.

2:42PM T25.00002 STM Studies of Graphene Films Prepared by Sonication-Assisted Dispersion, ELENA STOLYAROVA, KWANG TAEG RIM, GEORGE FLYNN, Columbia University, COLUMBIA UNIVERSITY TEAM, COLUMBIA UNIVERSITY, COLUMBIA UNIVERSITY TEAM, POHANG UNIVERSITY OF SCIENCE AND TECHNOLOGY COLLABORATION — We present experimental work on the work function variation of mono and bi-layer graphene device measured by scanning Kelvin probe microscopy (SKPM). Using the electric field effect (EFE), the work function of graphene can be adjusted as the gate voltage tunes the Fermi level across the charge neutrality point. Mono and bi-layer graphene samples are deposited on a silicon oxide covered silicon substrate by a mechanical exfoliation method and electrical contacts are fabricated by electron beam lithography. The underlying silicon substrate is used as a back gate to tune the carrier concentration of the graphene. After subtracting off the large background signal originating from the electrostatic environment, we obtain the work function of graphene samples modulated by the gate voltage. The change of work function can be ascribed by the Fermi level shift due to the EFE induced carrier doping and well quantified by the electronic band structure of mono and bi-layer graphene.

3:06PM T25.00004 Low temperature scanning probe imaging of electron transport in graphene nanostructures, JESSE BEREZOVSKY, ROBERT WESTERVELT, Harvard University — Experiments on the transport properties of graphene over the last several years have revealed numerous unusual and fascinating results. These studies typically rely on lithographically patterned contacts and gates that can obscure effects arising due to spatially varying properties. Using a biased scanning probe tip, we can create a local gate or scattering potential and observe the resulting change in the transport properties of a graphene structure. Simulations show that this technique can image the fluctuating potential in a graphene sheet with a spatial resolution of tens of nanometers. By patterning the graphene into a nanowire or nanoconstriction, the local potential of the tip may be used to probe the dependence of the confinement-induced energy gap on the local atomic structure of the edges. These types of measurements provide a means for directly imaging the flow and behavior of electrons in graphene devices.

The flakes were characterized using a homebuilt, room temperature, ultrahigh-vacuum scanning tunneling microscope. We report on the apparent electronic in situ the Dry Contact Transfer (DCT) method [1] to deposit nanometer-sized, monolayer graphene flakes, using scanning tunneling microscopy.

Rutter, et al [3]. Room-temperature scanning tunneling spectroscopy (STS) measurements of the graphene monolayers and bilayers on the Si(111)-7x7 surface that the electronic structure of a graphene monolayer on the Si(111)-7x7 surface leads to the transparency of monolayers and bilayers, similar to the findings of clean Si(111)-7x7 surfaces. The DCT method deposits single, double, and thicker layers of atomically clean graphene. We observe varying degrees of transparency in the dI/dV measurement. This is in contrast to traditional magnetic oscillations which typically only probe the Fermi level. This work was supported in part by NSF, NRI-INDEX, and the W. M. Keck Foundation.

3:42PM T25.00007 Magnetic Oscillations in Scanning Tunneling Spectroscopy of Epitaxial Graphene on SiC . KEVIN D. KUBISTA, DAVID L. MILLER, GREGORY M. RUTTER, MING RUAN, WALT A. DE HEER, PHILLIP N. FIRST, Georgia Institute of Technology, JOSEPH A. STROSCIO, Center for Nanoscale Science and Technology, NIST — Scanning tunneling microscopy (STM) and spectroscopy (STS) at a temperature of 4 K are used to study the electronic properties of epitaxial graphene on SiC in a magnetic field perpendicular to the graphene plane. While changing the magnetic field we observe Shubnikov de Haas-like magnetic oscillations in the tunneling conductance, dI/dV. The peak positions of these tunneling magnetic oscillations (TMO) vary periodically with inverse magnetic field, indicating they sample a constant cross-section of the graphene k-space. This new magnetic oscillation method can map extended parts of the electronic band structure of graphene as we vary the tunneling energy in the dI/dV measurement. We analyze our results in terms of graphene 2D electronic structure.

4:06PM T25.00009 Kondo Effect for Massless Dirac Fermions in Graphene1 , L. S. MATTOS, C. R. MOON, P. B. VAN STOCKUM, J. C. RANDEL, H. C. MANOHARAN, Stanford University, M. W. SPRINKLE, C. BERGER, W. A. DE HEER, Georgia Tech, K. SENGUPTA, SINP, A. V. BALATSKY, LANL — We experimentally probe the addition of the spin degree of freedom to the local physics of graphene. This real spin degree of freedom is expected to become intertwined in various coherent scattering processes involving pseudospin and chirality intrinsic to single monolayers of graphene. A Compendium of theoretical work on the interaction of localized spins with Dirac electrons predicts that low-temperature screening of localized magnetic moments by nodal quasiparticles gives rise to an unconventional Kondo effect, in which a critical exchange coupling can be controlled by charge carrier doping. We report the observation of this elusive Kondo ground state of Dirac particles, using scanning tunneling microscopy of adsorbed magnetic atoms on epitaxial graphene at low temperature. Tunneling spectroscopy and quasiparticle interference maps reveal chiral, linearly dispersing carriers by charge carrier doping. We report the observation of this elusive Kondo ground state of Dirac particles, using scanning tunneling microscopy of adsorbed magnetic atoms on epitaxial graphene at low temperature. Using Fourier-transform scanning tunneling spectroscopy and concomitant measurements in a high magnetic field, we deduce the origin of these features. We further probe atomic scale variations in the LDOS of graphene caused by impurities on the surface. We analyze our results in terms of graphene electronic structure.

1We acknowledge support from DOE

4:18PM T25.00010 Atomic-scale scanning tunneling microscopy and spectroscopy studies of nanometer-sized graphene on the Si(111)-7x7 surface . JUSTIN KOEPKE, JOSEPH LYDING, University of Illinois at Urbana-Champaign — We have used ultrahigh vacuum scanning tunneling microscopy to perform atomic-level studies of graphene on the Si(111)-7x7 surface. We used a dry contact transfer technique (DCT) developed by Albrecht and Lyding [1] to deposit mechanically exfoliated graphene in-situ [2] onto atomically clean Si(111)-7x7 surfaces. The DCT method deposits single, double, and thicker layers of atomically clean graphene. We observe varying degrees of transparency of the graphene monolayers and bilayers on the Si(111)-7x7 surface, where the substrate atomic structure is clearly seen through the graphene. We believe that the electronic structure of a graphene monolayer on the Si(111)-7x7 surface leads to the transparency of monolayers and bilayers, similar to the findings of Rutter, et al [3]. Room-temperature scanning tunneling spectroscopy (STS) measurements of the graphene monolayers and bilayers on the Si(111)-7x7 surface show predominantly metallic behavior. [1] P.M. Albrecht and J.W. Lyding, Appl. Phys. Lett. 83, 5029 (2003) [2] K.A. Ritter and J.W. Lyding, Nanotechnology 19, 015704 (2008) [3] G.M. Rutter, et al, Phys. Rev. B 76, 235416 (2007)

4:30PM T25.00011 Atomic-scale studies of nanometer-sized graphene on III-V semiconductors using scanning tunneling microscopy . KEVIN HE, JUSTIN KOEPKE, JOSEPH LYDING, University of Illinois - Urbana — We utilize the Dry Contact Transfer (DCT) method [1] to deposit nanometer-sized, monolayer graphene flakes, in situ, onto cleaved GaAs (110) and InAs (110) surfaces. The flakes were characterized using a homebuilt, room temperature, ultrahigh-vacuum scanning tunneling microscope. We report on the apparent electronic semi-transparent of the monolayer graphene flakes, such that the underlying III-V semiconductor lattice is revealed in our topographic images. This transparency is strongly dependent on the applied sample bias, similar to results seen on SiC (1000) for large sheets of graphene grown via thermal desorption [2].

I. Forbeaux et al. [1] have shown that the growth of graphene on Cu(001) leads to applications in future scalable graphene nano-electronics devices.

II. Chemical exfoliation of graphite in solvent of 1-pyrenecarboxilic acid in water. We confirm the presence of monolayer graphene sheets by Scanning transmission electron microscopy (STM) analysis. However, chemical approaches for high-yield production of graphene sheets is still absent. Here, we report that graphene dispersion produced by mechanical methods, exfoliation, epitaxial growth method and reduced graphene from two-dimensional crystallographic nature, which have resulted in intensive investigations of fundamental physics and promising applications. Up to now, several techniques have been used to produce small areas of graphene, such as mechanical methods, exfoliation, epitaxial growth method and reduced graphene from two-dimensional crystallographic nature, which have resulted in intensive investigations of fundamental physics and promising applications. The predicted supersaturation is highly nonlinear. Such behavior can be explained if carbon clusters must form as precursors to carbon attachment. As experiment and theory reveal, this could arise from strong bonding of monolayer monomers to the metal substrate.

III. We study the epitaxial growth of graphene on Ru(0001) measuring simultaneously the growth rate of individual graphene islands and the local, absolute concentration of vapor-deposited, mobile carbon adatoms. We have learned what controls the nucleation and growth rate of graphene, and what species transport carbon over the metal surface. We find that the growth rate is limited by C-atom attachment, not by C-atom diffusion, and that the absolute value of the supersaturation required for appreciable growth rates is comparable to that required to nucleate new islands. Thus, a step flow mechanism is unlikely to exist in monolayer graphene growth. The growth rate as a function of supersaturation is highly nonlinear. Such behavior can be explained if carbon clusters must form as precursors to carbon attachment. As experiment and theory reveal, this could arise from strong bonding of monolayer monomers to the metal substrate. We will discuss a model that explains and provides insight into the molecular processes by which graphene grows. This research is supported by the Office of Basic Energy Sciences, Division of Materials Sciences, U. S. D. O. E. under Contract No. DE-AC04-94AL85000.

IV. Large scale graphene synthesized on metal and transferred to insulators: Material and Electronic Properties. YONG P. CHEN, H. CAO, D. PANDEY, I. CHILDRES, D. ZEMLYANOV, V. DRACHEV, R. REIFENBERGER, Purdue University, Q. YU, S. H. Y. LEE, University of Houston, J. LIAN, RPI, H. LI, University of Missouri — We report a systematic study of the material and electronic properties of large scale graphene films grown on metal and transferred to insulator substrates. Few-layer graphene films as large as several cm’s in size are grown by cooling-induced surface segregation on Ni under ambient pressure (Q. Yu et al., APL 93, 113103 (2008)). The Ni is subsequently etched by acid and graphene film transferred on thin SiO$_2$ on doped Si wafer. TEM and STM images show the expected graphitic lattice structure locally with atomic resolution. XPS and Raman spectroscopies further confirm the high quality of transferred graphene films. At larger scale, various SPM and optical imaging reveal non-uniform thickness and considerable height fluctuation, with the film consisting with domains (~1 μm in size) separated by elevated ridges. Using the doped Si as backgate, we observe moderate field effect in such transferred graphene films. Magnetotransport at variable temperatures show negative magnetoresistance at low magnetic field and characteristic features of weak localization in graphene, allowing us to extract information on carrier scattering in such large scale graphene.

V. Epitaxial Graphene on Co(0001) Probed by STM Measurements and First Principles Calculations. DEBORAH PREZZI, Columbia University (NY-USA) & S3-CNR-INFM (Modena - ITALY), DA-JIN EOM, KWANG T. RIM, HUI ZHOU, MICHAEL LEFENFELD, COLIN NUCKOLLS, Columbia University, MARK HYBERTSEN, Brookhaven National Laboratory, TONY HEINZ, GEORGE FLYN, Columbia University — Structural and electronic properties of finite-sized graphene patches on Co(0001) have been investigated through a combined experimental and theoretical characterization. The analysis of low-temperature scanning tunneling microscopy images establishes an atomically uniform epitaxial configuration of graphene on the Co surface in which a C atom is atop the interface Co atom, in agreement with total energy calculations based on a density-functional theory (DFT) approach. Scanning tunneling spectroscopy measurements show that the electronic properties of the interface are significantly different than both the clean Co surface and isolated graphene, suggesting a strong electronic coupling at the interface. DFT calculations provide a detailed analysis of the spectroscopic features in terms of spin and site contributions and reveal the coupling between graphene p and Co d states.

2:30PM T26.00001 Evidence for graphene growth by C cluster attachment. ELENA LOGINOVA, NORMAN C. BARTEL, PETER J. FEIBELMAN, KEVIN F. MCCARTY, Sandia National Laboratories — Until now the detailed mechanisms of graphene growth have not been experimentally determined, owing to limitations of the available experimental techniques. We study the epitaxial growth of graphene on Ru(0001) measuring simultaneously the growth rate of individual graphene islands and the local, absolute concentration of vapor-deposited, mobile carbon adatoms. We have learned what controls the nucleation and growth rate of graphene, and what species transport carbon over the metal surface. We find that the growth rate is limited by C-atom attachment, not by C-atom diffusion, and that the absolute value of the supersaturation required for appreciable growth rates is comparable to that required to nucleate new islands. Thus, a step flow mechanism is unlikely to exist in monolayer graphene growth. The growth rate as a function of supersaturation is highly nonlinear. Such behavior can be explained if carbon clusters must form as precursors to carbon attachment. As experiment and theory reveal, this could arise from strong bonding of monolayer monomers to the metal substrate. We will discuss a model that explains and provides insight into the molecular processes by which graphene grows. This research is supported by the Office of Basic Energy Sciences, Division of Materials Sciences, U. S. D. O. E. under Contract No. DE-AC04-94AL85000.

2:42PM T26.00002 Large Scale Graphene Synthesized on Metal and Transferred to Insulators: Material and Electronic Properties. YONG P. CHEN, H. CAO, D. PANDEY, I. CHILDRES, D. ZEMLYANOV, V. DRACHEV, R. REIFENBERGER, Purdue University, Q. YU, S. H. Y. LEE, University of Houston, J. LIAN, RPI, H. LI, University of Missouri — We report a systematic study of the material and electronic properties of large scale graphene films grown on metal and transferred to insulator substrates. Few-layer graphene films as large as several cm’s in size are grown by cooling-induced surface segregation on Ni under ambient pressure (Q. Yu et al., APL 93, 113103 (2008)). The Ni is subsequently etched by acid and graphene film transferred on thin SiO$_2$ on doped Si wafer. TEM and STM images show the expected graphitic lattice structure locally with atomic resolution. XPS and Raman spectroscopies further confirm the high quality of transferred graphene films. At larger scale, various SPM and optical imaging reveal non-uniform thickness and considerable height fluctuation, with the film consisting with domains (~1 μm in size) separated by elevated ridges. Using the doped Si as backgate, we observe moderate field effect in such transferred graphene films. Magnetotransport at variable temperatures show negative magnetoresistance at low magnetic field and characteristic features of weak localization in graphene, allowing us to extract information on carrier scattering in such large scale graphene.

2:54PM T26.00003 Investigation of the early stages of graphene formation on 6H-SiC. J. R. SKUZA, Department of Physics, College of William and Mary, C. CLAVERO, K. YANG, Department of Applied Science, College of William and Mary, B. WINCHESKI, NASA Langley Research Center, R. A. LUKASZEWS, Departments of Applied Science and Physics, College of William and Mary — The predicted and/or observed unique properties of graphene have sparked tremendous research efforts to develop graphene-based ultra-high speed electronic and optical devices. The most promising technique to fabricate epitaxial graphene at the surface is via a high temperature sublimation of atomic layers of Si from monocrystalline SiC substrates [1,2]. However, this approach leads to rough surfaces and little work has been done to investigate graphene nucleation during the early stages of growth. We have used atomic force microscopy, scanning electron microscopy, and Raman spectroscopy to investigate the early stages of graphene nucleation and surface evolution when annealing semi-insulating and n-type doped 6H-SiC substrates under low vacuum (~ 10$^{-3}$ Torr) and ultra-high vacuum (10$^{-9}$ Torr) regimes. Scaling laws applied to the surface evolution in these two cases will be compared. [1] I. Forbeaux et al., Phys. Rev. B 58, 16396 (1998). [2] C. Berger et al., J. Phys. Chem. B 108, 19912 (2004).

3:06PM T26.00004 High-field production of graphene sheets by chemical exfoliation of graphite. XIAOHONG AN, SWASTIK KAR, MORRIS WASHINGTON, SAROJ NAYAK, Rensselaer Polytechnic Institute, DEPARTMENT OF PHYSICS, APPLIED PHYSICS AND ASTRONOMY TEAM — Graphene, a single atomic layer of graphite, has attracted vast interest recently owing to its perfect two-dimensional crystallographic nature, which have resulted in intensive investigations of fundamental physics and promising applications. Up to now, several techniques have been used to produce small areas of graphene, such as mechanical methods, exfoliation, epitaxial growth method and reduced graphene from graphitic oxide. However, chemical approaches for high-field production of graphene sheets is still absent. Here, we report that graphene dispersion produced by chemical exfoliation of graphite in solvent of 1-pyrenecarboxilic acid in water. We confirm the presence of monolayer graphene sheets by Scanning transmission electron microscopy and Raman spectroscopy. Large area of graphene sheets on SiO$_2$/Si substrate can be obtained by evaporating the graphene dispersion in oven and rinsing with methanol. We demonstrate the high-field production of graphene sheets by optical microscopy and scanning electron microscopy. Electrical and other applications of graphene developed this way are currently being investigated. This new graphene processing of chemical exfoliation of graphite could lead to applications in future scalable graphene nano-electronics devices.

3:18PM T26.00005 Scalable chemical vapor deposition of single- and few-layer graphene. LEWIS GOMEZ DE ARCO, YI ZHANG, AKSHAY KUMAR, CHONGWU ZHOU, University of Southern California — We report the implementation of a simple and scalable method to prepare single and few-layer graphene films by chemical vapour deposition. Micro Raman spectroscopy analysis of the synthesized films revealed the presence of single and few-layer graphene domains throughout the substrate. Synthesized graphene films were recovered on Si/SiO$_2$ substrates where back-gated FETs were fabricated. Four-probe measurements revealed sheet resistance of ~68 kΩ/sq for the recovered films. $I_{DS}$-$V_{DS}$ and transfer characteristics indicate a weak p-type behavior in the films and weak modulation of the drain current by the gate bias.
Temperature-dependence of Epitaxial Graphene Formation on SiC(0001)\textsuperscript{1}

LUXMI LUXMI, NISHHTHA SRIVASTAVA, PATRICK FISHER, RANDALL FEENSTRA, Carnegie Mellon University, JAKUB KEDZIERSKI, MIT Lincoln Laboratory, YUGANG SUN, Argonne National Laboratory, GONG GU, Sarnoff Corporation — The formation of epitaxial graphene on SiC(0001) (the Si-face) is studied using atomic force microscopy, Auger electron spectroscopy, low energy electron diffraction/microscopy, Raman spectroscopy, and electrical measurements. Starting from hydrogen-etched surfaces, graphene formation by vacuum annealing is observed to begin at about 1150 °C, with the overall step-terrace arrangement of the H-etched surface being preserved but with significant roughness (pit formation) on the terraces. At temperatures near 1350 °C, the surface morphology changes into relatively large flat terraces covered with several layers of graphene and containing a few large pits, with the terraces separated by step bunches. On the terraces the graphene thickness varies by typically ±1 monolayer. At higher temperatures the graphene film is observed to buckle and break up, presumably due to thermal mismatch with the SiC. Field-effect mobilities as high as 4200 cm\(^2\)/Vs for few-layer graphene films are found.

\textsuperscript{1}Supported by NSF, DARPA, and DOE (ANL). Opinions are those of the authors and not necessarily endorsed by the funding sources.

3:42PM T26.00007 Epitaxial Graphene Formation on SiC(0001)\textsuperscript{1}, NISHHTHA SRIVASTAVA, LUXMI LUXMI, PATRICK FISHER, RANDALL FEENSTRA, Carnegie Mellon University, JAKUB KEDZIERSKI, MIT Lincoln Laboratory, YUGANG SUN, Argonne National Laboratory, GONG GU, Sarnoff Corporation — The formation of epitaxial graphene on SiC(0001) (the C-face) is studied using atomic force microscopy, spatially resolved Auger electron spectroscopy, low energy electron diffraction, Raman spectroscopy, and electrical measurements. Starting from hydrogen-etched surfaces, graphene formation by vacuum annealing is observed over the temperature range 1200-1400 °C. Unlike the situation for the Si-face, it is found for the C-face that the initial graphene formation is three-dimensional. Micron-size islands with height of several nm are formed, with the graphene being thinner on these islands than between the islands. At higher formation temperatures the graphene layer becomes relatively flat, and has typical thickness of ∼10 monolayers. Electron diffraction indicates rotational disorder, with ±15 °-oriented spots observed in addition to the known ±2.2 °-spots. Field-effect mobilities as high as 4400 cm\(^2\)/Vs for multi-layer graphene films are found, with relatively good homogeneity over the wafer. \cite{Hass2008}.

\textsuperscript{2}Supported by NSF, DARPA, and DOE (ANL). Opinions are those of the authors and not necessarily endorsed by the funding sources.

3:54PM T26.00008 Band-gap tuning through progressive oxidative of graphene\textsuperscript{1}, TANESH BANSAL, ADITYA MOHITE, BRUCE ALPHENAAR, JACEK JASINSKI, MAHENDRA SUNKARA, University of Louisville, IAMRE, DEPT OF CHEM ENGG COLLABORATION — Graphene has a high electron mobility at room temperature, making it attractive for device applications. Because graphene is a zero-gap semiconductor, it is challenging to modulate its conductance using a field effect gate. Oxidation of graphene opens up a band gap, transforming oxidized graphene into an insulator. However, theory also suggests that there are a range of stable oxidation states corresponding to different oxygen coverage on the surface. Here, we demonstrate that it is possible to tune the band-gap of oxidized graphene by varying the surface oxygen concentration. Commercially obtained KISH graphite was converted to graphite oxide by treatment with a mixture of sulfuric acid and nitric acid. Oxidized graphene sheets were dispersed on quartz substrates following sonication and centrifugation of the graphite oxide. Using photocurrent spectroscopy the energy gap of individual oxidized graphene flakes were observed to increase from 0.62 eV to 0.69 eV with increasing oxidation time. Band-gap measurements were correlated with the surface oxygen concentration using XPS, UPS and FTIR.

\textsuperscript{3}Supported by NSF MRSEC DMR-0520020, JSTO DTRA, and ARO W911NF-06-1-0462.

4:06PM T26.00009 Electrical Characterization of Reduced Epitaxial Graphene Oxide\textsuperscript{1}, YIKE HU, XIAOSONG WU, MICHAEL SPRINKLE, NERASOA MADIOMANANA, MING RUAN, CLAIRE BERGER, WALTER DE HEER, Georgia Institute of Technology — We present results for on-chip oxidation of epitaxial graphene and sequential reduction of the insulating graphene oxide layers. In our previous work, we have used the Hummer’s method to oxidize epitaxial graphene and used electron beam exposure and heat treatment to reduce the epitaxial graphene oxide (EGO) band gap by changing the degree of oxidation. Here we further explore various oxidative and reduction methods on epitaxial graphene. EGO is characterized by atomic force microscopy, low-energy electron diffraction, ellipsometry, and Raman Spectroscopy. Mobility measurements of patterned structures are presented where epitaxial graphene layers pads are seamlessly connected to EGO ribbons.

\textsuperscript{3}This work was supported by the JSTO DTRA and the Army Research Office Grant # W911NF-06-1-0462 (ZL), and by the Nano/Bio Interface Center through the National Science Foundation DMR-0425780 (YL).

4:18PM T26.00010 Preparation of macroscopic graphene oxide membranes\textsuperscript{1}, ZHENTANG LUO, YE LU, LUKE SOMERS, A.T. CHARLIE JOHNSON, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA — Graphene oxide membranes up to 2000 square micrometers in size can be synthesized with ≥90 % yield in bulk quantities through a microwave assisted chemical method. Membranes are readily visualized on oxidized silicon substrate, which enables efficient fabrication of electronic devices and sensors. Field effect transistors made of the membrane show ambipolar behavior, and their conductivity is significantly higher than previously reported values.

\textsuperscript{3}Supported by NSF MRSEC DMR-0520020, JSTO DTRA, and ARO W911NF-06-1-0462.

4:30PM T26.00011 Optical and diamagnetic anisotropy of graphene oxide\textsuperscript{1}, A.L. EXARHOS, P.M. VORA, Z. LOU, A.T. JOHNSON, J.M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania — We have recently shown that graphene oxide (GO) emits a broad photoluminescence (PL) band in both solid and aqueous preparations. The origin of this PL is not yet well understood, but for absorptive and emissive optical processes originating in the two dimensional GO plane, one expects an in-plane polarization. Studies of optical anisotropy can therefore help to clarify the origin of the PL. Here we use a method of optical nanomagnetometry (Torrens, et al., JACS 129, p. 252 (2007)) to extract these quantities, also determining the magnetic anisotropy. We find that when aqueous preparations of GO are placed in a magnetic field, diamagnetically induced alignment leads to marked linear polarization anisotropy of absorbance and photoluminescence. By taking six optical measurements at each magnetic field, we are able to extract the intrinsic polarization anisotropies of optical absorption and emission of GO flakes and to quantify the orbital diamagnetic anisotropy. We discuss how these quantities give insight into electronic delocalization in these systems.

\textsuperscript{3}Supported by NSF MRSEC DMR-0520020, JSTO DTRA, and ARO W911NF-06-1-0462.

4:42PM T26.00012 Graphite oxide as a nanoscale dielectric\textsuperscript{1}, BRIAN STANDELEY, ANTHONY MENDEZ, California Institute of Technology, EMMA SCHMIDGALL, Imperial College London, MARC BOCKRATH, California Institute of Technology — Graphite oxide’s ease of deposition and graphene-like properties when chemically reduced make it a promising electronic material. To complement this effort, we are studying graphite oxide as a potential dielectric for nanoscale devices. While unreduced graphite oxide is known to have a sheet resistance in the GΩ range, its out-of-plane conductivity has yet to be measured. We have fabricated ultrathin capacitors from graphite oxide sheets, and will present our efforts to measure its leakage current and breakdown electric field, thus providing an assessment of its potential as a gate insulator.
4:54PM T26.00013 Diffusion and Self-alignment of Atomic Oxygens on the Graphene Surfaces: First Principles Calculations, TAKAZUMI KAWAI, YOSHIYUKI MIYAMOTO, Nano Electronics Labs., NEC Corp. — Graphene is attracting much attention for the application of nano-devices due to its interesting electronic properties and its robustness. For the device applications, it is very important to know the behaviors of atmospheric molecules such as adsorption, diffusion, and desorption on the graphene surface because the reaction with such chemicals cause the significant change in the electronic properties at Fermi level and even break the sp² network. Here, the oxygen is one of the most important impurities that we want to know and control the behavior. In this paper, we performed density function calculations for the diffusion of atomic oxygens on a graphene sheet in a periodic boundary condition. The results for a single atomic oxygen in our calculations are consistent with the previous works with cluster models. However, the favorable adsorption site for the next oxygen atom and diffusion barriers are completely different from them. The atomic oxygens prefer to align along armchair direction but not zigzag one. We will further discuss the stability and diffusion of the next oxygen atom on the other side of the graphene.

5:06PM T26.00014 Large area graphene growth on 6H-SiC(0001), I.I. JOHANSSON, C. VIROJANADARA, M. SYVÄJÄRVI, R. YAKIMOVA, IFM, Linkoping University, A.A. ZAKHAROV, T. BALASUBRAMANIAN, MAX-lab, Lund University — Large area graphene growth on commercial Si-face on-axis 6H-SiC(0001) is demonstrated in this work. Samples were produced in a prototype of an inductively heated furnace. The growth was carried out in strongly isothermal conditions at a temperature of 2000 °C and at an ambient argon pressure of 1 atm. The quality and thickness of the graphene layers grown, using this ex situ method, were investigated using PES, ARPES), LEED as well as LEEM, PEEM micro-LEED and micro-PES at specifically defined small areas. Our results show that single layer graphene is formed over quite large areas on the sample but that two different domains can exist on some parts. A comparison with an in situ graphene sample, prepared by resistive heating to 1275 °C, was made. The results then obtained were similar to earlier findings [1-2] and showed that the size of the graphene flakes were very small compared to those obtained on the samples prepared with our ex situ method.

[1] T. Ohta, F. El Gabaly, A. Bostwick, J.L. McChesney, K.V. Emtsev, A.K. Schmid, Th. Seyller, K. Horn, E. Rotenberg, New. J. Phys. to earlier findings [1-2] and showed that the size of the graphene flakes were very small compared to those obtained on the samples prepared with our ex situ method.

5:18PM T26.00015 Epitaxial graphene: Structure, growth and molecular interactions, ANDREW WEE, WEI CHEN, SIEW WAI POON, HAN HUANG, SHI CHEN, DONGCHEN QI, ENG SOON TOK, KIAN PING LOH, National University of Singapore — The discovery of graphene has opened up a new paradigm in nanoelectronics that could offer better performance than conventional semiconductor devices. We used in situ scanning tunnelling microscopy (STM), synchrotron synchrotron radiation techniques and density functional theory (DFT) calculations to investigate the structure of the various reconstructions of 6H-SiC(0001) prior to its thermal decomposition to form epitaxial graphene (EG). Using Co-decoration technique coupled with STM, the evolution of EG was found to preferentially begin at SiC step edges and occurs with the loss of Si and breakdown of the C-rich (hexagonal SiC) template, which provides the C source for graphene growth. The C-rich phase that forms at the interface acts as a buffer layer for graphene from the underlying bulk SiC. We show that the transition from monolayer to trilayer EG adopts a bottom-up growth mechanism. With increasing annealing temperature, the fluorescence yield of Si K-edge NEXAFS indicates an increase in disorder of Si atoms in the SiC substrate beneath the surface due to out-diffusion of Si atoms to the surface forming increased Si vacancies. We also show that EG thermally grown on 6H-SiC(0001) can be p-type doped via a novel surface transfer doping scheme by modifying the surface with the electron acceptor, F4-TCNQ.

Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T27 FLAP: Focus Session: Pulsed Laser Deposition of Electronic and Photonic Thin Films and Nanostructures 329

2:30PM T27.00001 Plasma Energetic in Pulsed Laser Deposition and Pulsed Electron Deposition1, SOLOMON KOLAGANI, Neocera, LLC, Beltsville, Maryland, USA — Surface bombardment by energetic particles strongly affects thin film growth and allows surface processing under non-thermal equilibrium conditions. Deposition techniques enabling energy control can effectively manipulate the microstructure of a film and site for the next generation of complex structures that incorporate metals, complex dielectrics, ferroelectrics, semiconductors and glasses. In the case pulsed ablation techniques such as Pulsed Laser Deposition (PLD) and Pulsed Electron Deposition (PED), the initial energetic s of the material flux are typically in the range of 100s of eV, much higher than the optimal values (≤ 10 eV) required for high quality film growth. To overcome this problem and to facilitate particle energy transformation from the original as-ablated to the one optimal for film growth, one needs to carefully select the ablation conditions, conditions for material flux propagation through a process gas (or vacuum) and location of the growth surface (substrate) within this flux. In this talk, I will discuss the energetics of the propagating materials flux in the case of PLD and PED, and identify parameters that require critical control for realizing optimum thin film growth. As an example, growth optimization of epitaxial GaN films is provided. PED is complementary to PLD and exhibits an important ability to ablate materials that are transparent to laser wavelengths typically used in PLD. Some examples include wide band gap materials such as SiO2, Al2O3, MgO etc. Both PLD and PED features can be integrated within a single deposition module. PLD-PED systems enable in-situ deposition of a wide range of materials required for exploring the next generation of complex structures that incorporate metals, complex dielectrics, ferroelectrics, semiconductors and glasses.

In collaboration with Mikhail Strikovski, Neocera, LLC.

3:06PM T27.00002 Interface-controlled thin film growth of conjugated polymers via pulsed laser deposition1, R.K. GUPTA, K. GHOSH, Missouri State University, SUCHI GUHA, University of Missouri-Columbia — Matrix-assisted pulsed laser evaporation, a derivative of pulsed laser deposition (PLD), is an alternative method of depositing polymer and biomaterial films that allows homogenous film coverage of high molecular weight organic materials for a layer-by-layer growth without any laser induced damage. Polyfluorene (PF1-based conjugated polymers have attracted considerable attention in blue-emitting displays. Di-octyl substituted polyfluorene (PF8), its copolymers, and thiophene-based polymers were deposited as thin films using matrix-assisted PLD by employing a KrF excimer laser. The optical and structural properties of these films are compared with spincoated films via Raman spectroscopy, absorption and photoluminescence. The Raman spectra of both PLD and spincoated films are similar indicating that the polymer films deposited via PLD maintain their molecular structure. We further discuss the application of interface-controlled PLD grown films in metal-insulator-semiconductor diodes and field-effect transistors.

1 In collaboration with Mikhail Strikovski, Neocera, LLC.

3:18PM T27.00003 Bi$_{0.4}$Ca$_{0.6}$MnO$_3$ Epitaxial Thin Films on Silicon for Electronic and Photonic Applications 1. VERA SMOLYANOVA, GRACE YONG, BENJAMIN HOFMANN, RAJESWARI KOLAGANI, Towson University, YONG LIANG, Motorola Labs — Thin films of rare-earth manganese oxides (manganites) are usually grown on oxide substrates. It is more challenging to grow thin films of these materials on technologically versatile silicon. Upon illumination with visible light, the resistivity of Bi$_{0.4}$Ca$_{0.6}$MnO$_3$ epitaxial thin films fabricated via PLD on oxide substrates decreases significantly in a wide temperature range due to the destruction of charge ordering. This makes Bi$_{0.4}$Ca$_{0.6}$MnO$_3$ thin films attractive for potential photonic and opto-electronic device applications. Having in mind device applications, we have extended our studies to Bi$_{0.4}$Ca$_{0.6}$MnO$_3$ epitaxial thin films grown on Si (001) with different buffer layers. The advantages of different buffer layer schemes on Si (001) will be discussed. Influence of deposition and annealing conditions on film photoresponse will be reported. Photoinduced and current induced effects in films grown on oxide substrates and on buffered Si substrates will be compared.

1 This work is supported by the NSF grant DMR-0348939.

3:30PM T27.00004 Photoinduced effects in Bi$_{1-x}$Ca$_x$MnO$_3$ thin films with different oxygen content 1. GRACE YONG, RAJESWARI KOLAGANI, KHIM KARKI, BENJAMIN HOFMANN, VERA SMOLYANOVA, Towson University — Doped rare-earth manganese oxides (manganites) attract interest due to a variety of electronic, magnetic, and orbital states and their drastic response to application of modest external fields. A photoinduced insulator to conductor transition in thin films of Bi$_{1-x}$Ca$_x$MnO$_3$ associated with melting of the charge ordering [1] is especially interesting for potential photonic and opto-electronic device applications. From this point of view it is important to know what factors influence the photoinduced effects. We have found that oxygen content of Bi$_{1-x}$Ca$_x$MnO$_3$ thin films significantly modify conductive, structural and photoinduced properties. The role of growing and annealing conditions will be discussed. The change in magnitude and lifetime of photoinduced changes in films with different oxygen content will be reported. The possible origin of these changes will be discussed. [1] V. N. Smolyanova at al., Phys. Rev. B 76, 104423 (2007)

3:42PM T27.00005 Strain-modulated Self-Assembly of Nanostructures within Epitaxial Thin-films via Pulsed Laser Ablation 1. AMIT GOYAL, SUNG-HUN WEE, YANFEI GAO, CLAUDIA CANTONI, KARREN MORE, YURI ZUEV, JUNSOO SHIN, ORNL — Nanocomposites comprising three-dimensionally (3D) ordered arrays of nanodots of one type of complex ceramic material embedded in another complex ceramic material are expected to exhibit novel physical properties, tunable by adjusting the overall composition, concentration, feature size and spatial ordering of the nanodots. Applications of such nanocomposites in the areas of multiferrics, photovoltaics, solid state lighting, ultra-high density storage and high temperature (high-Tc) superconductivity are of interest. A joint experimental, theoretical and computational study on achieving ordering via 3D self-assembly of nanodots of complex ceramic materials, such as 3D self-assembly of insulating BaZrO$_3$ (BZO) nanodots within high-Tc superconducting YBCO films, has been performed. Vertically or horizontally ordered arrays (or simultaneous ordering in both directions) of BZO nanodots within superconducting films have been made possible via strain modulation between nanodots. Experimental results obtained for novel nanocomposites for other applications involving perovskite-spinel mixtures such as CoFe2O4-BaTiO3, CoFe2O4-BiFeO3, etc. will also be presented. Such materials with ‘controlled self-assembly’ of nanostructures should find application in many areas.

3:54PM T27.00006 Efficiency and Plume Dynamics for Mid-IR Laser Ablation of Cornea 1. AROSHAN JAYASINGHE, BORISLAV IVANOV, M. SHANE HUTSON, Dept of Physics & Astronomy, Vanderbilt University — This paper reports ablation experiments on porcine corneal tissue using the Vanderbilt Mark III Free Electron Laser (FEL) and a tabletop Raman-shifted Alexandrite laser. These experiments were designed to test previous models that suggested wavelength and intensity dependent ablation mechanisms. In one test, we compare ablation efficiency and plume dynamics for two FEL wavelengths (λ=2.77, 6.45 μm) chosen such that different components of the tissue matrix act as the primary chromophore (water or protein respectively), while keeping the total absorption constant. We find small differences in ablation efficiency (with slightly more efficient ablation at 2.77 μm); no difference in shockwave propagation; and slightly more particulate matter in the plume at 6.45 μm. In a second test, we find that the Raman-shifted Alexandrite laser has similar ablation efficiency to the FEL in the 6-7 μm range — despite a ∼500-fold higher intensity. Although these results do not conform the previous model predictions, the findings do suggest that the Raman-shifted laser can be a viable alternative to the FEL for surgical applications.

1 Supported by DoD MPEF program (FA9550-04-1-0045).

4:06PM T27.00007 Pulsed-Laser Deposition of ZnO Thin Films and Heterostructures for Device Applications 1. DAVID NORTON, University of Florida — ZnO is a wide bandgap semiconductor being explored for transparent electronics, UV light emitting diodes, spin-based devices and chemical sensors. In this talk, we will discuss recent progress and understanding for carrier doping and interface formation in epitaxial ZnO thin films grown by pulsed-laser deposition. One of the critical issues for device applications is the formation of low resistivity, high carrier density p-type ZnO material for minority carrier injection. The behavior of acceptor dopants within the ZnO and ZnMgO matrices will be described. Discussion will include stability of transport properties, stabilization of surfaces, and device characteristics.

4:24PM T27.00008 Role of the top electrodes and their interfaces on the resistive switching behavior of epitaxial NiO thin films, S.R. LEE, J.H. BAK, Y.D. PARK, K. CHAR, Seoul National University, Korea, D.C. KIM, S. SEO, X.S. LI, G.S. PARK, Samsung Advanced Institute of Technology, Korea, R. JUNG, Kwangwoon Univ., Korea — Initial I-V characteristics of resistive switching behavior have been investigated with epitaxial NiO thin films grown on (100) SrRuO$_3$ by using Al, Pt, and CaRuO$_3$ as the top electrodes. SRO/NiO/Al and SRO/NiO/Pt require an electroforming process for the initialization of the resistive switching, while SrRuO$_3$/NiO/CaRuO$_3$ is initially in a low-resistance state. The temperature dependence of the initial I-V characteristics indicates that insulating layers exist at the NiO/Al and NiO/Pt interface, presumably broken by the electroforming process. On the other hand, SRO/NiO/Al does not show the resistive memory switching behavior despite the electroforming behavior. The resistive switching endurance is also dependent on the top electrodes. Our results suggest that the oxygen defects and their bonding energy with the top electrode metal play a critical role on the resistive switching behavior.

4:45PM T27.00009 Effect of cation substitution on the resistive switching behavior in epitaxial NiO, H.M. KIM, S.R. LEE, J.H. BAK, M.L. JO, Y.D. PARK, K. CHAR, Seoul N. Univ. — The resistive switching behavior of NiO has been extensively investigated due to the nonvolatile ReRAM device applications. In contrast to unipolar resistive switching of NiO grown on Pt, bipolar resistive switching is observed in NiO grown on SrRuO$_3$ (SRO). The unipolar switching has been explained by the formation and rupture of filamentary conduction with the Joule heating, while the bipolar switching is still controversial. Our previous study with epitaxial (epi) NiO, prepared under various growth conditions and electrodes, suggested that the oxygen defects at the NiO/top electrode (TE) interface may be responsible for the bipolar switching and TE may compensate the oxygen defects. In order to understand the role of the defect states at the interface on the resistive switching, 1-mm-thick epi-AI$_2$O$_3$ interlayer has been deposited on and under epi-NiO. The I-V characteristics have been investigated with an epi-CaRuO$_3$ (CRO) as TE, resulting in a clean interface with NiO. SRO/NiO/CRO shows poorer switching endurance in the less than 25% of measured cells. However, SRO/AI$_2$O$_3$/NiO/CRO exhibits bipolar switching in the most of measured cells with better endurance. This may imply the different oxygen defect states of each interface of NiO. As an effort to investigate the defect states in bulk and their effect on the unipolar switching, the I-V characteristics of Al substitution in epi-NiO will be presented.
The technique depends on the intensities of the laser pulses used, and propose a few candidate molecules for experimental tests of this concept. In this presentation, we will show results of computer simulations of this technique. We will show that even if the reaction rate constants are small, ground state. The result is that the molecules at the center of the pulses (in a region of size \( \lambda = 1064 \text{ nm}, 10 \text{ Hz repetition rate} \)) was used to ablate a Ge target. In-situ RHEED and STM and ex-situ AFM were used to study the morphology of the grown QD. The dependence of the QD morphology on substrate temperature and ablation and excitation laser energy density was studied. Electronic excitation is shown to affect the surface morphology. Laser irradiation of the Si substrate is shown to decrease the roughness of films grown at a substrate temperature of \( \sim 450 \text{ } ^\circ \text{C} \). Electronic excitation also affected surface coverage ratio and cluster density and decreased the temperature required to form 3-dimensional quantum dots. Possible mechanisms involved will be discussed.

Computer simulations of photochemistry controlled with subwavelength resolution\(^1\), TRIET NGUYEN, ALEX SMALL, California State Polytechnic University, Pomona — A technique called Stimulated Emission Depletion (STED) has recently been developed to beat the diffraction limit in imaging. We propose to adapt this technique to control chemical reactions with nanoscale resolution. We simulated a process in which a series of laser pulses is applied at each site on a surface. The first pulse excites the molecules and the second pulse (with a TEM10 “doughnut” profile) then causes the excited molecules away from the node at the center to undergo stimulated emission and return to the ground state. The result is that the molecules at the center of the pulses (in a region of size \(<<\lambda\)) remain in the excited state and can undergo chemical reactions. In this presentation, we will show results of computer simulations of this technique. We will show that even if the reaction rate constants are small, the application of several sequential pulses leads to a fractionation effect that compensates for low reaction rates. We will also show how the resolution of this technique depends on the intensities of the laser pulses used, and propose a few candidate molecules for experimental tests of this concept.

**Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T28 FIAP DMP: Focus Session: Thermoelectric Materials: Nanostructures**

**2:30PM T28.00001 SiGe Nanocomposites Thermoelectrics: The Knowns and the Unknowns**

GANG CHEN, Massachusetts Institute of Technology — Silicon-germanium has been used in spacecraft for a long time to convert heat from radio isotope heat sources into electricity for deep space missions. In this talk, we will discuss the current status of our understanding of thermoelectric transport in nanocomposites. Careful examination of the spectral details of the electron and phonon transport reveals a significant deficiency in our current understanding, even for bulk materials. Different interfacial transport processes further complicate the picture. In this talk, we will discuss the current status of our understanding of thermoelectric transport in nanocomposites. In collaboration with A. Minnich, H. Lee, B. Muralidharan, and M.S. Dresselhaus, Massachusetts Institute of Technology, Cambridge, MA 02139; and X. W. Wang, G. Joshi, G. H. Zhu, Y. C. Lan, D. Z. Wang, and Z.F. Ren, Boston College, Chestnut Hills, MA 02467.

**3:06PM T28.00002 Thermoelectric Power of high concentration embedded Nano-particle Samples**

MONA ZEBARJADI, KEIVAN ESFAJANI, ALI SHAKOURI, ZHIXI BIAN, University of California, Santa Cruz; JE-HYEOUNG BAHK, GEHONG ZENG, JOHN BOWERS, HONG LU, JOSHUA ZIDE, ART GOSSARD, University of California, Santa Barbara, UNIVERSITY OF CALIFORNIA, SANA CRUZ TEAM, UNIVERSITY OF CALIFORNIA, SANTA BARBARA TEAM — High concentrations of embedded nano-particles inside thermoelectric elements are desirable because they can increase the thermal conductivity. But they also affect the power-factor. Therefore they can enhance or suppress the figure of merit. We model the effect of such high concentrations on the power-factor using the coherent potential approximation. We optimize the power-factor versus nano-particle size, distribution and concentration. The analysis would help in designing nano-particle embedded matrices with high-performances. We characterize InGaAlAs samples with 3-10% volume concentration of ErAs nanoparticles and explain their properties such as the mobility and the Seebeck coefficient theoretically.

**3:18PM T28.00003 Transient Electrical and Thermal Characterization of InGaAlAs Thin Films with embedded ErAs Nanoparticles**

TELA FAVALORO, University of California, Santa Cruz School of Electrical Engineering, RAJEEV SINGH, JAMES CHRISTOFFERSON, YOUNES EZZAHRI, ZHIXI BIAN, ALI SHAKOURI, GEHONG ZENG, JE-HYEUNG BAHK, JOHN BOWERS, HONG LU, ARTHUR GOSSARD — We developed a system for accurate high-temperature characterization of thermoelectric materials and devices. This system can be used for electrical measurements of thermoelectric properties and contains an integrated optical thermoreflectance imaging system integrated into the thermostat for analysis of sample surface temperature profile resulting from the Peltier effect, Joule heating or external thermal excitation within the sample. Transient electrical and thermal measurements are useful to extract material diffusivity of each layer. We have performed high temperature transient analyses and thermal imaging of thin film devices optimized for direct figure of merit detection in the cross-plane direction. These devices consist of 25 micron thick samples of InGaAlAs films with embedded ErAs nanoparticles. Using the transient Harman technique, we determine the cross-plane figure of merit of each device. Heat sources are used to model the effect of such high concentrations on the power-factor using the coherent potential approximation. We optimize the power-factor versus nano-particle size, distribution and concentration. The analysis would help in designing nano-particle embedded matrices with high-performances. We characterize InGaAlAs samples with 3-10% volume concentration of ErAs nanoparticles and explain their properties such as the mobility and the Seebeck coefficient theoretically.

**3:30PM T28.00004 Characterization and modeling of the randomly distributed ErAs nanoparticles in InGaAlAs semiconductors for thermoelectric power generation**

JE-HYEUNG BAHK, UCSC, MONA ZEBARJADI, ZHIXI BIAN, UCSC, GEHONG ZENG, ASHOK RAMU, HONG LU, UCSC, ALI SHAKOURI, UCSC, ART GOSSARD, JOHN BOWERS, UCSC — We investigate temperature-dependent thermoelectric properties of the InGaAlAs semiconductors containing epitaxially embedded ErAs nanoparticles grown by Molecular Beam Epitaxy. Temperature-dependent Hall measurements and Seebeck coefficient measurements were performed for the materials with various Er concentrations and semiconductor compositions, and the results were analyzed using a theoretical modeling based on the ErAs nanoparticle’s carrier scattering behaviors. In the analysis, the nanoparticles are modeled as charged spheres with Schottky barrier height at the interface with semiconductor, and the potential profile around a particle is used as perturbation for electron scattering. The particle scattering rate is calculated using both Born approximation and the partial wave method, respectively, and the two methods are compared to check the validity of Born approximation in various conditions. The theoretical calculation of mobility and Seebeck coefficient based on the modeling of particle scattering and other scattering mechanisms fits the measurement results, and we find that further enhancement of thermoelectric power factor is possible by optimizing the particle scattering in the materials.
3:42PM T28.00005 Thermal and Thermoelectric Transport in Thin Films and Nanostructures

BO L. ZINK, R. SULTAN, A. D. AVERY, University of Denver — Interest in increasing efficiency of energy generation continues to spur the development of new thermoelectric materials. Though bulk materials hold the most promise for large-scale energy generation, many groups continue to explore increasing the thermoelectric figure-of-merit by taking advantage of techniques for creating nanostructured materials such as multilayered thin films and nanowires. These systems could prove to have high figures-of-merit and be important for integrating energy harvesting and/or cooling with micro- or nanoscale devices “on chip.” Though many promising systems have been identified, measuring their fundamental thermal transport often remains a major challenge. In this talk, we briefly describe our recent advances in measuring in-plane thermal transport, thermopower and electrical conductivity on thin-films or nanolithographically patterned systems. Our technique allows great flexibility for studying the thermoelectric properties of a wide range of materials, from amorphous semiconductors to semi-metallic nanowires.

We thank ACS-PRF, NERC, and the University of Denver for supporting this work

ROBERT WORTMAN, JEREMY SCHROEDER, POLINA BURMISTROVA, Birck Nanotechnology Center, Purdue University, MONA ŽEBARJADI, ZHIXI BIAN, ALI SHAKOUROUI, Department of Electrical Engineering, UC Santa Cruz, TIMOTHY SANDS, Birck Nanotechnology Center, Purdue University — A new class of thermoelectric materials based off of superlattices have been proposed that show a potential for enhanced thermoelectric performance. The increase of thermoelectric figure-of-merit ZT of these materials is due to both the energy filtering effect of the Schottky barriers as well as the reduced thermal conductivity that results from increased interface density. Our work has centered on the metal-semiconductor materials system of HfN-SnC. These are both high temperature materials (T_m > 2500°C). They have the same rocksalt crystal structure and similar lattice constants, allowing epitaxial growth. We have grown superlattices of these materials via DC magnetron sputtering. Results from x-ray diffraction, and electrical and thermal tests will be presented. Their potential as thermoelectric energy conversion materials will be discussed. I. G. D. Mahan et al, Phys. Rev. Lett., 80, 4016 (1998) 2 D. Vasas et al, Phys. Rev. Lett. 92, 106103 (2004)

4:06PM T28.00007 ABSTRACT WITHDRAWN

4:18PM T28.00008 Thermoelectric properties of nanoporous Ge

JOO-HYOUNG LEE, JEFFREY GROSSMAN, University of California-Berkeley — Recently, silicon nanowires were shown to have a thermoelectric (TE) figure of merit (ZT) two orders of magnitude larger than that of bulk Si. In addition, recent theoretical work predicted that Si with periodically arranged nanometer-sized pores (nanoporous Si) could result in a similar increase in ZT. These results open an exciting new pathway towards efficient thermoelectrics based on standard semiconductor materials. In the present work, we experimentally extend our earlier calculations on silicon to explore the TE properties of nanoporous Ge. Specifically, we calculate the thermal and electrical conductivities, Seebeck coefficient and figure of merit of nanoporous Ge for a range of configurations using a combined ab initio electronic structure calculation and Boltzmann transport approach. The results show a substantial increase in ZT compared with that of bulk Ge, as in the Si nanostructures. A detailed comparison between the TE properties of nanoporous Ge and Si will be presented.

4:30PM T28.00009 Solution processable routes to nanostructured thermoelectric materials

JOSEPH FESER, Department of Mechanical Engineering, University of California - Berkeley, ROBERT WANG, The Molecular Foundry, Lawrence Berkeley National Laboratory, LAWRENCE MAJUMDAR, Department of Mechanical Engineering, University of California - Berkeley, JEFFREY URBAN, The Molecular Foundry, Lawrence Berkeley National Laboratory — The previous decade of research has shown that nanostructured thermoelectric materials can have superior performance compared to their bulk counterparts. Often, the synthesis of nanostructured materials is performed by layer-by-layer methods, which hinders their ability to be produced as thick films. Here we show a scheme by which nanocrystals embedded in a thermoelectric matrix may be produced using solution processing. Using hydrazine chemistry, we prepare soluble precursors for Bi2O3 (X=S,Se,Te). Solutions containing those precursors are spun and drop-cast onto substrates, and their electrical and thermal properties are characterized. We show ongoing research to embed colloidal nanocrystals into a matrix made from the soluble precursors.

4:42PM T28.00010 Self-supporting (Bi0.11Sb0.29)(Te0.25Se0.41) nanowire arrays for thermoelectric microdevices

HATEM EL-MATBOULY, TIMOTHY SANDS, KALAPI BISWAS, Purdue University — Nanostructuring of thermoelectric material can lead to improved performance through suppression of the lattice contribution to thermal conductivity and enhancement of the power factor by quantum confinement or thermionic energy filtering. To take advantage of these effects in a Peltier microcooler or Seebeck generator, it is necessary to prepare nanostructure materials with leg lengths ranging from tens of microns to millimeters. We have developed a process for fabrication of thick, self-supporting (Bi0.11Sb0.29)(Te0.25Se0.41) nanowire arrays using a novel branched porous anodic alumina template that can be removed completely by selective etching following electrodeposition of the thermoelectric material, resulting in 100-micron-thick nanostructured thermoelectric material without the parasitic thermal shunt that is associated with the template. The electrodeposition process allows composition modulation and grading, effects that are difficult to achieve by bulk synthesis. Bandgaps of the electrodeposited material range from 0.13 eV for Bi2Te3 to an optical gap of 0.52 eV measured for a (Bi,Sb)(Te,Se) alloy, suggesting an operating temperature range from below room temperature to ~300°C.

4:54PM T28.00011 Thermoelectric Properties of Nanostructured n-type Yb3Co2Sb2Bulk

JIAN YANG, HUI WANG, YUCHENG LAN, XIAO YAN, BO YU, XIAOWEI WANG, GAOHUA ZHU, DEZHI WANG, ZHIFENG REN, Physics Department, Boston College, Chestnut Hill, MA 02467, QING HAO, GANG CHEN, Department of Mechanical Engineering, MIT, CAMBRIDGE, MA 02139, QIN-YU HE, South China Normal University, Guangzhou, CHINA MAIDRED S. DRESSELHAUS, Dept. of Electrical Engineering and Computer Science, Department of Physics, MIT, CAMBRIDGE, MA02139 — Nanostructured single phase of Yb3Co2Sb2 with a nominal composition of Yb3Co2Sb2 (X = 0.3, 0.35, 0.4, and 0.5) have been synthesized by ball milling and direct current induced hot press. Thermoelectric properties including electrical conductivity, Seebeck coefficient, and thermal conductivity from room temperature to 550°C were measured and discussed. It was found that Yb0.35Co2Sb2 has the optimal dimensionless figure of merit of 1.2 at 550°C.

5:06PM T28.00012 Thermoelectricity in Arrays of Thiolate Coated Au Nanoparticles

E. COVINGTON, F. BOHRER, E. T. ZELLERS, C. KURDACK, University of Michigan — We have developed a new technique to measure the thermopower of highly resistive films of thiolate coated Au nanoparticles. Using e-beam lithography, we fabricate two long parallel gold wires, spaced by 500 nm, on an insulating substrate and subsequently coat with a thin film of nanoparticles. The wires are used as electrodes for electronic conduction and heaters for thermopower measurements. We characterize the Joule heating in the wires using noise thermometry. To characterize the thermopower of the film, we excite one wire by an ac current with frequency . Due to Joule heating, we establish a temperature difference between the two wires modulated with frequency . We extract the thermopower by measuring the voltage signal between the wires using lock-in techniques. We used this method on Au nanoparticles with 1-octanethiol (C8) ligands where the thermopower was less than 10 µV/K at room temperature. From the sign of the thermopower, we determined transport was mainly due to tunneling of electrons through the lowest unoccupied molecular orbital of the C8 molecule.
5:18PM T28.00013 Molding Phonon Flow with Symmetry: Rational Design of Hypersonic Phononic Crystals

CHEONG YANG KOH, EDWIN L. THOMAS, Dept of Materials Science & Engineering, Massachusetts Institute of Technology — Phononic crystals structured at appropriate length scales allow control over the flow of phonons, leading to new possibilities in applications such as heat-management, sound isolation and even energy transfer and conversion. Symmetry provides a unified framework for the interpretation 1D to 3D phononic band structures, allowing utilization of a common set of principles for designing band structures of phononic crystals as well as actual purposeful defects such as waveguide location and boundary termination in finite devices. In this work, we explore the band structure properties of phononic crystals with non-symmorphic space groups, as well as those having quasi-crystalline approximants. We demonstrate gap opening abilities from both anti-crossing and Bragg scattering, as well as unique features like “sticking” bands. Symmetry concepts are also powerful means to tune the density of states of the structures. Importantly, we fabricate various theoretical designs and measure their experimental dispersion diagrams for comparison with theoretical calculation. This affords an elegant approach toward a design blueprint for fabricating phononic structures for applications such as opto-acoustic coupling.

Wednesday, March 18, 2009 2:30PM - 4:42PM —
Session T29 FEd: Focus Session: NSF’s Research Experience for Undergraduates (REU) Program: Overview and Perspectives 333

2:30PM T29.00001 Physics NSF-REU Site Director Workshop: What Did We Learn and What Questions Remain?1, MARIO AFFATIGATO, Coe College — The Research Experience for Undergraduates program, traditionally funded by the National Science Foundation and by other agencies (including the Department of Defense), has been a great success. Every year, hundreds of students have the chance to participate in research activities at Universities and research entities other than their own. These extended experiences have helped the students develop confidence in their abilities as practicing physicists, train on state of the art instrumentation, work on communication skills through presentations, and frequently reach a publication milestone. The REU program’s impact is manifold and complementary to the strong work done at the home institutions by faculty advisors and instructors. In this presentation we will discuss the current state of the program as determined by the recent (and first) meeting of the Physics REU site directors. In particular we will focus on the strengths of the program, shared good practices, data gathering, and some changes the new Steering Committee might implement. The intended audience should be current REU directors and faculty research supervisors; students who might be interested in the program; faculty at institutions who might be thinking of applying to become a site; and anyone attentive to undergraduate research in general.

3:06PM T29.00002 Past participant’s perspective on the Research Experience for Undergraduates program, DEREK PADILLA, San Diego State University — The Research Experience for Undergraduates (REU) programs funded by the National Science Foundation provide an outstanding opportunity for many students to participate in high-quality research at a facility other than their own institution. As a participant in the summer of 2006 I will attest to the success of a great REU program. This discussion will focus on my work and experience while in the program as well as the continuing relationship with my advisors and the host department as a whole. In collaborating with all levels of REU personnel we will improve the function of an already outstanding opportunity for undergraduate students for the coming years.

3:18PM T29.00003 Recuiting minority students into your REU program, DAVID ERNST, Vanderbilt University — It is important for the field of physics that we draw our talent from the broadest pool. However, African Americans, Hispanic Americans, and Native Americans are substantially underrepresented in physics. Since summer research experiences are a useful tool to assist students in gaining entrance into graduate school, it is particularly important that underrepresented minority students are fully able to participate. The NSF REU program at Vanderbilt University is historically comprised of one half minority students. How this comes about and how we pro-actively recruit minority students will be described.

3:30PM T29.00004 International Summer Research Program in Gravitational-Wave Physics operated by the University of Florida for the LIGO VIRGO Science Collaboration1, GUIDO MUELLER, BERNARD WHITING, University of Florida — The NSF-funded Laser Interferometer Gravitational-Wave Observatory (LIGO), 20+ US universities and colleges, and their international partners in Europe, Australia, and Japan are operating a network of six large scale interferometers to detect gravitational waves from neutron star or small black hole mergers, supernovae, and other galactic or cosmological sources. The data analysis as well as R&D activities for future gravitational-wave detectors are organized within the LIGO VIRGO Scientific Collaboration. This international frame provides the backdrop of our international summer research program. Our international partners offer currently up to 30 different research projects at 15 different institutions in 6 different countries on 3 different continents for US undergraduate students. Our primary target group are students from small US colleges who are active members of the LIGO Science Collaboration. In addition to the standard goal of exposing the students to cutting edge research, the students will also be exposed to a different culture (and usually language), and their research experience will help our small college groups to build-up or solidify their own research connection with our international partners. See http://www.phys.ufl.edu/reu for more details.

3:42PM T29.00005 REU in Physics at Kansas State University — an Evolving Program1, KRISTAN CORWIN, BRUCE GLYMOUR, AMY LARA, LARRY WEAVER, DEAN ZOLLMAN, Kansas State University — The REU site in the Physics Department at Kansas State University, funded by NSF for 13 years between 1992 and 2007, originally focused on atomic collision physics. Now the theme has broadened to include laser-matter interactions on atomic and nanoscales, and an ethics component is incorporated. Students study how atoms and molecules interact with ultra-fast optical and x-ray pulses, reveal the structure of nanoparticle crystallization and gel formation with scattered laser light, and develop computer codes for atomic interactions in Bose-Einstein condensates and nanoparticle self-assembly from lattices to gels; some have traveled to Japan for neutrino experiments. The students we select come primarily from smaller colleges and universities in the Midwest where research opportunities are limited. Prof. Weaver, who has served as PI since 1992, facilitates their transition from a teaching to research environment through lectures and individual interactions. Our program is in a period of transition. While Prof. Weaver continues to be the “impedance match” between students and mentors, other leadership roles are gradually being assumed by a team of faculty members who strive to preserve the intimacy and excellence of the program.

1Funded by the National Science Foundation Award No. 0552878.

1National Science Foundation, DoD, and other agencies are gratefully acknowledged for funding the REU program.
We acknowledge support from the NSF under Grant No. DMR-0646842.

Wednesday, March 18, 2009 2:30PM - 5:30PM –
Session T30 DMP GMAG: Focus Session: Excitations in Multiferroics 334

2:30PM T30.00001 Electromagnon spectra in multiferroic manganites $R\text{MnO}_3$, NOBUO FURUKAWA, Dept. of Physics, Aoyama Gakuin Univ., and ERATO-Multiferroics, JST — The magnetoelectric (ME) effect, in which electric polarization (magnetization) are controlled by magnetic (electric) field, have recently attracted intensive attention. One of the materials which exhibits large ME effects is the manganites $R\text{MnO}_3$. In this presentation I focus on electromagnon excitations (in a wide sense). In those manganites, cycloidal spin structures create ferroelectricity through spin-orbit couplings. Originally, electromagnon is defined as a collective excitation of spins in such a way that rotation of the cycloidal plane is driven by the electrical field of light coupled to the ferroelectric moment. Spectra for electrically excited magnons are indeed reported in TbMnO$_3$, GdMnO$_3$, (Eu,Y)MnO$_3$, and DyMnO$_3$. However, the selection rule observed in these compounds ($E^\parallel a$, irrespective of the cycloidal planes) is inconsistent with the theoretical prediction. Alternatively, couplings between electric field and spins through spin-dependent local polarizations have been proposed. I show both one- and two-magnon excitation spectra, and clarify consistencies and discrepancies of the model with experimental data. Roles of phonons and orbital orders in these compounds are also discussed.

3:06PM T30.00002 Selection rules for electromagnons in anharmonic cycloidal multiferroics$^1$, MARKKU STENBERG, ROGERIO DE SOUSA, University of Victoria — The coexistence of magnetic and ferroelectric phases in multiferroic materials gives rise to hybrid excitations with mixed magnetic and electric character. These excitations, so-called electromagnons, have been observed in several oxide materials, but their origin and optical selection rules are central questions that are not yet understood. We present a theory of electromagnon excitation in magnets with anharmonic cycloidal ground state. In contrast to previous theories, we show that multiple electromagnons are excited by light polarized along the cycloidal plane as well as perpendicular to it. Our results allow the distinction between different magnetoelastic couplings and have important implications for the interpretation of optical experiments in rare earth manganites as well as other materials with anharmonic spiral magnetic order.

$^1$We acknowledge support from NSERC and the University of Victoria - Faculty of Science

3:18PM T30.00003 Low-magnetic field control of electromagnon, N. KIDA, ERATO Multiferroics Project, S. ISHIWATA, Y. TAGUCHI, CMRG-RIKEN, R. SHIMANO, ERATO and Univ. Tokyo, T. ARIMA, Tohoku Univ., Y. TOKURA, ERATO, Univ. Tokyo, and CMRG-RIKEN — Since the 1960s, there has been intense debate concerning the presence of the spin excitation driven by the electric field of light $E^\parallel$ in ferromagnetic magnets. This is recently revived by the observation of the absorption peak structure around 3 meV in a ferroelectric magnet TbMnO$_3$ [1]. As an origin of this excitation, the hybridized spin excitation with electric polarization (now called electromagnon) was considered [2]. However, this issue remains controversial by our THz spectroscopic studies on a family of $R\text{MnO}_3$ [3] ($R = \text{Tb}, \text{Dy}$, and Gd), in a variety of spin phases tuned by temperature and magnetic field. Here we report an optical investigation of the low-energy ($\sim 10$ meV) spin dynamics for other ferromagnetic magnets, hexaferrite, by using THz time-domain spectroscopy. We find the signature of the genuine electromagnon at THz frequencies. As a manifestation of the strong magnetoelastic coupling inherent to the electromagnon, we demonstrate the low-magnetic field ($\sim 100$ Oe) control of the optical constants at THz frequencies. [1] A. Pimenov et al., Nat. Phys. 2, 97 (2006). [2] D. Senff et al., PRL 98, 137206 (2007). [3] N. Kida et al., PRB 78, 104414 (2008); Y. Takahashi et al., PRL 101, 187201 (2008); N. Kida et al., J. Phys. Soc. Jpn. Dec. issue (2008).
3:30PM T30.00004 Theory of novel one-magnon excitation induced by electric fields in cycloidal spin magnets. SHIN MIYAHARA, Japan Science and Technology Agency, NOBUO FURUKAWA, Aoyama Gakuin University — We propose a new mechanism to induce a novel one-magnon excitation by electric-field component of light in cycloidal spin states. We calculated optical spectra in the cycloidal spin structures as observed in multiferroic perovskite manganites. We showed that the novel excitation is driven by electric-field component of light is observed. When symmetric pairs of spins dependent electric polarizations are introduced, we have light absorptions at terahertz frequencies with one- and two-magnon excitations driven by electric-field components. Our results show that some parts of optical absorption peaks observed experimentally at terahertz frequencies are one-magnon excitation absorptions.

3:42PM T30.00005 Origin of electromagnons in multiferroic manganites. ROLANDO VALDES AGUILAR, Department of Physics, University of Maryland — The interest in multiferroic materials has increased in the last few years due to the fundamental physics of strong interaction between ferroelectric and magnetic orders, as well as for the promise of novel applications in future electronics. From powerful symmetry arguments and with modeling of the microscopic coupling mechanism, these efforts have led to the discovery of a vast set of multiferroic compounds. An important recent step in this regard was the discovery of a new kind of magnetic excitation that couples strongly to light by acquiring electric dipole activity from the infrared active phonons, called electromagnon, which is a hybrid excitation of magnon and phonon character. These discoveries have highlighted the importance of the dynamical aspects of the magnetoelectric coupling. Even though a wide consensus has been reached regarding the origin of the static magnetoelectric dynamic effect of electromagnons was not clear. In this talk a combination of theory and experiment is presented that clarifies the origin of the electromagnon excitations in RMnO3. This model is based on symmetric exchange striction and takes into account the lattice and magnetic symmetry of this family of perovskite manganites. It reproduces the fact that the observed selection rule for electromagnons in RMnO3 is independent of the spin plane. This result is due to the effective modulation of the exchange interaction between Mn spins induced by the electric field of light. The proposed mechanism is also related to the origin of static polarization in the E-phase of this RMnO3 multiferroic family. The model and experiments carried out so far demonstrate that the symmetric exchange interaction is responsible for all the observed dynamical magnetoelectric effects, and opens a new avenue for study of these multiferroic compounds.

4:18PM T30.00006 Infrared-active excitations related to the $R^{3+}$ ligand-field splitting in $RMn_2O_5$ ($R$=Ho, Dy, Tb). A. A. SIRENKO, S. M. O’MALLEY, T. D. KANG, K. H. KAHN, Department of Physics, NJIT, Newark, NJ, C. L. CARR, NSLS, Brookhaven National Laboratory, Upton, NY, L. MIHALY, Department of Physics and Astronomy, Stony Brook University, NY, S. PARK, S.-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, NJ — Optical transitions between ligand-field split states of $R^{3+}$ ions in $RMn_2O_5$ multiferroic single crystals have been studied at the phase transitions in the external magnetic field up to 13 T and uniaxial pressure up to 5 kbar. Spectra of the ligand field excitations change significantly in external magnetic field and correlate with the reversal of electric polarization induced by magnetic field. The oscillator strength and selection rules for ligand field excitations change with external uniaxial pressure. We discuss the relation between the ligand field on $R^{3+}$ with the magnetism and dielectric properties of this compounds.

4:30PM T30.00007 THz magneto-optical study of multiferroic compound TbMnO3. URMAS NAGEL, D. HÜVONEN, T. RÖÖM, NICPB, Akadeemia tee 23, 12618 Tallinn, S.B. KIM, C.L. ZHANG, S.-W. CHEONG, Rutgers Center for Emergent Materials & Department of Physics and Astronomy, Rutgers University, NJ — We present results of magneto-optical absorption measurements in the THz region on multiferroic TbMnO3 in magnetic fields up to 12 T. The temperature range of our studies covers the paramagnetic phase (T > 42 K), the collinear incommensurate spin density wave phase of Mn$^{3+}$ with 2 spins (28 K < 42 K), the ferro-electric phase with incommensurate elliptic spin order (T < 28 K) and the phase where the magnetic moments of Tb are ordered, T < 7 K. It is known that in the FE phase the magnetic field B0 $\parallel$ a equal to 10.5 T flips the electric polarization from P $\parallel$ c to P $\parallel$ a. The polarization P is in the plane of elliptical spiral and perpendicular to spiral order vector, k $\parallel$ b in TbMnO3. It is expected that the selection rule for the electric-dipole active spin excitation in the spiral phase changes from E $\parallel$ a to E $\parallel$ c. Polarization-sensitive absorption measurements are performed to distinguish between magnetic- or electric-dipole active spin excitations, i.e. magnons or electromagnons, respectively, in the whole temperature and magnetic field range.

4:42PM T30.00008 Magneto-optical THz study in multiferroic Ni$_3$V$_2$O$_8$. DAN HÜVONEN, U. NAGEL, T. RÖÖM, NICPB, Akadeemia tee 23, 12618 Tallinn, Estonia, N. ROGADO, DuPont Central Research and Development, Experimental Station, Wilmington, Delaware 19880, R. CAVA, Dept. of Chem. and Princeton Mat. Inst., Princeton Univ., Princeton, NJ 08544 — We present results of absorption measurements in THz region, from 3 to 220 cm$^{-1}$, in multiferroic Ni$_3$V$_2$O$_8$ in magnetic fields up to 12 T and temperatures above 2 K. Ni$_3$V$_2$O$_8$ is a magnetic insulator with Ni$^{3+}$ spin-1 ions arranged in a kagome staircase lattice. The phase diagram of Ni$_3$V$_2$O$_8$ is complicated - ground state changes from paramagnetic (PM) to high temperature incommensurate (HTI) helical state, at 9.1 K in zero field. In low temperature incommensurate (LTI) phase below 6.3 K spontaneous electric polarization P appears along the b axis. P$_b$ can be suppressed by further cooling below 3.9 K or by application of external magnetic field. Low energy optical excitations are discussed for all low-T phases of Ni$_3$V$_2$O$_8$. Polarization sensitive absorption measurements are performed to distinguish between magnetoanisotropic spin excitations i.e. magnons and electromagnons. Different optical selection rules for magnon and electromagnon excitations enable us to search for evidence of the spin helix plane orientation and its changes at critical magnetic fields and temperatures.

1The support by the EstSF grants 6138 and 7011 is acknowledged.
4:54PM T30.00009 Evolution of magnetic exchange interactions in the multiferroic Mn$_{1-x}$Fe$_x$WO$_4$  , JAIME FERNANDEZ-BACA, FENG YE, RANDY FISHMAN, HERB MOOK, Oak Ridge National Laboratory, YIMING QIU, NCNR, NIST, R.P. CHAUDHURY, Y.-Q. WANG, B. LORENZ, C.W. CHU, University of Houston — The experimental investigation of the spin dynamical properties in the multiferroic material Mn$_{1-x}$Fe$_x$WO$_4$ is essential to the understanding of the interplay between the magnetic and ferroelectric phenomena. We have systematically studied the low temperature magnetic excitations in the Fe-doped Mn$_{1-x}$Fe$_x$WO$_4$. The spin wave dispersion relations in the commensurate (CM) phase are well described by a model that accounts for the magnetic exchange coupling of up to nine nearest neighbors. Our results indicate that these magnetic systems are highly frustrated and the CM spin structures result from the competing interactions. The evolution of the spin dynamics reveals the role of the magnetic impurities and the influence of Fe-doping to the multiferroic properties are discussed. This work was partially supported by Division of Scientific User Facilities of the Office of Basic Energy Sciences, U.S. DOE.

5:06PM T30.00010 Long-wavelength magnetic excitations in multiferroic BiFeO$_3$, D. TALBAYEV, J. G. GIGAX, A. J. TAYLOR, Los Alamos National Laboratory, SEONGSU LEE, S.-W. CHEONG, Rutgers University — Magnetic and lattice vibrations play a central role in the properties of multiferroics. This low-energy electrodynamic field can help unravel the fundamental interactions between magnetic and lattice degrees of freedom. BiFeO$_3$ is a multiferroic material with robust room temperature ferroelectricity and antiferromagnetism and promising technological potential. The interaction between the ferroelectric and antiferromagnetic order parameters leads to the modification of the isotropic Heisenberg-antiferromagnet ground state that becomes an incommensurate cycloid with a very long period. The cycloidal magnetic structure results in a complex spectrum of zero-wavevector magnetic excitations; these magnetic modes were detected using Raman scattering. Here, we report a far-infrared spectroscopic study of a BiFeO$_3$ single crystal. We detected magnetic resonances at energies close to those reported in the Raman spectroscopy studies. The magnetic character of these excitations is supported by their characteristic temperature dependence. We will discuss our results in the context of possible electric-dipole activity of the observed resonances.

5:18PM T30.00011 Low energy excitations in multiferroic Ca$_3$CoMnO$_6$ in the far infrared, ANDREI SUSHKOV, H.D. DREW, University of Maryland, Y.J. CHOI, H.T. YI, S. LEE, S.W. CHEONG, Rutgers University — Ferroelectricity was recently discovered in Ca$_3$CoMnO$_6$ (Y.J. Choi et al., PRL 100 (2008) 047601) which is a quasi 1D spin up-up-down-down system. We report the results of infrared (5-250 cm$^{-1}$) transmission study of multiferroic Ca$_3$CoMnO$_6$ as a function of temperature T (3-300 K) and magnetic field H (0-8 T). Two peaks are observed at and below T$_N$ = 17 K. Narrow peak at 35 cm$^{-1}$ is observed at low T and is identified as the ground state feature. This feature is suppressed with raising T or in magnetic field and the other broad feature at 25 cm$^{-1}$ emerges. Neither peak is split or shifted by magnetic field. We will discuss the possible origin of these two excitations.

Wednesday, March 18, 2009 2:30PM - 5:18PM –

Session T31 DMP GMAG: Focus Session: Magnetic, Electric, and Photo-Induced Magnetization Reversal

2:30PM T31.00001 Ultrafast magnetic imaging of nanostructures, YVES ACREMANN, SLAC — Today's technology advances into smaller and more complex structures for information processing. As structures get smaller, many processes of interest become faster as the propagation speed of excitations couple the length scale with the time scale. Microscopic techniques with a spatial resolution reaching the atomic level are being developed with very impressive success. On the other hand, time resolved techniques based on ultrafast laser systems allow us to explore processes on the femtosecond time scale. The focus of this talk is to unite the two worlds, the ultra-fast and the ultra-small. A powerful approach to time resolved microscopy is based on x-ray techniques. The wavelength of x-rays offers a spatial resolution in the nanometer range. Ultrafast x-ray techniques are currently being developed based on synchrotron sources as well as free electron lasers. The talk will demonstrate ultrafast microscopy techniques on imaging magnetization reversal dynamics in spin transfer devices.

2:30PM T31.00001 Ultrafast magnetic imaging of nanostructures

3:06PM T31.00002 Magnetization Dynamics of Magnetic Nano-Elements on Ultrafast Time Scales, J.P. DAVIS, J.A.J. BURGESS, University of Alberta, Z. LIU, R.D. SYDORA, M.R. FREEMAN, University of Alberta — Recently, our group has systematically studied the switching of a single permalloy nano-disk (160 nm diameter) between the vortex and quasi-single domain ground states as a function of applied bias field, including the observation of real-time switching at particular fields [1]. This was performed using the time-resolved magneto-optical Kerr effect (TR-MOKE), which allows dynamics to be studied on sub-nanosecond time scales. To accurately simulate the switching behavior, it was necessary to take into account the domed shape of the nano-disks, which result from the lift-off fabrication. Because of the sensitivity of the magnetization dynamics to the shape of the disks, we have begun fabrication of nano-disks using a shadow mask procedure [2] with a collimated deposition source under ultra-high vacuum (UHV) to produce high quality nano-elements. Magnetization dynamics of these UHV fabricated nano-disks will be discussed, with complementary scanning probe microscopy characterization of the disks.

3:06PM T31.00002 Magnetization Dynamics of Magnetic Nano-Elements on Ultrafast Time Scales

3:18PM T31.00003 Ultrafast switching of a nanomagnet by a combined in-plane and out-of-plane polarized spin-current pulse, OUKJAEE LEE, V.S. PRIBIAG, P.M. BRAGANCA, P.G. GOWTHAM, E.M. RYAN, D.C. RALPH, R.A. BUHRMAN, Applied and Engineering Physics, Cornell University — For fast write operation of a spin-torque (ST) magnetic storage device, the exertion of a strong initial torque can switch the nanomagnet moment without the help of the thermal fluctuations. Use of an out-of-plane polarized reference layer can very quickly excite large free layer motion but reliable reversal requires precise ST pulse timing. The combination of strong in-plane and out-of-plane polarized spin currents can substantially relax this pulse-timing requirement. We have fabricated CPP spin-valve devices that incorporate both an out-of-plane polarizer, and an in-plane polarizer to quickly excite and reverse the moment of an in-plane polarized free layer. For pulse currents ranging between 100ps – 10ns, the reversal speeds are notably faster and much less thermally distributed than for a conventional spin-valve with the same pulse current amplitude. We will discuss the details of the short-pulse behavior of these device structures and the optimization of this approach for high-speed magnetic memory.
3:30PM T31.00004 Total angular momentum conservation in laser-induced femtosecond magnetism\textsuperscript{1}. GUOPING ZHANG, Department of Physics, Indiana State University, Terre Haute, Indiana 47809, YIHUA BAI, Center for Instruction, Research and Teaching, Indiana State University, Terre Haute, Indiana 47809, THOMAS F. GEORGE, Office of the Chancellor and Departments of Chemistry & Biochemistry and Physics & Astronomy University of Missouri-St. Louis — Spin momentum is not a classical quantity\textsuperscript{1,2}. It is unclear how the conservation law affects spin momentum change in laser-induced femtosecond magnetization\textsuperscript{3}. In solids, the rotational symmetry is lifted by the translational symmetry, and the spin and orbital momenta components of different total angular momentum mix to some extent. This mixing is the origin of the time-dependent total angular momentum in experiments. The remaining unmixed portion accounts for an extra spin change in three independent circularly-polarized laser experiments by G. P. Zhang et al., Phys. Rev. Lett. 85, 012407 (2000). \textsuperscript{2}G. P. Zhang and T. F. George, Phys. Rev. B 78, 052407 (2008). \textsuperscript{3}G. P. Zhang and W. Höhner, Phys. Rev. Lett. 103, 07B113 (2008).

3:42PM T31.00005 Evolution of magnetic states in ferromagnetic nanorings in an applied azimuthal field\textsuperscript{1}. ABBY GOLDMAN, KATHERINE AIDALA, Mount Holyoke College, TIANYU YANG, MARK TUOMINEN, University of Massachusetts, Amherst — Ferromagnetic nanorings form unique magnetic states that hold tremendous potential for maximizing data storage densities. One such state is the closed-flux vortex state, in which the magnetic field is completely enclosed within the ring, thus minimizing the magnetostatic energy, but also keeping the exchange energy low as adjacent magnetic moments are mostly aligned. A natural way to generate this state is through an external azimuthal field, as if from a current carrying wire passing through the center of the ring. We perform micromagnetic simulations to investigate the evolution of magnetic states in an external azimuthal field. For some applied current, the chirality of the ring will reverse, often into an intermediate state that evolves into a perfect vortex at higher current. Thin, wide rings have significantly lower switching currents than thick, narrow rings. We examine the dependence of the switching current and intermediate states on geometric properties such as the diameter, thickness, asymmetry and width of the ring.

\textsuperscript{1}This work was supported at Mount Holyoke in part by NSF NSEC materials was supported by the US DOE, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

3:54PM T31.00006 Polarity reversal of magnetic vortex core by in-plane non-resonant pulsed magnetic field\textsuperscript{1}. XUEMEI CHENG, DAVID KEAVNEY, Argonne National Laboratory, KRISTEN BUCHANAN, Colorado State University — Magnetic vortices have been of great interest because of their potential applications in non-volatile data storage. Recently, Van Waeyenberge et al. demonstrated vortex core reversal in permalloy squares using an in-plane r.f. excitation field with the frequency close to the translational-mode eigenfrequency. In this work we report polarity reversal of magnetic vortex core by non-resonant in-plane field pulses. The core polarity was first determined by watching the sense of vortex core gyration in a 6 micron permalloy disk imaged by time-resolved x-ray photoemission electron microscopy (TR-PEEM) with 1mT excitation field pulses. After the waveguide was pulsed at 5mT, we determined core polarity at 1mT again. We also found that the core polarity can be switched back and forth by pulsing at 5mT. The micromagnetic simulations and TR-PEEM images confirm that when the core is displaced beyond 25% of disk radius, distortions of the core region occur, promoting a transient domain state involving a complex cross-tie wall, and subsequent reversal of the core polarity.

4:06PM T31.00007 Hybridization of quantum spin waves in small structures, VALENTYN NOVOSAD, Argonne National Lab, S.T. CHUI, University of Delaware, SAM BADER, Argonne National Lab — We apply the Holstein-Primakoff and Bogoliubov transformations to compute the spin wave states of small magnetic structures including the effect of the dipolar interaction. We found that as the film gets thicker, states with a significant q=0 component are hybridized with states with higher Fourier components. In the presence of a static magnetic field opposite to the magnetization direction, surface states that are responsible for magnetization reversal are coupled to the extended states. The response function is increased by an order of magnitude. This suggests an intriguing scenario for assisted switching of the magnetization with an additional external a.c. field.

4:18PM T31.00008 Electric field-induced modification of magnetism in thin CoPd films.\textsuperscript{1}. MIKHAIL ZHERNENKOV, MICHAEL FITZSIMMONS, JERZY CHLISTUNOFF, JAREK MAJEWSKI, LANL, IOAN TUDOSA, ERIC FULLERTON, UCSD — Recently, M. Weisheit et al., Science 315, 349 (2007) reported modification of magnetic properties of thin-film ferromagnets by applying a large electric field at the surface of a ferromagnet. For an applied voltage of -0.6 V, the coercivities of 20 Å thick FePt and FePd films were changed by -4.5 and +1%, respectively. Here, we report polarized neutron reflectometry measurements of the magnetization depth profile of a 180 Å thick Co$_{50}$Pd$_{50}$ film immersed in an electrolyte as a function of applied electric field in an external magnetic field. The measurements were done at two values of applied electric potential of -0.6 volts and -1.2 volts and at zero volts (open-circuit potential). The applied magnetic field was 3 kG. We found a linear increase of the film magnetization with electric field. The change of magnetization occurred in the region of the film within 72 Å of the electrolyte/Co$_{50}$Pd$_{50}$ interface. The magnetization of the top part of the layer is increased by 2% (-0.6 V) and 3.6% (-1.2 V) compared to the open circuit potential result.

4:30PM T31.00009 Electric-field-driven spin resonance of a Mn dopant in GaAs, V.R. POVILUS, Department of Physics and Astronomy University of Iowa, J.-M. TANG, Department of Physics University of New Hampshire, M.E. FLATTE, Department of Physics and Astronomy University of Iowa — All-electric manipulation of the ground-state spin system of a Mn dopant in GaAs using a static electric field in combination with a transverse dynamic electric field requires careful positioning of two gates on the nanoscale\textsuperscript{1}. Here we propose a method of efficiently controlling the spin of a Mn dopant using parallel static and dynamic electric fields, but adding a small static magnetic field. In a scalable geometry this would permit full control of the ground-state J=1 spin of a Mn dopant using a single electric gate. The energy states and eigenfunctions of the Mn dopant system under the influence of both an electric and magnetic field cannot be simply described using an effective electric-field-dependent g tensor, as would be done in g tensor modulation resonance\textsuperscript{2}. However, the dynamical equations for the spin can be numerically solved and exhibits high-visiblity Rabi oscillations. For example, with a static electric field of 500 V/cm, a dynamic electric field of 300 V/cm with frequency 9.1 GHz, and a magnetic field of 0.1 Tesla, all oriented in the [113] direction, the Rabi oscillation period is 2.7 ns.

4:42PM T31.00010 ABSTRACT WITHDRAWN —
4:54PM T31.00011 Photoinduced Magnetism of Ternary Transition Metal Prussian Blue Analogos, D.M. PAJEROWSKI, M.W. MEISEL, Dept. Phys., Univ. Florida, J.E. GARDNER, D.R. TALHAM, Dept. Chem., Univ. Florida — The magnetism of Prussian blue analog materials (PBAs) can be tuned with external stimuli such as temperature, pressure, and light. Recently, novel effects have been seen in PBAs with substitutionally mixed ternary and quaternary transition metals, rather than the usual binary analogs. One noteworthy material we have studied is a Na$_{8}$Ni$_{1-x}$Co$_{x}$[Fe(CN)$_{6}$]$_{3}$·$n$H$_{2}$O powder, which can show either a photoinduced increase or decrease in magnetization depending upon the Ni substitution, the applied magnetic field, and the temperature. This result is the first example of a photoinduced decrease in magnetization while generating new spins via a charge transfer induced spin transition (CTIST) in a bulk material. Constrastingly, the photodecrease observed in PBA binary thin films has different microscopic origins [1-2]. Insight into the underlying mechanisms can be obtained by using mean field models, which qualitatively reproduce the experimental data. SQUID, magnetometer, FT-IR, TEM, and EDS data will be presented.

5:06PM T31.00012 Bismuth in strong magnetic fields: unconventional Zeeman coupling and correlation effects, JASON ALICEA, Caltech, LEON BALENTS, KITP — Recent experiments on bismuth have uncovered remarkably rich magnetization structure at fields well beyond the regime in which all carriers are expected to reside in the lowest Landau level. Motivated by these findings, we start from a microscopic tight-binding model and derive a low-energy Hamiltonian for the holes and three Dirac electrons pockets in bismuth. We find that an unconventional electron Zeeman effect, overlooked previously, suppresses the quantum limit for the electrons dramatically, giving rise to the observed anomalous magnetization hysteresis was observed. Here we find instabilities towards both charge density wave and Wigner crystal phases, and propose that hysteresis arises from a first-order transition out of the latter.

Session T32 GMAG DMP FIAP: Focus Session: Gilbert Damping and Non-local Spin Injection

2:30PM T32.00001 Anisotropic Damping in Single-Crystalline Ni/MgO(001) studied by the Time-Resolved Magneto-Optical Kerr effect (TR-MOKE), KEVIN SMITH, A. LUKASZEW, J. SKUZA, C. CLAVERO, K. YANG, A. REILLY, G. LÜPKE, William and Mary — The damping behavior of uniform spin precession in single-crystalline Ni/MgO(001) of various thicknesses from t = 10 nm to t = 60 nm is investigated in the time domain using TR-MOKE over a wide range of external field parameters and temperatures. Planar measurements indicate that the effective Gilbert damping parameter, $\alpha_{\text{eff}}$, is coupled to the magnetocrystalline anisotropy, as $\alpha_{\text{eff}}$ ranges from 0.05 near the hard axis to 0.10 near the easy axis. Previous experiments by other groups using FMR [1] and TR-MOKE on polycrystalline samples [2] have placed the intrinsic value of the damping at 0.045. When the field is applied normal to the film surface, $\alpha_{\text{eff}}$ increases to as high as 0.3 when the angle of the magnetization, as measured from the film plane, approaches 45 degrees from the easy axis of the film.

2:42PM T32.00002 Scattering Theory of Gilbert Damping, ARNE BRATAAS, Norwegian University of Science and Technology, Department of Physics, NO-7491 Trondheim, Norway, YAROSLAV TSERKOVNYAK, University of California, Los Angeles, Department of Physics and Astronomy, CA 90095, USA, GERRIT E.W. BAUER, Delft University of Technology, Kavli Institute of Nanoscience, Lorentzweg 1, 2628 C J Delft, The Netherlands — Magnetization relaxation is a collective many-body phenomenon that remains intriguing despite decades of theoretical and experimental investigations. It is important in topics of current interest since it determines the magnetization dynamics in magnetic memory devices and state-of-the-art magnetoelectronics experiments on Co-based films. In this talk, we discuss magnetization dynamics of a single domain ferromagnet in contact with a thermal bath by scattering theory. We recover the Landau-Lifshitz-Gilbert equation and express the Gilbert damping tensor in terms of the scattering matrix [2]. Dissipation of magnetic energy equals energy current pumped out of the system by the time-dependent magnetization, with separable spin-relaxation induced bulk and spin-pumping generated interface contributions. In linear response, our scattering theory for the Gilbert damping tensor is equivalent with the Kubo formalism [1] M. Stiles and J. Miltat, Top. Appl. Phys. 101, 225 (2006), and references therein. [2] A. Brataas, Y. Tserkovnyak, and G. E. W. Bauer, Phys. Rev. Lett. 101, 037207 (2005).

2:54PM T32.00003 Physical damping processes in Co-Cr granular films, SANGITA KALARICKAL, PAWOL KRIVOSIK, NAM MO, CARL PATTON, Colorado State University, Fort Collins, CO, STELLA WU, Seagate Technology, Fremont, CA — Recent ferromagnetic resonance (FMR) results on metallic ferromagnetic alloy films have shown that a simple one parameter Gilbert damping description is inadequate for most systems. New FMR results have been obtained on Co-Cr granular films with the columnar microstructure amenable to perpendicular media applications. The nominal 17.3 GHz FMR field and linewidth vs. the out-of-plane field angle was measured and analyzed for a 16 nm thick granular film with a relatively low effective anisotropy field of 1 kOe and a nominal grain size of 8 nm or so. The analysis reveals a three component linewidth comprised of a small Gilbert term with an $\alpha$-value of 0.003 that is consistent with intrinsic processes, a large two magnon term that derives from the grain-to-grain anisotropy variations, and an inhomogeneity broadening term due to anisotropy dispersion and grain size variations.

3:06PM T32.00004 Effect of rapid thermal annealing on ferromagnetic resonance line width of CoFeB thin films, YAPING ZHANG, XIN FAN, WEIGANG WANG, XING CHEN, Department of Physics & Astronomy University of Delaware, CHAOYING NI, Department of Materials Science University of Delaware, RONG CAO, JOHN XIAO, Department of Physics & Astronomy University of Delaware — Magnetization dynamics has attracted much attention recently due to their implication on magnetic recording and storage applications. CoFeB is one of most common magnetic layers used in MgO based magnetic tunnel junctions (MTJs). Unlike traditional thermal treatments, a giant Tunneling Magnetoresistance can be archived by rapid thermal annealing (RTA) [1]. We show the effect of RTA on magnetization dynamics. CoFeB thin film, subjected to RTA at 380 °C for various time, was investigated by ferromagnetic resonance (FMR) measurement. It is found that FMR linewidth reaches a minimum at 60 second annealing, after which the linewidth increases with annealing time. A clear trend of decreasing of uniaxial anisotropy and increasing of cubic anisotropy with annealing time indicates that competition between these anisotropies plays an important role in linewidth evolution. [1] WG. Wang et al., Appl. Phys. Lett. 92, 152501 (2008).
3:18PM T32.00005 Calculation of intrinsic damping in half metals, CHUNSHENG LIU, CLAUDIA K.A. MEWES, MAIRBEK CHSHIEV, TIM MEWES, WILLIAM H. BUTLER, MINT Center, University of Alabama, Tuscaloosa, AL — The extended Hückel tight binding method in combination with Kambersky’s torque correlation model [1] is used to calculate the precessional magnetization relaxation in half-metallic systems. In Kambersky’s model damping is described by a combination of spin-flip excitations and orbital excitations. An analytical expression of the transition matrix element which represents scattering events within a single band (intra-band) and between different bands (inter-band) respectively [2] can be obtained within the TB scheme, which enables a better understanding of the damping mechanisms in half-metallic structures. Due to the absence of spin-flip scattering in non-magnetic systems, the Gilbert damping rate of half-metals is expected to be much smaller than that of metals. Using this approach we calculated the damping for different half-metallic structures. The minimum intrinsic relaxation rate \( \lambda \) was calculated to be, 3.2 MHz, 1.1 MHz, 0.13 MHz, for the Heusler structures Co2MnGe, Co2MnSi and the Rutile structure CrO2 respectively. The damping rates for these half-metallic materials are much lower than that of bcc Fe, as we anticipated from the analytical analysis. References: [1] V. Kambersky, Czech. J. Phys. B 26, 1366 (1976). [2] K. Gilmore, Y.U. Izdebera and M.D. Stiles, Phys. Rev. Lett. 99, 027204 (2007).

3:30PM T32.00006 Unidirectional Damping in Exchange Biased Systems1, MATTHEW BRADFORD, HWACHOL LEE, ERIC EDWARDS, ZEENATH TADISINA, CLAUDIA MEWES, SUBHAJIT GUPTA, TIM MEWES, The University of Alabama — We report on the investigation of the angular dependence of the damping parameter in thin film NiFe, exchange biased by a layer of FeMn. By using a broadband ferromagnetic resonance technique (shorted waveguide), the resonant field and linewidth were determined as a function of the in-plane angle and the microwave frequency. We find that the effective damping parameter, as extracted from the frequency dependent linewidth data, shows a unidirectional anisotropy, displaying a sinusoidal behavior with respect to the in-plane angle. The effective damping parameter is minimal when the field during FMR measurements is applied parallel to the exchange bias direction and maximal for parallel alignment. These experiments in conjunction with thickness dependent measurements suggest that uncompensated spins at the ferromagnet/antiferromagnet interface are responsible for the increased magnetization relaxation observed in these structures.

1We gratefully acknowledge support from the NSF (DMR 0804243).

3:42PM T32.00007 The origin of intrinsic Gilbert damping1, MARK C. HICKEY, JAGADEESH S. MOODER, MIT — The damping of magnetization, represented by the rate at which it relaxes to equilibrium, is successfully modeled as a phenomenological extension in the Landau-Lifschitz-Gilbert equation. This is the damping term known as Gilbert damping and its direction is given by the vector product of the magnetization and its time derivative. Here we derive the Gilbert term from first principles by a non-relativistic expansion of the Dirac equation. We find that the Gilbert term arises when one calculates the spin observable in the presence of the full spin-orbital coupling terms, while recognizing magnetization and its time derivative. Here we derive the Gilbert term from first principles by a non-relativistic expansion of the Dirac equation. We find that the Gilbert term arises when one calculates the spin observable in the presence of the full spin-orbital coupling terms, while recognizing magnetization and its time derivative. The Gilbert damping rate is proportional to the dimensionless parameter \( \beta \) that can be applied to real materials. We also discuss the consequences of \( \alpha \) and \( \beta \) in out-of-equilibrium superconductors viewed as easy-plane ferromagnets in particle-hole space.

3:54PM T32.00008 Theory of Magnetization Relaxation in Conducting Ferromagnets, ION GARATE, University of Texas at Austin — The advent of technologically promising spintronics devices has revived efforts to achieve a microscopic understanding of magnetization damping in magnetic metals and semiconductors. In absence of an electric current, magnetization relaxation is described by the Gilbert parameter \( \alpha \), whose quantitative prediction relies on electronic structure calculations that treat disorder in an approximate fashion. We assess the reliability of these studies by using simple models where disorder may be treated exactly. Transport currents modify the magnetization damping. We associate this change with the non-adiabatic spin transfer torque, which is characterized by a dimensionless parameter \( \beta \). We derive a concise analytical expression for \( \beta \) that can be applied to real materials. We also discuss the counterparts of \( \alpha \) and \( \beta \) in out-of-equilibrium superconductors viewed as easy-plane ferromagnets in particle-hole space.

4:00PM T32.00009 Nonlocal Spin Valves With Very Short Injector Detector Distances, ANDREW MCCALLUM, MARK JOHNSON, Naval Research Laboratory — Nonlocal spin valves with a center to center distance of 42 nm between spin injector and detector have been fabricated. This distance is much less than the injector detector spacing in previously made nonlocal spin valves and is much shorter than the spin diffusion length of the Cu used as a channel. Nonlocal resistance changes of up to 2.6 m\( \Omega \) were seen in these devices at room temperature. From this data it was determined that the effective spin polarization of the ferromagnetic interfaces is between 4.5% and 5.9% at room temperature. The nonlocal resistance changes of these devices are much less sensitive to changes in temperature, as determined by measurements at liquid nitrogen temperature, than nonlocal spin valves with longer injector detector distances.

4:42PM T32.00010 Temperature dependence of the non-local spin signal in Cu-based lateral spin-valves, M.J. ERICKSON, C. LEIGHTON, P.A. CROWELL, University of Minnesota — We report on measurements of the \( T \) dependence of the non-local spin signal in lateral metal spin valves, focusing on the limit of transparent ferromagnet (FM) / normal metal (Cu) interfaces. Devices with channel width 250 nm and contact widths \( \approx 100 \) nm (NiFeFe\, or Co) were fabricated using in-situ shadow masking. We employed high purity sources in UHV, enabling one-shot deposition without air exposure of the interface. Multiple contact separations (250 – 800 nm) were fabricated on a single substrate to facilitate measurement of the spin diffusion length (\( \lambda_s \)). NiFe/Cu devices with 250 nm contact separation show a maximum non-local transresistance of 420 \( \mu \Omega \). Analysis of Hanle effect measurements yields spin lifetimes \( \approx 8 \) ps at low \( T \) which compare well to those extracted from the measured \( \lambda_s \) (300 nm) and resistivity (1.5 \( \mu \Omega \cdot \text{cm} \)), demonstrating consistency of our analysis. We observe a qualitatively different \( T \) dependence of the non-local signal depending on the relative sizes of the contact separation and \( \lambda_s \). When the separation becomes comparable to \( \lambda_s \), we observe a maximum in the non-local spin signal at 35 – 85 K, with strongly thickness dependent magnitude. These measurements of spin lifetime, resistivity, and \( \lambda_s \) vs \( T \) allow a quantitative comparison with the conductivity mismatch model. Work supported by the NSF MRSEC program.

4:54PM T32.00011 Bias-independent spin signals in a tunnel-junction-based non-local spin valve1, XIAOJUN WANG, HAN ZOU, L.E. OCOLA, R. DIVAN, YI JI2 — A pure spin current can be generated in the non-magnetic component of a non-local spin valve (NLSV). It has been demonstrated recently that the pure spin current can be used for spin transfer torque and spin-Hall effects. A high spin current density is desirable for realizing these effects, and therefore a large d.c. bias current will be applied. It is essential to maintain high degree of spin polarization at a high bias current. It has been previously reported that the spin polarization decreases drastically in a tunnel-junction-based CoFe/Au/NiFe NLSV. The goal of this study is to investigate the dependence of spin signals upon a d.c. bias current in tunnel-junction-based Co/Cu/Co NLSV’s. Submicron Co/Cu/Co NLSV’s are fabricated by e-beam lithography combined with angle deposition. A layer of 2 nm AlOx is deposited at the Co/Cu interface to form a tunnel barrier. A spin signal > 1m\( \Omega \) is observed at room temperature (RT). A d.c. current up to 1.0mA is applied at both 4.2 K and RT. No change of spin signal is observed for an injection current density > 10\( ^4 \) A/cm\(^2 \).

5:06PM T32.00012 Separating the Contributions of Spin Injection Efficiency and Spin Diffusion Length in Non Local Spin Valves1, MIKHAIL EREKHINSKY, FELIX CASANOVA, AMOS SHARONI, IVAN K. SCHULLER, University of California, San Diego — Non Local Spin Valves (NLSV) are unique devices which permit studies of spin transport related phenomena at the nanoscale. Two important parameters determine the signal in NLSV: a) the effective polarization of injected current from the ferromagnet (FM) through the interface, and b) the spin diffusion length of the non-magnetic metal (NM). We performed a systematic study of the NLSV signal for different device lengths as a function of NM thickness, composition and temperature. By fitting the near-exponential decay of the signal with distance we can separate the effects of polarization and NM spin diffusion length. We will discuss the contributions of surface effects on NM spin diffusion length, and FM/NM interface on efficiency of injection. In addition, we show the importance of adjacent FM electrodes in a multi-terminal spintronic device.

1This work was supported by US-DOE

5:18PM T32.00013 Control of Spin Injection by DC Current in Transparent Lateral Spin Valves1, AMOS SHARONI, FELIX CASANOVA, MIKHAIL EREKHINSKY, IVAN K. SCHULLER, UC San Diego — Lateral spin valves can be classified according to the type of interfaces (tunnel or transparent) between the ferromagnetic electrodes and the normal material. The tunnel barrier yields a large spin signal, but the maximum spin-polarized current was reported to decrease strongly with applied bias. In transparent interfaces the maximum current density through the interface is much larger, which is beneficial for some applications, but the effect on spin signal was not measured. To address this issue, we prepared metallic lateral spin valves with excellent transparent interfaces. In addition, instead of AC lock-in techniques commonly used to measure these devices, we perform DC measurements, which enables us to measure directly the effects of the current direction and magnitude on the spin signal. We compared the injection of majority spins from the ferromagnet into a non-magnetic metal (NM) with the reversed process where minority carriers are left in the NM. We were also able to study the effect of joule heating and identified the origin of voltage backgrounds usually observed in these devices.

Session T33 DMP: Focus Session: Iron Pnictides and Other Novel Superconductors XI: Penetration Depth and Magnetic Anisotropy 403

2:30PM T33.00001 Temperature Dependence of the Penetration Depth of LaFePO from Scanning SQUID Susceptometry, CLIFFIRD HICKS, THOMAS LIPPMAN, Geballe Laboratory for Advanced Materials, Stanford University, MARTIN HUBER, Departments of Physics and Electrical Engineering, University of Colorado at Boulder, JAMES ANALYTIS, JUIN-HAW CHU, IAN FISHER, KATHRYN MOLER, Geballe Laboratory for Advanced Materials, Stanford University — We use a scanning SQUID susceptometer to measure locally the temperature dependence of the penetration depth of the superconductor LaFePO. We observe a linear temperature dependence down to 850 mK, with a slope that varies with position on the sample. This is in contrast to recent measurements on the related iron arsenide family of superconductors, which indicate fully-gapped superconductivity. We also report on our ability to measure Tc locally, and observe local regions with weak superconductivity at temperatures well above the dominant Tc.

2:42PM T33.00002 Broadband microwave absorption of Fe-based superconductors, JAKE BOBOWSKI, PINDER DOSANJH, JAMES DAY, DOUG BONN, WALTER HARDY, Department of Physics and Astronomy, University of British Columbia — Preliminary microwave measurements of the penetration depth in single crystals of the hole-doped iron-based superconductor Ba1−xKxFe2As2, using cavity perturbation and ac susceptometry, have been performed by our group. These results hint at a gap with nodes plus the presence of scattering. As a complement to these techniques, we have also undertaken broadband microwave absorption (i.e., surface resistance) measurements on the same pnictide samples. Our initial results of the microwave conductivity are consistent with a system possessing a finite density of states at low temperature due to impurity scattering which then evolves with temperature above about 5 K.

2:54PM T33.00003 Lower Critical Fields and the Anisotropy in PrFeAsO1−y Single Crystals, RYUJI OKAZAKI, Department of Physics, Kyoto University, Kyoto 606-8502, Japan, MARCIN KONCZYKOWSKI, C.J. VAN DER BEEK, Laboratoire des Solides Irrades, Ecole Polytechnique, 91128, Palaiseau, France, TOMONARI KATO, KEN-ICHIRO HASHIMOTO, MASAAKI SHIMOZAWA, HIROAKI SHISIDO, MINORU YAMASHITA, TAKASADA SHIBAUCHI, Department of Physics, Kyoto University, Kyoto 606-8502, Japan, MOTOYUKI ISHIKADO, SHIN-ICHI SHAMOTO, Quantum Beam Science Directorate, JAEA, Tokai, Naka, Ibaraki 319-1195, Japan, HIJIRI KITO, AKIRA IYO, HIROSHI EISAKI, Nanoelectronics Research Institute, National Institute of Advanced Industrial Science and Technology, Tsukuba, Ibaraki 305-8568, YUJI MATSUDA, Department of Physics, Kyoto University, Kyoto 606-8502, Japan, Laboratoire des Solides Irrades, Ecole Polytechnique, 91128, Palaiseau, France — By utilizing miniature Hall-sensor array, we evaluated the lower critical fields Hc1 in Fe-based oxipnictide PrFeAsO1−y, single crystals for H||c and H||ab-planes. The temperature dependence of Hc1 for H||c is well scaled by the in-plane penetration depth and is consistent with a full-gap superconducting state. The anisotropy of penetration depths at low temperatures is estimated to be ≃ 3, which is much smaller than that of coherence lengths. This indicates the multiband superconductivity, in which the active band for the superconductivity is more anisotropic.

3:06PM T33.00004 Temperature Dependent Anisotropy of Oxypnictide Superconductors Studied by Torque Magnetometry, STEPHEN WEYENETH, Physics Institute, University of Zurich, 8057 Zurich, Switzerland, RO-MAN PUZNIAK, Institute of Physics, Polish Academy of Sciences, 02-668 Warsaw, Poland, NIKOLAI D. ZHIGADLO, SERGIY KATRICHYK, ZBIGNIEW BUKOWSKI, JANUSZ KARPINSKI, Laboratory for Solid State Physics, ETH Zurich, 8093 Zurich, Switzerland, URS MOSELE, STEFAN KOHOUT, JOSEF ROOS, HUGO KELLER, Physics Institute, University of Zurich, 8057 Zurich, Switzerland — Single crystals of different oxypnictide superconductors of the family ReFeAsO1−x−Fy (Re = Sm, Nd, Pr) with various carrier dopings and with masses m ≃ 100 mg have been investigated by means of torque magnetometry. We present most recent data, obtained by using highly sensitive piezoresistive torque sensors from which the superconducting anisotropy parameter γ and the in-plane magnetic penetration depth λc were extracted. As an important result γ was found to increase strongly as the temperature is decreased from Tc down to low temperatures. This unconventional temperature dependence of γ is similar to that observed in the two-band superconductor MgB2 and cannot be explained within the classical Ginzburg-Landau model. This scenario strongly suggests a new multi-band mechanism in the novel class of oxypnictide high-temperature superconductors.
3:18PM T33.00005 Magnetic penetration depth and critical current density in aligned grains of NdFeAsO(F)1, YURI L. ZUEV, E. D. SPECHT, D. K. CHRISTEN, Oak Ridge National Laboratory, J. R. THOMPSON, Dept. of Physics, University of Tennessee, and Oak Ridge National Laboratory, R. JIN, B. C. SALES, A. SEPAT, M. A. McGUIRE, D. G. MANDRUS, Oak Ridge National Laboratory — We have prepared a powder sample of NdFeAsO(F), where most crystallite particles are aligned with their c-axis along a common direction. We have measured magnetic penetration depth and a critical current density in the base-plane. The penetration depth shows a fully gapped superconducting state with two energy gaps, one roughly twice as large as the other. The in-plane critical current density is as high as several MA/cm² at low temperatures, zero field, which may be promising for applications.

1Research sponsored by the DOE Division of Materials Sciences and Engineering

3:30PM T33.00006 Low temperature penetration depth of Fe-based superconductors, JAMES DAY, BRAD RAMSHAW, JAKE BOBOWSKI, PINDER DOSANJH, DOUG BONN, WALTER HARDY, Department of Physics and Astronomy, University of British Columbia — The recent discovery of superconductivity in layered iron-based pnictide compounds has generated levels of excitement comparable to the early days of the copper-based oxide superconductors. While connections may be drawn between the cuprates and the pnictides, there exist important differences between the two materials. We report high-precision microwave measurements of the penetration depth in single crystals of the hole-doped iron-based superconductor Bax1−xK2Fe2As2. Using cavity perturbation techniques in conjunction with ac susceptometry, we find that the low temperature penetration depth does not fit well to a simple s-wave model. Furthermore, our initial results suggest that the temperature dependence of the superfluid density is consistent with a gap with nodes plus the presence of scattering.

3:42PM T33.00007 Penetration Depth and Quasiparticle Conductivity in Iron-based High-Temperature Superconductors, KEN-ICHIRO HASHIMOTO, TAKASADA SHIBAUCHI, TOMONARI KATO, KOSUKE IKADA, RYUJI OKAZAKI, HIROSKI SHISHIDO, Department of Physics, Kyoto University, C.J. VAN DER BEEK, M. KONCZYKOWSKI, Ecole Polytechnique, HIJIRI KITO, AKIRA IYO, HIROSHI EISAKI, AIST, MOTÖYUKI ISHIKADO, SHIN-ICHI SHAMOTÔ, JAE, H. TAKEYA, K. HIRATA, NIMS, SHIGERU KASAHARA, TAKAHITO TERAISHIMA, Research Center for Low Temperature and Materials Sciences, Kyoto University, YUIJI MATSUDA, Department of Physics, Kyoto University — We measure the in-plane penetration depth and the quasiparticle conductivity in the newly discovered Fe-based high-temperature superconductors PrFeAsO1−x[1] and Ba1−xK2Fe2As2[2], using a sensitive superconducting resonator. We show that the penetration depth exhibits a very flat behavior at low temperatures in both compounds, which indicates that the superconducting gap opens up all over the Fermi surface. The temperature dependence of the superfluid density is well fitted with the two gap model, suggesting the multi-gap nature of superconductivity in this system. Moreover, the observed large enhancement of the quasiparticle conductivity suggests a suppression of the quasiparticle scattering, reminiscent of the superconductors in strongly correlated electronic systems.[1] K. Hashimoto et al., arXiv:0806.3149., [2] K. Hashimoto et al., arXiv:0810.3506.

3:54PM T33.00008 London Penetration Depth in Single Crystals of Nd(Fe,Co)As(O,F) Superconductors, H. KIM, C. MARTIN, R.T. GORDON, M.A. TANATAR, M.E. TILLMAN, S. KIM, S.L. BUD’KO, P.C. CANFIELD, R. PROZOROV — Iron arsenide superconductors, with the general formula RFeAsO−x[1] (R=Nd,Sm,Pr,Gd), exhibit the highest transition temperatures among the compounds of the pnictide family, in excess of 50 K. London penetration depth measurements performed on single crystals, grown under high pressure with nominal fluorine content x=0.1, have revealed a nodeless superconducting state with a modestly anisotropic gap[1]. Since doping is one of the most efficient ways to perturb the superconductivity, we explore here the evolution of the London penetration depth with doping, achieved by F substitution on O sites and by Co substitution on Fe sites. Notable differences in the superconducting transition temperatures for the two sets of crystals suggests the importance of impurity scattering for quasiparticles, which is characteristic of a superconducting gap function possessing some type of nodal structure. The overall change in the superfluid density as a function of doping will be discussed. R. T. Gordon et al. arXiv:0807.0876

4:06PM T33.00009 Co-concentration dependence of the London penetration depth in single crystals of Ba(Fe1−x,Co)xAs2, R. T. GORDON, C. MARTIN, H. KIM, M.A. TANATAR, N. NI, S.L. BUD’KO, P.C. CANFIELD, J. SCHMALIAN, R. PROZOROV, Ames Laboratory and Department of Physics and Astronomy, Iowa State University — The in-plane London penetration depth, λab(T), has been measured in single crystals of Ba(Fe1−x,Co)xAs2 for several values of x using a tunnel diode resonator (TDR) technique. The low temperature behavior of the variation of the penetration depth follows a clear power law behavior, Δλ(T) ∝ T−n, for all measured Co concentrations with n varying between 2 on the underdoped side to about 2.5 at the optimal doping. This non-exponential behavior in Δλ indicates the existence of a significant number of superconducting quasiparticles, which is characteristic of a superconducting gap function possessing some type of nodal structure. The overall change in the superfluid density as a function of doping will be discussed. R. T. Gordon et al. arXiv:0810.2295 (2008).

4:18PM T33.00010 Magnetic force microscopy study of a Ba0.55K0.45Fe2As2 single crystal: Local penetration depth and flux pinning, LAN LUAN, OPHIR M. AUSLAENDER, KATHRYN A. MOLER, JAMES G. ANALYTIS, JIUN-HAW CHU, IAN R. FISHER, Stanford University — We use a magnetic force microscope (MFM) to study both the penetration depth (λab) and flux pinning in the iron-pnictide superconductor Ba0.10K0.45Fe2As2 by imaging and manipulating vortices. We observe the same regular signature from all vortices in a 50μm × 50μm field of view, implying lattices. While inhomogeneity of the superfluid density down to the sub-micron scale, Quantitative analysis of images between vortices and of the Meissner repulsion of the magnetic tip from the sample gives the temperature-induced change of λab and an estimate for its absolute value. We detect no long-range order in the vortex positions, suggesting the absence of correlated pinning in the material. We measure the force required to depin individual vortices and the force required to drag them across the entire sample. This allows us to characterize the pinning potential in the material and its distribution as well as to set bounds on the local critical current.

4:30PM T33.00011 Evidence for Two Energy Gaps in Superconducting Ba0.6K0.4Fe2As2 Single Crystals and Breakdown of the Uemura Plot, CONG REN, ZHAO-SHENG WANG, HUI-QIANG CHAI, HU, YUAN HUANG, LEI SHAN, HAI-HU WEN, National Laboratory for Superconductivity, Institute of Physics and Beijing National Laboratory for Condensed Matter Physics, CAS, NATIONAL LABORATORY FOR SUPERCONDUCTIVITY,IOP TEAM — We report a detailed investigation on the lower critical field Hc1 of the superconducting Ba0.6K0.4Fe2As2 (FeAs-122) single crystals. A pronounced kink is observed on the Hc1(T) curve, which is attributed to the existence of two superconducting gaps. By fitting the data Hc1(T) to the two-gap BCS model in full temperature region, a small gap of Δa(0) = 2.0 ± 0.3 meV and a large gap of Δb(0) = 8.9 ± 0.4 meV are obtained. The in-plane penetration depth λab(0) is estimated to be 105 nm corresponding to a rather large superfluid density, which points to the breakdown of the Uemura plot in FeAs-122 superconductors.

1This work is supported by the Natural Science Foundation of China(973 project No: 2006CB60100, 2006CB921107, 2006CB921802), and Chinese Academy of Sciences (Project IITSNEM)
4:42PM T33.00012 Anisotropic London Penetration depth in NdFeAsO$_{0.9}$F$_{0.1}$ and Ba$_{0.55}$K$_{0.45}$Fe$_2$As$_2$ — CATALIN MARTIN, R.T. GORDON, M.A. TANATAR, H. KIM, M.E. TILLMAN, N. NI, P.C. CANFIELD, V.G. KOGAN, R. PROZOROV. Ames Laboratory and Department of Physics & Astronomy, Iowa State University, H. LOU, Z. WANG, H.H. WEN, National Laboratory for Superconductivity — In and out of plane London penetration depth was measured in single crystals of NdFeAsO$_{0.9}$F$_{0.1}$ (Nd-1111) and Ba$_{0.55}$K$_{0.45}$Fe$_2$As$_2$ (BaK-122) as a function of temperature by using an rf-resonator technique. In Nd-1111, penetration depth shows exponential behavior at low temperature, implying a fully-gapped Fermi surface. Superfluid density is best described in the full temperature range by a slightly anisotropic order parameter. In contrast, penetration depth of BaK-122 shows power-law temperature dependence ($\Delta \chi(T) \propto T^n$, $n \approx 2$) down to $T \approx 10$ K, and anisotropy $\gamma$ varies from 2 at $T_c$ to about 4 at 0.5 K. Possible symmetries of the gap consistent with such behavior and comparison with results from other techniques and with proposed theoretical models will be discussed. Also, the temperature dependence of the anisotropy $\gamma_{\Delta}(T)$ for both compounds, will be compared to that of $\gamma_{\Delta}(T)/\gamma_{\Delta}(0)$. In connection with possible multiband superconductivity.

4:54PM T33.00013 Muon Spin Relaxation Study of Ba(Fe$_{0.93}$Co$_{0.07}$)$_2$As$_2$ — GRAEME LUKE, A. ACZEL, McMaster University, J.P. CARLO, Columbia University, T. GOKO, TRIUMF, T.J. WILLIAMS, McMaster University, N. NI, S.L. BUD'KO, P.C. CANFIELD, Ames Laboratory, Y.J. UEMURA, Columbia University — We have performed muon spin relaxation ($\mu$SR) measurements of superconducting Ba(Fe$_{0.93}$Co$_{0.07}$)$_2$As$_2$. Zero field measurements show that static magnetism is absent for this Co concentration. In the mixed state, we observe a well-formed vortex lattice which results in an anisotropic $\mu$SR lineshape. We have fit the spectra to a microscopic model for the vortex state to obtain the magnetic field penetration depth. The penetration depth is about 2000Å in low (200G) fields and increases with applied field. The temperature dependence of the superfluid density is well described by a power law; behaviour which is consistent with gap nodes, substantial gap anisotropy or multi-band superconductivity. Research at McMaster University is supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

5:06PM T33.00014 Anisotropic superconducting properties of aligned Sm$_{0.95}$La$_{0.05}$FeAsO$_{0.85}$F$_{0.15}$ microcrystalline powder — H.C. KU, B.C. CHANG, C.H. HSU, Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, Y.Y. HSU, Department of Physics, National Taiwan Normal University, Taipei 11677, Taiwan, Z. WEI, K.Q. RUAN, X.G. LI, Hefei National Laboratory for Physical Sciences at Microscale and Department of Physics, University of Science and Technology of China, Hefei, China — The Sm$_{0.95}$La$_{0.05}$FeAsO$_{0.85}$F$_{0.15}$ compound is a quasi-2D layered superconductor with a superconducting transition temperature $T_c = 52$ K. Due to the Fe spin-orbital related anisotropic exchange coupling (antiferromagnetic or ferromagnetic fluctuation), the tetragonal microcrystalline powder can be aligned at room temperature using the field-rotation method where the tetragonal $ab$-plane is parallel to the aligned magnetic field $B_0$ and $c$-axis along the rotation axis. Anisotropic superconducting properties with anisotropic diamagnetic ratio $\chi_{\Delta}/\chi_{\Delta0} \approx 2.4 + 0.6$ was observed from low field susceptibility $\chi(T)$ and magnetization $M(B)$. The anisotropic low- field phase diagram with the variation of lower critical field gives a zero-temperature penetration depth $\lambda_0(0) = 280$ nm and $\lambda_{ab}(0) = 120$ nm. The magnetic fluctuation used for powder alignment at 300 K may be related with the pairing mechanism of superconductivity at lower temperature.

5:18PM T33.00015 Diminishing anisotropy of PrFeAsO$_{1-y}$ single crystal as temperature goes zero — DAICHI KUBOTA, TAKEKAZU ISHIDA, Osaka Pref Univ (Sakai), MOTOYUKI ISHIKADO, SHIN-ICHI SHAMOTO, JAEWON PARK, HIROSHI EISAKI, AIIST, HIJIRI KITO, AKIRA IYO, AIIST (Tsukuba) — The magnetic torque of a high-quality PrFeAsO$_{1-y}$ single crystal has been investigated at temperatures from 10 K to 45 K in magnetic fields from 5 KG and 50 KG. The torque curves of the PrFeAsO$_{1-y}$ single crystal have been measured systematically. The superconducting anisotropy of PrFeAsO$_{1-y}$ is determined by analyzing the torque curves. The temperature and field dependence of $\gamma$ reflect that the Fe-oxypnictide superconductivity has the rather three-dimensional isotropic nature of Fe-As layer network. We consider that this is good evidence for the multi-band superconductivity in Fe-oxypnictide. We find that the superconducting anisotropy $\gamma$ in PrFeAsO$_{1-y}$ can be approximated by $\gamma \approx 1.08 + 0.0068T$ in all fields by employing the Kogan model. We find it surprising to have such a low anisotropy parameter $\gamma$ even for a layered superconductor. Such a small anisotropic parameter in Fe-oxypnictides is preferential to ensure the intergrain connectivity and the resulting high critical current density $J_c$.

Wednesday, March 18, 2009 2:30PM - 5:30PM – Session T34 DCMP: Superconductivity: Vortex Statics and Dynamics 404

2:30PM T34.00001 Manipulation of interlayer "kinks" in individual vortices in underdoped YBa$_2$Cu$_3$O$_{6+x}$ — OPHIR AUSLAENDER, LAN LUAN, Stanford University, DOUGLAS BONN, RUIXING LIANG, WALTER HARDY, University of British Columbia, KATHRYN MOLER, Stanford University — We use magnetic force microscopy (MFM) to both image and manipulate individual vortex lines threading single crystalline YBa$_2$Cu$_3$O$_{6+x}$, a layered superconductor. We find that when we pull the top of a pinned vortex, it may not tilt smoothly, as in more isotropic superconductors [1]. In some cases, we observe a vortex breaking into discrete segments that can be described as short stacks of two-dimensional pancake vortices. This is similar to the "kinked" structure proposed by Benkraouda and Clem [2]. Quantitative analysis gives an estimate of the pinning force and the coupling between the pancake stacks. Our measurements highlight the discrete nature of stacks of pancake vortices in layered superconductors.

1 This work was partly supported by a Grant-in-Aid for Scientific Research from MEXT (Grant No. 19206104) and a special grant from Osaka Prefecture University.
2:42PM T34.00002 Moving flux quanta, driven by high density currents in low-impurity samples of V$_3$Si, LuNi$_2$B$_2$C, and NbSe$_2$: Ordered flow and core-size effects. S. MORAES, R.P. KHADKA, A.A. ČAPUD, U. of South Alabama; A.P. REYES, L.L. LUMATA, National High Magnetic Field Lab, J.R. THOMPSON, U. of Tennessee, D.K. CHRISTEN, Oak Ridge National Lab — There is incomplete understanding about the dissipative motion of magnetic flux quanta in type II superconductors, especially under large Lorentz forces. This is mainly due to the technical challenges involving the application of large electric currents and the rarity of samples wherein flux quanta are relatively free to move — i.e., samples with weak “pinning” — which commonly make it impossible to observe dynamic phases. Progress towards overcoming these challenges is described, along with clear observations of flux-flow phases in high-quality samples of three “low T$_c$” superconductors, V$_3$Si, LuNi$_2$B$_2$C, and NbSe$_2$. Evidence of the rarely observed Bardeen-Stephen flux flow — a highly ordered, collective motion of flux quanta in near-unison — will be presented. These observations have also enabled an examination of a model by Kogan and Zelezhina [Kogan and Zhelezina, Phys. Rev B 71, 134505 (2005)] predicting the effect of a field-dependent flux core size on ordered flux flow, as will be discussed. Funded by the U. of South Alabama and by the Research Corporation. We thank P. Canfield and L. Delong for samples and helpful discussions.

2:54PM T34.00003 Lattice slips in slow moving magnetic vortex lattices in NbSe$_2$. MICHAEL DREYER, JONGHEE LEE, HUI WANG, University of Maryland, BARRY BARKER, LPS — We studied vortex matter in NbSe$_2$, a type II superconductor, at magnetic fields of 0.25 - 0.75 T and temperatures of 4.2 K. At these fields the vortices form an Abrikosov lattice. Due to a small residual resistance in our superconducting magnet the applied magnetic field slowly decayed, driving the vortex lattice. The velocity was low enough to allow acquiring highly resolved time series using a low temperature scanning tunneling microscopy (STM). From the images we were able to extract local variations in the lattice constant as well as time series of the average vortex position (path) and velocity. A more subtle observation where closed loops on the order of nanometer in diameter in the averaged path of the vortices. Although this was observed in more than one data series it was at first dismissed as an artifact. Later, similar loops where observed in simulations. The loops occurred when a lattice dislocation traveled through the vortex lattice. This observation, unexpected in the simulation, gave new credence to the previously observed loops in the data. Since the vortex lattice in NbSe$_2$ was in the Bragg glass phase we would expect locally ordered domains of several micrometer in diameter. It is conceivable that lattice slips occur at the domain boundaries and lead to the observed loops. The observation and simulation will be compared in detail. We would like to thank Eva Andrej and Helmut Berger for providing NbSe$_2$ samples.

3:06PM T34.00004 Vortex interactions in superconducting weak-pinning channel ratchets$^1$, K. YU, T.W. HEITMANN, C. SONG, M.P. DEFEO, B.L.T. PLOURDE, Syracuse University, M.B.S. HESSELBERTH, P.H. KES, Leiden University — We report on measurements of vortex ratchets fabricated from weak-pinning superconducting a-NbGe channels bounded by strong-pinning NbN banks with asymmetric sawtooth edges. This configuration for the vortex confinement potential results in an asymmetric response for the vortex dynamics in the channels. Interactions between vortices, both within a channel and between neighboring channels, have a substantial influence on the ratchet behavior, including certain regimes where the net vortex motion through the ratchet reverses direction. We discuss our measurements in terms of a model for describing the vortex interactions in the ratchet channels.

$^1$Supported by NSF DMR-0547147

3:18PM T34.00005 Flux-flow noise in a superconducting Corbino vortex ratchet channel$^1$, T.W. HEITMANN, K. YU, C. SONG, M.P. DEFEO, B.L.T. PLOURDE, Syracuse University, M.B.S. HESSELBERTH, P.H. KES, Leiden University — We report measurements of vortex dynamics in a single nanofabricated weak-pinning vortex channel of a-NbGe with strong-pinning NbN channel edges. The channel is arranged in a circle on a Corbino disk geometry with a radial bias current, thus eliminating the influence of edge barriers to vortex entry on the dynamics and resulting in closed circular orbits for the vortices. An asymmetric sawtooth shape for the channel walls produces a ratchet effect, resulting in large differences in the critical current for the two flow directions. The SQUID picovoltmeter that we have developed for resolving the flux-flow voltage provides a low noise floor such that we can resolve structure in the flux-flow noise, with substantial asymmetries for vortex motion in the two directions through the ratchet channel.

$^1$This work was supported by the FWO-Vl, the IAP, and the “Odysseus” program of the Flemish Government and FWO-Vl. V.R.M. is funded by the EU Marie Curie project, Contract No. MIF1-CT-2006-040816.

3:42PM T34.00007 Vortex dynamics simulation in high-$T_c$ superconductors with planar pinning arrays coexisting with point pinning sites. HIDEHIRO ASAI, SATOSHI WATANABE, University of Tokyo — The enhancement of critical currents $I_v$ by introducing artificial pinning sites is key issue in the application of high-$T_c$ superconductors. Planar defects such as twin boundary are well known as the possible candidates for tangible pinning sites. Recently, the improvement of $I_v$ has been reported in the samples having high-density planar defects. However, the pinning characteristics of planar defects, especially the change of the pinning efficiency in the presence of point pinning, are still unclear. We have studied the dynamics of vortices interacting with both planar pinning and point pinning sites using molecular dynamics simulation. We have fixed the pinning strength of planar pinning, and calculated the $I_v$ as a function of the point pinning strength $J_p$. With increasing $J_p$, $I_v$ changes from $I_v = I_{p0}$ ($J_p$: $I_v$ obtained in the system without point pinning) to $I_v = I_{p0} + \alpha$ ($J_p$: $I_v$ obtained in the system without planar pinning) and then to $I_v = J_p$. This behavior corresponds to the appearance of the kink structure and the drastic change of c-axis correlation function of the vortices. We have also performed the similar calculation with different anisotropy parameters and observed that the stiffness of vortex line changes the $I_v$ behavior as a function of $J_p$.
3:54PM T34.00008 The Peak Effect anomaly in low and high Tc superconductors: stable and metaestables vortex lattice configurations, VICTORIA BEKERIS, GABRIELA PASQUINI, DIEGO PEREZ DAROCA, CLAUDIO CHILOTTE, GUSTAVO LOZANO, Departamento de Fisica, FCEyN, Universidad de Buenos Aires, Pabellon I Ciudad Universitaria, Buenos Aires, Argentina. — Competing interactions in the vortex lattice (VL) of type II superconductors give rise to an order-disorder transition known as Peak Effect (PE) anomaly. The strong metaestability related to the PE masks the stationary VL configurations (VLCs), both in low and in high Tc superconductors. By means of linear ac susceptibility experiments, that avoid VL reorganization, we explore quasi-static stable and metastable states, applying different shaking protocols before measurements. In low Tc NbxSe2 crystals we identify TH regions where stationary configurations are maximally ordered (Bragg Glass), fully disordered or where ordered and disordered stable phases coexist. In contrast, in high Tc Yb2As3 (G07) crystals, metaestability seems to dominate and different metastable VLCs are accessed depending on the previous dynamic history, with no access to the lowest energy configuration. [1] G. Pasquini et al. Phys. Rev. Lett. 100, 247003 (2008)

4:06PM T34.00009 Dynamics of Josephson vortices mediated with pancake vortices, KAZUTO HIRATA, National Institute for Materials Science, SHUUICHI OOI, TAKASHI MOCHIKU, PHYSICAL PROPERTIES TEAM — Josephson vortices (JVs) flow very fast with a velocity up to tenth of the light velocity in Bi-2212. If the motion of JVs can be controlled, high-speed signal processing will be achieved. We have tried to apply symmetrical pinning centers in space and time-asymmetric input signals for controlling a dynamical behavior of JVs in Bi-2212. We have shown the periodic oscillations in JV flow-resistance against magnetic field in Bi-2212 (PRL99(2002)247002), which persist in wide range of temperature and magnetic field. Introducing pancake vortices (PVs) into JV system in Bi-2212, the JV flow-resistance abruptly decreases, because the JVs interact with the PVs strongly and the PVs are pinned in intrinsically existing pinning centers in Bi-2212. However, when the input current (signal) with two frequencies is applied, a finite dc voltage can be obtained even without the flow-resistance. This leads to a rectification effect in the JVs’ motion by the PVs. The nonlinearity in I-V characteristics induces the rectification effect with time-asymmetric input signals of two harmonics. This may open a new application of HTSCs.

4:18PM T34.00010 Exploring the Aging Effects in Pinned Vortex Lattices in Nb using Neutron Reflectometry, XI WANG, HELEN HANSON, XINSHENG LING, Brown University, BRIAN MARANVILLE, NIST — We report the first experiment using neutron reflectometry to explore the aging effects in pinned vortex lattices in Nb. A striking prediction of the Bragg glass model is the existence of a pinned elastic Bragg glass solid matter in the vortex state of weakly disordered type-II superconductors. According to this model, the system is pinned in the random-manifold regime with local metastable states, yet at large length scale, the system remains elastic. This seemingly paradoxical property is predicted to lead to novel aging dynamics. This work was supported by a grant from DOE-BES. The experiments were carried out at NG-1- Advanced Neutron Diffraction facility at NIST NCNR.

4:30PM T34.00011 Measurement of Vortex Bragg Glass Structure Factor in Nb using Neutron Reflectometry, HELEN HANSON, XI WANG, XINSHENG LING, Brown University, BRIAN MARANVILLE, NIST — One of the key predictions in the Bragg Glass model of weakly pinned vortex lattices is a power-law structure factor similar to that of a 2D solid. Previous attempts using SANS in Nb and HTSC have provided results that are consistent with the Bragg model. Here we report the first experiment using neutron reflectometry to resolve S(Q) in a Nb single crystal. This work was supported by a grant from DOE-BES. The experiments were carried out at NG-1- Advanced Neutron Diffraction facility at NIST NCNR.

4:42PM T34.00012 Small-angle neutron scattering study of vortex matter in superconducting Ba(Fe0.93Co0.07)2As2, M. R. ESKILDSEN, University of Notre Dame, T. BLASIUS, University of Michigan, A. I. GOLDMAN, Ames Laboratory and Iowa State University, J. M. DENSMORE, University of Notre Dame, C. D. DEWHURST, Institut Laue-Langevin, N. NI, A. KREYSSIG, S. L. BUD’KO, P. C. CANFIELD, Ames Laboratory and Iowa State University — We present small-angle neutron scattering studies of the superconducting vortices Ba(Fe0.93Co0.07)2As2. At all fields measured a ring of scattering was observed, indicating a highly disordered vortex configuration, and no discernable rocking curve could be measured. The field dependence of the magnitude of the scattering vector indicates vortex lattice domains of (distorted) hexagonal symmetry. An analysis of the scattered intensity due to the vortices shows a rapid decrease with increasing applied magnetic field, significantly exceeding what would be expected based on estimates of the upper critical field. These results are consistent with the existence of a vortex glass or Bragg glass phase in Ba(Fe0.93Co0.07)2As2.

1Supported by NSF through grant DMR-0804887. Work at Ames Lab is supported by the U. S. DOE, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

4:54PM T34.00013 Pauli Paramagnetic Effects in the Mixed State of CeCoIn5 Revealed by Small Angle Neutron Scattering, P. DAS, M. R. ESKILDSEN, L. DEBEER-SCHMITT, University of Notre Dame, IN, USA, J. S. WHITE, E. M. FORGAN, University of Birmingham, UK, A. D. BIANCHI, Universite de Montreil, Canada, M. KENZELMANN, J. L. GAVILANO, M. ZOLLIKER, S. GERBER, J. MESOT, ETHZ & Paul Scherrer Institute, Switzerland, C. WANG, E. D. BAUER, J. L. SARRAO, Los Alamos National Lab, NM, USA, C. PETROVIC, Brookhaven National Lab, NY, USA. — We report on extensive small-angle neutron scattering measurements on the vortex lattice (VL) in the mixed state of CeCoIn5, with the magnetic field (H) both parallel and perpendicular to the c-axis. We obtain the H- and T-dependence of the form factor (|F|2) - a measure of the field contrast in the mixed state. At low T, competition between Pauli paramagnetism and the antiparallel spin alignment of f-wave pairing gives “magnetized” VL cores, causing |F|2 to increase with H [1]. We observe a crossover to a state where |F|2 falls again near Hc2, the falling off extends outside the proposed FFLO region and is believed to arise from expansion of the magnetized cores. This core expansion may also explain the sequence of VL phase transitions observed in this material. At higher T, we observe a crossover towards more conventional behavior.

5:06PM T34.00014 Vortex phase diagram in weakly pinned Rh17S15, S. RAMAKRISHNAN, H. R. NAREN, ARUMUGAM TAMIZHAVEL, ARUN GROVER, TIFFR. — A vortex phase diagram of the strongly correlated superconductor Rh17S15 has been constructed via exploration of the anomalous variations in critical current density extracted from ac and dc magnetization measurements. The iso-field in-phase susceptibility experiments, that avoid VL reorganization, we explore quasi-static stable and metastable states, applying different shaking protocols before measurements. In low Tc NbxSe2 crystals we identify TH regions where stationary configurations are maximally ordered (Bragg Glass), fully disordered or where ordered and disordered stable phases coexist. In contrast, in high Tc Yb2As3 (G07) crystals, metaestability seems to dominate and different metastable VLCs are accessed depending on the previous dynamic history, with no access to the lowest energy configuration. [1] G. Pasquini et al. Phys. Rev. Lett. 100, 247003 (2008).

5:18PM T34.00015 ABSTRACT WITHDRAWN
2:30PM T35.00001 Role of fluorine in the iron pnictides: phonon softening and effective hole-doping¹, JESSE NOFFSINGER, FELICIANO GIUSTINO², STEVEN G. LOUIE, MARVIN L. COHEN, UC Berkeley, Lawrence Berkeley National Laboratory — Using first principles techniques, we investigate the influence of fluorine doping on the electronic structure, lattice dynamics and electron-phonon coupling in LaFeAsO. We explicitly simulate the F-doping using a supercell model in order to explore properties not described by virtual crystal models. Our analysis reveals that local lattice relaxation accompanies the fluorine doping and modifies the lattice dynamics, in accord with recent experimental data. In addition, it is found that the charge density of the doped electrons cannot be described by simplified models of electron-doping in the two-dimensional Fe-plane.

2:42PM T35.00002 Effects of Magnetic Ordering on Phonon Spectra in Iron-based Superconductors: First Principle Calculation and Theoretical Analysis¹, HIROKI NAKAMURA, MASAHIKO MACHIDA, CCSE, JAEA, ALFRED BARON², Spring-8/RIKEN, TATSUO FUKUDA³, Spring-8/JAEA, SHINICHI SHAMOTO⁴, MNRC JAEA — Recently, inelastic x-ray scattering measurements on single crystals of PrFeAsO₁₋₀.₂ have reported that phonons related with Fe-Fe and Fe-As bondsings are significantly more softened than those obtained by the first principle calculations [1]. However, it is noted that any previous calculations do not include the magnetic degree of freedom. Therefore, we performed the phonon structure calculations by taking into account the magnetic structure in mother compounds. The magnetic calculations are in better agreement with the observed softening. We show the results and clarify the reason.

2:54PM T35.00003 Cubic anharmonicity of the Fe-As bond of the iron-pnictides estimated from Raman spectroscopy. MATS GRANATH, Gothenburg University, JOHAN BIELECKI, JOAKIM HOLMLUND, CHRIS KNEE, Chalmers University of Technology, NAN LIN WANG, Beijing National Laboratory for Condensed Matter Physics, LARS BÖRJESSON, Chalmers University of Technology — We study the phonon spectrum of the iron-pnictide superconductors, (Ce,Nd)O₁₋₀.₃₅FeAs, using Raman spectroscopy. Based on the temperature dependent softening of the out of plane optical Fe-mode (B₁g, at 1') we estimate the magnitude of the cubic anharmonicity of the Fe-As bond by calculating the self-energy due to phonon-phonon interactions. This also gives an estimate of the lattice expansion or contraction due to Fe isotope substitution which may in turn influence electronic properties.

3:06PM T35.00004 Phonon Softening in PrFeAsO₁₋₀.₂ by Inelastic X-Ray Scattering¹, ALFRED Q.R. BARON, SPRING8/RIKEN and JASRI, TATSUO FUKUDA, SPRING8/RIKEN and JAEA, SHIN-ICHI SHAMOTO, JAEA, HIROSHI UCHIYAMA, SPRING8/JASRI, JUN-ICHIRO MIZUKI, JAEA, HIROKI NAKAMURA, MASAHIKO MACHIDA, CREST, JST, JAEA, MOTOYUKI ISHIKADO, JAEA, MASATOSHI ARAI, J-PARC JAEA, HIJIRI KITO, HIROSHI EISAKI, NERI, AIST — We present phonon dispersion measurements from single crystals of PrFeAsO₁₋₀.₂ with Tₐ (onset) of 42 to 45 K made using inelastic x-ray scattering with 1.5 meV resolution at BL35XU of SPring-8. In agreement with our previous results on powders and crystals [1] we see pronounced softening of the in-plane Fe-As modes compared to phonon calculations using pseudopotential methods in the tetragonal (non-magnetic) structure. C-axis modes are somewhat harder. No strong changes in phonon spectra across Tₐ were observed at the momentum transfers investigated. We also compare our results against calculations of phonons in the magnetic parent material. [1] Fukuda, et al., J. Phys. Soc. Japan, 77 (2008), 103715.

3:18PM T35.00005 CaFe₂As₂ Phonons via Inelastic X-ray Scattering and First Principles Calculations, STEVEN HAHN, Ames Laboratory and Iowa State University, AHMET ALATAS, BOGDAN LEU, Advanced Photon Source, Argonne National Laboratory, YONGBIN LEE, NI, Ames Laboratory and Iowa State University, DUCK YOUNG CHUNG, ILIYA TODOROV, Materials Science Division, Argonne National Laboratory, MERCOURI KANTZIDIS, Materials Science Division, Argonne National Laboratory and Department of Chemistry, Northwestern University, ERCAN ALP, Advanced Photon Source, Argonne National Laboratory, PAUL CANFIELD, ALAN GOLDMAN, ROBERT MCQUEENFY, BRUCE HARMON, Ames Laboratory and Iowa State University — In the iron pnictides, the sensitivity of the iron magnetic moment to the arsenic position suggests a strong relationship between phonons and magnetism. We measured the phonon dispersion of several branches in the high temperature tetragonal phase of CaFe₂As₂ using inelastic x-ray scattering on single-crystal samples. These measurements were compared to ab-initio calculations of the phonons. Spin polarized calculations imposing the antiferromagnetic order present in the low temperature orthorhombic phase dramatically improves agreement between theory and experiment. This is discussed in terms of the strong antiferromagnetic correlations that are known to persist in the tetragonal phase.

3:30PM T35.00006 Magnetic and lattice coupling in the AFe₂As₂ (A=Ca, Ba, and Sr) compounds¹, HAIFENG LI, DAVID VAKNIN, JEREL ZARESTKY, WEI TIAN, ANDREAS KREYSSIG, NI NI, SERGEY BU’DKO, PAUL CANFIELD, ROBERT MCQUEENFY, ALAN GOLDMAN, Ames Laboratory and Physics Department and Astronomy, Iowa State University, Ames, IA — Systematic elastic and inelastic neutron scattering studies of the AFe₂As₂ (A=Ca, Ba, and Sr) compounds reveal some common and distinguished properties that may shed light on the nature of the coupling between the magnetic and lattice degrees of freedom. We find, that for all three samples, the structural and antiferromagnetic (AFM) transition temperatures coincide within the experimental uncertainty of measurements. We also find that the AFM propagation vector is unequivocally along the long a- orthorhombic axis for all three compounds. The coupling between the magnetic and chemical structure is in play below the transition down to the lowest temperatures. More results and discussion on the nature of the transitions will be presented.

3:42PM T35.00007 Large electron-A_{1g} phonon interaction in doped LaOFeAs: coupling with antiferromagnetism1, FELIX YNDRUAIR, JOSE SOLER, Universidad Autonoma de Madrid — We present first principles calculations of the atomic and the electronic structure of electron-doped LaOFeAs. We find that whereas the undoped compound has an antiferromagnetic arrangement of magnetic moments at the Fe atoms, the doped system becomes non magnetic at a critical electron concentration. We have studied the electron-phonon interaction in the doped paramagnetic phase. For the A_{1g} phonon, the separation between the As and Fe planes induces a non-collinear arrangement of the Fe magnetic moments. This arrangement is anti parallel for interactions mediated by As, and perpendicular for Fe-Fe direct interactions, thus avoiding frustration. This coupling of magnetism with vibrations induces anharmonicities and an electron-phonon interaction much larger than in the pure paramagnetic case. We propose that such enhanced interactions play an essential role in superconducting compounds close to an antiferromagnetic phase transition.

3:54PM T35.00008 Phonon and magnetic excitations in the novel BaFe1.8Co0.2As2 superconductor, DAN PARSHALL, Univ of Tennessee, Dept of Physics, KONSTANTIN LOKSHIN, Univ of Tennessee, Dept of Materials Science, MATTHEW STONE, DOUGLAS ABERNATHY, MARK LUMSDEN, ANDREW CHRISTIANSON, DAVID MANDRUS, ATHENA SAFAF-SEFAT, ORNL, TAKESHI EGAMI1, ORNL, Univ of Tennessee, Dept of Physics and Materials Science — Phonon and magnetic excitations in the BaFe1.8Co0.2As2 superconductor single crystal were studied by inelastic neutron scattering using the ARCS time-of-flight spectrometer at the Spallation Neutron Source. Most of the phonon branches show a good agreement with the density functional theory calculations. However, the As-Raman vibrations along the c-axis demonstrate strong softening contrary to the flat behavior expected from the LDA calculations. The softening is strongest along the (0.5, 0.5, L) direction by up to 4 meV. At the same time a sharp magnetic response was found along the same (0.5, 0.5, L) direction over a wide range of L-values at energy transfer of 10-25 meV. This dynamic magnetic responses indicates on a 2-D character of antiferromagnetic spin fluctuations in the superconducting phase, in strong contrast to the 3-D static antiferromagnetism in the undoped non-superconducting BaFe2As2. Thus, in Fe-As based superconductors magnetism shows strong sensitivity to the lattice, suggesting a possibility of spin-phonon coupling playing a role in superconductivity.

4:06PM T35.00009 3d crystal field excitations in iron pnictides studied by Raman spectroscopy, TAO ZHOU, ZHEN QIN, SEAN O’MALLEY, KWOK LO, New Jersey Institute of Technology, CHENG LIN ZHANG, SANG-WOOK CHEONG, Rutgers University — We have measured the Raman spectra of LaFeAsO1-xFx (x = 0, 0.1 and 0.33) as well as A2Fe2As2 (A = Ca, Sr, Ba) polycrystalline samples at different temperatures. We found that in addition to the phonon excitations at low frequency below 250 cm\(^{-1}\), there are many strong excitations in the range between 250 cm\(^{-1}\) and 1000 cm\(^{-1}\). We attribute them to the crystal field excitations of Fe 3d electrons. This down turn in the Cp/T vs. T\(^2\) plot, however, is suppressed in both poly-crystal samples and under high fields. We attribute this feature to the crystal field excitations of Fe 3d electrons.

4:18PM T35.00010 Evidence for two gaps from specific heat in LiFeAs single crystals, FENGYAN WEI, Texas Center for Superconductivity at University of Houston and Department of Physics, BING LV, Texas Center for Superconductivity at University of Houston and Department of Physics — We have measured the Raman spectra of LaFeAsO1-xFx (x = 0, 0.1 and 0.33) as well as A2Fe2As2 (A = Ca, Sr, Ba) polycrystalline samples at different temperatures. We found that in addition to the phonon excitations at low frequency below 250 cm\(^{-1}\), there are many strong excitations in the range between 250 cm\(^{-1}\) and 1000 cm\(^{-1}\). We attribute them to the crystal field excitations of Fe 3d electrons. This down turn in the Cp/T vs. T\(^2\) plot, however, is suppressed in both poly-crystal samples and under high fields. We attribute this feature to the crystal field excitations of Fe 3d electrons.

4:30PM T35.00011 Coexistence of superconductivity and ferromagnetism in BaFe1.8Co0.2As2, MARIO S. DA LUZ, Montana State University, R. K. BOLLINGER, Montana State University, J. J. NEUMEIER, Montana State University, A. SEFAT, M. A. MCGUIRE, R. JIN, B. C. SALES, M. MANDRUS, Oak Ridge National Laboratory — Thermal expansion and heat capacity measurements were performed on three single crystals of BaFe1.8Co0.2As2 with superconducting transition temperatures \(T_c = 16.5, 19, \) and 22 K. The thermal expansion coefficients \(\gamma_i\) (i = a, b, c) were determined. Magnetization measurements reveal the presence of ferromagnetism at the same temperature transition as superconductivity in some of the samples. The ferromagnetism has a small moment on the order of 0.5x10\(^{-3}\) \(\mu_B/\text{Fe (Bohr magneton)}\). Thus, two phases: superconductivity and magnetism coexist in some BaFe1.8Co0.2As2 samples. This ferromagnetism could be associated with a canted (non- collinear) antiferromagnetic order. This material is based upon work supported by the U. S. Department of Energy (DE-FG02-07ER46259) and the National Science Foundation (DMR-050476 and DMR-052458).

4:42PM T35.00012 Comprehensive Characterization of Superconductivity in Co-doped BaFe2As2, TSUYOSHI TAMEGAI, YASUYUKI NAKAJIMA, TOSHIHIRO TAEN, Dep. of Appl. Physics, The University of Tokyo — We have grown high-quality single crystals of BaFe2As2 by self-flux method. Superconducting properties of these single crystals are characterized by measuring magnetization, resistivity, upper critical field, Hall coefficient, and magneto-optical images. A sharp drop of susceptibility is observed around 24 K for x=0.1. Irreversible magnetization shows fish-tail feature in a wide temperature range, indicating the presence of inhomogeneities in the crystal. The critical current density \(J_c\) for \(x=0.1\) is over \(10^6\) A/cm\(^2\) at low temperatures up to 50 K. Upper critical field determined by resistive transition is anisotropic with anisotropic \(J_c\). Hall effect measurements indicate that \(BaFe_{1-x}Co_xAs_2\) is a multiband system with a dominant conduction by electron. Magneto-optical image for \(x=0.1\) at 25 K reveals the presence of trapped vortices in a part of the crystal, which leads us to expect that bulk superconductivity above 25 K can be realized by fine tuning the Co-doping level.

4:54PM T35.00013 Superconductivity in Sr(Fe,Ni)2As2 single crystals, NICHOLAS BUTCH, SHANTA SAHA, KEVIN KIRSHENBAUM, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Dept. of Physics, University of Maryland, College Park — Iron pnictide compounds are the subject of intense research efforts because of their relatively high superconducting critical temperatures and the interplay of magnetic, structural, and superconducting phases found in these materials. Of the known superconducting iron pnictide compounds, those with the ThCr2Si2 structure appear to have the best chemical homogeneity. We present transport, magnetic, and specific heat measurements of Ni-substituted SrFe2As2 flux-grown single crystals.

In the established LDA+ experimental values. The implementation within the KKR band structure method. density approximation method, implemented within multiple scattering theory. We briefly describe the formalism and discuss important technical issues of its

Laboratory, UK — In this work we study the electronic structure of 3d-transition metal oxides as obtained with the self-interaction corrected-local spin f positions of the occupied and unoccupied localized UC Sant Barbara, CA 93106 — Understanding the physics of f systems, characterized by the competition between itinerant (delocalized) and highly localized f-states, is regarded as a great challenge in condensed-matter physics today. As a first step towards a systematic ab initio understanding of f-electron systems, we apply many-body perturbation theory in the $G_0W_0$ approach based on LDA+$U$ ground state calculations ($G_0W_0$) to a selected set of lanthanide oxides (CeO$_2$ and Ln$_2$O$_3$ (Ln=lanthanide series)). These compounds have important technological applications, in particular in catalysis and microelectronics. We demonstrate good agreement between the $G_0W_0$ density of states (DOS) and experimental spectra for CeO$_2$ and Ce$_2$O$_3$. For the whole Ln$_2$O$_3$ series $G_0W_0$ reproduces all main features found for the optical experimental band gaps. Inspection of the DOS reveals that the relative positions of the occupied and unoccupied f-states predicted by $G_0W_0$ confirm the experimental conjecture derived from phenomenological arguments.

2:30PM T36.00001 New approach on calculating Green’s functions in Full-Potential Multiple Scattering Methods. AURELIAN RUSANU, Oak Ridge National Laboratory, YANG WANG, Pittsburgh Supercomputing Center, G. M. STOCKS, Oak Ridge National Laboratory, JOHN S. FAULKNER, Florida Atlantic University — The most common methods of computing Green’s functions in modern full-potential multiple scattering applications rely on solving Schrödinger (Dirac) equations for regular and irregular solutions of a single-site scatterer over an energy contour in the complex plane. While, for spherical potentials, the standard formulae for calculating the Green’s function are numerically stable they often result in unphysical behavior for non-spherical potentials, particularly close to the nucleus and for large angular momentum quantum numbers. Here we use a new analytical and numerical method that does not require calculation of the irregular solution, to which the numerical instability can be traced. The new approach results in the correct analytic behavior and numerical stability.

2:42PM T36.00002 Local excitations in charge-transfer insulators: a super atom approach via Wannier functions CHI-CHENG LEE, WEIGUO YIN, Brookhaven National Laboratory, WEI KU, Brookhaven National Laboratory and SUNY Stony Brook University — Local excitations in strongly correlated charge-transfer insulator are very often tied to the rich functionalities of these materials. However, these tightly bound local excitations prove to be difficult to calculate from first-principles. In particular, the strong local interactions render the typical first-principles perturbation approach (via diagrammatic Bethe-Salpeter equation) inapplicable to describe the multiplets. In this talk, our recent progress in evaluating the local excitations in NIO will be presented. Utilizing the gauge freedom of the Wannier functions, the oxygen (charge-transfer) degrees of freedom can be integrated into a “super atom”, in which the strong local interactions can be incorporated on the equal footing as the strong coupling between the oxygen p- and Ni d- orbitals. Our results lead to good agreement with recent non-resonant inelastic X-ray scattering data [1] and the cluster calculation [2] for both q-dependence and excitation energies. Finally, extension to propagation of the local excitation will be addressed to include the dispersion in momentum space.

1Supported by the DOE and the Division of Scientific User Facilities U.S. DOE.

2:54PM T36.00003 Self-healing diffusion quantum Monte Carlo algorithms: Theory and Applications F.A. REBOREDO, P.R.C. KENT, M.L. TIAGO, Oak Ridge National Laboratory, R.Q. HOOD, Lawrence Livermore National Laboratory — We present a method to obtain the fixed node ground state wave function from an importance sampling Diffusion Monte Carlo (DMC) run. The fixed node ground state wave-function is altered to obtain an improved trial wave-function for the next DMC run. The theory behind this approach will be discussed. Two iterative algorithms are presented and validated in a model system by direct comparison with full configuration interaction (CI) wave functions and energies. We find that the trial wave-function is systematically improved. The scalar product of the trial wave-function with the CI result converges to 1 even starting from wave-functions orthogonal to the CI ground state. Similarly, the DMC total energy and density converges to the CI result. In the optimization process we find an optimal non-interacting nodal potential of density-functional-like form. An extension to a model system with full Coulomb interactions demonstrates that we can obtain the exact Kohn-Sham effective potential from the DMC data. Subsequently we apply our method to real molecules such as benzene and find that we can improve the ground state energy as compared with the single determinant result even starting from random wave-functions. Results for other molecular systems and comparison with alternative methods will be presented.

3:06PM T36.00004 Removal of residual nonspherical self-interaction error in LDA+$U$ FEI ZHOU, VIDVUDS OZOLINS, UCLAn — In the established LDA+$U$ method, the electron self-interaction, which is generally nonspherical and orbital-dependent, is removed in a mean-field way. This results in residual self-interaction errors, particularly pronounced for f-electrons. An alternative double counting scheme that modifies the exchange, not Hartree, energy of LDA is proposed as a remedy. We show that LDA+$U$ with our approach preserves the expected degeneracy of f$^1$ and f$^2$ states in free ions and the correct ground states in the PrO$_2$ solid.

3:18PM T36.00005 The f-electron challenge: localized and itinerant states in lanthanide oxides united by GW@LDA+$U$ MATTHIAS SCHEFFLER, HONG JIANG, RICARDO I. GOMEZ-ABAL, FHI, Berlin, Germany, PATRICK RINKE, UC San Barbara, CA 93106 — Understanding the physics of f-electron systems, characterized by the competition between itinerant (delocalized) and highly localized f-states, is regarded as a great challenge in condensed-matter physics today. As a first step towards a systematic ab initio understanding of f-electron systems, we apply many-body perturbation theory in the $G_0W_0$ approach based on LDA+$U$ ground state calculations ($G_0W_0$) to a selected set of lanthanide oxides (CeO$_2$ and Ln$_2$O$_3$ (Ln=lanthanide series)). These compounds have important technological applications, in particular in catalysis and microelectronics. We demonstrate good agreement between the $G_0W_0$ density of states (DOS) and experimental spectra for CeO$_2$ and Ce$_2$O$_3$. For the whole Ln$_2$O$_3$ series $G_0W_0$ reproduces all main features found for the optical experimental band gaps. Inspection of the DOS reveals that the relative positions of the occupied and unoccupied f-states predicted by $G_0W_0$ confirm the experimental conjecture derived from phenomenological arguments.

3:30PM T36.00006 Self-interaction correction in multiple scattering theory — Application to transition metal oxide MARKUS DAENE, Oak Ridge National Lab, WOLFRAM HERGERT, Martin Luther University Halle, Germany, ARTHUR ERNST, Max Planck Institute for Microstructure Physics, Halle, Germany, MARTIN LUEDERS, ZDZISLAW SZOTEK, WALTER TEMMERMAN, Daresbury Laboratory, UK — In this work we study the electronic structure of 3d-transition metal oxides as obtained with the self-interaction corrected-local spin density approximation method, implemented within multiple scattering theory. We briefly describe the formalism and discuss important technical issues of its implementation within the KKR band structure method. We present results of such important properties as lattice constants, local magnetic moments, band gaps and discuss them in comparison with the LSD and the experimental values.
3:42PM T36.00007 Computational Modeling of Actinide Complexes Pertinent to Environment — KRISHNAN BALASUBRAMANIAN, Lawrence Livermore National Lab — We discuss computational projects relevant to actinide separation, complexes and the possibility of actinide sequestration by engineered mesoporous materials. We have carried out computational studies on a number of actinide complexes in aqueous solution; as such complexes are of considerable importance in our understanding of behavior of actinide species in the environment and high level nuclear waste, especially experimental-theoretical collaboration on curium (III) complexes with multi-dentate ligands with Nitsche and coworkers at LBLNL. Cu(III) complexes with phosphonic acid (PFA) were studied for assessing relative binding strengths of the two ligands with varying pH. Possible isomers of CmH2PPA2+ and CmHPPA+ 13C NMR spectra and bond geometry will be discussed. The effects of the aqueous solvent in the configuration preferences of CmH2PPA2+ and We have also studied aqueous complexes of U(VI), Np(VI) and Pu(VI) with OH-. We will discuss the results of our extensive ab initio computations on the equilibrium structure, infrared spectra, and bonding characteristics of a variety of hydrated NpO2(CO3)3^2- complexes by considering the solvent as a polarizable dielectric continuum as well as the corresponding anhydrate complexes in the gas-phase. The work at CSU Eastbay was supported in part by Office of Basic Energy Sciences of DOE, and the work at LLNL was carried out under contract number W-7405-Eng-48.

3:54PM T36.00008 The converse approach to NMR chemical shifts from first-principles: application to finite and infinite aromatic compounds — T. THONHAUSER, Wake Forest University, D. CERESOLI, N. MARZARI, MIT — We present first-principles, density-functional theory calculations of the NMR chemical shifts for polycyclic aromatic hydrocarbons, starting with benzene and increasing sizes up to the one- and two-dimensional infinite limits of graphenic ribbons and graphene. These calculations are performed using a combination of the recently developed theory of orbital magnetization in solids, and a novel approach to NMR calculations where chemical shifts are obtained from the derivative of the orbital magnetization with respect to a microscopic, localized magnetic dipole. Using these methods we study on equal footing the 1H and 13C shifts in benzene, pyrene, coronene, in naphthalene, anthracene, naphthacene, and pentacene, and finally in graphene, graphite, and an infinite graphene ribbon. Our results show very good agreement with experiments and allow us to characterize the trends for the chemical shifts as a function of system size.

4:06PM T36.00009 NMR chemical shifts from first-principles using the converse approach in periodic boundary conditions — DAVIDE CERESOLI, TIMO THONHAUSER, MIT, NICOLA MARZARI — An alternative, converse approach to the first-principles calculation of NMR shielding tensors can be formulated where NMR chemical shift are obtained from the derivative of the orbital magnetization with respect to the application of a microscopic, localized magnetic dipole. We apply here the modern theory of orbital magnetization to validate this formalism to the case of extended systems in periodic boundary conditions, finding very good agreement with established methods and experimental results. These results underscore the advantages of the converse approach over existing methods: (1) it can be applied to either isolated or periodic systems, (2) it avoids any linear response calculation, allowing to treat systems containing hundreds of atoms, and (3) it is not plagued by the gauge-origin problem.

4:18PM T36.00010 MP2 and RPA applied to solid state systems 1 — MARTIJN MARSMAN, Faculty of Physics, University Vienna, ANDREAS GRUENEIS, JUDITH HARL, GEORG KRESSE — We present ab initio total energy calculations at the level of Hartree-Fock + 2nd-order Møller-Plesset perturbation theory (HF+MP2), and the random-phase-approach within the framework of the adiabatic-fluctuation-dissipation-theorem (ACFDT-RPA), for extended systems under periodic boundary conditions, using plane wave basis sets. We characterize and compare the accuracy of these methods with respect to their description of the lattice constants, bulk moduli, and atomizations energies of several archetypical solid state systems. Furthermore, we present calculations of HF+MP2 quasiparticle gaps and compare them to results obtained within the GW approximation to the electronic self-energy.

4:30PM T36.00011 Bridging the size gap between density-functional and many-body perturbation theory — PAOLO UMARI, CNR-INFM Dimocritos — The calculation of quasi-particle spectra based on the GW approximation is extended to systems of hundreds of atoms and the calculation of empty states is avoided. This is achieved through an optimal strategy, based on the use of Wannier-like orbitals, for obtaining a basis for the polarization propagator. Then, a Lanczos chain approach permits to calculate the self-energy. Our method is validated by calculating the vertical ionization energies of the benzene molecule and the band structure of crystalline silicon. Its potentials are then demonstrated by addressing the quasi-particle spectrum of models of vitreous materials, as well as of large organic molecules.

4:42PM T36.00012 Quasiparticle properties of DNA bases from GW calculations in a Wannier basis — XIAOFENG QIAN, NICOLA MARZARI, Department of Materials Science and Engineering, MIT, PAOLO UMARI, Theory at Elettra Group, CNR-INFM Dimocritos, Basovizza (Trieste), Italy — The quasiparticle GW-Wannier (GWW) approach [1] has been recently developed to overcome the size limitations of conventional GW and wave function calculations. By taking advantage of the localized properties of the maximally-localized Wannier functions and choosing a small set of polarization basis we reduce the number of Bloch wavefunctions products required for the evaluation of dynamical polarizabilities, and in turn greatly reduce memory requirements and computational efficiency. We apply GWW to study quasiparticle properties of different DNA bases and base-pairs, and solvation effects on the energy gap, demonstrating in the process the key advantages of this approach. [1] Umari, G. Stenuit, and S. Baroni, cond-mat/0811.1453

5:06PM T36.00013 Reliable Prediction of Charge Transfer Excitations in Molecular Complexes — LEEOR KRONIK, Weizmann Institute of Science, Israel, TAMAR STEIN, ROI BAER, Hebrew University of Jerusalem, Israel — We show how charge transfer excitations at molecular complexes can be calculated quantitatively using time-dependent density functional theory (DFT). Predictive power is obtained from range-separated hybrid functionals using non-empirical tuning of the range-splitting parameter. Excellent performance of this approach is obtained for a series of complexes composed of various aromatic donors and the tetracyanoethylene (TCNE) acceptor, paving the way to systematic non-empirical quantitative studies of charge-transfer excitations in real systems.

5:06PM T36.00014 Transcorrelated method applied to solids: numerical assessment of the SCF effect — KEITARO SODEYAMA, University of Tokyo, KEI SAKUMA, Chiba University, SHINJI TSUJIEYUKI, University of Tokyo — To calculate the electronic structures of solids including electron correlation effects, we have developed the transcorrelated (TC) method which was first proposed by Boys and Handy. In the TC method, the wave function is represented by a correlated wave function FΦ, where Φ is a single Slater determinant and F is a Jastrow function, F = exp[− Σ ij ρij uij]. uij is a two-body function called Jastrow factor. The many-body Hamiltonian H is similarity transformed to an effective Hamiltonian H_TC = F−1HF with up-to-three-body interaction. One-electron orbitals and their orbital energies are optimized by solving a set of Hartree-Fock (HF)-like single particle equations derived by minimizing the variance of the H_TC. In this study, we have investigated the effect of the self-consistent field (SCF) approach which was used in solving the HF-like single particle equations in the TC method. For this purpose, band gaps of Si, SiC, and LiF were calculated as a one-shot perturbation by using the unperturbed LDA orbitals as initial guess orbitals. The difference between the one-shot TC and conventional SCF TC results is small for Si but large for SiC, and especially large for LiF. From this result, we found that the SCF effect was important for strongly polarized solids such as LiF because the initial LDA orbitals were poorly described for such polarized solids.

Wednesday, March 18, 2009 2:30PM - 4:30PM — Session T37 DCP: Focus Session: Structure and Dynamics of Interfacial Water III

2:30PM T37.00001 Study of Water Adsorbed on the Cu(110) Surface using Scanning Tunneling Microscopy and Electron Stimulated Desorption Ion Angular Distribution, JUNSEOK LEE, Department of Chemistry, University of Virginia — The structure of water layer on the Cu(110) surface formed via hydrogen bonding has been investigated with scanning tunneling microscopy (STM), electron stimulated desorption ion angular distribution (ESDIAD), and density functional theory (DFT) calculations. STM results revealed 1D chain and 2D island growth at low temperature (~80 K) and at low coverage regime. ESDIAD results at low coverage indicate that there are two kinds of O-H bonds of water molecules that are pointing out of the surface plane. At higher coverage the two-dimensional islands of water prevail, eventually covering the whole surface at the saturation coverage. Dynamic changes in the structure of the water layer and the local O-H bond direction have also been investigated as a function of annealing temperature. Using DFT calculation, a model of the 1D chain structure will be presented.

3:06PM T37.00002 Theoretical description of excited state dynamics in nanostructures1, ANGEL RUBIO, Nano Bio spectroscopy group and ETSF, Universidad del Pais Vasco and Centro Mixto CSIC-UPV/EHU — There has been much progress in the synthesis and characterization of nanostructures however, there remain immense challenges in understanding their properties and interactions with external probes in order to realize their tremendous potential for applications (molecular electronics, nanoscale opto-electronic devices, light harvesting and emitting nanostructures). We will review the recent implementations of TDDFT to study the optical absorption of biological chromophores, one-dimensional polymers and layered materials. In particular we will show the effect of electron-hole attraction in those systems. Applications to the optical properties of solvated nanostructures as well as excited state dynamics in some organic molecules will be used as text cases to illustrate the performance of the approach. Work done in collaboration with A. Castro, M. Marques, X. Andrade, J.L Alonso, Pablo Echenique, L. Wirtz, A. Marini, M. Gruning, C. Rozzi, D. Varsano and E.K.U. Gross.

1Work supported by Spanish MEC(FIS2007-65702-C02-01), Grupos Consolidados UPV/EHU of the Basque Country Government (IT-319-07) EC e-I3 ETSF and NANOQUANTA projects.

3:42PM T37.00003 Interfacial water in electric field1, ALENKA LUZAR, Department of Chemistry, Virginia Commonwealth University (VCU), D. BRATKO, Department of Chemistry, VCU and Department of Chemical Engineering, UC Berkeley, C.D. DAUB, Department of Chemistry, VCU — As accessible experimental length scales become shorter, the modification of interfacial properties of water using electric field (electrowetting) must come to grips with novel effects existing at the nanoscale. I will briefly survey some of our recent progress we have made in understanding these effects using molecular simulations.

1Supported by NSF

3:54PM T37.00004 Molecular Simulation of Reverse Micelles1, JANAMEJAYA CHOWDHARY, BRANKA LADANYI, Department of Chemistry, Colorado State University — Reverse micelles (RM) are surfactant assemblies containing a nanosized water pool dissolved in a hydrophobic solvent. Understanding their properties is crucial for insight into the effect of confinement on aqueous structure, dynamics as well as physical processes associated with solutes in confinement. We perform molecular dynamics simulations for the RM formed by the surfactant Aerosol-OT (AOT) in isooctane (2,2,4-trimethyl pentane) in order to study the effect of reverse micelle size on the aqueous phase. The structure of the RM is quantified in terms of the radial and pair density distributions. Dynamics are studied in terms of the mean squared displacements and various orientational time correlation functions in different parts of the RM so as to understand the effect of proximity to the interface on aqueous dynamics. Shape fluctuations of the RM are also analyzed.

1NSF

4:06PM T37.00005 Ti-O bond distance fluctuations at the hydrated rutile (110) surface, NITIN KUMAR, Department Of Physics, Penn State University, PAUL KENT, ORNL, DAVID COLE, DAVID WESOLOWSKI, Chemical Sciences Division, ORNL, JAMES KUBICKI, Department of Geosciences, The Pennsylvania State University, JORGE SOFO, Department of Physics, The Pennsylvania State University — We studied water on the rutile (110) surface using ab-initio molecular dynamics simulations in NVT ensemble at 280K, 300K, and 320K. Water adsorbs on the 5-fold coordinated titanium atoms or dissociates transferring a proton to a bridging-oxygen atom. The equilibrium between these configurations is dynamical and depends on temperature and water coverage. The titanium-oxygen bond distances at the surface can change as much as 12% depending on the number of hydrogen atoms bonded to oxygen. Hydrogen bonds also affect this distance. A measurement of the Ti-O distance at the surface can be used to estimate the average degree of dissociation. In view of our simulation results, the experimental evidence, such as photoelectron diffraction, indicates a low degree of dissociation under dry conditions.
The TiO$_2$ surface, JIN ZHAO, Dept. of Physics and Astronomy, Univ. of Pittsburgh, KENNETH JORDAN, Dept. of Chemistry, Univ. of Pittsburgh, JINLONG YANG, Hefei Natl. Lab. for Physical Sciences at Microscale, Univ. of Science and Technology of China, HRVOJE PETEK, Dept. of Physics & Astronomy, Univ. of Pittsburgh — At metal-oxide/protic-solvent interfaces, partially hydrated or “wet electron” states represent the lowest energy pathway for electron transfer. Through a joint two-photon photoemission (2PP) experiment and density function theory (DFT) study, we identified the electronic states corresponding to the partially solvated or wet electron state in H$_2$O overlayers on rutile TiO$_2$(110) surface. We find that a network of dangling H atoms can stabilize photoexcited electrons, in so-called wet-electron states. The energies of the “wet electron” states correlate closely with the number and configuration of the dangling H atoms involved in stabilizing them. We also performed DFT calculations of H$_2$O and H covered anatase (101) surface. Comparing with rutile (110), anatase (101) surface accommodates weaker H$_2$O molecule-surface hydrogen bonding. Our calculated wet electron state on anatase (101) surface has a lower energy than on rutile. Moreover, the longer distance between the adjacent adsorbate sites and the lower binding energy of H$_2$O allow for greater freedom for the adsorbed molecules to undergo structural relaxation in solvation of injected electrons. These differences might contribute to the higher photocatalytic activity of anatase compared with rutile. [1] K. Onda B. Li, J. Zhao, K.D. Jordan, J. Yang and H. Petek, Science 308, 1154 (2005).

Wednesday, March 18, 2009 2:30PM - 5:06PM – Session T38 DCP: Focus Session: The Transition State in Physics, Chemistry, and Astrophysics

2:30PM T38.00001 Transition State Theory for Higher-Rank Saddles, GEORGE HALLER, Massachusetts Institute of Technology & Morgan Stanley — Recent developments in transition state theory have lead to a geometric characterization of molecular reactions in phase space. Central to this new characterization is the existence of codimension-one surfaces in the energy shell; these invariant surfaces guide reactiv trajectories through sections of no return, the transition states. The existence of codimension-one invariant surfaces has only been shown in the vicinity of rank-one saddles, i.e., near fixed points with one stable and one unstable direction in addition to neutrally stable directions. For higher-rank saddles, the current framework of geometric transition state theory has remained inapplicable. Here we describe a generalization of the theory to saddles of arbitrary rank. As an application, we describe the nonsequential ionization of helium atoms, a problem with a rank-two saddle.

3:06PM T38.00002 Exploring Topographies and Dynamics on Many-Dimensional Landscapes, R. STEPHEN BERRY, The University of Chicago — A major challenge to understanding and using kinetics is finding the relationships between the topography of the many-dimensional potential energy landscape (or landscapes, for systems with multiple accessible electronic states) and the way that topography, local and large-scale, determines how systems change their structures, relax and anneal. One major difficulty is simply the complexity of the landscape: one is forced to work with small statistical samples of the surface; how should these samples best be chosen? What characteristics of the topography provide the most important information? Another: how does the nature of the interparticle forces determine the topography and hence the character of motion on the surface? And what are the most useful diagnostic tools to tell us about that behavior? We shall address these questions, more in terms of progress toward, rather than providing definitive answers.

3:42PM T38.00003 Transition State Theory: The Phase Space Perspective, TURGAY UZER, Georgia Institute of Technology — Transition State Theory (TST), which is at the basis of chemical reactivity calculations, assumes that once reactants pass through the Transition State, they cannot return. This “no-recrossing” rule serves to define the TS and is a necessary assumption in TST. Conventional transition states always lead to overestimates of the reaction rate because each intersection of the trajectory with the TS counts as a reactive event. Enforcing this no-recrossing condition beyond two degrees of freedom has been the major obstacle to applying TST in multidimensional systems. We will explain the solution of this problem based on dynamical systems theory.

4:18PM T38.00004 Phase Space Transition States for Deterministic Thermostats, GREGORY EZRA, Cornell University, STEPHEN WIGGINS, Bristol University — We describe the relation between the phase space structure of Hamiltonian and non-Hamiltonian deterministic thermostats. We show that phase space structures governing reaction dynamics in Hamiltonian systems, such as the transition state, map to the same type of phase space structures for the non-Hamiltonian isokinetic equations of motion for the thermostatted Hamiltonian. Our results establish a general theoretical framework for analyzing thermostat dynamics using concepts and methods developed in reaction rate theory. Numerical results are presented for the isokinetic thermostat.

4:30PM T38.00005 Using invariant manifolds to classify chaotic transport pathways in mixed phase space, KEVIN MITCHELL, University of California Merced — We describe how the topological structure of stable and unstable manifolds embedded within a chaotic phase space can be used to extract a symbolic classification of chaotic transport and escape pathways. We pay particular attention to phase spaces that contain a mixture of both chaos and regularity. For such systems, the dynamics in the vicinity of “stable islands” is known to be particularly troublesome to analyze. We describe a technique that utilizes the structure of invariant manifolds in the vicinity of such stable islands to extract a symbolic model for the islands’ influence on the transport process. Though our analysis focuses on Hamiltonian systems of two degrees-of-freedom, we also discuss the extension of our technique to higher dimensional phase spaces.

4:42PM T38.00006 Transition State Theory: Variational Formulation, Dynamical Corrections, and Error Estimates, ERIC VANDEN-EIJNDEN, Courant Institute — Transition state theory (TST) is discussed from an original viewpoint: it is shown how to compute exactly the mean frequency of transition between two predefined sets which either partition phase space (as in TST) or are taken to be well separate metastable sets corresponding to long-lived conformational states (as necessary to obtain the actual transition rate constants between these states). Exact and approximate criteria for the optimal TST dividing surface with minimum recrossing rate are derived. Some issues about the definition and meaning of the free energy in the context of TST are also discussed. Finally precise error estimates for the numerical procedure to evaluate the transmission coefficient $\kappa_S$ of the TST dividing surface are given, and it shown that the relative error on $\kappa_S$ scales as $1/\sqrt{\kappa_S}$ when $\kappa_S$ is small. This implies that dynamical corrections to the TST rate constant can be computed efficiently if and only if the TST dividing surface has a transmission coefficient $\kappa_S$ which is not too small. In particular the TST dividing surface must be optimized upon (for otherwise $\kappa_S$ is generally very small), but this may not be sufficient to make the procedure numerically efficient (because the optimal dividing surface has maximum $\kappa_S$, but this coefficient may still be very small).

1We are grateful to the US National Science Foundation for their support of this research.

3Supported by NSF grant PHY-0748828.
The time scale to escape from this metastable state is exponentially large. In both cases, our result fit with experimental measurements pretty well.

When the Gag-Gag attraction is relatively high, the membrane elastic energy provides a kinetic barrier for the two pieces of the partial capsids to merge. This slow and effectively trapped partial budding process, by varying the attractive energy of retroviral proteins (call Gags), relative to the membrane elastic energy.

The budding and assembly is effectively trapped at local free energy minimum, corresponding to a partially budded state. The energy barrier, but a free energy barrier. Energy barriers in biochemical processes are often significant even for reactions proceeding at room temperature因为分子的热运动，使分子不相的势垒成为有效不可逾越。The budding of viruses with varying membrane elasticity creates such a kinetic barrier, as the retroviral proteins (Gag) have higher affinities at higher temperatures. slower budding process is observed, consistent with the experimental observations. This suggests that the budding event is significantly influenced by the membrane elasticity.

The budding and assembly of retroviruses, including HIV, is a complex process that involves the interaction between the viral proteins and the host cell membrane. The budding process is influenced by various factors, including the membrane elasticity, the temperature, and the relative affinities of the viral proteins. Understanding these interactions is crucial for the development of antiviral therapies.

We thank the NIH CHEETAH center grant for financial support.

3:06PM T39.00002 How viral capsids adapt to mismatched cargoes: identifying mechanisms of morphology control with simulations

3:30PM T39.00004 Mechanisms of viral capsid assembly around a polymer

3:42PM T39.00005 Kinetics of human immunodeficiency virus budding and assembly

2:30PM T39.00001 Stochastic modeling of virus capsid assembly pathways

We present a coarse-grained computational model inspired by the assembly of viral capsid proteins around functionalized nanoparticles. With this model, we find parameter values for which subunits faithfully form empty capsids with a single morphology, but adaptively assemble into different icosahedral morphologies around nanoparticles with different diameters. Analyzing trajectories in which adaptation is or is not successful sheds light on the mechanisms by which capsid morphology may be controlled in vitro and in vivo, and suggests experiments to test these mechanisms. We compare the simulation results to recent experiments in which Brome Mosaic Virus capsid proteins assemble around functionalized nanoparticles, and describe how future experiments can test the model predictions.

3:06PM T39.00002 How viral capsids adapt to mismatched cargoes: identifying mechanisms of morphology control with simulations

1Supported by HHMI.

3:18PM T39.00003 The role of protein interactions in HIV-1 Capsid Shape and Stability: A Multiscale Analysis

A coarse grained model of the HIV-1 CA dimer is constructed based on all-atom molecular dynamics simulations of the C-Terminal capsid dimer. Systematic approaches to identify coarse graining sites within the dimer are presented, and the relationship of the coarse grained model parameters to atomistic properties of the capsid discussed. Coarse grained representations of the capsid shell are constructed and their stability examined. The critical importance of an additional carboxyl-hexameric amino terminal interaction is demonstrated. It is shown that this interaction is responsible for generating the curvature of the capsid shell. It is demonstrated that variation of the strength of this interaction for different proteins in the lattice can cause formation of asymmetric, conical shaped closed capsid shells and it is proposed that variations in the structure of the additional carboxyl-amino terminal binding interface during self assembly are critical to capsid cone formation.

3:30PM T39.00004 Mechanisms of viral capsid assembly around a polymer

Mechanisms of viral capsid assembly around a polymer

3:42PM T39.00005 Kinetics of human immunodeficiency virus budding and assembly

The budding of HIV is an essential process that allows the virus to infect new cells. The budding process is influenced by various factors, including the membrane elasticity, the temperature, and the relative affinities of the viral proteins. Understanding these interactions is crucial for the development of antiviral therapies.
3:06PM T39.00007 Exploring the remarkable limits of continuum elastic theory to understand the nanomechanics of viruses. WOUTER ROOS, Natuur- en Sterrenkunde, Vrije Universiteit, Amsterdam, MELISSA GIBBONS, WILLIAM KLUG, Department of Mechanical and Aerospace Engineering, UCLA. GIJS WUITE, Natuur- en Sterrenkunde, Vrije Universiteit, Amsterdam — We report nanindentation experiments by atomic force microscopy on capsids of the Hepatitis B Virus (HBV). HBV is investigated because its capsids can form in either a smaller T=3 or a bigger T=4 configuration, making it an ideal system to test the predictive power of continuum elastic theory to describe nanometre-sized objects. It is shown that for small, consecutive indentations the particles behave reversibly linear and no material fatigue occurs. For larger indentations the particles start to deform non-linearly. The experimental force response fits very well with finite element simulations on coarse grained models of HBV capsids. Furthermore, this also fits with thin shell simulations guided by the Föppl-von Kármán (FvK) number (the dimensionless ratio of stretching and bending stiffness of a thin shell). Both the T=3 and T=4 morphology are very well described by the simulations and the capsid material turns out to have the same Young’s modulus, as expected. The presented results demonstrate the surprising strength of continuum elastic theory to describe indentation of viral capsids.

4:18PM T39.00008 to be determined by you. JAMES CONWAY, TBD — No abstract available.

4:54PM T39.00009 Conformational changes of Gag HIV-1 on a lipid bilayer measured by neutron reflectivity provides insights into viral particle assembly. ROBBIN BRUINSMA, JOSEPH RUDNICK, Dept of Physics and Astronomy, UCLA. — The self-assembly of the protein shell (“capsid”) of a virus is believed to obey the Law of Mass Action (LMA) despite the fact that viral assembly is not a reversible process. In this paper we examine a soluble model for irreversible capsid assembly, the “Assembly-Line Model.” We show that, in this model, viral assembly from a supersaturated solution is characterized by a shock front propagating in the assembly configuration space from small to large aggregate sizes. If this shock front is able to reach the size of an assembled capsid, then transient state develops characterized by a “pseudo” LMA. This pseudo LMA describes partitioning of capsid proteins between assembled capsids and a metastable, supersaturated solution of free proteins that decays logarithmically slowly. We show that the line energy of assembly intermediates is the key parameter that determines this metastable state.

5:18PM T39.00011 A comparison of the elastic moduli of an animal and plant virus. D. GUI, X. CHEN, A.L.N. RAO, S. GILL, U. MOHIDDEEN, R. ZANDI, University of California, Riverside, CA — We have used Atomic Force Microscopy (AFM) to image single Sindbis and BMV viruses. The AFM was then used in force spectroscopy mode to measure their elastic Modulii. The similarities and differences will be discussed.

Wednesday, March 18, 2009 2:30PM - 5:06PM — Session T40 DBP: Focus Session: Knots and Loops in Biomolecules

2:30PM T40.00001 Dodging the crisis of folding proteins with knots. JOANNA SUŁKOWSKA, University of California, San Diego — Proteins with nontrivial topology, containing knots and slipknots, have the ability to fold to their native states without any additional external forces invoked. A mechanism is suggested for folding of these proteins, such as YbK and YbA, which involves an intermediate configuration with a slipknot. It elucidates the role of topological barriers and backtracking during the folding event. It also illustrates that native contacts are sufficient to guarantee folding in around 1-2% of the simulations, and how slipknot intermediates are needed to reduce the topological bottlenecks. As expected, simulations of proteins with similar structure but with knot removed fold much more efficiently, clearly demonstrating the origin of these topological barriers. Although these studies are based on a simple coarse-grained model, they are already able to extract some of the underlying principles governing folding in such complex topologies.

3:06PM T40.00002 Size and Shape of Knotted Polymers. ERIC RAWDON, University of St. Thomas — We use numerical simulations to investigate how the size and bulk of a filament change when it is self-avoiding, where the self-avoiding property is the main effect of knotting. In particular, we analyze different types of geometric containers that enable polymer configurations and describe the similarities and differences between them. This work has been done in collaborations with Akos Dobay, John Kern, Kenneth Millett, Michael Piatek, Patrick Plunkett, and Andrzej Stasiak.

3:18PM T40.00003 On the geometry of stiff knots. OLIVIER PIERRE-LOUIS, Oxford Theoretical Physics and LSP, Univ. J.Fourier, Grenoble — We report on the geometry and mechanics of knotted strings. We focus on the situation where the string is stiff (it has a large bending rigidity), and thin (its width is much smaller than its length). We find that: (i) the equilibrium energy depends on the type of knot as the square of the bridge number; (ii) braid localization is a general feature of stiff strings entanglements; (iii) there is an upper bound for the multiplicity of the braids and contact points in the ground state. (iv) Finally, a general confinement inequality is used to derive an upper bound on the knot gyration radius. We shall also discuss the asymptotic behavior of the knot when the filament width is small, both in the presence and in the absence of torsion (twist) energy. We conjecture a universal ground state geometry for thin strings with torsion rigidity in the presence of a large twists. Ref: R. Gallotti, O. Pierre-Loius, Phys. Rev. E 75, 031801 (2007).
3:30PM T40.00004 Conformation and Dynamics of Linear Chains, Circular and Partial Loops, JEN-FANG CHANG, Institute of Physics, Academia Sinica, YENG-LONG CHEN, Institute of Physics & Research Center for Applied Science, Academia Sinica. POLYMER PHYSICS & COMPLEX FLUIDS TEAM — Recent single molecule experiments have reported the diffusivity ratio between circular and linear DNA of the same molecular weight to be 1.3, between the ratio predict by renormalization group theory (1.45) and classical Kirkwood theory (1.18). In earlier light and neutron scattering measurements of synthetic polymers, the ratio has been reported to be around 1.1-1.2. Our work employs the Lattice-Boltzmann method with Brownian dynamics to examine the diffusivity ratio for a long chain (N=320). We also examined partially closed loops that are half-closed, quarter-closed, and eighth-closed with the same contour length. Just surprisingly, we find that the loop with the smallest radiiuses of gyration and the highest diffusivity is not the fully closed (circular) loop, but a partially-closed one.

3:42PM T40.00005 Modeling the behavior of DNA-loop-extruding enzymes, ELNAZ A. BAUM-SNOW, JOHN F. MARKO, Northwestern University — Condensins proteins are large complexes belonging to a family of ATP hydrolyzing proteins known as SMC (Structural Maintenance of Chromosomes). Condensins are believed to play a vital role in chromosomal assembly and segregation in eukaryotic cells but the details of their function along chromatin are poorly understood. Here, we propose a model to describe the behavior of DNA-loop-extruding proteins, such as type I restriction enzymes, which we believe can be used to understand condensin’s function. We assume an effective motor behavior for these enzymes in which the bias of the two dimer heads is to travel away from each other, which results in loop formation along the DNA lattice. Processivity causes the enzymes to stack on top of each other. We further discuss the results of theory and computer simulations for different values of motor bias and processivity.

3:54PM T40.00006 Intricate knots in proteins: statistics, function and evolution, PETER VIRNAU, Johannes Gutenberg University Mainz — Protein knots, mostly regarded as intriguing oddities, are gradually being recognized as significant structural motifs. These elusive knots are present in the backbone of only about 1 in 200 proteins. It is by and large unclear how these exceptional structures actually fold, and only recently, experiments and simulations have begun to shed some light on this issue. In this talk I will present an overview of these peculiar structures from the current version of the Protein Data Bank and discuss some particularly intriguing examples of this set as well as evolutionary and functional implications.

4:30PM T40.00017 The Role of Entropic Effects on DNA Loop Formation, DAVID WILSON, U of Michigan, ALEXEI TRACHENKO, University of Michigan, TODD LILLIAN, NOEL PERKINS, JENS CHRISTIAN MEINERS, University of Michigan — The formation of protein mediated DNA loops often regulates gene expression. Typically, a protein is simultaneously bound to two DNA operator sites. An example is the lactose repressor which binds to the Lac operator of E. coli. We characterize the mechanics of this system by calculating the free energy cost of loop formation. We construct a Hamiltonian that describes the change in DNA bending energy due to linear perturbations about the looped and open states, starting from a non-linear mechanical rod model that determines the shape and bending energy of the inter-operator DNA loop while capturing the intrinsic curvature and sequence-dependent elasticity of the DNA. The crystal structure of the Lac protein provides the boundary conditions for the DNA. We then calculate normal modes of the open and closed loops to account for the thermal fluctuations. The ratio of determinants of the two Hamiltonians yields the partition function, and the enthalpic and entropic cost of looping. This calculation goes beyond standard elastic energy models because it fully accounts for the substantial entropic differences between the two states. It also includes effects of sequence dependent curvature and stiffness and allows anisotropic variations in persistence length. From the free energy we then calculate the J-factor and ratio of loop lifetimes.

4:42PM T40.00008 Helical growth trajectories in plant roots interacting with stiff barriers, SHARON GERBODE, Physics Department, Cornell University, ROSLYN NOAR, MARIA HARRISON, Boyce Thompson Institute for Plant Research, Cornell University — Plant roots successfully navigate heterogeneous soil environments with varying nutrient and water concentrations, as well as a variety of stiff obstacles. While it is thought that the ability of roots to penetrate into a stiff lower soil layer is important for soil erosion, little is known about how a root actually responds to a rigid interface. We have developed a laser sheet imaging technique for recording the 3D growth dynamics of plant roots interacting with stiff barriers. We find that a root encountering an angled interface does not grow in a straight line along the surface, but instead follows a helical trajectory. These experiments build on the pioneering studies of roots grown on a tilted 2D surface, which reported “root waving,” a similar curved pattern thought to be caused by the root’s sensitivity to both gravity and the rigid surface on which it is grown. Our measurements extend these results to the more physiologically relevant case of 3D growth, where the spiral trajectory can be altered by tuning the relative strengths of the gravity and touch stimuli, providing some intuition for the physical mechanism driving it.

4:54PM T40.00009 The Penrose-Hameroff Orchestrated Objective-Reduction Proposal for Human Consciousness is Not Biologically Feasible, JEFFREY REIMERS, LAURA MCKEMMISH, NOEL HUSH, The University of Sydney, ROSS MCKENZIE, ALAN MARK, The University of Queensland — Penrose and Hameroff have argued that conventional models of brain function based solely on neural linear-computational elements cannot account for human consciousness, claiming instead that quantum-computation elements are required. We construct a Hamiltonian that describes the change in DNA bending energy due to linear perturbations about the looped and open states, starting from a non-linear mechanical rod model that determines the shape and bending energy of the inter-operator DNA loop while capturing the intrinsic curvature and sequence-dependent elasticity of the DNA. The crystal structure of the Lac protein provides the boundary conditions for the DNA. We then calculate normal modes of the open and closed loops to account for the thermal fluctuations. The ratio of determinants of the two Hamiltonians yields the partition function, and the enthalpic and entropic cost of looping. This calculation goes beyond standard elastic energy models because it fully accounts for the substantial entropic differences between the two states. It also includes effects of sequence dependent curvature and stiffness and allows anisotropic variations in persistence length. From the free energy we then calculate the J-factor and ratio of loop lifetimes.

Wednesday, March 18, 2009 2:30PM - 5:30PM — Session T41 DMP DCMP: Ferroelectricity and Structural Phase Transitions 413

2:30PM T41.00001 Strained enabled Ferroelectricity in CaTiO$_3$ Thin Films Probed by Non-linear Optics and Scanning Probe Microscopy, EFTIHIA VLHASO, AMIT KUMAR, SAVA DENEV, CHARLES BROOKS, Materials Science and Engineering, Pennsylvania State University, DARRELL SCHLOM, Materials Science and Engineering, Cornell University, CARL-JOHAN EKLUND, KARIN M. RABE, Department of Physics and Astronomy, Rutgers University, CRAIG J. FENNIE, Applied and Engineering Physics, Cornell University, VENKATARAMAN GOPALAN, Materials Science and Engineering, Pennsylvania State University — Calcium titanate, CaTiO$_3$, is not a ferroelectric in its bulk form. However, first principles calculations predict that biaxially tensile strained CaTiO$_3$ thin films should become ferroelectric. Here, we indeed confirm that strained CaTiO$_3$ films become ferroelectric with a Curie temperature of ~125K. Optical second harmonic generation (SHG) measurements, polarization studies, and in-situ electric-field measurements for a number of films with different strain values will be presented: CaTiO$_3$/DyScO$_3$(110), CaTiO$_3$/SrTiO$_3$(100), CaTiO$_3$/GdScO$_3$/NdGaO$_3$(110). CaTiO$_3$/LaSrAlO$_3$(001) as well as for a single crystal CaTiO$_3$. From these studies, we conclude that strained CaTiO$_3$ films are ferroelectric with a point group symmetry of mm2, and show reversible domain switching characteristics under an electric field. We also present results of variable temperature piezoelectric force microscopy for imaging the polar domains in the ferroelectric phase. These results suggest that strain is a valuable tool for inducing polar, long range ferroelectric order in even non-polar ceramic materials such as CaTiO$_3$. 
2:42PM T41.00002 Potential and piezoelectric response imaging of 180° domain of atomically ordered clean surfaces of BaTiO₃ single crystals in UHV, YUKIO WATANABE, Kyushu University, S. KAKU, D. MATSUMOTO, S.W. CHEONG, Rutgers Uinn. — We report the electrostatic and piezoelectric properties of the clean, free surface of BaTiO₃ single crystal in ultra high vacuum (UHV). The topographic imaging by AFM confirmed that the surface is atomically wellordered exhibiting clear one-lattice-height atomic steps. The amplitude and the phase image of piezoelectric response microscopy (PFM) identified 180° domains. The electrostatic potential mapping by Kelvin force microscopy (KFM) of these domains revealed that the shapes of the domains agreed exactly with the PFM images, which confirms the correctness of the standard 180° domain theory and agrees with closure domains. However, the potential difference of upward and downward domain is approx. 0.1V, which is 100 times smaller than the value estimated by the standard theory. Similar measurements with changing temperature across Curie temperature show that this result cannot be explained by the compensation of the spontaneous polarization by contamination or oxygen deficiency or ionic conduction. The present results suggest that an intrinsic electrostatic shielding mechanism exists for 180° domains, which is consistent with the reports of surface electron/ hole layers [1].

2:54PM T41.00003 Magnetic Color Symmetry of Lattice Rotations in a Non-magnetic Material, SAVA DENEV, A. KUMAR, M. D. BIELGALSKI, Pennsylvania State University, H. W. JANG, C. M. FOLKMAN, University of Wisconsin-Madison, A. VASUDEVARAO, Pennsylvania State University, Y. HAN, I. M. REANEY, University of Sheffield, S. TROLLEY-MCKINSTRY, Pennsylvania State University, C.-B. EOM, University of Wisconsin-Madison, D. G. SCHLOM, V. GOPALAN, Pennsylvania State University — Oxygen octahedral rotations are the most common phase transitions in perovskite crystal structures. Here we show that the color symmetry of such pure elastic distortions is isomorphic to magnetic point groups, which allows their probing through distinguishing polar versus magnetic symmetry. We demonstrate this isomorphism using nonlinear optical probing of the octahedral rotational transition in a compressively strained SrTiO₃ thin film that exhibits ferroelectric (4mm) and antiferrodistortive (1′4mn) phases evolving through independent phase transitions. The approach has broader applicability for probing materials with lattice rotations that can be mapped to color groups.

3:06PM T41.00004 Spontaneous polarization and piezoelectricity in polar molecular crystals, IVO BORRIELLO, University of Naples Federico II, Naples Italy, GIOVANNI CANTELE, CNR-COHERENTIA, University of Naples Federico II, Naples Italy, DOMENICO NINNO, GIUSEPPE IADONISI, University of Naples Federico II, Naples Italy — Molecular materials with a polar arrangement of the constituent dipoles are good candidates for exhibiting piezoelectric properties, directly related to the strain-induced polarization. The metal-organic molecular crystal (4-dimethylaminopyridyl)bis(acylacetato)zinc(II) (ZND) has been investigated from first principles. The spontaneous polarization and the piezoelectric properties have been studied by means of the modern theory of polarization, focusing on the relation between the piezoelectric properties of the organic crystal and the electronic properties of the polar molecule.

3:18PM T41.00005 Interfaces in ferroelastics: fringing fields, scaling, size and shape effects, TURAB LOOKMAN, Los Alamos National Laboratory — We consider the problem of determining the elastic fields and microstructure within a transformable region of size L, in which structural transformations from a parent to a product phase with variants can occur, that is surrounded by a fixed parent matrix. By demanding mechanical equilibrium and strain compatibility at the parent-product interface, we demonstrate that for sufficiently coarse twins the width of the twinned product phase varies as sqrt(L), but this breaks down if L is small enough for the surface and bulk energies to compete. As L decreases further, a transition to a stable checkboard pattern containing the parent and product variants occurs and this subsequently disappears if L is too small. We relate our findings to the behavior of transformations in nanograins of NiTi within an amorphous matrix and nanoscale checkboard microstructure seen in inorganic spinels. Understanding how microstructure emerges from a given configuration of interfaces is a non-trivial task and our overarching theme is to study the interplay of orientations, decaying strain fields, length scaling of energy and dependence of transition on size and shape of a transformable region within a parent matrix.

3:30PM T41.00006 Local Polarization Dynamics and Bias-Induced Phase Transitions in Ferroelectric Relaxors: Time-resolved Spectroscopy and Ergodic Gap Mapping, S.V. KALININ, B. RODRIGUEZ, M.P. NIKIFOROV, N. BALKE, S. JESSE, O.S. OVCHINNIKOV, A.A. BOKOV, Z.-G. YE, ORNL TEAM, SIMON FRAZER UNIV. TEAM — Mesoscopic domain structure and dynamics in PMN-PT sols solutions is studied using spatially resolved time- and voltage spectroscopic imaging modes. For compositions close to the MPB, we observe the formation of classical ferroelectric domains with rough self-affine boundaries. In the ergodic phase (PMN and PMN-10PT), the region of size L, in which structural transformations from a parent to a product phase with variants can occur, that is surrounded by a fixed parent matrix.

3:42PM T41.00007 Field Dependence of Glassy Freezing in a Relaxor Ferroelectric, MATTHEW DELGADO, EUGENE COLLA, MICHAEL WEISSMAN, University of Illinois at Urbana-Champaign, PHILIP GRIFFIN, University of Tennessee — Magnetic susceptibility measurements on the cubic relaxor ferroelectric (PbMg₁/₃Nb₂/₃O₃)₀.₉₈(PbTiO₃)₀.₁₂ were performed at various DC electric field strengths applied along the [111] direction. The temperature-frequency-dependencies fits the Vogel-Fulcher form, allowing the extraction of a frequency-independent glassy freezing temperature. These Vogel-Fulcher temperatures showed significant reductions in applied fields, following an empirical Gabay-Toulouse form, similar to vector spin glasses. The magnitude of the sensitivity indicates that the glassy state is formed by interactions among the same entities that account for the susceptibility, i.e. the polar nanoregions. This interpretation is supported by data on a powder sample of PbMg₁/₃Nb₂/₃O₃ (PMN), with grains too small to support large-scale inter-nanoregion cooperativity, in which the Vogel-Fulcher behavior is lost [1]. [1] J. Carreau et al., Appl. Phys. Lett. 92, 242902 (2008).

[1]Work performed in collaboration with M. Porta, T. Castan, P. Lloveras (U. of Barcelona), A. Saxena (LANL) and S. Shenoy (U. of Hyderabad).

3:54PM T41.00008 The three characteristic Temperatures of Relaxor Dynamics and their Meaning, JEAN TOULOUSE, Lehigh University — In this report, we compare the temperature evolution of several physical properties of the relaxor systems PZN, PMN and KTN. We show that three rather than two characteristic temperatures can be identified, Tₚ, T⁺ and T⁻, and discuss their meaning in light of dielectric, Raman and neutron scattering experimental results.

Ridge National Laboratory, USA — The transition metal dihydride TiH
study
we provide evidence for the presence of a continuous martensitic transition in the binary AuZn system. In AuNi,Zn, elastic neutron scattering
detects new commensurate Bragg peaks (modulation) appearing at \( Q = (1.33, 0.67, 0) \) at temperatures corresponding to each sample’s martensitic transition
temperature, \( T_M \). The pressure dependence of the transition in each alloy, shows a low-temperature saturation of the order parameter (strain-shuffle) that leads
to highly non-linear phase boundaries in temperature-pressure space and to superconductivity in the case of AuNi,Zn.

18PM T41.00010 First principles determination of phase transitions in magnetic shape memory alloys\(^1\), TILMANN HICKEL, MPI fuer Eisenforschung GmbH, MATTHE JUITTEWAAL, JOERG NEUGEBAUER — Magnetic shape memory alloys have recently attracted a lot of excitement, since they allow shape changes of more than 10% with a frequency in the kHz regime. The fundamental origin of this effect is related to a martensitic phase transition. The material system Ni\(_2\)MnGa is the most promising candidate for applications, but its operation temperatures and ductility still need to be improved. Hence, an extension of the currently very limited knowledge on the phase diagram is decisive. In order to identify the stable structures and their transitions we performed ab initio calculations of free energies for the austenite, the (modulated) pre-martensite and the unmodulated martensite. Quasiharmonic phonons and fixed-spin magnons are considered, employing density functional theory. Using this approach we were able to successfully describe the phase transition in detail, to reveal the involved delicate interplay of vibrational and magnetic excitations and to accurately
determine the transition temperature. The methods are used to interpret the experimental findings and to make predictions for modified material compositions.

4:30PM T41.00011 A fluctuation-based probe to criticality in structural transitions , U. CHANDNI, ARINDAM GHOSH, Department of Physics, Indian Institute of Science, Bangalore 560 012, H.S. VIJAYA, S. MOHAN, Department of Instrumentation, Indian Institute of Science, Bangalore 560 012 — Many natural phenomena, extending from biology to material science, involve slowly driven dissipative systems that are far from thermal equilibrium, triggered only by a slowly varying external field and to which the systems respond through scale-free avalanches in physical observables. In spite of decades of research, experiments are inconclusive whether these systems self organize to the critical state over a broad range of external field, or if there exists a unique critical point that is smudged by a wide critical zone. Here, through the higher order statistics of time dependent avalanches, or noise, in electrical resistivity during temperature-driven martensite transformation in thin nickel-titanium films, we demonstrate for the first time, the existence of a singular 'global instability' or divergence of the correlation length as a function of temperature. These results not only establish a mapping of non-equilibrium first order phase transition and equilibrium critical phenomena, but perhaps also call for a re-evaluation of many existing experimental claims of self-organized criticality. 4:42PM T41.00012 Structural transformations and dislocations within the Landau theory , ROMAN GRÖGER, TURAB LOOKMAN, AVADH SAXENA, Los Alamos National Laboratory — We propose a two-dimensional model (Gröger et al., PRB76:194101, 2008) that demonstrates how the Landau theory of first order phase transitions can be coupled with plasticity. It is based on Kröner’s continuum theory of dislocations that views each dislocation as a source of incompatibility between the components of the elastic strain tensor. This incompatibility then couples to the order parameter that is a local representation of the space group of the crystalline lattice. The order parameter field is obtained by minimizing the free energy and this provides both the stress fields and the Peach-Koehler forces on individual dislocations. The evolution of the dislocation density is then obtained by a Fokker-Planck equation. Updating the dislocation density results in a new estimate of the distribution of strain incompatibilities and this serves as an input to the subsequent minimization of the free energy. This self-consistent procedure thus allows for a simultaneous evolution of the order parameter texture and the density of dislocations. To develop a clear link between the microscopic and mesoscopic dislocation density, the crystal dislocations in individual slip systems are restricted to glide in their well-defined slip planes. Upon cooling, the finite dislocation density gives rise to heterogeneous nucleation of the martensite and thus results in a shift of the transformation temperature.

5:45PM T41.00013 Spontaneous phase transition of nano-sized boron nitride – A quantum size effect , HONGLI DANG, University of Tulsa, Y.G. SHEN, City University of Hong Kong, SANWU WANG, University of Tulsa — We report first-principles quantum-mechanical calculations that predict a novel phase transition of nano-sized boron nitride (BN) thin-films. When the thickness of the BN film is below 1.4 nm, a spontaneous phase transition from the diamond-like structure to a graphite phase is predicted. The process would involve no energy barrier. When the thickness of the film increases, on the other hand, energy barriers for the phase transition would appear and gradually increase with the thickness. Calculations show that while the graphite structure has a lower total energy than the corresponding diamond-like structure for the BN thin-film with any thickness, the spontaneous phase transition would occur only when the size is small. We attribute this phenomenon to the quantum size effect.

3Supported in part by the NSF (CMMI-0645953), by the NSF’s TeraGrid resources provided by the National Center for Supercomputing Applications (TG-DMR080005N), and by the National Center for Computational Sciences at Oak Ridge National Laboratory.

5:06PM T41.00014 High Pressure Studies of the Metal-Insulator Transition in Pure NiS\(_2\) , ARNAB BANERJEE, YEJUN FENG, RAFAEL JARAMILLO, THOMAS F. ROSENBAUM, James Frank Institute, The University of Chicago, APS, ANL, SECTOR 4 AND 6 TEAM, JOE PLUTH/ANL APS SECTOR 13 COLLABORATION — Ni(S,Se)\(_2\) is one of the few Mott-Hubbard systems where a structural phase transition does not preclude quantitative study of the localization of charge at the \( T = 0 \) metal-insulator transition. Using diamond anvil cell techniques, we study the corresponding behavior of pure NiS\(_2\) at its quantum critical point. We characterize the electronic, magnetic and structural behavior of this model system through a combination of transport and synchrotron scattering techniques, with a particular interest in the effects of disorder at a quantum phase transition.

5:18PM T41.00015 Effect of pressure on the tetragonal distortion in TiH\(_2\) : a first-principles study , R. DE COSS, R. QUIJANO, Department of Applied Physics, Cinvestav-Merida, A.P. 73 Cordemex 97310 Merida, Yucatan, Mexico, D.J. SINGH, Oak Ridge National Laboratory, USA — The transition metal dihydride TiH\(_2\) present the fluoride structure (CaF\(_2\)) at high temperature but undergoes a tetragonal distortion with \( c/a < 1 \) at low temperature. Early electronic band structure calculations have shown that TiH\(_2\) in the cubic phase display a nearly flat double degenerated band at the Fermi level. Thus the low temperature tetragonal distortion has been associated to a Jahn-Teller effect. Nevertheless, recently we have show that the instability of fcc-TiH\(_2\) is likely to be related with a van Hove singularity. In the present work, we have performed ab-initio calculations of the electronic structure and the tetragonal distortion for TiH\(_2\) under pressure (0-30 GPa). We found that the fcc-fct energy barrier and the tetragonal distortion increases with pressure. The evolution of the tetragonal distortion is analyzed in terms of the electronic band structure. This research was supported by Consejo Nacional de Ciencia y Tecnología (Conacyt) under Grant No. 49985.
In the past decade, the study of our Universe has entered a data-driven era. Indeed, observational advances indicate that cosmologists can understand the evolution of our Universe in exquisite detail and use our Universe as a laboratory with which to make profound statements about the laws of physics. Cosmologists have mapped out the relic radiation from the big bang itself and have succeeded in enormous projects to map the patterns of galaxies and the evolution of our Universe in exquisite detail and use our Universe as a laboratory with which to make profound statements about the laws of physics. 10:24AM V1.00005 Activity-dependent stochastic resonance in recurrent neuronal networks, VLADISLAV VOLMAN, UCSD — An important source of noise for neuronal networks is that of the stochastic nature of synaptic transmission. In particular, there can occur spontaneous asynchronous release of neurotransmitter at a rate that is strongly dependent on the presynaptic Ca2+ concentration and hence strongly dependent on the rate of spike induced Ca2+. Here it is shown that this noise can lead to a new form of stochastic resonance for local circuits consisting of roughly 100 neurons - a "microcolumn"- coupled via noisy plastic synapses. Furthermore, due to the plastic coupling and activity-dependent noise component, the detection of weak stimuli will also depend on the structure of the latter. In addition, the circuit can exhibit short-term memory, by which we mean that spiking will continue to occur for a transient period following removal of the stimulus. These results can be directly tested in experiments on cultured networks.

Thursday, March 19, 2009 8:00AM - 11:00AM — Session V2 DCMP DPOLY: Constrained Polymers Spirit of Pittsburgh Ballroom BC

8:00AM V2.00001 The low-force elasticity of single-stranded DNA, OMAR A. SALEH, Materials Dept., UCSB — Single-molecule manipulation experiments, in which a single polymer is stretched with a known force while its extension is measured, are typically described by ideal models (e.g. the worm-like chain or freely-jointed chain) that account only for the polymer’s local stiffness, but ignore long-range ‘excluded-volume’ interactions. Yet, the basic (and successful) Flory scaling theory indicates that long-range interactions must be included to describe the zero-force self-avoiding walk structure of a polymer. Here, we reconcile single-molecule force-extension data with scaling theories of polymer elasticity: measurements of denatured single-stranded DNA show a regime where the extension grows as a non-linear power law with force, in accord with previously-unproven ‘tensile blob’ models. Analysis of the salt dependence of this regime indicates that the polymer’s Kuhn length is proportional to the Debye length. This contradicts the classic Odijk-Školnick-Fixman theory; I will discuss possible explanations for this discrepancy.

8:36AM V2.00002 Confinement Effects on the Structure of Complex Fluids, MAHN KIM, KAIST — Actin is a key component of the protein complex responsible for producing contractile force in skeletal muscle. Filamentous actin, called F-actin, is a two-stranded helical protofilament with a diameter of ~8nm and a contour length of ~10m. The experimental results show that the persistence length of the F-actin is 4 -20 m. One of interesting problems is to find the structure of a semiflexible filament in a confined space [1], such as a channel width less than the persistence length. The other interesting problem is to find the surface treatment effect on the liquid crystal structure in a confined space. The boundary conditions imposed by the walls of the microchannel generate the spatial patterning of defect domains in a smectic liquid crystal [2] and the formation of a large-area ordered structure [3] by using the structure of smectic liquid in the microchannels. We found that the F-actin undergoes a transition from a 2D randomly oriented regime to a 1D biaxially confined regime with the effective persistence length. We were able to generate defect domains that are nearly uniformly arranged in 2D ordered patterns by controlling the surface hydrophobicity. Furthermore, the formation of a large-area ordered structure of toric focal conic domains was generated. This work was done with C. R. Safinya’s group at UCSB and Hee-Tae Jung’s group at KAIST.

9:48AM V2.00004 Gene brushes on a chip: From crowding and the search problem to synthetic systems, ROY BAR-ZIV, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovot, 76100, Israel — We assemble DNA polymer brushes coding for entire genes on a surface by means of a new photolithographic approach. The gene density can be controlled from dilute to high density where the local concentration - Megabase pairs per micron cubed – is comparable to that in a bacterium. The gene brush, therefore, emulates the crowded medium of the cell, allowing us to study DNA transactions in vitro under native conditions. We find that transcription/translation from these gene brushes is highly sensitive to DNA density, orientation and composition. As a step towards multi-gene synthetic systems, we integrated on a chip two spatially separated gene brushes, and implemented a two-stage transcription/translation cascade.

Thursday, March 19, 2009 8:00AM - 11:00AM — Session V3 DCMP DAMOP: Correlated Phases in Fermi Gases of Ultracold Atoms 301/302

8:00AM V3.00001 A Mott insulator of fermionic atoms in an optical lattice, HENNING MORITZ, ETH Zurich — In a solid material strong interactions between the electrons can lead to surprising properties. A prime example is the Mott insulator, where the suppression of conductivity is a result of interactions and not the consequence of a filled Bloch band. The proximity to the Mott insulating phase in fermionic systems is the origin for many intriguing phenomena in condensed matter physics, most notably high-temperature superconductivity. Compared to real materials, a fermionic quantum gas trapped in an optical lattice offers a very pure realisation of the Hubbard model, giving a new approach to understand the physics of strongly correlated systems. We report on the formation of a Mott insulator of a repulsively interacting two-component Fermi gas in an optical lattice. It is signalled by three features: a drastic suppression of doubly occupied lattice sites, a strong reduction of the compressibility inferred from the response of double occupancy to atom number increase, and the appearance of a gapped mode in the excitation spectrum. In collaboration with Robert Jördens, Niels Strohmaier, and Daniel Greif, ETH Zurich; Kenneth Günter, ETH Zurich, ENS Paris; Leticia Tarruell and Tilman Esslinger, ETH Zurich.
8:36AM V3.00002 The phase-diagram of a superfluid two-component Fermi gas1. WOLFGANG KETTERLE, Research Laboratory for Electronics, MIT-Harvard Center for Ultracold Atoms, and Department of Physics, MIT, Cambridge, MA 02139 — What is the benefit of realizing superfluidity in a gas a million times more dilute than air? Such systems consist of well-separated atoms which can be observed and manipulated with the control and precision of atomic physics, and which can be treated with first-principles calculations. By implementing scattering resonances, we have realized the strong-coupling limit of the Bardeen Schrieffer-Cooper (BCS) mechanism and observed a normalized transition temperature of 20% of the Fermi temperature, higher than in any superconductor. When the population of the two spin states is imbalanced, pairing is frustrated, and superfluidity is quenched at the Chandrasekhar-Clogston limit. When the fermions can form molecules, we observe the emergence of bosonic behavior, and an imbalanced two-component Fermi system can be described as a boson-fermion mixture. Pairing correlations have been studied by rf spectroscopy, determining the fermion pair size and the pairing gap energy in a resonantly interacting superfluid. These studies illustrate a new approach to condensed-matter physics where many-body Hamiltonians are realized in dilute atomic gases.

1Work done in collaboration with Yong-Il Shin, Andre Schirotzek and Christian Schunck.

9:12AM V3.00003 Trapping and cooling fermionic atoms into the Mott and Néel states1, CORINNA KOLLATH, CPHT, Ecole Polytechnique, CNRS, 91128 Palaiseau, France — Atomic gases cooled to Nanokelvin temperatures are a new exciting tool to study a broad range of quantum phenomena. In particular, the outstanding degree of control which has been achieved over these quantum systems facilitates access to strongly correlated quantum many body physics. For example, optical lattices have been created to mimic condensed matter systems. We perform a theoretical study of a fermionic gas with two repulsively interacting hyperfine states confined to an optical lattice. We determine a generic state diagram in the presence of a harmonic confining potential. We discuss implications for current experiments. Further we outline different strategies to reach the antiferromagnetic phase.

1L. De Leo, A. Georges, M. Ferrero, O. Parcollet

9:48AM V3.00004 Polarized Fermi condensates, MEERA PARISH, Princeton University — We theoretically investigate the polarized two-component Fermi gas, which is the simplest fermion system displaying both superfluidity and “magnetism”. In particular, we show that the elusive Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) modulated superfluid phase may be realized by embedding the polarized Fermi gas in an array of weakly-coupled parallel 1D “tubes” produced by a two-dimensional optical lattice. We argue that the most promising regime for observing the FFLO phase is in the quasi-1D regime, where the atomic motion is largely 1D but there is weak tunneling in the transverse directions that stabilizes long range order. Moreover, within this system, there is an additional phase transition in the FFLO phase, where the quasiparticle spectrum changes from gapless near the 3D limit to gapped in the quasi-1D regime.

10:24AM V3.00005 A Three-Component Degenerate Fermi Gas. SEILIM JOCHIM, Max-Planck-Institute for Nuclear Physics and Heidelberg University — We have realized a three-component Fermi gas consisting of the three lowest spin states (|1⟩, |2⟩, |3⟩) of the Li atom. Interactions in this system are governed by three different scattering lengths (a_{12}, a_{23}, a_{13}) between the three states, which all exhibit broad and overlapping Feshbach resonances. This enables us to tune the interactions of the system to become both strongly repulsive and strongly attractive, making it a generic three-component system. It is therefore ideally suited to study predictions of exotic phases such as color superconductivity that are expected for example inside of neutron stars. It is also possible to tune the scattering lengths to very small values simultaneously, which facilitates the preparation of the mixture: Starting from a degenerate mixture of atoms in states |1⟩ and |2⟩, we simultaneously apply radio frequencies resonant with the |1⟩-|2⟩ and |2⟩-|3⟩ transitions. This causes the three states to be mixed. To obtain an incoherently mixed sample within a few hundred milliseconds we apply a small magnetic field gradient along the weak axis of our trap. In first experiments we studied the collisional stability of our gas with respect to the magnetic field |1⟩. We observe an intriguing three-body loss resonance that occurs when all two-body scattering lengths are negative and no two-body bound state exists. The mixture is stable where the scattering lengths are relatively small, which is an important prerequisite for the preparation of the gas. The stable gas is also a good starting point for experiments in the strongly interacting regime, where we aim to observe many-body effects. Progress on this effort will be reported.

8:36AM V4.00002 Equilibrium features in the arrested phase separation of PNiPAM microgels, VERONIQUE TRAPPE, Dept. of Physics, University of Fribourg, Switzerland — We investigate the arrested phase separation of poly-N-isopropylacrylamide (PNiPAM) microgels. At large enough concentrations we observe the formation of a macroscopic gel-body that exhibits a peculiar temperature dependence. In a temperature-range, where the volume of the individual particles no longer changes, the final dimension of the macroscopic gel body depends on the depth of the quench into the phase separation regime. Increasing the quench depth results in a decrease of the dimension of the gel-body; this is reminiscent of a thermodynamically driven phenomenon and contrasts with the fact that the formation of the gel-bodies is due to the arrest of a phase separation process.
modeling and experiments has greatly accelerated our efforts, and several examples illustrating the benefits of this approach will be presented. An overview of recent efforts at Ford aimed at developing new materials for reversible, solid state hydrogen storage. A tight coupling between first-principles efficient storage of hydrogen has been identified as one of the key materials-based challenges to realizing a transition to FC vehicles. This talk will present fossil-fuel-powered internal combustion engines – namely, the proton exchange membrane FC – utilizes hydrogen as a fuel. Although hydrogen has about three

10:24AM V4.00005 Phase behavior and rheology of ionic microgels, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Our aim is to understand and control the mechanical properties of dense microgel suspensions, where the softness of the constituent particles can have important effects over the macroscopic behavior. In particular, we are using ionic microgel particles based on poly(vinylpyridine), a monomer that ionizes with pH. When de-swollen, the particles are essentially charged hard spheres and crystallize at high enough volume fractions. By contrast, when the microgels are swollen, light and neutron scattering experiments show that the suspension does not crystallize, irrespective of particle density. But even more remarkably, these highly packed systems remain essentially liquid and do not seem to exhibit glassy behavior. This phenomenology is markedly different to that of ordinary colloids and suggests that the properties of the single particle can dramatically affect the phase behavior and mechanical properties of the packed suspension.

Thursday, March 19, 2009 8:00AM - 11:00AM – Session V5 FIAP: Computational Design of Hydrogen Storage Materials 401/402

8:00AM V5.00001 Computational Discovery of Novel Hydrogen Storage Materials and Reactions, CHRISTOPHER WOLVERTON, Northwestern University — Practical hydrogen storage for mobile applications requires materials that exhibit high hydrogen densities, low decomposition temperatures, and fast kinetics for absorption and desorption. Unfortunately, no reversible materials are currently known that possess all of these attributes. Here we present an overview of our recent efforts aimed at developing a first-principles computational approach to the discovery of novel hydrogen storage materials. We have developed computational tools which enable accurate prediction of decomposition thermodynamics, crystal structures for unknown hydrides, and thermodynamically preferred decomposition pathways. We present examples that illustrate each of these three capabilities. Specifically, we focus on recent work on crystal structure and dehydriding reactions of borohydride materials, such as Mg(BH₄)₂, MgB₆H₁₂, and mixtures of complex hydrides such as the ternary LiBH₄/LiNH₄/MgH₂ system. References:

8:36AM V5.00002 Combining computation and experiment to accelerate the discovery of new hydrogen storage materials, DONALD SIEGEL, Ford Motor Company — The potential of emerging technologies such as fuel cells (FCs) and photovoltaics for environmentally-benign power generation has sparked renewed interest in the development of novel materials for high density energy storage. For applications in the transportation sector, the demands placed upon energy storage media are especially stringent, as a potential replacement for fossil-fuel-powered internal combustion engines – namely, the proton exchange membrane FC – utilizes hydrogen as a fuel. Although hydrogen has about three times the energy density of gasoline by weight, its volumetric energy density (even at 700 bar) is roughly a factor of six smaller. Consequently, the safe and efficient storage of hydrogen has been identified as one of the key materials-based challenges to realizing a transition to FC vehicles. This talk will present an overview of recent efforts at Ford aimed at developing new materials for reversible, solid state hydrogen storage. A tight coupling between first-principles modeling and experiments has greatly accelerated our efforts, and several examples illustrating the benefits of this approach will be presented.
9:12AM V5.00003 Novel hydrogen storage approaches using organometallics, SHENGBAI ZHANG, Rensselaer Polytechnic Institute — Storing molecular hydrogen in organometallics can ensure fast kinetics, low heat management, high energy efficiency, and superb reversibility. The gravimetric density is, however, low for room temperature storage. The reason for the too low density is because the binding is too weak. First-principles calculations [1,2] suggested that organometallics may significantly increase the binding, which is also correlated with decreasing inter-molecular distances and hence a significantly increased volumetric density [3]. Current experimental difficulties are twofold: a) how to synthesize the organometallics and b) how to avoid the transition metal atoms from clustering [4]? Recent experiment [5] on titanium-doped porous silica and theoretical predictions on calcium doping [3,6] may shed new lights on these difficult problems.

9:48AM V5.00004 Computational methods to determine the structure of hydrogen storage materials², TIM MUELLER, Massachusetts Institute of Technology — To understand the mechanisms and thermodynamics of material-based hydrogen storage, it is important to know the structure of the material and the positions of the hydrogen atoms within the material. Because hydrogen can be difficult to resolve experimentally, computational research has proven to be a valuable tool to address these problems. We discuss different computational methods for identifying the structure of hydrogen storage materials and the positions of hydrogen atoms, and we illustrate the methods with specific examples. Through the use of ab-initio molecular dynamics, we identify molecular hydrogen binding sites in the metal-organic framework commonly known as MOF-5 [1]. We present a method to identify the positions of atomic hydrogen in imide structures using a novel type of effective Hamiltonian. We apply this new method to lithium imide (Li2NH), a potentially important hydrogen storage material, and demonstrate that it predicts a new ground state structure [2]. We also present the results of a recent computational study of the room-temperature structure of lithium imide in which we suggest a new structure that reconciles the differences between previous experimental and theoretical studies.

²Supported by the U.S. Department of Energy grant DE-FG02-05ER46253.

10:24AM V5.00005 Kinetics of bulk and surface mass transport in complex metal hydrides, HAKAN GUNAYDIN, UCLA — Metal hydrides can be used to store hydrogen in high gravimetric and volumetric densities. However, the kinetics of hydrogen release and uptake are slow in complex metal hydrides. Clarification of the mechanism of hydrogen release and uptake in complex metal hydrides can aid in a rational design of new hydrogen storage materials with fast kinetics or catalysts that will catalyze the rate of hydrogen release from the existing materials. The release of hydrogen in metal hydrides requires the transport of hydrogen and/or heavier species. The kinetics of such mass transport in metal hydrides can be the rate-limiting process for the release of hydrogen. For example, the rate-determining step for the release of hydrogen from NaAlH4 is the creation and diffusion of neutral AlH3 defects in NaAlH4. The release of hydrogen from LiH destabilized LiNH2 also proceeds via the creation of neutral point defects. The mechanism of mass transport in prototypical hydrogen storage materials such as NaAlH4 and LiNH2 and the mechanism of hydrogen diffusion in aluminum will be discussed.

Thursday, March 19, 2009 8:00AM - 11:00AM — Session V6 DCOMP: Recent Advances in Biomolecular Simulations 406

8:00AM V6.00001 Metadynamics simulation of large scale motion in proteins, MICHELE PARRINELLO, Department of Chemistry and Applied Biosciences, ETH Zurich, USI Campus, Via Giuseppe Buffi 13, 6900 Lugano, Switzerland — Understanding large scale protein motions is essential in the study of many biological processes. Molecular dynamics simulations could provide important clues, but they are hampered by the fact, that they can only explore time scales, smaller than most interesting phenomena. To circumvent this problem, our group has developed a number of enhanced sampling techniques that allow exploring many such long time scale phenomena. In particular, a very recent development permits reconstructing complex pathways without the need of introducing collective variable. A number of large scale applications will be presented.

8:36AM V6.00002 Quantum Simulations of Solvated Biomolecules Using Hybrid Methods, MIROSLAV HODAK, North Carolina State University — One of the most important challenges in quantum simulations on biomolecules is efficient and accurate inclusion of the solvent, because the solvent atoms usually outnumber those in the biomolecule of interest. We have developed a hybrid method that allows for explicit quantum-mechanical treatment of the solvent at low computational cost. In this method, Kohn-Sham (KS) density functional theory (DFT) is combined with an orbital-free (OF) DFT. Kohn-Sham (KS) DFT is used to describe the biomolecule and its first solvation shells, while the orbital-free (OF) DFT is employed for the rest of the solvent. The OF part is fully O(N) and capable of handling 10⁵ solvent molecules on current parallel supercomputers, while taking only ~ 10 % of the total time. The compatibility between the KS and OF DFT methods enables seamless integration between the two. In particular, the flow of solvent molecules across the KS/OF interface is allowed and the total energy is conserved. As the first large-scale applications, the hybrid method has been used to investigate the binding of copper ions to proteins involved in prion (PrP) and Parkinson’s diseases. Our results for the PrP, which causes mad cow disease when misfolded, resolve a contradiction found in experiments, in which a stronger binding mode is replaced by a weaker one when concentration of copper ions is increased, and show how it can act as a copper buffer. Furthermore, incorporation of copper stabilizes the structure of the full-length PrP, suggesting its protective role in prion diseases. For alpha-synuclein, a Parkinson’s disease (PD) protein, we show that Cu binding modifies the protein structurally, making it more susceptible to misfolding — an initial step in the onset of PD. In collaboration with W. Lu, F. Rose and J. Bernholc.
9:12AM V6.00003 Urea’s action on the hydrophobic interaction in physical and biophysical systems

B.J. BERNE, Columbia University — For more than a century, urea has been commonly used as an agent for denaturing proteins. However, the mechanism behind its denaturing power is still not well understood. The mechanism of denaturation of proteins by urea is explored using all-atom molecular dynamics simulations of hen lysozyme generated on BlueGene/L. Accumulation of urea around lysozyme shows that water molecules are expelled from the first hydration shell of the protein. We observe a two stage penetration of the protein, with urea penetrating the hydrophobic core before water, forming a “dry globule.” The direct dispersion interaction between urea and the protein backbone and sidechains is stronger than for water, which gives rise to the intrusion of urea into the protein interior and also to urea’s preferential binding to all regions of the protein. This is augmented by preferential hydrogen bond formation between the urea carbonyl and the backbone amides which contributes to the breaking of intra-backbone hydrogen bonds. Our study supports the “direct interaction mechanism” whereby urea has a stronger dispersion interaction with protein than water. We also show by molecular dynamics simulations that a 7 M aqueous urea solution unfolds a chain of purely hydrophobic groups which otherwise adopts a compact structure in pure water. The unfolding process arises due to a weakening of hydrophobic interactions between the polymer groups. Again the action of urea is found to be direct, through its preferential binding to the polymer or plates. It is, therefore, acting like a surfactant capable of forming hydrogen bonds with the solvent. The preferential binding and the consequent weakened hydrophobic interactions are driven by enthalpy and are related to the difference in the strength of the attractive dispersion interactions of urea and water with the polymer chain or plate. We also show that the indirect mechanism, in which urea acts as a chaotrope, is not a likely cause of urea’s action as a denaturant. These findings suggest that, in denaturing proteins, urea (and perhaps other denaturants) forms stronger attractive dispersion interactions with the protein side chains and backbone than does water and, therefore, is able to dissolve the core hydrophobic region.

9:48AM V6.00004 Systematic Coarse-Graining of Biomolecular Systems

GREG VOTH, University of Utah — A multiscale theoretical and computational methodology will be presented for studying biomolecular systems across multiple length and time scales. The approach provides a systematic connection between all-atom molecular dynamics, coarse-grained modeling, and mesoscopic phenomena. At the heart of the methodology is the multiscale coarse-graining method for rigorously deriving coarse-grained models from the underlying molecular-scale forces. Applications of the multiscale approach will be given for membranes and proteins. Recent advances in coarse-graining large protein complexes will also be described along with key applications.

10:24AM V6.00005 Multi-resolution protein modeling by combining theory and experiment

CECILIA CLEMENTI, Rice University — The detailed characterization of the overall free energy landscape associated with the folding process of a protein is the ultimate goal in protein folding studies. Modern experimental techniques provide accurate thermodynamic and kinetic measurements on restricted regions of a protein landscape. Although simplified protein models can access larger regions of the landscape, they are oftentimes built on assumptions and approximations that affect the accuracy of the results. We present new methodologies that allows to combine the complementary strengths of theory and experiment for a more complete characterization of a protein folding landscape at multiple resolutions. Recent results and possible applications will be discussed.

Thursday, March 19, 2009 8:00AM - 10:24AM
Session V7 GMAG: Applications of Magnetic Thin Films with Tilted Anisotropy

8:00AM V7.00001 Magnetic Thin Films for Perpendicular Recording

KAI-ZHONG GAO, Seagate Technology — Magnetic recording technology has shown a rapid growth over the past decade or more with the areal density growth rate more than 40% due to introduction of giant magneto-resistive (GMR), tunneling magneto-resistive (TMR) head and perpendicular recording technology. Current products are in the range of 300-400Gb/in² and demonstrations of 600-800Gb/in² have occurred for perpendicular recording. Recent progresses are mainly due to improvement in magnetic thin film media signal to noise ratio. In this talk, we give a brief summary of recent progresses on perpendicular recording media technology and look at possible extension for ultra high areal density recording based on recording physics and media designs. First we are going to give a brief review on the advantages of the 1st generation of perpendicular recording media as compared to longitudinal recording media. Then the effect of media switching field and switching field distribution will be discussed. We show several different media designs and show its impact to the recording technology, including media with tilted anisotropy, media with coupled granular continuous (CGC) structure, media with exchange coupled composite structure and media with exchange spring system. In addition, we will discuss the impact of media grain size on achievable areal density, the ultimate limit for magnetic recording based on continuous media. Finally, a possible extension and its impact are discussed. As stated before, here we will not try to dig into very specific detail of each topic but look at the basic concept and physics behind each topic that may potentially lead to new technology break through.

8:36AM V7.00002 Approaches and Applications of Tilted Magnetic Anisotropy in Hard Disk and STT-RAM Magnetic Recording for Extremely High Areal Density

JIAN-PING WANG, University of Minnesota — Using tilted magnetic anisotropy in magnetic recording media has been proposed and demonstrated to address several key challenges for future hard disk magnetic recording several years ago. Recent simulations show the potential benefit of using tilted magnetic anisotropy in patterned composite magnetic media that can supports the recording areal density up to several Terabit per square inch. In this talk, I will first present the fundamental physics of the advantages of using tilted magnetic anisotropy in magnetic recording media and spin torque transfer random access memory (STT-RAM). Then several approaches to experimentally make magnetic films in tilted anisotropy media will be presented and discussed in details. These include: 1) crystallographically controlling the tilted magnetic easy axis by using proper underlayers and seedlayers; 2) physically engineering the tilted magnetic easy axis by oblique sputtering on smooth or curved substrates; 3) mechanically engineering the tilted magnetic easy axis by self-assembling magnetic nanoparticles with special shape (such as octahedral-shaped L10 phase FePt nanoparticles); 4) micromagnetically engineering the tilted magnetic easy axis by exchange-coupling two magnetic layers with different magnetic easy axis and anisotropy constant. Results based on hcp phase Co-alloy and L10 phase FePt and FePd films will be presented in details. Finally, I will propose and discuss how to use tilted magnetic anisotropy for the magnetic free layer in the magnetic tunnel junction (MTJ) to reduce the critical switching current density while keeping the thermal stability, which can extend the recording density of the proposed STT RAM further.

The author thanks the support from Information Storage Industry Consortium (INSIC) Extremely High Density Recording Program (EHDR), NSF ECCS 0702264 and NSF Minnesota MRSEC.
9:12 AM V7.00003 Magnetic nanocap arrays with tilted magnetization. MANFRED ALBRECHT, Chemnitz University of Technology — In modern magnetic recording materials the "superparamagnetic effect" has become increasingly important as new magnetic hard disk drive products are designed for higher storage densities. In this regard, patterned media [1], where two-dimensional arrays of nanostructures are used, is one of the concepts that might provide the required areal density in future magnetic recording devices. However, also nanostructure arrays will ultimately need high anisotropy material such as L10-FePt to provide enough thermal stability and thus much higher writing fields than currently obtainable from perpendicular magnetic recording heads. One proposed solution to this problem is the use of tilted magnetic recording media [2]. The basic idea is to tilt the easy axis of the magnetic medium from the perpendicular direction by 45 degrees. In this case, the switching field will be reduced by a factor of two in the Stoner-Wohlfarth limit. Recently, this approach was realized by oblique film deposition onto arrays of self-assembled spherical particles [3-5]. In this presentation, recent results on different film systems including Co/Pt multilayers, FePt and CoPtCr-SiO2 alloys which have been deposited onto SiO2 particle monolayers will be presented. It turned out that by tuning the growth conditions single domain nanocaps with enhanced magnetic coercivity and tilted anisotropy axis can be achieved even for particle sizes below 50 nm.

9:48 AM V7.00004 Spin-torque oscillators with tilted fixed layer magnetization. CHAOLIN ZHA, Department of Microelectronics and Applied Physics, Royal Institute of Technology, Sweden — One of the promising applications based on the spin transfer effect [1-3] is the Spin Torque Oscillator (STO) with signal generation at microwave frequencies related to ferromagnetic resonance. The STO may be thought of as a nanoscopic Yttrium Iron Garnet (YIG) oscillator with a similarly broad frequency range, but significant advantages such as easy on-chip integration, and current tunability instead of only field tunability. However, STOs still typically require a large, static, magnetic field for operation; removing the need for this field is currently an intensely researched topic. Three different STO designs have been attempted to address zero field operation: i) the perpendicularly polarized STO [4], ii) the wavy torque STO [5], and iii) the vortex STO [6]. Recently we proposed the Tilted Polarizer STO (TP-STO) having a fixed layer with an out-of-plane magnetic easy-axis tilted a finite angle away from the film normal [7]. In this talk, I will review our simulation work of the TP-STO and show its potential to generate large output signal in zero field. I will present detailed structural and magnetic characterization of single layer L10 (111) FePt with tilted magnetic anisotropy and show how we have fabricated FePt/Cu/NiFe pseudo spin valves with magnetoresistance values of about 0.5%, and as much as 5% if each interface is doped with CoFe. Finally, I will present our preliminary work on observing actual microwave signal generation in nano-contact TP-STOs and discuss their potential for applications.

Thursday, March 19, 2009 8:00AM - 11:00AM — Session V8 FPS DBP: The Physics of Imaging and Radiotherapy 414/415

8:00 AM V8.00001 Dedicated breast CT. JOHN BOONE, University of California Davis — Dedicated breast computed tomography (CT) systems were designed and fabricated in our laboratory, and patient scanning commenced in November 2004. The breast CT scanner was designed utilizing several off-the-shelf components, including the x-ray system, the flat-panel detector, and a position encoder - bearing - motor system. These components were integrated into a custom designed scanner frame and gantry. The breast CT scanners utilize a 17 second acquisition during patient breath-hold, and during this time 500 projection images are acquired over 360 degrees around the breast. The radiation levels are adjusted such that the mean glandular dose is equal to that of traditional diagnostic imaging, robotically controlled biopsy, and other interventional procedures.

8:36 AM V8.00002 Tomographic Imaging: Visualization of the Unseeable. XIAOCHUAN PAN, The University of Chicago — Tomographic imaging is a noninvasive approach to acquiring information within the subject under study, and it plays an increasingly important role in the improvement of health care by providing valuable information for diagnosis of diseases, for guidance of disease treatment and therapy, and for assessment/monitoring of treatment response. It has also found a wide variety of applications in other disciplines, ranging from molecular imaging to material sciences to security scan to paleontology. Over the last 30 years, biomedical imaging has involved into an important discipline in its own right. Physics and mathematics form the foundation of advanced tomographic imaging. Computed tomography (CT) and magnetic resonance imaging (MRI) represent two well-known tomographic imaging modalities. In this talk, I will first introduce the basic physics and mathematics principles on which some of the advanced tomographic imaging techniques such as CT are based, with an emphasis on what and how physical signals are detected, how they are used for producing images, and what physical information is that can be extracted from these images. I will then touch upon some of the recent exciting advances in tomographic imaging technology, followed by a brief discussion of some of the important applications of advanced tomographic imaging in medicine and other areas.

9:24AM V9.00008 Dynamics of priority-queue networks, BYUNGJOON MIN, KWANG-IL GOH, IN-MOOK KIM, Korea University — Recent application of priority queue models for human dynamics opened a way to study the human behavior under quantiative framework. Given the evident active engagement in social networking of individuals, dynamics of priority queues forming networks needs to be understood. Along this line, here we study the dynamics of priority-queue networks by generalizing the binary interacting priority queue model of Oliveira and Vazquez (OV). We found that the OV model with AND-type protocol for interacting tasks is in general not scalable for the queue networks with more than two queues, because the dynamics for interacting tasks become highly correlated. We thus propose a model with OR-protocol. Of further interest is to explore the effects of the number of queues and the network topology on the waiting time dynamics of the priority-queue networks, finding that its distribution exhibits power-law tail in all cases considered, yet with exponents dependent on the network topology. We also show that when the tasks in the queue networks are executed synchronously, priority conflicts affect the waiting time dynamics strongly, resulting in a different power law.

9:36AM V9.00009 About human activity, long-term memory, and Gibrat’s law1, DIEGO RYBSKI, Levich Institute, City College of New York, New York, NY 10031, SERGYEV. BULDYREV, SHLOMO HAVLIN, FREDRIK LILJEROSS, HERMAN A. MAKSE — A central research question in the social sciences for several centuries has been whether any law like patterns in the unintended outcomes of human action exist. Here we investigate the existence of scaling laws in the human activity of communication, considering the number of messages sent by individuals as a growth process in time. We analyze millions of messages sent in two social online communities and uncover power-law relations between fluctuations in the growth rate and the activity of the members. We attribute this scaling law to a long-term persistence of human activity beyond daily or weekly cycles holding up to more than a year. Based on such an underlying long-term correlated dynamics, we elaborate a consistent framework for the empirical evidences, establishing a missing link between the scaling behavior in the growth and long-term persistence. Our results indicate that large fluctuations in communication activity can be expected as an unintended consequence of human interaction. This finding is of importance for both designing communication systems and for understanding the dynamics of social systems.

9:48AM V9.00010 Tour de Sys: The traveler’s view of a network, DANIEL GRADY, CHRISTIAN THIEMANN, DIRK BROCKMANN, Northwestern University, Evanston IL, USA — The plight of the Flattander is imperfect information about a high-dimensional object. Yet even so, the clever inhabitant of a low-dimensional world can gain a great deal of information about such an object by examining it from many perspectives. We analyze complex transportation networks by using shortest-path trees to measure universal network properties from different locations. Furthermore, by defining a measure of a node’s geographical access area we give a more realistic characterization of the centrality or remoteness of a location. The network topology indicates a clear distinction between the center and edge of a network, but we find that examining the weights of links is crucial, as the distinction in the weighted network for some quantities is even more pronounced. Often prior research has not focused on the weightedness of transportation networks, in spite of the fact that this property has an obvious bearing on how the networks are actually used. We show that measuring networks with weighted edges significantly affects their statistics. Our analysis indicates dynamical processes occurring on these networks should behave in a manner very different than what is predicted by considering topology alone.

10:00AM V9.00011 Universality and the lack of it in multiscale human mobility networks, RAFAEL BRUNE, CHRISTIAN THIEMANN, DIRK BROCKMANN, Northwestern University, Evanston, IL, USA — Although significant research effort is currently devoted to the understanding of complex human mobility and transportation networks, their statistical features are still poorly understood. Specifically, to what extent geographical scales impose structure on these networks is largely unknown. In particular, in light of the use of human mobility models in the development and testing theories for spatial disease dynamics, a comprehensive understanding of their structure is of fundamental importance. The large majority of statistical properties (degree distributions, centrality measures, clustering, etc.) of these networks have been obtained either for large scale networks or on small scale systems, indicating significant yet poorly understood deviations. We will present the first investigation of multiscale and multi-national mobility networks, covering length scales of a few to a few thousand kilometers. We will report that certain properties such as mobility flux distribution are universal and independent of length scale, whereas others vary systematically with scale. In particular, controversial properties such as scale-free degree distributions lose their heavy tails in small to intermediate length-scale windows.

10:12AM V9.00012 Monte Carlo Studies of the Isoperimetric Dimension of Growing Droplets in Metastable Decay of the Ising Model on Small-World Graphs, HOWARD L. RICHARDS, Physics & Physical Science, Marshall University — For the Ising model on a regular, nearest-neighbor lattice of less than 6 dimensions, metastable decay occurs via the nucleation of critical droplets: subcritical droplets are biased toward shrinkage, whereas supercritical droplets are biased toward growth. The size of a critical droplet is governed by the competition between the coupling of the magnetic field to the volume of the droplet, which lowers the free energy, and the coupling of the droplet of the stable state to metastable state at the boundary of the droplet, which increases the free energy. This competition between volume effects and surface effects makes the isoperimetric dimension relevant to metastable decay. The simulations discussed here are for a triangular lattice with a small percentage of “small-world” connections. The system initially has only one “down” spin, from which the droplet grows; switching is irreversible and only occurs for “up” spins adjacent to at least one “down” spin.

10:24AM V9.00013 Functional vs. Structural Modularity: do they imply each other?1, ZOLTAN TOROCZKAI, University of Notre Dame — While many deterministic and stochastic processes have been proposed to produce heterogeneous graphs mimicking real-world networks, only a handful of studies attempt to connect structure and dynamics with the function(s) performed by the network. In this talk I will present an approach built on the premise that structure, dynamics, and their observed heterogeneity, are implementations of various functions and their compositions. After a brief review of real-world networks where this connection can explicitly be made, I will focus on biological networks. Biological networks are known to possess functionally relevant features in addition to obvious structural ones. While proposals have been made for the evolutionary emergence of modularity, it is far from clear that adaptation on evolutionary timescales is the sole mechanism leading to functional specialization. We show that non-evolutionary learning can also lead to the formation of functionally specialized modules in a system exposed to multiple environmental constraints. A natural example suggesting that this is possible is the cerebral cortex, where there are clearly delineated functional areas in spite of the largely uniform anatomical construction of the cortical tissue. However, as numerous experiments show, when damaged, regions specialized for a certain function can be retrained to perform functions normally attributed to other regions. We use the paradigm of neural networks to represent a multitasking system, and use several non-evolutionary learning algorithms as mechanisms for phenotypic adaptation. We show that for a network learning to perform multiple tasks, the degree of independence between the tasks dictates the degree of functional specialization emerging in the network. To uncover the functional modules, we introduce a method of node knockouts that explicitly rates the contribution of each node to different tasks (differential robustness). Through a concrete example we also demonstrate the potential inability of purely topology-based clustering methods to detect functional modules. The robustness of these results suggests that similar mechanisms might be responsible for the emergence of functional specialization in other multitasking networks, as well, including social networks.

Session V10 DCMP: Artificially Structured Materials for Optical Manipulation 304
discuss the possibility of generating and detecting these waves in porous metals and porous superconductors. We have also calculated the plasmonic band structure for waves propagating through a three-dimensional inverse opal structure of pores in a metallic host. In contrast to the analogous plasmonic waves propagating along periodic chains of metallic nanoparticles in a dielectric, the pore waves do not suffer radiative losses, and the tight-binding approach is not restricted to the quasistatic approximation or to particles small compared to a wavelength. We dispersion relations and group velocities of plasmonic waves propagating along a periodic chain of nanoscale pores in a Drude metal, using a tight-binding approach to provide in-plane measurements of the strength of the scatter in all transmitted and reflected angles. This data is used to generate Bi-directional Scatter Distribution Functions (BSDFs), which can be either physically or empirically based, to model the reflected and transmitted scatter for all incident angles.

8:36AM V10.00004 ABSTRACT WITHDRAWN —

8:48AM V10.00005 Theory of Plasmonic Wave Propagation Along a Periodic Chain of Nanoscale Pores in a Metal, DAVID STROUD, Ohio State Univ., KWANGMOO KIM, Univ. of Maryland — We have calculated the dispersion relations and group velocities of plasmonic waves propagating along a periodic chain of nanoscale pores in a Drude metal, using a tight-binding approach. The propagating modes are Bloch waves constructed from linear combinations of electromagnetic modes of the individual pores embedded in a metallic host. In contrast to the analogous plasmonic waves propagating along periodic chains of metallic nanoparticles in a dielectric, the pore waves do not suffer radiative losses, and the tight-binding approach is not restricted to the quasistatic approximation or to particles small compared to a wavelength. We have also calculated the plasmonic band structure for waves propagating through a three-dimensional inverse opal structure of pores in a metallic host.

We discuss the possibility of generating and detecting these waves in porous metals and porous superconductors.

9:48AM V10.00010 Transformation media with negative refractive indices1, C.T. CHAN, Physics, HKUST, Hong Kong, Y. LAI, H.Y. CHEN, JACK NG, Z.Q. ZHANG, PHYSICS DEPARTMENT, HONG KONG UNIVERSITY OF SCIENCE AND TECHNOLOGY, HONG KONG TEAM — Artificially structured materials with a negative refractive index designed by transformation optics can have interesting properties. Based on merging the concept of complementary media and transformation media, we propose an invisibility cloak operating at a finite frequency that can make an object invisible with a pre-specified shape and size within a certain distance outside the shell. The cloak is comprised of a dielectric core, a negative index metamaterial shell and an “anti-object” embedded inside the shell. The cloaked object is not blinded by the cloaking shell since it lies outside the cloak. Full-wave simulations in two dimensions have been performed to verify the cloaking effect. We also show that a positive index core coated with a negative index shell can result in a frequency selective super-absorber which has an absorption cross section that is significantly higher than the geometric cross section.

10:00AM V10.00011 Electromagnetic transparency by graded metallic coating2, L. SUN, K.W. YU, The Chinese University of Hong Kong — Recently there has been an increasing interest in achieving cloaking or invisible devices for electromagnetic fields. The study has been based on Pendry’s transformation media concept. In this work, we have studied electromagnetic scattering by coated spheres with a homogeneous core and a radially inhomogeneous dielectric shell described by the lossless graded Drude model \( \varepsilon(r) = 1 - \omega_p^2(r)/\omega^2 \). The plasma frequency depends on \( r \) as \( \omega_p^2 = 1 - cr^2 \), where \( c \) and \( k \) are positive constants. The electromagnetic field distribution has been calculated within the fully electromagnetic Mie scattering theory. When \( k = 2 \), exact analytic solutions can be obtained for the field distribution in terms of Whittaker functions. The total scattering cross section can be obtained from the scattering field amplitudes and is found to be dependent on both the graded profile and the cross-shell ratio. The analytic expressions of the total scattering cross section allow us to assess the conditions for achieving better transparency[1], resulting in tunable electromagnetic cloaking. [1]. A. Ali and N. Engheta, Phys. Rev. E 72, 016623 (2005)

10:12AM V10.00012 Wave-Front Engineering by Huygens-Fresnel Principle for Nonlinear Optical Interactions in Domain Engineered Structures1, ZHU YONGYUAN, QIN YIQIANG, ZHANG CHAO, Nanjing University — Wave-front engineering for nonlinear optical interactions was discussed. Using Huygens-Fresnel principle we developed a general theory and technique for domain engineering with conventional quasi-phase-matching (QPM) structures being the special cases. We put forward the concept of local QPM, which suggests that the QPM is fulfilled only locally not globally. Experiments agreed well with the theoretical prediction. The proposed scheme integrates three optical functions: generating, focusing, and beam splitting of second-harmonic wave, thus making the device more compact.

10:24AM V10.00013 Electromagnetic Response of Josephson Junction Metamaterials in Positive and Negative Permittivity Regimes1, STEVEN ANLAGE, LAURA ADAMS, Center for Nanophysics and Advanced Materials, Physics Department, University of Maryland, College Park, MD 20742-4111 — Negative index of refraction metamaterials have shown strikingly different behavior than their positive index of refraction counterparts, enabling for example cloaking and super lensing. Josephson junction (JJ) metamaterials which are tunable and have low loss are a distinct advantage not only because of their nonlinearity but also due to their ability to be scaled down in size. We will present microwave measurements of JJ arrays that behave differently depending on whether the arrays resonate above or below the cutoff frequency of an electromagnetic waveguide. Below cutoff, resonances indicate a macroscopic phase coherence of the JJ arrays with emission of photons. Above cutoff, we interpret the interaction between the arrays and the electromagnetic waves as indications of vortex-anti-vortex physics. We will describe how the JJ arrays respond to controlled changes of the input power, temperature and dc magnetic fields and how these responses depend on the sign of the permittivity.

10:36AM V10.00014 Anomalous infrared monochromatic transmission through a film of type-II superconductor in magnetic field and a superconducting multiple conductor system, ROMAN YA. KEZERASHVILI, OLEG L. BERMAN, VLADIMIR S. BOYKO, New York City College of Technology, CUNY, YURI E. LOZOVIK, Institute of Spectroscopy — Anomalous far infrared monochromatic transmission through a lattice of Abrikosov vortices in a type-II superconducting film is found. The transmitted frequency corresponds to the photonic mode localized by the defects of the Abrokosov lattice. These defects are formed by extra vortices placed out of the nodes of the ideal Abrokosov lattice. The extra vortices can be pinned by crystal lattice defects of a superconductor. The frequency is studied as a function of magnetic field and temperature in the framework of the Dirac-type two-band model. The control of the transmitted frequency by varying magnetic field and/or temperature is analyzed. Besides, anomalous monochromatic transmission through a superconducting multiple conductor system consisting of parallel superconducting cylinders is found. The transmitted frequency corresponds to the localized photonic mode in the forbidden photonic band, when one superconducting cylinder is removed from the node of the ideal two-dimensional lattice of superconducting cylinders. Our approach is valid for all type-II superconductors but the specific calculations have been performed for the YBCO film in the magnetic field and for the YBCO superconducting cylinders.

8:00AM V11.00001 Momentum statistics of tunneling electrons in nanoelectromechanical systems, STEVEN D. BENNETT, AASHISH A. CLERK, McGill University — When a mesoscopic conductor is used to measure the position of a nanomechanical oscillator, electrons in the conductor exert a fluctuating back-action force on the oscillator. What is the statistical distribution of the momentum transferred to the oscillator by this force? Motivated by recent experiments that studied a mechanical oscillator coupled to a single tunnel junction[4] or a quantum point contact[5] we investigate theoretically the statistics of back-action force in these systems as well as correlations between the force and the current. Our approach is based on a scattering matrix that depends parametrically on the oscillator position, allowing us to go beyond weak tunneling and study conductors with arbitrary transmittance. We identify two mechanisms of momentum transfer: one involves forces exerted in the scattering region and dominates in the limit of weak tunneling; the other is associated with transferred electron momentum and dominates in the limit of perfect transmission. We also discuss the effects of a spatially asymmetric conductor on the force noise and on the quantum limit of position detection.

Mechano-electronic Superlattices in Silicon Nanoribbons

8:12AM V11.00002

Mechano-electronic Superlattices in Silicon Nanoribbons1

M. HUANG, C.S. RITZ, B. NOVAKOVIC, F. FLACK, D.E. SAVAGE, P.G. EVANS, J. KNEZEVIC, University of Wisconsin-Madison, D. YU, Y. ZHANG, F. LIU, University of Utah, M.G. LAGALLY, University of Wisconsin-Madison — Single crystal silicon nanomembranes (SiNMs) have the mechanical compliance fundamentally different from bulk materials or supported thin films that can produce unique structural and electronic effects. The growth of nanostressors on SiNMs utilizes this mechanical compliance to create a “strain lattice” consisting of tiny regions of local curvature in the SiNMs, the order occurring because the locally bending SiNMs provides a strong feedback for self-organization of the nanostressor. We demonstrate that a high degree of order occurs when Ge or SiGe nanostressors are grown on both sides of free-standing but end-tethered Si nanoribbons. Our calculations prove that the strain lattice in the Si produces a modulation in the electronic band structure, and thus an electronic superlattice. Our calculations also demonstrate that discrete minibands can be observable in such an electronic superlattice at 77K. It is expected that an electric conductivity will be increased in the superlattice. We predict that it is possible to observe discrete minibands at room temperature if other nanostressors are used.

‘Spring-Like’ and Photo-actuated Molecular-Junctions between Nanoparticles

KABEER JASUJA, VIKAS BERRY, Kansas State University — Here we present a study on (1) “molecular-spring” nano-device, where controllable and confined forces are applied on collective molecular-junctions between nanoparticles and (2) photo-actuated nano-junction system where azo-molecules incorporated between nanoparticles apply confined forces to displace them. Both systems are built by using covalently/epitaxially crosslinked polyelectrolyte (cPE) molecules sandwiched between gold nanoparticles (GNP), where cPE molecular-junctions are reversibly compressed and stretched by applying electrically and centrifugally induced forces respectively. The GNPs play a dual role (a) of movable connectors to apply forces and (b) of nanoelectrodes to measure molecular deformation via electron tunneling change. The ‘molecular-spring’ junctions were found to have a spring constant between 10−7 and 10−4 N/m depending on the thickness of the junction. We will also demonstrate the dynamics of these junctions via a motion-in-viscous-media model. The ability to store the compression energy in a molecular-device-architecture and to manipulate these by actuating junctions has the potential to power future molecular devices by stored molecular-energy and controlling properties of nanocomponent based devices.

Noise characterization of metal oxide nanowire FETs with electronic properties controlled by surface geometry

WENYONG WANG, University of Wyoming, HAO XIONG, CURT RICHTER, NIST, WOONG-KI HONG, TAKHEE LEE, GIST, NANOWIRE COLLABORATION — In this talk we present the results of low-frequency noise and random telegraph signal (RTS) characterization of metal oxide nanowire (NW) field-effect transistors (FETs). ZnO nanowires with different surface geometry properties such as corrugated and smooth surfaces have been synthesized. FETs fabricated from these NWs exhibit different electronic transport characteristics. Noise characterization has been performed on NW FET devices with different surface properties. The obtained noise power spectra at room temperature show 1/f frequency dependences, and the Hooge’s constants have been calculated from the gate voltage dependence to the 1/f noise for the devices with different surface geometries. The characteristics of low frequency noise in the drain current have been further investigated through random telegraph signals measurements at 4.2 K, where the channel current RTSs can be attributed to the correlated carrier number and mobility fluctuation due to the trapping and detrapping of the carriers by discrete border/surface traps. The effects of the NW surface properties on the RTS behaviors will be discussed.

A Bistriator: Modulating the Current of a Nanodevice with a Living Cell

JENNIFER KANE, JASON ONG, RAVI SARAF, University of Nebraska-Lincoln — Isolated single nanoparticles and array of nanoparticles act as a single-electron transistors (SETs) when a single electron is charged. For a typical 5 nm Au particle the switching barrier energy due to Coulomb blockade from a single electron charging is approximately 100 meV, making room temperature switching difficult and very noisy. In an array, the switching energy can be a few eV (at cryogenic temperatures), but unlike a single nanoparticle, the energy barrier reduces linearly and vanishes at room temperature. We have developed a “reactive self-assembly” method to make a network of one-dimensional necklaces of nanoparticles that behaves as a single-electron device at room temperature. Furthermore, upon cementing the particles with an inorganic semiconductor, the switching behavior at room temperature is significantly improved. To demonstrate an interesting application of room temperature single-electron switching, we couple the network to a living microorganism to modulate the device current by regulating the cell’s metabolic activity. In the talk we will describe fabrication of the necklace and biotransistor device.

Bistable tunneling current through a quantum dot array junction

YIA-CHUNG CHANG, Research Center for Applied Sciences, Academia Sinica, Taiwan and University of Illinois, Urbana-Champaign, DAVID M.T. KUO, National Central University, Taiwan — We investigate the tunneling current through a six-fold degenerate p–like states of a one- dimensional (1D) or two-dimensional (2D) quantum dot (QD) array in the x-y plane. Due to the coupling of pₓ and pᵧ orbitals at neighboring QDs, a 1D or 2D conduction band (pₓ) is formed, whereas the pᵧ orbitals remain localized due to their weak in-plane coupling. The on-site repulsive Coulomb interaction in the pₓ levels (U) and that between the pₓ level and pₓ/pᵧ level (Uₓₓ) are taken into account in an extended Anderson model, which is used to investigate the tunneling characteristics of the system. Tunneling current through localized pₓ state is calculated in the framework of the Green function technique. Due to the effect of Uₓₓ, the 1D/2D conduction band states are shifted by a self-energy term 2Nuₓₓ. We find that bistable current can be observed for this system in the Coulomb blockade regime, which makes the system a valid candidate for ultra-high-density memory device.

Tunneling Between a Quantum Wire and a Two-Dimensional Electron Gas

DOMINIQUE LAROCHE, McGill University and Sandia National Laboratories, JOHN RENO, Sandia National Laboratories, GUILLAUME GERVAIS, McGill University, MIKE LILLY, Sandia National Laboratories — We study 1D-2D tunneling between a quantum wire and a 2D electron gas as a function of magnetic field, source drain bias, temperature and 1D subband occupation. The transition from 2D-2D to 1D-2D tunneling is clearly observed through a sharpening of the tunneling resonance, confirming that the measurements are performed in a 1D-2D state. The device used is fabricated in a GaAs/AlGaAs parallel double quantum well heterostructure with an 11 nm wide Al₀.₉Ga₀.₁As barrier separating the quantum wells. Quantum wires are created via electron beam lithography defined split gates fabricated on both sides of the sample, albeit only one of the wires is used in the experiment. The design is such that the 1D density can be independently controlled over a large conduction range and is uniform over the length of the quantum wire. Both wires show non-ballistic quantum steps up until a conductance of 10 x 2e²/h. Magnetotransport results are compared to tunneling in the 1D-1D and 2D-2D regimes.

8:00 AM V12.00001 Morphological Study of MBE Grown Iron Nitride Films on Zinc-Blende GaN(001)

— YOKO SAKURAI, SHINTARO NOMURA, YUKIHIRO TAKADA, KENJI SHIRAISHI, University of Tsukuba, MASAKAZU MURAGUCHI, TETSUO ENDOH, Tohoku University, YOKO SAKURAI, SHINTARO NOMURA, YUKIHIRO TAKADA, KENJI SHIRAISHI, University of Tsukuba, MITSUHISA IKEDA, KATSUNORI MAKIHARA, SEIICHI MIYAZAKI, Hiroshima University — We report that gate voltages required for electron injection to quantum dots (QDs) from electron gas and for emission from QDs strongly depend on temperature. For this experiment, Si-QDs floating gate MOS capacitors were designed and fabricated. Displacement current (I) was measured as a function of the gate voltage (V). Peaks in I-V curves appear as a result of charging and discharging of Si-QDs. We have found that the gate voltages for the electron injection to and for the emission from QDs shift toward more positive and negative values with decreasing temperature, respectively. Theoretical study predicts that electron tunneling is strongly enhanced when initial state of 2DES is localized below the QD [1]. Based on this discussion, the experimentally obtained results suggest that localization of electron gas induced by thermal fluctuation is responsible for enhanced electron tunneling.

8:12AM V12.00002 Iron and Iron Nitride Layers on Wurtzite Gallium Nitride Studied Using MBE/STM, WENZHI LIN, JEONGHIM PAK, YINGHAO LIU, KANGKANG WANG, ABHIJIT CHINCHORE, DAVID INGRAM, ARTHUR SMITH, Nanoscale and Quantum Phenomena Institute, Department of Physics and Astronomy, Ohio University, Athens, OH 45701, KAI SUN, Department of Materials Science and Engineering, University of Michigan, Ann Arbor, Michigan 48109 — It is of interest to study epitaxial growth of iron and iron nitride (FeN) layers on wurtzite gallium nitride (w-GaN) as a possible magnetic/wide-gap semiconductor system for spintronics. X-ray diffraction (XRD) and reflection high energy electron diffraction (RHEED) of Fe deposited on GaN(0001) suggest the existence of the epitaxial relationship [110]$_{FeN}||[0001]_{GaN}$. Furthermore, multi-streak RHEED patterns indicate the formation of a multi-domain but smooth film. Also, we have investigated the growth of $\sim$1:1 iron nitride on w-GaN(0001) using nitrogen plasma-assisted molecular beam epitaxy (MBE). Both reciprocal and real space techniques were used to study the growth of FeN, including RHEED and scanning tunneling microscopy/spectroscopy (STM/STS). Bulk characterization was also applied, including XRD and transmission electron microscopy (TEM). The results indicate that zinc-blende FeN grows on GaN(0001) with the epitaxial relationship [111]$_{FeN}||[0001]_{GaN}$, and initial atomically-smooth FeN layers are formed. This work has been supported by DOE (Grant #DE-FG02-06ER46317).

8:24AM V12.00003 Stability of Mg-incorporated InN surfaces: first-principles study, T. AKIYAMA, K. NAKAMURA, T. ITO, Mie Univ., Japan, J.-H. SONG, A. J. FREEMAN, Northwestern Univ. — InN films are attractive materials for electronic and optoelectronic applications. The growth of InN epitaxial films with $n$-type and $p$-type conductivity has traditionally been performed along the polar <0001> direction, which may result in large polarization fields along the growth direction, reducing the radiative efficiency of quantum-well light emitters. To overcome this drawback, the growth along nonpolar orientation such as (10$k\bar{2}1$) and (1120) planes and its $p$-type doping have been recently carried out. We have addressed this issue by performing first-principles pseudopotential calculations for Mg-incorporated InN surfaces in various orientations, including (10$k\bar{2}1$) and (1120) as well as (0001) and (0001) surfaces. The calculated surface energies demonstrate that qualitative trends in the stability of Mg-incorporated surfaces agree with those on GaN surfaces, although several surface reconstructions differ from those on GaN surfaces. The effects of growth conditions on $p$-type doping are also discussed.

1 Supported by the NSF’s MRSEC at N. U.

8:36AM V12.00004 Ferromagnetic $\delta - MnGa$ On Wurtzite GaN(0001): Interface Formation And Film Properties, KANGKANG WANG, ABHIJIT CHINCHORE, WENZHI LIN, JEONGHIM PAK, ARTHUR SMITH, Department of Physics and Astronomy, Ohio University, KAI SUN, Department of Materials Science and Engineering, University of Michigan — Ferromagnetic (FM) metal/wide band-gap semiconductor contacts are of great interest due to their potential for novel spintronics applications, such as blue and ultra-violet light-emitting diodes. One promising candidate is $\delta - MnGa$ on wurtzite GaN, whose epitaxial growth has recently been reported, with controllable magnetism via controlling of the Mn:Ga flux ratio. Here we report further studies on MnGa/GaN system grown by N$_2$-plasma equipped molecular beam epitaxy (MBE). Reflection high-energy electron diffraction (RHEED) data suggests a quicker and more abrupt interface formation when grown on Ga-polar GaN surface as compared to N-polar. In-situ scanning tunneling microscopy (STM) measurements on the first few monolayer’s as well as thicker MnGa films will be presented, revealing details of interface formation and other film properties. Stoichiometry dependence of the growth and magnetic properties will also be discussed. This work is supported by DOE (Grant No. DE-FG02-06ER46317) and NSF (Grant No. 0730257). Equipment support from ONR is also acknowledged. [1] S.A. Wolf et al, Science 294, 1488 (2001) [2] E.Lu et al, Phys.Rev.Lett. 97, 146101 (2006)

8:48AM V12.00005 Low-temperature transport properties of disordered tantalum and tantalum nitride films, NICHOLAS BREZNAY, MIHIR TENDULKAR, AHARON KAPITULNIK, Stanford University — Tantalum nitride thin films are used in a wide range of electronic applications, such as in thin film resistors and diffusion barriers in silicon microstructures. Growth and thorough characterization of ultrathin tantalum nitride films may prove useful in potential applications and also facilitate the study of disordered, low-dimensional systems. We will discuss the low-temperature transport properties of reactively sputtered tantalum and tantalum nitride ultrathin films as a function of film structure and composition, and connect our results to recent studies of both these and other similar two-dimensional disordered systems.

9:00AM V12.00006 First Principles Phases of Sub-Monolayer Sr and La on Si (001), KEVIN GARRITY, J.W. REINER, F.J. WALKER, C.H. AHN, S. ISMAIL-BEIJI, Yale, CRISP, CRISP TEAM — The epitaxial integration of complex oxides with semiconductors is a key requirement for many emerging technologies. In the short term, the scaling down of the dielectric layer in current CMOS technology will soon require new materials with higher dielectric constants to prevent quantum mechanical leakage currents. More generally, the epitaxial integration of complex oxides with semiconductors would allow new devices to take advantage of the wide range of oxide properties. To date, the first step of the only known method to grow complex oxides on silicon epitaxially has required 1/2 ML of an alkaline earth metal, usually Sr, to be deposited on a clean silicon surface at about 600 C. Using first-principles density functional theory calculations, we examine the growth of sub-monolayer coverages of both Sr and La on Si (100). For Sr on Si, we report on a novel 1/6 ML structure which explains the complex temperature dependence observed experimentally below 1/2 ML Sr. We compare these results to the case of La on Si, and elucidate some differences which hinder the growth of epitaxial oxides on La template layers. Our results predict an experimentally verified low temperature path to epitaxy using a Sr template layer.

1Supported primarily by NSF MRSEC DMR 0520495.

9:12AM V12.00007 From STM Images to Chemical Understanding: Kinetic Monte Carlo Simulations of Si(100) Etching, ANKUSH GUPTA, IAN T. CLARK, BRANDON S. ALDINGER, MELISSA A. HINES, Cornell University, Ithaca NY — Etching reactions literally write a record of their chemical reactivity in the morphology of the etched surface — a record that can be read using scanning tunneling microscopy (STM) and decoded with the help of simulation. We have developed a fully atomistic kinetic Monte Carlo simulation of Si(100) etching that is appropriate for aqueous etchants that produce fully H-terminated surfaces [e.g., NH$_4$F(aq), KOH(aq) and even H$_2$O]. The model assumes that the reactivity of individual surface sites is determined by the local geometry. As an example, we simulate the production of near-atomically flat Si(100) surfaces, recently observed experimentally, and show that interadsorbate stress plays a crucial role in determining the steady-state etch morphology. The simulated morphologies are in good agreement with experimental observations.
9:24AM V12.00008 Atomic-Scale Effects of Applied Strain on Etching of Si(100). MARC F. FAGGIN, BRANDON S. ALDINGER, ANKUSH GUPTA, MELISSA A. HINES, Cornell University — An ideal hydrogen-terminated Si(100) surface would be highly stressed due to unfavorable steric interactions between neighboring surface sites (i.e. neighboring silicon dihydride species). As a result, some aqueous etchants selectively remove every other silicon dihydride to relieve the stress, producing an unusual striped morphology. In these experiments, we apply a uniaxial strain to the surface during etching. Using a combination of scanning tunneling microscopy and surface infrared spectroscopy, we show that applied strains dramatically alter the etch morphology and the surface species, in some cases promoting the formation of hillocks. These effects are explained in terms of the site-specific reactivity of the etching silicon surface.

9:36AM V12.00009 Aqueous Etching Produces Si(100) Surfaces of Near-atomic Flatness. BRANDON S. ALDINGER, ANKUSH GUPTA, IAN T. CLARK, MELISSA A. HINES, Cornell University — The production of atomically flat Si(100) surfaces is a long-standing technological challenge, as these surfaces are the basis for today’s microelectronic devices. We use a combination of STM and vibrational spectroscopy to show that a simple aqueous etch can produce Si(100) surfaces of surprising and unprecedented smoothness. The etched surfaces are characterized by long rows of H-terminated Si atoms. The chemical origins of this perfection are uncovered, in part, by a new polarization-based, spectral deconvolution technique that significantly simplifies the analysis of the well-known H/Si(100) vibrational spectrum. Kinetic Monte Carlo simulations yield further insights into the site-specific chemical reactions that govern the steady-state etch morphology. The effects of interadsorbate stress, etchant pH, and gas evolution will also be discussed as time permits.

9:48AM V12.00010 Quantitative Correlations of Stress Field and Threading Dislocation Configurations in Si/Si$_{1-x}$Ge$_x$/Si(100) Strained Layers. CHI-CHIN WU, Virginia Military Institute, ROBERT HULL, Rensselaer Polytechnic Institute — The equilibrium configurations of the threading dislocation connecting misfit dislocation dipoles in Si/Si$_{1-x}$Ge$_x$/Si(100) heterostructures have been analyzed by simulation, and compared to experimental images to investigate the correlations of stress field variations and dislocation configuration in capped heteroepitaxial thin films. Calculations are based on the energy equations for dislocations in elastically isotropic crystals over all possible dislocation angular configurations, and the orientations with the minimum total energy are determined as functions of the magnitude and variations of the film stresses. It is determined that the configuration with the misfit dislocation leading at the cap/film interface (as opposed to the film/substrate interface) is increasingly favored either with increasing magnitude of local film stress/strain or with the variation in calculated geometry of the threading dislocation.

10:00AM V12.00011 Ordering mechanisms of periodic stripe arrays on boron-doped Si(100).1 IVAN ERMANOSKI, GARY KELLOGG, NORMAN BARTELT, Sandia National Laboratories — We have used low energy electron microscopy to determine the factors that control the degree of order in as-deposited periodic stripe arrays on the atomically flat Si(100) with high boron doping. The stripes consist of extremely elongated vacancy islands of single atomic height, formed at ∼900°C, confined in micrometer-sized pits. “Perfect” arrays of parallel stripes (in pits of up to ∼10nm in size) were formed by allowing various defects to heal over relatively long periods of time. Sublimation was compensated for by an external Si doser, allowing observation of stripe evolution over the course of hours, with no net loss or gain of Si from the area of interest. Stripe formation and ordering mechanisms include spontaneous nucleation and growth of new islands, longitudinal splitting, as well as coarsening due to surface diffusion. Stripe periodicity depends on temperature, allowing for control of this property. Stripes are stable in a range of ∼100°C, outside of which they assume the familiar shape of elongated islands, shaped by the anisotropy in step energy. Stripe order can be preserved to room temperature by quenching. References: [1] J.-F. Nielsen et al., Appl. Phys. Lett. 79 (2001) 3857

10:12AM V12.00012 On the Growth Mechanisms of Plasma Deposited Amorphous Silicon Thin Films. DIMITRIOUS MARoudas, SUMEET PANDEY, TEJINDER SINGH, University of Massachusetts, Amherst — We present a theoretical study of the growth mechanism of plasma deposited amorphous silicon (Si) thin films based on kinetic Monte Carlo simulations according to a transition probability database constructed by first-principles density functional theory calculations. Based on the results of the study, we propose a comprehensive mechanism of amorphous Si thin film growth by plasma deposition under conditions that make the silyl radical the dominant deposition precursor. The growth mechanism consists of various surface kinetic events including radical-surface interactions, adsorbed radical-radical interactions, radical surface diffusion, and surface hydride dissociation reactions. Of particular importance to the Si film growth process and the resulting surface composition is the radical dissociative adsorption mediated by Si over-coordination defects along the reaction pathway. The proposed mechanism explains the experimentally measured surface composition of plasma deposited Si films under the deposition conditions considered.

10:24AM V12.00013 Fundamental Study of Boron Carbide Sputtering. SUDARSHAN KARKI, DAE YEOUN, SAAD JANJUA, MARCUS DRIVER, ANTHONY CARUSO, University of Missouri Kansas City — Boron-rich carbides belong to a special class of solids whose main structural unit is the twelve atomicosahedra. When depositing thin films of boron carbide (nominally B$_x$C) by RF or pulsed DC magnetron sputtering, the individual sputtered or ablated cluster size, and the temperature of the substrate to which the clusters adsorb to form the film, greatly affects the bulk film physical and electronic structure. This talk will present mass spectrometry data of the target clusters as a function of RF power, DC bias and chamber pressure toward the goal of modeling and understanding how theicosahedral based boron-rich materials sputter and the resultant control over the final film properties. Argon trapped into the film during the deposition as determined by X-Ray photoemission will also be discussed.

10:36AM V12.00014 Correlation between Bonding Geometry and Band Gap States at Organic–inorganic interfaces: Catechol on Rutile TiO$_2$ (110). ULRlKE DIEBOLD, SHAO-CHUN LI, Department of Physics, Tulane University, JIAN-GUO WANG, Department of Chemistry, Princeton University, PETER JACOBSON, Department of Physics, Tulane University, XUE-QING GONG, ANNABELLA SELLONI, Department of Chemistry, Princeton University — Adsorbate-induced band gap states in semiconductors are of particular interest due to the potential of increased light absorption and photoactivity. A combined theoretical (DFT) and experimental (STM, photoemission) study of the molecular-scale factors involved in the formation of gap states in TiO$_2$ is presented. Using the organic catechol on rutile TiO$_2$ (110) as a model system it is found that the bonding geometry strongly affects the molecular electronic structure. At saturation catechol forms an ordered 4 x 1 overlayer. This structure is attributed to catechol adsorbed on rows of surface Ti$_x$ atoms with the molecular plane tilted from the surface normal by about ±27° in an alternating fashion. In the lowest-energy structure one of the two terminal OH groups at each catechol dissociates and the O binds to a surface Ti atom in a monodentate configuration, while the other OH group forms a H-bond to the next catechol neighbor. Through proton exchange with the surface this structure transforms into one where both OH groups dissociate and the catechol is bound to two surface Ti in a bidentate configuration. Only bidentate catechol introduces states in the band gap of TiO$_2$. 

10:46AM V12.00015 Atomic-Scale Effects of Applied Strain on Etching of Ge(110).1 MARC F. FAGGIN, BRANDON S. ALDINGcr, ANKUSH GUPTA, MELISSA A. HINES, Cornell University — An ideal hydrogen-terminated Ge(110) surface would be highly relaxed due to unfavorable steric interactions between neighboring surface sites (i.e. neighboring silicon dihydride species). As a result, some aqueous etchants selectively remove every other silicon dihydride to relieve the stress, producing an unusual striped morphology. In these experiments, we apply a uniaxial strain to the surface during etching. Using a combination of scanning tunneling microscopy and surface infrared spectroscopy, we show that applied strains dramatically alter the etch morphology and the surface species, in some cases promoting the formation of hillocks. These effects are explained in terms of the site-specific reactivity of the etching silicon surface.
Theoretical adhesion strength of diamond coating with metallic interlayers. 
HAIBO GUO, University of South Carolina, YUE QI, Materials and Processes Lab, GM R&D Center, XIAODONG LI, University of South Carolina — 
Metallic interlayers are often needed to enhance the adhesion of diamond coatings to substrates and to promote diamond nucleation and growth. The interfaces between diamond coatings and metallic interlayer materials with different carbide formation enthalpies, Cu, Al, and Ti, are studied using density functional theory. The ideal interface strength or the work of separation at the interface with the fracture energy of the metal, a fracture is likely to initiate in the metal phase near the interface, therefore a tough metal with a large surface energy is needed to achieve a higher overall toughness. In addition, when the surface energy is larger than the interface energy, a wetted diamond/metal interface is formed during diamond nucleation, which also contributes to good adhesion. The interface energy, which is an energy barrier to diamond nucleation, is found to decrease with the carbide formation enthalpy. These results indicate strong carbide formability and a large surface energy of the interlayer enhances the adhesion and the fracture resistance of the interface, and also conduce to the diamond nucleation on the interlayer.

Thursday, March 19, 2009 8:00AM - 10:36AM —
Session V13 FEd FHP: Physics Education and History

8:00AM V13.00001 Physics Education in Sub-Saharan African Schools and Universities. TILAHUN DERSUSSU, Addis Ababa University — This talk will give an overview of physics teaching and research in Sub-Saharan African Schools and Universities. 
Secondary School Physics Curricula and physics teacher training curricula from 10 African countries are compared from content, methods of delivery and evaluation perspectives. The characteristics of physics study and research in universities, both at the undergraduate and the graduate levels, are described.

8:12AM V13.00002 Physics That Works: Shift in Physics Education Paradigm Based on Work-Integrated Physics Education.1. BAHRAM ROUCHANI, Kettering University — A nontraditional work integrated undergraduate physics degree program that balances the option of pursuing a career path after graduation versus graduate studies will be presented. The main components of this undergraduate physics education model, which will be presented are; work-integrated physics education, emphasis on industrial and applied physics, nontraditional undergraduate research and thesis, an altered academic calendar, required technical sequence courses, and flexibility for each student to engage in courses that best complement physics. The impact on the growth of the physics program, the challenges and rewards involved, as well as pros and cons of such program in contrast with the traditional physics degree programs will be discussed.

1This presentation reflects the work done by the entire Physics Department at Kettering University.

8:24AM V13.00003 Strengthen Instructional Components in Peer-Lead Problem-Solving Workshop with eTEACH. JIA-LING LIN, B. CHOE, P. FOWLER, R. GILSDORF, T. KIRCHDOERFER, A. KOKEMOOR, G. LUCAS, T.J. MAIDEN, A. ROMENS, M. SPRINGER, University of Wisconsin-Madison — Physics and mechanics are core topics that sometimes frighten beginning engineering students. Statistics have shown that an increasing number of students have given up engineering because of struggle in these courses. One common realization is a consensus among educators that the quality of teaching needs to be improved, and that traditional lectures, even with stellar instructors, fail to motivate students to meet learning challenges. One of the responses from the College of Engineering at UW-Madison has been comprehensive academic support services, specifically the Supplementary Instruction (SI) Program. SI, a student-lead problem-solving workshop has made a significant impact on teaching and learning in engineering for the past eight years. In this report, we describe how we develop eTEACH (an on-line teaching tool) to integrate features of subject- and problem-based learning. We discuss how we incorporate eTEACH to promote better interactions between instructors and students, as well as among students. Our initial results showed that this change has assisted students with different learning preferences to improve problem-solving and learning strategies. We acknowledge support from Dr. G. Moses, Dr. D. Woolston, and the 2010 project in engineering college.

8:36AM V13.00004 Student thinking regarding derivative of slope concepts in multivariable calculus1. WARREN CHRISTENSEN, JOHN THOMPSON, University of Maine — Previous work on students’ understanding of graphical interpretation of slope, derivative, and area under curves in various physics contexts has shown substantial difficulties, most notably in kinematics. Concurrently, several reports point toward a lack of algebraic acumen as a likely cause for low achievement in a physics classroom. As part of ongoing research on mathematical challenges that may underlie documented physics difficulties, we focus on single- and multivariable calculus concepts to students near the end of a Calculus III course. Some of the questions are based on our earlier work in thermal physics that are essentially stripped of their physics content. Initial findings show that as many as one in five students encounter some type of difficulty when asked to rank the slopes at five different points along a single path. Students asked to rank the derivatives of three different functions at a single value of the variable face additional difficulties.

8:48AM V13.00005 An Engineer's Physics Lab — using a Large Force Frame. CHRISTY HEID, DONALD RAMPOLLA, Chatham University — We have constructed very economical, easy to assemble force frames that are used by students in our general physics laboratory at Chatham University. The force frame is used at the beginning of the semester to study vector properties of forces. The force frame can be used as a horizontal or vertical force table. Angles of forces are measured using a large movable (rotation and translation) Cartesian coordinate board attached to the frame with large binder clips. The force frame is a versatile device which is used for a number of other experiments, including beam bending and torsion, mechanical resonance, projectile trajectories, torque, mechanical equilibrium, an isolated non-magnetic support for magnetic field experiments, easily adjustable support for inclined plane experiments, support for traveling wave experiments with heavy rope, and support for large scale fluid flow experiments. One advantage to a wood frame is that things can be easily stapled, nailed, screwed or glued just about anywhere on the frame, and damaged frame members can be replaced easily. As one of the few remaining women's undergraduate institutions, we have found the use of these frames to provide an additional advantage in helping women overcome their fear of simple power tools and assembly of mechanical parts as they become comfortable with these through working with the force frames throughout the semester. We intend to describe and model these applications during the session.

9:00AM V13.00006 Explain the latent heat and specific heat of water, ammonia, and methanol with degrees of freedom. LIANYI MA, Blinn College — There are 15 known crystalline solid phases of water and all of them are called ice. But here the ice in our context is the one when water is cooled down to 0 °C at 1 atmosphere. It is well known that at 0 °C and 1 atmosphere, the density of water is 0.9998 g/cm3 and the density of ice is 0.9162 g/cm3. Question: For 0 °C water and ice, which has a higher internal energy? Because they have same temperature, their molecules should have same kinetic energies. Therefore their potential energies among molecules need to be compared. Because ice’s density is lower so it should have larger potential energy, which indicates an incredible conclusion that ice has higher internal energy. How do we explain this paradox? The internal energies of 0 °C water and ice are considered from the perspective of degree of freedom and latent heat of fusion of water is calculated, which is in good agreement with the published value. With the same consideration, the latent heats of fusion of ammonia and methanol are calculated and the results are in reasonable agreement with the published values. This simple strategy can give specific heats of water, liquid ammonia, and methanol, which are in good agreement with known data.
9:12AM V13.00007 Introducing Raman Spectroscopy of Crystalline Solids in the Undergraduate Curriculum, BAHRAM ROUGHANI, Kettering University, DAVID WARNER, UMA RAMABADRAN, Kettering University — We describe an experiment designed as an upper level physics laboratory that introduces students to Raman Scattering of electronic materials and research methodology. This experiment is an effective approach in demonstrating the relationship between the Raman intensity of the scattered light from crystals and symmetry dependent Raman selection rules. In our measurements we alter the angle between the crystal axis and the polarization of the incident laser beam by sample rotation. The three dimensional plot of the intensity profile versus the theoretical model is used to distinguish between various crystal plans of the same electronic material. This experiment combines knowledge regarding properties of materials with optical characterization. It is suitable as an upper level physics laboratory or for introducing new graduate student to use Raman spectroscopy as a research tool.

9:24AM V13.00008 Civic Engagement through Differential Equations?SHAFIQUUR RAHMAN, Allegheny College, Meadville, PA 16335 — A civic society such as ours, optimal allocations of limited resources frequently require a clear understanding of the sciences. However, policy makers often lack background in this area, and physics majors almost never get exposed to ideas that lie at the intersection of science and society, certainly not in a quantitative way. As a result, the latter show little interest in such issues. To address this problem, we have developed a short course titled Civic Engagement for Physicists. A substantial part of the course is quantitative. For example, when covering issues connected to energy, a topic of major current interest, we use a differential equation from population dynamics to study predictions about when the peak in world oil production might occur, and what the true amount of world oil reserve might be. On the other hand, topics such as Characteristics of Science and National Science Policy are covered in a qualitative way. In this talk, I’ll present details of both the quantitative and the qualitative areas covered by the course, as well as reaction of students.

1Supported by a Civic Engagement Grant from The Center for Political Participation at Allegheny College.

9:36AM V13.00009 Challenges and opportunities of undergraduate research, DANIELA M. TOPASNA, GREGORY A. TOPASNA, Virginia Military Institute — Undergraduate research at small schools is becoming the norm rather than the exception that it was years ago. Faculty are now faced with the challenges of incorporating students with varying degrees of academic preparedness and motivation in their research. This coupled with the students’ own constraints within the academic schedule can make undergraduate research a challenge for both students and faculty. Like many small undergraduate schools, VMI’s faculty and students are faced with these obstacles when engaging in undergraduate research. However, such difficulties can lead to creative solutions that lead to multiple benefits for students and faculty mentors. We present our unique perspective and experiences for this challenging yet rewarding experience as related to thin film research performed at VMI.

9:48AM V13.00010 Reacting to Galileo: Introducing a New Approach for Gen Ed Science, MICHAEL PETTERSEN, Washington and Jefferson College — Either Galileo was right, or he was wrong; either way, why was there ever any debate about it? And why should we care today about the opposing ideas, which proven wrong so long ago? In the “Reacting to the Past” series of curricular materials, students engage with key turning points in human intellectual history by taking sides and recreating the original debate. In this way, students personally identify with points of view that they would otherwise find wrong, boring, and incomprehensible — and they learn how we test ideas by challenging them, and defend them by marshalling evidence, which is the core of critical thinking. Students almost universally report that the “Reacting” experience is tremendously engaging. I shall describe an application of the “Reacting” format to the case of Galileo. The scientific issues involved are comprehensible to non-science majors, the cultural context of Renaissance Italy is rich and wonderful, and Galileo’s personal history is tremendously moving. The materials include labs designed to be taught by non-scientists teaching cross-disciplinary liberal arts courses. Other “Reacting” science materials have been published or are under development.

10:00AM V13.00011 Flint and the British Tradition of Relativity Theory, JAMES BEICHLER, Semi-retired — Most scientists and scholars are familiar with Sir Arthur Eddington’s role in verifying General Relativity in 1919. A few less are aware of his work introducing the theory to the English scientific community. Still less know of Eddington’s extensions of relativity theory, especially his attempts to develop a unified field theory. But very few scholars, historians or even physicists are aware of the important role played by other English scientists in the acceptance and development of relativity. In fact, H.T. Flint and his colleagues published more than thirty-five articles in peer reviewed journals in Britain over a period of four decades in an attempt to extend relativity to include electromagnetism and the quantum. Yet his work and that of his close associates is almost completely unknown today, in spite of the fact that he published a book describing his complete unified field theory in the 1960s, well before most quantum theorists even began thinking along the lines of unification. In a world filled with speculations about gravitons, superstrings, quantum loops and other unification models, Flint did it first, but his work has all but disappeared from the scientific consciousness. From Eddington to Flint, the English school of relativists has produced ardent supporters of relativity and numerous advances beyond the standard interpretations of general relativity.

10:12AM V13.00012 Ukrainian Physical-Technical Institute (UFTI) in the 1930’s, D.H. MCNEILL, Consultant, 3955 Bigelow Blvd., Pittsburgh, PA 15213, YU. N. RANYUK, O.S. SHEVCHENKO, Kyhrik Inst. of Physics and Technology, Ukraine — UFTI (Ukrainian Physical-Technical Institute; now Kharkiv Institute of Physics and Technology, KhFTI), founded in 1928, was among the first national laboratories. In the 1930’s, L. Shubnikov, B. Podolsky, G. Placzek, L. Tisza, F. Houtermans, A. Weissberg, V. Weisskopf, and others worked there on important and interesting research in many areas (low-temperature, electronics, nuclear physics, theory). 2008 was the centenary of Lev Landau, who established his school of theoretical physics and began his Course of Theoretical Physics in Kharkiv. It is now ~70 years since the Great purge at UFTI (and, simultaneously, throughout the USSR). UFTI’s history, a stark reminder of politics in science, is less known than that of institutions in Moscow and St. Petersburg. “Delo” UFTI 1935-1938 [The UFTI Affair, Yu. V. Pavlenko, Yu. N. Ranyuk, and Yu. A. Khramov, Kyiv, 1998] is a study, using documents available after 1990, of the lab’s early years and its near destruction in the Stalinist purges. Many scientists at UFTI were killed or imprisoned. Documents from this time will be shown. A timeline of the 1930’s at UFTI will be presented.

10:24AM V13.00013 Experience in teaching intensive course of thermal physics for undergraduate physics students, FARKHAD ALIEV, Universidad Autonoma de Madrid — This talk of non-technical nature describes experience of the author in teaching the intensive course of thermal physics for the undergraduate physics students at the Universidad Autonoma de Madrid, Spain. After brief introduction to the program, description of the WEB support of the course, I shall describe practical classes ( home-works, visits to the Laboratories, experimental demonstrations, typical problems and typical topics for presentations on the advanced thermodynamics, etc.). I shall further discuss different possible actions to wake up an interest of the students to the thermal physics and ways to simulate their active participation in the class discussions. I also describe different schemes employed in the last few years to evaluate effectively and the students work and knowledge. Finally, I will analyze the efficiency of our methodic in improving teaching of thermal physics at University level.

1Supported by Universidad Autonoma Madrid and Spanish MEC (MAT2006-07196)

Thursday, March 19, 2009 8:00AM - 10:36AM
Session V14 DFD GSNP: Disordered Systems, Glassy Dynamics, and Jamming II
8:00AM V14.00001 Specific Heat Anomalies in Glassy Fluids Due to Cluster Micro-Melting
GEORGE HENTSCHEL, Emory University, VALERY ILYIN, ITAMAR PROCACCIA, NURITH SCHUPPER, Weizmann Institute of Science — We will discuss the specific heat anomalies observed in new simulations of equimolar mixtures of particles interacting via soft core repulsive potentials under external pressure that are known to show glassy dynamics at low temperatures. The simulations show both long-lived states of microcrystalline clusters that do not nucleate a crystalline ground state and also the appearance of two specific heat peaks which were not observable in earlier simulations. We argue that the appearance of two peaks is due to the micro-melting of two types of clusters and discuss the form of the resulting specific heat anomalies. Our arguments suggest that the glass transition will typically show non-universal features.

8:12AM V14.00002 The building blocks of Dynamical Heterogeneities in dense granular media
RAPHAEL CANDELIER, OLIVIER DAUCHOT, GIULIO BIROLI, CEA — Unveiling the connection between the short term relaxation and the long term dynamical heterogeneities as observed near the glass transition in super-cold liquids and the jamming transition in granular materials remains a major challenge in the physics of glassy systems. On one hand, KMC models relate dynamical heterogeneities to a non trivial structure in the trajectory space, inherited from the local dynamical rules. On the other hand, recent studies of hard spheres close to isostaticity suggest that the collective aspect of the relaxation would stem from the extended character of the softest degrees of freedom, along which the system yields from one meta-bassin to another. There is still no direct experimental evidence in favour of one or the other mechanism in super-cold liquids nor in dense granular media. Here we will show that for a dense granular layer under cyclic shear dynamical heterogeneities result from a two timescales process. Short time but already collective events consist in clustered cage jumps, which concentrate most of the non affine displacements. Such clusters aggregate both temporally and spatially within an avalanche process, which ultimately builds the large scales dynamical heterogeneities. The typical timescale of the dynamical heterogeneities appears as the crossover between the short time separating successive event within the avalanches and the long time separating the successive jumps of any given particle.

8:24AM V14.00003 Role of Shape Anisotropy on the Glassy Dynamics of Colloidal Suspensions
MUKTA TRIPATHY, KENNETH SCHWEIZER, University of Illinois, Urbana-Champaign — Center-of-mass ideal mode coupling theory (MCT), the nonlinear Langevin active particle hopping theory, and the Reference Interaction Site Model have been employed to investigate the structure and slow dynamics of suspensions composed of hard and rigid nonspherical objects. Objects of dimensionality one (rods, rings), two (discs), and three (polyhedra) have been studied. For non-compact particles the volume fraction of ideal kinetic arrest, corresponding to a crossover to activated dynamics, decreases with particle dimensionality and/or aspect ratio. On the other hand, the ideal vitrification volume fraction of compact 3-dimensional objects is a complex and subtle function of particle shape. Calculations of the entropic barrier for activated transport, mean relaxation time, transient localization length, diffusion constant, elastic modulus, and effective fragility have been performed. Deep in the ideal glassy region the barrier height and mean hopping time are controlled by the shape-dependent mean square confining force exerted on a particle by its surroundings. A nearly universal collapse of many dynamical properties is achieved based on a dimensionless difference variable that quantifies the magnitude of the mean square force compared to its critical value at the ideal MCT transition.

8:36AM V14.00004 Coupled Translational and Rotational Glassy Dynamics in Hard Dicollloid Suspensions
RUI ZHANG, KENNETH SCHWEIZER — Naive mode coupling theory (NMCT) and the nonlinear Langevin equation (NLE) theory of activated glassy dynamics have been generalized to treat the coupled center-of-mass translation and rotational motions of hard linear objects of variable aspect ratio. Two types of ideal nonequilibrium transitions are predicted corresponding to localization of only translation (plastic glass for small aspect ratios) or simultaneous arrest of translation and rotation (double glass). The NMCT kinetic arrest transition signals a crossover to activated dynamics controlled by entropic barriers. Specifically, a two-dimensional dynamical free energy surface (function of translational displacement and rotational angle) is constructed which quantifies effective rates of all process corresponding to the trajectory of lowest entropic barrier is associated with a system-specific translation-rotation cooperative motion. Mean alpha relaxation times as a function of dicollid aspect ratio and volume fraction are computed using multidimensional Kramers theory.

8:48AM V14.00005 Constitutive relations in dense granular flows
JOHN DROZD, COLIN DENNISTON, University of Western Ontario — We use simulations to investigate constitutive relations in dry granular flow. Our system is comprised of mono- and poly-disperse sets of spherical grains falling down a vertical chute under the influence of gravity. We observe three phases or states of granular matter: a free-fall dilute granular gas region at the top of the chute, a granular fluid in the middle and then a glassy region at the bottom. We test various proposed constitutive relations to provide a basis for analytically solving for the stresses in granular flows. Finally, we examine the energy conservation and heat flow in our systems and show that the heat conductivity constitutes distinct power-law dependencies on the granular temperature in the glassy and fluid regions of our system.

9:00AM V14.00006 Polytetrahedral Frustration of Crystallization: A Study of 4d Hard Spheres
PATRICK CHARBONNEAU, Duke University, JACOBUS A. VAN MEEL, FOM Institute for Atomic and Molecular Physics, DAAN FRENKEL, Cambridge University — Geometrical frustration is thought to be the supercooling of a liquid. In 3d hard spheres the preferred local cluster is isohedral and the densest packing is tetrahedral, but no periodic lattice is consistent with either symmetry in Euclidian space, so a crystal phase with a different symmetry nucleates upon compression. For 2d disks in contrast triangular or hexagonal order is both locally and globally preferred and crystallization of a metastable fluid is quasi-instantaneous. Yet the precise origin of geometrical frustration remains unclear, because in 2d and 3d polytetrahedral structures are often equated conceptually to the optimal local cluster. Here, we conduct a computational study of the 4d analogue, where the optimal local cluster and global order are commensurate, but the polytetrahedral order is not. We observe no sign of facile crystal formation, which support the polytetrahedral frustration scenario. We also find the fluid to be structurally very different from the crystal. The resulting high interfacial free energy sheds new light on 3d geometrical frustration and its role in glass formation.

9:12AM V14.00007 Noise as a Probe of Ising Spin Glass Transitions
ZHI CHEN, CLARE YU, University of California, Irvine — Noise is ubiquitous and is often viewed as a nuisance. However, we propose that noise can be used as a probe of the fluctuations of microscopic entities, especially in the vicinity of a phase transition. In recent work we have used simulations to show that the noise increases in the vicinity of phase transitions of ordered systems. We have recently turned our attention to noise near the phase transitions of disordered systems. In particular, we are studying the noise near Ising spin glass transitions using Monte Carlo simulations. We monitor the system as a function of temperature. At each temperature, we perform slow shear of colloidal glasses using a confocal microscope and shear-cell set up. The particles are tracked in time and space to construct the local strain field, which is observed to be non-uniform with high strain and low strain zones interspersed in space. Our measurements at a volume fraction ~ 58% show the existence of homogeneous sheared regime, at a shear rate ~5x10^{-15} s^{-1} and shear localization at higher shear rates (~10^{-4} s^{-1}). The set-up offers a unique opportunity to elucidate the evolution of shear-bands using the concept of shear transformations. In particular, the aim is to understand the role of correlation between the shear transformations in the growth of shear bands. We present an overview over the homogeneous versus inhomogeneous shear regime in terms of a deformation map for these systems.

Work supported by DOE grant DE-FG02-04ER46107.

9:24AM V14.00008 Shear banding in colloidal glasses
VIJAYAKUMAR CHIKKADI, University of Amsterdam, THE NETHERLANDS, ANDREW SCHOFIELD, University of Edinburgh, U.K., PETER SCHALL, University of Amsterdam, The Netherlands — We perform slow shear of colloidal glasses using a confocal microscope and shear-cell set up. The particles are tracked in time and space to construct the local strain field, which is observed to be non-uniform with high strain and low strain zones interspersed in space. Our measurements at a volume fraction ~ 58% show the existence of homogeneous sheared regime, at a shear rate ~5x10^{-15} s^{-1} and shear localization at higher shear rates (~10^{-4} s^{-1}). The set-up offers a unique opportunity to elucidate the evolution of shear-bands using the concept of shear transformations. In particular, the aim is to understand the role of correlation between the shear transformations in the growth of shear bands. We present an overview over the homogeneous versus inhomogeneous shear regime in terms of a deformation map for these systems.
9:36AM V14.00009 Correlations between Dynamical Heterogeneity and Viscoelasticity of Confined Colloidal Suspensions under Oscillatory Shear, PRASAD SARANGAPANI, YINGXI ELaine ZHU, University of Notre Dame, Department of Chemical and Biomolecular Engineering, Notre Dame, IN 46556 — In this talk, we present a recent rheological study of confined amorphous colloidal thin films under oscillatory shear using a home-designed micron-gap rheometer interfaced with a confocal microscope. We visualize the response of "hard-sphere" poly-(methyl methacrylate) (PMMA) particles of 1.2 µm in diameter to applied shear deformation and simultaneously measure the viscos and elastic moduli of PMMA colloidal thin films of bulk volume fraction, φ = 0.430-0.57, confined at gaps ranging from 50 µm to 1.2 mm. For confined PMMA colloids under shear at gaps where an applied deformation is sufficiently large to induce non-linear responses, we find commonality in particle dynamics where strongly non-affine motion causes particles to move as cooperatively rearranging groups. However, on average the length scale of these groups is larger than the typical length scales of dynamical heterogeneities for the un-sheared thin films and typically approaches the order of confining dimension. We quantify the nature of shear induced flow cooperativity and its relation to a shear thickening transition observed in the limit of large strain amplitudes.

9:48AM V14.00010 Aggregation of athermal particles induced by capillarity, MICHAEL BERHANU, ARSHAD KUDROLLI, Department of Physics, Clark University, Worcester, MA 01610. — Aggregation of cohesive particles floating in a medium is a very broad physical phenomena occurring in colloidal systems, soot particles, and intergalactic dust under gravitation. We investigate the geometrically constrained dynamics of aggregation with new experiments using floating spheres at the air-water interface. A short range attractive force can be induced by careful choice of buoyancy and capillarity to create self-assembled particle structures which can be tracked by imaging. First, the particles are placed randomly at the interface, and then aggregation is induced by smoothly decreasing the area of the interface which causes the particles to come within the attractive force range caused by capillarity. We measure the area fraction at which the connectivity and rigidity percolation transitions are observed and further characterize the aggregates with two-point correlation functions. We then compare and contrast our results with gelation and jamming transitions reported with colloids and granular matter. Finally, we study the reverse phenomena, where we probe the response of the aggregate to an increase in interface area.

10:00AM V14.00011 Correlation range in a supercooled liquid via Green-Kubo expression for viscosity, local atomic stresses, and MD simulations, VALENTIN A. LEVASHOV, TAKESHI EGAMI, JAMES R. MORRIS, University of Tennessee and Oak Ridge National Laboratory — We present a new approach to the issue of correlation range in supercooled liquids based on Green-Kubo expression for viscosity. The integrand of this expression is the average stress-stress autocorrelation function. This correlation function could be rewritten in terms of correlations among local atomic stresses at different times and distances. The features of the autocorrelation function decay with time depend on temperature and correlation range. Through this approach we can study the development of spatial correlation with time, thus directly addressing the question of dynamic heterogeneity. We performed MD simulations on a single component system of particles interacting through short range pair potential. Our results indicate that even above the crossover temperature correlations extend well beyond the nearest neighbors. Surprisingly we found that the system size effects exist even on relatively large systems. We also address the role of diffusion in decay of stress-stress correlation function.

10:12AM V14.00012 Dynamics in Complex Fluids Formed by Conjugated Polymers, NAresh OSTI, Department of Chemistry, Clemson University, Clemson, SC 29634, MADHUSUDAN TYAGI, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, MD 20899, DILRU RATNAWEERA, Department of Chemistry, Clemson University, Clemson, SC 29634, UWE BUNZ, Department of Chemistry and Biochemistry Georgia Institute of Technology, Atlanta, GA 30332, DVORA PERAHIA, Department of Chemistry, Clemson University, Clemson, SC 29634 — Alkyl di-substituted para-polyphenyleneethylene (PPE) associates into several complex fluids in dilute solutions of toluene. At high concentrations these molecules are strongly flattened, associating in the direction perpendicular to the long molecular axis. At the temperature of the glass transition the molecules associate and eventually jam to a fragile gel. These phases are optically active where the dynamic processes affect their optical characteristics. Inelastic Neutron Back Scattering conjunction with Neutron Spin Echo was used to characterize the dynamics on multiple length scales at different temperatures. The current talk will introduce the neutron backscattering results that follow internal dynamics within the PPE molecules as they are confined into aggregates and jams to form a fragile phase. The data will be discussed in terms of Kohlrausch-Williams-Watt model that provides characteristics time constants for the different dynamic processes.

10:24AM V14.00013 Spontaneous transition in TiNiFe strain glass system, JIAn ZHANG, XIAOBING REN, YU WANG, KAZUHIRO OTSUKA, JUN SUN, Multi-disciplinary Materials Research Center, Xi an Jiaotong University,710049, P.R. China; Ferroic physics group, NIMS, Tsukuba, Japan — Glass has been considered as one major challenge for the statistic mechanics, for the presumption of ergodicity is no longer valid. Hence, glass transition was normally viewed as solely kinetic driven process, including ferroic cluster glasses. Whereas, the ferroic cluster glasses appear once the thermodynamics driven ferroic phases are suppressed by the point defects. It seems quite intriguing why the power of thermodynamics is immediately rewritten in terms of correlations among local atomic stresses at different times and distances. Through this approach we can study the development of spatial correlation with time, thus directly addressing the question of dynamic heterogeneity. We performed MD simulations on a single component system of particles interacting through short range pair potential. Our results indicate that even above the crossover temperature correlations extend well beyond the nearest neighbors. Surprisingly we found that the system size effects exist even on relatively large systems. We also address the role of diffusion in decay of stress-stress correlation function.

Thursday, March 19, 2009 8:00AM - 10:48AM — Session V15 DFD: Liquid Crystals I 316

8:00AM V15.00001 Interaction and Response of a Smectic-A liquid crystal to a 2 nm Nanometer Particle: Phase transition due to the Functionalization Compound, LUZ J MARTINEZ-MIRANDA, University of Maryland, LYNN K KURIHARA, Naval Research Laboratories — We have studied the in-plane (parallel to the magnetic field) alignment of 8CB mixed with FeCo nanoparticles covered with different functionalization compounds. The functionalization compounds are Polyethylene glycol (PEG (3000)), hydroxyl succinimide (NHS), aminopropyl tri-ethoxy silane (APTS) and mercapto hexa-decanoic acid (MHD). We have studied them using X-ray scattering. We have found that the inverse integrated intensity of the X-ray scans in the plane of the magnetic field is a good measure of how much energy the system (liquid crystal, nanoparticles, functionalization compound) will need to reorient the liquid crystal in the magnetic field. In addition, we have observed that the orientation the liquid crystal adopts with respect to the nanoparticles can result in a phase transition that takes the liquid crystal to a more disordered and symmetric phase that favors the rotation, as happens in the smectic-nematic transition, observed in the sample with APTS. We relate the disordering to the changes observed in the transition for the liquid crystal and this termination to recent heat capacity measurements by Cordoyiannis et al. [1].

8:12AM V15.00002 Theory of Ferroelectric Nanoparticles in Nematic Liquid Crystals, LENAPATINA, JONATHAN SELINGER, Liquid Crystal Institute, Kent State University. Many recent experiments have reported that ferroelectric nanoparticles have drastic effects on nematic liquid crystals. Low concentrations of such particles increase the nematic-isotropic transition temperature by over 10 °C, and greatly increase the sensitivity of the nematic phase to applied electric fields. To understand these effects, we develop a theory for the statistical mechanics of ferroelectric nanoparticles in liquid crystals. In this theory, the key issue is the distribution of orientations for the electrostatic dipole moments of the nanoparticles. This distribution is characterized by an orientational order parameter, which interacts with the orientational order of the liquid crystals and stabilizes the nematic phase. We estimate the coupling strength and calculate the resulting enhancement in the transition temperature, in good agreement with experiments. We also predict the response to applied electric fields, showing that the Kerr effect is enhanced above the isotropic-nematic transition. These predictions apply even when the electrostatic interactions are partially screened by moderate concentrations of ions.

8:24AM V15.00003 Unconventional dimerization in mesogenic semi-phasmidic type carboxylic acid*, SHIN-WOONG KANG, SEUNG-YEON JEONG, DENA MAE AGRA-KOOLJAN, SATYENDRA KUMAR, Department of Physics, Kent State University, VEENA PRASAD, SANJAY VARSHNEY, Centre for Liquid Crystal Research, Bangalore, INDIA. Nematic and columnar mesophases formed by a semi-phasmidic type carboxylic acid are investigated by DSC, X-ray scattering, FTIR spectroscopy, and polarizing optical microscopy. FTIR spectroscopy and X-ray diffraction reveal that two semi-phasmidic type carboxylic acid molecules form a mesogenic dimer through inter-molecular hydrogen bonding. X-ray diffraction results obtained under in-situ magnetic field reveal unique characteristics that set them apart from conventional linear dimers formed via hydrogen bonding. These dimers possess negative dielectric and diamagnetic anisotropies. Values of the length scales corresponding to the diffraction peaks and their orientation relative to the magnetic field strongly suggest the formation of a “bent-core-like” mesogenic dimers rather than conventional coplanar linear dimers.

4Supported by grant NSF/DMR-060991.

8:48AM V15.00005 The shape and conformation of the mesogenic group in tetrapodic liquid crystals, HYUNGYOUNG YOON, SHINWOONG KANG, Department of Physics, Kent State University, GEORGE H. MEHL, Department of Chemistry, University of Hull, UK, SATYENDRA KUMAR, Department of Physics, Kent State University. The nematic mesophases formed by tetrapodic mesogens based on Si- or Ge-core have been investigated by various methods [1]; deuterium NMR, polarized IR spectroscopy, and light scattering. In these studies, biaxiality of the nematic phase has been a central issue. The average statistical shape of such a complex molecule adopts and how the four mesogens attached to Si/Ge atom are oriented in the nematic and lower temperature phases are naturally important questions. However, these have not been sufficiently discussed. We performed synchrotron x-ray diffraction experiments on magnetic aligned Ge-tetrapodes, augmented by conoscopy, capacitance, and electro-optical experiments. The results of these studies and the inferences drawn for the mesogenic group formation will be presented. [1] K. Neupane, S.W. Kang, S. Sharma, D. Carney, T. Meyer, G. H. Mehl, D.W. Allender, S. Kumar, and S. Sprunt, Phys. Rev. Let. 97, 207802 (2006), and references there in.

9:00AM V15.00006 Quantum dot dispersion in nematic liquid crystal, J. KIRCHHOFF, Florida State University, ROBERT INMAN, D.S. CHANDHOK, S. GHOSH, L.S. HIRST, University of California Merced. Optical and electrical properties of quantum dots can be significantly altered by aligning the dots in a linear chain. Dispersing quantum dots in liquid crystals can lead to the formation of linear chains due to the partial ordering of the liquid crystal molecules. Typically, this results in a red shift in the emission spectrum of the dots as the induced order leads to enhanced dipolar interactions, resulting in electronically coupled states. Dispersions of quantum dots are studied as a function of the concentration, size, and shape of the dots in a nematic rod-like liquid crystal material. The quantum dots are seen to aggregate if the concentration of the dots is too high, leading to enhanced dipolar interactions, resulting in electronically coupled states. Dispersions of quantum dots are studied as a function of the concentration, size, and shape of the dots in a nematic rod-like liquid crystal material. The quantum dots are seen to aggregate if the concentration of the dots is too high, leading to little correlation between the quantum dot dispersion and liquid crystal texture. In decreasing the quantum dot concentration the aggregates lessen in size and are more uniformly distributed within the liquid crystal. Spherical, rod-like, and disc-like quantum dots with emission peaks ranging from 490 nm to 640 nm were studied using polarized optical microscopy and scanning microscopy photoluminescence measurements.

9:12AM V15.00007 Dielectric and Optical Properties of Nematic ODBP-Ph-C7*, BOHDAN SENYUK, HUGH WONDERLY, SERGIY SHIYANOVSKII, OLEG LAVRENTOVICH, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, VICTOR P. PENGAMENSHCHIK, Display and Semiconductor Physics, Korea University, Kangwon 339-700, South Korea; Institute of Physics, Prospect Nauky 46, Kyiv 03039, Ukraine. Thermotropic biaxial nematic liquid crystals are promising for application in fast switching electro-optical devices. In the present work, we study the optical and dielectric properties of the nematic phase of thermotropic LC material, 4,13,6(3,4-x-dioxadiol2,5-diyl) diphenylbenzoate (ODBP-Ph-C7) with boomerang-like molecules, reported to exhibit the biaxial nematic phase [2]. We study ODBP-Ph C7 in well-aligned "monocristalline" states. The experiments show that the uniaxial and dielectric properties of the material, such as high dielectric dispersion and dielectric relaxation times increase with temperature. We also analyze defect structures formed by ODBP-Ph-C7 in different geometries of confinement and boundary conditions. [1] G. R. Luckhurst, Thin Solid Films 393, 40 (2001); 2 B. R. Acharya, A. Primak, T. J. Chengmans, E.T. Samulski and S. Kumar, Pramana J. Phys. 61, 231 (2003).

9:36AM V15.00009 Theory and simulation of two-dimensional nematic and tetragonic phases1 . JUN GENG, JONATHAN V. SELINGER, Liquid Crystal Institute, Kent State University — Recent experiments and simulations have shown that two-dimensional systems can form tetragonic phases with four-fold rotational symmetry, even if they are composed of particles with only two-fold symmetry. To understand this effect, we propose a model for the statistical mechanics of particles with almost four-fold symmetry, which is weakly broken down to two-fold. We introduce a coefficient \( \kappa \) to characterize the symmetry breaking, and find that the tetragonic phase can still exist even up to a substantial value of \( \kappa \). Through a Landau expansion of the free energy, we calculate the mean-field phase diagram, which is similar to the result of a previous hard-particle exclusion-volume model. To verify our mean-field calculation, we develop a Monte Carlo simulation of spins on a triangular lattice. The results of the simulation agree very well with the Landau theory.

9:48AM V15.00010 Quadrupolar particles in a nematic liquid crystal: Effects of particle size and shape . FRANCISCO HUNG, Cain Department of Chemical Engineering, Louisiana State University — We investigate the effects of particle size and shape on the quadrupolar (Saturn ring-like) defect structures formed by a nematic liquid crystal (NLC) around nm- and micron-sized particles with spherical, spherocylindrical and cubic shapes. Our calculations, based on a Landau-de Gennes expansion in terms of the tensor order parameter \( \mathbf{Q} \), indicate that for pairs of nanoparticles in close proximity, the most stable defect structure is the "entangled hyperbolic" [1]. For pairs of micron-sized particles the NLC forms entangled "figure of eight" defects [1] around pairs of spheres and spherocylinders. In contrast, we only observed unentangled defect structures around pairs of micron-sized cubic particles. For pairs of spherical and spherocylindrical particles, the transition between "entangled hyperbolic" and "figure of eight" structures occurs when the particle diameter is between 100 nm and 1 micron. Our calculations suggest that the NLC-mediated interactions between the nanoparticles are fairly strong (up to 5700 kT). These interactions can bind the particles together at specific locations, and thus could be used to assemble the particles into ordered structures with different morphologies. [1] M. Ravnik et al., Phys. Rev. Lett. 99, 247801 (2007)

10:00AM V15.00011 A Model Liquid Crystalline System Based on Rodlike Viruses with Tunable Chirality , DANIEL BELLER, EDWARD BARRY, ZVONIMIR DOGIC, Brandeis University — Filamentous bacteriophages such as the fd virus have long been used as ideal model systems to investigate the phase behavior of suspensions of rodlike particles. We study the structure and phase behavior of a mutant, fd Y21M, and compare them to the properties of conventional fd wild-type (wt). These two viruses exhibit dramatically different phase behavior despite differing only by a single amino acid of the major coat protein pVII. We find that this is attributable to significant differences in the flexibility of the viruses. Using the more rigid fd Y21M, we are able for the first time to quantitatively test the Onsager description of the isotropic-nematic phase transition of rigid rods. Even more surprising are the differences in the behavior of the cholesteric phase of fd Y21M and fd wt. While fd wt forms a cholesteric pitch with a left-handed helix, fd Y21M forms a cholesteric pitch with the opposite handedness. In addition, the magnitude of the cholesteric pitch changes by almost fivefold. Using mixtures of the two viruses, we are able to create liquid crystal systems with tunable control over the macroscopic chiral behavior.

10:12AM V15.00012 Apparent Broken Reciprocity in Chiral Liquid Crystals1 , MICHELE MOREIRA, NITHYA VENKATARAMAN, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University, LORENZO MARRUCCI, Dipartimento di Scienze Fisiche, Università di Napoli "Federico II" — Reciprocity in optics is predicated on bounded scattering media with symmetric and linear permittivity, conductivity and permeability. Due to their anisotropy and chirality, cholesteric liquid crystals (CLCs) form periodic dielectric structures. If the periodicity is comparable to the wavelength of light, these phases are self-assembled photonic band gap structures. There appear in the permittivity odd powers of the wave vector resulting from nonlocality and broken inversion symmetry. Evidence of non-reciprocity has been found in optically active crystals by Bennett [1] and in stacks of cholesteric and nematic liquid crystal cells by Takezoe [2]. We investigate experimentally and theoretically the possibility of a violation of optical reciprocity of a hetero-photonic-bandgap structure made of two CLC cells of different pitch. We have observed a significant apparent violation, but we show that the effect is due to light scattering, and in fact these cholesteric structures are reciprocal.

10:24AM V15.00013 Raman scattering study of orientation order parameters in thermotropic biaxial nematic LC , MIN SANG PARK, BUM JIN YOON, JUNG OK PARK, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology, Atlanta, GA, USA, VEENA PRASAD, Center for Liquid Crystal Research, Bangalore, India , MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA, USA — There has been considerable interest in the liquid crystalline phases formed by bent-core molecules, since these molecules were considered to have a biaxial nematic phase. In an effort to understand the orientation behavior and the degree of phase biaxiality in bent-core mesogens, Raman spectroscopy has been used to measure the scattering intensities for orthogonal linear polarization. This straightforward methodology allows the values of both uniaxial, \( \langle P_{200} \rangle \) and \( \langle P_{400} \rangle \), and biaxial order parameters, \( \langle P_{220} \rangle \), \( \langle P_{202} \rangle \), and \( \langle P_{410} \rangle \) to be quantified. From experimentally derived order parameters, the most probable orientation distribution functions are constructed. The results of these measurements will be presented in the context of experimental evidence of phase biaxiality obtained by other methods including X-ray diffraction and NMR.

10:36AM V15.00014 Liquid crystalline behaviors of H-bonded dimer formed from the semi-phasicdride type carboxylic acid * , SEUNG-YEON JEONG, SHIN-WOONG KANG, SATYENDRA KUMAR, Department of Physics, Kent State University, VEENA PRASAD, SANJAY VARSHNEY, Centre for Liquid Crystal Research, Bangalore, INDIA — Liquid crystalline properties of acid-functionalized semi-phasicdride azo-compound were characterized by DSC, polarizing optical microscopy, and electro-optical measurements. The results suggested that this unconventional mesogen has a non-typical effective "bend" angle where two monomers form the hydrogen bond. To confirm this, we performed electro-optical experiments in the nematic phase with strong external electric and magnetic fields. Cells with different surface geometries and treatments we used. The results reveal a behavior that is very distinct from that expected of conventional linear mesogenic dimers formed by a hydrogen bonding. The results confirm negative values of dielectric and diamagnetic anisotropies. Our observations indicate that "bent-like" dimeric mesogens are formed through an unconventional inter-molecular association. *Work supported by grant NSF/DMR-086991.

Thursday, March 19, 2009 8:00AM - 10:24AM – Session V16 DCMP: Solid Helium: Experiment 317
8:00AM V16.00001 Bose-Einstein condensation in solid helium, RICHARD AZUAH, NIST Center for Neutron Research, Gaithersburg, SOULEYMANE DIALLO, Ames Laboratory, Ohio, OLEG KIRICHEK, ISIS Spallation Neutron Source, Didcot, UK, HENRY GLYDE, University of Delaware — We report new measurements of the Bose-Einstein condensate fraction in solid helium. The goal is to reveal whether there is BEC associated with the superfluid fractions that have been observed in solid helium [1,2]. The condensate fraction, n_0, is obtained from neutron scattering measurements of the momentum distribution, n(k), of the atoms in the solid. We use commercial grade helium (^{4}He concentration of 0.3 %) where the T_c for superflow is T_c = 200 mK and have measured the n(k) at 3 temperatures, 500 mK, 150 mK and 65 mK. We use a sample cell that has a large surface to volume ratio (S/V) ≈ 40 cm^{-1} where large superfluid fractions have recently been reported[2]. We use a large sample volume (100 cm^3) and high instrument resolution to improve precision beyond that of previous measurements [3]. No clear sign of BEC has been observed but the data is being analyzed so that specific values of n_0 can be reported. [1] E. Kim and M.H.W. Chan, Science, 305:1941 (2004); Nature, 427:225, 2004. [2] A. S. C. Rittner, and J. D. Reppy, Phys. Rev. Lett., 98:175302, 2007. [3] Díallo et al. Phys. Rev Lett. 98, 205301 (2007).

8:12AM V16.00002 Pressure-driven mass flow in solid 4He, ANN SOPHIE C. RITTNER, Department of Physics and Astronomy and Rice Quantum Institute, Rice University, Houston, TX 77251, USA, WONSUK CHOI, Physics Department, KAIST, Daejeon, South Korea, JOHN D. REPPY, Laboratory of Atomic and Solid State Physics and the Cornell Center for Materials Research, Cornell University, Ithaca, NY 14853, USA — We report on two experiments that explore pressure-driven flow in solid 4He. In the first experiment, two pancake-shaped chambers are connected by a narrow slit. The pressure in one chamber is varied periodically at 2 mHz and we look for a superfluid pressure response in the second chamber. When the cell is filled with liquid, we observe a large pressure signal in the second chamber as expected for superfluid flow. In solid helium, no pressure response is detected outside the noise level. In a second experiment, we generate an oscillating pressure in a torsional oscillator by blocking an annulus. We expect the pressure difference to drive the supersolid component through a radial channel orthogonal to the rotational motion of the oscillator.

1Supported by NSF Grants DMR-0203244 and DMR-0520404

8:24AM V16.00003 Observation of Mass Flux through solid 4He, ROBERT HALLOCK, MICHAEL RAY, Univ. of Mass. Amherst — We have developed a novel apparatus and technique that allows us to maintain an interface between superfluid helium and hcp solid 4He at pressures greater than ≈ 25 bar, the low temperature solid-liquid coexistence pressure. We use this apparatus to inject helium into one side of the solid, creating a chemical potential difference across the solid, and we then look for a response in the pressure on the other side. We observe a flux of atoms through the solid[1] which tends to decrease with increasing solid pressure. There is also a complicated temperature dependence, which suggests hysteretic behavior. We will describe the experimental apparatus, and some of our results.

1Supported by the NSF

8:36AM V16.00004 Growth of hcp Solid 4He from the Superfluid, MICHAEL RAY, ROBERT HALLOCK, Univ. of Mass. Amherst — Using the same experimental apparatus that we developed to search for mass flux in hcp solid 4He at pressures greater than 25 bar[1], we study the growth of solid helium from the superfluid at constant temperature. As the pressure of the solid is driven above the melting curve, with helium continuously being added to the sample cell, we observe apparently random events during which the pressure of the solid drops. These pressure drops are accompanied by a sharp transient rise in the temperature of the cell. We will present the data, along with some discussion of what might cause these transients.

1Supported by the NSF

8:48AM V16.00005 Velocity dependence of supersolid He-4 in a torsion oscillator, ETHAN PRATT, BENJAMIN HUNT, VIKRAM GADAGKAR, Cornell University, MINORU YAMASHITA, Kyoto University, J.C. SEAMUS DAVIS, Cornell University, Brookhaven National Laboratory, University of St. Andrews — We have developed a free-inertial-decay mapping technique which allows us to acquire the complete velocity-temperature phase diagram of supersolid He-4. A striking new feature of the resulting supersolid response map is the appearance of an enhanced dissipation superpeak. We discuss these results in context of various microscopic mechanisms for the velocity-induced suppression of the supersolid response, including a superfluid critical velocity, defect network critical shear, and a glassy dynamical susceptibility.

9:00AM V16.00006 Torsional oscillator measurements on solid helium in a partially blocked annular channel, DUK YOUNG KIM, SANG-IL KWON, HYOUNGSOON CHOI, EUNSEONG KIM, KAIST, CSQR AND DEPARTMENT OF PHYSICS TEAM — We employed a torsional oscillator technique to investigate the non-classical response of solid helium. We grow solid helium samples within an annular channel that is divided by two Vycor blocks. The melting pressure of helium in narrow pores of Vycor glass is elevated up to about 37 bar due to partial blocking the pressure. This work is supported by Creative Research Initiative of MOST/KOSEF.

9:12AM V16.00007 Simultaneous Oscillation of Annular Solid 4He Samples at Two Mode Frequencies in Compound Torsion Pendulum, MICHAEL C. KEIDERLING, HARRY KOJIMA, Rutgers University — We have extended our studies on the non-classical behavior of solid 4He contained in compound torsional oscillator (TO) cell below 1 K. Our unique TO design allows observations on the identical sample at two distinct frequencies (f_1=493 and f_2=1165 Hz). The sample was grown by blocked capillary method in an annular cell(id = 8.0 mm, od = 10.0 mm, height = 9.0 mm). We focus here on experiments in which the two modes are excited simultaneously. While keeping the drive of f_1 mode at a very low level, the drive of f_2 mode was varied from high to low levels to produce substantial variations in the non-classical rotation inertia fraction (NCRIf). When the NCRIf seen by f_1 mode is reduced by 89, 91 and 94 % at 9.7, 23.5 and 56.5 mK, respectively, the NCRIf seen by f_2 mode (driven at low level) is reduced by 62, 68 and 80 %. The discrepancies and their temperature dependence in the observed reductions in NCRIf are not yet understood. Similar Measurements with the roles of the drive levels of the modes reversed as well as the changes in the dissipation of the torsional oscillator during the simultaneous drive will be reported.

3Supported in part by NSF grant DMR-0704120.
9:24AM V16.00008 Effects of $^3$He Impurities on the Non-Classical Rotation Inertia of Solid $^4$He as Measured by Compound Torsion Pendulum, DAVID RUFFNER, MICHAEL KEIDERLING, PATRYK GUMANN, HARRY KOJIMA, Rutgers University — An intriguing observation related to the discovery of non-classical rotational inertia (NCRI) of solid $^4$He at low temperatures is the extreme sensitivity to $^3$He concentration ($x_3$). Both the magnitude and temperature dependence of the NCRI are affected by relatively low $x_3$ introduced into solid $^4$He samples.[1] We are exploring the $^3$He impurity effect using our compound torsional pendulum which allows probing the NCRI of the identical solid $^4$He sample at two different frequencies (~493 and ~1165 Hz). The NCRI fractions were derived from the measured shifts in the oscillator frequency of the two modes as functions of temperature. The NCRI fraction derived from the higher frequency mode is greater than that derived from the lower frequency mode at all temperatures. If the NCRI fractions of both modes are normalized at their maximums, the temperatures at which they decrease to 50 % of the maximum are greater in the higher mode by ~9, 31 and 56 mK when the nominal $x_3$ added is 0.3, 3 and 10 ppm, respectively. Greater values of $x_3$ are currently being studied.[1]Kim, et al., Phys. Rev. Lett. 100 065301(2008).

1Supported in part by NSF grant DMR-0704120.

9:36AM V16.00009 Sample quality dependence of the specific heat peak in solid $^4$He, XI LIN, Z. G. CHENG, M. H. W. CHAN, Penn State U. — We reported a broad peak in specific heat of solid $^4$He at low temperatures is the extreme sensitivity to $^3$He concentration ($x_3$). Both the magnitude and temperature dependence of the NCRI are affected by relatively low $x_3$ introduced into solid $^4$He samples.[1] We are exploring the $^3$He impurity effect using our compound torsional pendulum which allows probing the NCRI of the identical solid $^4$He sample at two different frequencies (~493 and ~1165 Hz). The NCRI fractions were derived from the measured shifts in the oscillator frequency of the two modes as functions of temperature. The NCRI fraction derived from the higher frequency mode is greater than that derived from the lower frequency mode at all temperatures. If the NCRI fractions of both modes are normalized at their maximums, the temperatures at which they decrease to 50 % of the maximum are greater in the higher mode by ~9, 31 and 56 mK when the nominal $x_3$ added is 0.3, 3 and 10 ppm, respectively. Greater values of $x_3$ are currently being studied.[1]Kim, et al., Phys. Rev. Lett. 100 065301(2008).

9:48AM V16.00010 Torsional oscillator and specific heat studies of 4He in Vycor, Z.G. CHENG, X. LIN, J.T. WEST, M.H.W. CHAN, Penn State University — Non-classical rotational inertia (NCRI) was first reported in solid helium confined in Vycor using the torsional oscillator technique [1]. Most of the work since then has focused on bulk solid helium. Recent specific heat measurements of bulk solid helium show a peak centering near the NCRI onset temperature [2], a good indication that the two may be related. We report on a series of experiments to study the NCRI fraction and specific heat of solid helium in Vycor. The torsional oscillator experiment is revisited to study the stability of the NCRI fraction. The purpose of the specific heat measurement is to probe the relation between the specific heat peak and NCRI.

The work is supported by NSF Grants No. DMR-0706339.

10:00AM V16.00011 Second sound in supersolid $^4$He, NORBERT MULDERS, Department of Physics, University of Delaware, SANGIL KWON, EUNGSEONG KIM, Center for Supersolid Quantum Matter Research and Department of Physics, KAIST, Korea — In a system that consists of two interpenetrating continuous phases that are free to move with respect to each other, one would expect to find two longitudinal sound modes. A good example is fourth sound in superfluid helium in a porous matrix, but the phenomena can also be observed with water in rocks. If one interprets the observation of a non-zero NCRI in solid helium below ~100 mK as due to the independent motion of a supersolid fraction with respect to the crystal, it follows that two longitudinal sound modes should exist, with the slow mode disappearing at the supersolid transition. We will report on our efforts to find this slow mode.

10:12AM V16.00012 Supersolidity of Solid $^4$He Confined in 25 Angstrom Nanopores, KEIYA SHIRAHAMA, HITOMI YOSHIMURA, YOSHIYUKI SHIBAYAMA, Keio University — There has been growing consensus that dislocations play an important role on the supersolid behaviors observed in torsional oscillator experiments for solid $^4$He. When solid He is confined in nanopores, dislocations may not exist, or even if they exist their motion is suppressed, and supersolidity should therefore be greatly modified. Study of solid $^4$He in confined geometries may therefore give an important clue to elucidate the mechanism of supersolidity. Earlier studies of solid $^4$He in Vycor by Kim and Chan [1] found no difference in the supersolid behaviors from bulk solid. We have performed torsional oscillator experiments for solid $^4$He in a porous Gelsil glass that has nanopores of 25 angstroms in diameter. We have observed an increase in oscillator frequency indicating supersolidity below 200 mK. This result suggests that the existence of dislocations is not a necessary condition for supersolidity. Thursday, March 19, 2009 8:00AM - 11:00AM – Session V17 GQI: Superconducting Transmons and Circuit QED

8:00AM V17.00001 Experimental study of transmon type qubits coupled to a fast tunable transmission line resonator, MARTIN SANDBERG, CHRIS WILSON, FREDRIK PERSSON, IO-CHUN HOI, PER DELSING, Chalmers University of Technology — We experimental study a high quality factor (Q-value) transmission line resonator terminated in a superconducting quantum interference device (SQUID). Using an on-chip fast flux bias line we show that we can tune the frequency of such a resonator by hundreds of line widths on a time scale faster the photon lifetime of the resonator. Such a resonator could then be used for dynamic coupling of superconducting quantum bits (qubits). We present preliminary data of two transmon type of qubits coupled to a fast tunable resonator. We show spectroscopy and Rabi oscillations of the qubits far detuned from the resonator. Data showing a relaxation time of 1μs and a Rabi time of 200 ns have so far been obtained.
8:12AM V17.00002 Superconducting qubits can be coupled and addressed as trapped ions\(^1\), Y.X. LIU, L.F. WEI, J.R. JOHANSSON, RIKEN, Japan, J.S. TSAI, RIKEN and NEC, Japan, F. NORI, RIKEN, Japan, and the Univ. of Michigan, Ann Arbor, USA — Exploiting the intrinsic nonlinearity of superconducting Josephson junctions, we propose a scalable circuit with superconducting qubits (SCQs) which is very similar to the successful one now being used for trapped ions. The SCQs are coupled to the “vibrational” mode provided by a superconducting LC circuit or its equivalent (e.g., a superconducting quantum interference device). Both single-qubit rotations and qubit-LC-circuit couplings and/or decouplings can be controlled by the frequencies of the time-dependent magnetic fluxes. The circuit is scalable since the qubit-qubit interactions, mediated by the LC circuit, can be selectively performed, and the information transfer can be realized in a controllable way. Y.X. Liu, L.F. Wei, J.R. Johansson, J.S. Tsai, F. Nori, Superconducting qubits can be coupled and addressed as trapped ions, Phys. Rev. B 76, 144518 (2007). 8:24AM V17.00003 Second order dispersive regime of circuit QED with a transmon qubit, MAXIME BOISSONNEAULT, Universite de Sherbrooke, J. M. GAMBITTA, IQC and University of Waterloo, ALEXANDRE BLAIS, Universite de Sherbrooke — In many recent circuit QED experiments, a transmon-type qubit is fabricated inside a high-Q transmission line resonator. Compared to the Cooper-pair box (CPB), the transmon has both a stronger coupling to the resonator and a significantly longer dephasing time. By going to the dispersive regime, where the qubit-resonator detuning is much larger than the coupling strength, the qubit can be controlled and measured through the resonator. In previous work, we have shown that one must include non-linear corrections to the dispersive approximation in strong measurements of a CPB qubit. These corrections cause a saturation of the signal-to-noise ratio and photon-dependant qubit decay and dephasing rates. In this talk, we will show how these non-linear corrections come into play with the transmon, and how they could be used to improve the measurement. [1] Houck et al, Nature, 2007, 449, 328 [2] Majer et al, Nature, 2007, 449, 443 [3] Koch et al, PRA, 2007, 76, 042319, [4] Schreier et al PRB 77, 180502 (2008), [5] Boissonneault et al, PRA, 2008, 77, 060305(R).

8:36AM V17.00004 Two Cavity Circuit QED, BLAKE JOHNSON, Yale University, ANDREW HOUCK, Princeton University, JAY GAMBITTA, University of Waterloo, ALEXANDRE BLAIS, University of Sherbrooke, STEVEN GIRVIN, MICHEL DEVORET, ROBERT S. SCHOELKOPF, Yale University, YALE CIRCUIT QED TEAM — The circuit QED architecture has proven useful for dispersive manipulation and measurement of superconducting qubits. Previous experiments have shown how to use the AC-Stark shift to spectroscopically extract information about the photon number in the cavity[1]. Here we will show how to extend this toward building a photon statistics analyzer by adding a second cavity to the circuit QED architecture. The second cavity allows for decoupling of the preparation and readout of the cavity field state, opening the way for a measurement of the full photon statistics and reconstruction of the Wigner distribution.

8:48AM V17.00005 Multi-Transmon circuit QED using local and fast flux biasing, LEONARDO DICARLO, JERRY CHOW, Yale University, JOHANNES MAJER, Vienna University of Technology, LUIGI FRUNZIO, Yale University, JAY GAMBITTA, University of Waterloo, ALEXANDRE BLAIS, Universite de Sherbrooke, STEVEN GIRVIN, ROBERT S. SCHOELKOPF, Yale University — We report local and fast flux tuning of Transmon qubits in circuit QED by means of proximal short-circuited coplanar waveguides. We characterize the effect of these additional microwave channels on qubit lifetime. We demonstrate one-qubit Z-gates and time-domain control of two-qubit interaction via virtual photon exchange. Gate performance is characterized by process tomography and compared to gating by AC Stark shift as previously investigated by the Yale CQED team [1]. Research supported by NSF, NSA and ARO. [1] Majer et al., Nature 449, 443 (2007).

9:00AM V17.00006 Inline Cavity Qubit with Bifurcation Readout, MARKUS BRINK, NICHOLAS A. MASLUK, KURTIS L. GEERINGS, Yale University, MICHAEL METCALFE, NIST Gaithersburg, VLADIMIR MANUCHARYAN, LUIGI FRUNZIO, STEVEN M. GIRVIN, ROBERT J. SCHOELKOPF, MICHEL H. DEVORET, Yale University — We present the design and data from a new, strongly coupled superconducting qubit based on Josephson junctions and a strictly 1-dimensional distributed element geometry that operates in the Transmon regime. A cavity bifurcation amplifier is used to read the state of the qubit. The same circuit also supports a linear dispersive readout, which enables direct comparison between the latching and dispersive scheme. Most recent results will be discussed.

9:12AM V17.00007 Generation of entangled states in circuit QED using sideband transitions, P.J. LEEK, S. FILIPP, P. MAURER, ETH Zurich, A. BLAIS, Universite de Sherbrooke, A. WALLRAFF, ETH Zurich, ETH QUANTUM DEVICE TEAM — The deterministic generation of entanglement between pairs of distant qubits is an important goal in the development of a quantum information processor. A promising and potentially scalable method of achieving this is through the use of sideband transitions between qubits and a globally coupled harmonic oscillator. Most recent results will be discussed.

9:24AM V17.00008 Generating entanglement by measurement in circuit QED, JAY GAMBITTA, CHANTAL HUTCHISON, University of Waterloo, ALEXANDRE BLAIS, Universite de Sherbrooke, FRANK WILHELM, University of Waterloo — In this talk, we will show theoretically how to induce entanglement by measurement in circuit QED. I will use quantum trajectory theory to derive an equation for the conditional state of a two qubit system, conditioned on continuous-in-time measurement of the amplitude and phase of the field leaving the resonator. I will show that with experimental parameters, we can have a decoherence-free subspace to generate an entangled state with a high concurrence and with a success probability of 1/2. Finally I will show that with a simple feedback scheme the same concurrence can be achieved with a success probability of one.

9:36AM V17.00009 Towards proving non-classicality with a 3-qubit GHZ state in circuit QED, LEV S. BISHOP, Yale University, JAY M. GAMBITTA, University of Waterloo, ERAN GINOSSAR, STEVEN M. GIRVIN, Yale University, ANDREW A. HOUCK, Princeton University, JENS KOCH, ANDREAS NUNENKAMP, DAVID J. PRICE, ROBERT J. SCHOELKOPF, Yale University, LARS TORNBERG, Chalmers University of Technology, YALE CIRCUIT QED TEAM — The demonstration of violation of Bell-type inequalities remains challenging for superconducting qubits, due to short coherence times and limited measurement fidelity. Here, we propose to utilize 3-qubit GHZ states in a circuit QED system to accomplish this key step. In contrast to other schemes where the qubits are measured individually, circuit QED offers the advantage that a single dispersive measurement can directly reveal the parity (\(\sigma_1 \otimes \sigma_2 \otimes \sigma_3\)). When combined with appropriate 1-qubit rotations, this provides the necessary ingredients to obtain an effective measurement of Mermin’s Bell operator with less stringent requirements on the measurement fidelity. Generation of the GHZ state can proceed via either 1- and 2-qubit gates or preparation by measurement. We present results from quantum trajectory calculations and estimate the resulting violation of the Mermin inequality, based on experimentally feasible parameters.
9:48AM V17.00010 Exploration of the Tavis-Cummings Model with Multiple Qubits in Circuit QED
J.M. Fink, ETH Zurich, A. Blais, Universite de Sherbrooke, A. Wallraff, ETH Zurich, ETH Quantum Device Team — Superconducting qubits in coplanar waveguide resonators provide an unprecedentedly large dipole coupling strength to microwave frequency photons confined in an on-chip waveguide resonator [1]. In contrast to atoms in traditional vacuum QED a controlled number of qubits remain at fixed positions with constant coupling to the cavity field at all times. Utilizing these properties we have performed measurements with up to three independently flux-tunable qubits to study cavity mediated multi-qubit interactions. By tuning the qubits in resonance with the cavity field individually, we demonstrate the square root of $N$ scaling of the collective dipole coupling strength with the number of resonant atoms $N$ as described by the Tavis-Cummings model. To our knowledge this is the first observation of this nonlinearity in a system in which the atom number can be changed one by one in a discrete fashion. In addition, the energies of both bright and dark coupled multi-qubit / photon states are well explained by the Tavis-Cummings model over a wide range of detunings. On resonance we obtain an equal superposition of a photon and a Dicke state with an excitation equally shared among the $N$ qubits.

10:00AM V17.00011 Two-photon probe of the Jaynes-Cummings model and controlled symmetry breaking in circuit QED, Frank Deppe, Matteo Mariantoni, E. P. Menzel, A. Marx, R. Gross, Walther-Meissner-Institut and TU Muenchen, Germany, S. Saito, K. Kakuyanagi, H. Tanaka, K. Semba, NTT Basic Research Laboratories, NTT Corp., Japan, T. Meno, NTT Advanced Technology, NTT Corp., Japan, H. Takayanagi, Tokyo University of Science and International Center for Materials Nanoelectronics, Japan, E. Solano, Universidad del Pais Vasco - Euskal Herriko Unibertsitatea, Spain — Superconducting qubits behave as artificial two-level atoms. Coupling them on-chip microwave resonators has given rise to the field of circuit quantum electrodynamics (QED). In this work, we report on the observation of key signatures of a two-photon driven Jaynes-Cummings model, which unveils the upconversion dynamics of a superconducting flux qubit coupled to an on-chip resonator. Our experiment and theoretical analysis show clear evidence for the coexistence of one- and two-photon driven level anticrossings of the qubit-resonator system. This results from the controlled symmetry breaking of the system Hamiltonian, causing parity to become a not well-defined property. Our study provides deep insight into the interplay of multiphoton processes and symmetries in a qubit-resonator system. We acknowledge support from SFB631, NIM, CREST-JST, JSPS-KAKENHI (18201018), MEXT-KAKENHI (18001002), EuroSQIP, and the Ikerbasque Foundation.

10:12AM V17.00012 Dynamics of dispersive single qubit read-out in circuit QED, R. Bianchetti, S. Filipp, A. Blais1, A. Wallraff, ETH Zurich, ETH Quantum Device Team — In a circuit quantum electrodynamics setup the qubit state is inferred from the response of the coupled qubit-cavity system to a microwave signal applied close to the cavity resonance. We experimentally investigate the frequency dependence of the response for both weak continuous and pulsed measurement signals. We find excellent agreement with theoretical predictions from a generalized Jaynes-Cummings model which includes dissipation and dephasing. The quantitative understanding of the system response is used to optimize the measurement frequency maximizing the signal-to-noise ratio. This allows for an accurate determination of the qubit excited state population from the measured field response.

1 Université de Sherbrooke

10:24AM V17.00013 Two-qubit tomography with joint dispersive read-out in circuit QED, S. Filipp, P. Maurer, P. J. Leek, ETH Zurich, A. Blais, Universite de Sherbrooke, A. Wallraff, ETH Zurich, ETH Quantum Device Team — Quantum state tomography is an important tool in quantum information science for complete characterization of multi-qubit states and their correlations. We demonstrate that for two superconducting qubits coupled to a common resonator mode a reconstruction of the full density matrix can be achieved by measuring the transmission through the resonator — without the need for single-shot measurement of individual qubits. Since the resonator transmission depends non-linearly on the dispersive cavity pull of different qubit states, information about qubit-qubit correlations is intrinsically present in the averaged measurement signal. It is shown that this simultaneous two-qubit read-out can be used for quantum state tomography of both separable and entangled states.

10:36AM V17.00014 Measurement of Autler-Townes and Mollow transitions in a strongly driven superconducting qubit, M. Baur, S. Filipp, ETH Zurich, A. Blais, Universite de Sherbrooke, A. Wallraff, ETH Zurich, ETH Quantum Device Team — The spectrum of a multilevel atom can be significantly modified when interacting with electromagnetic fields. In the simplest case where a two-level atom is driven on resonance, two sidebands offset from the main atomic line by the Rabi frequency Ω appear in the fluorescence spectrum, referred to as the Mollow triplet. Similarly, when probing transitions into a third atomic level, the absorption spectrum shows two spectral lines separated by Ω, called the Autler-Townes doublet. Here we present a measurement of the Autler-Townes doublet and the sidebands of the Mollow triplet in a strongly driven superconducting qubit. The corresponding transitions are detected using dispersive read-out of the qubit coupled off-resonantly to a microwave transmission line resonator. The observed frequencies of the Autler-Townes and Mollow spectral lines are in excellent agreement with a generalized dispersive Jaynes-Cummings model.

10:48AM V17.00015 Microwave Photon Detector in Circuit QED, Juan Jose Garcia-Ripoll, Instituto de Física Fundamental, CSIC, Guillermo Romero, Departamento de Fisica, Universidad de Santiago de Chile, Enrique Solano, Departamento de Quimica-Fisica, Universidad del Pais Vasco, Bilbao — In this work we propose a design for a microwave photodetector based on elements from circuit QED such as the ones used in qubit designs. Our proposal consists on a microwave guide in which we embed circuit elements that can absorb photons and irreversibly change state. These incoherent absorption processes constitute the measurement itself. We first model this design using a general master equation for the propagating photons and the absorbing elements. We find that the detection efficiency for a single absorber is limited to 50%, and that this efficiency can be quickly increased by adding more elements with a moderate separation, obtaining 80% and 90% for two and three absorbers. Our abstract design has at least one possible implementation in which the absorbers are current biased Josephson junction. We demonstrate that the coupling between the guide and the junctions is strong enough, irrespectively of the microwave guide size, and derive realistic parameters for high fidelity operation with current experiments. Patent pending No. 200802933, Oficina Espanola de Patentes y Marcas, 17/10/2008.
8:00AM V18.00001 Spectroscopic Analyses of Microstructures Associated with Plant Based Polymers

SHAW LING HSU, Polymer Science and Engineering Department, University of Massachusetts at Amherst — Currently, less than 0.02% of polymers used are plant based with the remaining 99.98% of polymers produced from petroleum. The use of plant based polymers can have a significant impact on the cost of the petroleum. Because of their size scale, it is most appropriate to use vibrational and NMR spectroscopy to characterize the microstructure of these plant based polymers. We present a number of examples in order to illustrate the use of these alternative polymers. Soybean is one of the most promising alternatives. Both its saturated and unsaturated components can be utilized. In various applications, the saturated component is important because the rapid crystallization directly controls the rheological behavior. This is especially significant if co-crystallization with other polymers, especially statistically random copolymers, is an important consideration. Crystallization kinetics and subsequent morphological units formed have yet to be characterized. In addition, the unsaturated component can be modified to form various polyols for use in reactive mixtures. The miscibility behavior of such polymers with other oligomers or polymers strongly influences the reaction kinetics and the products formed. The extreme hydrophobic nature of soybean based polymers is reflected in that it has a characteristic of poly(lactic acid). We have characterized the inherent structural rigidity, correlating the changes in chain conformation to the chain conformation. We have identified the intermolecular forces which stabilized the crystalline units. In addition, we have been able to control the crystallization process resulting from addition configurational defects. This presents an opportunity the we have available in a world which may embrace such a set of polymers.

8:36AM V18.00002 Toughening and reinforcing degradable polymers to extend their properties and applications

SUPING LYU, Medtronic Inc, JIANBIN ZHANG, ADAM BUCKALEW, JIM SCHLEY, BRYANT PUDIL, LIAN LUO, CHRIS HOBOT, MIKE BENZ, RANDY SPARER, JULIE TRUDEL — Polymer materials made from renewable feedstocks mainly are cellulose derivatives and aliphatic polyesters such as polylactide. There are two challenges in the use of these materials to replace petroleum based polymers. One is how to easily process these materials to make them into needed shapes and other is how to broaden the properties of these materials so that they can be used for applications where petroleum based polymers play major roles. Most of the renewable source based materials are brittle. This abstract presents a method of how to toughen and reinforce polylactide to make a family of polymers that cover broad ranges of toughness and strength for various applications such as biomedical device manufacturing.

8:48AM V18.00003 A QC-MD Study of the Enzymatic Degradation of Cellulose Thin Films

DAN GLICKMAN, OLEH TANCHAK, MICHAEL REID, AMANDA QUIRK, DARRELL COCKBURN, COLIN MACDOUGALL, ANTHONY CLARKE, JACEK LIPKOWSKI, JOHN DUTCHER, University of Guelph — A sophisticated surface-sensitive technique, the quartz crystal microbalance with dissipation monitoring (QC-MD), was used to study the interaction of a mixture of cellulolytic enzymes from the fungus T. reesei with cellulose thin films deposited onto polycrystalline gold surfaces. It was found that the amylolytic enzymes on the gold substrate led to two processes that occur during the enzyme mixture-cellulose thin film experiment: adsorption of the enzyme to the film surface, and the subsequent degradation of the cellulose thin film. A model describing the measured frequency shift in the QCM data will be described, which gives excellent fits to the experimental data.

9:00AM V18.00004 An Atomic Force Microscopy Study of the Mechanism of Cellulose Biodegradation

AMANDA QUIRK, MAOHUI CHEN, DARRELL COCKBURN, SARAH REGLI, ANTHONY CLARKE, JOHN DUTCHER, JACEK LIPKOWSKI, University of Guelph, SHARON ROSCOE, Acadia University — Cellulose, a biopolymer consisting of long chain β-(1→4) linked glucose sugars, is used as structural material by plants and bacteria. Degradation of cellulose to glucose, a sugar easily fermented to ethanol, occurs by the enzymatic hydrolysis of cellulose by cellulase enzymes. The enzymes have a complex structure including carbohydrate binding modules and catalytic domains responsible for the binding and degradation of cellulase, respectively. Atomic force microscopy (AFM) was used to study native cellulose films prepared from Acetobacter xylinum using a novel application of the Langmuir-Blodgett technique. These films allowed AFM images of single fibers and their microfibril structure to be obtained. Further in situ AFM studies of single fibers were performed in solution using cellulolytic enzymes. The in situ degradation of cellulose fibers was monitored over 20-hours using AFM. These studies provided insight into the degradation timeline of a single fiber. Complementary studies of proteins adsorbed on cellulose fibers revealed information about the binding of the enzymes to the substrate. Studying the modular enzyme action separately will provide insight into the mechanism of cellulose binding and contribute to our understanding of the degradation process.

9:12AM V18.00005 Observation of Biodegradation of Cellulose Fibers Using Surface Plasmon Resonance Imaging

OLEH M. TANCHAK, SCOTT ALLEN, Department of Physics, University of Guelph, DARRELL COCKBURN, ANTHONY J. CLARKE, Department of Molecular and Cellular Biology, University of Guelph, JACEK LIPKOWSKI, Department of Chemistry, University of Guelph, JOHN R. DUTCHER, Department of Physics, University of Guelph — Cellulose is the most abundant biopolymer on Earth and can provide a renewable supply of ethanol fuel to replace fossil fuels. A fundamental understanding of the mechanisms of the biodegradation of cellulose is essential to the development novel enzyme systems that can efficiently and selectively degrade a variety of biomass substrates. A novel Surface Plasmon Resonance Imaging (SPRI) instrument was used to study the biodegradation of cellulose fibers anchored to a titiated gold surface. The kinetics of binding of the inactive enzymes to cellulose fibers and their digestion by catalytically-active homologs will be presented.

9:24AM V18.00006 Sustainable Engineering and Improved Recycling of PET for High-Value Applications: Transforming Linear PET to Lightly Branched PET with a Novel, Scalable Process

CYNTHIA PIERRE, JOHN TORKELSON, Northwestern University — A major challenge for the most effective recycling of poly(ethylene terephthalate) concerns the fact that initial melt processing of PET into a product leads to substantial degradation of molecular weight. Thus, recycled PET has insufficient melt viscosity for reuse in high-value applications such as melt-blowing of PET bottles. Academic and industrial research has tried to remedy this situation by synthesis and use of “chain extenders” that can be added to branched PET (with higher melt viscosity than the linear recycled PET) via condensation reactions with functional groups on the PET. Here we show that simple processing of PET via solid-state shear pulverization (SSSP) leads to enhanced PET melt viscosity without need for chemical additives. We hypothesize that this branching results from low levels of chain scission accompanying SSSP, leading to formation of polystyrene radicals in the melt which then participate in condensation reactions with other PET chains and thereby to in situ branch formation. The pulverized PET exhibits vastly enhanced crystallization kinetics, eliminating the need to employ cold crystallization to achieve maximum PET crystallinity. Results of SSSP processing of PET will be compared to results obtained with poly(butylene terephthalate).

9:36AM V18.00007 Spontaneously Formed Biocompatible Surfaces in Water by Segregation of Amphiphilic Block Copolymers

HIDEAKI YOKOYAMA, The University of Tokyo, TAKASHI ISHIZONE, Tokyo Institute of Technology, NAOYA TORIKAI, High Energy Accelerator Research Organization, JAROSLAW MAJEWSKI, Los Alamos National Laboratory, AYAKO OYANE, AIST — Reduction of hydrophobic interaction in water is important in biological interfaces. We have found that poly(styrene-b-oligo ethylene glycol methyl ether methacrylate) (PS-PENMA) segregates the PENMA block to the surface in hydrophobic environment such as in air or in a vacuum, and shows remarkable resistance against adsorption or adhesion of proteins, platelets and cells in water. We studied the interfacial structures between PS modified by the spontaneous segregation of PS-PENMA and water using neutron reflectivity and adhesion force measurement using atomic force microscope with hydrophobic probes. The interfacial structure and hydrophobic interaction depend on the number of ethylene glycol (EO) units in PENMA. PENMAs with two or more EO units show distinct swollen layers with two sharp interfaces at polymer/water interfaces, which effectively reduce hydrophobic interaction in water, while PENMA with one unit of EO displays broader single interface with unsatisfactory reduction.
9:48AM V18.00008 Electros spun Nanofibers for Neural and Tissue Engineering, YOUNAN XIA, Washington University — Electros spinning has been exploited for almost one century to process polymers and other materials into nanofibers with controllable compositions, diameters, porosities, and porous structures for a variety of applications. Owing to its small size, high porosity, and large surface area, a nonwoven mat of electros spun nanofibers can serve as an ideal scaffold to mimic the extracellular matrix for cell attachment and nutrient transportation. The nanofiber itself can also be functionalized through encapsulation or attachment of bioactive species such as extracellular matrix proteins, enzymes, and growth factors. In addition, the nanofibers can be further assembled into a variety of arrays or architectures by manipulating their alignment, stacking, or folding. All these attributes make electros spinning a powerful tool for generating Nanostructured materials for a range of biomedical applications that include controlled release, drug delivery, and tissue engineering. This talk will focus on the use of electros spun nanofibers as scaffolds for neural and bone tissue engineering.

10:24AM V18.00009 Control of Protein Adsorption on Surfaces with Grafted Polymers, IGAL SZLEIFFER, Northwestern University, JAN GENZER, North Carolina State University — Non-specific protein adsorption is the first process in the foreign body response. The molecular design of surface modifiers that prevent non-specific adsorption requires the understanding of the factors that determine protein adsorption. The hierarchy of time and length scales present in the adsorption requires a multiscale approach to treat the complexity of the process. We will discuss the driving forces that determine protein adsorption and how end-grafted polymers can be used to modify the ability of the proteins to reach the surface. We will show the differences between preventing protein adsorption thermodynamically and kinetically. For practical applications the relevant time scales are hours or days. We will show how a molecular approach can be used to study these time scales. In particular we will show two different levels of approximations based on a molecular understanding of the adsorption process that enables, through the proper integration of degrees of freedom, to determine the kinetics of adsorption over 16 orders of magnitude in time. This approach is applied to explain recent experimental observations carried out on orthogonal modified surfaces that suggest that protein adsorption is a universal function of the product of grafted polymer surface coverage and molecular weight.

10:36AM V18.00010 Optimization of Polymer Surfaces for Specific Targeting2, ELENA DORMIDON-TOVA, MATTHEW HAGY, SHIHU WANG, Department of Macromolecular Science and Engineering, Case Western Reserve University — Using Monte Carlo simulations we studied reversible binding between a polymer layer functionalized by ligands and a receptor surface. By analyzing distance-dependent profiles for the average number of ligands bound to receptors, the total free energy of polymer layer-cell surface interaction and the interaction force the influence of different design parameters of a polymer layer on the affinity and specificity of binding were investigated. We show that planar polymer layers with a smaller chain length and grafting density, larger degree of functionalization, and larger absolute binding energy exhibit higher affinity to the cell surfaces with a large density of mobile receptors. A high binding specificity can be achieved by the polymer layers with intermediate ligand-receptor binding energies or an intermediate number of ligands, as a larger binding energy or number of ligands lacks specificity while a smaller binding energy or number of ligands provides inadequate affinity. As a result, the optimal design of the polymer layers can be achieved by using several different strategies, which will be discussed.

Thursday, March 19, 2009 8:00AM - 11:00AM — Session V19 DPOLY: Focus Session: Hierarchically Ordered Systems

8:00AM V19.00001 Semi-crystalline PMMA Stereocomplex Fibers, MATIJA CRNE, School of Chemistry and Biochemistry, Georgia Institute of Technology, SHIN-WOONG KANG, Department of Physics, Kent State University, JUNG OK PARK, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology, SATYENDRA KUMAR, Department of Physics, Kent State University, MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology — A mixture of isotactic and syndiotactic PMMA polymers forms a supramolecular helical structure, called "stereocomplex" PMMA, which is held together by non-covalent bonding. The helices can pack together, resulting in a semi-crystalline material with a melting point of 172°C. Furthermore, the solutions exhibit gelation behavior in appropriate solvents. We have utilized these properties to make oriented stereocomplex PMMA fibers by three different methods — wet spinning, gel spinning and electrospinning. These fibers are highly oriented and crystalline. They are resistant to high temperatures up to 160°C. They are also resistant to the PMMA polymerization conditions. We have examined the fibers using X-ray diffraction and Raman spectroscopy. The results agree with the recently proposed triple helical structure where two isotactic PMMA chains wrap around each other in a double helix and then the syndiotactic chain wraps around this double helix. The resulting structure is a triple helix with a 1:2 molar ratio of isotactic : syndiotactic PMMA.

8:12AM V19.00002 Hierarchically Organized Pyrolyzed Core-Silica Shell Hybrids, AYSEGUL ALTUNBAS, NIKHIL SHARMA, DARRIN J. POCHAN, University of Delaware, Department of Materials Science & Engineering, JOEL P. SCHNEIDER, UNIVERSITY OF DELAWARE, DEPARTMENT OF CHEMISTRY & BIOCHEMISTRY COLLABORATION — A biomimetic approach was applied for the fabrication of a 3D hybrid network that displays hierarchical organization of an inorganic layer around an organic self-assembled peptide fibril template. The 20 amino acid peptide used in this study consisted of alternating hydrophilic (lysine) and hydrophobic (valine) residues flanking a four amino acid turn sequence in the center. After intramolecular folding into a beta-hairpin conformation on addition of a desired solution stimulus, this peptide self-sembles into a 3D network of entangled fibrils rich in beta-sheet with a high density of lysine groups exposed on the fibril-surfaces. The lysine-rich surface chemistry was utilized to create a silica shell around the fibrils. The mineralization process of the fibrils was initiated under physiological conditions by adding the silica precursor, tetramethyl orthosilicate, to the pre-assembled hydrogel, which results in a porous silica network that retains the mesoscale structure of the peptide fibril network. Structural characterization via Transmission Electron Microscopy, cryogenic-Scanning Electron Microscopy, Small Angle Neutron and X-ray Scattering and mechanical characterization via oscillatory rheology will be presented.

8:24AM V19.00003 Hierarchically Structured Regioregular Conjugated Polymer via Evaporative Self-Assembly

MYUNGHWAN BYUN, ROBYN LASKOWSKI, Iowa State University, FENG QIU, The Key Laboratory of Molecular Engineering of Polymers at Fudan University, Shanghai, China. We acknowledge the supports from NSF (CBET-0730611), 3M, and the Key Laboratory of Molecular Engineering of Polymers at Fudan University, Ministry of Education, China.

8:36AM V19.00004 Combining Small Molecule with Block Copolymer: a Facile Approach to Direct Hierarchical Assembly of Nanoparticles

TING XU, University of California, Berkeley — Precise control over the spatial organization of nanoscopic building blocks over multiple length scales is a bottleneck in the “bottom-up” approach to generate technologically important materials. We demonstrate a new paradigm to control the hierarchical assembly of nanoparticles through the synergistic co-assembly of block copolymers (BCP), small molecules and readily available nanoparticles. Organizations of nanoparticles into one, two and three-dimensional arrays with controlled inter-particle separation and ordering were achieved without any chemical modification of the BCPs, the order and distribution of small molecules within the BCPs are temperature dependent. These efforts have involved developing new synthetic techniques. The hierarchical structure was fabricated from a volume of material by combining holographic patterning (HP) and block copolymer (BCP) self-assembly. The structure of the BCP was investigated as a function of the BCP architecture, BCP concentration and crystallization temperature. Upon heating the BCP, a non-monotonic change in the structure of the BCP occurred; on cooling the reverse occurs reflecting the dynamic change in the hierarchical structure. Transmission electron microscopy, in-situ FTIR and optical spectroscopy were used to correlate the optical property change with BCP/HPC morphology. This approach could open a gateway to fabricating multifunctional hierarchical nanostructured materials.

9:12AM V19.00005 Hierarchical volume gratings by combining holographic-patterning and block copolymer self-assembly

MICHAEL BIRKRANT, RUSSELL MARRON, CHRISTOPHER LI, Department of Material Science & Engineering, Drexel University, Philadelphia, PA; LALGUIDI NATARAJAN, VINCENT TONDIGLIA, TIMOTHY BUNNING, Materials Manufacturing Directorate, Wright-Patterson Airforce Base, OH — A novel hierarchical photonic crystal (HPC) was fabricated by combining top-down and bottom-up nanomanufacturing techniques. The hierarchical structure was fabricated from a volume of material by combining holographic patterning (HP) and block copolymer (BCP) self-assembly. The structure of the HPC was investigated as a function of the BCP architecture, BCP concentration and crystallization temperature. Upon heating the photonic crystal a red shift in the reflected wavelength occurs; but, an initial decrease in diffraction efficiency (DE) followed by an increase in DE indicates a non-monotonic change in the structure of the HPC. Upon cooling the reverse occurs reflecting the dynamic change in the hierarchical structure. Transmission electron microscopy, in-situ FTIR and optical spectroscopy were used to correlate the optical property change with BCP/HPC morphology. This approach could open a gateway to fabricating multifunctional hierarchical nanostructured materials.

9:24AM V19.00006 Heteroarm Star Block Copolyampholytes as Templates for Hierarchically-Ordered Polyelectrolyte-Surfactant Complexes

MATTHEW HAMMOND, CHAOXU LI, Univ. of Fribourg, Switzerland, CONSTANTINOS TSITSIKLISIANS, Univ. of Patras, Greece, RAFFAELE MEZZENGA, Univ. of Fribourg, Switzerland — We report on the hierarchical ordering observed in dry, solid samples of polyelectrolyte-surfactant complexes based upon a novel heteroarm star block terpolymer bearing short polystyrene (PS) arms and an equal number of longer poly(2-vinylpyridine)-block-poly(acrylic acid) (P2VP-b-PA) arms. The amphoteric nature of the star block copolymer allowed for complexation to be carried out on either the P2VP blocks (with negatively charged surfactants) or on the PA blocks (with positively charged surfactants), depending only on the pH at which the complexation reaction was carried out. X-ray scattering and transmission electron microscopy data reveal that the various complexes display self-organization on the length scale of the polyelectrolyte-surfactant complex (ca. 3 - 4 nm) and on that of the overall copolymer (ca. 20 - 40 nm), with the specific repeat distances and self-organized morphologies being dramatically affected by the choice of block to be complexed. This study clearly illustrates how topological design possibilities in hierarchical self-assembly of block copolymer-based supramolecular complexes can be greatly enhanced by increasing the level of complexity of the macromolecular templates used.

9:36AM V19.00007 Assembly of Organic/Nanoparticle Hybrid Systems

STEPHEN Z.D. CHENG, University of Akron, YINGFENG TU, CHUN YE, WENBINS CHANG, XINFEI YU, RYAN M. VAN HORN, CHIEN-LUNG WANG — The structure, dispersion, and chemical functionality of particles in a material are critical to the material’s properties. We are working to build the scientific and technological foundations of using particles such as C60 and POSS to develop new, highly functional, self-assembled materials. These efforts have involved developing new synthetic techniques to efficiently and precisely manipulate particles to control their dispersion and structure within the organic material. First, C60-polymer and POSS-polymer molecules have been synthesized. These materials are capable of crystallizing in solution, enabling the formation of highly conducting or insulating sheets on the basal surfaces of the crystals. Additionally, these molecules may form micelles in solution. Next, POSS-C60-porphyrin molecules were synthesized and were found to self-assemble into discotic columnar structures where the intimately arranged porphyrin core harvests photons and the C60 enhances charge transport, making these materials ideal for organic photovoltaic applications. Finally, C60-POSS conjugate molecules have been synthesized that crystallize into a bilayer organization of nanoscopic building blocks over multiple length scales, where the intimately arranged porphyrin core harvests photons and the C60 enhances charge transport.

9:48AM V19.00008 Quantification of the Molecular Topology for Hierarchical Macromolecules

GREGORY BEAUCAGE, University of Cincinnati — Hierarchical structures are often produced from ramified macromolecules such as comb, star, hyperbranched and dendritic polymers. We have recently derived a method for the description of complex molecular and nanostructural topologies based on a statistical analysis [1,2]. The method has been applied to a wide range of hierarchical materials from long chain branched polyolefins, hyperbranched polymers [3], star polymers, H-branched polymers to cyclcics, biopolymers [4], and branched nanostructured aggregates. This method, when applied to neutron scattering data, yields the molecular fraction of a structure involved in branching, the number of branch sites, the average branch length, and the number if inner chain segments. Further, quantitative measures of the tortuosity or connectivity of the structure and the connectivity of the branching network can be made, opening a new window for our understanding of complex molecular topologies. This understanding has recently been applied to biological chain molecules to understand protein and RNA folding [4] for example as well as to aggregated, nanostructured, carbon soot.

Glass Transition in Thin Supported Polymer Films

The observation of finally smooth ultra-thin regenerated cellulose fibers were obtained under high relative humidity. The water vapor played an important role in leading to "skin formation" which helped to stabilize the fibrous morphology, and chloride (AMIMCl) was investigated. It was found that the introduction of co-solvent dimethyl sulfoxide (DMSO) contributed to a continuous jet. The problems alter glass transition temperature assignment will be discussed. Residual gas can affect data even at the pressures mentioned above [1]. An ionization gauge, both linear and modulated temperature scans [1, 2]. A well-defined glass transition in 5 nm thick PS and 10 nm thick PMMA films is observed. Factors that can decrease the bead density that appears in the electrospun microfiber mat. Scanning and transmission electron microscopies are used to investigate both the surface and internal morphology of these fibers, along with the robustness of the micelles. The combination of self-assembled structures within a polymer matrix can lead to fascinating response behavior dependent on temperature; if the sample is heated and the melting point of PFS is surpassed, the micelles will melt upon electrospinning.

The PFS-P2VP homopolymer solution and electrospun. Addition of the cylindrical micelles is found to improve the ability of P2VP to be electrospun and dramatically develop in dimethylformamide (DMF), a P2VP-selective solvent, with lengths exceeding one micron. These self-assembled micelles are then incorporated into P2VP homopolymer solution and electrospun. Addition of the cylindrical micelles is found to improve the ability of P2VP to be electrospun and dramatically decrease the bead density that appears in the electrospun microfiber mat. Scanning and transmission electron microscopies are used to investigate both the surface and internal morphology of these fibers, along with the robustness of the micelles. The combination of self-assembled structures within a polymer matrix can lead to fascinating response behavior dependent on temperature; if the sample is heated and the melting point of PFS is surpassed, the micelles will melt and then form classical morphologies. In the case of self-assembled, conductive cylinders of PFS block copolymers, heating the sample destroys conductive pathways. The PFS-P2VP self-assembled cylinders have also been incorporated into other DMF-selective polymers to verify that the micelles remain intact upon electrospinning.

Electrospinning of native cellulose from nonvolatile solvent system. SHAN-SHAN XU, AIHUA HE, CHARLES C. HAN, Institute of Chemistry, CAS — Electrospinning of cellulose in a highly efficient RTIL of 1-allyl-3-methylimidazolium chloride (AMIMCl) was investigated. It was found that the introduction of co-solvent dimethyl sulfoxide (DMSO) contributed to a continuous jet. The problems lying in nonvolatility and the high ionic strength of the RTIL were successfully resolved using a rotating copper-wire drum as a collector and solidifying the jet under high relative humidity. The water vapor played an important role in leading to “skin formation” which helped to stabilize the fibrous morphology, and finally smooth ultra-thin regenerated cellulose fibers were obtained.

8:24AM V20.00003 Physical Aging in Nanoconfined Polymer Films: Importance of 3D vs. 1D Thermal Contraction in the Resulting Physical Aging Response. CONNIE B. ROTH, ELIZABETH A. BAKER, Dept. of Physics, Emory University, Atlanta, GA 30322, PERLA RITTIGSTEIN, JOHN M. TORKELSON, Dept. of Chemical & Biological Eng., Dept. of Materials Science & Eng., Northwestern University, Evanston, IL 60208 — Studies of physical aging in confined geometries have reported conflicting observations of changes in physical aging rates with decreasing film thickness. Accelerated physical aging with decreasing film thickness has been observed with gas permeation and ellipsometry in stiff backbone, so-called “high free volume,” polymers traditionally used in gas separation membranes. In contrast, no change or suppressed physical aging has been observed with fluorescence in flexible carbon-carbon backbone polymers. We have developed a new streamlined ellipsometry procedure that allows us to relatively quickly (~6 hrs) evaluate the physical aging characteristics of both stiff and flexible backbone polymers in a thin film geometry. We present measurements of physical aging rates using our new approach and compare these to existing results in the research literature. In addition, we also address the importance of 3D vs. 1D thermal contraction in the resulting physical aging response, which we believe is one of the key factors accounting for the observed qualitative differences in physical aging rate upon confinement from the existing studies.

8:36AM V20.00004 Segmental dynamics of supported and freestanding polystyrene thin films probed by dye reorientation. KEEWOOK PAENG, HAU-NAN LEE, STEPHEN SWALLEN, MARK EDGER, University of Wisconsin-Madison — The dynamics of both freestanding and supported polystyrene thick films (down to 15 nm) were studied by measuring the reorientation of dye molecules. Well below Tg, dye molecules were photobleached using intense linearly polarized light creating an anisotropic distribution. The anisotropy decay was measured using circularly polarized light and probing fluorescence parallel and perpendicular to the bleaching beam during linear temperature ramping. Temperature ramping anisotropy measurements allow us to compare both dynamics and the distribution of relaxation times in thin and thick films. Both freestanding and supported thin films show faster and more broadly distributed dynamics than thick films. For 17.5 nm supported films, temperature ramping experiments show up to 14K shift in dynamics. The corresponding shift for 16.5nm freestanding films was 22K.

8:48AM V20.00005 Modeling Dielectric Relaxation in Simulations of Polymer Glasses and Thin Films. HENDRIK MEYER, Institut Charles Sadron, CNRS UPR22, Strasbourg, France, SIMONE PETER, J. BASCHNAGEL — We perform molecular dynamics simulations to study the dielectric relaxation of a bead-spring model for a polymer melt in the bulk and in supported films [1]. By assigning dipole moments parallel and perpendicular to the backbone of all chains in the completed simulation trajectories we calculate the dielectric spectra of so-called type-A polymers which exhibit relaxation processes due to the local motion of chain segments (“segmental mode”) and due to fluctuations of the end-to-end vector (“normal mode”). We find that the relaxation of both modes is enhanced in the films relative to the bulk. For the segmental mode this difference between film and bulk dynamics increases on cooling toward the glass transition. By a layer-resolved analysis of the segmental relaxation we show that the acceleration of the average film dynamics is a consequence of a smooth gradient in relaxation, originating from both interfaces where the segmental dipoles relax much faster than in the bulk.

9:00AM V20.00006 Neighboring Domains Perturb Glass Transition Temperature on Multilayer Films and Nanostructured Polymer Blend Systems. SOYOUNG KIM, CONNIE ROTH, RODNEY PRIESTLEY, JOHN TORKELSON, Northwestern University — The impact of free surface and polymer-substrate interfaces on the glass transition temperature (Tg) in nanoconfined geometries has been studied for over a decade. Free surfaces reduce the requirement for cooperative dynamics and tend to decrease Tg; attractive interactions with a substrate interface reduce mobility and tend to increase Tg. Employing a multilayer fluorescence technique, we show how the Tg dynamics of PS layers are perturbed by immiscible polymer-polymer interfaces. We determine the length scale over which adjoining layers can perturb the PS layer. Finally, we demonstrate the tunability of the Tg of ultrathin PS layers atop different types of polymers. Our results indicate that the cooperative segmental dynamics of an ultrathin PS layer are strongly coupled to the neighboring domains through the narrow polymer-polymer interface. These results suggest a novel route to create new material properties controlled by the type and thickness of polymers in a multilayer film geometry. Studies with nanostructured blends to monitor Tg perturbation by neighboring domain are also underway.

9:12AM V20.00007 Near Surface Dynamics of Polymers Probed with Nanoparticle Embedding. DONGPING QI, JAMES A. FORREST, Dept. of Physics and Astronomy, University of Waterloo — We use nanoparticle embedding to probe the dynamics of the near surface layer of glassy polymer films. We observe evidence for heterogeneous dynamics in the first 5-10 nm near the free surface of glassy polymers. We observe that the relaxation into the polymer immediately below the free surface is irreversible, even after a period of 1 year. On the other hand, further embedding (5-10 nm) appears to be reversible. The results are discussed in terms of possible models of near surface mechanical properties.

9:24AM V20.00008 Glass Transition of Thin Star Polymer Films. EMMANOUIL GLYNOS, University of Michigan, Ann Arbor, PETER GREEN, University of Michigan — The thickness dependence of the glass transition, Tg, of thin film polystyrene (PS) star molecules, supported by SiO2 substrates, has been examined using spectroscopic ellipsometry and compared to the behavior of linear PS chains. Linear PS chains exhibit a film thickness dependence on SiO2 substrates, decreasing with decreasing film thickness, for thicknesses h less than approximately 45 nm. This thickness dependence, when normalized by the bulk Tg, is observed for chains with a wide range of degrees of polymerization N, from N < Nc. (molecular weight between entanglements) to very large values of N. The Tg's of long chain star molecules, of low functionalities, f, exhibit the same thickness dependence. However, as the degree of polymerization of an arm length, Na, decreases the thickness dependence undergoes a transition, wherein Tg increases with decreasing h. These effects are discussed in terms of the role of architecture and entropic effects on the structure of the system. Implications on the chain dynamics will also be discussed.

9:36AM V20.00009 The Glass Transition in Ultra-Thin Polymer Films Confined between Structured Surfaces. VIJKRAM KUPPA, University of Cincinnati, GREGORY RUTLEDGE, MIT — Molecular Dynamics simulations are used to probe the structure and dynamics of polymers in ultra-thin slit pores. The simulation setup follows the structure of polymer nanocomposites, depicting chains intercalated between layered inorganic silicates. The structure and dynamics of bead-spring oligomers are studied for different film thicknesses, surface-segment interactions and temperature. In particular, we focus on the glass transition of the confined films as a function of layer thickness, interaction strength and density profiles: Tg is demonstrated to increase with confinement and attraction of the polymer with adjacent surfaces. The fragility of the polymer glasses is drastically different from the corresponding bulk system, and is shown to be dependent on the effective co-ordination number.

9:48AM V20.00010 Apparent changes in the molecular dynamics of thin polymer layers due to the impact of interfacial layers. ANATOLI SERGHEI, University of Massachusetts Amherst, MARTIN TRESS, FRIEDRICH KREMER, University of Leipzig, Germany — Possible mechanisms leading to an apparent faster glassy dynamics in thin polymer layers, as investigated by means of Broadband Dielectric Spectroscopy, are analyzed in detail. It is shown that manifold experimental findings can be traced back to the influence of interfacial sub-layers, where — due to the proximity to solid interfaces — the dielectric function of the polymer is altered and modifies, by that, the overall dielectric response of the polymer films. A large amount of experimental data is analyzed to evidence how the contribution of the interfacial dynamics combines with that of the bulk in order to give the total response of a thin polymer film. It is shown that the non-linear character of this combination could lead to apparently discrepant experimental results.
10:00AM V20.00011 Post-confinement Relaxation Behavior of Nanostructures on Polymer Surface

SHANHONG XU, GREGORY B. MCKENNA, Department of Chemical Engineering, Texas Tech University — Dimensional relaxation of nanostructures on polymer film was studied to understand dynamics at surfaces and post-confinement relaxation. Line gratings from 33 nm and up on PS surface were formed by nanoimprint lithography, and AFM was used to monitor their relaxation with time and temperature. When annealed at temperatures in the vicinity of the bulk Tg, the grating height slumps – or shrinks – as surface tension and other driving forces overcome the viscosity. The temperature for rapid slumping decreases at smaller and smaller gratings of all molecular weights, but a simple explanation based on enhanced surface mobility due to increased surface to volume ratio fails to explain the results. Analysis of viscosity shows that the stress from surface tension may cause shear thinning and thus contribute to the reduced nanostructure stability. More importantly, confinement of polymer chains to spatial dimensions comparable to or even smaller than the radius of gyration seems to enhance molecular relaxation, which may be the major factor for the surprisingly low slumping temperature.

10:12AM V20.00012 Molecular weight and chain architecture dependence of glassy compliance of ultrathin freely standing polymer films

SHANHONG XU, GREGORY B. MCKENNA, Texas Tech University — Glassy compliance of ultrathin linear polystyrene of different molecular weights was investigated with the novel nanobubble inflation techniques developed in our lab. Previous work by O’Connell, Hutcheson and McKenna [1] indicates that the glassy compliance decreases as the film thickness decreases for a polystyrene sample with molecular weight of 1M g/mol. However the glassy stiffening is not nearly as dramatic as that observed in the rubbery plateau regime [2]. Preliminary results in the present work show that the glassy compliance decreases as the molecular weight increases. We are now examining a three-arm star polystyrene with branch molecular weight the same as that of the lower molecular weight linear material and eight-arm stars will also be investigated with the purpose of determining chain architecture effects on the glassy and rubbery behaviors of ultrathin polymer films.

10:24AM V20.00013 Surface Chemistry Effects on the Reactivity and Properties of Nanoconfined Bisphenol M Dicyanate Ester in Controlled Pore Glass

SHANHONG XU, GREGORY B. MCKENNA, Department of Chemical Engineering, Texas Tech University — The influence of nanoconfinement on the cure kinetics and glass transition temperature of a bisphenol M dicyanate ester/polycyanurate material is investigated as a function of surface chemistry and nanoconfinement size in controlled pore glass (CPG). The glass transition temperature and conversion as a function of cure time is investigated using differential scanning calorimetry. The native CPG surface accelerates the cure of bisphenol M dicyanate to a larger extent compared to the silanized hydrophobic CPG presumably because of the catalytic nature of surface hydroxyl groups of the native pores.

The length scale associated with the secondary Tg is depressed by 60 K at 11.5 nm, and the secondary Tg is 10 to 33 K above the primary Tg. The length scale associated with the secondary Tg is approximately 0.8 nm. Based on the measurements of both Tg and sol content as a function of conversion, the network structure does not change upon nanoconfinement.

10:36AM V20.00014 Relation Between Glass Transition Temperatures in Polymer Nanocomposites and Polymer Thin Films

JAMIE KROPKA, SANDIA NATIONAL LABORATORIES, VICTOR PRYAMITSYN, VENKAT GANESAN, Texas A&M University — Motivated by recent experiments, we examine within a percolation model whether there is a quantitative equivalence in the glass transition temperatures of polymer thin films and polymer nanocomposites (PNCs). Our results indicate that while the qualitative behaviors of these systems are similar, a quantitative equivalence cannot be established in general. However, we propose a phenomenological scaling collapse of our results which suggests a simple framework by which the results of the thin films may be used to quantitatively predict the properties of PNCs. Sandia is a multi-program laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under Contract DE-AC04-94AL85000.

10:48AM V20.00015 Finite Element Analysis of Nanoparticle embedding into glassy polymers

MARK ILTON, JAMES A. FORREST, Dept. of Physics and Astronomy, University of Waterloo — The embedding of rigid nanospheres into the surface of thin film glassy polymers was modelled using a Finite Element Analysis. This method of analysis readily adapts to various material models, film thicknesses, and substrates. Moreover, it allows for modelling of the related hole relaxation process when embedded nanospheres are removed from the film. Calculations using a viscoelastic constitutive model with depth dependent material properties are compared to recent experimental results. The results are discussed in the context of the proposed near surface enhanced dynamics in thin film glassy polymers.
8:12AM V21.00002 Crystal orientation control of CdTe epitaxial layers grown on (100) GaAs with ZnSe buffer layer by molecular beam epitaxy¹, QIANG ZHANG, WILLIAM CHARLES, BINGSHENG LI, AIDONG SHEN, CARLOS MERILES, MARIA TAMARGO, The City College of the City University of New York — Based on our previous experience with the growth of ZnSe on GaAs, we have improved the substrate, on which we deposit CdTe by first depositing a ZnSe buffer on the bulk GaAs crystals. This allows us to control the I-V/III-V heterovatent epitaxy prior to the CdTe deposition. Depending on the control of the interface between ZnSe and CdTe, it was possible to stabilize the growth of either (100) or (111) CdTe epitaxial layers on the (100) ZnSe/GaAs substrate. Reflection high-energy electron diffraction was used to observe the nucleation of the epitaxial layers in situ during the growth, while x-ray diffraction and photoluminescence measurements indicate that the CdTe is of high structural quality despite the large lattice constant mismatch of 14.3% between CdTe and ZnSe. To explore the full impact of controllable-orientation growth technique, optical pumping and time-resolved Faraday rotation experiments were performed on CdTe films grown in different crystal orientation.

8:24AM V21.00003 Development of a Wafer Fusion Process for Producing Patterned GaP Templates, KRONGTIP TERMKOAA, VAIBHAV MATHUR, XIFENG QIAN, WILLIAM GOODHUE, Photonics Center, Dept. of Physics and Applied Physics, University of Massachusetts Lowell, DAVID BLISS, Air Force Research Laboratory/RWLA, Hanscom AFB, RITA PETERSON, Air Force Research Laboratory/RYJW. Wright-Patterson AFB — Quasi-phase-matching (QPM) is an effective technique for nonlinear optical frequency conversion to generate IR wavelengths not readily available from direct laser sources. The QPM gratings can be produced by electric field poling in ferroelectric oxide materials, or by crystal growth of alternating phase domains in the case of semiconductors. For semiconductor materials GaAs and GaP we are developing new patterning methods to produce optical gratings for QPM. The state of the art for producing orientation-patterned GaAs material is already well developed. Gallium phosphide (GaP), also transparent at IR wavelengths, is attracting interest for nonlinear optical frequency conversion due to its high second-order nonlinear susceptibility, high thermal conductivity, wide band gap and low optical loss. Here we report a method to fabricate a GaP periodic domain inversion template using a process combining wafer fusion, substrate removal, lithographic patterning, and wet/dry etching.

8:36AM V21.00004 Growth of GaN from Ga:In and Ga:Si liquid alloys¹, KATHLEEN KASH, CHALLA BEKELE, JOHN ANGUS, Case Western Reserve University — We grew GaN from Ga:Sn and Ga:In melt solutions that varied in composition from pure Ga to a few at.% Ga. Growth was done at 900 °C and 100 mtorr pressure by exposing the melt surface to a nitrogen plasma. A fit to a model of growth rate versus melt composition yielded estimates of the reaction rates for the formation of GaN versus composition of the melt that were, within experimental uncertainty, independent of the choice of diluents. Near-band-edge emission features were prominent in the photoluminescence spectra at both room temperature and 10 K for material grown from the entire range of melt compositions for both diluents. Lattice parameters measured by powder x-ray diffraction spectroscopy revealed an interesting dependence on melt composition; the “a” lattice parameter varied by as much as 1% and exhibited a minimum for material grown from melts with compositions between 60 and 70 at% Ga, for both diluents. One motivation for this work is growth of large area, high quality single crystal substrates.

8:48AM V21.00005 Epitaxial Growth and Characterization of Void-Free 3C-SiC Films on Germanium-Modified Si Substrates using RTCVD, DOMINGO FERRER, SHAGANDEEP KAUR, SAYAN Saha, SEYOUNG KIM, EMANUEL TUTUC, SANJAY BANERJEE, Microelectronics Research Center, The University of Texas at Austin, NILRATAN MAZUMDER, Department of Applied Physics, IERCEM Institute of Information Technology (WBUT) — Cubic silicon carbide (3C-SiC) is an attractive wide band gap semiconductor, frequently employed under extreme conditions such as high temperature, high frequency and high power, due to its superior physical and chemical properties. The electronic properties of epitaxial graphene grown on SiC integrated on silicon substrates also offer great potential as a viable candidate for “beyond CMOS” devices. A detailed understanding of both the structure and growth of epitaxial graphene, and the SiC/Si interfaces is very important for designing feasible devices. To this end, the work will analyze the growth and characterization of 3C-SiC on Si(100) and Si(111) substrates. 3C–SiC epitaxial crystal growth was carried out at temperatures as low as 750°C using Rapid Thermal CVD. A thin germanium buffer layer was deposited on Si substrates prior to epitaxial growth of SiC to suppress the formation of voids. The precursors utilized were (CH3)3SiH and GeH4, for silicon carbide and germanium deposition, respectively.

9:00AM V21.00006 The role of strontium in oxide epitaxy on silicon (001), JAMES REINER, KEVIN GARRITY, FRED WALKER, SOHRAIB ISMAIL-BEIGI, CHARLES AHN, Yale University — The integration of crystalline oxides and semiconductors has been made possible by the development of techniques that allow crystalline SrTiO3 to be grown on the silicon (001) surface. The most successful approach to realizing these epitaxial oxide-silicon (001) heterostructures requires manipulating substrate temperature and oxygen pressure on a layer-by-layer basis during the deposition of the metal oxide layers. The transition layer between the semiconductor and crystalline oxide is an alkaline earth metal, most often strontium, that is deposited on the silicon surface at around 650 °C. Motivated by the desire to develop a fundamental understanding of this important transition layer, we have studied the surface structures formed by strontium on miscut silicon wafers, which, unlike regular silicon wafers, have a unique surface termination. At high temperatures, this reaction rearranges the top layer of silicon to replace the original top layer with strontium. At low temperatures, this reaction is suppressed, leading to a different, but symmetry related, ordered surface structure. We find that complex oxides can be grown on either surface with comparable crystallinity.

9:12AM V21.00007 ABSTRACT WITHDRAWN

9:24AM V21.00008 Continuum model of surface roughness evolution of a-Si:H films grown by low-temperature PECVD, YEVGEN KRYUKOV, NIK PODRAZA, ROBERT COLLINS, JACQUES AMAR, University of Toledo — Using real-time spectroscopic ellipsometry the evolution of the surface roughness in a-Si:H thin-films grown on smooth c-Si/native oxide substrates by low-temperature plasma-enhanced chemical vapor deposition (PECVD) has been studied as a function of the H2 dilution ratio R = ([H2]/[SiH4]) with 15 ≤ R ≤ 60. The best amorphous Si photovoltaic films correspond to a relatively high dilution ratio (R ~ 60) such that the surface roughness is minimized but close to the amorphous-microcrystalline transition. After a brief period of nucleation of 3D islands, the roughness decreases but then eventually increases rapidly at large bulk layer thicknesses. Using a 3D continuum equation which includes a negative surface tension to take into account the destabilizing effects of short-range attraction and/or shadowing, as well as a smoothing term to take into account surface diffusion we have been able to obtain excellent agreement with experimental results for the evolution of the surface roughness. The dependence of our model parameters on the dilution ratio R is also discussed.
9:36AM V21.00009 In-situ growth of two-terminal silicon nanowires from locally heated cantilevers. CHRISTIAN KALLESOE, DTU Nanotech, Technical University of Denmark, FRANCES ROSS, CHEN-YEN WEN, IBM TJ Watson Research Center, KRISTIAN MOLHAVE, PETER BOGGILD, DTU Nanotech, Technical University of Denmark — Resistively heated crystalline silicon cantilevers extending over the edge of a chip offer excellent control of local growth of nanowires, without heating the entire micro-system. Besides being CMOS compatible, the cantilevers also have a rapid temperature cycling, and furthermore the freestanding cantilevers are suitable for in-situ studies of nanowire growth inside a TEM, offering the possibility of applying electrical fields to direct the growth and growing bridging wires between cantilevers thereby making two-terminal in-situ electrical measurements of nanowires possible. We have used such cantilever loops to study the growth of nanowires in-situ in UHV TEM. Epitaxial growth was observed from the crystalline cantilevers and the rapid temperature cycling ensured a very fast reaction time when crystalizing or melting the catalytic particle. The silicon wires were grown towards a cold cantilever loop, thereby forming bridging nanowires and the nanowire contact was seen to depend on the wetting ability of the gold catalytic particle to the cold cantilever. Furthermore various two-terminal measurements were performed on the bridging silicon nanowires in-situ in UHV.

9:48AM V21.00010 Time-Evolution of the Grain Size Distribution in Random Nucleation and Growth Crystallization Processes. ANDREAS BILL, ANTHONY V. TERAN, Department of Physics & Astronomy, California State University Long Beach, RALF B. BERGMANN, Bremen Institute for Applied Beam Technology (BIAS), 28359 Bremen, Germany — The micromorphology of solids impacts in an essential way their mechanical, electronic, optical or magnetic properties. Hence, it is an important task to characterize properly the granularity of materials. One central quantity providing such information is the grain size distribution. We propose an analytical derivation of this distribution during the random nucleation and growth crystallization process of a $d$-dimensional solid ($d = 1, 2, 3$). We describe how the grain size distribution evolves from early stages of crystallization to its final form when complete crystallization is achieved. We also discuss the remarkable result that for certain classes of nucleation and growth rates the asymptotic limit of large times is a lognormal type distribution. Finally, we apply the theory to the time-evolution of the grain size distribution during solid-phase crystallization of Si-films.

10:00AM V21.00011 ABSTRACT WITHDRAWN

10:12AM V21.00012 Nanocrystalline Silicon Films by HWCVD Method. PURABI GOGOI, HIMANSHU S. JHA, PRATIMA AGARWAL, Department of Physics, IIT Guwahati, Guwahati 781039, India — High quality nano-crystallites embedded amorphous silicon films are deposited using HWCVD technique by varying the substrate temperature $T_S$ (100-350 $^\circ$C) and chamber pressure P (0.08-8mbar). The precursor gas used is semiconductor grade hydrogen diluted silane (10 % silane in hydrogen) from Matheson Inc. Film temperature ($T_F$) is kept constant at 1800 $^\circ$C. The films are characterized by different tools viz. XRD, SEM, TEM, UV-Vis NIR spectroscopy, FTIR and PL. Both XRD and HRTEM studies indicate the presence of Nanocrystallite (size 5-10nm) in these films. The deposition rate ranges from 5-13 Å/Sec, whereas the hydrogen content varies between 2.5-5. The films deposited at high pressure have high deposition rate, low hydrogen content and high band gap. The films are found to be of superior electronic properties suitable for photovoltaic device applications. The tunable band gap, high deposition rate and low hydrogen content is ideal for cost effective device fabrication.

10:24AM V21.00013 Growth and physical properties of epitaxial GdN and SmN. BEN RUCK, BART LUDBROOK, JOE TRODAHL, ANDREW PRESTON, CLAIRE MEYER, Victoria University, Wellington, IAN FARRELL, STEVE DURBIN, ROGER REEVES, University of Canterbury, Christchurch, MATTHIAS KUBEL, Victoria University, Wellington, LAURENT RANNO, Institute Neel, Grenoble — The epitaxial growth and passivation of GdN and SmN by pulsed laser deposition on [100] YSZ substrates has been refined. We report on the growth kinetics, including the relaxation of the films, and the incorporation of oxygen at the substrate-film interface. Magnetic susceptibility measurements confirm a Tc of 70K and small coercive field for GdN. Resistivity measurements show an anomalous peak at Tc, while magnetic transport measurements indicate the films are electron doped to degeneracy, and show a strong anomalous Hall contribution below Tc.

10:36AM V21.00014 Synthesis and Magnetism of High Curie Temperature Prussian Blue Analogue Molecular Nanomagnet-Chromium Cyanide Molecule Nanowire Arrays. PINGHENG ZHOU, 1 Center for Advanced Microstructures and Devices (CAMD), Louisiana State University, Baton Rouge, LA 70806, DESHENG XUE, JINLI YAO, Key Laboratory for Magnetism and Magnetic Materials of MOE, Lanzhou University, Lanzhou 730000, China — The goal to synthesize molecular nanomagnets that exhibit spontaneous magnetic ordering close to room temperature might enable one to apply them in the fields of magnetic memory devices and microelectronics. Chromium cyanide molecule nanowires arrays with diameters of about 50 nm and lengths up to 4μm have been synthesized by an electrodeposition technology based on anodizing anodic aluminum oxide films. Characterization measurements show that the oxidation state of the chromium ions in the chromium cyanide nanowires can be expressed as Cr$_{3+}$-CN-Cr$_{3+}$.$\cdot$ Magnetic properties measurements indicate that the Curie temperature of chromium cyanide nanowire is 200 K, which is closer room temperature compared with current molecular nanomagnet systems.

Session V22 GMAG DMP FIAP: Focus Session: Dilute Magnetic Oxide Semiconductors 324

8:00AM V22.00001 A few ways in which LDA et al can produce a wrong description of magnetism in oxides. ALEX ZINGER, S. LANY, H. RAEBIGER, NREL — Part of the anarchy that exist in the literature regarding conflicting predictions of ferromagnetism in oxides can be attributed to problems in LDA and its application:(1) LDA et al tend to place the oxide conduction band minima CBM) at much too deep energies; transition-metal impurity levels then incorrectly appear within the (delocalized) LDA continuum (instead of in the gap). This leads to overly optimistic result of long-range magnetism. This is not fixable via LDA+U.(2) Oxides are naturally off-stoichiometric, exhibiting significant concentration of indigenous free-carriers that greatly affect the occupancy of impurity levels. Yet, such non-stoichiometry is ignored in many calculations using instead a perfect host crystals. This alters the magnetic properties. (3) LDA Predicted magnetism in defected oxides without TM impurities often rely on the defect orbitals (e.g, cation vacancy) being equally delocalized over all of its ligand atoms. While inherent to LDA, experiment, as well as more correlated approaches reveal that such orbitals are "locked" instead onto a single ligand. This symmetry-breaking causes them to become too localized for (percolative) magnetism. We show here how such problems might be fixed.

8:12AM V22.00002 First-principles study of the effect of vacancies on magnetic properties. YOSHI KAWAZOE, Tohoku University, QIANG SUN, Peking University and Virginia Commonwealth University, PURU JENA, Virginia Commonwealth University — Due to the high solubility of Co in ZnO, the magnetic properties of Co-doped ZnO thin films have been extensively studied experimentally. Unfortunately, these results have led to diverse conclusions. To better understand the origin of the controversial experimental findings, we have carried out detailed theoretical studies, focusing on the role of concentration and distribution of Zn and O vacancies on the magnetism of Zn1-xCoxO thin films. We find that when Co atoms are substitutionally doped in ZnO thin films without any defects, the magnetic coupling between Co atoms is intrinsically anti-ferromagnetic. The coupling, however, changes to ferromagnetic when sufficient oxygen vacancies are introduced. On the other hand, Zn vacancies stabilize the anti-ferromagnetic coupling, in sharp contrast with that found in Zn1-xMnxO thin films. Our theoretical studies explain the origin of the different magnetic behavior observed experimentally.

8:24AM V22.00003 On the possibility of ferromagnetism in MgX (X = O, S, Se) with/without conventional magnetic atoms. VAN AN DINH, ISIR, Osaka University, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA — We present a first principle study on the half-metallicity and ferromagnetism in rock salt MgZ (Z = O, S and Se) with and without conventional magnetic elements. The electronic structure, effective exchange coupling constant and chemical pair interaction are calculated within SIC-LSDA. The Curie temperature is predicted by performing Monte Carlo simulation. A possibility of spinodal decomposition is investigated and simulated. For transition-metal-doped MgO, our results reflect the observation in the experiment [1]. Without oxygen vacancy, Co- and Ni-doped MgO is anti-ferromagnetic. Except Ti and Cr, another transition metals cause the anti-ferromagnetic behavior in MgO. The ferromagnetism can be stabilized by oxygen vacancies. Oxygen vacancies also change the chemical interaction trend of transition metal atoms, and cause an inhomogeneous distribution in MgO. It is also found that N atoms which substitute for anions can introduce the half-metallic ground state and ferromagnetism in MgZ. Monte Carlo simulation shows the above room temperature ferromagnetism in MgO NO Z. Nitrogen atoms in MgO and MgS have a tendency to create clusters, whereas the distribution of N atoms in MgSe is homogeneous at dilute regime. [1]. J. Narayan et al., Appl. Phys. Lett. 93 (2008) 082507.

8:36AM V22.00004 Ferromagnetism in MgO by Nitrogen Doping. CHEHAN YANG, MAHESH SAMANT, STUART PARKIN, IBM Almaden Research Center — The new group, dilute ferromagnetic oxide and nitride, provides a promising technology potential to combine the magnetic (TM) and electronic properties. Studies in creating ferromagnetism in thin films of doped oxide materials without the inclusion of transition metal (TM) or rare-earth (RE) metal have been speculated in recent years. However, there have been many reports of ferromagnetism in large numbers of different material systems with poor control and reproducibility of these data. Our interest is exploring the possibility of ferromagnetism in oxide and nitride films without the introduction of any TM or RE elements. In this study, we have successfully incorporated substantial amounts of nitrogen up to 13 at% into MgO films using molecular beam epitaxy (MBE) technique. N-doped MgO films were carried out by evaporating the Mg in the presence of both atomic oxygen and nitrogen from two different RF sources. Upon the post-annealing, N atoms generate holes on oxygen and so create magnetic moment as high as 0.4 µB per N. In undoped MgO films, no magnetic signature was seen either in the as-deposited film or the film after annealing, which is a strong indication that the moment arises from the N dopants. The pre-edge feature of oxygen K-edge measured in Near Edge X-ray Absorption Fine Structure (NEXAFS) shows apparent evidence for the substitution of nitrogen for oxygen after post-annealing.

8:48AM V22.00005 Electric field control of magnetic semiconductor (Zn,Co)O. HYEON-JUN LEE, ERIK HELGREN, FRANCES HELLMAN, Dept. of Physics, Univ. of California, Berkeley — The magnetic transport of a conducting Al(2%) doped (Zn,Co)O field-effect transistor is investigated at low temperature (2-10 K). The Al doped (Zn,Co)O channel layer (~26 nm-thick) was deposited by magnetron sputtering at 550°C and processed into a 40 µm thick Hall bar geometry by photolithography and wet etching. An 80nm-thick AlOx layer was deposited at room temperature as the insulating barrier and Cr/Au was used as electrodes. The Hall effect and sheet resistance were measured from 2 - 10 K as a function of temperature, magnetic field and gate electric field. For gate electric field E=0 V/cm, the electron concentration is 2.58 x 10¹⁴/cm² at 5 K and there is no saturation of magnetic moment with increasing gate electric field at low temperature. This research was supported by both DOE and WIN.

9:00AM V22.00006 Electron mediated ferromagnetism in cobalt doped ZnO. SU-HUAI WEI, ARON WALSH, JUAREZ L.F. DA SILVA, National Renewable Energy Laboratory — The potential to simultaneously tune both charge and spin in spintronic materials has lead to great interest in searching room temperature dilute ferromagnetic semiconductors. Among them, cobalt doped ZnO has become a focus of attention in creating ferromagnetism in thin films of doped oxide materials without the inclusion of transition metal (TM) or rare-earth (RE) metal have been speculated in recent years. However, there have been many reports of ferromagnetism in large numbers of different material systems with poor control and reproducibility of these data. Our interest is exploring the possibility of ferromagnetism in oxide and nitride films without the introduction of any TM or RE elements. In this study, we have successfully incorporated substantial amounts of nitrogen up to 13 at% into MgO films using molecular beam epitaxy (MBE) technique. N-doped MgO films were carried out by evaporating the Mg in the presence of both atomic oxygen and nitrogen from two different RF sources. Upon the post-annealing, N atoms generate holes on oxygen and so create magnetic moment as high as 0.4 µB per N. In undoped MgO films, no magnetic signature was seen either in the as-deposited film or the film after annealing, which is a strong indication that the moment arises from the N dopants. The pre-edge feature of oxygen K-edge measured in Near Edge X-ray Absorption Fine Structure (NEXAFS) shows apparent evidence for the substitution of nitrogen for oxygen after post-annealing.

9:12AM V22.00007 Origin of the co-dopant induced enhancement of ferromagnetism in (Zn,Mn)O. YAN ZHU, JUEXIAN CAO, Department of Physics and Astronomy, University of California, Irvine, California, Z.Q. YANG, Surface Physics Laboratory (National Key Laboratory), Fudan University, Shanghai 200433, China, RUQIANG WU, Department of Physics and Astronomy, University of California, Irvine, California 92617-4575, USA — Using the density functional calculations, we elucidate the mechanism of co-dopant induced enhancement of ferromagnetism of (Zn,Mn)O. Li and Cu atoms tends to segregate toward Mn atoms and strongly promote the ferromagnetic coupling via either RRKKY or superexchange interaction. The hole states produced by either Li or Cu are rather delocalized and they are efficient in mediating magnetic ordering. These findings shed new light for the design of dilute magnetic semiconductors with co-dopants for spintronic applications.

9:24AM V22.00008 Synthesis and Magnetic Properties of Cobalt doped ZnO Nanowires. RA-MAKRISHNA PODILA, JIAN HE, AMAR NATH, APPARAO RAO, DEPARTMENT OF PHYSICS AND ASTRONOMY, CLEMSON UNIVERSITY, CLEMSON, SC, 29634 COLLABORATION, DEPARTMENT OF CHEMISTRY, THE UNIVERSITY OF NORTH CAROLINA AT ASHEVILLE, ASHEVILLE, NC, 28804 COLLABORATION — Here we report the synthesis of cobalt (Co) doped ZnO nanowires using a chemical vapor deposition technique. About 50 mM aqueous solution of ZnCl₂ and Co (CH₃COO)₂ was injected (rate of 0.1ml/min)into a quartz tube reactor maintained at 550 °C. A constant flow (10:1) of O₂ and H₂ was maintained at 500 sccm. The as-prepared nanowires are typically ~1-2 micrometers in length and tens of nanometers in diameter. X-ray diffraction, scanning electron microscopy and energy dispersive X-ray spectroscopy were employed to confirm the presence of the Co atoms in the nanowires. Significant magnetic signature was observed in the 2 atomic % Co-doped ZnO nanowires with a coercive field of 50 Oe. Furthermore, no saturation of magnetic moment was observed up to a field of 5T and 5K. A Curie-Weiss law fit to the temperature dependent magnetic susceptibility data yielded a magnetic moment µ = 1.99µB for Co²⁺ ion, consistent with the low spin state. Based on Hall measurements and Seebeck coefficient data, the nature of the carriers and origin of magnetism in Co doped ZnO nanowires will be presented.
observed. The magneto-resistive properties are analyzed with respect to recent models of spin-dependent scattering in magnetic semiconductors.

In materials science, the properties of magnetic semiconductor (MSS) and metallic nanostructures, such as nanowires and nanoparticles, have been extensively studied due to their potential applications in spintronics and other magnetic devices. For example, magnetic semiconductor (MSS) and metallic nanostructures, such as nanowires and nanoparticles, have been extensively studied due to their potential applications in spintronics and other magnetic devices. 9:48AM V22.00010 Magnetism of TiO and TiO2 Clusters, XIAOHUI WEI, RALPH SKOMSKI, B. BALAMURUGAN, Z. SUN, University of Nebraska, D.J. SELLMYER, UNIVERSITY OF NEBRASKA TEAM — Ferromagnetism in wide-bandgap semiconductors has sparked interest due to its potential applications in spintronic devices. Previous research has focused on dopant TiO2 thin films, with little work on undoped TiO2 and no report on TiO clusters. To investigate the magnetism of small TiO clusters, TiO2 and TiO clusters with sizes from 15 to 50 nm were grown by gas condensation and examined with TEM, AFM, XRD, and SQUID. Ferromagnetism was found within the investigated temperature range of 10 to 400 K for all clusters including TiO. Interestingly, all clusters exhibit a magnetization enhancement after exposure in air for an extended time, which is probably due to the generation of oxygen vacancies and of Ti3+ or Ti4+, whose coupled spins may create the observed ferromagnetism. The relationship between cluster structure, size, defects and magnetism will be discussed. - This research is supported by NSF-MRSEC, ONR and NCMN. 1 J. M. D. Coey, Curr. Opin. Solid State Mater. 8:00AM V23.00001 Phase separation in hydrogen-helium mixtures at high pressure, MIGUEL MORALES, University of Illinois at Urbana-Champaign, ERIC SCHWEGLER, Lawrence Livermore National Laboratory, DAVID CEPERLEY, University of Illinois at Urbana-Champaign, CARLO PIERLEONI, University of L’Aquila, L’Aquila (Italy), SEBASTIAN HAMEL, KYLE CASPERSSEN, Lawrence Livermore National Laboratory — We study the properties of hydrogen-helium mixtures at Mbar pressures and intermediate temperatures (4000 to 10000 K) using first-principles molecular dynamics simulations. Our main goal is to calculate the temperature, as a function of pressure, at which helium becomes insoluble in dense metallic hydrogen. We perform an extensive study of the equation of state of the mixture as a function of density, temperature, and composition and, together with a variety of thermodynamic integration techniques, we calculate the Gibbs free energy of mixing. We will show how to calculate the entropic contribution of the free energy using coupling constant integration methods, which allows us to directly calculate immiscibility temperatures without the need to resort to approximations of the entropy of mixing. These results are relevant to models of the interior structure and evolution of Jovian planets. We find demixing temperatures that are sufficiently high to cross the planetary adiabat of Saturn at pressures around 5 Mbar, implying the existence of partially miscible regions over a significant portion of the interior of the planet.

8:12AM V23.00002 Molecular dynamics simulations of electron-ion temperature equilibration in an SF6 plasma, LORIN X. BENEDICT, JAMES N. GLOSFI, DAVID F. RICHARDS, FREDERICK H. STREITZ, STEFAN P. HAU-RIEGE, FRANK R. GRAZIANI, Lawrence Livermore National Lab, MICHAEL S. MURLILLO, JOHN F. BENAGE, Los Alamos National Lab — We use classical MD to investigate electron-ion temperature equilibration in a two-temperature SF6, plasma. We choose a density of 1.0\times10^{25} (dissociated) SF6 molecules per cm^3 and initial temperatures of T_e \sim 100 \text{ eV} and T_i \sim 15 \text{ eV} in accordance with experiments currently underway at Los Alamos National Laboratory. Our computed relaxation time is significantly longer than that predicted by the classic theory of Landau and Spitzer. Similar discrepancies are found when comparing to predictions made be more recent theories of electron-ion equilibration. These differences should be large enough to be measured in the upcoming experiments.

8:24AM V23.00003 Optical signature of the OCP crystallization in a boron plasma, FLAVIEN LAMBERT, STÉPHANE MAZEVET, JEAN CLÉROUIN, CEA, DAM, DIF — We have calculated the DC conductivity of a boron plasma along the 1 eV isotherm up to 25 times the normal density. We use the free and orbital free molecular dynamics coupled with, respectively, the Kubo-Greenwood formulation and the semi-classical Ziman theory. We find that the DC conductivity obtained using a full quantum mechanical treatment exhibits a significant jump at the one component plasma phase transition — specifically the OCP crystallization — jump that is not reproduced using the semi-classical Ziman description. This difference — reaching up to a factor of four — remains well beyond the phase transition and up to the highest density explored. This shows that a full quantum mechanical treatment of the optical and electrical quantities is required in this regime even if semi-classical theories are reliable to obtain both the thermodynamical, and, ionic dynamical and structural properties.

8:36AM V23.00004 Mixtures in the Warm, Dense Matter Regime, LEE A. COLLINS, Los Alamos National Laboratory — The bulk of normal matter from planets to the intergalactic medium exists as a composite of various elemental constituents. The interactions among these different species determine the basic properties of such diverse environments. For dilute systems, simple gas laws serve well to describe the mixing. However, once the density and temperature increase, more sophisticated treatments of the electronic component and dynamics become necessary. For the warm, dense matter (WDM) region \[10^{22} - 10^{25} \text{ atoms/cm}^3 and 300K - 10^6 \text{ K}, quantum Monte Carlo and molecular dynamics, utilizing finite-temperature density functional theory (DFT), have served as the basic exploratory tools and benchmarks for other methods. The computational intensity of both methods, especially for mixtures, which require large sample sizes to attain statistical accuracy, has focused considerable attention on mixing prescriptions based on the properties of the pure atomic constituents. Though extensively utilized in many disciplines, these rules have received very little verification[1,2]. We examine the validity of such rules as density and pressure mixing, for several systems and concentrations by comparing against quantum calculations of the fully-interacting composite. We find considerable differences in some regimes, especially for optical properties. We also probe dynamical properties such as diffusion and viscosity as well as the role of impurities. Finally, as a means of extending DFT results to higher temperature regimes, we also study orbital-free molecular dynamics (OFMD) approaches[3] based on various approximations to the basic density functional. These OFMD schemes permit a smooth transition from the WDM region to simpler one-component plasma and ideal gas models. Research in collaboration with J.D. Kress (LANL), D.A. Horner (LANL), and Flavien Lambert (CEA).

9:12AM V23.00005 Electrical Conductivity of Synthetic Uranus, SEBASTIEN HAMEL, ERIC SCHWEGLER, LLNL — Mixtures of accreted water, ammonia, and methane at high pressures and temperatures are thought to be major components of the giant planets such as Uranus and Neptune. The pressures and temperatures in their deep interiors can reach several Mbar and several thousands Kelvin, conditions corresponding to the fluid phase. At such extreme interior conditions it is expected that these molecules react chemically to produce a complex mixture. Observables properties such as the magnetic field of these planets are thought to be determined by the physical and chemical properties of matter within this water mixture layer. Using quantum molecular dynamics, we explore the properties of water mixtures at planetary conditions. In particular we discuss the electrical conductivity at high pressure and high temperature of those mixtures in comparison to pure water. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

9:24AM V23.00006 Magnetism and vibrations in the phase ϵ of Oxygen, TUAN ANH PHAM, University of California, Davis, RALPH GEBAUER, SANDRO SCANDOLO, The Abdus Salam International Centre for Theoretical Physics — Sandwiched between a set of magnetic phases at lower pressure, and a non magnetic phase at higher pressure, the magnetic state of phase ϵ of oxygen has so far been elusive, together with its crystal structure. Neutron diffraction data indicate absence of antiferromagnetism, but do not exclude a ferromagnetic order. The recent refinement of the internal atomic positions from single-crystal diffraction finally provides us with a correct structural model to study the possible occurrence of a magnetic ground state. By employing non-collinear spin-polarized density-functional theory we show that the ground state of ϵ-O2 is non magnetic. We also calculate vibrational spectra and show that ϵ-O2 possesses an additional vibron mode with large Raman cross section, not seen in experiments yet.

9:36AM V23.00007 Ab-initio calculations of the X-ray absorption spectra of shocked compressed aluminum, STEPHANE MAZEVET, VANINA RECOULES, GILLES ZERAH, CEA-DIF F91297 Arpajon France — Molecular dynamics (MD) simulations, using density functional (DF) electronic structure techniques, provide a powerful, predictive tool for examining materials from solids to plasmas over a wide range of densities and temperatures. Using the Kubo-Greenwood formulation, we can access to the frequency-dependent electrical conductivity as well as additional optical properties consistent with the Equation of State. Due to the use of pseudopotentials, the calculations of these properties have, so far, been limited to low photon frequencies, i.e. below 100eV, where only the valence electrons contribute. We recently extended those calculations into the X-ray domain within the PAW formalism. This allows us to describe for the first time, X-ray absorption spectra of shocked compressed aluminum from an ab-initio standpoint.
9:48AM V23.00008 High-pressure spectroscopic studies on solid germane$^1$, XIAOJIA CHEN, VIKTOR V. STRUZHKIN, ZHEN-XIAN LIU, MÜHETAER AIHAI, YUE MENG, HOU-KWANG MAO, RUSSELL J. HÉMELY, Carnegie Institution of Washington, Washington, DC 2005, CHAO ZHANG, RUI-QIN ZHANG, City University of Hong Kong, Kowloon, Hong Kong, YANLING LI, HAI-QING LIN, The Chinese University of Hong Kong, Shatin, Hong Kong — We performed extensive spectroscopic studies on dense germane up to 110 GPa. Pressure — temperature phase diagram has been established from Raman and infrared spectra. There is no any trace of decomposition of Ge and H$_2$ over the pressure range studied. Infrared measurements provide spectroscopic evidence of the metallization of this material at pressure around 16 GPa which is much lower than that observed in sister system - silane. Angle-dispersive powder x-ray diffraction studies reveal that only a structural transition is accompanying when germane enters its metallic state. These experimental observations are examined by ab initio calculations. The theoretical results of the electronic, lattice dynamical, and superconducting properties of metallic phase of this material are also presented.

10:12AM V23.00010 Influence of Fermi Surface Topology on Superconductivity in High-Pressure Phases of Silane$^1$, TIAN CUI, XILIAN JIN, State Key Lab of Superhard Materials, Jilin University — Both a semimetallic molecular phase with P$\bar{2}1$/m symmetry and a metallic atomic phase with P$\bar{2}$1/c symmetry are found using ab initio geometry optimization method from initial configurations of random molecular SiH$\text{3}$ and atoms Si and H, respectively. The molecular phase shows a pressure-induced metallization, which can be described quantitatively by Fermi surface (FS) filling constant defined in our work. The lower superconducting critical temperature (Tc) about 16.2 K at 175 GPa and its peculiar superconductivity behavior that its Tc decreases initially and increases later with pressure agree with a recent experimental results. Different electron-phonon coupling mechanisms are uncovered during the increase and decrease of Tc with pressure. The atomic phase shows a higher Tc of about 47 K at 190 GPa and its Tc increases with pressure in its dynamically stable range. The FS filling constant and FS topology transitions under pressure mostly account for the different superconductivity between the molecular and atomic phases.

10:24AM V23.00011 Structural Properties of Superconducting CaLi$\text{2}$ At High Pressures, HAHN-BIDT RHEE, WARREN PICKETT, RICHARD SCALETAR, UC Davis Physics Dept, WILLIAM EVANS, LLNL High Pressure Physics Group, DAVID YOUNG, Louisiana State Univ Dept of Physics & Astronomy — The hexagonal Laves phase of CaLi$\text{2}$, a superconductor at high pressures, has been studied in the diamond anvil cell at varying pressures and temperatures. CaLi$\text{2}$ is known to have a maximum superconducting transition temperature of 13 K at 40 GPa. X-ray diffraction measurements were done up to 40 GPa, from room temperature down to 10 K, and phase stability in relation to pressure and temperature has been examined. We present our study to provide more insight into phonon-mediated superconductors and simple-metal systems such as Li. This work was performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344 and under Contract DE-FG01-06NA26204. HPCAT use is supported by DOE-BES, DOE-NNSA, NSF, and the W.M. Keck Foundation. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

10:36AM V23.00012 Fe K pre-edge of Fe$_\text{2}$O$_\text{3}$ at High Pressure$^1$, SHIBING WANG, Department of Applied Physics, Stanford University, WENDY MAO, Department of GE, Stanford University, Photon Science, SLAC National Accelerator Laboratory, YONG CAI, Brookhaven National Laboratory, NOZOMU HIRAOKA, HIROFUMI ISHII, National Synchrotron Radiation Research Center, Taiwan, YANG DING, YUMING XIAO, PAUL CHOW, HO-KWANG MAO, JINFU SHU, Geophysical Laboratory, Carnegie Institution of Washington, CHICHANG KAO, Brookhaven National Laboratory — Hematite (α-Fe$_\text{2}$O$_\text{3}$), an archetypal 3d transition metal oxide and important earth mineral, undergoes a series of electronic transitions and structural changes at high pressure. At ambient conditions, Fe$_\text{2}$O$_\text{3}$ adopts the α-Al$_\text{2}$O$_\text{3}$ structure and is an antiferromagnetic Mott insulator, with five 3d electrons on a high-spin state. Upon increasing pressure, it transforms from a high-spin state to a low-spin state in the 40-70 GPa range. Here we report experimental results for the Fe K-edge spectra of Fe$_\text{2}$O$_\text{3}$ collected in-situ at high pressure using synchrotron x-ray absorption spectroscopy in partial fluorescence yield geometry. The pre-edge features give explicit information about the crystal field splitting energy (CFSE) of octahedrally coordinated Fe$^{\text{3+}}$ in Fe$_\text{2}$O$_\text{3}$ as a function of pressure, mapping the electronic structure (high-spin to low-spin) transition. The K-α emission spectra at high pressure are also presented.

10:48AM V23.00013 High Pressure Phase Transitions in FeO from Density Functional Theory, Quantum Monte Carlo and Dynamical Mean Field Theory, LUKE SHULENBURGER, KEN ESLER, Geophysical Laboratory, Carnegie Institution, SERGEJ SAVRAŠOV, Department of Physics, University of California, Davis, JONGNIM KIM, University of Illinois at Urbana-Champaign, R. E. COHEN, Geophysical Laboratory, Carnegie Institution — FeO has a rich behavior under pressure, exhibiting a structural phase transition as well as an insulator-metal transition and a spin collapse. The electronic transitions have been particularly difficult to explain because of the failure of Density Functional Theory (DFT) to capture the electronic state of FeO. We present results from three different methods to better understand the nature of this material. First, from DFT calculations we explore competing explanations for the spin collapse, finding that the increase in bandwidth is at least as important as the crystal field splitting. Additionally, we find that the ligand field effects are responsible for the majority of the change in the local energy levels on the Fe rather than the electrostatic crystal field effect. Secondly, we have performed Dynamical Mean Field Theory (DMFT) calculations. From these we find that the metal insulator transition involves the reorganization of the existing bands and not the appearance of new states at the Fermi level. Finally we test the validity of the approximate results obtained by DFT and DMFT by performing highly accurate Diffusion Monte Carlo calculations.
8:00AM V24.00001 Broken Optical Symmetry in DNA-SWNT Hybrids: Spectroscopic Signaling of the Helical Wrap* SLAVA V. ROTKIN, Lehigh University — Functionalizing single-stranded DNA on a single-wall carbon nanotube (SWNT) has allowed isolating individual tubes, making them soluble, and separating SWNTs according to their chirality. Such strong technological impact motivated our study of the optical properties of the DNA-SWNT hybrids, commonly used now for the solution-based fabrication and experiments. The helicity of the DNA wrap may interfere with the intrinsic Hamiltonian of the SWNT and result in bandstructure modulation. Our modeling predicts a symmetry lowering in the hybrid due to the Coulomb potential of the regular helical wrap of the ionized backbone of the ssDNA, followed by the qualitative changes in the cross- or circularly polarized SWNT absorption spectrum (with or little change in the parallel polarization). In particular, we predict the appearance of a new peak in the cross-polarized absorption of the ssDNA-SWNT at a frequency lower than that of all allowed transitions in the bare tube. Such effect can be used for optical identification of the wrap at sufficient ssDNA coverage. Wrap signaling happens also via another optical effect, a strong circular dichroism even in the complex with an achiral SWNT, and even at the frequencies where ss-DNA has no absorption features at all. Symmetry of the wrap is central to determine such a circualar dichroism of the hybrid. Having in mind that the exact geometry of a DNA wrap for an arbitrary tube is not precisely known yet, we put forward a general model capable of tracking optical effects, varying the parameters of the wrap and/or tube diameter. For various ssDNA backbone helical angles and for various tubes we predict different absorption spectra, though a general qualitative feature of the helical symmetry breaking, the appearance of new Van Hove singularities and circular dichroism, must be present.

8:36AM V24.00002 Color Detection Using Chromophore-Nanotube Hybrid Devices , XINJIAN ZHOU, THOMAS ZIFER, BRYAN WONG, KAREN KRAFCIK, FRANÇOIS LÉONARD , ANDREW VANCE. Sandia National Laboratories — In this talk, we will present a nanoscale color detector based on a single-walled carbon nanotube functionalized with azobenzene chromophores, where the chromophores serve as photoabsorbers and the nanotube as the electronic read-out. By synthesizing chromophores with specific absorption windows in the visible spectrum and anchoring them to the nanotube surface, we demonstrate the controlled detection of visible light of low intensity in narrow ranges of wavelengths. Our measurements are consistent with those proposed from first-principles density functional theory showing that a single nanotube can serve as a molecular optical detector, similar to several known macroscopic devices. We show that by investigating the optical properties of these hybrid systems using density functional theory. Including the contributions for the non-local dispersive interactions, we examine the unique mechanical and electronic properties of nanotubes with the desired optical properties of π conjugated chromophores. We investigate structural, cohesive and optical properties of various fullerene derivatives using density functional theory. Including the contributions for the non-local dispersive interactions, we examine in a systematic manner the effect of tube diameter and chirality on the stability and bonding characteristics of the peapod as well as the position of the molecule in the dielectric and loss functions due to transitions between the states of the molecule and the nanotube.

8:48AM V24.00003 Spectral Features of Carbon Nanotube Films Changeable With Increasing Thickness , JOHN H. LEHMAN, The National Institute of Standards and Technology, KATALIN KAMARAS, ARON PEKKER, Hungarian Academy of Sciences, KATHERINE E. HURST, The National Institute of Standards and Technology, D.B. TANNER, University of Florida — We have investigated an apparent contradiction with respect to optical spectroscopy of carbon nanotube films. The measured absorbance shows “inverted” features: local maxima for dilute suspensions correspond to local minima for thick films. The inversion is reconciled by taking into account the saturation of absorption in thick films, when all the light is absorbed in the sample. In this case, the measured direct absorption is (1-R), and independent of thickness. Kramers-Kronig analysis of transmittance data, which provides a means to model absorbance for material ranging from nearly transparent to almost completely opaque, provides values of refractive index for a film of nanotubes. (Borondics et al., PRB 74, 045431 (2006)). From these values, we determined (1–R~T) at many values of the film thickness. This calculation is corroborated with measurements based on the spectral responsivity of a pyroelectric detector and the absolute absorbance of the films. These results are consistent with data on nanotube suspensions by Zhang et. al. (J. Phys. Chem B, 108, 8136 (2004)), representing the limiting case of transparent samples, as well as films by Lehman et. al. (J. Phys. Chem. C, 112, 11776–11778 (2008)) representing the other limiting case of completely opaque samples.

9:00AM V24.00004 Light emitting peapods: A first-principles study , MATUS MILKO, TAYEBEH MOVALI-ROOY, CLAUDIA AMBROSCH-DRAML, Chair of Atomic Modelling and Design of Materials, University of Leoben, Franz-Josef-Strasse 18, 8700 Leoben, Austria — Nanohybrids i.e. single wall carbon nanotubes with encapsulated organic molecules have been proposed for opto-electronic devices as they combine the unique mechanical and electronic properties of nanotubes with the desired optical properties of π-conjugated molecules. We investigate structural, cohesive and optical properties of various fullerene derivatives using density functional theory. Including the contributions for the non-local dispersive interactions, we examine in a systematic manner the effect of tube diameter and chirality on the stability and bonding characteristics of the peapod as well as the position of the molecule inside the tube. We find that these systems are almost exclusively van-der-Waals bound. Based on a series of oligo-thiophenes encapsulated into zig-zag nanotubes, we explore how the presence of the molecules inside the cavity can alter the electronic and optical properties. In particular, we inspect new features in the dielectric and loss functions due to transitions between the states of the molecule and the nanotube.

9:12AM V24.00005 Friction and Stability of Carbon Onions Films in Vacuum R.A. AL-DUHAILEB, Michigan State University, B.W. JACOBS, Sandia National Laboratories, CA, M.A. CRIMP, V.M. AYRES, Michigan State University, A. HIRATA, M. HORIKOSHI, Tokyo Institute of Technology, Japan, M.G.I. GALINATO, N. LEHNERT, University of Michigan — Planar graphite is a state-of-the-art low friction solid lubricant. However, in vacuum environments, graphite-based solid lubricants require potentially harmful heavy metal additives to maintain tribological performance. Recent experiments by our group indicate that carbon onions show excellent tribological performance (~0.03 friction coefficient) without the addition of heavy metal additives. They are therefore good candidates for environmentally benign solid lubricants for use in vacuum. Carbon onion film stability to prevent exposure of un-lubricated surfaces is also an important issue. Tribological performance assessed using ball-on-disk friction measurements equivalent to a 10 m sliding distance indicated that a 15 wt.% solution at 80 °C peroxide oxidation treatment improved the film stability. In the present work, carbon onion friction and film stability are correlated with fundamental structural and chemical properties investigated by high-resolution transmission electron microscopy (HRTEM), electron energy loss spectroscopy (EELS) and multi-wavelength micro-Raman spectroscopy at 77K.

9:24AM V24.00006 Computational Study on the Structural and Electronic Properties of Various Fullerene Derivatives* SORA PARK, JEUNG SUN AHN, Department of Physics, Kyung Hee University, YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University — Using ab initio density functional theory, we investigate the structural and electronic properties of various fullerene derivatives. The equilibrium structures of various additives adsorbed on a fullerene molecule forming fullerene adducts are computed through the geometry relaxation. For a given fullerene adduct, we also calculate the optimum configuration with a different number of additives. In tandem with the structural studies, we calculate the dependence of the HOMO-LUMO gap of each fullerene adduct on the number of additives, and on their relative positions and orientations. Further, using the GW approximation, we also examine the quasiparticle electronic structure of various fullerene derivatives.

9:36AM V24.00007 Diffusion of Various Molecules through Crystalline C$_{60}$ Solid and their Electronic and Vibrational Properties$^1$, YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University — First-principles density functional theory is used to study the diffusion of various molecules including diatomic molecules, inert gas molecules, and small metal atoms, and so on, through the C$_{60}$ solid. For each case, the energy surface of a diffusion path is calculated while performing full geometry relaxation of the whole system. Such studies are performed while changing the concentrations of diffusing molecules. The effects of these molecules on the electronic properties of C$_{60}$ solid are also examined. Especially for diatomic molecules, such as H$_2$, N$_2$, and O$_2$, their frequency shifts are calculated relative to their corresponding counterparts.

This research was supported by the Kyung Hee University Research Fund in 2008 (KHU-20081558).

9:48AM V24.00008 Simulation of Fe$_n$-doped C$_{60}$ Monolayer on h-BN/Ni (111)$^1$, LAN LI, HAI-PING CHENG, Quantum Theory Project and Department of Physics, University of Florida — We have performed first-principles calculations based on density functional theory to investigate the structural, electronic structure and magnetic properties of Fe$_n$-C$_{60}$ complexes. Interfaces that consist of a C$_{60}$ monolayer, a supporting h-BN/Ni (111) layers, and the transition metal Fe$_n$ (n = 1-4 & 15) have been thoroughly characterized. Electron transfer has been observed from the Fe ions to the C$_{60}$ molecules, which leads to the domination of ionic character on the Fe-C$_{60}$ bonding. Furthermore, the Fe$_n$-doped C$_{60}$ systems show strong hybridizations between s-, d- orbitals of Fe atoms and p-orbital (γ-like) of C atoms. The spin of the net transferred electrons from Fe$_n$ to C$_{60}$ is spin minority, which leads to a magnetic moment in C$_{60}$ opposite to the total magnetic moment of the system. All of the electronic structure calculations have been performed in generalized gradient approximation (GGA) and local density approximation (LDA). In Fe$_n$C$_{60}$ and Fe$_{15}$C$_{60}$ systems, we have also performed GGA+U and LDA+U calculations for comparison.

This work is supported by the U.S. Department of Energy.

10:00AM V24.00009 Superatom states in an endohedral fullerene$^1$, TIAN HUANG, MIN FENG, JIN ZHAO, HRVOJE PETEK, Dept. of Physics and Astronomy, University of Pittsburgh, SHANGFENG YANG, LOTHAR DUNSCH, Group of Electrochemistry and Conducting Polymers, Leibniz-Institute for Solid State and Materials Research (IFW), Dresden — Motivated by the recent discovery of superatom states in C$_{60}$[1], we studied the electronic structures of an endohedral fullerene, Sr$_2$N@C$_{80}$, adsorbed on copper surface by LT-STM experiment and DFT calculation. Both experimental and calculated results show that superatom states also exist in Sr$_2$N@C$_{80}$. Different from the C$_{60}$, the encapsulated cluster (Sr$_2$N—) in Sr$_2$N@C$_{80}$ distorts the nearly-spherical potential of the carbon cage, making the atom-like orbitals look asymmetric in the STM images. The adsorbed molecules exhibit various shapes of superatom orbitals due to the different orientation of the Sr$_2$N cluster on the surface. When two molecule form the dimer, we were able to study the strong intermolecular hybridization which perturbs the penetration induced by the inside clusters, making all the dimers to have similar H$_2$-like molecular orbitals with clear bonding and anti-bonding characteristics. [1] Min Feng, Jin Zhao, Hrvoje Petek Science, 320, 359, 2008.

This research was sponsored by the Keck Foundation and DOE.

10:12AM V24.00010 Isotropic Wave Function Delocalization in C$_{60}$ Molecular Assemblies, MIN FENG, JIN ZHAO, HRVOJE PETEK, University of Pittsburgh — Electronic wave function delocalization in a molecular material is highly surprising. Here, we describe a new paradigm of strong intermolecular hybridization of a hollow core-bound molecular state in C$_{60}$ assemblies. In 1D C$_{60}$ wire and 2D C$_{60}$ island, LT-STM revealed extensive, isotropic wave function delocalization at energy above 3.5eV, in contrast with the poor intermolecular wave function overlap of the π-molecular orbitals. DFT indicates that a new kind of molecular orbital, which is derived from the central potential of the hollow cage shape of C$_{60}$, is responsible for this NFE like wave function delocalization. This central potential derived from the screening interaction and gives rise to s, p, d, etc., symmetry orbitals, which we dub the superatom molecular orbitals (SAMOs). Studies show how these atomlike orbitals hybridize into H$_2$ moleculer orbitals and p symmetry bonding/antibonding orbitals of C$_{60}$ dimers, and for larger aggregates, with alkali atom-like NFE dispersions. As a common consequence of a hollow topology, we expect that similar SAMO states will exist in other molecules derived by wrapping and rolling molecular sheets into hollow cages and nanotubes.

10:24AM V24.00011 First-principles calculation of electronic structures of new C$_{60}$ polymers, TAICHI KOSUGI, SHINJI TSUNEYUKI, Department of Physics, University of Tokyo — C$_{60}$ fullerene molecules form fcc crystalline structure at an ambient pressure and temperature. It has been both theoretically and experimentally confirmed that this structure undergoes phase transitions into various structures at high temperatures and high pressures. Yamanaka et al. experimentally found that the individual C60 molecules in fcc structure, which are weakly bonded via van der Waals interactions, are connected to its neighbouring molecules under high temperature and high pressure, leading to the two-dimensional layered insulating rhombohedral polymer 2D-r, which is further polymerized under higher pressure and temperature into the three-dimensional polymer 3D-r. We searched for a new rhombohedral structure of C$_{60}$ polymer using ab initio calculations of the electronic structures and compared it with the experimentally observed data. In addition we quantitatively analyzed how the difference between the chemical bondings in these structures affect their energetics.

10:36AM V24.00012 Role of OH Adsorption on the Properties of MRI contrast agent Gd$_3$N@C$_{80}$, VINCE ONG, SHIV KHANNA, PANOS FATOUROS, Virginia Commonwealth University, SHIV KHANNA RESEARCH GROUP COLLABORATION, PANOS FATOUROS COLLABORATION — Endohedral metallofullerenes Gd$_3$N@C$_{80}$ decorated with hydroxyl groups are now known to be excellent contrast enhancement agents for Magnetic Resonance Imaging (MRI) leading to strong relaxivity enhancements. One of the outstanding issues is the nature of OH adsorption and its effect on the properties of endohedral Gd$_3$N motif. We have carried out theoretical studies on the electronic structure and magnetic properties of the endohedral metallofullerenes functionalized with hydroxyl groups to demonstrate that the nature of OH can have significant effect on the magnetic spin density. The new findings may provide physical insight into the observed strong relaxivity enhancements.

10:48AM V24.00013 Imaging and Spectroscopy of Diamondoid-Fullerene Hybrid Molecules$^1$, J.C. RANDEL, H.C. MANOHARAN, Stanford University — Diamondoids have attracted attention as potential building blocks for nanometer-scale electronic and mechanical devices. The ability to functionalize diamondoids with various atomic and molecular groups enables customizable chemistry, as well as tunable electronic properties. Recently, the library of realizable functional groups has expanded beyond a few atoms, and now includes C$_{60}$ fullerene. This addition provides a novel opportunity to study a material that combines the sp$^2$ and sp$^3$ forms of carbon bonding in one hybrid molecule. We investigate these molecules using scanning tunneling microscopy and spectroscopy. We find that thin films of the molecules pack in a well-ordered lattice on Au(111), and report on spectral measurements with single-molecule resolution. We comment on the connection between strong features in these electronic structure measurements and the nature of electron transport through single hybrid molecules.

We thank J. E. P. Dahl, R. M. Carlson, and P. R. Schreiner for materials and synthesis, and acknowledge support from DOE and the Chevron Corporation.
Thursday, March 19, 2009 8:00AM - 11:00AM –
Session V25 DMP: Focus Session: Graphene XIII: Spectroscopic and Transport Properties 327

8:00AM V25.00001 Charged Impurity Scattering in Graphene induced by adsorption of calcium, MASAHIRO ISHIGAMI, JYOTI KATOCH, Department of Physics, University of Central Florida — We have measured the impact of charged impurity scattering induced by adsorbed calcium atoms on the transport properties of graphene sheets. We vary the density of adsorbed atoms on the surface of graphene-based devices which are otherwise devoid of any surface adsorbates in ultra high vacuum environment. We will discuss the impact of calcium atoms on the charge carrier mobility, gate-dependent conductivity and minimum conductivity in comparison with earlier measurements performed using potassium.

8:12AM V25.00002 Current-Phase Measurements in Single Layer Graphene, CESAR CHIALVO, ION MORARU, DANIEL BAHR, NADYA MASON, DALE VAN HARLINGEN, Department of Physics and Materials Research Laboratory, University of Illinois at Urbana-Champaign — The current-phase relationship (CPR) of a Josephson junction can provide key information about the microscopic processes that make up a supercurrent. However, CPR has not been previously measured in graphene. We have successfully fabricated a variety of Josephson junctions containing single-layer graphene as a weak link, and with different junction width to length ratios. We present results of measurements based on a phase-sensitive SQUID technique, where we determine the supercurrent amplitude and phase, as well as a possibly anomalous shape of the CPR.

8:24AM V25.00003 Landau level spectroscopy of Dirac fermions in multilayer epitaxial graphene and graphite, MAREK POTEMSKI, Grenoble High Magnetic Field Laboratory, CNRS — The results of magneto-absorption studies of epitaxial multilayer graphene on SiC and of graphite will be presented. The talk will be focused on inter Landau level transitions characteristic of electronic states with Dirac-like dispersion relations which are distinctive of graphene but persist in multilayer epitaxial graphene and are also present at the H-point of bulk graphene. The high energy limits of the Dirac-cone in epitaxial graphene will be discussed from experiments carried out in the near-infrared spectral range. Probing the nearest vicinity of the Dirac point with far-infrared light will be testified. An exceptional quality of essentially neutral multilayers of graphene on SiC (low temperature carrier mobilities ~250 000cm²/Vs) will be discussed from cyclotron resonance absorption resonance. This resonance will be shown to persist up to room temperature with negligible changes of the width which indicates no relevant thermally activated scattering process in this material.

9:00AM V25.00004 Charged Impurity Scattering in Bilayer Graphene, SHUDONG XIAO, JIANHAO CHEN, ELLEN D. WILLIAMS, MICHAEL S. FUHRER — Materials Research Science and Engineering Center and Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, MD, 20742, USA We have examined the impact of charged impurity scattering on the charge carrier transport in bilayer graphene in ultra-high vacuum (UHV) at low temperatures. Bilayer graphene sheets are experimentally exfoliated on Si/SiO₂ substrates, and the number of layers is verified by micro-Raman spectroscopy. Charged impurity density is varied over a wide range (up to 2x10¹⁵ cm⁻²) by deposition of potassium atoms on clean bilayer graphene in UHV. At a gate-induced charge carrier density of 4.3 x 10¹² cm⁻², the mobility is inversely proportional to the charged impurity density \( \mu = 5 \times 10^{15} \text{ V}^{-1}\text{s}^{-1}\text{cm}²/\text{V}_{\text{imp}} \). Surprisingly, the coefficient relating \( \mu \) to \( 1/|n_{\text{imp}}| \) has a similar magnitude to that for single-layer graphene, indicating a similar strength for charged impurity scattering at this carrier density. The magnitude of charged impurity scattering, as well as the implications for the source of disorder in undoped bilayer graphene, will be discussed in the context of Boltzmann transport theory.

9:12AM V25.00005 Band structure asymmetry of bilayer graphene revealed by infrared spectroscopy, ZHIQIANG LI, University of California, San Diego, ERIK HENRIKSEN, ZHIGANG JIANG, ZHAO HAO, Lawrence Berkeley National Laboratory, MATT ZHANG, MICHAEL MARTIN, Lawrence Berkeley National Laboratory, PHILIP KIM, Columbia University, HORST STORMER, Columbia University/Bell Labs, DIMITRI BASOV, University of California, San Diego — We report on infrared spectroscopy of bilayer graphene integrated in gated structures. The dominant feature of the optical conductivity is a resonant peak due to interband transitions between the two conduction bands or two valence bands. Both the frequency and the voltage dependence of the peak show a significant asymmetry upon electrostatic doping of electrons and holes. We show that this finding arises from a marked asymmetry between the valence and conduction bands, which is mainly due to the inequivalence of the two sublattices within the graphene layer and the interlayer coupling. From the conductivity data, the energy difference of the two sublattices and the interlayer coupling energy are directly determined.

9:24AM V25.00006 On the dynamical and dc conductivity of graphene, TOBIAS STAUBER, University of Minho — It was only recently shown that a simply-observable quantity as the optical transparency of suspended graphene is defined solely by the fine structure constant [1]. In this talk, I will give the theoretical explanation to this experiment, i.e., show that even in the visible-optics regime the corrections to the Dirac cone approximation are small (a few percent) and the effect of next-nearest neighbor hopping is negligible [2]. I will also discuss the infrared conductivity of graphene on a substrate where electron-phonon and impurity scattering become important [3]. Finally, I will comment on the still unsettled question of dc conductivity in graphene and discuss - apart from Coulomb scattering - an alternative scattering mechanism based on midgap states [4].

10:00AM V25.00007 Thermoelectric and Magnetothermoelectric Transport Measurements of Graphene, YURI M. ZUEV, Applied Physics, Columbia University, WILLY CHANG, PHILIP KIM, Physics, Columbia University — We investigated the electronic, thermoelectric, and magnetothermoelectric transport properties of graphene as a function of temperature and carrier density. Microfabricated heater and thermometer electrodes were used to simultaneously measure conductance and thermoelectric power (TEP) of graphene in the temperature range of 4-300K. Graphene exhibits both positive and negative values of TEP, with a peak value on the order of kBT/|e|, when the Fermi energy is below and above the charge neutrality point, respectively. A quantitative comparison of the conductance and TEP can be made using the semiclassical Mott relation. We observed an excellent quantitative agreement between the measured TEP and the Mott relation based on the mesoscopic two terminal conductance in the low temperature regime (T < 30K). At higher temperatures, the Mott relation employing the local conductivity is necessary. Upon applying magnetic field, the magneto-thermopower exhibits characteristic oscillations in accordance with the Shubnikov-de Hass oscillations in conductance. In the quantum Hall regime at high B field, we observed the quantizing transverse and longitudinal thermopower components which are also in good agreement with the generalized Mott relation, except near the charge neutral Dirac point.
10:12AM V25.00008 Piezoresistivity of graphene-based thin films, RAHUL RAVEENDRAN NAIR, K.S. NAVOSELOV, DA JIANG, SOREN NEUBECK, LEONID PONOMARENKO, A.K. GEIM, School of Physics and Astronomy, University of Manchester — Large-scale production of graphene films is of particular interest because of graphene’s extraordinary electronic, mechanical and optical properties. We report the properties of graphene films produced by spraying or spinning of a graphene suspension obtained by ultrasonic cleavage of graphene in organic solvents, the route that does not involve graphene oxide [1]. Wafer-scale uniform films of overlapping submicron graphene crystallites were made on transparent substrates and exhibited sheet resistivity of a few kΩ with more than 80% transmission with respect to white light. Electric measurements and Raman studies suggest that the films are p-doped. In particular, we have investigated the piezoresistive effect in such films by depositing them on flexible plastic substrates. Fully reversible changes in the resistance were observed as a function of strain that could exceed 8% before the films started loosing their continuity. The piezoresistive gauge factor was up to ~30 for our films. [1] Peter Blake et al., Nano Lett. 2008, 8,1704-1708.

10:24AM V25.00009 Graphite in the bi-layer regime: in-plane transport, CHUN HUNG LUI, KIN FAI MAK, MATTHEW SFEIR, JAMES MISEWICH, TONY HEINZ, COLUMBIA UNIVERSITY, NEW YORK, NY 10027 — Bilayers of graphene have attracted intense interest because of the possibility of tuning of their band gap by the application of a perpendicular electric field [Tsaiuke Ohta et al. Science 313, 951 (2006)]. Indeed, such gate electric fields induce both 1) tuning of the chemical potential and 2) modification of the bilayer electronic structure by the development of potential difference across the two layers. These effects have significant consequences for the infrared absorption, which probes the interband transitions, of bilayer samples. We have examined these issues by measuring the evolution of the optical conductivity (for photon energies of 0.2 - 0.8 eV) of graphene bilayer field-effect transistors constructed with a transparent top gate. The infrared absorption shows a significant and reproducible variation with gate voltage. The behavior for positive and negative gate voltages reveals an electron/hole asymmetry, reflecting corresponding differences in the band structure. The role of the development of a band gap in these structures and the effect of electrostatic screening will be discussed. Work supported by the AFOSR.

10:36AM V25.00010 Tuning the Infrared Absorption of a Bilayer Graphene Field-Effect Transistor, WEIGANG WANG, KO MUNAKATA, MICHAEL ROZLER, FRANCOISE KIDWINGIRA, MALCOLM BEASLEY, Stanford University — Scanning tunneling potentiometry (STP) is a local transport measurement that was demonstrated some time ago, but has only recently been developed in a generally useful form. Near equilibrium, STP measures the electrochemical potential along a sample surface with near nanometer spatial resolution. With our newly developed STP system, we report preliminary results on few-layer graphene at room temperature and 4.2K. Room temperature STP data show a constant drift in the electric properties. At low temperature, however, our data show no such drift. Possible evidence for Landauer resistivity dipoles will be presented. Work supported by the AFOSR.

Thursday, March 19, 2009 8:00AM - 11:00AM — Session V26 DMP: Focus Session: Graphene XIV: Magnetism and Bilayers 328

8:00AM V26.00001 Defect-induced magnetism in graphene nanoflakes, E. MARTINEZ-GUERRA, M.E. CIFUENTAS-QUINTAL, R. DE COSS, Departamento de Física Aplicada, Cinvestav-Merida, Yucatan, Mexico — The interaction between electron spin and the magnetic moments of vacancies in graphene nanoflakes can open new opportunities for spintronic and quantum computation. In that direction, we have studied the magnetic properties of graphene nanoflakes (GnFs) with a simple vacancy. Using a pseudopotential LCAO method with a Generalized Gradient Approximation (GGA) for the exchange-correlation energy functional, in particular, we have calculated the magnetic moment of graphene nanoflakes of different diameters with a simple vacancy. We have found that the total spin-polarization of the graphene nanoflakes with a simple vacancy decreases as the diameter increases. In particular, we show that the vacancy induces the appearance of a midgap state at Fermi level. Thus, the spin degeneracy is broken, being only one of the spin channels of the midgap state occupied, the other being empty. This feature could be exploited for future spintronic applications. This research was supported by Consejo Nacional de Ciencia y Tecnología (Conacyt) under Grant No. 83604.

8:12AM V26.00002 Magnetism in Nanopatterned Graphene and Graphite Film, LI CHEN, DECAI YU, ELISABETH LUPTON, FENG LIU, University of Utah — We report first-principles calculations of magnetic properties of nanopatterned graphene-based nanostructures (GNBs) and nanopatterned graphite films (NGPFs). We introduce a simple geometric rule to design several novel magnetic GNBs: 6D FM nanodots with the highest possible magnetic moments, 1D FM nanoribbons, and 2D magnetic superlattices, whose predicted ground-sate magnetic ordering is confirmed by first-principles calculations. Furthermore, we show that nanopatterned graphite films (NGPFs) can exhibit magnetism similar to GNBs. In particular, graphite films with patterned nanoscale triangular holes and channels with zigzag edges all have ferromagnetic ground states.

1The work is supported by DOE.

2Current Address: Linyi Normal University,China

8:24AM V26.00003 Tunable band structure in double gated trilayer graphene, MONICA CRACIUN, SAVERIO RUSSO, MICHISAYA YAMAMOTO, Department of Applied Physics, The University of Tokyo, Japan, JEROEN OOSTINGA, ALBERTO MORPURGO, DPMC & GAP, University of Geneva, Switzerland, SEIGO TARUCHA, Department of Applied Physics, The University of Tokyo, Japan — graphene based materials are promising candidates for nano electronic applications. It is currently unclear which layer thickness is better suited for a given application, as only the properties of monolayers and bilayers have been investigated systematically. For the optimization of future devices, it is important to understand how the electronic properties of graphene based materials evolve from Dirac particles, in monolayer, to massive particles in bulk graphite. We experimentally address this question by investigating trilayer graphene, the thinnest few layer graphene system in which all the parameters determining the band structure of graphite are first found. Contrary to monolayer and bilayer (which are both zero gap semiconductors), we find that trilayer is a semimetal with a finite overlap of conduction and valence bands. We show that the low energy band structure of trilayer graphene can be tuned by a large amount by means of an external perpendicular electric field, achieving 100% change in band overlap a property not known to occur in any other semimetal.
We address this controversy by providing clear experimental evidence that metal free carbon can be ferromagnetic at room temperature using dichroism x-ray absorption spectro-microscopy. For this purpose we acquired soft x-ray microscopy images of magnetic structures on a thin carbon film that have been produced by irradiation with a focused 2.25MeV proton beam. Our element specific magnetic probe shows no indication of magnetically ordered Fe, Co or Ni impurities in these samples. Combination of the microscopy data with element specific spectroscopy and hysteresis measurements shows furthermore that only the carbon z-electronic states contribute to the long range ferromagnetic order of the sample.

The recent discovery that the application of an external electric field induces a band gap opening in doped bilayer graphene, in presence of different bottom and top gate, in particular, the dependence of the band gap on the doping, on the average external electric field and temperature has been analysed. We find that our ab-initio results differ with respect to those obtained with standard Tight Binding (TB) calculations [2]. In particular, we show important charge effects, which are crucial for the description of the electronic properties of bilayer graphene, and which are not included in TB models. Moreover, we compare our results with experimental measurements of the band gap, cyclotron mass and work function. [1] Ohta et al., Science v.313, 951 (2006). [2] Castro Neto et al., Phys. Rev. Lett. v.99, 216802 (2007).

This work is supported by the DOE under DE-FG02-07ER46453 through the Frederick Seitz Materials Research Laboratory.
The measurement of protein interaction provides an intriguing opportunity for Atomic Force Microscopy (AFM)-based force measurements. The AFM has the advantage that it is relatively easy to use and widely available. However, the interpretation of the force data is lagging behind the experimental capabilities of the technique. In this talk, I will present some recent results of rupture force measurements between two proteins, and discuss our efforts to interpret the resulting data in terms of the underlying energy landscape. We performed measurements on matrix metalloproteinases and their natural inhibitors at pulling speeds ranging over 3 orders of magnitude (30-48000 nm/s). However, we found that commonly used theory to interpret such data is inadequate and does not capture the physics of the problem. Consequently, data analysis based on such theories leads to highly erroneous results. We will discuss our attempts to improve the theory and present parameters extracted from the data that reflect the underlying energy landscape of the studied protein-protein interaction.

10:12AM V26.00012 Plasmon Dispersion and Damping in Electrically-isolated Two-dimensional Charge Sheets, YU LIU, ROY WILLIS, Pennsylvania State University — Using high resolution reflection electron-energy-loss-spectroscopy (HREELS), we compare experimental results for the wavevector-dependent behavior of plasmons in a graphene nanoribbon on SiC(0001) with that due to a filled band of surface states on semiconducting silicon. There are significant differences in behavior between the two systems, and the behavior predicted for a classical two-dimensional sheet of electrons. In particular, the damping increases with wavevector independent of any obvious inelastic scattering channel. The results illustrate the importance of finite-momentum, non-local potential effects for the dynamical behavior of electrically-isolated charge sheets.

10:24AM V26.00013 ABSTRACT WITHDRAWN —

10:36AM V26.00014 Edge Phonons of Graphene from Tight-Binding, DANIEL FINKENSTADT, U.S. Naval Academy, Physics Department, N. BERNSTEIN, D. GUNLYCZE, M.J. MEHL, U.S. Naval Research Laboratory, Washington, DC — Edge-states in graphene can affect the band-gap and carrier group velocities in narrow (< 5 nm) graphene nanoribbons. As a first, tight-binding approximation from simple nearest-neighbor hopping, it is shown that armchair nanoribbons have large band-gaps compared to zigzag nanoribbons, which are metallic, unless certain crucial effects are included in the calculation, e.g. magnetic, quasiparticle, charge-self-consistent, and/or relaxation-based degeneracy lifting. All of these effects open a small band gap, and the interplay between relaxation and electronic structure may be examined by calculating the edge phonons of graphene. To this end, we expand on our previous, all-neighbor tight-binding Hamiltonian [Phys. Rev. B 76, 121405(R) (2007)] and include charge self-consistency at the edge of a zigzag nanoribbon. By allowing charge transfer and structural-relaxation at zigzag edges, we are able to remove imaginary phonons and verify the opening of a small band-gap in zigzag ribbons, which is characterized by the phonon-density-of-states and normal modes of carbon-hydrogen edge bonds. These calculations are relevant to ribbons cut along non-ideal directions, as well, and we will discuss edge-disorder.

1Supported by the Office of Naval Research, National Research Council.

10:48AM V26.00015 Optical Conductivity and quasiparticle properties of Bilayer graphene, YAFIS BARLAS, KUN YANG, NHMFL, Tallahassee, FL — The low energy properties of Bernal stacked bilayer graphene can be adequately described by chiral quasiparticles exhibiting a Berry phase of 2π with a parabolic dispersion. When the Fermi energy lies at the neutrality point the Fermi surface consists of a pair of points where dominant inter-band excitations determine the effect on electronic correlations. The particle-hole continuum due to the inter-band excitations is given by Ω > q²/(4m) in frequency-momentum space. The full wavevector and frequency dependent polarization bubble and optical conductivity is calculated within the RPA. We also calculate the quasiparticle properties for short-ranged interactions and comment on the breakdown of Fermi liquid theory.

Thursday, March 19, 2009 8:00AM - 10:48AM — Session V27 GIMS: Focus Session: Emerging Scanning Probe Microscopy Methods for Biological Applications 329

8:00AM V27.00001 Kinetic parameters of association and dissociation between single molecules measured by single-molecule force spectroscopy, BORIS AKHREMITCHEV, Duke University — This presentation is focused on development of experimental scanning probe microscopy (SPM) approaches to quantify kinetic parameters of association and dissociation between receptor-ligand pairs. The potential of mean force (pmf) between interacting molecules is quantified by single molecule force spectroscopy (SMFS) approach. In SMFS molecules are allowed to interact and form molecular bond. Consequent measurements of rupture forces are used to characterize the attractive part of the pmf by extracting the distance from the equilibrium to the transition state, the rate of dissociation at no force and the activation energy. Factors affecting accuracy of the measured kinetic parameters are discussed including effects of the polymeric tether stiffening and possible contribution of non-single molecule events to the statistics of rupture forces. The developed SMFS method accounts for pertinent systematic errors and is tested using specific biotin-streptavidin interactions. The measured kinetic parameters show quantitative agreement with theoretical predictions. In addition, a new single-molecule approach to measure the activation energy of association is proposed. This approach uses the dependence of the probability to form molecular bonds on probe velocity when one of the interacting molecules is tethered by a flexible polymeric linker to the AFM probe. The application of the developed method to study interactions between biomolecules is demonstrated with measurements of the activation energy of biotin-streptavidin association.

8:36AM V27.00002 Coaxial and Triaxial Atomic Force Microscope Probes for Nanoassembly, KEITH A. BROWN, JONATHAN AGUILAR, R.M. WESTERVELT, Harvard SEAS and Physics — We present a technique for the controlled three dimensional assembly of nanoscale objects using a modified atomic force microscope (AFM) probe. A conducting AFM probe is coated with alternating insulating and metal layers then etched at the tip to expose coaxial electrodes. The fabrication allows freedom to specify the size of the tip and therefore the length scale of objects to manipulate. An RF voltage is applied to the electrodes to trap objects at the tip with dielectricphoresis (DEP). The object may be released when it has been moved to the desired location by turning off the field. We present a two electrode coaxial configuration capable of positive DEP and a three electrode triaxial configuration for negative DEP which holds the trapped object away from the tip to overcome the “sticky finger” problem. The integration of three dimensional assembly with the nanometer precision and force-imaging capability of an AFM creates a platform for imaging and constructing structures at the nanoscale. We describe initial experiments and fabrication.

8:48AM V27.00003 Protein bond rupture measured by AFM and the energy landscape problem, PETER HOFFMANN, ESSA MAYYAS, LINDSAY RUNYAN, Wayne State University — The measurement of protein interaction provides an intriguing opportunity for Atomic Force Microscopy (AFM)-based force measurements. The AFM has the advantage that it is relatively easy to use and widely available. However, the interpretation of the force data is lagging behind the experimental capabilities of the technique. In this talk, I will present some recent results of rupture force measurements between two proteins, and discuss our efforts to interpret the resulting data in terms of the underlying energy landscape. We performed measurements on matrix metalloproteinases and their natural inhibitors at pulling speeds ranging over 3 orders of magnitude (30-48000 nm/s). However, we found that commonly used theory to interpret such data is inadequate and does not capture the physics of the problem. Consequently, data analysis based on such theories leads to highly erroneous results. We will discuss our attempts to improve the theory and present parameters extracted from the data that reflect the underlying energy landscape of the studied protein-protein interaction.
9:00AM V27.00004 AFM method to detect differences in adhesion of silica beads to cancer and normal epithelial cells. IGOR SOKOLOV, Clarkson University, SWAMINATHAN IYER, University of Western Australia, RAVI GAIKWAD, CRAIG WOODWORTH, Clarkson University — To date, the methods of detection of cancer cells have been mostly based on traditional techniques used in biology, such as visual identification of malignant changes, cell growth analysis, specific ligand-receptor labeling, or genetic tests. Despite being well developed, these methods are either insufficiently accurate or require a lengthy complicated analysis. A search for alternative methods for the detection of cancer cells may be a fruitful approach. Here we describe an AFM study that may result in a new method for detection of cancer cells in vitro. We use atomic force microscopy (AFM) to study adhesion of single silica beads to malignant and normal cells cultured from human cervix. We found that adhesion depends on the time of contact, and can be statistically different for malignant and normal cells. Using these data, one could develop an optical method of cancer detection based on adhesion of various silica beads.

9:12AM V27.00005 Rapid Cellular Identification by Dynamic Electromechanical Response; VLADIMIR REUKOV, MAXIM NIKIFOROV, ALEXEI VERTEGEL, GARY THOMPSON, STÉPHEN JESSE, SERGEI KALININ, OAK RIDGE NATIONAL LABORATORY TEAM, CLEMSON UNIVERSITY TEAM — Quick and reliable identification of individual prokaryotic organisms and cellular types is of utmost importance for various applications. A number of strategies for cellular identification are currently used to meet this challenge. All of the existing techniques require culturing bacteria prior to measurement, which increases the time needed for experimentation and analysis considerably. Here, we report on a method for rapid cellular identification and mapping using the detection of broadband electromechanical response. Electromechanical spectra from M. Lysodeikits and P. Fluorescens deposited on PLL-coated mica were collected over wide frequency range. Principal component analysis of the spectra bundled with neural network analysis provides a robust algorithm for identification of the cellular organisms based on their electromechanical properties.

9:24AM V27.00006 Simultaneous Nanomechanical and 3d Optical Microscopy: Cellular Distortions and Structural Dynamics; BRYAN HUEY, University of Connecticut, Institute of Materials Science — Combined SPM and Optical systems are increasingly used to study biological structures, including living cells. Here, an AFM is employed to expose cells to foreign bodies and biochemicals, and to measure the resulting attractive and repulsive forces exerted by the cell. 3d optical fluorescence measurements are simultaneously performed revealing distortions and/or restructuring of the cell, membrane, actin cytoskeleton, etc. The work focuses primarily on MH-S cells (mouse lung macrophages) transfected with GAP-43 GFP to identify cell membranes and/or mCherry Actin to identify cytoskeleton dynamics. During standard AFM, optical-cross sections reveal drastic cell distortions up to 50 percent. The viscoelastic response of the cells to nanoNewton induced forces by Silica and Polystyrene beads is also quantified via Structural Recovery After Probing (STRAP), which monitors the rate of cellular recovery following nanodentation.

1Supported by NSF-Nanobiomechanics (#0626231).

10:00AM V27.00007 Spectral Oscillations in Backscattering of Light from a Biological Cell; ALEXANDER HEIFETZ, Argonne National Laboratory, ALEXANDER PATASHINSKI, VADIM BACKMAN, Northwestern University — Based on general electrodynamics principles, we provide an explanation for spectral oscillations in the intensity of visible light elastic backscattering from a live epithelial biological cell. We suggest that the source of spectral oscillations in backscattering from a cell is the nucleus, which is a spheroidal particle several times larger than the incident wavelength, and has a sharp boundary. Because of the small optical contrast of the nucleus relative to surrounding cytoplasm, contribution of single scattering to the overall signal is comparable to that of multiple scattering. We show that the high frequency spectral oscillations in backscattering are due to single scattering, which can be obtained in the first Born approximation. Multiple scattering effects result in slow envelope spectral oscillations. We expand the Mie backscattering cross-section of a uniform sphere in power series to show that the equivalence between the first order Mie backscattering and first Born series.

10:12AM V27.00008 Single-molecule detection of near-infrared phthalocyanine dyes; YOU LI, BRIAN CANFIELD, LLOYD DAVIS, University of Tennessee Space Institute — The major advantage associated with near-IR monitoring is the fact that few compounds exhibit intrinsic fluorescence in this region of the spectrum. Phthalocyanine dyes provide excellent photostability and hence are an attractive candidate for fluorescence bioassay applications. However, because of their small Stokes shifts, non-standard methods are needed for separation of fluorescence from scattered laser light. We have developed a custom confocal microscope that uses a low-cost laser diode operating at 665.8 nm for sample excitation and an angle-tuned Raman notch filter to block scattered laser radiation and provide high-throughput of fluorescence. Also, a diffraction grating is used to isolate the laser excitation wavelength from the broad background luminescence of the laser. We have used the system to observe photon bursts from single molecules of zinc phthalocyanine fluorophores in an ethanol solution. The autocorrelation function of the photon trace provides a measure of the signal-to-noise ratio. We also discuss ongoing experiments to characterize the limits of detection of near-infrared fluorophores in aqueous solution using the microscope.

10:24AM V27.00009 Chemical Recognition Tunneling via Hydrogen Bond; JIN HE, the Biodesign Institute, Arizona State University, SHUAI CHANG, LISHA LIN, SHUO HUANG, ASHLEY KIBEL, MYEONG LEE, PEIMING ZHANG, OTTO SANKEY, STUART LINDSAY, Arizona State University — Hydrogen bonds enhance electron tunneling rates over vacuum tunneling as well as making chemically selective attachments to target molecules when patterns of donors and acceptors match. This raises the possibility of a completely new approach to transducing chemical information into electrical signals, based on forming an electrical circuit via a target molecule that bridges a gap between two electrodes by means of hydrogen bonding. Hydrogen-bond sensitive contrast has recently been demonstrated in scanning-tunneling microscope (STM) images of DNA bases. In this presentation, I will first show that the tunnel-current vs. distance decay curves acquired by STM change shape with the number of hydrogen bonds mediating an interaction. [1] Base composition of DNA oligomers can be resolved by this method. Further studies demonstrate that these tunnel-current decay signals can be used to count the number of hydrogen bonds in interactions between DNA bases and related compounds. The signals are partially mechanical in origin, reflecting the tensile strength of a tunnel junction held together with hydrogen bonds.

10:36AM V27.00010 Nanoscale Properties of Neural Cell Prosthetic and Astrocyte Response, D.A. FLOWERS, Wayne State University, MI, V.M. AYRES, Michigan State University, R. DELGADO-RIVERA, Rutgers University, NJ, I. AHMÉD, S.A. MEINERS, University of Medicine and Dentistry of New Jersey — Preliminary data from in-vivo investigations (rat model) suggest that a nanofiber prosthetic device of fibroblast growth factor-2 (FGF-2)-modified nanofibers can correctly guide regenerating axons across an injury gap with aligned functional recovery. Scanning Probe Recognition Microscopy (SPRM) with auto-tracking of individual nanofibers is used for investigation of the key nanoscale properties of the nanofiber prosthetic device for central nervous system tissue engineering and repair. The key properties under SPRM investigation include nanofiber stiffness and surface roughness, nanofiber curvature, nanofiber mesh density and porosity, and growth factor presentation and distribution. Each of these factors has been demonstrated to have global effects on cell morphology, function, proliferation, morphogenesis, migration, and differentiation. The effect of FGF-2 modification on the key nanoscale properties is investigated. Results from the nanofiber prosthetic properties investigations are correlated with astrocyte response to unmodified and FGF-2 modified scaffolds, using 2D planar substrates as a control.

Thursday, March 19, 2009 8:00AM - 11:00AM — Session V28 FLAP: Focus Session: Graphene Device and Applications III 330

8:00AM V28.00001 Graphene field-effect transistors for RF applicatons1, KENNETH SHEPARD, Columbia University — There has been growing interest in graphene as a replacement for III-V materials in MMIC applications because of its high mobility, its potential for high saturation velocity, and its nearly perfect two-dimensional electrostatics. We present results from the first experimental high-frequency measurements of graphene field-effect transistors (GFETs), demonstrating an fT of 14.7 GHz for a 0.5-µm-length device with a 30-nm-thick HfO2 gate-poly. Despite lOn/loff ~7, high transconductances (>533 µS/µm) and current saturation are achieved. We present detailed measurement and analysis of velocity saturation in GFETs, demonstrating the potential for velocities approaching 10^6 cm/sec and the effect of an ambipolar channel on current-voltage characteristics. We find that the saturation velocity is sheet-carrier dependent and limited by interfacial phonon scattering from the SiO2 substrate upon which the graphene is fabricated.

8:36AM V28.00002 Tunable spin-polarized terahertz excitations in graphene nanoribbons1, JUN-QIANG LU, University of Puerto Rico, XIAOGUANG ZHANG, Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University — Graphene nanoribbons have an energy gap that is tunable from zero to terahertz (THz) regime by an external gate field. The indirect energy gap in a nanoribbon of infinite length, however, is unsuitable for optical excitations. We report a theoretical investigation of such nanoribbons with a finite, nanoscale length. We show that such nanoribbons can be excited optically and exhibit unique electronic excitations in the THz regime. The results unveil THz radiation-induced edge standing spin waves with different wavelengths at the two edges and a resonant frequency that can be controlled by an external gate voltage, opening the possibility of THz “opto-spintronic” applications.

1Work at CNMS at ORNL sponsored by Division of User Facilities, Office of Basic Energy Sciences, US Department of Energy.

8:48AM V28.00003 THz Emission from Graphite Surfaces, CHEN XIA, JIE SHAN, Physics Department, Case Western Reserve University — Graphite formed by Van der Waals force between adjacent graphite sheets has been studied for more than six decades due to its relatively simple quasi-two-dimensional structure. Lately, because of its close relationship to carbon nanotubes and new physics originating from graphite’s linear excitations spectrum and the 4-fold degeneracy of the electronic states, graphite materials have attracted much of research attention. However, still little is known about the high-frequency transport properties of these materials. In this work, we investigate graphite materials in THz regime by THz emission spectroscopy. Picosecond THz pulses were observed from a highly oriented pyrolytic graphite (HOPG) surface when it was illuminated by intense ultrafast optical pulses at an oblique angle. The emission was mostly p-polarized and increased linearly with pump fluence. Several potential mechanisms for the emission including surface nonlinearities will be discussed in the talk.

9:00AM V28.00004 Low - Frequency Noise in Graphene Transistors2, GUANXIONG LIU, QINGHUI SHAO, DESALEGNE TEWELDEBRHAN, ALEXANDER BALANDIN, Nano-Device Laboratory, Electrical Engineering, University of California Riverside, Riverside, CA, SERGUEI ROUMYANTSEV, MICHAEL SHUR, Center for Integrated Electronics, Electrical, Computer and Systems Engineering, Rensselaer Polytechnic Institute, Troy, New York — We present the results of the experimental investigation of the low-frequency noise in three-terminal bilayer graphene devices. The quality of graphene layers has been verified with micro-Raman spectroscopy. Back-gated devices were fabricated using electron beam lithography and evaporated. The back-gate was used to adjust electrical conductivity through the graphene layer placed on top of Si/SiO2 substrate. The charge neutrality point for examined devices was ~10 V. The noise spectral density was rather low (on the order of ~10E−21−10E−22 A2/Hz at frequency of 1 kHz). The noise reveals generation-recombination (G-R) bulges. Presence of G-R bulges and deviation from the 1/f spectrum suggest that the noise is of carrier-number fluctuation origin due to carrier trapping by defects [1]. The low values of the low-frequency noise add validity to the proposed electronic applications of graphene.

9:12AM V28.00005 Environmental Effects on 1/f Noise in Graphene and CNT Based Devices3, BRETT R. GOLDSMITH, YE LU, ZHENG TANG LUO, A.T. CHARLIE JOHNSON, University of Pennsylvania — Graphite related materials such as carbon nanotubes, graphene and graphene oxide show promise for future electronic and chemical sensor applications. Nanotubes and graphene, in particular, have been shown to make exquisitely sensitive chemical sensors. Due to their low carrier density, the 1/f noise in these nanomaterials is very high. Understanding the cause of this noise is particularly important for chemical sensing applications, and the noise common to these materials may be one barrier to current practical success for graphitic sensors outside the lab. We have compared the noise power spectral density (PSD) of these three materials in different chemical environments and at different temperatures. This information should play a key role in guiding the development of future sensing devices as well as helping to illuminate the atomic scale interactions which lead to enhanced or suppressed 1/f noise in graphitic materials.

9:24AM V28.00006 ABSTRACT WITHDRAWN —
10:00AM V28.00007 Progress towards graphene as a quantum-limited electro-mechanical resonator

R. G. KNOBEL, A. CHIA, Queens University, Department of Physics — With its high stiffness, low density and relatively simple fabrication, graphene promises to be an ideal system for exploring the quantum limits of mechanical measurements. In particular, electronic transport through a graphene sheet suspended over an electrode can be strongly modulated by vibrations of the sheet — whether through the standard field effect which changes the carrier density in the sheet, or through modification of the Coulomb blockade in quantum dots formed in the sheet. In this work we present the novel fabrication scheme we are using for this work, which involves exfoliation and identification of single-layer graphene sheets on a PMMA layer above a silicon substrate, cross-linking of the PMMA to form supports for the graphene and metal electrodes, and subsequent lithography to form electrodes. Raman scattering measurements before and after patterning confirm the single-layer nature of the graphene, and preliminary low-temperature transport measurements show the feasibility of this system for quantum-limited sensitivity of resonant motion of the sheet.

10:12AM V28.00008 Developing resonant tunneling devices based on graphene

ERIC YU, SANDIP TIWARI, Department of Electrical and Computer Engineering, Cornell University, DEREK STEWART, Cornell Nanoscale Facility, Cornell University — We present an ab-initio study of the electronic properties of patterned graphene structures as candidate resonant tunneling devices. We consider graphene nanoribbons that have been modified with one or more narrow constrictions or patterned with periodic nanoscale antidotes[1]. Specifically, we focus on semi-metallic armchair nanoribbons with narrow semiconducting regions and semi-metallic zigzag nanoribbons patterned with antidots. Using a first-principles density functional theory (DFT) approach, we investigate the induced band-gap opening and transmission coefficients. We examine how varying the lengths of the constrictions, changing the separation between dots and their sizes affect transport properties. We will also discuss I-V characteristics of these graphene structures and evaluate the possibility of a negative differential resistance in these devices. [1] T. G. Pedersen et al., Physical Review Letters, 100 136804 (2008)

10:24AM V28.00009 Coherent Graphene Devices: Movable Mirror, Buffer and Memory

L. ZHAO, Department of Physics, University of Connecticut, Storrs, CT 06269; ITAMP, Harvard-Smithsonian Center for Astrophysics, Cambridge, MA 02138 — We theoretically report that, at a sharp electrostatic step potential in graphene, massless Dirac fermions can obtain a Goos-Hänchen-like shift under total internal reflection. Based on these results, we study the coherent propagation of the quasiparticles along a sharp graphene p-n-p waveguide and derive novel dispersion relations for the guided modes. Consequently, coherent graphene devices (e.g. movable mirror, buffer and memory) induced only by the electric field effect can be proposed.

We would like to acknowledge funding from NSF.

10:36AM V28.00010 Graphene interferometry

DANIEL GUNLYCKE, CARTER WHITE, Naval Research Laboratory — Ballistic transport calculations of graphene connected to two contacts are presented. The calculations are based on the nearest-neighbor, tight-binding approximation but are otherwise treated exactly within a Green function formalism. It is shown that under certain circumstances stable collective resonances emerge from a resonant structure that in general could be quite complicated. These collective resonances originate from a large number of non-equivalent conduction channels and are evenly spaced, except for a region close to the Fermi level. The separation between neighboring collective resonances depends to first order only on the contact separation. Their contrast, on the other hand, is affected by the width of the sample, temperature, and unevenness in the contact interfaces. Despite the existence of many potential sources that could degrade the collective resonances, these resonances could still prove to be observable experimentally.

10:48AM V28.00011 Nanotube Films and Their Application For Mode-Locked Lasers

Thursday, March 19, 2009 8:00AM - 11:00AM
Session V29 GMAG: Correlated Electrons

8:00AM V29.00001 Emergence of spin structure in quantum wires under strong magnetic fields

GILAD BARAK, GEORG SCHUSTERTSCH, AMIR YACOBY, Harvard University. LOREN PFEIFFER, KEN WEST, Bell Labs, Lucent Technologies — We study the effects of a perpendicular magnetic field on the spin and charge structure of a quantum wire. Using momentum resolved tunneling between two parallel wires we measure the dispersion relation for different perpendicular magnetic fields. We find that as the magnetic field increases, charges with opposing spin separate in the cross section of the wire giving rise to strips of polarized and unpolarized electrons. We argue that this structure results from the exchange interaction between electrons in the wire. We discuss the applicability of these results to the structure of Quantum Hall edge states.
8:12AM V29.00002 Nonequilibrium transport in the Anderson model of a biased quantum dot1, SUNG CHAO, GUILLAUME PALACIOS, Rutgers University, ANDRES JEREZ, New Jersey Institute of Technology, CARLOS BOLECH, Rice University, PANKAJ MEHTA, Princeton University, NATAN ANDREI, Rutgers University — We derive the transport properties of a quantum dot subject to a source-drain bias by means of the Scattering Bethe Ansatz, a generalization of the traditional Thermodynamic Bethe Ansatz to open systems out of equilibrium, which allows a description of the the system in nonequilibrium steady state over the full range of its parameters. Solving the equations at zero temperature and magnetic field we present here the non-linear conductance against the bias voltage with arbitrary tunneling rate and with the gate voltage varying from the mixed valence to the Kondo regime.

1Work supported by Grant number: DMR - 0605941.

8:24AM V29.00003 Imaging the Fano lattice in the heavy fermion material URu$_2$Si$_2$ by scanning tunneling spectroscopy1, ANDREW SCHMIDT, MOHAMMAD HAMIDIAN, Cornell University, PETER WAHL, Max Planck Institut, FOCKO MEIER, Cornell University, GRAEME LUKE, McMaster University, J.C. DAVIS, Cornell University, CORNELL UNIVERSITY TEAM, MCMASTER UNIVERSITY TEAM — We present scanning tunneling spectroscopy measurements of the heavy fermion material URu$_2$Si$_2$. Two dimensional differential conductance maps of mechanically cleaved surfaces reveal a narrow Fano lineshape about the Fermi level that is pervasive across the field of view. Such a lineshape is expected whenever a discrete energy level is coupled to a continuum of levels. By fitting the spectra to a Fano function, we produce maps showing the variation of the Fano parameters across the surface.

8:36AM V29.00004 Theory of the Unusual Quasiparticle Excitations in USb$_2$, PETER RISEBOROUGH, XIAODONG YANG, Temple University — A band of long-lived quasiparticles with a renormalized dispersion relation that does not cross the Fermi surface has been observed in USb$_2$ by angle resolved photoemission measurements. The existence of a kink in the quasiparticle dispersion relation of a band that does not cross the Fermi energy is unprecedented. We show that the observed renormalization does not come from the standard theory of electron-phonon renormalizations. We consider the effect of the interband self-energy and vertex corrections as possible causes for the formation of the renormalized quasiparticles. The effect of temperature is also considered.

8:48AM V29.00005 Kink in the dispersion of f-electrons, TOMASZ DURAKIEWICZ, PETER S. RISEBOROUGH, CLIFFORD G. OLSON, JOHN J. JOYCE, PETER M. OPPENEEER, SAAD ELGAZZAR, ERIC D. BAUER, JOHN L. SARRAO, ELA GUZIEWICZ, DAVID P. MOORE, MARTIN T. BUTTERFIELD, KEVIN S. GRAHAM, LOS ALAMOS NATIONAL LABORATORY, TEMPLE UNIVERSITY, AMES LAB, UPPSALA UNIVERSITY, PAN, LLNL TEAM — Many-body interactions may result in the formation of long-lived heavy quasi-particles that exhibit kinks in their energy dispersion. Kinks are often seen in d-electron correlated systems and are attributed to many different origins, such as coupling to phonons, extended spin-fluctuations, or electron-electron correlations. We have found that the renormalization of a 5f electron band in USb$_2$ leads to the formation of a kink characterized by two distinct regions with different quasiparticle masses, peak asymmetries, lifetimes and a record-breaking small width of 3meV. The kink energy scale of 17meV originates from renormalization of a point-like Fermi surface, and is a factor of two smaller than previously measured in correlated materials.

1Research supported by DOE BES and LANL LDRD.

9:00AM V29.00006 Localized 5f antiferromagnetism in cubic UIn$_5$: $^{115}$In-NMR/NQR Study, H. SAKAI, S. KAMBE, Y. TOKUNAGA, H. CHUDO, Japan Atomic Energy Agency, Y. TOKIWA$^1$, D. AOKI$^2$, Osaka University, Y. HAGA, Japan Atomic Energy Agency, Y. ÔNUKI$^3$, Osaka University, H. YASUOKA, Japan Atomic Energy Agency — $^{115}$In nuclear magnetic resonance (NMR) and nuclear quadrupole resonance (NQR) measurements have been performed on an antiferromagnet UIn$_5$ with the cubic AuCu$_3$-type structure. The NQR frequency ($\nu_Q$) and Knight shift (K) of $^{115}$In in UIn$_5$ have been estimated in the paramagnetic state from NMR experiments under applied field. The perpendicular component of transferred hyperfine coupling constant ($A_\perp$) has been deduced from scaled behavior of K to the static susceptibility ($\chi$). Under zero field, the observation of the NQR spectrum has led to an estimated $\nu_Q$ of 11.8 MHz at 90 K. The temperature variation of the NQR relaxation rates ($1/T_1$) far above the Néel temperature $T_N$=88 K approaches a constant value, which indicates a localized nature for the 5f- electrons in this system. On the other hand, in the antiferromagnetically ordered state at 4 K (well below $T_N$), the $^{115}$In-NQR spectrum has been scanned over frequencies ranging from ~20 to ~70 MHz under zero applied field. From the analysis of the NMR spectrum, we propose that the direction of U moments in the AF state is neither (100) nor (111), but may be (110).

9:12AM V29.00007 Studies of the Ferromagnetic Superconductors URhGe and UCuGe, TRAVIS WILLIAMS, ADAM ACZEL, WEIQIANG YU, McMaster University, YASUTOMO UEMURA, JEREMY CARLO, Columbia University, TATSUO GOKO, TRUMF, JIM GARRETT, Brockhouse Institute for Materials Research, GRAEME LUKE, McMaster University — Superconductivity (SC) cannot cooperatively exist with ferromagnetism (FM) in conventional superconductors, since ferromagnetism would act to destroy Cooper pairs. Thus, in FM superconductors such as URhGe and UCuGe, a more exotic pairing type must exist. I will outline the growth and characterization of URhGe and UCuGe crystals, and our measurements of the FM and SC properties of these combined results from DC Resistivity, Bulk Magnetometry and Muon Spin Relaxation show FM properties in the samples, including a clear FM transition at 9.5K in the URhGe crystal. We will discuss our results and their implications for the nature of the SC state in these materials.

9:24AM V29.00008 Renormalization of electronic structure close to Fermi level of CeIrIn$_5$ at 20K, YINWAN LI, TOMASZ DURAKIEWICZ, JOHN J. JOYCE, KEVIN S. GRAHAM, JOHN L. SARRAO, ERIC D. BAUER, Los Alamos National Laboratory, CLIFFORD G. OLSON, Ames Lab, Iowa State University — The electronic structure of heavy-fermion super-conductor CeIrIn$_5$ is investigated at ~20K by high-resolution angle-resolved photoemission (ARPES). The low energy ARPES spectra indicate a kink near the Fermi surface within the energy scale of the order of 20meV. Existence of a kink may suggest coupling of electron to a collective boson mode of unknown origin.

$^1$Research supported by DOE BES and LANL LDRD.
9:36AM V29.00009 Interplay of magnetism and screening in the Kondo Lattice1, PIERS COLEMAN, ANDRIY NEVIDOMSKYY, Dept Physics and Astronomy, Rutgers University — An increasing body of experimental evidence suggests that frustration and the Kondo effect have complimentary roles that act together to either reduce, or completely eliminate magnetic order in heavy electron systems[1]. I will review our attempts to explore the joint effects of frustration and Kondo effect in the Kondo Heisenberg model, using the large N Schwinger boson approach[2]. These results will be discussed in the context of recent doping experiments on YbRh2Si2 [3], where an intermediate spin liquid appears to develop between the antiferromagnet and the large Fermi surface metal.

1 Supported by the Foundation for Polish Science (FNP), the Polish Research Project N202 068 32/1481, and the NSF grant DMR-0706020.

9:48AM V29.00010 Electronic band structure of Pr-based filled skutterudite antimonides1, J.W. ALLEN, B.J. KIM, RAVI S. SINGH, University of Michigan, O. KRUPIN, J.D. DENLINGER, Lawrence Berkeley National Lab, R.E. BAUMBACH, M.B. MÄPLE, UC San Diego — Filled skutterudites exhibit a wide range of strongly correlated electron phenomena including heavy fermion, superconductivity, non-Fermi liquid and quantum critical behaviors. Knowledge of the electronic structures of these materials is almost entirely from band calculations and dhvA studies. We present the first angle-resolved photoemission spectroscopy (ARPES) measurements of the filled skutterudites antimonides: PrOs4Sb12 and PrRu4Sb12. Band dispersions and Fermi surface maps of these three-dimensional materials will be discussed and compared to available LDA band structure calculations.

1Supported by the U.S. DOE at the Advanced Light Source (DE-AC02-05CH11231), at UM (DE-FG02-07ER46379) and UCSD (FG02-04ER46105 & FG02-04ER46178).

10:00AM V29.00011 High frequency thermal transport for the 2d Hubbard model1, LOUIS-FRANCOIS ARSENAULT, SYED HASSAN, ANDRE-MARIE TRÉMBLAY, Université de Physique et RQMP, Université de Sherbrooke — In order to calculate thermal transport coefficients of correlated systems when the Boltzmann equation is not applicable, Shastry [1] has developed a new theoretical approach. Although, in this theory, quantities such as the thermopower depend only upon the one particle Green’s function, vertex corrections are included. The price to be paid is that only the high frequency limit is accessible. This may be adequate for aforementioned transport coefficients. Results for the triangular lattice t-J model and the 1d Hubbard model are already in the literature but there are no results for the 2d Hubbard model, the prototype of correlated electron systems. We thus applied the Shastry approach to the 2d Hubbard model using quantum cluster approaches that include CDMFT + exact diagonalization, Bethe’s lattice DMFT + CTQMC and CDMFT + CTQMC. Results were obtained for the thermopower as a function of temperature (T), chemical potential (μ), and band structure. Since infinite frequency is reached differently in the t-J and in the Hubbard model, our results enable us to assess the degree to which infinite frequency is related to experimental results on DC transport. [1] B. Sriram Shastry, Phys. Rev. B 73, 085117 (2006)

10:12AM V29.00012 Time evolution of excited state in the system with first-order metal-insulator transition, W. KOSHIBAE, CROSS-CORRELATED MATERIALS RESEARCH GROUP (CMRG), RIKEN, CREST, JST, N. FURUKAWA, Aoyama-Gakuin Univ., ERATO-Multiferroics, JST, c/o Dept. of Appl. Phys., Univ. of Tokyo, N. NAGAOSA, CMRG, RIKEN, CREST, JST, N. FURUKAWA, Aoyama-Gakuin Univ., ERATO-Multiferroics, JST, c/o Dept. of Appl. Phys., Univ. of Tokyo — We have studied numerically the relaxation process in the system with a first-order metal-insulator transition using the double-exchange model: $H = -t \sum \langle i,j \rangle \sum_{\sigma} (c_{i \sigma}^\dagger c_{j \sigma} + h.c.) - J_\parallel \sum \langle i \rangle \sum_{\alpha \beta} (\alpha \beta_{\alpha \beta} \delta_{\alpha \beta}) \cdot \vec{S}_i \cdot \vec{S}_ j$. The localized spin is considered to be a classical vector with a magnitude $S$. In the two-dimensional system and in the case of $S J_\parallel / t < 4$, the ground state shows a metal-insulator transition due to the change of the magnetic state. When the magnitude of the parameter $S J_\parallel / t$ is not large enough, the antiferromagnetic insulating state is stabilized because of a perfect nesting-condition of the system. The metallic state appears with the ferromagnetic state. We have numerically investigated the time evolution of the coupled electronic and spin states by combining the exact diagonalization and the Landau-Lifschitz-Gilbert equation. Due to the effect of the Gilbert dumping, the excited electronic state goes back to the ground state. In the light of the theoretical results, we will discuss the relaxation process and cross-effects in the system with a first-order metal-insulator transition.

10:24AM V29.00013 Chiral spin states in the pyrochlore Heisenberg magnet: Fermionic mean-field theory and variational Monte Carlo calculations, JUNGHOO KIM, JUNG HOON HAN, Sungkyunkwan University — Fermionic mean-field theory and variational Monte Carlo calculations are employed to shed light on the possible uniform ground states of the Heisenberg model on the pyrochlore lattice. Among the various flux configurations, we find the chiral spin states carrying $\pi / 2$ flux through each triangular face to be the most stable both within the mean-field theory and the projected wave- function studies. Properties of the spin-spin correlation function and the chirality order parameter are calculated for the projected wave functions. Meanfield band structures are examined.

10:36AM V29.00014 Spectral properties of orbital polarons in Mott insulators1, KRZYSZTOF WOHLFELD, Jagiellonian University, Cracow, MARIAN DAGHOFER, Oak Ridge National Lab, University of Tennessee, ANDRZEJ M. OLES, Jagiellonian University, Cracow, Max-Planck-Institut FKF, Stuttgart, PETER HORSCH, Max-Planck-Institut FKF, Stuttgart — Since orbital symmetry is lower than SU(2), superexchange in Mott insulators with orbital degrees of freedom is typically not Heisenberg-like and hole propagation is highly nontrivial [1]. We investigate cases with Ising-like superexchange, where the hole cannot propagate by its coupling to spin fluctuations. We find that the usually neglected three-site hopping determines hole motion [2]. One realization of Ising superexchange is the Falicov-Kimball model, where only electrons with one orbital flavor can move, and the other ones are localized — then a hole inserted into the Mott insulator either moves via three-site hopping processes, or remains trapped in a small polaron. In another case of Ising exchange, a class of $t_{2g}$ or $e_g$ orbital systems, renormalized three-site hopping leads to one-dimensional hole propagation, with its direction determined by the orbital flavor of the hole.

10:48AM V29.00015 Spin conservation and Fermi liquid near a Pomeranchuk transition. ANDREY CHUBUKOV, University of Wisconsin, DMITRII MASLOV, University of Florida — We analyze system behavior near a Pomeranchuk instability in terms of Fermi liquid theory. We argue that the original assumption that a single Landau parameter approaches \(-1\) at a Pomeranchuk transition, while others are non-critical in \(D \leq 3\). We show that, near the transition, a system enters into a novel regime in which all other Landau components increase and eventually diverge at the critical point. We demonstrate that in this novel regime the relation between the Landau function and the full vertex is different from that in a conventional Fermi liquid theory — the proportionality factor 
\[ g \] contains its running effective mass, and has a value near \(-1\) for the boundary between a conventional Fermi liquid and the novel Fermi liquid behavior. We show how to restore spin conservation near a Pomeranchuk transition and discuss extra features specific to Pomeranchuk instabilities in the spin channel.

Thursday, March 19, 2009 8:00AM - 11:00AM – Session V30 DMP GMAG: Focus Session: Multiferroic Properties of Oxide Films

8:00AM V30.00001 Understanding Magnetism in Multiferroics. MIKIEL HOLCOMB, University of California Berkeley — Multiferroics are interesting materials not only because of their exciting order parameters, but for the potential for parameter coupling. In order to understand the magnetoelectric coupling, the individual order parameters must first be understood. BiFeO\(_3\) (BFO), a room temperature ferroelectric and an antiferromagnet, is an excellent model system for understanding the coupling between ferroelectricity and magnetism. A combination of in-plane and out-of-plane piezoelectric microscopy (PFM) allows 3D mapping of the ferroelectric polarization directions in micron-sized regions of the films. The magnetic order of BFO was obtained by using x-ray linear dichroism images using a photoelectron emission microscope (PEEM). When compared with our dichroism models, angle and temperature dependent absorption measurements allow decoupling and direction determination of the two order parameters, ferroelectric and magnetic, contributing to the photoemission signal. These studies reveal a strain-driven reduction in magnetic symmetry in thin films, leading to the formation of a preferred magnetic axis as opposed to the observed easy plane for bulk films. This reduction along with the previous proof of FE-AFM coupling allows electrical control of its magnetic axis. This electrical BFO control has a strong effect on ferromagnets even at room temperature.

8:36AM V30.00002 Infrared and Raman spectroscopy of the magneto-electric coupling in BiFeO\(_3\) films. PETER MAKSYMOWYCH, THOMAS K. LEFIN, Lawrence Berkeley National Laboratory, TN, 73831, SERGEY LESENKO, LAURENT BELLICAHE, University of Arkansas, AK, 72701, NINA BALKE, MARK HUIJBEN, RAMAMOORTHY RAMESH, University of California, Berkeley, CA, 94720, ARTHUR P. ADDARDO, Oak Ridge National Laboratory, TN, 73831, SERGEI V. KALININ, Oak Ridge National Laboratory, TN 73831 — The ferroelectric size effect is a highly pursued and controversial topic encompassing the scaling of polar distortion, domain structure and switchable polarization. We have studied epitaxial BiFeO\(_3\) films using ultrahigh vacuum piezoelectric microscopy and high temperature data, up to 1200 K, on ceramics (infrared) or single crystals (Raman) also show phonon frequency renormalization at the Néel temperature. Our results reinforce a picture where the ferroelectric character of BiFeO\(_3\) plays an important role.

8:48AM V30.00003 Ferroelectric Size-effect on BiFeO\(_3\) Films in Ultra-high Vacuum. PETER MAKSYMOWYCH, STEPHEN JESSE, Oak Ridge National Laboratory, TN, 73831, SERGEY LESENKO, LAURENT BELLICAHE, University of Arkansas, AK, 72701, NINA BALKE, MARK HUIJBEN, RAMAMOORTHY RAMESH, University of California, Berkeley, CA, 94720, ARTHUR P. ADDARDO, Oak Ridge National Laboratory, TN, 73831, SERGEI V. KALININ, Oak Ridge National Laboratory, TN 73831 — The ferroelectric size effect is a highly pursued and controversial topic encompassing the scaling of polar distortion, domain structure and switchable polarization. We have studied epitaxial BiFeO\(_3\) films using ultrahigh vacuum piezoelectric microscopy and high temperature data, up to 1200 K, on ceramics (infrared) or single crystals (Raman) also show phonon frequency renormalization at the Néel temperature. Our results reinforce a picture where the ferroelectric character of BiFeO\(_3\) plays an important role.

9:00AM V30.00004 Electrical conduction at domain walls in multiferroic BiFeO\(_3\). JAN SEIDEL, LANE MARTIN, QING HE, UC Berkeley, QIAN ZHAN, Lawrence Berkeley National Lab, YING-HAO CHU, National Chiao Tung University, Taiwan, AXEL ROTHER, TU Dresden, Germany, MICHAEL HAWKIDGE, Lawrence Berkeley National Lab, PETER MAKSYMOWYCH, Oakridge National Lab, PU YU, MARTIN GAJK, NINA BALKE, UC Berkeley, SERGEI KALININ, Oakridge National Lab, SYBILLE GEMMING, TZ Dresden-Rossendorf, Germany, FENG WANG, UC Berkeley, GUSTAV ATZEL, JAMES SCOTT, Unigemt, and M. JOSEPH ORENSTEIN, RAMAMOORTHY RAMESH, UC Berkeley — We report the observation of room temperature electronic conductivity at ferroelectric domain walls in BiFeO\(_3\). The origin and nature of the observed conductivity is probed using a combination of conductive atomic force microscopy, high resolution transmission electron microscopy and first-principles density functional computations. We show that a structurally driven change in both the electrostatic potential and local electronic structure (i.e., a decrease in band gap) at the domain wall leads to the observed electrical conductivity. We estimate the conductivity in the wall to be several orders of magnitude higher than for the bulk material. Additionally we demonstrate the potential for device applications of such conducting nanoscale features.

9:12AM V30.00005 Ferroelastic domain formation in epitaxial La\(_{0.7}\)Sr\(_{0.3}\)MnO\(_3\) thin films. TIM FISTER, DILLON FONG, JEFFREY EASTMAN, PAUL FUOSS, Materials Science Division, Argonne National Laboratory, KAVAIPTALI BALASUBRAMANIAM, PAUL SALVADOR, Department of Materials Science & Engineering, Carnegie Mellon University — Epitaxial La\(_{0.7}\)Sr\(_{0.3}\)MnO\(_3\) (LSMO) thin films are known to form domains to reduce substrate-induced strain. For instance, on cubic SrTiO\(_3\) (100), LSMO thin films can have up to four rhombohedrally-strained variants. These individual strain states can distort the MnO\(_6\) octahedra and lead to unique electrical and magnetic properties. We have used synchrotron x-ray diffuse scattering to probe the in- and out-of-plane domain structure of a 5 nm LSMO film grown on SrTiO\(_3\) (100). Satellites are present near integer order and half-order peaks. This study exhibits two important points: first, the bounding phase of LSMO domains, and second, the strain state of each variant. Implications of the domain structure on magnetic properties will be discussed.

9:24AM V30.00006 Development of All Oxide Exchange Bias Systems. DAVID KIRKWOOD, Department of Materials and Science and Engineering, University of Virginia, Charlottsville, VA 22904, YONGHANG PEI, Department of Physics, University of Virginia, Charlottesville, VA 22904, NAM DAO, JIWEI LU, STUART WOLF, Department of Materials Science and Engineering, University of Virginia, Charlottsville, VA 22904 — Multiferroic materials exhibit multiple states of order which are often coupled. Bismuth Ferrite (BFO\(_3\)) is a room temperature antiferromagnetic, ferromagnetic materials, where electrical control of magnetism and vice versa has been established. BFO\(_3\) with ferromagnetic oxides such as Magnetite (Fe\(_3\)O\(_4\)) or Lanthanum Strontium Manganite (L\(_2\)S\(_3\)MO\(_3\)) could yield interesting system with electrically controllable exchange bias. We have used a novel deposition tool employing two pulsed electron beam sources (PEBS) to deposit epitaxial layers of BFO\(_3\), LSMO, and Fe\(_3\)O\(_4\) onto STO, LAO, and MgO substrates. We are in the process of making bilayers of these materials and examining the quality and influence of the oxide interface on the development and control of the exchange bias.

9:36AM V30.00007 Growth and characterization of multiferroic BiMnO$_3$ thin films$^1$, AMLAN BISWAS, G. SINGH-BHALLA, CHELSEY MORIEN, HYOUNG JEEN JEEN, PATRICK MICKEL, SEFAATIN TONGAY, JULIA NEFF, A. F. HEBARD, Department of Physics, University of Florida, Gainesville, FL 32611 — BiMnO$_3$ is a rare single phase, multiferroic compound which displays both ferromagnetic and ferroelectric properties. However, it is complicated to grow thin films of BiMnO$_3$ due to the volatility of bismuth and substrate induced strain. We have grown thin films of BiMnO$_3$ on SrTiO$_3$ (100) substrates using pulsed laser deposition. These films have a ferromagnetic $T_C$ of about 95 K and electric polarization vs. electric field curves have confirmed their ferroelectric properties. The structure and chemical composition of these thin films have been characterized using x-ray diffraction, atomic force microscopy, scanning electron microscopy, and Auger electron spectroscopy. We will present evidence of the sensitivity of the multiferroic properties of BiMnO$_3$ thin films to the growth conditions and substrate induced strain.

9:48AM V30.00008 Multiferroicity in half-doped manganites, SANJEEV KUMAR, Leiden University, GIANLUCA GIOVANNETTI, JEROEN VAN DEN BRINK, SILVIA PICOZZI — Using a joint approach of density functional theory and model calculations, we focus on unconventional physical mechanisms leading to multiferroicity in a prototypical half-doped manganite, La$_{0.5}$Ca$_{0.5}$MnO$_3$. We focus on the strong competition between two exotic charge/orbital-ordered spin ordered states. These are, (1) the charge and orbital ordered zig-zag spin state, also known as the CE-state, and (2) a spin-dimer Zener-polaron state. Both these states respect the inversion symmetry of the lattice and hence can not be ferroelectric. We identify a single variational parameter in terms of the coherent rotation of spin-dimers which interpolates between these two ordered states. It is shown that the true groundstate could be intermediate between these two and can break the inversion symmetry of the lattice. Using DFT calculations we show that the groundstate is indeed ferroelectric with a polarization up to few $\mu C/cm^2$.

10:00AM V30.00009 Element specific magnetic moments of Ni and Mn in multiferroic Bi$_2$NiMnO$_6$ film grown on SrTiO$_3$ substrate , VEMURU KRISHNAMURTHY, Chemical Sciences Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, DAVE KEAVNEY, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, DAVID SINGH, Materials Science and Tech. Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee, 37831, USA, A. VENIMADHAV, Department of Cryogenic Engineering, Indian Institute of Technology, Kharagpur 721302, India, Q. LI, Department of Physics, Penn State University, University Park, Pennsylvania 16802, USA — X-ray magnetic circular dichroism (XMCD) and x-ray absorption spectroscopy (XAS) at Ni L$_2$ of Cryogenic Engineering, Indian Institute of Technology, Kharagpur 721302, India, Q. LI, Department of Physics, Penn State University, University Park, Pennsylvania 16802, USA — X-ray magnetic circular dichroism (XMCD) and x-ray absorption spectroscopy (XAS) at Ni L$_2$ and Mn K$_2$ edges have been performed at 4.5 K and higher temperatures in a multiferroic thin film grown on SrTiO$_3$(001) substrate. These spectra show that Ni is in a disordered state and Mn is in a tetrahedral state. The total magnetic moment of Mn is found to be about 2.8 $\mu_B$ at 0.2 K. The total magnetic moment at the Ni site is strongly reduced from the 2.0 $\mu_B$ expected for divalent Ni. We have also detected a small orbital magnetic moment at both Mn and Ni sites. We suggest that the weaker crystal fields at the Ni and Mn sites in the thin film give rise to an orbital moment. These results will be compared with the predictions of local spin density calculations. Supported by US Dept. of Energy.

10:12AM V30.00010 Field Modulated Intrinsic Positive Exchange Bias in Novel Ferrite Ru$_{25}$Cr$_{75}$O$_{77}$ near the Compensation Point , KEVIN G. WEST, NAM DAO, University of Virginia, JIWEI LU, STUART A. WOLF — In some ferrimagnetic materials systems a compensation point is observed where the opposing sublattice magnetizations are equal and opposite resulting in a zero net magnetization. The resulting magnetization decreases below zero at temperatures below $T_C$ and then increase to zero at $T_C$. We observe this type of unusual ferrimagnetic behavior in the Ru$_{25}$Cr$_{75}$O$_{77}$ system. In addition, near the compensation point we observe positive exchange bias that can be modulated using an external applied magnetic field. Possible mechanisms will be discussed.

10:24AM V30.00011 Polarization Coupling in Ferroelectric Multilayers as a Function of Interface Charge Concentration , MAHMUT OKATAN, Institute of Materials Science, University of Connecticut, CT, 06269, JOSEPH MANTESSE, United Technologies Research Center, East Hartford, CT, 06108, PAMIR ALPAY, Institute of Materials Science, University of Connecticut, Connecticut, CT, 06269 — Intriguing properties of multilayered and graded ferroelectrics follow from the electrostatic and electromechanical interactions. The strength of the interlayer coupling depends on the concentration of interfacial defects with short-range local electrostatic fields. Defects may locally relax polarization differences and thus reduce the commensurate bound charge concentration at the interlayer interfaces. In this talk, we develop a theoretical analysis based on non-linear thermodynamics coupled with basic electrostatic relations to understand the role of charge compensation at the interlayer interfaces. The results show multilayered ferroelectrics with systematic variations in the composition may display a colossal dielectric response depending upon the interlayer electrostatic interactions. It is expected that other properties such as the pyroelectric and piezoelectric response will yield concomitant increases through the dielectric permitivity.

The work at UConn was supported by the U.S. Army Research Office through Grant Nos. W911NF-05-1-0528 and W911NF-08-C-0124.

10:36AM V30.00012 Magnetolectric effects in SrRuO$_3$/BaTiO$_3$ heterostructures: A First Principles Study , M.K. NIRANJAN, J.D. BURTON, S.S. JASWAL, E.Y. TSYMBAL, University of Nebraska, Lincoln, USA, J.P. VELEV, University of Puerto Rico, San Juan, USA — Ferroelectric materials in combination with ferromagnets have emerged as structures in which strong magnetoelastic coupling may exist originating from unconventional physical mechanisms. The use of oxides such as SrRuO$_3$ as a metal electrode has been found to be of fundamental importance for the realization of ferroelectric films with critical thicknesses down to three unit cells. Here we present a study of SrRuO$_3$/BaTiO$_3$ heterostructures within the framework of density functional theory. This heterostructure is interesting since SrRuO$_3$ is a weak ferromagnetic oxide metal and hence, when used as an electrode on BaTiO$_3$, presents the possibility of coupling between electric and magnetic order parameters. In particular we study the magnetoelastic (ME) effect at the interface of SrRuO$_3$/BaTiO$_3$ by treating SrRuO$_3$ as spin polarized metal. We find that magnetic properties at the interface are affected as the ferroelectric polarization in the BaTiO$_3$ is reversed. We discuss the origins of ME effect and compare them with previously proposed ME coupling mechanisms in Fe/BaTiO$_3$, Fe$_2$O$_3$/BaTiO$_3$, and SrRuO$_3$/SrTiO$_3$ heterostructures$^{1,2}$. $^1$Niranjjan et al., Phys. Rev. B, 78, 140405 (2008); $^2$Rondinelli et al., Nat. Nanotechnology, 3, 46 (2008).

10:48AM V30.00013 Surface Magnetoelectric Effects from First Principles , CHUN-GANG DUAN, Key Laboratory of Polarized Materials and Devices, East China Normal University, Shanghai, China, CE-WEN NAN, Department of Materials Science and Engineering, Tsinghua University, Beijing, China, SITARAM S. JASWAL, EVGENY Y. TSYMBAL, Department of Physics and Astronomy, University of Nebraska, Lincoln, Nebraska, USA — A magnetoelastic effect allows magnetic properties of materials by applying electric fields which may be interesting for potential technological applications such as electrically controlled magnetic data storage. We use density functional calculations to reveal and elucidate magnetoelastic effects due to an electric field applied to ferromagnetic metal surfaces. $^1$We find that the surface magnetoelastic effect originates from spin-dependent screening of the electric field and leads to notable changes in the surface magnetization and the surface magnetocrystalline anisotropy. If the ferromagnet is a half-metal the screening charge is formed entirely by a single conducting spin channel which leads to the surface magnetoelastic coefficient being the universal constant $\mu_B/2e^2 \approx 6.44 \times 10^{-14}$ Gcm$^2$/V. This is in an excellent agreement with our first-principles calculation result for the half-metal CrO$_2$. These results are of considerable interest in the area of electrically-controlled magnetism and magnetoelectric phenomena. 1. C.-G. Duan et al., Phys. Rev. Lett. 101, 137201 (2008).
estimate the order parameter to be $M^2$ for a square lattice with an error comparable to quantum Monte Carlo. For the triangular lattice, we verify the existence of three-sublattice magnetic order, and

1 diagram of the frustrated ferromagnetic couplings,

1 Jonas Gustafsson, Goldman Sachs, Daoxin Yao, Erica Carlson, Purdue University, Anders Sandvik, Boston University — We study the system on clusters with a cylindrical geometry to test for the presence of the order.

3 Queensland, Dept of Physics — We show that dimer coverings on the star lattice (aka the 3-12, Fisher, expanded kagome or triangle-honeycomb lattice) have

L $\sim$ Combining the improved DMRG accuracy with the use of non-traditional clusters for rapidly converging finite-size scaling, we study the ordering in the square-

1 aspect ratio depends on the boundary conditions, with a simple and convenient choice being precisely the geometry optimal for the DMRG method. Combining the improved DMRG accuracy with the use of non-traditional clusters for rapidly converging finite-size scaling, we study the ordering in the square-

1 aspect ratio ($l_x/l_y$ close to 2), in agreement with the effective $\sigma$-model. We determine the thermodynamic limit of $M$ for the square lattice with an error comparable to quantum Monte Carlo. For the triangular lattice, we verify the existence of three-sublattice magnetic order, and estimate the order parameter to be $M = 0.205(15)$.

1 Supported by the DOE (DE-FG02-04ER46174, S.C.) and NSF (DMR-0605444, S.W.)

8:24AM V31.00003 Classical and quantum dimers on the star lattice

1 John Fjaerestad, University of Queensland, Dept of Physics — We show that dimer coverings on the star lattice (aka the 3-12, Fisher, expanded kagome or triangle-honeycomb lattice) have $Z_2$ arrow and pseudo-spin representations analogous to those for the kagome lattice, and use these to construct an exactly solvable quantum dimer model (QDM) with a Rokhsar-Kivelson (RK) ground state. This QDM, first discussed by Moessner and Sondhi from a different point of view, is the star-lattice analogue of a kagome-lattice QDM analyzed by Misguich et al. We discuss various properties of the classical equal-weight dimer model on the star lattice, most of which are related to those of the RK state. Using both the arrow representation and the fermionic path integral formulation of the Pfaffian method, we calculate the number of dimer coverings, dimer occupation probabilities, and dimer, vison, and monomer correlation functions. The results show unusual features similar to those of dimers on the kagome lattice. We also discuss some generalizations to general Fisher lattices and their “reduced” lattices (the kagome, squagome, and triangular-kagome lattice being examples of the latter). Ref.: J. O. Fjaerestad, arXiv:0811.3789

1 Research supported by the Australian Research Council

8:36AM V31.00004 Spatially anisotropic Heisenberg kagome antiferromagnet

, Oleg Starykh, University of Utah — We study the quasi-one-dimensional limit of the spin-1/2 quantum Heisenberg antiferromagnet on the kagome lattice. The lattice is divided into antiferromagnetic spin-chains (exchange $J$) that are weakly coupled via intermediate “dangling” spins (exchange $J'$. Using one-dimensional bosonization, renormalization group methods, and current algebra techniques the ground state is determined in the limit $J' \ll J$. We find that the dangling spins and chain spins form a spiral with $O(1)$ and $O(J'/J)$ static moments, respectively, atop of which the chain spins exhibit a smaller $O((J'/J)^2)$ antiferromagnetically ordered component along the axis perpendicular to the spiral plane. We describe similarities and differences of our findings with other recent studies, based on semi-classical and large-N approaches. Critical comparison of quasi-one-dimensional kagome antiferromagnet with other quasi-one-dimensional models will be presented as well.

9:12AM V31.00005 Ordered States on the Kagome Antiferromagnetic Heisenberg Model

, Simeng Yan, Steven White, University of California, Irvine — We numerically study the spin 1/2 Kagome antiferromagnetic Heisenberg Model with DMRG techniques. Recently, Singh and Huse proposed a dimerized ground state with a 36 site unit cell. To test this proposal, we have simulated the system on clusters which favor this order. If the order was not found, this would disprove the proposal. However, the results do show the proposed order. The strength of the dimerization on the pinwheels is surprisingly strong, with $<S \cdot S>$ taking values of -0.71 on the strong bonds and -0.11 on the weak. We also have studied the system on clusters with a cylindrical geometry to test for the presence of the order.

9:24AM V31.00006 Universality Classes of Dimerized Bond-Disordered Quantum Spin Models

, Jonas Gustafsson, Goldman Sachs, Daoxin Yao, Erica Carlson, Purdue University, Anders Sandvik, Boston University — We study the dimerized bond disordered $S=1/2$ Heisenberg models on the square lattice. Each spin belongs to one strong bond (a dimer) by introducing strong and weak couplings, $J_x, J_y$. By means of quantum Monte Carlo simulations, we find two different universality classes for the random dimer model and the random plaquette model. The change of universality class may be associated with the cancellation of Berry phase. Furthermore, we study the dilution effect by setting some strong bonds to 0.

9:36AM V31.00007 Emergent multipolar spin correlations in a fluctuating spiral - The frustrated ferromagnetic $S=1/2$ Heisenberg chain in a magnetic field

, Andreas Lauchli, Max Planck Institute for Physics of Complex Systems, Dresden, Germany, Julien Sudan, Andreas Luscher, IRMA - EPF Lausanne, Switzerland — We present the phase diagram of the frustrated ferromagnetic $S=1/2$ Heisenberg $J_x,J_y$ chain in a magnetic field, obtained by large scale exact diagonalizations and density matrix renormalization group simulations. A vector chirally ordered state, metamagnetic behavior and a sequence of spin-multipolar Luttinger liquid phases up to hexadecapolar kind are found. We provide numerical evidence for a novel locking mechanism, which can drive spiral states towards spin-multipolar phases, such as quadrupolar or octupolar phases. Our results also shed new light on previously discovered spin-multipolar phases in two-dimensional $S=1/2$ quantum magnets in a magnetic field. We conclude by presenting numerical results on the dynamical spin structure factor in the various phases which are valuable in identifying multipolar phases in experiments.
Dynamically dominant excitations of string solutions in the antiferromagnetic Heisenberg chain in magnetic fields. MASANORI KOHNO, International Center for Materials Nanoarchitectonics, NIMS — We investigate behaviors of dynamical structure factors in the spin-1/2 antiferromagnetic Heisenberg chain in magnetic fields, using Bethe-ansatz solutions. We uncover a well-defined continuum in $S^{z}(k,\omega)$, which comes from 2-string solutions in the Bethe ansatz. It continuously connects the des Cloizeaux-Pearson mode in the zero-field limit and the bound state of overturned spins from the ferromagnetic state near the saturation field. Also, we give a natural interpretation to particles in magnetic fields, psion and antipsion, as those carrying fractional quantum numbers $S^{z}=+1/2$ and $-1/2$, respectively. We argue that not only psions and antipsions but also particles representing strings play important roles for dynamical properties of the antiferromagnetic Heisenberg chain in magnetic fields. We confirm the relevance of the present results to real materials through comparisons with experimental results.

10:00AM V31.00009 Interplay between interaction and (un)correlated disorder in Heisenberg spin-1/2 chains. FRIEDA DUKESZ, MARINA ZILBERGERTS, LEA SANTOS, Yeshiva University — We consider a Heisenberg spin-1/2 chain and study the interplay between the Ising interaction and on-site disorder, while keeping the hopping amplitude constant. Disorder is characterized by both: uncorrelated and long-range correlated random on-site energies. The level of delocalization, quantified by the number of principal components, is largest in clean systems with non-interacting particles. However, in the presence of uncorrelated disorder, delocalization becomes maximum for a non-zero value of the interaction amplitude. The inclusion of long-range correlated disorder may further extend two-particle states, but the effect decreases with the number of excitations and the strength of the interaction, and may even be reversed, as shown for half-filled chains. Quantum correlations, determined by a global entanglement measure, present similar behavior, but the largest value appears for clean systems with interacting particles.

10:12AM V31.00010 Algebraic spin liquid in an exactly solvable spin model. HONG YAO, SHOU-CHENG ZHANG, STEVEN KIVELSON, Stanford University — We have introduced an exactly solvable quantum spin-3/2 model on the square lattice. Its ground state is a spin liquid with half integer spin per unit cell. The fermionic excitations are gapless with a linear dispersion, while the topological “vison” excitations are gapped. Moreover, the massless Dirac fermions are stable against any small perturbations with time-reversal symmetry. Thus, this model is, to the best of our knowledge, the first exactly solvable model whose ground state is an “algebraic spin liquid” with half integer spin per unit cell.

10:24AM V31.00011 Extended supersolid phase of frustrated hard-core bosons on a triangular lattice. FA WANG, FRANK POLLMANN, ASHVIN VISHWANATH, UC Berkeley — We study a model of hard-core bosons with frustrated nearest-neighbor hopping (t) and repulsion (V) on the triangular lattice. We argue for a supersolid ground state in the large repulsion limit (V >> |t|) limit where a dimer representation appears. By constructing a unitary mapping to the well understood unfrustrated hopping case, this generalized ‘Marshall sign rule’ allows us to establish the precise nature of the supersolid order by utilizing a recently proposed dimer variational wavefunction, whose correlations can be efficiently calculated using the Grassmann approach. By continuity, a supersolid is predicted over the wide parameter range, V -2|t| > 0. This also establishes a simple phase diagram for the triangular lattice spin 1/2 XXZ antiferromagnet.

10:36AM V31.00012 A Γ-matrix generalization of the Kitaev model. HSING-HSUAN HUNG, CONGJUN WU, DANIEL AROVAS, University of California, San Diego — We extend the Kitaev model defined for the Pauli-matrices to the Clifford algebra Γ-matrices by taking the 4x4 representation as an example. In a 2D decorated square lattice, the ground state spontaneously breaks time-reversal symmetry and exhibits a topological phase transition. The topologically non-trivial phase carries gapless chiral edge modes along the sample boundary. In the 3D diamond lattice, the ground states exhibit gapless 3D Dirac cone-like excitations and gapped topological insulating states. The generalizations to even higher rank Γ-matrices are also discussed.

10:48AM V31.00013 Dzyaloshinskii-Moriya interactions in valence bond systems II. MAYRA TOVAR, KUMAR RAMAN, KIRILL SHTENGEL, UC Riverside — We investigate the effect of Dzyaloshinskii-Moriya interactions on the low temperature magnetic susceptibility for a system whose low energy physics is dominated by short-range valence bonds (singlets). Our general perturbative approach is applied to specific models expected to be in this class, including the Shastry-Sutherland model of the spin-dimer compound SrCu$_2$(BO$_3$)$_2$ and the antiferromagnetic Heisenberg model of the recently discovered $S = 1/2$ kagome compound ZnCu$_3$(OH)$_6$Cl$_2$. The central result is that a short-ranged valence bond phase, when perturbed with Dzyaloshinskii-Moriya interactions, will remain time-reversal symmetric in the absence of a magnetic field but the susceptibility will be nonzero in the zero temperature limit. Applied to ZnCu$_3$(OH)$_6$Cl$_2$, this model provides an avenue for reconciling experimental results, such as the lack of magnetic order and lack of any sign of a spin gap, with known theoretical facts about the kagome Heisenberg antiferromagnet.

— NSF DMR-0749295

Thursday, March 19, 2009 8:00AM - 10:24AM — Session V32 GMAG DMP FIAP: Focus Session: Vortex and Domain Wall Dynamics 336

8:00AM V32.00001 Dynamics of Exchange-Biased Magnetic Vortices. T. Y. CHEN, M. K. CHAN, P. A. CROWELL, University of Minnesota — We have studied magnetization dynamics in micron-sized circular disks composed of ferromagnetic (FM)-antiferromagnetic (AFM) bilayers. The patterned samples of FeMn/NiFe are field-cooled (FC) or zero-field cooled (ZFC) from above the blocking temperature to room temperature. Time-resolved Kerr microscopy measurements show that the vortex gyrotropic mode fluctuates in frequency as the vortex core is displaced by a static in-plane magnetic field. The average gyrotropic frequency and the magnitude of its fluctuations, which are due to pinning of the vortex core, are larger than in single layer films. The enhancement of the gyrotropic frequency is largest in the ZFC samples, in which the effective field due to exchange coupling is expected to enhance pinning of the vortex core at the center of the disk. We find, however, that micromagnetic simulations incorporating uniform or vortex-like exchange-bias fields do not explain our results quantitatively. We interpret this discrepancy as a consequence of randomly oriented AFM domains, which are comparable in size to the vortex core. This work was supported by NSF and the Univ. of Minnesota Graduate School.

8:12AM V32.00002 Ferromagnetic resonance force spectroscopy of a magnetic vortex. G. DE LOUBIES, J. O. KLEIN, N. SPEC, CEA Saclay, A. RIEGLER, F. LOCHNER, G. SCHMIDT, L.W. MOLENKAMP, Universität Würzburg, H. HURDEQUINT, LPS, Orsay, F. BOUST, ONERA, N. VUKADINOVIC, Dassault Aviation, A.N. SLAVIN, Oakland University — Due to its nanometer size (of the order the exchange length), probing the high frequency dynamics of a magnetic vortex core is an experimental challenge. Precessional dynamics of the magnetization of individual nano-disks of NiMnSb perpendicularly magnetized is measured in a wide range of bias magnetic fields using a magnetic resonance force microscope (MRFM). A full dynamic phase diagram, demonstrating excitation of a Kittel-type dipolar mode in the saturated disks and the gyrotropic mode of vortex core rotation in the vortex-state unsaturated disks, is established. Switching of the vortex core polarity in a negative (anti-parallel to core) bias magnetic field is registered dynamically. Analytic theory and micromagnetic simulations provide a quantitative description of the experimental results.
8:24AM V32.00003 Spin motive electric field driven by magnetic vortex motion. JUN-ICHIRO OHE, Tohoku University, STEWART E. BARNES, University of Miami, SADAMICHI MAEKAWA, Tohoku University — The current-induced magnetization dynamics realized in spintronics devices involve both of charge and spin degrees of freedom. Recently, it has been pointed out that the magnetization dynamics induces an effective electric field acting on the conduction electrons through the spin Berry phase. The effective electric field, or a “spin motive electric field,” was investigated for a simple one-dimensional domain wall. It is difficult to estimate analytically this effective electric field in actual systems, because the magnetization dynamics obeys the non-linear Landau-Lifshitz equation. In this report, we describe numerical studies of the spin motive electric field induced by the dynamics of a vortex core. The vortex structure can be realized in a Permalloy disc. It is known that the magnetic vortex core shows a resonant motion when the oscillating magnetic field is applied. The direction of the core is switched rapidly by applying a pulsed such magnetic field. During the core motion, we obtain an electric field near the core. The direction of the electric field is perpendicular to the direction of the core motion. We also obtain the electric field driven by spin waves which are excited by the core switching. We propose an experimental setup for measuring the electric field. The calculated voltage is large enough to measure. We show that the voltage induced by core switching is quite large.

8:36AM V32.00004 Thickness and field dependence of the driven dynamic mode-splitting of magnetic vortices1, KRISTEN BUCHANAN, Colorado State University — We have explored the effects of increased driving field amplitude on the dynamics of magnetic vortices using a microwave reflection technique and found that the vortex translational eigenmode profile first takes on a distorted shape and then splits into two well-defined peaks as the field is increased [1]. Here we examine the thickness and field dependence of this mode-splitting phenomenon via measurements of lithographically patterned micron-sized Permalloy ellipses with thicknesses of 20, 40, and 60 nm. The experimental results will be compared to numerical calculations that incorporate a critical velocity parameter and provide new insight into the origin of the observed vortex dynamic mode splitting. Acknowledgments: Thank you to Marcos Grimsditch, Frank Fradin, Sam Bader, and Val Novosad for stimulating discussions. [1] Buchanan et al. PRL 99,267201 (2007).

9:00AM V32.00006 High frequency spin dynamics in soft magnetic dots in biased vortex state: precise probing and nature of the eigenmodes1, FARKHAD ALIEV, JUAN FRANCISCO SIERRA, AHMAD AWAD, Universidad Autonoma de Madrid, GLEB KAKAZEI, Universidade do Porto, DONG-SOO HAN, Seoul National University, SANG-KOONG KIM, HONGKI MIN, TOHOKU UNIVERSITY, KRISTEN BUCHANAN, Colorado State University — We have explored the effects of increased driving field amplitude on the dynamics of magnetic vortices using a microwave reflection technique and found that the vortex translational eigenmode profile first takes on a distorted shape and then splits into two well-defined peaks as the field is increased [1]. Here we examine the thickness and field dependence of this mode-splitting phenomenon via measurements of lithographically patterned micron-sized Permalloy ellipses with thicknesses of 20, 40, and 60 nm. The experimental results will be compared to numerical calculations that incorporate a critical velocity parameter and provide new insight into the origin of the observed vortex dynamic mode splitting. 9:12AM V32.00007 Spin-Torque Ferromagnetic Resonance Spectroscopy of Permalloy Nanowires, CARL BOONE, JORDAN KATINE, JEFF CHILDRESS, JIAN ZHU, XIAO CHENG, ILYA KRIVOROTOV, KRIVOROTOV GROUP COLLABORATION, HITACHI GLOBAL STORAGE COLLABORATION — We develop a technique for studies of spectral properties of spin waves excited by spin transfer torque in metallic ferromagnetic nanowires, and apply this technique to measure frequencies and damping constants of several low-energy quantized spin wave modes in permalloy nanowires of rectangular cross section. Our measurements demonstrate that the spin wave spectrum of nanowires as narrow as 100 nm is well described by an analytic theory of dipole-exchange spin waves in thin ferromagnetic strips. Geometric quantization of the spin wave spectrum in nanowires significantly reduces the phase space for magnon-magnon scattering leading to opening and closing of discrete scattering channels as a function of magnetic field. These scattering channels manifest themselves as peaks in plots of spin wave damping versus magnetic field. In particular, we observe damping enhancement of the lowest energy spin wave mode at the values of magnetic field corresponding to three-magnon confluence processes in which two lowest energy magnons merge into a single higher-energy mode magnon.

9:24AM V32.00008 Effects of disorder and temperature on vortex domain wall dynamics1, HONGKI MIN, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD 20899-6202, MICHAEL DONAHUE, Mathematical and Computational Sciences Division, National Institute of Standards and Technology, Gaithersburg, MD 20899-8910, MARK STILES, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Gaithersburg, MD 20899-6202 — Domain wall motion, whether driven by applied magnetic fields or electrical current, can be strongly affected by sample irregularities. Using micromagnetic simulations and a collective coordinate approach, we study the dynamics of domain wall motion driven by a spin-polarized current or an external magnetic field in the presence of extrinsic random potential at finite temperatures. We compare these calculations and discuss the region of validity of the approximations in the simple model. Information about the strength of the random potential is taken from recent magnetic resonance experiments.

on a DW in terms of an electron drift speed \( u = -\frac{P*J}{\mu_B} \) where \( \mu_B \) is the Bohr magneton and \( M \) the saturation magnetization. While appropriate for adiabatic torques, this quantity \( u \) is misleading and not the best choice in the case of non-adiabatic torques. For example, it leads to beta not equal to alpha, where beta represents the intensity of the non-adiabatic torque, and alpha is the damping parameter. By writing equations of motion for conduction- electron spins in a moving frame where the electron gas is at rest, we find a direct relation between damping and non-adiabatic torques. The correct electron drift speed turns out to be the speed of the frame, and is \( v = \frac{P*J}{(n*q)} \) where \( n \) and \( q \) are the carrier density and charge. It is related to the ordinary Hall constant \( R_h \) by \( v = \frac{P*R_h}{J} \). After substituting \( v \) for \( u \) in the expression of the non-adiabatic torque, we find that beta = alpha holds now. Because \( v \) is larger than \( u \) in Permalloy, it can explain better the large current-induced DW speeds found \(^4\) experimentally. In materials where \( R_h > 0 \) and the carriers are dominantly hole-like, \( v \) and \( u \) have opposite signs, leading to different predictions for the sense of DW motion. We discuss examples of such materials. \(^1\) G. Tataru and H. Kohno, Phys. Rev. Lett. 92, 086601 (2004). \(^2\) H. Kohno et al., J. Phys. Soc. Japan, 75, 113706 (2006). \(^3\) L. Berger, Phys. Rev. B 75, 174401 (2007).

8:24AM V33.00003 Frequency dependence of the intrinsic Hall conductivity in a chiral $p + ip$ superconductor with impurities$^1$. PAVEL NAGORNYKH, ROMAN LUTCHYN, VICTOR YAKOYENKO, University of Maryland — We calculate frequency dependence of the intrinsic Hall conductivity induced by impurity scattering in a chiral $p_x + ip_y$ superconductor. We find that, at large frequencies compared to the superconducting gap ($\Omega \gg \Delta$), the real part of the intrinsic Hall conductivity at zero temperature is proportional to $\Delta/\Omega^3 \log(\Omega/2\Delta)$. Using our results for the Hall conductivity, we estimate the Kerr angle and compare it with the experimental data on Sr$_2$RuO$_4$ by Xia et al., Phys. Rev. Lett. 97, 167002 (2006).

8:36AM V33.00004 Electromagnetic response of time reversal invariant triplet superconductors . RAHUL ROY, CATHERINE KALLIN, JOHN BERLINSKY, McMaster University — We study the effective action of time reversal invariant triplet superconductors in two and three dimensions and obtain the electromagnetic response. The B-phase of Helium 3 and its two dimensional analog are topologically non-trivial phases. The two dimensional triplet superconductor may be regarded as two copies of a chiral $p_x + ip_y$ superconductor. We discuss signatures of the non-trivial topology in the effective action and in the electromagnetic response.

8:48AM V33.00005 Microscopic analysis of the stability of half-quantum vortices in $p_x + ip_y$ superfluids in an annular geometry.$^1$. VICTOR VAKARYUK, University of Illinois at Urbana-Champaign — We present a microscopic analysis of the thermodynamic stability of a half-quantum vortex (HQV) in $p_x + ip_y$ variant of equal-spin-pairing state which, under suitable conditions, is believed to be realized in Sr$_2$RuO$_4$ and $^3$He-A. Our approach is based on a description of the HQV in terms of a BCS-like wave function with a spin-dependent boost. Stability criteria are found by comparing energies of half- and full-quantum vortices with appropriate account taken of Fermi liquid corrections. While we confirm earlier phenomenological findings by Suk Bum Chung et al. (2007) for the stability of the HQV in the annular geometry, we also predict a novel feature that the HQV, if exists, should be accompanied by a non-zero spin polarization of the system.

9:00AM V33.00006 Josephson tunneling studies of odd-parity superconductivity in Sr$_2$RuO$_4$ , RONALD MYERS, YING LIU, Pennsylvania State University, D. FOBES, Z. MAO, Tulane University, H. YAGUCHI, Y. MAENO, Kyoto University — In the recent phase-sensitive work that provided the most unambiguous evidence for odd-parity superconductivity in Sr$_2$, RONALD MYERS, YING LIU, Pennsylvania State University, D. FOBES, Z. MAO, Tulane University, H. YAGUCHI, Y. MAENO, Kyoto University — In the recent phase-sensitive work that provided the most unambiguous evidence for odd-parity superconductivity in Sr$_2$RuO$_4$, we used Au$_{3,5}$In$_{0,5}$ as the s-wave superconducting counter electrode in the SQUID structure. However, Au$_{3,5}$In$_{0,5}$ has a $T_c$ less than that of Sr$_2$RuO$_4$, making detection of the pairing symmetry near the $T_c$ of Sr$_2$RuO$_4$ inaccessible to the phase sensitive measurements. To go beyond this limit and open up possibilities of several other experiments involving Josephson tunneling into Sr$_2$RuO$_4$, we seek an alternative material system with an s-wave superconductor of $T_c > 1.5K$ that would exhibit Josephson coupling with Sr$_2$RuO$_4$. An Ag/Pb/Pb trilayer has been chosen for this purpose. Ag/Pb/Sr$_2$RuO$_4$ tunneling devices were prepared that showed a suppressed superconducting gap feature of Sr$_2$RuO$_4$, suggesting the presence of superconductivity at the polished ac face of a Sr$_2$RuO$_4$ crystal. However, no Josephson coupling between Ag/Pb and Sr$_2$RuO$_4$ was detected. More experiments are currently underway, and new results will be presented.

9:12AM V33.00007 Measurements of superconducting energy gap in individual Ru islands embedded in Sr$_2$RuO$_4$ , YIQUN YING, B. CLOUSER, R. MYERS, N. STALEY, YING LIU, Pennsylvania State University, D. FOBES, Z. MAO, Tulane University, Y. XIN, Florida State University, J. ALLARD, Oak Ridge National Laboratory — We report our tunneling measurements on individual single-crystalline Ru islands embedded in a bulk Sr$_2$RuO$_4$ single crystal. Tunneling junctions were prepared on large (micron size) and small (submicron size) Ru islands by fabricating tunneling windows using quartz filaments as shadow masks. Our measurements revealed the presence of an energy gap below a temperature close to the $T_c$ of bulk Ru. In the zero temperature limit, the gap was found to be 0.07 meV for large Ru islands, consistent with our measurements on bulk polycrystalline Ru. However, in small Ru islands a gap of 0.1 meV, clearly larger than that seen in large Ru islands, was observed. The difference in energy gap may reflect difference in pairing state in Ru islands of different sizes. Above the $T_c$ of Ru but below the $T_c$ of Sr$_2$RuO$_4$, we detected no proximity induced energy gap. This observation is unexpected as our $^3$He-contrasted transmission electron microscope study showed that the interface between a Ru island and Sr$_2$RuO$_4$ is atomically sharp, which appears to rule out the suppression of the proximity effect by disorder. We argue that these observations are associated with chiral p-wave superconductivity in Sr$_2$RuO$_4$.

9:24AM V33.00008 Magnetic response of Sr$_2$RuO$_4$ nanocrystals: search for chiral currents and fractional vortices$^1$. D. J. BAHR, M. J. A. STOUTIMORE, R. BUDAKIAN, D. J. VAN HARLINGEN, University of Illinois at Urbana-Champaign, Urbana IL, Y. MAENO, Kyoto University, Kyoto, Japan — The ruthenate superconductor Sr$_2$RuO$_4$ may have a chiral order parameter of the form $p_x \pm ip_y$, making it a candidate for nucleation of excitations with non-Abelian statistics that could enable topologically protected quantum computing. To test this scenario, we have measured the magnetic response of Sr$_2$RuO$_4$ nanocrystals to search for spontaneous chiral currents and half-integer vortices. Each nanocrystal ($1 \mu m \times 1.5 \mu m \times 0.5 \mu m$) was extracted from a large single crystal with bulk transition temperature in the range 1.2K-1.4K. We then glued it into the pickup loop of a flux transformer or a gradiometer that is inductively coupled to a dc-SQUID magnetometer. We have observed the diamagnetic screening of the crystal and the entry of discrete vortices in an applied magnetic field. We report on our search for spontaneously generated currents, chiral domain dynamics and the nucleation of half-integer vortices, which we should be sensitive to due to the small size of the crystal.

9:36AM V33.00009 Investigating magnetic order in Sr$_2$RuO$_4$ using cantilever torque magnetometry$^1$. RAFFI BUDAKIAN, JOONHO JANG, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign, YOSHI MAENO, Kyoto University — Following the initial $^3$He and NMR studies suggesting that Sr$_2$RuO$_4$ is a spin-triplet superconductor, there has been a great deal of interest to understand the nature of the order parameter. Although Sr$_2$RuO$_4$ is similar in structure to the layered high-Tc cuprate superconductors, it is thought to possess chiral $p_x \pm ip_y$ pairing symmetry. The complex order parameter can give rise to a rich variety of new correlated states, such as domains having orbital order that possess a net magnetic moment and half-integer vortices with zero-energy modes. We have applied ultrasensitive cantilever torque magnetometry to measure the magnetic moment, susceptibility, and vortex entry into micron-size Sr$_2$RuO$_4$ in search of magnetic moments generated by chiral edge currents and fractional vortices. This talk will present recent data in this effort.

9:48AM V33.00010 Orbital magnetic moment in the chiral p-wave superconductor Sr2RuO4. 
JAMES ANNETT, University of Bristol, KAROL WYSÓKINSKI, M. Curie Skłodowska University, BALÁZS GYORFFY, University of Bristol — The existence and magnitude of a bulk orbital angular momentum of the condensate chiral a phase in superfluid helium-3 is a longstanding matter of controversy. The analogous problem in a chiral p-wave superconducting material is the existence of a finite orbital magnetic moment in the bulk. In Sr2RuO4 the existence of such an orbital moment is strongly suggested by experimental evidence for spontaneously time reversal symmetry breaking (TRS) in the superconducting state, but the theories disagree on the exact magnitude of this moment. We show that a non-zero orbital magnetization density arises naturally in a realistic band model for Sr2RuO4, and its temperature dependence is qualitatively similar to those of the muSr and Kerr effect experimental results. The simplest model which leads to the orbital moment requires at minimum two degenerate atomic orbitals per Ru, which correspond to the Ru d xz and d yz states. This is in contrast to the theories of orbital angular momentum in the isotropic superfluid 3-He, or models of orbital moment in Sr2RuO4 which assume only a single band at the Fermi level. The implications of this surprising result are explored.

10:00AM V33.00011 Absence of superconductivity in the half-filled anisotropic triangular lattice Hubbard model. 
HONGTAO LI, University of Arizona, R.T. CLAY, Mississippi State University, S. MAZUMDAR, University of Arizona — The superconducting κ-(BEDT-TTF)2X salts, with one hole per molecular site and strong dimerization are widely thought to have an effective 1/2-filled band. The presence of antiferromagnetism (AFM) near superconductivity (SC) in their pressure-temperature phase diagram has led to the suggestion suggest that the SC can be explained within an anisotropic triangular lattice 1/2-filled band Hubbard Hamiltonian. In this model increasing frustration suppresses the AFM transition, and it has been suggested that d-wave SC appears near the metal/AFM interface. We performed exact diagonalizations on a 16-site periodic anisotropic triangular lattice and determined the full phase diagram. We confirm the Mott metal-insulator transition and AFM, change of the AFM wavevector for large anisotropy, and the presence of a non-magnetic insulating phase. We do not find any hint of long range superconducting correlations. In our results the Hubbard U always suppresses the superconducting pair-pair correlations over their non-interacting value. We conclude that the Hubbard model is too simple to explain the SC in organic charge-transfer solids.

10:12AM V33.00012 Nuclear spin-lattice relaxation rate as a link between antiferromagnetism and superconductivity in organic conductors. 
CLAUDE BOURBONNAIS, Departement de Physique, Universite de Sherbrooke, Sherbrooke, (QC), Canada J1K-2R1, ABDELOUAHAB SEDEKI, Departement de Physique, Universitede Sherbrooke, Sherbrooke, (QC), Canada J1K-2R1 — The interdependence of antiferromagnetism and superconductivity in the Bechgaard salts series of organic conductors is examined in the light of the anomalous temperature dependence of the nuclear spin-lattice relaxation rate. We use the renormalization group approach to the electron gas model to demonstrate that the metallic state anomaly of the nuclear relaxation rate found in the Bechgaard salts and the mechanism of passage from antiferromagnetism to superconductivity can be both described within a unified framework.

1Supported by National Sciences and Engineering Research Council of Canada (NSERC) and Canadian Institute for Advanced Research (CIFAR).

10:24AM V33.00013 New details in the phase diagram of λ-(BETS)2GaCl4 made by advancing the art of RF penetration depth measurements in pulsed fields using a tunnel diode oscillator. 
WILLIAM A. CONIGLIO, LAUREL E. WINTER, KYUIL CHO, BRAUEN E. SMITH, C.C. AGOSTA, Clark University, L.K. MONTGOMERY, Indiana University — We report improvements to the Tunnel Diode Oscillator method of measuring the penetration depth of a superconductor at RF frequencies above 100 MHz. Optimizations to the circuit for high frequency and pulsed fields are briefly discussed as well as a digital demodulation technique for rendering the oscillation frequency with accuracy suitably better than the stability of the oscillator itself. Using a 390 MHz oscillator, we measured the penetration depth of λ-(BETS)2GaCl4 with the magnetic field oriented parallel to the conducting planes of the sample using fields up to 21 T and temperatures from 400 mK to 5.5K. Our new data crunching techniques have allowed us to resolve two phase transitions between the superconducting and normal states as well as a third transition that appears at low temperature as an enhancement to the upper critical field. We explore the properties of the phase diagram in two samples.

1We acknowledge DOE support from DE-FG02-05ER46214.

LAUREL E. WINTER, WILLIAM A. CONIGLIO, KYUIL CHO, BRAUEN E. SMITH, C.C. AGOSTA, Clark University, L.K. MONTGOMERY, Indiana University — The upper critical fields for the highly anisotropic organic superconductor λ-(BETS)2GaCl4 have been studied by measuring the in-plane RF penetration depth with a tunnel diode oscillator technique in pulsed fields. At zero field we found a Tc of 5 K. With the field perpendicular to the conducting layers we extrapolate Hc2,Τ=0 to 2.8 T and with the field parallel Hc2,Τ=0 is 11 T. With the field applied parallel to the conducting layers, for Τ > 0.5Tc the Hc2 follows the superconducting gap function √1 - Tc/Τ, then saturates below 0.5Tc. Below 0.35Tc we see a clear enhancement of 1.5 T in Hc2 and in addition there is a second phase line at a lower field than Hc2. These features are both characteristic of the FFLO state. We will discuss this second phase line in relation to the Pauli Limit as calculated in a similar empirical method and compare our phase diagram to previous results.

1We acknowledge DOE support from DE-FG02-05ER46214.

10:48AM V33.00015 Mesoscopic conductance oscillations in superconducting nanoparticle films. 
AL-AMIN DHIRANI, BRIAN LAM — Recent advances in nanoparticle synthesis yield control over key nanoparticle characteristics such as structure and chemical composition. This in turn enables fabrication of nanostructured materials with novel and controlled properties. We have found that superconducting 100 nm niobium nanoparticles can be sintered to make porous macroscopic films that routinely exhibit conductance oscillations as a function of bias voltage and magnetic field. We speculate the effect is related to electron-hole interference previously observed at interfaces between disordered normal materials and superconductor electrodes. Our results show that the oscillations in the present system are associated with nanoparticle state (superconducting vs. normal) and ubiquitous elastic scattering at length scales dictated by nanoparticle size. Robust observation of this mesoscopic interference phenomenon in a disordered, macroscopic system is remarkable. It is enabled by the present approach’s ability to balance counterrevering considerations: sufficient disorder to induce elastic scattering and restricted averaging to limit dephasing.

Thursday, March 19, 2009 8:00AM - 11:00AM —
Session V34 DCMP: Superconductivity: Spectroscopy 404
8:00AM V34.00001 Comparing the three characteristic electronic excitations in the pseudogap state of underdoped $\text{Bi}_2\text{Sr}_2\text{Ca}_0.8\text{Y}_{0.2}\text{Cu}_2\text{O}_8$ \cite{1}. K. FUJITA, JHINHWAN LEE, C. K. KIM, A. SCHMIDT, Cornell University, H. EISAKI, NI-AIST Tsukuba, S. UCHIDA, University of Tokyo, J. C. DAVIS, Cornell University and Brookhaven National Laboratory — We investigate the quasiparticle interference processes as a function of temperature for heavily underdoped $\text{Bi}_2\text{Sr}_2\text{Ca}_0.8\text{Y}_{0.2}\text{Cu}_2\text{O}_8$ ($T_c$=42K). We demonstrate that three types of electron excitations exist in the pseudogap phase: (1) metallic excitations on the Fermi Arc, (2) the Bogoliubov quasiparticle excitations of what appears to be a phase incoherent d-wave superconductor in the confined area in momentum space (Jhinwan Lee et al (2009)) and (3) the high energy pseudogap excitations seen in the anti-nodal region outside the $\sqrt{2}x/2$ Brillouin zone (Y. Kohsaka et al. Nature 454, 1072 (2008)). We discuss the relationship of these three components of the electronic structure to the thermodynamic and transport characterization of this phase.

8:12AM V34.00002 Quasiparticle interference above and below $T_c$ in underdoped cuprates \cite{1}. AAKASH PUSHP, COLIN PARKER, ABHAY PASUPATHY, KENJIRO GOMES, Princeton University, SHIMPEI ONO, CRIEPI, Japan, YOICHI ANDO, ISIR, Osaka University, JINSHENG WEN, ZHUJIN XU, GENDA GU, Brookhaven National Laboratory, ALI YAZDANI, Princeton University — There is considerable debate over the evolution of quasiparticle excitations between the superconducting and pseudogap phases in the underdoped cuprates. In the superconducting phase, dispersive real space modulations are observed \cite{1}, which can be explained by quasi-particle interference (QPI), whose location in momentum space is consistent with ARPES. What should happen to these modulations in the pseudogap state, where ARPES indicates a finite arc of gapless Fermi surface? We will present STM data from underdoped $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8$ that investigates the nature of this change and its connection with the non-dispersive features seen above $T_c$ \cite{2}. [1] Kohsaka et al. Nature 454, 1072 (2008). [2] Vershchin et al. Science 305, 1993 (2004).

8:24AM V34.00003 Extinction of quasiparticle interference in underdoped cuprates with coexisting order. BRIAN ANDERSEN, University of Copenhagen, PETER HIRSCHELF, University of Florida — Recent scanning tunnelling spectroscopy measurements [Y. Kohsaka et al., Nature 454, 1072 (2008)] have shown that dispersing quasiparticle interference peaks in Fourier transformed conductance maps disappear as the bias voltage exceeds a certain threshold corresponding to the coincidence of the contour of constant quasiparticle energy with the antiferromagnetic zone boundary. Here we argue that this is caused by quasistatic short-range coexisting order present in the d-wave superconducting phase, and that the most likely origin of this order is disorder-induced incommensurate antiferromagnetism. We show explicitly how the peaks are extinguished in the related situation with coexisting long-range antiferromagnetic order, and discuss the connection with the realistic disordered case. Since it is the localized quasiparticle interference peaks rather than the underlying antinodal states themselves which are destroyed at a critical bias, our proposal resolves a conflict between scanning tunneling spectroscopy and photoemission regarding the nature of these states.

8:36AM V34.00004 Quasiparticle interference and vortex “checkerboard” in $\text{Bi}_2\text{Sr}_2\text{Ca}_0.8\text{Y}_{0.2}\text{Cu}_2\text{O}_y$. T. HANAGURI, Y. KOHSAKA, RIKEN, T. TAMEGAI, Univ. Tokyo, H. TAKAGI, RIKEN, Univ. Tokyo — Relationship between the “checkerboard” electronic modulation in a vortex core \cite{1} and the quasiparticle interference effect has been studied using STM/STS in optimally- doped $\text{Bi}_2\text{Sr}_2\text{Ca}_2\text{O}_8$. We found that the vortex- induced signals in Fourier-transform spectroscopic images appear in the close vicinity to some of the “octet” scattering vectors for the quasiparticle interference \cite{2}, suggesting that the vortex “checkerboard” is associated with the Fermi momentum. Conductance spectrum taken at the center of the vortex core shows a sharp peak at a low energy (~meV) in the empty state. We argue the possible relationship between these observations and the quantum-limit nature of the vortex core. [1] J. E. Hoffman et al., Science 295, 466 (2002). [2] K. McElroy et al., Nature 422, 592 (2003).

8:48AM V34.00005 Quasiparticle scattering from impurities in the cuprates, E.A. NOWADNICK, I.M. VISHIK, B. MORITZ, W.S. LEE, Z.X. SHEN, T.P. DEVEREAUX, Stanford University and SLAC, K. TANAKA, Osaka University — Scanning tunneling spectroscopy (STS) measurements have shown that the local density of states in the cuprate superconductors is spatially inhomogeneous. Fourier-transformed STS has been used to investigate the mixing of momentum space eigenstates of the superconducting quasiparticles in the presence of this inhomogeneity, and has observed the extinction of the quasiparticle peaks upon approaching the antinodal region of the Fermi surface. We present calculations of momentum dependent quasiparticle scattering from impurity sites. Our results demonstrate that the quasiparticle extinction observed in FT-STS can be interpreted as resulting from the momentum dependence of the quasiparticle scattering rather than the absence of the quasiparticle itself. This interpretation agrees with recent ARPES measurements that observe quasiparticle peaks over the entire Fermi surface.

9:00AM V34.00006 Echolocation of Scatterers by Quasiparticles in Cuprate Superconductors, SUMIRAN PUJARI, CHRISTOPHER HENLEY, Cornell University — How much can STM techniques tell us about the realization of disorder in a particular sample under study? We propose a new method of STM-data analysis which allows for the determination of the position and strength of impurities/scatterers. Furthermore, for cuprates, it can potentially be used to distinguish if the scatterer is “ordinary” or “anomalous” \cite{1}, i.e. part of the pairing potential. The method relies on quasiparticle interference \cite{2}[as observed in cuprates \cite{3}]. As for much of the STM phenomenology in cuprates \cite{1-3}, our starting point is the existence of well-defined Bogoliubov quasiparticles defined by a quadratic phenomenological Hamiltonian with intrinsic disorder. By Energy “Fourier-Transforming” the measured local density of states (LDS) spectrum from a single point, one can extract the “echo” time that a quasiparticle takes to go to and return from a nearby scatterer; doing this at several points in a local patch allows a “sonar”–like echolocation of the scatterer. This method is complementary to Fourier-Transform Scanning Tunneling Spectroscopy \cite{4} wherein Space Fourier transforms of LDS data yield the quasiparticle dispersion.

9:12AM V34.00007 Interference of nematic quantum critical quasiparticles: a route to the octet model. EUN-AH KIM, Cornell University, MICHAEL LAWLER, Binghamton University & Cornell University — Given the presence of glassiness and inhomogeneity in cuprate superconductors, the capability of quasiparticle interference (QPI) in inferring momentum space electronic structure from real space local density of states(LDOS) images is surprising. Particularly, the simplicity of the QPI image, a set of well defined dispersing peaks is striking. Regarding the nature of QPI peaks, the “octet model” was based on the observation that the peak positions are determined by the eight tips of the “banana” shaped qp energy contours. However, a key open question has the mechanism for the accumulation of coherence at the tips. Here we show that nematic quantum critical fluctuations, combined with the known extreme velocity anisotropy, provide a natural mechanism for the accumulation of coherence at those special points \cite{1}. Our results raise the intriguing question of whether the nematic fluctuations provide the unique mechanism for such a phenomenon.

9:24AM V34.00008 Tunneling-mediated Impurity Resonances in Bilayer Cuprate Superconductors, DEGANZ ZHANG, CHIN-SEN TING, Texas Center for Superconductivity and Department of Physics, University of Houston, TX 77204 — We have studied tunneling-mediated local density of states (LDOS) of the surface layer of a bilayer cuprate, where a Zn impurity is located on the second Cu-O layer. When the tunneling strength between two Cu-O layers is larger than a critical value, the LDOS on the site just above the Zn impurity first exhibits a resonant peak near the Fermi surface. The larger the tunneling strength, the stronger the resonant peak. It is also shown that the height of the resonant peak oscillates decreasingly with the distance from the site just above the Zn impurity. The location of the resonant peak in the surface LDOS depends on doping, energy gap, and the tunneling strength, and has an opposite bias voltage to that on its nearest neighboring sites. The results could be tested by the STM experiments and be used to further understand the electronic properties of high temperature superconductors.

9:36AM V34.00009 Spin Filtering and Dephasing through an Aluminum Nanoparticle, FELIPE TTIWA BIRK, Georgia Institute of Technology, CHRISTOPHER MALEC, Georgia Institute of Technology, DRAGOMIR DAVIDOVIC, Georgia Institute of Technology — Measurements of spin-polarized current through a single Al nanoparticle in weak tunnel contact with two ferromagnets will be discussed. As a function of the bias voltage across the particle, spin polarized current saturates within the first few discrete energy levels above the ground state. The saturation is related to the energy dependence of the spin relaxation time \( T_1 \), from which we find that \( T_1 \) is about microsecond for the lowest excited state. Spin polarized current is extremely sensitive with respect to the direction of the applied magnetic field relative to magnetization. The discrete levels filter the spin of transmitted electrons along the direction specified by the applied magnetic field, explaining the directional dependence both qualitatively and quantitatively. In zero magnetic field, the filtering direction is determined by the field of the environment, making spin-filtering a new technique to study electron spin-dephasing in single metallic particles and other quantum dots. The spin-dephasing time in the nanoparticle at 4.2K is \( T_2 \gg 8\mu s. \)

9:48AM V34.00010 Possible competing order-induced Fermi arcs and self-consistent gap evolution with temperature in cuprate superconductors, G.P. LOCKHART, A.D. BEYER, M.L. TEAGUE, B.-L. YU, J.C.F. WANG, N.-C. YEH, Physics Dept., Caltech, Pasadena, CA — We explore, via numerical simulations, the possibility that competing orders (CO’s) induce both the pseudogap (PG) and Fermi arc phenomena in cuprate superconductors. We find that both phenomena occur in hole-type cuprates if (1) a CO arises below a FG PG temperature, \( T^\ast \), which is greater than the superconducting transition temperature, \( T_C \), and (2) the periodic wave-vector of the CO, \( Q \), is parallel to the Cu-O bonding direction. In contrast, neither phenomena is observed in electron-type cuprates because \( T^\ast < T_C \), but we find evidence that the CO scenario may explain the so-called non-monotonic d-wave gap observed in electron-type cuprates for \( T^\ast < T_C \) if \( Q \) is parallel to the nodal direction, as in the case of commensurate spin density waves. Finally, we consider a candidate model for self-consistently calculating the superconducting and CO energy gaps as a function of temperature and doping in the hole-type cuprates, as well as estimating the value of \( T^\ast \). Ref.: B.-L. Yu, et al. [arxiv:0804.4028].

10:00AM V34.00011 How does the gap change at \( T_C \) in underdoped cuprates?, COLIN PARKER, AAKASH PUSHP, ABHAY PAPASUTHY, Princeton University, KENJIRO GOMES, SHIMPEI ONO, CRIEPI, Japan, YOICHI ANDO, ISIR, Osaka University, JINSCHENG WEN, ZHIJUN XU, GENDA GU, Brookhaven National Laboratory, ALI YAZDANI, Princeton University — Many measurements on underdoped cuprates have shown a gap that persists up to room temperature. This raises an important question: what happens at \( T_C \) in order to cause the loss of perfect conductivity? In ARPES, the nature of the gap changes from d-wave below \( T_C \) to Fermi arcs above \( T_C \). However, ARPES necessarily averages over significant nanoscale disorder. We will present detailed STM spectroscopy on underdoped \( Bi_2Sr_2CuO_4 \) single crystals both above and below \( T_C \). Unlike overdoped samples, the STM spectrum in underdoped cuprates shows two energy scales [1]. We will compare our data to models based on ARPES, with emphasis on the difference between the superconducting and pseudogap phases. [1] Gomes et al., Nature 447, 569 (2007) [2] Pasupathy et al., Science 320, 196 (2008)

10:12AM V34.00012 The Effect Of Spontaneous Magnetization On The Reliability Of The Value For The Spin Polarization As Fitted From Ferromagnet/Superconductor Point Contact Data, PAUL J. DOLAN, JR., Northeastern Illinois University, CHARLES W. SMITH, University of Maine — The generalized BTK model for charge transport in a ferromagnet/superconductor point contact can be used to estimate the spin polarization in a ferromagnet. However, even when these measurements are carried out in zero applied magnetic field, there can be a substantial field in the active region of the contact due to the spontaneous magnetization of the ferromagnet itself. We estimate the effect of spontaneous magnetization on the reliability of the value of the spin polarization parameter for various ranges in contact transparency, inelastic scattering and temperature.

10:24AM V34.00013 Coherence factor effects in the antisymmetrized LDOS correlators, MARI-ANNA MALTSEVA, Dept of Physics and Astronomy, Rutgers University, P. COLEMAN, Dept Physics and Astronomy, Rutgers University — Recent scanning tunneling experiments on underdoped cuprates by Hanaguri et al [1] show the appearance of coherence factor effects. Unlike conventional observables, we show that the tunneling density of states in a superconductor does not have a well defined coherence factor. However, by extracting the component that is either even, or odd in the bias voltage, we show that these separate components have well-defined coherence factors. These results are used to understand the appearance of coherence factor effects in the antisymmetrized local density of states correlators in recent scanning tunneling experiments.

1Supported by DMR NSF-0605935.

10:36AM V34.00014 Visualizing electronic segregation in lightly-doped \( Ca_{2-x}Na_xCuO_2Cl_2 \). YUKI KOHSAKA, TETSUO HANAGURI, RIKEN, MASAKI AZUMA, MIKIO TAKANO, Tokyo Univ., J. C. SEAMUS DAVIS, Cornell Univ., HIDENORI TAKAGI, RIKEN/Univ. of Tokyo — We report spectroscopic imaging on evolution of the electronic state in a lightly-doped cuprate superconductor \( Ca_{2-x}Na_xCuO_2Cl_2 \) across the metal-insulator critical doping. We find nm-scale electronic segregation between regions breaking and showing the lattice symmetry. The former shows \( C_2 \) symmetry characterized by the unidirectional nano-domains and the V-shaped pseudogap found in superconducting samples [1] while the latter shows \( C_3 \) symmetry and wider U-shaped gap prominent in non-superconducting samples. This indicates that the local symmetry breaking is inherent in the electronic states created inside the Mott gap by hole doping. We also discuss spectra in \( C_2/C_3 \) domains and superconducting/insulating samples.

describe the consequences of this for the Leggett mode and outline possible experimental signatures of this sign difference between the two superconducting gaps. Unlike previously studied systems, in this model the superconducting order parameters of the particle and hole Fermi surfaces naturally have opposite sign. We calculate the spectrum of this mode in a short-range exchange model of iron pnictide superconductors. We analyze the implications of our results with experimental data for Fe-pnictides, where such a sign-changing $s$-wave state may be realized. We consider a phenomenological model for sign changing $s$-wave order parameters appropriate for the ferropnictide superconductors. We compare our results with experimental data for Fe-pnictides.

Thursday, March 19, 2009 8:00AM - 10:48AM –

Session V35 DMP: Focus Session: Iron Pnictides and Other Novel Superconductors XIII: Pairing Symmetry, Theory and Experiment  405

8:00AM V35.00001 On the magnetic fluctuations and unconventional superconducting pairing in iron pnictides 1, JINHUA ZHANG, RASTIKO SKNEPNKE, JOERG SCHMALIAN, Ames Laboratory and Department of Physics and Astronomy, Iowa State University — We explore the role played by spin and density fluctuations in the FeAs based superconductors using the fluctuation-exchange (FLEX) approach. We calculate the superconducting transition temperature and the fluctuation induced pairing gap. In order to compare with experiments, we evaluate the change of the penetration depth with temperature and the evolution of the order parameter. Because of the multi-band feature in this type of material, the interplay between intra- and inter-band fluctuations gives rise to rich physics.

1Supported by the U.S. Department of Energy Contract No. DE-AC 02-07CH11358.

8:12AM V35.00002 Signatures of the $s^+$ superconducting gap in electronic Raman Scattering and optical conductivity of Fe-based superconductors  , ILYA EREMIN, MPI for Physics of Complex Systems, ANDREY V. CHUBUKOV, MAXIM M. KORSHUNOV — We analyze the consequences of the extended $s$-wave symmetry of the superconducting gap, proposed recently in Fe-based superconductors, for the electronic pairing Raman scattering and optical conductivity. We calculate conductivity and Raman intensity for elastic scattering and find that an extended $s$-wave superconducting gap gives rise to several specific features in optical and Raman response functions. In particular, we find that, for the $A_{1g}$ symmetry of the incoming light, there will be a resonant collective mode in the Raman response function at an energy $\omega < 2\Delta$. The latter is as a hallmark of the $s^+$ superconductivity. Furthermore, the Cooper-pair weakening due to strong inter-band impurity scattering shifts the $2\Delta$ features towards higher energies in both Raman scattering and optical conductivity. We argue that these features are present in the experimental data for iron-based superconductors.

8:24AM V35.00003 Experiments for probing the macroscopic quantum coherence and pairing state in FeAs-based superconductors  , C.C. TSUEI, CHING-TZU CHEN, M.B. KETCHEN, IBM T.J. Watson Research Center, Z.A. REN, Z.X. ZHAO, Chinese Academy of Sciences, Beijing, China, X.H. CHEN, University of Science and Technology of China, Anhui, China — The recent discovery of superconductivity in FeAs-based pnictides has added another member to the growing family of high-temperature superconductors. In sharp contrast to cuprates, the new superconductor has a $T_c$ up to 55 K despite the absence of strong electronic correlation. Furthermore, its physical properties are best described by the multi-orbital electronic band structure. It is therefore of great interest to explore the consequences of these novel characteristics on the nature of Cooper pairing in the new Fe As superconductors. In this talk, we will present the design and implementation of experiments which probe the pairing state and the macroscopic quantum coherence across the interface between a pnictide and a conventional $s$-wave superconductor. Preliminary results will be discussed.

8:36AM V35.00004 Limits on the Superconducting Order Parameter in NdFeAsO$_{1−\delta}$F$_y$ and SmFeAsO$_{1−\delta}$ From Scanning SQUID Microscopy  , THOMAS LIPPMAN, CLIFFORD HICKS, Geballe Laboratory for Advanced Materials, Stanford University, Stanford, California, 94305, USA, MARTIN HUBER, Department of Physics and Electrical Engineering, University of Colorado Denver, Denver, Colorado, 80217, USA, ZHI-AN REN, ZHONG-XIAN ZHAO, National Laboratory for Superconductivity, Chinese Academy of Sciences, P.O. Box 603, Beijing 100190, P.R. China, KATHRYN MOLER, Geballe Laboratory for Advanced Materials, Stanford University, Stanford, California, 94305, USA — As a test of the symmetry of the order parameter of the ferric oxyarsenide family of superconductors $R$FeAsO$_{1−\delta}$F$_y$, where $R$ is a rare earth, we perform scanning SQUID microscopy on dense polycrystalline samples of NdFeAsO$_{0.94}F_{0.06}$ and SmFeAsO$_{0.85}$. Dominant $d$- or $p$-wave orders, for example, would result in direction-dependent phase shifts in tunneling. In well-coupled polycrystalline samples, these phase shifts would result in spontaneous orbital currents and magnetization in the superconducting state. We do not find any spontaneous currents in NdFeAsO$_{0.94}F_{0.06}$ or SmFeAsO$_{0.85}$, ruling out order parameters with direction-dependent phase shifts in tunneling.

8:48AM V35.00005 Effect of disorder on sign reversing s-wave pair state for Fe-pnictides  , VIVEK MISHRA, G. BOYD, S. GRASER, P. J. HIRSCHFELD, Department of physics,University of Florida, Gainesville, FL-32611,USA. — In this work, we consider a phenomenological model for sign changing s-wave order parameters appropriate for the ferropnictide superconductors. We consider both magnetic and non-magnetic impurities within the Born approximation, and study the effects of this disorder on transport properties in superconducting state. Our results can be used to guide experiments and design Fe-pnictides.

9:00AM V35.00006 Phase fluctuations in a magnetic exchange model of iron-based superconductors  , F.J. BURNELL, Princeton University, B. ANDREI BERNEVIG, MEERA M. PARISH, Princeton Center for Theoretical Science — We analyze the phase fluctuations in a two band model of iron-based superconductors. Multi-band superconductors have a sound-like collective excitation (Leggett mode) due to phase oscillations between different condensates. We calculate the spectrum of this mode in a short-range exchange model of iron pnictide superconductors. Unlike previously studied systems, in this model the superconducting order parameters of the particle and hole Fermi surfaces naturally have opposite sign. We describe the consequences of this for the Leggett mode and outline possible experimental signatures of this sign difference between the two superconducting gaps.
9:12AM V35.00007 Near degeneracy of several pairing channels in a multi-orbital model for the Fe-pnictides. THOMAS MAIER, Oak Ridge National Laboratory, SIEGFRIED GRASER, PETER HIRSCHFELD, University of Florida, DOUGLAS SCALAPINO, University of California, Santa Barbara — The experimental evidence regarding the gap structure in different iron pnictide superconductors is currently conflicting. In addition, weak-coupling approaches to the pairing problem in multi-orbital models of the iron pnictides have predicted a wide variety of superconducting ground states. We argue here that this controversy is naturally explained by the near-degeneracy of different pairing channels in superconductors with many distinct Fermi surface sheets. In particular, we will present results for the spin susceptibility and the pairing symmetry within a five-band random phase approximation model. We will discuss the robustness of these results for different dopings, interaction strengths, and variations in the band structure, in the light of recent experiments.

9:24AM V35.00008 Pairing Symmetry in a Two-Orbital Exchange Coupling Model of Oxypnictides. B. ANDREI BERNEVIG, Princeton University, KANGJUN SEO, JIANGPING HU — We study the pairing symmetry of a two orbital $J_1 - J_2$ model for FeAs layers in oxypnictides. We show that the mixture of an intra-orbital unconventional $s_{+2} \sim \cos(k_x) \cos(k_y)$ pairing symmetry and a small $d_{x^2-y^2}$ component is favored in a large part of $J_1 - J_2$ phase diagram. A pure $s_{+2}$ pairing state is favored for $J_2 \gg J_1$. The signs of the $d_{x^2-y^2}$ order parameters in the two different orbitals are opposite. While a small $d_{x^2-y^2} \sim \sin(k_x) \sin(k_y)$ inter-orbital pairing coexists in the above phases, the intra-orbital $d_{x^2-y^2}$ pairing is not favored even for large $J_2$.

9:36AM V35.00009 Self-consistent calculations of the local density of states of FeAs superconductor/ferromagnet bilayers. NAYOUNG LEE, HAN-YONG CHOI, SungKyunKwan University — We study the local density of states (L DOS) of the superconductor/ferromagnet (S/F) bilayers using the self-consistent Bogoliubov-de Gennes equation, where the S is modeled in terms of the $s+\pi$ pairing state. The $s+\pi$ pairing is an $s$-wave pairing state with an internal $\pi$ phase between the two condensates of a two band superconductor which seems relevant for the FeAs superconductors. We calculate the pairing and magnetic order parameters self-consistently to obtain LDOS as a function of the energy and position of S/F bilayers. The results will be discussed in terms of the interplay between the internal and external $\pi$ phases.

9:48AM V35.00010 Possible time-reversal symmetry breaking pairing state in FeAs superconductors. WEI-CHENG LEE, University of California, San Diego, SHOU-CHENG ZHANG, Stanford University, CONJUN WU, University of California, San Diego — We investigate the consequences of the intra-band $s$-wave and $d$-wave pairing order parameters in the iron-based superconductors. Because of the frustrating pairing interactions among the electron and the hole Fermi pockets, a time reversal symmetry breaking $s+id$ pairing state could be favored. We analyze this pairing state within the Ginzburg-Landau theory, and explore the experimental consequences. In such a state, spatial inhomogeneity induces supercurrent near a non-magnetic impurity and the corners of a square sample. The resonance mode between the $s$ and $d$-wave order parameters can be detected through the $B_{1g}$-Raman spectroscopy.

10:00AM V35.00011 Spin fluctuation mediated extended s-wave pairing from multiple Fermi surfaces in iron pnictide superconductors. KAZUHIKO KUROKI, Department of Applied Physics and Chemistry, The University of Electro-Communications and JST, TRIP, SEICHIRO ONARI, Department of Applied Physics, Nagoya University and JST, TRIP, RYOTARO ARITA, Department of Applied Physics, University of Tokyo and JST, TRIP, HIDETOMO USUI, Department of Applied Physics and Chemistry, The University of Electro-Communications and JST, TRIP, YUKIO TANAKA, Department of Applied Physics, Nagoya University and JST, TRIP, HIROSHI KONTANI, Department of Physics, Nagoya University and JST, TRIP, HIDEKO AOKI, Department of Physics, University of Tokyo and JST, TRIP — For the superconducting iron pnictides, we have constructed a minimal model, where all the five Fe d bands turn out to be involved. We study the fluctuation dynamics of these superconducting states, as well as d- and p-wave states. The coupling between spin fluctuations and the quasiparticles of the superconducting state leads to damping of the former. The gap structure leaves a signature in the form of this damping. This can be used to diagnose the order parameter in spin sensitive experiments. We also discuss the case of coexistence of superconductivity and spin-density wave.

10:12AM V35.00012 Spin fluctuation dynamics and multiband superconductivity in iron pnictides. VALENTIN STANEV, JIAN KANG, ZLATKO TESANOVIC, Johns Hopkins University — Multiband superconductivity, involving resonant pair scattering between different bands, has emerged as a likely possibility for the iron pnictides. In this scenario the gap changes sign between the hole and the electron Fermi surfaces (separated by wave-vector M). In the quest to distinguish this extended s- from an ordinary s- wave state, it is essential to use experiments that have momentum space resolution and can probe momenta of order M. We study the fluctuation dynamics of these superconducting states, as well as d- and p-wave states. The coupling between spin fluctuations and the quasiparticles of the superconducting state leads to damping of the former. The gap structure leaves a signature in the form of this damping. This can be used to diagnose the order parameter in spin sensitive experiments. We also discuss the case of coexistence of superconductivity and spin-density wave.

1. Research supported in part by the NSF under Grant No. DMR-0531159 and by the DOE under Grant No. DE-FG02-08ER46544

10:24AM V35.00013 Emergent symmetry of superconductivity and antiferromagnetism in the iron pnictides. YONG BAEK KIM, DANIEL PODOLSKY, HAE-YOUNG KEE, University of Toronto — We show the presence of an emergent symmetry that unifies superconductivity and magnetism in the iron pnictides. We discuss the expected experimental consequences of this symmetry.

10:36AM V35.00014 Two-band Model for Unconventional Superconductivity in Iron-Based Superconductors. YAN CHEN, (1) Dept. of Physics and Lab of Advanced Materials, Fudan University (2) Texas Center for Superconductivity, University of Houston — The recent discovery of FeAs superconductors with high Tc has triggered intensive efforts to explore magnetism and superconductivity in this family of materials. We adopt an effective model Hamiltonian including a two-band tight-binding term as well as a spin-spin exchange interaction term. The first term can fit approximately the multi-band dispersions near electron/hole Fermi-pockets while the second term may lead to the appropriate superconducting pairing symmetry as well as the SDW state at low doping. Different pairing symmetry candidates of FeAs materials are evaluated for various model parameters. In particular, we study the local electronic structure at vortex cores in the system subject to an external magnetic field. The relevance to recent STM measurements will be discussed. Moreover, we calculate the tunneling conductance of various superconducting junctions, including the Josephson current in the superconducting state. The Josephson current can be decomposed into two parts, an interband and an intraband component. Distinct interference effects can be used to distinguish the pairing symmetry of FeAs systems.
8:12AM V37.00002 Nonlinear Response Functions in Model Dissipative Anharmonic Systems

MOHAMMAD SAHRAPOUR, NANCY MAKRI, University of Illinois at Urbana-Champaign — We report the results of simulations of third order response functions \( R^{(3)}(\tau_1, 0, \tau_1) = \text{Tr} \left( \hat{\alpha}(\tau_1) \hat{\alpha}(\tau_1) \hat{\alpha}(\tau_1) \right) \) where \( \hat{\alpha} \) is the polarizability for harmonic, Morse, and anharmonic model systems in a linearly dissipative environment. These simulations are carried out via the iterative path integral methodology developed earlier in our group which delivers efficient, numerically exact long time quantum dynamics. We find that even minor anharmonicity in the potential qualitatively changes the response function; rotating the pattern seen by 45° in the \( \tau_1 - \tau_3 \) plane. We also observe that modulations in the \( \tau_2 \) direction increase in frequency as we go to a more anharmonic potential. As the temperature is increased, these modulations also appear in the \( \tau_1 \) direction. It is also found that asymmetry in the potential, at least at temperatures considered here, does not have a significant effect. Finally, in all three systems we notice that decay in the \( \tau_2 \) direction is faster than in the \( \tau_1 \) direction. The observed sensitivity of the response function to anharmonicities in the potential can be exploited to construct more accurate molecular potentials once the appropriate non-linear spectroscopic experiments have been performed.

8:24AM V37.00003 Hamiltonian Monodromy: Unexpected behavior of quasi-linear molecules, atoms in traps and of hydrogen in crossed fields

J.B. DELOS, William and Mary, C. SCHLEIF, UC Merced, D. SADOVSKII, G. DHONT, B. ZHILINSKII, U. du Littoral — A system exhibits monodromy if we take the system around a closed loop in its parameter space, and we find that the system does not come back to its original state. Many systems have this property, including quasi-linear molecules, atoms in a trap or a hydrogen atom in crossed fields. Using classical perturbation theory, Sadowski and Cushman predicted the presence of monodromy in perpendicular fields. It shows up as a defect in the lattice of quantum states. When the fields are tilted from perpendicular, this lattice defects undergo a series of bifurcations. Atoms in a trap can display a newly discovered dynamical manifestation of monodromy. This phenomenon will also occur with oriented dipolar molecules in fields or with quasilinear molecules. (Supported by NSF and Region Nord–Pas-de-Calais)

8:36AM V37.00004 On the internal photorelaxation mechanism of DNA

JESSICA A. THOMAS, LEONARDO ALVAREZ-VALTIERRA, DAVID W. PRATT, University of Pittsburgh — Gas phase rotationally resolved electronic spectra were collected for the origin and several vibronic transitions of 1,3-benzodioxole. For each band, an autocorrelation function \( \alpha(\tau_1, 0, \tau_0) = \text{Tr} \left( \hat{\alpha}(\tau_1) \hat{\alpha}(\tau_1) \right) \) where \( \hat{\alpha} \) is the polarizability) for harmonic, Morse, and anharmonic model systems in a linearly dissipative environment. These simulations are carried out via the iterative path integral methodology developed earlier in our group which delivers efficient, numerically exact long time quantum dynamics. We find that even minor anharmonicity in the potential qualitatively changes the response function; rotating the pattern seen by 45° in the \( \tau_1 - \tau_3 \) plane. We also observe that modulations in the \( \tau_2 \) direction increase in frequency as we go to a more anharmonic potential. As the temperature is increased, these modulations also appear in the \( \tau_1 \) direction. It is also found that asymmetry in the potential, at least at temperatures considered here, does not have a significant effect. Finally, in all three systems we notice that decay in the \( \tau_2 \) direction is faster than in the \( \tau_1 \) direction. The observed sensitivity of the response function to anharmonicities in the potential can be exploited to construct more accurate molecular potentials once the appropriate non-linear spectroscopic experiments have been performed.

8:48AM V37.00005 Tunneling Splitting in the Rotationally Resolved Electronic Spectrum of 1,3-Benzodioxole

TUNELLA, DAVID W. PRATT, University of Pittsburgh — Gas phase rotationally resolved electronic spectra were collected for the origin and several vibronic transitions of 1,3-benzodioxole. For each band, an autocorrelation function \( \alpha(\tau_1, 0, \tau_0) = \text{Tr} \left( \hat{\alpha}(\tau_1) \hat{\alpha}(\tau_1) \right) \) where \( \hat{\alpha} \) is the polarizability) for harmonic, Morse, and anharmonic model systems in a linearly dissipative environment. These simulations are carried out via the iterative path integral methodology developed earlier in our group which delivers efficient, numerically exact long time quantum dynamics. We find that even minor anharmonicity in the potential qualitatively changes the response function; rotating the pattern seen by 45° in the \( \tau_1 - \tau_3 \) plane. We also observe that modulations in the \( \tau_2 \) direction increase in frequency as we go to a more anharmonic potential. As the temperature is increased, these modulations also appear in the \( \tau_1 \) direction. It is also found that asymmetry in the potential, at least at temperatures considered here, does not have a significant effect. Finally, in all three systems we notice that decay in the \( \tau_2 \) direction is faster than in the \( \tau_1 \) direction. The observed sensitivity of the response function to anharmonicities in the potential can be exploited to construct more accurate molecular potentials once the appropriate non-linear spectroscopic experiments have been performed.

9:00AM V37.00006 Vacuum Ultraviolet Absorption of Supercritical Water

DAVID BARTELS, IRENEUSZ JANIK, Notre Dame University, TIMOTHY MARIN, Benedictine University — The first continuum \( \sim \) peak in the gas phase absorption spectrum of H$_2$O (maximum at 7.4 eV), is ascribed to promotion of a nonbonding valence electron to a dissociative excited state which is an admixture of antibonding sigma and 3s Rydberg orbitals. Due to the large spatial extent of this orbital the \( \sim \) peak is strongly perturbed by the local environment. In liquid water, this peak is notably broadened and shifted to the blue, with an absorption maximum of 8.3 eV at room temperature. An obvious question is how this transition changes as a function of the water density in the supercritical regime as the system transitions from liquid to gas. As density decreases, most water molecules form hydrogen bonds. When the fields are tilted from perpendicular, this lattice defects undergo a series of bifurcations. Atoms in a trap can display a newly discovered dynamical manifestation of monodromy. This phenomenon will also occur with oriented dipolar molecules in fields or with quasilinear molecules. (Supported by NSF (CHE-0615755))
9:24AM V37.00008 Ab Initio Torsion-Wag Surface for the Ethyl Radical\(^1\), RAM S. BHATTA, DAVID S. PERRY, Department of Chemistry, The University of Akron — The torsion-wag potential of the ethyl radical has a 6-fold barrier to internal rotation and the minimum energy path involves deviations of the \(\text{CH}_2\) wag angle of 6 to 11 degrees on either side of planar. Partially optimized 2-dimensional surfaces were calculated at the B3LYP, MP2, and CCSD(T) levels with 6-311++G(d,p) and 6-311++G(3df, 2p) basis sets and they were fit to a function containing a polynomial in the wag angle \(\tau\) and trigonometric functions of the torsional angle \(\alpha\). Comparison is made with the corresponding surfaces for \(\text{CH}_3\text{NH}_2\) and \(\text{CH}_3\text{OH}\). Unlike \(\text{CH}_2\text{CH}_2\), both have a substantial barrier to inversion. The dominant torsion-wag coupling term in all three cases has the form \(\tau \cos \alpha\).

\(^1\)The work was supported by the Office of Basic Energy Sciences, Office of Energy Research, U.S. Department of Energy under Grant No. DE-FG02-90ER14151.

9:36AM V37.00009 Terahertz Investigations of Extraordinarily Efficient Conduction in a Redox Active Ionic Liquid. VERNER THORSMOLLE, JAN BRAUER, Ecole Polytechnique Federale de Lausanne, GIDRO ROTHENBERGER, Polytechnique Federale de Lausanne, DAIBIN KUANG, Sun Yat-Sen University, SHAIK ZAKEERUDDIN, MICHAEL GRÄTZEL, JACQUES MOSER, Polytechnique Federale de Lausanne — In this talk, we will present our terahertz investigations of extraordinary charge transport in a redox-active ionic liquid, namely [\(\text{C}_{18}\text{H}_{37}\text{N}_{14}\text{S}_{6}\text{O}_{5}\)]\(^{2+}\)\((\text{DO}_{2})_2\)\(^{2-}\) in \(\text{CH}_{3}\text{OH}\). The redox-active ionic liquid shows a high conductivity of \(10^{-3}\) S/cm at room temperature, which is comparable to other reports on redox-active ionic liquids. Our terahertz investigations reveal that the charge transport in this ionic liquid is dominated by the redox-active \(\text{C}_{18}\text{H}_{37}\text{N}_{14}\text{S}_{6}\text{O}_{5}\)^{2+} cations, which show a reaction field relaxation time of \(\tau_r = 540\) fs. This relaxation time is much shorter than the thermal relaxation time, which suggests that the charge transport is driven by a reaction field relaxation mechanism. The ionic liquid retains its conductivity in a high pressure environment up to \(15\) GPa, and a high pressure phase transition is observed at \(9.3\) GPa, which is accompanied by a decrease in the conductivity.

9:48AM V37.00010 Investigation of the Order-Disorder Transition in the Hybrid Inorganic-Organic System [(\text{CH}_3)_2\text{NH}]_2\text{Zn(HCOO)}_2, by means of \(^1\)H NMR. T. BESARA, P. JAIN, Department of Chemistry, Florida State University, Tallahassee, FL, USA, A.P. REYES, P.L. KUHN, National High Magnetic Field Laboratory, Tallahassee, FL, USA, A.K. CHEETHAM, Materials Research Laboratory, University of California, Santa Barbara, CA, USA — [(\text{CH}_3)_2\text{NH}]_2\text{Zn(HCOO)}_2, a hybrid ABX\(_3\) perovskite, with A=(\text{CH}_3)_2\text{NH}, B=Zn and X=HCOO, undergoes a paraelectric-antiferroelectric transition around 156 K. Synchrotron studies indicate that hydrogen bonding between the H-atoms in the NH\(_2\) group and O-atoms from the formate group is involved. The dimethylethylamine cation is ordered with nitrogen existing in three different positions, but not known whether statically or dynamically. We have investigated it by means of Spin-lattice relaxation time, \(T_1\), using proton NMR. We find that the cation is dynamically disordered and that the transition involves its slowing down. Evidence is seen for tunneling of the CH\(_2\) groups, and for the compound becoming a glass, with the cation displaying several metastable equilibrium geometries (\(T_1\) trajectories).

10:00AM V37.00011 High Resolution Cavity Ringdown Spectroscopy of Jet-Cooled Reactive Intermediates, GABRIEL JUST, PATRICK RUPPER, LINSEN PEI, TERRY MILLER, The Ohio State University — Alkyl peroxy radicals long have been well known to be key intermediates in atmospheric and chemistry as well as in low-temperature combustion. For the last several years, our group has generated a data set for these radicals using room-temperature cavity ringdown spectroscopy. We have recently extended our investigations of the peroxy radicals to obtain a high-resolution data set of spectra under jet-cooled conditions using a quasi-Fourier-transform-limited laser source and a supersonic slit jet discharge expansion. Over the last few years, we have developed our capability to obtain narrow-bandwidth, near-infrared (NIR) radiation for performing high-resolution cavity ringdown spectroscopy using the post-amplification of a Ti:Sa ring laser. The NIR light can be generated by either stimulated Raman shifting or by working in the post-amplification of a Ti:Sa ring laser. The NIR light can be generated by either stimulated Raman shifting or by working in the post-amplification of a Ti:Sa ring laser. The NIR light can be generated by either stimulated Raman shifting or by working in the post-amplification of a Ti:Sa ring laser. The NIR light can be generated by either stimulated Raman shifting or by working in the post-amplification of a Ti:Sa ring laser. The NIR light can be generated by either stimulated Raman shifting or by working in the post-amplification of a Ti:Sa ring laser. The NIR light can be generated by either stimulated Raman shifting or by working in the post-amplification of a Ti:Sa ring laser.
Observation of the $\tilde{A} - \tilde{X}$ Electronic Transitions of Cyclopentyl and Cyclohexyl Peroxy Radicals Via Cavity Ringdown Spectroscopy

The $\tilde{A} - \tilde{X}$ transitions of cyclopentyl and cyclohexyl peroxy radicals are important intermediates in combustion chemistry. These molecules, formed from the addition of oxygen to alkyl radicals, are pivotal species in many atmospheric processes. We have previously targeted the $\tilde{A} - \tilde{X}$ transitions of straight- and branched aliphatic peroxy radicals. This research has now been extended towards cyclic systems starting with cyclopentyl peroxy ($C_5H_9O_2$) and cyclohexyl peroxy ($C_6H_{11}O_2$), which are predicted by ab initio and DFT calculations to have four and two low-lying conformers respectively. Both have conformers which differ on the O-O bond with respect to the cyclic skeleton namely, cis- and gauche-, with $C_6H_{11}O_2$ also having conformers with axial and equatorial placement on the ring. We observe strong bands for both peroxies in the near-IR which are favorably assigned as the origin and the O-O stretch in agreement with the calculations. We have also obtained the spectrum of $C_6O_1D_2$ which facilitates the assignments of the weaker vibrational structure in $C_6H_{11}O_2$.

Dynamic light scattering in an aqueous solution of 3-methylpyridine

DIMITRY IVANOV, ANNA TRUBETSKAYA, University of Maryland, ANDREI KOSTKO, Virginia Commonwealth University, MIKHAIL ANISIMOV, JAN SENGERS, University of Maryland — We report a set of dynamic light scattering experiments in an aqueous solution of 3-methylpyridine. The dynamic correlation functions appear to exhibit two modes: one associated with a normal diffusion process and another one with network relaxation. The observed correlations seem to be associated with long-living nonequilibrium structures. To obtain further insight into this phenomenon we have made systematic studies of the nature of the observed dynamics as a function of time and concentration.

Quantum Transition State Theory

HOLGER WAALKENS — The main idea of Wigner’s transition state theory (TST) is to compute reaction rates from the flux through a dividing surface placed between reactants and products. In order not to overestimate the rate the dividing surface needs to have the no-crossing property, i.e. reactive trajectories cross the dividing surface exactly once, and nonreactive trajectories do not cross it at all. The long standing problem of how to construct such a dividing surface for multi-degree-of-freedom systems was solved only recently using ideas from dynamical systems theory. Here a normal form is available for a local decoupling of the classical dynamics which leads to the explicit construction of the phase space structures that govern the reaction dynamics through transition states. The dividing surface is spanned by a normally hyperbolic manifold which is the mathematical manifestation of the transition state as an unstable invariant subsystem of one degree of freedom less than the full system. The mere existence of a quantum version of TST is discussed controversially in the literature. The key issue is the presence of quantum mechanical tunneling which prohibits the existence of a local theory analogous to the classical case. Various approaches have been developed to overcome this problem by propagating quantum wavefunctions through the transition state region. These approaches have in common that they are computationally very expensive which seriously limits their applicability. In contrast the approach by Roman Schubert, Stephen Wiggins and myself is local in nature. A quantum normal form allows us to locally decouple the quantum dynamics to any desired order in Planck's constant. This yields not only the location of the scattering and resonance wavefunctions relative to the classical phase space structures, but also leads to very efficient algorithms to compute cumulative reaction probabilities and Gamov-Siegert resonances which are the quantum imprints of the transition state.

Transition States in a Noisy Environment

THOMAS BARTSCH, Loughborough University — No abstract available.

Statistical Theory of Asteroid Escape Rates

CHARLES JAFFE, Department of Chemistry, West Virginia University — Transition states in phase space are identified and shown to regulate the rate of escape of asteroids temporarily captured in circumplanetary orbits. The transition states, similar to those occurring in chemical reaction dynamics, are then used to develop a statistical semianalytical theory for the rate of escape of asteroids temporarily captured by Mars. Theory and numerical simulations are found to agree to better than 1%. These calculations suggest that further development of transition state theory in celestial mechanics, as an alternative to large-scale numerical simulations, will be a fruitful approach to mass transport calculations.

Exploring remnants of invariants buried in a deep potential well in chemical reactions

TAMIKI KOMATSUZAKI, Hokkaido University — How the reacting system climbs through saddles from one basin to another on potential energy surface has been one of the most intriguing subjects not only in chemistry but also physics and biology. This decade significant progress has been achieved in establishing the concept of the so-called transition state (TS), that is, a hypersurface of co-dimension one through which the system passes through only once from one basin to another [1-3]. However, there exist still open problems to be resolved; 1) how the no-return TS ceases or bifurcates as the energy increases [4, 5] or how one can generalize the concept of return TS besides the region of first-rank saddles. Related to the problem 2), most of all the chemical reaction theories assume that all of the available energy redistributes statistically through the dofs of system in the reactant well before the reaction takes place. It is implicitly expected that the ratio of the measure occupied by tori in phase space is that of the ambient space decreases exponentially as the dimensionality of the system increases. Here we present a novel technique to scrutinize the remnant of invariants buried in chaos in many-degrees of freedom systems [7]. This is regarded as the remnants of a destroyed invariant manifold that may dominate the transport in phase space even at high energy regions where most of all tori vanish. We demonstrate the potentiality of our technique for HCN isomerization, where the conventional procedure based on a finite order truncation in the coordinate transformation of canonical perturbation theory prevent us from detecting remnants of invariants.

Session V39 DBP: Biological Networks and Systems Biology

8:00AM V39.00001 Boolean modeling of collective effects in complex networks1. JOHANNES NORRELL, JOSHUA SOCOLAR, Duke University Physics Department — Complex systems are often modeled as Boolean networks in attempts to capture their logical structure and reveal its dynamical consequences. Approximating the dynamics of continuous variables by discrete values and Boolean logic gates may, however, introduce dynamical possibilities that are not accessible to the original system. We show that large random networks of variables coupled through continuous transfer functions often fail to exhibit the complex dynamics of corresponding Boolean models in the disordered (chaotic) regime, even when each individual function appears to be a good candidate for Boolean idealization. A simple criterion identifies continuous systems that exhibit the full dynamical range of their Boolean counterparts. Transfer functions inferred from the literature on transcriptional regulation of genes do not satisfy the criterion.

1. This work was supported by grants from NSF (PHY-0417372) and NIH (1P50-GM081883).

8:12AM V39.00002 A Network Model For Sea Urchin Development1. XINWEI GONG, Department of Physics, Duke University, XIANRUI CHENG, Computational Biology and Bioinformatics Program, Duke University, JOSHUA SOCOLAR, Department of Physics, Duke University — The sea urchin embryo developmental gene regulatory network has been a subject of experimental study for decades. While current knowledge of the network is incomplete, boolean network models with autonomous updating can reveal dynamical features of the known network. Our analysis of such a model based on the network provided by Davidson et al [http://surg.caltech.edu/endomes/index.html] shows that, with the suggested initial inputs and certain sets of logic functions that are consistent with the known regulatory relations, a 3-cell system settles into an attractor that corresponds to the 3 different cell fates expected for the organism. The attractor is not sensitive to modest variations in the time delay parameters.

1. This research is supported by NSF and NIH through Grant Nos. PHY-0417372 and 1P50-GM081883.
8:24AM V39.00003 Achieving optimal growth: lessons from simple metabolic modules. SID-HARTRA GOYAL, Physics, THOMAS CHEN, Applied Mathematics, NED WINGREEN, Molecular Biology, Princeton University — Metabolism is a universal property of living organisms. While the metabolic network itself has been well characterized, the logic of its regulation remains largely mysterious. Recent work has shown that growth rates of microorganisms, including the bacterium Escherichia coli, correlate well with optimal growth rates predicted by flux-balance analysis (FBA), a constraint-based computational method. How difficult is it for cells to achieve optimal growth? Our analysis of representative metabolic modules drawn from real metabolism shows that, in all cases, simple feedback inhibition allows only optimal growth. Indeed, product-feedback inhibition is found in every biosynthetic pathway and constitutes about 80% of metabolic regulation. However, we find that product-feedback systems designed to approach optimal growth necessarily produce large pool sizes of metabolites, with potentially detrimental effects on cells via toxicity and osmotic imbalance. Interestingly, the sizes of metabolite pools can be strongly restricted if the feedback inhibition is ultraspesensitive (i.e. with high Hill coefficient). The need for ultraspesensitive mechanisms to limit pool sizes may therefore explain some of the ubiquitous, puzzling complexity found in metabolic feedback regulation at both the transcriptional and post-transcriptional levels.

8:36AM V39.00004 Bifurcation in stochastic differential equations with delayed feedback. GAUDREAU-L MATHIEU, JORGE VINALS, McGill University — The bifurcation diagram of a model nonlinear Langevin equation with delayed feedback is obtained numerically. This model relates to a common motif in genetic regulatory networks, and we study the effect of fluctuating parameters on the bifurcation diagram of the network. We observe both direct and oscillatory bifurcations in different ranges of model parameters. Below threshold, the stationary distribution function \( p(x) \) is a delta function at the trivial state \( x = 0 \). Above threshold, \( p(x) \sim x^\alpha \) at small \( x \), with \( \alpha = -1 \) at threshold, and monotonously increasing with the value of the control parameter above threshold. Unlike the case without delayed feedback, the bifurcation threshold is shifted by fluctuations by an amount that scales linearly with the noise intensity. With numerical information about time delayed correlations, we derive an analytic expression for \( p(x) \) which is in good agreement with the numerical results.

8:48AM V39.00005 Constraints imposed by nonfunctional protein-protein interactions on gene expression and proteome size. JINGSHAN ZHANG, Harvard University, SERGEI MASLOV, Brookhaven National Laboratory, EUGENE SHANKOVICH, Harvard University — Crowded intracellular environments present a challenge for proteins to form functional specific complexes while reducing nonfunctional interactions with promiscuous nonfunctional partners. Here we show how nonfunctional interactions limit the proteome diversity and the average concentration of co-expressed and co-localized proteins. We use yeast proteomes to verify our hypothesis that the proteome has evolved to operate closely to the upper limit of its size, while keeping individual protein concentrations sufficiently low to reduce nonfunctional interactions. These findings have implication for conceptual understanding of intracellular compartmentalization, multicellularity, and differentiation.

9:00AM V39.00006 Effect of TNF autocrine signaling on dosage-dependent NF-kappaB response to lipopolysaccharide stimulation. JAEWOOK JOO, BRYAN CARSON, CATHY BRANDA, JENS POSCHET, Sandia National Labs — We will present the dosage-dependent characteristics of NF-kappaB translocation patterns from single macrophages stimulated by E. Coli lipopolysaccharide. The NF-kappaB translocation patterns in single cells are found to be quite heterogeneous: The patterns are more heterogeneous with low dosage stimulation than with high dosage stimulation. For low dosage stimulation, most of cells take a rising pattern and we demonstrate that it is due to the TNFanalptra autocrine signaling effect. The above results are predicted and explained by a computational model, and corroborated and verified by a single cell fluorescence imaging technique.

9:12AM V39.00007 Gain control in molecular signaling without feedback1. ILYA NEMENMAN, Los Alamos National Laboratory — Statistical properties of environments experienced by biological systems in the real world change, and this requires adaptation to achieve a high fidelity information transmission in cellular networks. One form of such adaptive response is gain control. When the mean response of a signaling system is matched to the mean value of its signal, rescaling the gain allows to respond to signals with different variances without saturation and by utilizing the entire available dynamic range of the response. Here we argue that a certain simple mechanism of gain control, understood well in the context of systems neuroscience, translates to molecular signaling systems as well. The mechanism allows to transmit more than one bit (on or off) of information about the signal independently of the source variance. The mechanism does not require additional molecular circuitry beyond that already present in many molecular systems, and, in particular, it does not depend on existence of feedback loops. This analysis provides a plausible explanation for certain structural aspects of cellular networks.

9:24AM V39.00008 Noise in Random Boolean Networks. TIAO PEIXOTO, BARBARA DROSSEL, Technische Universität Darmstadt — We investigate the effect of noise on Random Boolean Networks. Noise is implemented as a probability \( p \) that a node does not obey its deterministic update rule. We define two order parameters, the long-time average of the Hamming distance between a network with and without noise, and its deterministic update rule. The bifurcation diagram of a model nonlinear Langevin equation with delayed feedback is obtained numerically. This model relates to a common motif in genetic regulatory networks, and we study the effect of fluctuating parameters on the bifurcation diagram of the network. We observe both direct and oscillatory bifurcations in different ranges of model parameters. Below threshold, the stationary distribution function \( p(x) \) is a delta function at the trivial state \( x = 0 \). Above threshold, \( p(x) \sim x^\alpha \) at small \( x \), with \( \alpha = -1 \) at threshold, and monotonously increasing with the value of the control parameter above threshold. Unlike the case without delayed feedback, the bifurcation threshold is shifted by fluctuations by an amount that scales linearly with the noise intensity. With numerical information about time delayed correlations, we derive an analytic expression for \( p(x) \) which is in good agreement with the numerical results.

9:36AM V39.00009 The effect of negative autoregulation on eukaryotic gene expression. DMITRY NEVOZHAY, RHYS ADAMS, Dept. of Systems Biology, UT M. D. Anderson Cancer Center, KEVIN MURPHY, Harvard Medical School, KRESIMIR JOSIC, Dept. of Mathematics, University of Houston, GÁBOR BALÁZSI, Dept. of Systems Biology, UT M. D. Anderson Cancer Center — Negative autoregulation is a frequent motif in gene regulatory networks, which has been studied extensively in prokaryotes. Nevertheless, some effects of negative feedback on gene expression in eukaryotic transcriptional networks remain unknown. We studied how the strength of negative feedback regulation affects the characteristics of gene expression in yeast cells carrying synthetic transcriptional cascades. We observed a drastic reduction of gene expression noise and a change in the shape of the dose-response curve. We explained these experimentally observed effects by stochastic simulations and a simple set of algebraic equations.

9:48AM V39.00010 Cell stimulation with optically manipulated microsources. HOLGER KRESS, JINGYU PARK, CECILE MEJEAN, JASON FORSTER, JASON PARK, SPENCER WALSE, DIANQING WU, Yale University, ORION WEINER, UC San Francisco, TAREK FAHYMI, ERIC DUFRESNE, Yale University — Many cells can sense spatial and temporal heterogeneities in concentrations of soluble molecules. The cellular signal transduction which forms the basis of this ability consists of signaling cascades and loops whose length and time scales are largely unknown. The systematic study of these networks requires control over the chemical microenvironment of cells. We present a novel technique to create molecular concentration patterns that are chemically, spatially and temporally flexible. Our approach uses optically manipulated colloidal particles which act as microsources of soluble molecules. This technique for flexible cell stimulation is combined with quantitative live cell microscopy measurements of cellular responses. We demonstrate the method by inducing chemotaxis in neutrophils. We quantify the intracellular calcium release, actin distribution, shape and motility of single cells. The possibility for quantitative stimulus-response measurements on single cells makes this method applicable to a wide range of systems biology studies.

1 Supported by DOE under Contract No. DE-AC52-06NA25586
10:12AM V39.00012 Determining Regulatory Networks Governing the Differentiation of Embryonic Stem Cells to Pancreatic Lineage. IPSITA BANERJEE, University of Pittsburgh — Knowledge of pathways governing cellular differentiation to specific phenotype will enable generation of desired cell fates by careful alteration of the governing network by adequate manipulation of the cellular environment. With this aim, we have developed a novel method to reconstruct the underlying regulatory architecture of a differentiating cell population from discrete temporal gene expression data. We utilize an inherent feature of biological networks, that of sparsity, in formulating the network reconstruction problem as a bi-level mixed-integer programming problem. The formulation optimizes the network topology at the upper level and the network connectivity strength at the lower level. The method is first validated by in-silico data, before applying it to the complex system of embryonic stem (ES) cell differentiation. This formulation enables efficient identification of the underlying network topology which could accurately predict steps necessary for directing differentiation to subsequent stages. Concurrent experimental verification demonstrated excellent agreement with model prediction.

10:24AM V39.00013 Stabilizing Motifs in Autonomous Boolean Networks and the Yeast Cell Cycle Oscillator¹. VOLKAN SEVIM, XINWEI GONG, JOSHUA SOCOLAR, Physics Department, Center for Nonlinear and Complex Systems, and IGSP Center for Systems Biology, Duke University, Durham, North Carolina 27708, USA — Synchronously updated Boolean networks are widely used to model gene regulation. Some properties of these model networks are known to be artifacts of the clocking in the update scheme. Autonomous updating is a less artificial scheme that allows one to introduce small timing perturbations and study stability of the attractors. We argue that the stabilization of a limit cycle in an autonomous Boolean network requires a combination of motifs such as feed-forward loops and auto-repressive links that can correct small fluctuations in the timing of switching events. A recently published model of the transcriptional cell-cycle oscillator in yeast contains the motifs necessary for stability under autonomous updating [1].

10:36AM V39.00014 The Transition Pathway from Nonspecific to Specific Complex of DNA with a DNA-Bending Protein. SERGEI KUZNETSOV, PAULA VIVAS, YOGAMBIGAI VELMURUGU, ANJUM ANSARI, University of Illinois at Chicago — Integration host factor (IHF) from E. coli is a DNA-bending protein that recognizes and binds to its specific sites primarily by the indirect read-out mechanism, in which sequence-dependent DNA dynamics and flexibility play an important role. The crystal structure of IHF bound to a 35-bp long cognate site H indicates that the DNA is kinked at two sites separated by ~9 bp, resulting in a “U-turn” bend of the DNA. To probe the DNA bending dynamics, we use a laser T-jump, and time-resolved FRET on end-labeled DNA substrates. Our results show that DNA bending occurs on the same time-scales as thermal disruption of single base-pairs in B-DNA, suggesting that spontaneous kinking may be the rate-limiting step. To test this hypothesis, we modified the DNA at the site of the kinks by introducing (i) a nick in the sugar-phosphate backbone, and (ii) mismatches to create internal loops. For each of these substrates, the 4-20 fold increase in the binding affinity is reflected in a corresponding increase in the bending rates. Furthermore, the DNA bending rates are independent of the salt concentration. These results indicate that in the transition state ensemble the DNA is kinked, but specific protein-DNA interactions involving ion release have not occurred.

Session V40 DBP: Mechanics of Biomolecular Systems II

8:00AM V40.00001 Non-monotonic wave dispersion in one-dimensional spiral track of cardiac cells. TAE YUN KIM, OKYU KWON, KYOUNG J. LEE, Center for Cell Dynamics and Department of Physics, Korea University — Alternans, periodic cardiac beat-to-beat alternation, is an important precursor to cardiac fibrillation. The underlying mechanism for this phenomenon has been discussed mostly based on the electro-chemical kinetics of constituent cells (myocytes) that comprise the heart system. An important unexplored aspect of this phenomenon is the role of wave dispersion that reflects the cell-to-cell coupling as well as the local kinetic properties. A recent modeling study in fact suggests that a non-monotonic wave dispersion can be a source for alternans. We have designed and built very long (~ 15 cm) in vitro quasi-one dimensional tracks of rat ventricular cells for elucidating the instability responsible for the transition to alternans. One dimensional tracks are favorable, since it excludes the effect of local wave curvature. Systematic investigations based on S1-S2 stimulation protocols are carried out and here we present some preliminary evidence of non-monotonicity in cardiac wave dispersion.

8:12AM V40.00002 Periodic reversals allow bacteria to swarm. YILIN WU, University of Notre Dame, DALE KAISER, Stanford University, YI JIANG, Los Alamos National Laboratory, MARK ALBER, University of Notre Dame — Many bacteria can rapidly traverse surfaces from which they are extracting nutrient for growth. They generate flat, spreading colonies, called swarms because they resemble swarms of insects. We seek to understand how members of any dense swarm track their neighbors while interfering minimally with the motion of others’. We choose myxobacteria as our model system. Individual myxobacteria cells regularly reverse their gliding directions. With a cell- and behavior-based computational model, we show that reversals of gliding direction are essential for swarming and that reversals increase the outflow of cells across the edge of the swarm. We also find that the reversal period predicted to maximize the outflow of cells is the same (within the errors of measurement) as the period observed in experiments with normal myxobacteria cells. This coincidence suggests that the circuit regulating reversals evolved to its current sensitivity under selection for growth achieved by swarming. Our work suggests a crucial component in the general behavioral algorithm governing bacterial swarming.

8:24AM V40.00003 Do Recurred Sensory Organs in Drosophila Form Through a Turing-Type Bifurcation? YUHUIFENG ZHU, Department of Physics University of Houston — We study the recurved bristles on Drosophila wing margin of wild-type and mutant. The expression levels of the achase-caste complex protein determine the epidermal or neural fate of a pro-neural cell. In wide-type flies, the development ends in a state where a recurved bristle grows out nearly every fifth cell. Recent experiments have shown that the frequency of recurved bristles can be changed by adjusting the mean concentrations of the zinc-finger transcription factor Senseless and the micro-RNA miR-9a. With reduced levels of miR-9a, mutant flies grow regular organization of recurved bristles, but with a lower periodicity. We argue that the characteristics of bristle organization are signatures of a Turing-type bifurcation which emerges from a uniform background in reaction-diffusion process, in continua. In contract, fly wing margin consists of a discrete array of cells with possible cross-species interactions. Further, proteins do not diffuse between cells. We argue that the intracellular actions can play the role of diffusion in a discrete cell array. However, the analogs of diffusion coefficients can be positive or negative. Intracellular actions should give a conserved cell number periodicity. We introduce a simple model to study pattern formation in such cellular arrays based on intracellular actions. Also, we observe that periodicity both in length and cell numbers from different group of flies.
8:36AM V40.00004 Sisyphus at the Nanoscale: Bacterial Topotaxis in a Microfabricated Environment.  
GUILLAUME LAMBERT, Princeton University, PETER GALAUDTA, TU Deft, DAVID LIAO, ROBERT H. AUSTIN, Princeton University — The ballistic-like motion of self-propelled particles at low-Reynolds number can be exploited to influence their direction of motion. In particular, it has been demonstrated that by using the right topography (in this case a micro-fabricated array of funnel-like asymmetrical barriers), E.coli bacteria can be “pumped” between two adjacent regions (Galauda 2007, Wan 2008). We built upon this idea and developed a micro-habitat array in which chemotaxis and topotaxis—nutrient- and topology-driven movement, respectively—are in opposition, leading to an inherently unstable environment in which a bacterium is constantly pushed away from the fitness landscape’s summit in a Sisyphean fashion. Surprisingly, we find that the bacterial population as a whole is able to overcome the rectifying array. An in-depth microscopic analysis of the swimmer’s motion is used to quantify the strategies adopted by the bacteria.

1Partially supported by and performance at the CNF ECS-0335765, NBTC ECS-9876771, DARPA, NSERC, and NDSEG

8:48AM V40.00005 Microrheology of swimming bacteria suspension.  
ANDREY SOKOLOV, IGOR ARONSON, Argonne National Laboratory — We study rheology of suspension of swimming bacteria Bacillus Subtilis at high concentrations. Experiments were performed in a free standing fluid film contained in a transparent chamber with adjustable Oxygen/Nitrogen ratio. The swimming velocity of bacteria is controlled by the concentration of dissolved Oxygen: it reduces to zero when Oxygen is completely replaced by Nitrogen. Macroscopic flow in a film is produced by oscillations and rotations of magnetic particles by rotating external magnetic field. To extract the effective viscosity, we measured macroscopic velocity field generated by the particles using PIV of fluorescent markers seeded to the film. We discovered that viscosity of bacterial suspension is increasing with decreasing swimming speed of bacteria due lack of Oxygen.

This work was supported by the US DOE, grant DE-AC02-06CH11357.

9:00AM V40.00006 Microrheology of Actin Network Depends on Probe Size, Surface Chemistry and Depletion Effect.  
JUN HE, JAY TANG, Brown University — Microrheological properties of F-actin were measured by video particle tracking using beads with different size and surface chemistry. We found that the mean square displacements of probe particles scale with bead diameter with an exponent of about -0.45 instead of -1. This scaling behavior results in the measured shear moduli of F-actin network varying with the probe size. The main features of our data can be accounted for by the probe surface stickiness and the opposing depletion effect, both of which are confirmed by confocal imaging of beads in the actin network.

9:12AM V40.00007 Mechanics of biomimetic systems propelled by actin comet tails.  
HYERAN KANG, Department of Physics, Brown University, DHANANJAY TAMBE, School of Public Health, Harvard University, VIVEK SHENOY, Division of Engineering, Brown University, JAY TANG, Department of Physics, Brown University — The motility of intracellular bacterial pathogens such as Listeria monocytogenes is driven by filamentous actin comet tails in a variety of trajectories. Here, we present the in vitro study on the actin-based movements using spherical beads of different sizes coated with VCA protein, a partial domain of N-Wasp, in platelet extracts. Long term two-dimensional trajectories of the spherical beads motility show characteristic difference than those observed for bacteria, which have both elongated shape and asymmetric expression of the polymerization inducing enzyme. The trajectories also vary sensitively with the bead size and shape. These results provide a useful test to our new analytical model including the rotation of the bead relative to the tail.

TIMOTHY LEZON, ERAN EYAL, IVET BAHAR, University of Pittsburgh — Elastic network models (ENMs) are widely employed for approximating the coarse-grained equilibrium dynamics of proteins using only a few parameters. An area of current focus is improving the predictive accuracy of ENMs by fine-tuning their force constants to fit specific systems. Here we introduce a set of general rules for assigning ENM force constants to residue pairs. Using a novel method, we construct ENMs that optimally reproduce experimental residue covariances from NMR models of 68 proteins. We analyze the optimal interactions in terms of amino acid type, pair distances and local protein structures to identify key factors in determining the effective spring constants. When applied to several unrelated globular proteins, our method shows an improved correlation with experiment over a standard ENM. We discuss the physical interpretation of our findings as well as its implications in the fields of protein folding and dynamics.

9:36AM V40.00009 Pulling helices inside bacteria: imperfect helices and rings.  
ANDREW RUTENBERG, Dalhousie University, JUN ALLARD, University of British Columbia — We study steady-state configurations of intrinsically-straight elastic filaments constrained within rod-shaped bacteria that have applied forces distributed along their length. Perfect steady-state helices result from axial or azimuthal forces applied at filament ends, however azimuthal forces are required for the small pitches observed for MreB filaments within bacteria. Helix-like configurations can result from distributed forces, including co-existence between rings and imperfect helices. Levels of expression and/or bundling of the polymeric protein could mediate this co-existence.

9:48AM V40.00010 Bending rigidity of type I collagen homotrimer fibrils.  
SEJIN HAN, University of Maryland, SERGEY LEIKIN, National Institutes of Health, WOLFGANG LOSERT, University of Maryland — Normal type I collagen is an α1(I)/α2(I) heterotrimeric triple helix, but α1(I) homotrimers are also found in fetal tissues and various pathological conditions, e.g., causing bone fragility and reducing tendon tensile strength. It remains unclear whether homotrimers alter mechanical properties of individual fibrils or affect tissues by altering their organization at a higher level. To address this question, we investigated how homotrimers affect fibril bending rigidity. Homotrimer fibrils have been shown to be more loosely packed so that we expected them to be more susceptible to bending. However, homotrimer fibrils were more rigid despite being thinner and more hydrated. To quantify fibril rigidity, we analyzed their shape by Fourier decomposition, determined the correlation function for the direction along each fibril, and calculated the distribution of local fibril curvature. The estimated persistence length of homotrimer fibrils was 3 ~ 10 times longer than for heterotrimer fibrils, indicating much higher bending rigidity of homotrimer fibrils.

10:00AM V40.00011 Surface manipulation of protein filaments.  
LAURENT KREPLAK, DOUGLAS STAPLE, Dalhousie University, MARKO LOPARIC, Biozentrum, University of Basel, HANS-JUERGEN KREUZER, Dalhousie University — Within mammalian tissues, cells move by actively remodeling the structure of collagen fibrils. In order to study this situation, we analyze the force response of two types of filamentous protein structures, desmin intermediate filaments 12 nm in diameter and collagen fibrils 80 nm in diameter. Both types of filaments were adsorbed at a solid-liquid interface and locally moved with an AFM tip at constant velocity against surface friction in the interfacial plane. In the case of collagen fibrils, that have an extensibility below 30% extension, we observed that microns long fibrils could be moved by the tip and deformed into shapes that could not be explain by the linear elastic theory for a stiff rod. In the case of desmin filaments that can be stretched up to 3.5 times their length, we observed local stretching of the filaments and discreet steps in the torsional force measured with the cantilever. In order to describe both types of filaments' behaviors, we described the protein filaments as a chain of beads of mass m linked together by a mass-less polymer linker. By solving the Newtonian equations of motions for the coupled beads in the presence of a point load and a viscous drag due to the surface-filament interactions we were able to reproduced our experimental data and extract information on friction.

This work was supported by grants from NSERC.
impurities, suggesting that these defects play an important role in supersolidity. We have now extended our elastic measurements to both bcc and hcp below 200 mK. It has the same dependence on temperature, frequency, amplitude and bundling, and extension of the constituent fibrin molecules. We develop constitutive models that integrate these quantitative observations and suggest that fibrin extensibility and elasticity are largely manifestations of protein unfolding.

These measurements, and comparisons to new torsional oscillator results, clarify the roles of quantum statistics and crystal structure in the behavior of solid helium. A novel 'cysteine shotgun' method of labeling the in situ proteome reveals differences in assembly or conformation of several abundant cytoskeletal proteins, including vimentin, filamin and myosin.

A.C. Clark, J.T. West, Pennsylvania State University — After a multitude of experimental and theoretical efforts over the past few years attempting to explain the microscopic origin of non-classical rotational inertia (NCRI) signals seen in torsional oscillator (TO) experiments, disorder has emerged as a crucial factor for determining the supersolid behavior. In an attempt to discover the type of disorder relevant to the NCRI effect we have performed TO experiments on solid 4He impurity to a screw dislocation in solid 4He. Monte Carlo simulations addressed the physics of vacancy-induced supersolidity in 4He, Phys. Rev. Lett. 99, 155301 (2007).

We find that certain types of edge and screw dislocations are superfluid while other remain insulating, depending on their orientation, Burgers vector and possible splitting of the core. The mechanism for superfluidity is provided by the strain near the core of the defect exceeding a threshold value. Superfluid dislocations can build a network of phase coherent tubes (the so-called Shevchenko state), which might lead to an observable mass decoupling in experiment. I will also look at the interactions between a Helium-3 impurity atom and a screw dislocation and make contact with recent experiments.

Experiments performed in collaboration with A.C. Clark and M.H.W. Chan with support from NSF grant DMR 0706359.
Using x-ray synchrotron radiation, we have studied the nature of crystals of solid $^3$He at temperatures down to 50 mK. Measurements of peak intensities and lattice parameters do not show indications of the supersolid transition. Between 50 mK and 0.6K the relative change in the lattice parameters is less than $2 \times 10^{-5}$ and that in $\langle u^2 \rangle$ less than $4 \times 10^{-3}$. Scanning with a small (down to $10 \times 10 \mu m^2$) beam, we resolve a mosaic structure within these crystals consistent with numerous small angle grain boundaries. The mosaic shows significant motion even at temperatures far from melting. When grown in aerogel, solid $^3$He polycrystalline, with an hcp crystal structure (as in bulk) and a crystallite size of approximately 100 nm. In contrast to the expectation that the highly disordered solid will have a large supersolid fraction, torsional oscillator measurements show a behavior that is strikingly similar to high quality crystals grown from the superfluid phase. The low temperature supersolid fraction is only $\sim 3 \times 10^{-3}$ and the onset temperature is $\sim 100$ mK. Work done in collaboration with C.A. Burns, M.H.W. Chan, C.N. Koditwakku, L.B. Lurio, A. Said and J.T. West.

Thursday, March 19, 2009 11:15AM - 2:15PM — Session W2 DCM P Q1: Progress in Understanding the Nature of the 5/2 Fractional Quantum Hall State  
Spirit of Pittsburgh Ballroom BC

11:15AM W2.00001 Finite-Layer Thickness Stabilizes the Pfaffian State for the 5/2 Fractional Quantum Hall Effect: Wave Function Overlap and Topological Degeneracy  
MICHAEL PETERSON, University of Maryland — The fractional quantum Hall effect (FQHE) in the second orbital Landau level at even-denominator filling factor $5/2$ remains mysterious and is currently motivating many scientists not only because of its connection to a possible implementation of a fault tolerant topological quantum computer (Das Sarma et al., PRL 94, 166802(2005)). In this work, we theoretically consider the effect of the quasi-two-dimensional nature of the experimental fractional quantum Hall systems on a number of FQHE states in the lowest three orbital Landau levels. Our primary result is that the finite width of the quasi-two-dimensional systems produce a physical environment sufficient to stabilize the Moore-Read Pfaffian state thought to describe the FQHE at filling factor $5/2$. This conclusion is based on exact calculations performed in the spherical and torus geometries, studying wave function overlap and ground state degeneracy. Furthermore, our results open the possibility of creating optimal experimental systems where the $5/2$ FQHE state would more likely be described by the Moore-Read Pfaffian. We also discuss the role of the three-body interaction Hamiltonian that produces the Moore-Read Pfaffian as an exact ground state and particle-hole symmetry in the FQHE at $5/2$. We acknowledge support from Microsoft Project Q. Work done in collaboration with Sankar Das Sarma, Thierry Jojoliceur, and Kwon Park.

11:51AM W2.00002 Understanding the 5/2 fractional quantum Hall effect without the Pfaffian wave function  
CSABA TOKE, Lancaster University — The fractional quantum Hall effect (FQHE) in the second Landau level has attracted attention, because the lowest Landau level theories do not straightforwardly generalize to these states, and several of the proposed models feature excitations with non-Abelian braiding statistics, with possible applications in topological quantum computing. In particular, the FQHE states at $\nu = 5/2$ and $7/2$, which have no lowest Landau level analogons, are usually understood in terms of the paired composite fermion model proposed by Moore and Read. I present an alternative understanding of the $5/2$ FQHE within the composite fermion theory. I argue that the residual interaction between composite fermions plays a crucial role in establishing incompressibility at $5/2$. The low-energy spectrum and the activation gap are estimated with the help of a perturbative procedure that incorporates inter-composite-fermion interactions. This approach is amenable to systematic improvement, and produces ground as well as excited states. It, however, does not relate to non-Abelian statistics in any obvious manner. The emergence of incompressibility due to inter-composite-fermion interactions is also observed other fractions in the second Landau level, notably at $\nu = 2 + 2/5$ and $2+3/8$.

12:27PM W2.00003 Density Matrix Renormalization Group Studies of Incompressible Fractional Quantum Hall States  
ADRIAN FEIGUIN, Microsoft Station Q — In this talk I introduce a powerful technique, the density-matrix renormalization group (DMRG), for studying ground and excited state properties of incompressible FQH states on the sphere. This method not only reproduces the numerical results obtained earlier in the exact diagonalization studies, but we are able to extend our understanding of the ground-state and low-lying excited state properties of these FQH states to substantially larger system sizes. We address a very important open problem in fractional quantum Hall physics, namely, if the half-filled second Landau level state can exhibit non-Abelian statistics. By studying large systems on the sphere, and extrapolating to the thermodynamic limit, we determine that the ground state for this filling fraction is fully polarized for shifts corresponding to both the Moore-Read Pfaffian state and its particle-hole conjugate (anti-Pfaffian). This result is found to be robust against small variations of the interaction, strongly supporting the argument favoring a non-Abelian state. We further extend the application of this technique to identify other incompressible Hall states in the second Landau level.

---

nu=8/3 and 5/2. These measurements suggest significant roles for quasiparticle spin in the competing quantum phases that emerge in the second Landau level.

While the collapse of the spin wave at fillings near nu=1 had been linked to loss of spin polarization due to formation of spin textures, the low-lying excitation modes seen in the N=1 level below nu=3 seem much more complex because a sharp spin wave does not recover for fractional quantum Hall states such as the 7/3 FQH gap is observed to be enhanced by an applied parallel magnetic field, the 5/2 gap is strongly suppressed, in spite of the two gaps being energetically comparable at zero parallel fields in our sample. This calls into question the prevailing theoretical belief that they should behave similarly if both are spin-polarized, and raises doubt as to whether or not the 5/2 state is indeed described by a spin-polarized Pfaffian Moore-Read wavefunction.

1:15AM W3.00001 Single-molecule Force Spectroscopy of Intercellular Adhesion in Cancer, DENIS WIRTZ, Department of Chemical and Biomolecular Engineering, Johns Hopkins University — The progress of several human cancers correlates with the loss of a-catenin from E-cadherin-rich intercellular junctions and loss of adhesion. However, the potential role of a-catenin in directly modulating the adhesive function of individual E-cadherin molecules in human cancer is unknown. Here we use single-molecule force spectroscopy to probe the tensile strength, lifetime, and interaction energy between live human parental breast cancer cells lacking a-catenin and these cells where a-catenin is re-expressed. We find that the tensile strength and lifetime of single E-cadherin bonds between parental cells are significantly lower over a wide range of loading rates. Statistical analysis of the force-displacement spectra reveals that single cadherin bonds between cancer cells feature an exceedingly low energy barrier against tensile forces and low molecular rigidity. These results suggest that the loss of a-catenin drastically reduces the adhesive force between individual cadherin pairs on adjoining cells, explain the global loss of cell adhesion in human breast cancer cells and show that the forced expression of a-catenin in cancer cells can restore both higher intercellular avidity and intermolecular E-cadherin affinity.

1:15AM W3.00002 Studying Cell Motility and Cell Mechanics with “Designer Cells”, BARTOSZ A. GRZYBOWSKI, Department of Chemical and Biological Engineering, Northwestern University — Micro/nanopatterning allows for the creation of cells of identical morphologies and with “designed” organization of the cytoskeleton. Analysis of such “Designer Cells” via high-resolution microscopy allows for studying the intracellular processes related to cytoskeletal dynamics and cancer invasiveness in quantitative detail. In addition, three-dimensional imaging can be used to reconstruct cell shapes and describe these shapes by mathematical functions - it is found that cells are constant-curvature surfaces corresponding to the minima of relatively simple energy functionals describing cell micromechanics. These and other results have implications for physical assays with which to diagnose the metastatic form of cancer.

1:27PM W3.00003 Nanostructured Substrates for Capturing Circulating Tumor Cells in Whole Blood, HSIAN-RONG TSENG, Department of Molecular & Medical Pharmacology, Crump Institute for Molecular Imaging, David Geffen School of Medicine, UCLA — Over the past decade, circulating tumor cells (CTCs) has become an emerging “biomarker” for detecting early-stage cancer metastasis, predicting patient prognosis, as well as monitoring disease progression and therapeutic outcomes. However, isolation of CTCs has been technically challenging due to the extremely low abundance (a few to hundreds per ml) of CTCs among a high number of hematologic cells (109 per mL) in the blood. Our joint research team at UCLA has developed a new cell capture technology for quantification of CTCs in whole blood samples. Similar to most of the existing approaches, epithelial cell adhesion molecule antibody (anti-EpCAM) was grafted onto the surfaces to distinguish CTCs from the surrounding hematologic cells. The uniqueness of our technology is the use of nanostructured surfaces, which facilitates local topographical interactions between CTCs and substrates at the very first cell/substrate contacting time point. We demonstrated the ability of these nanostructured substrates to capture CTCs in whole blood samples with significantly improved efficiency and selectivity. The successful demonstration of this cell capture technology using brain, breast and prostate cancer cell lines encouraged us to test this approach in clinical setting. We have been able to bond our first validation study with a commercialized technology based on the use of immunomagnetic nanoparticles. A group of clinically well-characterized prostate cancer patients at UCLA hospital have been recruited and tested in parallel by these two technologies.
1:03PM W3.00004 A portable circulating tumor cell capture microdevice. RAM H. DATAR, Department of Pathology, Miller School of Medicine of University of Miami — Sensitive detection of earliest metastatic spread of tumors in a minimally invasive and user-friendly manner will revolutionize the clinical management of cancer patients. The current methodologies for circulating tumor cell (CTC) capture and identification have significant limitations including time, cost, limited capture efficiency and lack of standardization. We have developed and optimized a novel parylene membrane filter-based portable microdevice for size-based isolation of CTC from human peripheral blood. Following characterization with a model system to study the recovery rate and enrichment factor, a comparison of the microdevice with the commercially available system using blood from cancer patients demonstrated superior recovery rate and the promise of clinical utility of the microdevice. The development of the microdevice and its potential clinical applicability will be discussed.

1:39PM W3.00005 Detection and Characterization of Circulating Tumor Cells. RICHARD BRUCE, Scripps-PARC Institute for Advanced Biomedical Sciences, Palo Alto Research Center — Circulating tumor cells (CTCs) occur in blood below the concentration of 1 cell in a hundred thousand white blood cells and can provide prognostic and diagnostic information about the underlying disease. While enumeration of CTCs has provided useful information on progression-free and overall survival, it does not provide guidance of treatment choice. Since CTCs are presumed to contain features of their metastatic tissue, the characterization of cancer markers on these cells could help selection of treatment. At such low concentrations, reliable location and identification of these cells represents a significant technical challenge. Automated digital microscopy (ADM) provides high levels of sensitivity, but the analysis time is prohibitively long for a clinical assay. Enrichment methods have been developed to reduce sample size but can result in cell loss. A major barrier in reliable enrichment stems from the biological heterogeneity of CTCs, exhibited in a wide range of genetic, biochemical, immunological and biological characteristics. We have developed an approach that uses fiber-optic array scanning technology (FAST) to detect CTCs. Here, laser-printing optics are used to excite 300,000 cells/sec, and fluorescence from immuno-labels is collected in an array of optical fibers that forms a wide collection aperture. The FAST cytometer can locate CTCs at a rate that is 500 times faster than an ADM with comparable sensitivity and improved specificity. With this high scan rate, no enrichment of CTCs is required. The target can be a cytoplasm protein with a very high expression level, which reduces sensitivity to CTC heterogeneity. We use this method to measure expression levels of multiple markers on CTCs to help predict effective cancer treatment.

11:15AM W4.00001 Magnetically driven spiral ferroelectrics with high transition temperature, TSUYOSHI KIMURA, Division of Materials Physics, Graduate School of Engineering Science, Osaka University — In the past few years, a new class of materials such as orthorhombic rare earth manganites RMnO$_3$, both types of magnetic states are ferroelectric. This competition has important implications for the dynamic magnetoelectric coupling between spin waves and polar phonons resulting in mixed electromagnon excitations. We will discuss microscopic mechanisms of the single-magnon and bi-magnon excitation by an electric field of light in multiferroic and magnetoelectric materials, focusing in particular on the recently observed electromagnon peaks in orthorhombic manganites and Kagome magnets carrying monopole and toroidal magnetic moments. I will show that optical studies can provide useful information about competing multiferroic states in frustrated magnets.

1 Financial support of FOM is gratefully acknowledged.

12:27PM W4.00003 Multiferroic domain wall and its relevance to magnetoelectric phenomena in ferroelectric helimagnets. YOSHINORI ONOSE, University of Tokyo — Recently, magnetically induced ferroelectricity and the giant magnetoelectric (ME) effect in helimagnets (HMs) have attracted much attention. In the ferroelectric HMs, the ferroelectric domain walls (DWs) may be driven by the DW of the magnetic field along $b$-axis induces the $P$-flop $P||c$ to $P||a$. The dielectric constant shows a large enhancement in the course of the $P$-flop. We have investigated the dielectric dispersion of the giant magneto-capacitance (GMC) effect and found that the GMC is attributable to the motion of the DW between $bc$ plane spin cycloid ($P||c$) and $ab$ plane spin cycloid ($P||a$) domains.

In collaboration with H. Murakawa, K. Kagawa, S. Ishiwata, Y. Kaneko, K. Ohgushi, M. Mochizuki, N. Furukawa, and Y. Tokura
Thomson (Lord Kelvin) first posed the problem: what kind of foam of equal-sized bubbles minimises area (or energy)?

Carfrae of the Arup Corporation, it makes a spectacular impression on those who enter. It provokes thoughts on aesthetics, order/disorder, optimisation, and beams that are arranged as in the Weaire-Phelan structure of an ideal foam, with an outer facing of transparent “cushions.” Brilliantly conceived by Tristram "Water Cube," constructed for the Beijing Olympics, is unusual in that its very structure has a physical significance. It consists of a massive framework of steel perhaps the best known quasicrystal pattern.
