8:36AM A1.00002 Scanning tunneling microscopy and spectroscopy of graphene on graphite\(^1\), GUOHONG LI, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854 — Graphene, a single atomic layer of crystalline carbon, exhibits fascinating electronic properties owing to low energy quasiparticles that resemble relativistic Dirac fermions. Recent experiments on graphene deposited on insulating substrates revealed that substrate-induced potential fluctuations obscure the Dirac fermion nature of the carriers. Using low temperature scanning tunneling microscopy (STM) and spectroscopy (STS) we demonstrated that substrate-induced potential fluctuations are substantially reduced when graphene is deposited on graphite and that in these samples the intrinsic structural and electronic properties of graphene become accessible. We observed the honeycomb structure and the V-shaped density of states that vanishes at the Dirac point, characteristic of Dirac fermions. In finite magnetic field we observed the appearance of a single sequence of Landau levels, with square root dependence on level index and field, further attesting to the Dirac fermion nature of the charge carriers. The experiments give access to the fundamental parameters of the electronic spectrum in graphene including the Fermi velocity, electron-phonon coupling constant and electron-electron interactions. In addition they revealed the appearance of a small gap at the Dirac point and an anomaly at the Fermi energy. Work in collaboration with E.Y. Andrei and A. Luican.

9:12AM A1.00003 Tuning the properties of Dirac fermions in graphene\(^1\), ALESSANDRA LANZARA, University California, Berkeley — Graphene, a one atom thick layer of carbon, the supposedly ideal Dirac material, has been under the radar of theorists and experimentalist for many decades. Although novel physical properties were envisioned, graphene, as any other 2D material, was presumed not to exist in its free state because of long wavelength fluctuations that easily destroy purely 2D membranes. The recent success in isolating a single sheet of graphene has certainly challenged this view. In this talk I will present our experimental work in this field using a combination of spectroscopic and microscopy tools. I’ll present experimental evidence of what drives the stability of a graphene membrane and show comparison between exfoliated and epitaxial graphene. I will then discuss the nature of fermions in graphene sheets and how their peculiar electronic structure can be tuned by engineering small terraces of graphene down to nm size, where the physics gets dominated by quantum confinement. The implications of our study on the properties of Dirac materials and their potential role for applications are discussed.

9:48AM A1.00004 The infrared conductivity of graphene\(^1\), ANTONIO CASTRO NETO, Boston University — The discovery of graphene is probably one of the most important events in modern condensed matter physics. Besides being a material that is only one atom thick, it has electronic properties which are usual when compared with ordinary metals and semiconductors. These unusual properties are reflected in its infrared conductivity. We will discuss the physical processes that affect the low frequency conductivity of graphene. We show that while the standard model of graphene is capable of explaining most of the features, it also fails in some aspects, indicating that we still do not have a full understanding of the physical mechanisms that control the electronic properties of this amazing material.

8:00AM A2.00001 Infrared spectroscopy of gated structures based on single- and bi-layer graphene\(^1\) DMITRI BASOV, UCSD — Infrared spectroscopy was employed to investigated the charge dynamics in graphene integrated in tunable gated devices (Nature Physics 4, 532 (2008)). These measurements verified that electrons in single-layer graphene behave like Dirac quasiparticles but most importantly revealed several unexpected results that are beyond the theoretical predictions for idealized graphene. Several of our findings including, a systematic enhancement of the Fermi velocity at low energy and also the “residual” conductivity at frequencies below 2EF are indicative of many-body interactions. Recent infrared study of bilayer graphene uncovered a pronounced asymmetry in the optical conductivity upon injection of electrons and holes (arXiv:0807.3776). We believe this result is suggestive of a marked asymmetry between the valence and conduction bands in bilayer samples.

1Work performed in collaboration with Thilo Kopp

8:36AM A2.00002 Oxide Nanoelectronics On Demand\(^1\), JEREMY LEVY, University of Pittsburgh — Electronic confinement at nanoscale dimensions remains a central means of science and technology. I will demonstrate nanoscale lateral confinement of a quasi-two-dimensional electron gas at the LaAlO\(_3/\)SrTiO\(_3\) interface and show how it can be exploited to create a variety of electronic devices. Using a conducting AFM probe it is possible to create tunnel junctions and field-effect transistors (FETs) with feature sizes comparable to the diameter of a single-wall nanotube. These devices can be modified or erased without complex or irreversible lithographic procedures. This new, on-demand nanoelectronics platform has the potential for widespread technological application.

\[1\] Support from the National Science Foundation is gratefully acknowledged (DMR-0704022).
9:12AM A2.00003 Role of the surface in the interfacial metal-insulator transition in LaAlO$_3$/SrTiO$_3$¹, C. STEPHEN HELLBERG, Naval Research Lab — The observed metal-insulator transition in thin films of LaAlO$_3$ on SrTiO$_3$ depends critically on the film thickness: a reversible transition consistently works best with films 3 unit cells thick. Using first-principles density functional calculations, the role of the surface in the interfacial metal insulator transition will be examined. Water adsorsbs strongly to the surface, dissociating and causing an unusual striped reconstruction. The adsorbates allow the creation of wires and devices at the interface. The positively charged AFM removes OH adsorbates, changing the interface from insulating to metallic. The negatively charged AFM removes H adsorbates, reversing the process.

9:48AM A2.00004 Potential Barrier Lowering and Electrical Transport at the LaAlO$_3$/SrTiO$_3$ Interface, YURI SUZUKI, University of California, Berkeley — Interfacial phenomena form the basis for modern-day devices and continue to be an area of fundamental interest in condensed matter research. Advances in oxide thin film fabrication have enabled the synthesis of atomically precise oxide interfaces and hence have allowed for controlled investigation of interfacial phenomena in these materials. With the rich variety of functionalities exhibited by transition-metal oxides, a wide array of novel properties may be achieved at oxide heterointerfaces. An exemplary study is the discovery of metallicty at the interface of two band insulators, LaAlO$_3$ (LAO) and SrTiO$_3$ (STO), which has stimulated many subsequent experimental as well as theoretical studies. However, there is still intense debate on the origin of metallicty, specifically whether it arises from electronic reconstruction or oxygen vacancies. Using a combination of vertical transport measurements across and lateral transport measurements along the LAO/STO heterointerface, we demonstrate that significant potential barrier lowering and band bending are the cause of interfacial metallicity. Transport measurements across the heterointerface, indicate that barrier lowering and enhanced band bending extends over 2.5 nm into LAO as well as STO. We explain the origins of high-temperature carrier saturation, lower carrier concentration, and higher mobility in the sample with the thinnest LAO film on a STO substrate. Lateral transport results suggest that parasitic interface scattering centers limit the low-temperature lateral electron mobility of the metallic channel.

Monday, March 16, 2009 8:00AM - 11:00AM Session A3 DCMP: Fe-based Superconductors: Pairing Symmetry 301/302

8:00AM A3.00001 Andreev reflection spectroscopy of iron-based superconductors, C.L. CHIEN, Johns Hopkins University — After a reign of over two decades by the cuprate superconductors, several new families of iron-based high-temperature superconductives have recently been discovered. Essential to a superconductor is the nature of the superconducting gap, its value, its structure, and its temperature dependence. Point contact Andreev reflection (PCAR) spectroscopy operating in the ballistic limit is one of few techniques that can quantitatively measure the gap of these new Fe-based superconductors and its temperature dependence. In SmFeAs$_1-y$F$_y$ (0.15 ≤ y ≤ 0.30), we have determined a single gap $2\Delta/k_BT_C \approx 3.5-3.6$ close to the BCS s-wave prediction and with a BCS-like temperature dependence. These results will be compared with various theoretical possibilities and those obtained by other measurements, such as ARPES and penetration depth. While the principles of the PCAR spectroscopy are well established, poor contact control and ballistic heating might lead to the appearance of spurious gaps and pseudogaps in PCAR measurements. In collaboration with T. Y. Chen, S. X. Huang and Z. Tesanovic at JHU and R. H. Liu and X. H. Chen at USTC.

8:36AM A3.00002 Pairing symmetry of iron-based superconductors revealed by ARPES, HONG DING, Institute of Physics, Chinese Academy of Sciences — The recent discovery of superconductivity in iron-arsenic compounds with a transition temperature ($T_c$) as high as 56 K ended the monopoly of copper oxides in the family of high-$T_c$ superconductors. In this talk I will report our angle-resolved photoemission observation of the superconducting gap, including its momentum, temperature, and Fermi surface (FS) dependence in single crystals Ba$_2$K$_4$Fe$_2$As$_2$ ($T_c = 37$ K). We found two nodeless and nearly isotropic superconducting gaps around their respective FS sheets: a large gap ($\Delta \sim 12$ meV) on the two small hole-like and electron-like FS sheets, and a small gap ($\sim 6$ meV) on the large hole-like FS. The isotropic pairing interactions are strongly orbital dependent, as the ratio $\Delta_1/\Delta_2$ switches from weak to strong coupling on different bands. In addition, we have observed a dispersion kink that is likely related to a spin mode. These results reveal the importance of inter-band interactions in the pairing mechanism, and support the anti-phase s-wave pairing symmetry in the Fe-based superconductors.

9:12AM A3.00003 Magnetic penetration depth of oxy-ferropnictide superconductors, ANTONY CARRINGTON, University of Bristol — The determination of the symmetry of the superconducting order parameter is an important first step toward uncovering the mechanism of superconductivity in any material. In this regard, measurements of the magnetic penetration depth $\lambda$ have played an important role. Although not a true bulk probe, like specific heat, penetration depth measurements in the Meissner state probe a few thousand Angstroms below the crystal surface and so should be reasonably representative of the bulk. In this talk I will present data for the in-plane magnetic penetration depth of three different families of oxy-ferropnictide superconductors, measured on single crystals using a sensitive radio frequency tunnel diode oscillator technique. Our results for samples of SmFeAs$_1-y$F$_y$ (y ≤ 0.2) with $T_c \approx 45$ K show that $\lambda(T)$ has an exponential temperature dependence suggesting that the Fermi surface is fully gapped. However, data for Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ ($T_c \approx 22$ K) show power-law behavior, $\Delta \lambda(T) \sim T^{1.7}$, at low temperature, possibly suggestive of line-nodes. Finally, data for LaFePO ($T_c \approx 6$ K) also show a power-law behavior for $\lambda(T)$, but in this case the temperature dependence is almost perfectly linear down to $T \approx 100$K. The results suggest that the gap symmetry may not be universal in all the oxy-ferropnictide superconductors.

9:48AM A3.00004 Antiferromagnetic Correlation and the Pairing Mechanism of the Cuprates and Iron Pnictides: A View From the Functional Renormalization Group Studies, DUNG-HAI LEE, U.C. Berkeley — We study the pairing symmetry of the iron pnictide superconductor using the functional renormalization group method. By comparing the results for the cuprates and the iron pnictides a coherent picture emerges. It suggests that antiferromagnetic correlation causes pairing for both materials. In collaboration with Fa Wang, Hui Zhai, Ying Ran, and Ashvin Vishwanath, University of California, Berkeley.

¹Work supported by DOE.
10:24AM A3.00005 Superconductivity, magnetism, and pairing symmetry in Fe-based superconductors\textsuperscript{1}.
ILYA EREMIN, Max-Planck Institute for Physics of Complex Systems, Dresden — We analyze antiferromagnetism and superconductivity within the renormalization group (RG) technique in novel Fe-based superconductors. We find that the T dependencies of the spin susceptibility and NMR relaxation rate for such state are exponential only at very low T, and can be well fitted by power-laws over a wide T range below Tc. We further show that below Tc excitonic resonance appears in the spin excitations spectrum.

\textsuperscript{1}Work done in collaboration with A.V. Chubukov, D. Efremov, and M.M. Korshunov

Monday, March 16, 2009 8:00AM - 11:00AM — Session A4 DPOLY: Polymers and Energy Applications

8:00AM A4.00001 Ion solvation and its effects on the miscibility of binary polymer blends.
ZHENGANG WANG, Division of Chemistry and Chemical Engineering, California Institute of Technology — We study the effects of adding salt ions on the miscibility of a binary blend of polymers having different dielectric constants. The competition between the preference of the ions to be solvated by the component of the higher dielectric constant and the entropic tendency for the ions to be distributed uniformly results in non-trivial effects on the miscibility. We first study the thermodynamics of the polymer blend-ion mixture using a simple Born model in a uniform dielectric medium of the average composition of the polymer blend. We then study the effect of local enrichment of the higher dielectric constant polymer near the ion. We find that when the dielectric constants of the polymers are both low, adding salt decreases the miscibility, while when the dielectric constants of the polymers are both high, the addition of salt enhances the miscibility. When the blend consists of a high dielectric constant polymer and a low dielectric constant polymer, miscibility is decreased if the low dielectric constant component is the majority and is increased if the high dielectric constant component is the majority. The effect becomes significant at ion concentrations corresponding to an order of one ion per polymer chain. The quantitative change in the effective $\chi$ parameter depends on the functional form of the composition dependence of the dielectric constant of the mixture. We also illustrate the difference between fixed ion concentration and fixed chemical potential of the ions.

8:36AM A4.00002 The Nanostructure of Nafion for Fuel-Cell Membranes from Small-Angle Scattering and NMR Analysis\textsuperscript{1}.
KLAUS SCHMIDT-ROHR, Ames Laboratory and Dept. of Chemistry, Iowa State University, Ames, IA 50011, USA — We have investigated the long contentious nanometer-scale structure of the Nafion ionomer used in proton exchange membranes of H$_2$/O$_2$ fuel cells. Using a simple algorithm based on 3D numerical Fourier transformation, we have quantitatively simulated previously published small-angle scattering data of hydrated Nafion. The characteristic "ionomer peak" arises from long, parallel but otherwise randomly packed water channels surrounded by the partially hydrophilic sidebranches, forming inverted-micelle cylinders. The channels are stabilized by the considerable stiffness of the Nafion backbones, detected by $^{13}$C and $^{19}$F NMR. An upper limit of 300 nm to the persistence length of the water channels has been estimated from $^{2}$H NMR of $^{2}$H$_2$O in the channels. At 20 vol% water, the water channels have diameters between 1.8 and 3.5 nm, with a 2.4-nm average. The hydration-induced changes in small-angle scattering patterns and in the surface-to-volume ratio have also been analyzed in quantitative detail. Nafion crystallites ($\sim$10 vol%), which form physical crosslinks crucial for the mechanical properties of Nafion films, are elongated and parallel to the water channels, with cross sections of $\sim$5 nm$^2$. Simulations for a dozen other models of Nafion, including Glarke’s cluster and the polymer-bundle model, do not match the scattering data. The water-channel model is the first without constraints of $\sim$1.2 nm diameter; it can explain important features of Nafion, including fast diffusion of water and protons through Nafion and its persistence at low temperatures.

YUE-LIN LOO, Princeton University — Organic solar cells have been proposed as low-cost and sustainable alternatives for power generation. To realize the low cost aspects of organic solar cells, conventional vacuum deposition technologies are to be replaced with solution processing. Our group has focused on the development of solution processable conductive polymers. Conductive polymers, like polyaniline, are generally doped with small-molecule acids. Though highly conductive, such materials are not processable. To overcome this intractability, polymer-acid dopants have replaced small-molecule acids. While the introduction of polymer acids render the conductive polymer solution processable, such gains in processability are accompanied by reduced conductivities. With a post-processing solvent-annealing treatment, however, we have been able to dramatically improve the electrical properties of polymer-acid doped conductive polymers; these polymers make efficient anodes in organic solar cells. To further improve the efficiencies of organic solar cells, we have introduced fractional amounts of additives within the active layer of the device. Depending on the hydrophobicity of the additives, they preferentially segregate into the electron donor phase, effectively enhancing phase separation between the electron donor and electron acceptor. This change in morphology increases charge separation; we see a two-fold increase in the short-circuit current in such devices over those without additives in the active layer.

9:48AM A4.00004 Charge Transport and Storage within Radical Redox Polymers as Electroattractive Materials in Energy Devices.
HIROYUKI NISHIDE, Waseda University — No abstract available.

10:24AM A4.00005 Polymers as active components in harnessing solar energy.
JAYANT KUMAR, University of Massachusetts, Lowell — In the last couple of decades molecular and polymeric photovoltaic cells have attracted considerable attention as a possible low cost alternative to conventional semiconductor solar cells. While considerable advances in improving device efficiencies have been made, significant challenges in developing efficient, reliable and low cost solar cells using polymers as an active component remain. Some of these advances and challenges as well as ongoing efforts to mass manufacture solar cells modules will be discussed.

Monday, March 16, 2009 8:00AM - 11:00AM — Session A5 FIAP: Nanostructuring with Ions

401/402
8:00AM A. VAN KAN, CIBA, Physics Dept, NUS — Proton beam writing (PBW) is a new direct write lithography using MeV protons, and is unique because of its ability to fabricate 3D structures of high aspect ratio structures directly in resist material like PMMA, SU-8 and HSQ. The introduction by CIBA, Singapore of a dedicated PBW facility, capable of writing at the micro- and nano-scale has facilitated high aspect ratio nanostructuring. PBW has demonstrated high aspect ratio walls in HSQ down to the 20nm level. In recent experiments details down to sub 20 nm have been achieved in PMMA. Monte-Carlo calculations have shown that structuring down to the nanometer level is feasible. All this is possible because of the virtual absence of proximity effects (unwanted resist exposure by stray secondary electrons). The design and performance of this unique nanopatterning facility will be discussed. Two potential fields of application (nanofluidics and nanowire integration) of PBW will be discussed. Currently nanofluidics devices have typically only one critical dimension below 100 nm. Here we will introduce PBW as a powerful technique to fabricate molds for replication of PDMS nanofluidic circuits down to the sub 100 nm level in two dimensions. Initial chips with dimension down to 150 nm have successfully been used to study DNA folding in quasi-1d nanochannels in tandem with fluorescence imaging. Since the size of these PDMS nanochannels is not limited by the PDMS or PBW further miniaturization down to the sub 100 nm level is a realistic goal and initial results will be discussed. Nanowires are a potential building block for nano-electronic devices, and one critical problem is the integration of nanowires to form contacts. Porous alumina templates and high energy ion-tracks have been used for the production of nanowire templates in a random orientation. Since PBW is the only true 3D direct write nanolithographic technique it can be used to fabricate nanowire templates in a controlled manner.

9:12AM ANDREAS DIRK WIECK, Ruhr-Universität Bochum, D-44780 Bochum — The maskless implantation of FBIs in semiconductors creates a local dop. In n-type conducting sheets, p-lines are written to insulate n-regions laterally from each other or vice versa. In this way, conducting areas can be biased with respect to each other. Narrow paths are easily driven into depletion, creating lateral transistor channels. The advent of multi-focused-ion-beams allows a more parallel writing of such integrated circuits. For ion beam milling, a new long-life Bismuth (Bi) source is developed and employed [1]. Bi is the heaviest, non-radioactive element and has thus a maximal impact on the material to be sputtered locally. It is non-toxic, well available, mono-isotopic, and inexpensive, has a low melting temperature, and comes even in clusters and the single charged particles make up 95% of the whole FIB-beam. This means that the chromatic errors of the electrostatic Einzel-lenses in the FIB system are not important. Since heavy ions are slower than light ones at the same energy, Bi penetrates to a minimal depth into the target, leaving minimal contaminations. The sputter rate is about 5 times higher than the one of the usual Ga. Since Bi is the only element in this source, it is not necessary to separate it from other ions by a mass filter. Bi is thus a good candidate to improve the performance of spatter-FBIs ultimately or replacing Ga. We developed FBIs liquid metal ion sources of nearly all application elements in the periodic table. In this way, practically all dopants can be introduced into semiconductors after epitaxial growth in a full ultra-high vacuum process, which enhances the flexibility of the material choice enormously.

9:48AM — The helium ion microscope (HeIM) is a new, powerful instrument for nano-meterology and nanotechnology. As an emerging imaging and measurement tool it offers several advantages over the traditional scanning electron microscope (SEM) currently in use in research and manufacturing facilities across the world. First, resolution 2 to 4 times better than that from comparable SEMs is theoretically possible, due to the very high source brightness and the short wavelength of the helium ions. Ion images with unprecedented resolution have been routinely obtained on a wide range of samples with sub-nanometer features. More importantly, the interaction volume of the helium ion beam in the sample is substantially different in its size and shape from that of the electron beam in an SEM. As a consequence, the signals generated, especially secondary electrons, reveal more surface details. Imaging by the HeIM can further benefit from the superb depth of field and the fact that He ion imaging is less susceptible to sample charging. In addition, it is possible to compensate for charging by the use of an electron flood gun. Scattered He ions produced as a result of Rutherford scattering of the incident ions on the target nuclei can provide material contrast information that can be used for quantitative compositional analysis. Beyond imaging, the HeIM is a potent tool for milling and modifying surface structures at the nanometer scale, due to the relatively low mass of the helium ion, the narrow ion beam, and especially the low beam currents. It is possible to drill close to 10 nm diameter holes and mill other nanoscale structures that cannot be fabricated with any other method. It is expected that, as with the electron beam, it is feasible to deposit and deposit various materials with He ion beam irradiation. The work is at its exploratory stage, and likely soon will yield more exciting results. This presentation will report on some of the newest research work on the NIST helium ion microscope. 

10:24AM JOHN MELNGAILIS, University of Maryland — Both focused ion beams and electron beams can be used for direct, maskless, resistless nanofabrication as well as for lithography. So far the direct fabrication has been limited to applications such as photomask repair, circuit restructuring, failure analysis, and the creation of various highly specialized structures. Recent developments in maskless fabrication, so far aimed mainly at to resist exposure, suggest that this picture might change. For example, IMS in Vienna, Austria is developing an instrument that can be characterized as an ion beam or electron beam dot matrix printer. The total current on the sample available from this kind of instrument is at least three orders of magnitude larger than from a single beam instrument. This may lead to new applications of charged particle beam fabrication, as well as enable applications considered in the past but rejected because of very low throughput. An example of one such application is the direct writing of the identity in RFID tags using ion beam implantation. Recently we have also shown that electron beams can be used to deposit relatively pure platinum from an inorganic precursor gas, Pt(PF3)4. Such metal deposits can be used as contacts to carbon nanotubes, semiconductor nano wires, organic fibers, or other structures where conventional lithography is impractical.

1Some of the material for this talk is provided by Hans Loeschner and Elmar Platggerummer from IMS Nanofabrication AG, Vienna Austria
circuits, which will allow us to discern the function of natural systems and aid us in engineering synthetic systems. We have endeavored to address the following two questions: What makes the Start transition irreversible? How does the cell pool resources to achieve this transition? This motivates our use of the budding yeast model organism, whose Start checkpoint integrates multiple internal (e.g., cell size) and external signals into an irreversible decision to enter the cell cycle. We have undertaken a systems biology approach to address these questions by applying the tools of computational and systems biology. In particular, we have used systems biology to develop a mathematical model to describe the cell cycle, and we have used this model to make predictions and test hypotheses. We have also used directed evolution to identify novel factors that affect the Start transition. We have found that Start is regulated by a complex network of interactions between multiple factors, and that the network is highly dynamic and responsive to changes in the environment. This work has provided new insights into the regulation of the cell cycle and the development of new strategies for controlling cell proliferation in disease. In addition, it has highlighted the role of systems biology in advancing our understanding of complex biological processes.
9:12AM A7.00003 Signal integration, gain, and integral feedback in the *Escherichia coli* chemotaxis network, NED WINGREEN, Princeton University — Bacteria are able to sense chemicals in their environment, allowing cells to swim towards nutrients (attractant chemicals) and away from repellents (toxic chemicals). The chemotaxis network of the model bacterium *Escherichia coli* possesses remarkable signaling properties including high sensitivity to small changes in chemical concentration over a wide range of ambient concentrations. These signaling properties rely on the architecture of the circuit, including elements that implement signal integration, gain, and integral feedback. All of these elements rely on receptor clustering, which occurs at multiple length scales. At a small scale, the chemotaxis receptors form stable homodimers which then assemble into a larger complex in which receptors of different chemical specificities are intermixed, with trimers of dimers believed to be the smallest signaling unit. At a larger scale, ~10,000 receptors form large polar and lateral receptor clusters. I will discuss recent experimental and theoretical progress in understanding how the biophysics of chemotaxis receptors leads to the remarkable signaling properties of the chemotaxis network.

9:48AM A7.00004 Dissecting the nitrogen assimilation system of *E. coli*: from molecules to physiology, TERRY HWA, U.C. San Diego — Nitrogen assimilation is a major branch of cellular metabolism. For enteric bacteria such as *E. coli*, all of the nitrogen groups needed in biosynthesis are converted from ammonia by a relatively simple system comprised of 3 enzymes and 3 intermediate metabolites. This system is intricately regulated, at both the transcriptional and post-translational levels according to the nitrogen and carbon/energy status of the cell. While specific pieces of this regulation have been known for a long time, the strategy of regulation relating nitrogen influx to cellular demand is poorly understood. Clearly, the paradigm of end-product feedback inhibition well-established for the regulation of individual metabolic pathways is inadequate since there are too many products involving nitrogen. Through extensive experimental studies including quantitative characterization of the levels of key metabolites and enzymes for a carefully chosen spectrum of growth conditions and mutants, we obtain a dynamic picture of how the cell matches its rate of nitrogen assimilation with physiological needs through the intermediate metabolites.

1This research is supported by the Human Frontiers in Science Program and by the NSF.

10:24AM A7.00005 Building a genetic transistor in yeast: How protein sequestration generates a tunable ultrasensitive or all-or-none response, NICOLAS BUCHLER, Rockefeller University — Protein sequestration, where an active protein (A) is bound in an inactive complex by an inhibitor, is a common molecular mechanism in natural regulatory circuits. The inhibitor serves as a molecular sink that can buffer and titrate low concentrations of A. If sufficient protein A is produced, then the sink is saturated and A will exhibit an ultrasensitive or all-or-none response. Theory demonstrates that this ultrasensitivity grows both as a function of inhibitor concentration and increased binding affinity. Although protein sequestration can theoretically generate tunable ultrasensitive responses, this regulatory principle has never been tested experimentally. We used a synthetic genetic circuit in budding yeast to show that sequestration of a basic leucine zipper transcription factor (C/EBPa) by a dominant-negative inhibitor converts a graded transcriptional response into an ultrasensitive response, with apparent Hill coefficients up to 12. We developed a simple quantitative model for this genetic network that demonstrates how the threshold and degree of ultrasensitivity depend upon the abundance of the inhibitor, exactly as observed in our experimental results. Many proteins in natural regulatory networks involve the formation of inactive protein-protein complexes, e.g. stoichiometric inhibitors of kinases and dominant-negative inhibitors of transcription factors. Our results demonstrate that protein sequestration can provide potent and tunable ultrasensitivity in genetic networks. Ultrasensitive or all-or-none responses are critical for robust bistable or oscillatory genetic networks, and our findings suggest that protein sequestration might play an unappreciated role in facilitating the evolution of bistable or oscillatory circuits in natural systems.

Monday, March 16, 2009 8:00AM - 11:00AM —
Session A8 GQI: Quantum Information meets Many-Particle Physics 414/415

8:00AM A8.00001 Preparing ground states of quantum many-body systems on a quantum computer, DAVID POULIN, Département de Physique, Université de Sherbrooke, QC, Canada — The simulation of quantum many-body systems is known algorithm to prepare the ground state of a classical many-body system on a quantum computer [3,2]. This provides strong evidence that for a quantum computer can naturally implement the dynamics of a quantum system — i.e. solve Schrödinger’s equation — there was until now no general method for a carefully chosen spectrum of growth conditions and mutants, we obtain a dynamic picture of how the cell matches its rate of nitrogen assimilation with physiological needs through the intermediate metabolites.

8:36AM A8.00002 Topological Quantum Order from Symmetry and the Role of Temperature, GERARDO ORTIZ, Indiana University — What does a fractional quantum Hall liquid and Kitaev’s proposals for topological quantum computation have in common? It turns out that they are physical systems that exhibit degenerate ground states with properties seemingly different than ordinary (Landau-type) phases of matter, such as ferromagnets. For example, those (topologically quantum ordered) states cannot be characterized by (local) order parameters such as magnetization. How does one characterize this new order? I will present a unifying framework which will allow us to engineer physical systems displaying topological quantum order. What are the physical properties of these new orders? How robust are they to temperature effects? What are they useful for? Topologically quantum ordered states of matter seem to be ideal physical systems to store and manipulate quantum information since they are believed to be robust against decoherence with an environment, and thus appropriate for building a quantum computer and quantum memories. I will discuss the role of temperature in the protection of quantum information. Have we finally found a new technological application for quantum Hall liquids?

1Work done in collaboration with Zohar Nussinov
9:12AM A8.00003 Tensor-entanglement renormalization. ZHENGCHENG GU, M.I.T. — Traditional mean-field theory is a simple generic variational approach for analyzing various symmetry breaking phases. However, this simple approach only applies to symmetry breaking states with short-range entanglement. Tensor-entanglement renormalization group (TERG) is a generic approach for studying 2D quantum phases with long-range entanglement (such as topological phases) based on a new class of trial wavefunctions - the tensor product states (TPS), also known as projected entangled pair states (PEPS). Those TPS (PEPS) are built from local tensors. They can describe both states with short-range entanglement (such as the symmetry breaking states) and states with long-range entanglement (such as topological/classical order). TERG is a real space renormalization group algorithm that can efficiently simulate expectation values for TPS wave functions in 2D and higher dimensions. As an attempt in this direction, we demonstrate our algorithm by studying several simple 2D quantum spin models, including both symmetry breaking phase transitions and topological phase transitions. However, as any variational method, the TERG approach could not find all the degenerate ground states for gapped systems and generally could not give out (approximately) correct critical exponent for critical systems. To solve these problems, we study the renormalization group flow of a Lagrangian (partition function) by representing its path integral through a tensor network. Using a tensor-entanglement-filtering renormalization group (TEFRG) method that removes local entanglement and coarse grains the lattice, we show that the renormalization flow of the tensors in the tensor network has a nice fixed-point structure. The isolated fixed-point tensors characterize various phases. The tensor fixed points can describe both the symmetry breaking phases and topological phases. The ground state degeneracy for gapped systems can be easily read out from the fixed point tensor. The scaling dimensions, the central charge and dynamic correlation functions for the critical systems that describe the continuous phase transitions between symmetry breaking and/or topological phases can also be calculated from the TEFRG approach.

9:48AM A8.00004 Can multi-particle systems be too entangled to be useful for quantum computation? JENS EISERT, Blackett Laboratory, Imperial College London — In the context of “quantum information meets many-particle physics”, we pose the question of the role of entanglement in the quantum computational power of many-particle quantum systems (1) and the magnitude of quantum fluctuations (2). Our results show that computational universality is actually a rare property in quantum states. For the proof we make use of a link between the quantum probabilistic method and ideas on quantum many-body systems. This work stresses a new aspect of the question concerning the role entanglement plays for quantum computational speed-ups. We will also investigate a new classification of primitives from projected entangled pair states (PEPS) that can be used in order to systematically construct new models for measurement-based computation (2,3) and demonstrate for example that computational efficiency is actually a rare property in quantum states.

Monday, March 16, 2009 8:00AM - 11:00AM — Session A9 GSNP: Systems Far from Equilibrium I 303

8:00AM A9.00001 Directed motion and useful work from an isotropic non-equilibrium distribution. DANIEL KOSOV, University of Maryland, MAXIM GELIN, TU Munich — Since the Maxwell demon thought experiment, the extraction of useful work and directed motion from unbiased non-equilibrium distributions has been the source of fascination, intrigue, and confusion. Being a fundamental scientific problem, it is also of significant practical interest for various biological and nanotechnological applications. We propose a new type of “motor” driven by the heat flow between non-equilibrium velocity and equilibrium coordinate distributions. Namely, we demonstrate that a gas of classical particles trapped in an external asymmetric potential undergoes a quasiperiodic motion, if the temperature of its initial velocity distribution Tne differs from the equilibrium temperature Teq. The “loading” and “unloading” of the gas particles change directions of their motion, thereby creating a possibility of shuttle-like motion. The system works as a Carnot engine where the heat flow between kinetic and potential parts of the non-equilibrium distribution produces the useful work. Phys.Rev. E 77, 011115 (2008)

8:12AM A9.00002 Coherent transport and heat, entropy fluctuations in a thermal Brownian motor. RONALD BENJAMIN, University of Alabama at Birmingham — We investigate the heat, entropy and work fluctuations in a thermal Brownian motor driven by spatially inhomogeneous temperature. We show that the total heat, entropy production and the work fluctuations satisfy the fluctuation theorem in the steady state over finite time trajectories. The transport coherence of the motor, as determined by the Peclet number is also investigated as a function of various parameters of the system.

1 I thank the University of Alabama, Birmingham Graduate school for GAFP Fellowship.
36: A00004 Rapidly forced quantum Brownian motion. MUSTANSIR BARMA, MALAY BANDYOPADHYAY, Department of Theoretical Physics, Tata Institute of Fundamental Research, Mumbai 400005, India — We study the steady state behaviour of a confined quantum Brownian particle which is subjected to a space-dependent, rapidly oscillating time-periodic force. To leading order in the period of driving, the result of the oscillating force is to produce an effective static potential which has a quantum contribution $V_q$, which adds on to the classical result. This is shown by using a coherent state representation of bath oscillators which leads to a c-numbered generalized quantum Langevin equation. We evaluate $V_q$ exactly in the case of an Ohmic dissipation bath and show that it takes on different forms in different regimes, determined by the ratio of the thermal wavelength to the spatial spread of the driving force.

4: A00005 Deciding how far is far from equilibrium. ANTONIO CADILHE, ARTHUR VOTER, Theoretical Division, T-1, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545 — Nonequilibrium systems have both fundamental and technological interest for their unusual behavior with research efforts mainly focused on their properties. Surprisingly, little research effort has been put on diagnosing how far a system is from equilibrium. Clearly, addressing such an issue is of fundamental and technological relevance. To this end, we present results of how a particle in contact with a heat reservoir is being driven away from equilibrium by a time dependent potential well. The methodology can be straightforwardly extended to systems with the influence of under the more realistic potentialials. More particles and under the influence of more realistic potentialials.

8: A00006 Random Sequential Adsorption on patterned substrates: jammed state structure and kinetic properties N. A. M. ARAUJO, J. F. MARQUES, GCEP-Centro de Fisica da Universidade do Minho, Braga, Portugal, A. CARDILHE, GCEP-Centro de Fisica da Universidade do Minho, Braga, Portugal. T-1 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM, USA, V. PRIVMAN, Department of Physics, and Center for Advanced Materials Processing, Clarkson University, Potsdam, NY, USA — The irreversible adsorption on a patterned substrate is studied through extensive Monte Carlo simulations. As a pattern, we adopted square cells positioned at the vertices of a square lattice. Particles attempting adsorption can only stick to the substrate if they do not overlap previously adsorbed ones (excluded volume interaction) and if their geometrical centers land inside a cell. Once a particle is adsorbed, it does not detach from or diffuse on the substrate, thus representing an extended random sequential adsorption model. The distribution of particles sizes follows a truncated gaussian-size distribution with values of the size dispersion varying from zero (monodisperse) to 20% (polydisperse) of the mean particle radius. We address the influence of both the pattern and size dispersion on the jammed state structure. We also present results on how the kinetics of approach to the jammed state is affected by the particular values taken by parameters like cell size and cell-cell separation and show that they can lead to either exponential or power-law functional dependences.

8: A00007 Phase Transition with Non-Thermodynamic States in Reversible Polymerization, ELI BEN-NAIM, Los Alamos National Laboratory, PAUL KRAPIVSKY, Boston University — We investigate a reversible polymerization process in which individual polymers aggregate and fragment at a rate proportional to their molecular weight. We find a nonequilibrium phase transition despite the fact that the dynamics are perfectly reversible. When the strength of the fragmentation process exceeds a critical threshold, the system reaches a thermodynamic steady state where the total number of polymers is proportional to the system size. The polymer length distribution has a sharp exponential tail in this case. When the strength of the fragmentation process falls below the critical threshold, the steady state becomes non-thermodynamic as the total number of polymers grows sub-linearly with the system size. Moreover, the length distribution has an algebraic tail and the characteristic exponent varies continuously with the fragmentation rate.

8: A00008 Stochastic continuum theory of active nematics, SHRADHA MISHRA, Syracuse University, FRANCESCO GINELLI, HUGUES CHATE, CEA Service de Physique de l’Etat Condense, CEN Saclay, 91191 Gif-sur-Yvette, France, SANJAY PURI, School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore 637371, Singapore, SIRIRAM RAMASWAMY, Centre for Condensed Matter Theory, Department of Physics, Indian Institute of Science, Bangalore, India — We derive a stochastic continuum theory of active nematics by direct coarse-graining of a generic microscopic model and study numerically. This allows to characterize the microscopic origin of the various terms found and to determine the non-trivial structure of the noises. We show in particular that two terms coupling density and order the non-equilibrium active current argued before to be at the origin of giant density fluctuations, and a multiplicative conserved noise are necessary to obtain a faithful description of the original model.

8: A00009 Fokker-Planck Dynamics in the Energy Domain1, GCINA MAVIMBELA, Dept of Physics and Astronomy, Ohio University, HORACIO E. CASTILLO, Dept of Physics and Asatromony, Ohio University, CLAUDIO CHAMON, Physics Dept, Boston University — We derive a Fokker-Planck Equation (FPE) in the energy domain for a system in an infinite heat bath by coarse-graining its microscopic Master Equation. The resulting FPE carries information on the dynamics through a function $\lambda(E)$, which is a sum over all possible transitions given a state of energy $E$. We investigate the effects of changing the assumptions about the transition rates without changing the Hamiltonian of the model. By determining the eigenvalues of the equivalent Schrodinger Equation (SE), we get the relaxation spectrum of the FPE. We find that in the thermodynamic limit the equivalent SE approaches the classical limit, and we use the WKBJ approximation to solve it. We illustrate the use of the method by applying it to several examples, including a system of harmonic oscillators, and a paramagnet in an external magnetic field.

9: A00010 Doing the Impossible: Very Rare Events in the Harmonic Measure. DAVID ADAMS, LEONARD SANDER, ROBERT ZIFF, University of Michigan — We have developed a method of obtaining accurate data of rare events using biased sampling of random walkers. We have robust the harmonic measure, analogous to the perpendicular electric field on a charged conductor, for percolation, Ising model, and Diffusion Limited Aggregation (DLA) clusters. We measured probabilities down to $10^{-300}$ for percolation and Ising model clusters. These small probabilities allowed us to verify the theoretical predictions for the harmonic measure made by Duplantier. For DLA, which has no theory, we obtained probabilities down to $10^{-110}$. The previous lowest probability was obtained using iterative conformal maps and was limited to small clusters and comparatively high probabilities. For all systems we have obtained the generalized dimension $D_q$, the singularity spectrum $f(\alpha)$, and the distribution of probabilities.
10:00 AM A9.00011 Anisotropic 2-dimensional Robin Hood model. SERGEY BULDYREV, GABRIEL CWILICH, FREDY ZYPMAN, Department of Physics - Yeshiva University — We have considered the Robin Hood model introduced by Zaitsev [1] to discuss flux creep and depinning of interfaces in a two-dimensional system. Although the model has been studied extensively analytically in 1-d [2], its scaling laws have been verified numerically only in that case. Recent work suggest that its properties might be important to understand surface friction [3], where its 2-dimensional properties are important. We show that breaking the rotational symmetry between the different ways of introducing that anisotropy lead to different exponents and scaling laws, in analogy with directed percolation, with which this model is closely related [4]. We show that breaking the rotational symmetry between the x and y axes does not change the scaling properties of the model, but the introduction of a preferential direction of accretion (‘robbing’ in the language of the model) leads to new scaling exponents. [1] S.I.Zaitsev, Physica A189, 411 (1992) [2] M. Paczuksi, S. Maslov and P.Bak, Phys Rev. E53, 414 (1996) [3] S. Buldyrev, J. Ferrante and F. Zypman Phys. Rev E64, 066110 (2006) [4] G. Odor, Rev. Mod. Phys. 76, 663 (2004).

10:12 AM A9.00012 A Cellular Automaton Model of Catastrophic Failure1. C. A. SERINO, W. KLEIN, Boston University — We introduce a two-dimensional cellular automaton model for studying the catastrophic failure of materials under stress. Our model is similar to the Olami-Feder-Christensen earthquake model [Z. Olami et al., Phys. Rev. Lett. 68, 1244 (1992)] except that after a site fails f-times, it no longer can receive stress from its neighbors. In the limit that the interaction range, R, goes to infinity, our model is equivalent to the global load sharing fiber bundle model of Pierce [F. T. Pierce, J. Text. Ind. 17, 355 (1926)] and Daniels [H. E. Daniels, Proc. Roy. Soc. London A 183, 405 (1945)]. By varying the interaction range, we observe two qualitatively different failure modes. For R ≈ 1, catastrophic failure resembles a nucleation-like event which grows symmetrically from a single initiating site and fails every site in the lattice. In contrast, for R ≈ 1 a percolating cluster of failed sites spans the system despite the many active sites that persist, even after catastrophic failure. We use the stress-fluctuation metric to study the ergodicity of our model and hence the validity of equilibrium descriptions of fracture.

10:24 AM A9.00013 Heat transport in quantum spin chains: the relevance of integrability1. JINSHAN WU, MONA BERCU, UCSB — Heat transport in quantum spin chains is investigated through the master equation in Lindblad form derived from the Schrödinger equation of a system coupled with two baths via the projector operator technique. We find that the Fourier’s Law of heat transport is obeyed in some systems. Although a general proof has not been established, after a survey of various quantum spin chains, our results suggest the criteria of anomalous heat transport is not the integrability of the Hamiltonian, but whether or not it can be mapped to non-interacting fermions.

10:36 AM A9.00014 Hard-core Bosons in time-varying traps. ADITYA RAGHAVAN, University of Southern California, MARCOS RIGOL, Georgetown University, STEPHAN HAAS, University of Southern California — We present a study of the time evolution of hard-core bosons (HCBs) in a one-dimensional, time-varying optical trap. Previous results have shown that one-dimensional HCBs can form superfluid and Mott-insulator phases. Using an exact numerical approach, we study the dynamics of the system when the trap curvature is modulated. We find the dynamics to be markedly different in the two phases, and address its relevance in the observation of these phases in optical lattice experiments.

10:48 AM A9.00015 Control of Transport Behavior in spin-1/2 Heisenberg Systems. LEA SANTOS, Yeshiva University — A complete understanding of transport behavior in many-body systems is one of the utmost challenges in fundamental studies of non-equilibrium statistical mechanics. In the classical domain, it is widely believed that chaotic systems should show diffusive transport, whereas integrability should be associated with ballistic transport. In the quantum domain, the conditions that determine specific transport behaviors are still under debate. Here, we analyze transport of local magnetization in finite spin-1/2 Heisenberg systems. By adjusting parameters in the Hamiltonian, these quantum systems may show both integrable and chaotic limits. We provide examples of chaotic systems leading to diffusive and also to ballistic transport. In addition, we develop schemes to control the transport behavior in these systems, showing that quantum control methods may be used to induce a transition from diffusive to ballistic transport.

Monday, March 16, 2009 8:00AM - 11:00AM
Session A10 DMP: Focus Session: Ferroelectrics I

8:00 AM A10.00001 First-principles modeling of closure domains in ferroelectric ultrathin films1. JAVIER JUNQUERA, Universidad de Cantabria — Capacitors based on ferroelectric perovskites are potentially attractive for nanoelectronic devices. However, in many cases their use depends on the stability of a ferroelectric state with an out-of-plane polarization. The interplay between mechanical and electrical boundary conditions, and the local chemistry at the surface or interface might give rise to exotic patterns of the polarization, especially in the thin film regime. The screening of the interfacial polarization charges by real metallic electrodes has been extensively discussed in the literature. We have carried out first-principles computations on two other screening mechanisms in ultrathin capacitors made of a few unit cells of BaTiO3 with metallic SrRuO3 electrodes. First, the simulation of the energetic, structural, and electronic properties of ferroelectric domains in short circuit. The domains are stabilized down to two unit cells, adopting the form of a domain of closure, common in ferromagnetic thin films. The domains are closed by the in-plane relaxation of the atoms in the first SrO layer of the electrode, that behaves more like SrO in highly polarizable SrTiO3 than in metallic SrRuO3. Even if small, these lateral displacements are essential to stabilize the domains, and might provide some hints to explain why some systems break into domains while others remain in a monodomain configuration. An analysis of the electrostatic potential reveals preferential points of pinning for charged defects at the ferroelectric-electrode interface, possibly playing a major role in films fatigue. The closure domain structure, predicted also by other phenomenological and effective Hamiltonian models, is more general than expected. Second, the possibility of screening by a surface state or metallization of the first few layers of the ferroelectric without a top electrode is also explored.

1Work done in collaboration with P. Aguado-Puente, and supported by MEC under Project No. FIS2006-02261
8:36AM A10.00002 Polarization Switching at the Intrinsic Coercive Field of PbTiO$_3$ by Changing Oxygen Partial Pressure 1, M. HIGHLAND, T.T. FISTER, M.-I. RICHARD, D.D. FONG, J.A. EASTMAN, S.K. STREIFFER, P.H. FOUSS, G.B. STEPHENSON, Argonne National Laboratory, Argonne, IL, CAROL THOMPSON, Dept. of Physics, Northern Illinois University, DeKalb, IL — Previously we have found that changing the partial pressure of oxygen in the gas above ultrathin PbTiO$_3$ films on SrRuO$_3$ can induce inversion in the sign of the polarization. Here we present x-ray measurements that allow us to determine the polarization magnitude and domain distribution during switching. For films of thickness above ∼5 nm, switching occurs by the usual mechanism of nucleation and growth of 180° domains having the same polarization magnitude but opposite signs. However, in thinner films switching of the polarization occurs without nucleation; the polarization magnitude decreases to zero and changes sign uniformly without domain formation, indicating that the intrinsic coercive field (E$_{JC}$) is reached. Since E$_{JC}$ has never been reached in oxide ferroelectrics using applied electric field, our results suggest that the barrier to nucleation is large during chemical switching. Work supported by the Dept. of Energy under Contract DE-AC02-06CH11357.

8:48AM A10.00003 Understanding the surface reconstruction during chemical switching of ultrathin PbTiO$_3$ films from density functional theory 1, JUN HE, BRIAN STEPHENSON, SERGE NAHKMANSON, Argonne National Laboratory — First-principles calculations are used to understand the structure and energetics of the newly discovered 4×1 surface reconstruction that forms under reducing conditions during chemical switching of the ferroelectric polarization in ultrathin films of PbTiO$_3$ with SrRuO$_3$ bottom electrodes coherently strained to SrTiO$_3$ (001). Relaxed surface structures are obtained for polar films with various oxygen stoichiometries in the outermost PbO layer. To model the behavior of many-unit-cell thick films, which are observed to have polarizations near the bulk value, the lowest unit cell(s) of the PbTiO$_3$ film are forced to be polar. The observed surface reconstructions are compared with experimental synchrotron x-ray measurements.

9:00AM A10.00004 First-principles calculations of structural energetics of Pb-O divacancies in PbTiO$_3$ and their role in up-down asymmetry of thin films 1, O. PAZ, S. P. BECKMAN, D. VANDERBILT, K. M. RABE, Rutgers University — Defects have been proposed as an important influence on the performance of technologically relevant ferroelectric (FE) materials, even at low concentrations. In PbTiO$_3$, V$_{Pb}V_{O}$ vacancy pairs (VPs) are neutral defects, with a local electric dipole moment that can couple to the bulk polarization. To investigate the role that these defects might play in imprint behavior (i.e., a history-dependent up-down asymmetry), we carried out first-principles supercell calculations of VPs in PbTiO$_3$. While previous works considered a cubic host $\Sigma$ we study the tetragonal FE case for periodic arrays of $\Sigma$ and $\Sigma$-neighbor VPs at densities as low as 3%. Our lowest energy VP is a $\Sigma$-neighbor one oriented so as to break the bulk symmetry between the up and down polarization states. Other VP arrangements are higher in energy by at least 0.2 eV. Atomic relaxation is of particular importance in lowering the energy of the $\Sigma$ below that of the $\Sigma$-neighbor VP. Berry-phase polarization calculations reveal that the total polarization is only slightly modified for VPs whose dipoles are aligned with the polarization, but is significantly suppressed by antialigned VPs.

9:12AM A10.00005 Study on the electro-optic effect in Pb(Zr,Ti)O$_3$ (001) film using spectroscopic ellipsometry 1, TAE DONG KANG, Department of Physics, New Jersey Institute of Technology, XIAO BO, VITALIY AVRUTIN, UMIT OZGUR, HADIS MORKOC, Department of Electrical and Computer Engineering, Virginia Commonwealth University, JUN WOO PARK, HO SUK LEE, HOSUN LEE, Department of Physics, Kyung Hee University, South Korea, XIAOYU WANG, DAVID SMITH, Department of Physics, Arizona State University — Spectroscopic ellipsometry was applied to study electro-optic effect in lead zirconate titanate (PZT) thin films grown epitaxially on Nb-doped SrTiO$_3$ (001) substrates by radio frequency magnetron sputtering. Multilayer model analysis was applied to extract the ordinary and extraordinary refractive indices of the PZT thin film with electric field applied along the (001) direction. The effective linear and quadratic coefficients at a wavelength of 632.8 nm were estimated to be $-134.6 \times 10^{-12}$ m/V and $8.5 \times 10^{-18}$ m$^2$/V$^2$, respectively, while the individual linear electro-optic coefficients $\gamma_{33}$ and $\gamma_{34}$ were -157.1 and 22 pm/V, respectively. We attributed existence of the linear electro-optic effect in unpoled PZT films to the presence of a built-in polarization and simultaneous poling during ellipsometric measurements.

9:24AM A10.00006 A first-principles study of enhancement of polarization with electric field in tetragonal PbTiO$_3$ 1, ANINDYA ROY, Rutgers University, MASSIMILIANO STENGEL, UCSB, DAVID VANDERBILT, Rutgers University — We present first-principles calculations of the electric polarization and $c/a$ ratio of ferroelectric tetragonal PbTiO$_3$ as an external electric field is applied parallel to the polarization direction. The work is motivated in part by experimental observations showing an anomalous enhancement (i.e., nonlinear piezoelectric response) in the $c/a$ ratio for electric fields above $\sim$200 MV/m in PbZr$_{0.2}$Ti$_{0.8}$O$_3$. Working here with pure PbTiO$_3$ for reasons of computational convenience, we calculate the strain response to an electric field applied parallel to the spontaneous polarization. We focus mainly on the case of fixed in-plane lattice constants, which appear most suitable to the experimental conditions, but we also study the case in which all lattice constants are relaxed. In addition explore the effects of artificial negative pressure, with and without the in-plane epitaxial constraint. Two ab-initio computer codes are used for this purpose, and the results are compared to each other and to the experiment.

9:36AM A10.00007 Polarization reversal and backswitching kinetics in epitaxial ferroic thin films 1, JIANHENG LI, BRUCE WESSELS, Northwestern University — Polarization reversal and backswitching kinetics were investigated in epitaxial ferroelectric BaTiO$_3$ thin films. Using the electro-optic effect to monitor domain dynamics, the dynamic response was measured as a function of bias pulse magnitude and temperature. The dynamics followed a Kohlrausch-Williams-Watts (KWW) stretched exponential function in time. From the measurements the activation field for polarization reversal and the activation energy for domain motion were determined. The measured activation energy of 6-12 kJ/mol is in good agreement with prior experiments on bulk material and recent theoretical calculations using molecular dynamics simulations.

Supported by NSF DMR-0605292
Thickness dependent ferroelectric properties of ultrathin BaTiO$_3$ thin films

D.A. FELKER, H.W. JANG, C.B. EOM, M.S. RZCHOWSKI, University of Wisconsin - Madison — The thickness dependence of the coercive field and the spontaneous polarization were studied for epitaxial trilayer heterostructures with SrRuO$_3$ and ultrathin BaTiO$_3$ ferroelectric layers grown on TiO$_2$ terminated (001) SrTiO$_3$ substrates. The BaTiO$_3$ thickness ranged from 2.4 (6 unit cells) to 50 nm. The 3.2 nm (8 unit cells) sample provides the thinnest direct electrical measurement of ferroelectricity in BaTiO$_3$ in a device structure, showing the thickness dependence of ferroelectric properties down into the ultrathin regime and providing a new experimental upper bound on the critical thickness. The coercive field increases dramatically in thinner samples consistent with the Kay-Dunn model of domain nucleation and propagation. Below 10 nm the spontaneous polarization decreases with decreasing thickness due to decreasing screening of the depolarization field by the electrodes. For barriers thicker than 10 nm the polarization decreases due to strain relaxation in the ferroelectric barrier. We discuss these measurements, as well as the temperature dependence of the coercive fields and hysteresis loops.

10:00AM A10.00009 Temperature dependence of the dielectric properties of strained barium strontium titanate films for tunable microwave applications

LISA A. ALLREDGE, WONTAE CHANG, STEVEN KIRCHOEFER, JEFFREY POND, Naval Research Laboratory — Understanding strain effects is critical to achieve desirable dielectric properties in ferroelectric films, which are of interest for tunable microwave applications. Sputter-deposited Ba$_{1-x}$Sr$_x$TiO$_3$ films on (001) MgO were studied in various strain states: in-plane or out-of-plane tetragonal lattice distortions. The optimal system calibration for microwave measurements changes greatly with temperature, requiring frequent recalibration. A temperature-dependent intercalation calibration technique was developed to increase the efficiency of measurements taken as a function of temperature. The films showed significant differences in the ferroelectric phase transition due to lattice distortions, with a strong temperature dependence of the in-plane dielectric behavior for films under tensile strain and a weak temperature dependence for films under compressive strain. We believe that films under tensile strain have polarizations aligned parallel to the applied electric field and so the in-plane dielectric properties are strongly coupled with the field, while films under compressive strain have polarizations perpendicular to the field, resulting in minimal influence on the in-plane dielectric behavior.

10:12AM A10.00010 Density functional study of ferroelectric-electrode interfaceal effects on the stability of ferroelectricity in thin-films

WISSAM A. AL-SAIDI, University of Pennsylvania, ALEXIE KOLPAK, Yale University, ILYA GRINBERG, ANDREW RAPPE, University of Pennsylvania — Ferroelectric (FE) thin-films are very promising materials for various technological applications. The continuous demand of miniaturization of devices based on FE thin-films by the micro-electronic industry demands an understanding of the critical thickness of ferroelectricity in thin films. Using an ab initio density-functional approach, we study the properties of several capacitor-like structures which are based on Pt/TiO$_2$ and BaTiO$_3$ ferroelectric materials. Different electrodes are used in our study to gain a thorough understanding of the electrode-ferroelectric interfaces, and the role of the interfacial chemical bonding and charge transfer in stabilizing the FE polar phase. We finally used our ab initio results to develop a phenomenological predictive model based on a Landau-Ginzburg-Devonshire functional.

10:24AM A10.00011 Boundary conditions on ferroelectricity in ultrathin SrTiO$_3$ films on silicon

ALEXIE KOLPAK, FRED WALKER, JAMES REINER, CHARLES AHN, SOHRAB ISMAIL-BEI, Yale University, CRISP COLLABORATION — The properties of SrTiO$_3$ films epitaxially grown on Si(001) are strongly influenced by the electronic structure of the interface. Using density functional theory, we demonstrate the presence of an intrinsic interface dipole, the direction of which is independent of the particular combination of Sr, Ti, O, and Si atoms at the interface, and therefore independent of growth conditions. As a result of this intrinsic dipole, a local, positive polarization is induced in the SrTiO$_3$ interfacial region, fixing the electrostatic boundary conditions at the interface and preventing the formation of a negatively polarized state with a single domain. We suggest ways in which this constraint on the ferroelectric behavior can be overcome by interfacial cation doping, allowing for the integration of ferroelectricity with traditional silicon-based devices.

Boundary conditions on ferroelectricity in ultrathin SrTiO$_3$ films on silicon

10:36AM A10.00012 Strain Effect in the Problem of Critical Thickness for Ferroelectric Memory

A.M. BRATKOVSKY, Hewlett-Packard Labs, Palo Alto, A.P. LEVANYUK, U Autonoma Madrid, Spain — We account for inhomogeneous strains while calculating two characteristic thicknesses arising in the problem of critical thickness for ferroelectric memory. One of them marks the stability limit of metastable single domain state under zero external voltage with respect to small fluctuations (spinodal point of the single domain state.) The second one appears when the energies of the single and multidomain state become equal while the latter is considered within one-sinusoidal approximation [1]. At this thickness the single domain state remains metastable, but one may hope that the lifetime of this state becomes suitable for the memory applications[2]. We use the Landau approach for elastically isotropic solid with a single electrostriction constant to illustrate general behavior. It is found that the effect of the elastic strains is qualitatively different for free-standing films versus films on substrates.

10:48AM A10.00013 Unusual polarization patterns in flat epitaxial ferroelectric nanoparticles

IVAN NAUMOV, ALEXANDER BRATKOVSKY, Hewlett-Packard Laboratories — We investigate the effects of a lattice misfit strain on a ground state and polarization patterns in flat perovskite nanoparticles (nanoslands of BaTiO$_3$ and PbZr$_{0.5}$Ti$_{0.5}$O$_3$) with the use of an ab-initio derived effective Hamiltonian. We show that the strain strongly controls the balance between the depolarizing field and the polarization anisotropy in determining the equilibrium polarization patterns. Compressive strain favors 180° stripe/tweed domains while a tensile strain leads to in-plane vortex formation, with the unusual intermediate phase (s) where both ordering motifs coexist [1]. The results may allow to explain contradictions in recent experimental data for ferroelectric nanoparticles. [1] Ivan Naumov and Alexander M. Bratkovsky, Phys. Rev. Lett. 101, 107601 (2008).
8:00AM A11.00001 Coverage-Dependent Faceting of Au Chains on Si(557) , F. J. HIMPEL, J. BARKE, F. ZHENG, S. BOCKENAUER, K. SELL, V. V. OEYNHAUSEN, K.H. MEINES-BRÖER, Dept. of Physics, University of Wisconsin Madison, 1150 University Ave, Madison, WI 53706; Institut fuer Physik, Universitaet Rostock, Germany — The structural and electronic phase diagram of Au on Si(557) is established using scanning tunneling microscopy (STM) and angle-resolved photoemission (ARPES). Five phases consisting of altogether seven facets are observed in the sub-monolayer regime. Four of them consist of two coexisting structures. In order of increasing Au coverage the five phases are: Si(111)7×7 + Si(112), Si(557)×2-Au, Si(111)5×2-Au + Si(335)-Au, Si(111)√3×√3-Au + Si(335)-Au, and Si(111)√3×√3-Au + Si(5 5 11)-Au. The relative surface areas of the five phases and seven facets are determined accurately by depositing a Au wedge ranging from 0 to 0.8 monolayer and performing automatic pattern recognition on large-scale STM images. Angle-resolved photoemission spectra are decomposed into contributions from the five phases. The Fermi wave vectors of various facets are identified. Using Si(557)×2-Au as reference we find a coverage of 3 Au chains per unit cell for the frequently-studied Si(111)5×2-Au surface (instead of the widely-used value of 2 Au chains). The impact of this finding on structural models is discussed.

8:12AM A11.00002 The Alignment of Gold Nanorods in Macroscopic Domains , JAKE FONTANA, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University, ASHISH AGARWAL, NICHOLAS KOTOV. Chemical Engineering, University of Michigan — The uniform alignment of nanoparticles in domains with macroscopic length scales is critical to the production of self-assembled composite metamaterials for optical applications. We describe methods of self-assembly leading to films and suspensions with a high loading of orientationally ordered nanoparticles in macroscopic domains. The nanoparticles are short aspect ratio gold nanorods, with both plasmon peaks in the visible spectrum. Orientational order can be achieved via applied electric field, mechanical strain, as well as via interactions with anisotropic hosts and among nanoparticles. We have determined the orientational order in our samples from polarized absorbance measurements.

8:24AM A11.00003 Role of the three Si suboxides at the surface of Si quantum dots and in Si/SiO$_2$ quantum wells on optical response of nanoparticles were fabricated with this technique.

8:36AM A11.00004 Formation of Colloidal Nanoparticle Superlattices in a Two Solvent System , CHENQUANG LU, AUSTIN AKEY, IRVING HERMAN, Columbia University — A two solvent system consisting of a high boiling point solvent and a low boiling point solvent was found to greatly aid the self-assembly of nanoparticle superlattices. Nanoparticle mixtures were prepared under multiple suitable solvent evaporation conditions and the products were analyzed by TEM and SEM. The formation process of various binary nanoparticle superlattices was investigated to elucidate the optimal conditions for self-assembly. Superlattice formation in this two solvent system was further investigated with various spatial confinement conditions. Here, the capillary effect during the evaporation of solvents may be the driving factor in the self-assembly. Micrometer scale superlattices of CdSe nanoparticles were fabricated with this technique.

8:48AM A11.00005 Modeling the Self-assembly of Nanorod Superlattices , ALEXEY TITOV, PETR KRAL. University of Illinois at Chicago — Colloidal semiconductor CdSe/CdS nanorods (NR) of diameters of 3-10 nm and lengths of 4-40 nm typically self-assemble into nematic and smectic phases, which are parallel to the substrate, or simple hexagonal (SH) superlattices, which are perpendicular to the substrate [1-2]. We model the formation of these structures by semi-classical means, starting from the forces between the nanorods, their coupling to the substrate and to the external electric fields. We determine the conditions under which superlattices with different number of particles, number of monolayers, aspect ratios of nanorods, etc. can be observed [3], and show that the obtained results agree well with the available experimental data. Our previous results of modeling superlattices of self-assembled monodisperse nanoparticles are also presented.

9:00AM A11.00006 Morphology of Cu$_2$S-CdS and Ag$_2$S-CdS Nanorod Heterostructures , DENIS DEMCHENKO, Virginia Commonwealth University, BRUCE SADTLER, University of California, Berkeley, HAIMEI ZHENG, A. PAUL ALIVISATOS, LIN-WANG WANG, Lawrence Berkeley National Laboratory — A partial cation exchange has been used to synthesize Cu$_2$S-CdS and Ag$_2$S-CdS nanocrystal heterostructures, with two very different morphologies. Cu$^+$ cation exchange takes place preferentially at the ends of CdS nanorods, Cu$_2$S segments grow into the nanorod from both ends. Ag$^+$ exchange is non-selective, Ag$_2$S islands nucleate and grow over the entire surface of the nanorod. This leads to very different patterns, striped Ag$_2$S-CdS superlattice with several equidistant Ag$_2$S segments in a CdS nanorod, and an asymmetric Cu$_2$S-CdS heterostructure with Cu$_2$S segments at the ends of the CdS nanorod. We use first-principles calculations to obtain formation energies of the different epitaxial interfaces between Cu$_2$S-CdS and different facets of CdS nanorods. Comparison of chemical and elastic contributions to the interface formation energy for the Cu$_2$S-CdS heterostructure shows that the relative stability of the interfaces determines the nucleation of Cu$_2$S and the resulting morphology. Furthermore, since two end facets of CdS nanorod are not crystallographically equivalent a controlled asymmetric nucleation of Cu$_2$S can occur.

9:12AM A11.00007 Self-assembly of molecular wires , ANDREAS Riemann, Western Washington University, WESTERN WASHINGTON UNIVERSITY COLLABORATION — Scanning Tunneling Microscopy (STM) has been used to study the self-assembly of the naturally occurring amino acid L-methionine on different surfaces. It has been found that methionine forms highly regular structures on an Ag(111) surface under UHV conditions as well as on a graphite surface under ambient conditions. Methionine arranges itself into an array of molecular wires of uniform width and separation. The spacing of these wires can be controlled by means of the deposition amount. Molecular mechanics calculations are used to suggest a model for the methionine configuration on the surfaces. The width of the wires is determined by two methionine molecules arranged with their carbonyl group facing each other. The regular separation of individual wires suggests a long range interaction between these wires.
9:24AM A11.00008 An STM Study of Atomic Co Wires, NADER ZAKI, DENIS POTAPENKO, Columbia University, PETER JOHNSON, DANDA ACHARYA, PERCY ZAHL, PETER SUTTER, Brookhaven National Lab, RICHARD OSGOOD, Columbia University — Due to stronger electron-electron interactions, 1-D systems are predicted and, in some cases, have been shown to exhibit unique and exotic electronic properties. One route to the formation of 1-D systems is by self-assembly using low-index vicinal crystal surfaces. In this regard, we have successfully formed 1-atom wide Co wires using Cu(775), a 7-atom wide stepped array with (111) terraces. Contrary to a recently reported DFT prediction, the Co wires are not laterally encapsulated but are positioned exactly at the step edge. We will present STM studies of this system performed at room temperature and STS measurements made at low temperature. While vicinal Cu(111) does exhibit “friz” at the steps when scanning above cryogenic temperatures, the Co wires pin the edges, visually accentuating their presence under STM. Furthermore, we observe a lower local density of states for the Co wires as compared with the Cu steps, which also serves to differentiate the two metals. Cu(111) possess a surface projected bandgap which may electronically decouple the wire electrons that reside in this gap. However, we also see resonances at the Fermi level which suggests electronic coupling between the vicinal Cu surface and the Co electrons.

9:36AM A11.00009 III-V nanowires grown in a simple, homebuilt system.1, M. D. SCHROER, J. R. PETTA, Princeton University — Semiconductor nanowires are promising experimental platforms for studying quantum transport due to their built-in, one-dimensional confinement of charge carriers. To enable the study of III-V semiconducting nanowires, we built a simple tube furnace based MOCVD reactor. Growth of InP and InAs nanowires using trimethylindium, di-tert-butylphosphine and triethylarsenic has been studied as a function of temperature, pressure, precursor concentration and growth substrate. At optimal growth conditions, wires of 20-60 nm in diameter and up to 10 μm in length are achievable on InAs substrates. Characterization was performed using SEM, EDS and TEM; both wurtzite and zincblende structures have been observed. We will also present transport measurements of nanowires grown using this system.

1We thank Hongkun Park, Stephen Weinman, and Chun Liang Yu for helpful discussions. This work was supported by the Army Research Office (W911NF-08-1-0189) and the National Science Foundation MRSEC Program through the Princeton Center for Complex Materials

9:48AM A11.00010 Fabrication of nanowire-nanotube hybrid arrays in porous aluminum oxide membranes, ZUXIN YE, HAIHONG CHEN, ISABEL SCHULTZ, WENHAI WU, D. G. NAUGLE, I. LYUKSYUTOV, Texas A & M University — Fabrication of ordered nanowire-nanotube hybrid arrays embedded in porous anodic aluminum oxide (AAO) membranes is demonstrated. Arrays of TiO2 nanotubes were first deposited into the pores of AAO membranes by an electroless sol-gel technique. For subsequent electrochemical deposition of Co nanowires into the TiO2 nanotubes, a thick Au layer was first evaporated on one surface of the membrane to serve as the cathode. Co nanowires were then electrochemically deposited into the TiO2 nanotubes through the other surface to form the hybrid nanowire-nanotube arrays. SEM and TEM measurements showed a high Co nanowire filling factor and a clean interface between the Co nanowires and the TiO2 nanotubes. The TiO2 nanotubes were found to be composed of nanometer sized TiO2 crystals, while the Co nanowires were polycrystalline with Co crystal size comparable to the nanowire diameter. This technique can be extended to the fabrication of hybrid arrays of various materials. This work was supported by DOE No. DE-FG02-07ER46450, NSF No. DMR-0606529, and the Robert A. Welch Foundation A-0514.

10:00AM A11.00011 First Observation of Quantum Size Effects in Metal Films on Insulator, HAWONG HONG, Argonne National Laboratory, AARON GRAY, University of Illinois, Urbana-Champaign, RUQING XU, University of Illinois, Urbana-Champaign, and Hobart and William Smith Colleges — It has long been a goal of the materials science community to study quantum size effects in metal films on insulators and metals. Here the first observation of the quantum effects in metal films on insulators will be reported. Pb thin films, which exhibit the most dramatic quantum-size-effects were chosen again for this effort. Sapphire (001) substrates were used after they were annealed at 1500 °C in air and cleaned in a UHV chamber by heating. X-ray diffraction was measured during and after the deposition-annealing processes. Most of the structural aspects observed with Pb on Si(111) also appeared in Pb films on sapphire. The preferred island heights (or magic heights) appeared as 7, 10, 12, 14 layers from the preliminary analysis. This contrasts the magic heights on the Si substrates (5, 7, 9, . . .). This difference is coming from the phase shifts of confined electrons through the different interfaces. This magic selection of island-heights stays quite strong even at elevated temperatures up to 200–300 °C. Time resolved 3-D reciprocal space mapping also showed very strong ordering between islands during deposition and annealing of the films.

10:12AM A11.00012 Surface Dislocation of Al Films on Ag(111), BO XU, ERKUANG ZHU, CHAO LU, YONGJUN TIAN, Yanshan University — Ordered dislocation structures of metal surfaces are of particularly interests because they can provide templates for building nanostructures with novel electronic, magnetic, and catalytic properties. Here we report two dislocation structures formed for Al on Ag(111). Depending on substrate temperature, Al films demonstrate distinct surface structures. At room temperature, Al nanocrystals with the (111) orientation are formed. At 500 K, a herringbone reconstruction, similar with the well known Au(111) reconstruction surface, is formed, while at 600K, a trigonal reconstruction surface is formed. Molecular self assembly processes on these surfaces are investigated.

10:24AM A11.00013 Theoretical Analysis of Equilibrium Surface Segregation in Ternary III-V and II-VI Semiconductor Nanostructures, SUMEET PANDEY, TEJINDER SINGH, DIMITRIOS MAROUDAS, University of Massachusetts, Amherst — We present an atomic-scale analysis of equilibrium surface segregation in ternary compound (III-V and II-VI) semiconductor nanostructures. The analysis is based on a computational scheme for compositional and structural relaxation that combines Monte Carlo with conjugate-gradient methods according to properly modified/extended parameterizations of the valence-force-field (VFF) description; the VFF parameterizations employed in the analysis are validated by comparison with first-principles density functional theory calculations. We report equilibrium concentration distributions in slabs of InxGa1-xAs and ZnxSe1-xS, as a function of composition, x, slab thickness, and slab surface crystallographic orientation, as well as in InxGa1-xAs and ZnxSe1-xS nanocrystals with well-defined surface facets as a function of x and nanocrystal size. The results are discussed in the context of synthesis of core/shell structures of ternary compound semiconductor nanocrystals for increased quantum-dot photoluminescence efficiency.

10:36AM A11.00014 Growth and optical properties of highly oriented ZnSSe alloy nanowires, SUI KONG HARK, YAO LIANG, The Chinese University of Hong Kong — ZnS, ZnSe and their alloys are important semiconductors for optical applications in the UV-blue spectral range. Nanowires, nanobelts and nanotubes of ZnS and ZnSe, but rarely their alloys, had been synthesized, typically as a random, inhomogeneous assembly. For future basic studies and applications, it is necessary to control the orientation and composition of the nanowires. We have grown ZnSSe alloy nanowires epitaxially on GaAs substrates by metal-organic chemical vapor deposition. Their orientation was adjusted by changing the crystallographic orientation of the substrate. Through controlled alloying, they have also achieved band gap engineering. The nanowires were characterized by SEM, HRTEM and XRD. Their optical properties were studied by Raman, cathodoluminescence and photoluminescence spectroscopy. In addition to the nanowires, the growth conditions and optical properties of ZnSSe alloy nano-tetrapods were studied.

**8:36AM A12.00002 Kinetic Monte Carlo Simulations of Nanostructure Evolution During Unstable Growth on Patterned GaAs(001)**

CHUAN-FU LIN, KRISTA COSERT, AJMI HAMMOUDA, University of Maryland, HUNG-CHIH KAN, National Chung-Cheng University, Taiwan, ROC, RAY PHANEUF, University of Maryland — We present results of kinetic Monte Carlo simulations, which include a diffusion barrier, lateral atom interaction energy, and Ehrlich-Schwoebel barrier to investigate unstable growth for comparison with our observations on patterned GaAs(001) surfaces at typical growth conditions [1-3]. Our results show a profound change in the mode by which an initial lithographic pattern evolves during growth, with growth mounds dominating at low temperatures and island nucleation and growth at higher temperatures. We describe the use of height-height correlation maps as a tool to facilitate the statistical characterization of the evolution of periodic patterns during growth, and correlate peaks in the maps with the change in growth mode with temperature.

**8:48AM A12.00003 Nanopatterning as a Probe of Unstable Growth on GaAs(001)**

KRISTA COSERT, CHUAN-FU LIN, AJMI HAMMOUDA, University of Maryland, HUNG-CHIH KAN, National Chung-Cheng University, Taiwan, ROC, KANAKARAJU SUBRAMANIAM, CHRIS RICHARDSON, Laboratory for Physical Sciences, RAY PHANEUF, University of Maryland — We report on observations of unstable growth on patterned GaAs(001) surfaces. For growth at 500°C, 1 ML/sec and an As2/Ga beam equivalent pressure ratio of 10:1, we find that grooves oriented at right angles to [110] produce a build up of ridges of GaAs at the upper edges, while for grooves oriented at right angles to [110] no ridges form; instead cusps evolve at the bottoms of such grooves [1]. The cusp-forming grooves show a pronounced initial amplification of depth during growth which changes with height/width ratio and becomes more narrow. The ridge-forming grooves instead broaden during growth. We compare these experimental observations with kinetic Monte Carlo simulations in which a small anisotropic Ehrlich-Schwoebel barrier is included. [1] T. Tadayyon-Eslami, H.-C. Kan, L. C. Calhoun and R. J. Phaneuf, Phys. Rev. Lett. 97, 126101 (2006)

**9:00AM A12.00004 Optimization of air-assisted CVD growth of vertically-aligned ZnO nanowires, guided by structural analysis using X-ray scattering**

JONG G. OK, A. JOHN HART, Mechanical Engineering, University of Michigan, Ann Arbor, MI 48109, USA — ZnO nanowires (ZNWs) are of significant interest for applications ranging from optical sensors to vibrational energy harvesters, due to properties including UV photoluminescence and piezoelectricity. We have studied low-pressure growth of ZNWs using a vapor transport method in air flowing within a tube furnace, giving vertically-aligned ZNW arrays on sapphire substrates seeded by Au catalysts. The growth rate and the average length of ZNWs depend on the flow rate of air and the total growth time, while multiple parameters such as catalyst thickness, pressure, and temperature also interdependently affect the ZNW characteristics. Grazing incidence small-angle X-ray scattering (GI-SAXS) measurements enable non-destructive quantification of ZNW diameter and alignment. By fitting GI-SAXS images using analytical models of the array as a population of solid cylinders having a Gaussian diameter distribution, we establish precise relationships between the structural characteristics and the growth conditions; for example, we determine rates of radial growth and size distribution broadening in comparison to axial growth. Control of the temperature gradient within the furnace also enables growth of well-aligned arrays at substrate temperatures as low as 600°C.

**9:12AM A12.00005 Influence of impurities on phase transition in quasi-one-dimensional nanowires on Si surface**

GEUNSEOP LEE, WOOSANG LEE, HYUNJOO SHIM, Inha University, Korea, SANG-YONG YU, JA-YONG KOO, Korea Research Institute of Standards and Science, Korea — We investigated using low-energy electron diffraction the influence of impurity doping on the structural phase transition in an array of quasi-one dimensional In nanowires on Si(111). A clean Si(111)×1 surface, in its pristine form, undergoes a structural phase transition into a 8×2 phase below 120 K. Introducing various impurities (hydrogen, oxygen, and alkali metals) on the surface at room temperature was found to affect the 4×1-to-8×2 structural phase transition by changing the transition temperature (Tc). Adsorption of the two types of the gases affected the transition in opposite ways: hydrogen adsorption lowered the Tc, whereas oxygen adsorption raised the Tc. Dosing of different alkali metals (Na, K, and Li) all decreased the Tc. Usually, impurities are expected to suppress the phase transition into the symmetry-broken phase (the low-temperature phase) by acting as random fluctuations in structure. In this sense, the increase in Tc by the oxygen adsorption is an exceptional case enhancing the phase transition. Possible mechanisms leading to different influences of the various impurities on the structural phase transition of this In/Si(111) will be discussed.

**9:24AM A12.00006 Numerical simulations of VLS heteroepitaxial nanowire growth**

VIVEK SHENOY, Brown University. KLAUS SCHWARZ, JERRY TERSOFF, IBM T. J. Watson Center — Nanowires are particularly attractive for designing heterostructures, as effective radial strain relaxation allows heterostructures with a wider range of material combinations. The electrical, optical, and thermal properties of the nanowire are highly dependent on the accurate control of the locations and thicknesses of such heterostructures. However, in the case of nanowire growth from a metal seed particle, the composition of the seed particle will vary for growth of different materials due to alloying, which may cause problems in controlling interface abruptness. Also, recent experiments have shown that in many cases, growth instabilities do not allow for the formation of nanowires with desired morphology and material combinations. We have developed a continuum model for the growth of heteroepitaxial nanowires, and we use it to study the factors that control interface abruptness and instabilities during growth. Our model includes the following features that are critical for capturing the composition profiles in nanowires: 1) the differences of the attachment rates of the alloy components at the catalyst-wire interface, 2) the possibility of miscibility gap in the alloy phases of the catalyst and the nanowire, 3) composition dependence of the surface energies of the nanowire and nanowire-catalyst interface and 4) anisotropy in surface energies leading to faceted morphologies.
9:36AM A12.00007 Three Dimensional, Single-crystal, Oxide NANOFENCES for Epitaxial Growth of Electronic, Magnetic or Electromagnetic Nanoscale-Devices¹. AMIT GOYAL, SUNG-HUN WEE, KARREN MORE, ELIOT SPECHT, ORNL — A unique, three-dimensional (3D), single-crystal, MgO, NANOFENCE comprised of single crystal MgO nanowire units was synthesized via epitaxial growth on (100) SrTiO₃ substrates. Individual single crystal MgO nanowire units comprising the nanofence were observed to have high aspect ratios with small diameters of 10-20 nm and long lengths from 100 nm up 1 μm. X-ray diffraction shows that the 3D MgO nanofence has an epitaxial relation with (100) SrTiO₃ substrates with only a single {100} <100> orientation and with full-width-half-maximum values of (200) ω-scan and (110) φ-scan with 4.5° and 5.5°, respectively. Such nanofences offer a single crystal, 3D nanotemplate for epitaxial growth of wide-ranging, 3D, electronic, magnetic and electromagnetic nanodevices.

9:48AM A12.00008 Hierarchical Assembly of Epitaxial Quantum Dot Nanostructures on Templated Substrates. ROBERT HULL, Rensselaer Polytechnic Institute — Using the focused ion beam (FIB), we have modified the local topography and chemistry of Si(100) surfaces, and demonstrated control of the geometry, size, location and proximity of epitaxial Ge(Si) quantum dot (QD) nanostructures which are nucleated on these templated surfaces. We show how QDs can be located with a precision ~ 10 nm using local Ga⁺ FIB doses ~ 10¹⁵ cm⁻², and how QD size and morphology can be modified by local surface chemistry. We further describe how growth kinetics can control formation of more complex nanostructures with internal length scales bridging the ∼ 10 nm dimensions necessary for application to potential nanoelectronic device architectures and dimensions that are accessible through external lithography. In particular, we describe the self assembly of “quantum dot molecule” (QDM) GeₓSi₁₋ₓ nanostructures where a four-fold QD structure forms around shallow strain relieving pits. Positional control of these QDMs using external lithographic templating allows formation of hierarchically assembled systems with length scales ranging from ∼ 10 nm in QD size and proximity, through the ∼ 100 nm dimensions of the QDM, to the micro/macro-scopic dimensions accessible with external lithography. We also describe methods for electronic and magnetic functionalization of these nanostructures by separation of ion species from alloy liquid metal sources in a mass selecting FIB column. This allows generation of ion beams comprising electronically non-invasive species for nanoscale surface templating (e.g. Si, Ge), electronic doping (e.g. As, B), or spin doping (e.g. Mn). Application of such structures to potential novel nanoelectronic device structures will be discussed. This work is done in collaboration with J. Floro, J. Graham, M. Gherasimova, J. Thorp (UVA), F. Ross (IBM), A. Portavoce (CNRSS), M. Kammier (U. Duisburg) and J. Gray (U. Pittsburgh).

10:24AM A12.00009 Fabrication Methods for Positioning of Quantum Dots¹. REBECCA KRAMER², RUPERT OULTON, VOLKER SORGER, NITIPAT PHOLCHAI, University of California, Berkeley, XIANG ZHANG, NSF Nanoscale Science and Engineering Center, University of California, Berkeley — Quantum dot positioning is highly useful in terms of integrating nanoelectromitters into nanostructures, such as nanocavities and quantum dot waveguides. Demonstration of control over the positioning of quantum dots has proven difficult, and consequently construction of single-photon emitting systems has been hindered. We report the ability to reliably position nanoscale functional objects, specifically quantum dots, within a well-defined location. Programmed assembly of DNA linked quantum dots on both gold and silver substrates is obtained by Electron Beam Lithography patterning and a series of surface chemical functionalizations. A single quantum dot was successfully positioned within 100 nm of the desired location in 36 percent of the experiments. Furthermore, the method was completely reproducible within 500 nm accuracy. This method has the potential to functionalize quantum dots in even smaller pattern sizes.

²This work was done at Berkeley, however the author is now affiliated with Harvard University.

10:36AM A12.00010 Stress-driven self-assembly of Si-based nanomembranes for on-chip applications. FRANCESA CAVALLO, Leibniz-Institut für Festkörper- und Werkstofforschung Dresden, Helmholtzstrasse 20, 01067-Dresden, Germany, RUDEESAN SONGMUANG, YONGFENG MEI, ARMANDO RASTELLI, OLIVER SCHMIDT, Leibniz-Institut für Festkörper- und Werkstofforschung Dresden, Helmholtzstrasse 20, 01067-Dresden, Germany — A new field of Si technology based on transferable and engineered nanomembranes has developed with the realization of the fact that properties of bulk Si are preserved in nm-thin layers released from the substrate surface. We demonstrate the ability to pattern Si-based films with nano-scale features, and fold them into a predetermined 3D configuration by finely tuning the strain distribution in the membranes by well-established deposition processes, i.e., MBE, PVD, and thermal oxidation. Our major contributions are the fabrication of integrated microtube resistors based on Si:B/SiGe:B tubes; the use of the Ge condensation technique to tailor the strain distribution in SiGe films on insulator; the manufacturing of fully scalable and CMOS compatible—self—seeding hybrid tubes; the fabrication of linear and circular networks formed by interconnected wrinkled structures; the experimental demonstration of light emission from Ge and Si nanoparticles integrated in a tube wall; the observation and investigation of the waveguiding effect along the axis of SiOx/Si tubes.

10:48AM A12.00011 Isotropic and anisotropic strain-induced self-assembled oxide nanostructures. MARTA GIBERT, PATRICIA ABELLAN, ALESSANDRO BENEDETTI, FELIP SANDIUMENGE, TERESA PUIG, XAVIER OBRADORS, Institut de Ciencia de Materials de Barcelona, ICMAB-CSIC, 08193 Bellaterra, Catalunya, Spain — The apparition of new functionalities based on size- and shape-dependent properties requires strategies for the formation of well-defined structures at nanometric scale. We have developed a bottom-up low-cost chemically-derived methodology based on the control of strain and surface energies anisotropies in CeO2/LAO system to tune the lateral aspect ratio, orientation and kinetics of interfacial oxide nanostructures. Self-organized uniform square-based nanopyramids form under isotropic strain [1]. In contrast, highly elongated nanostructures (long/short axis ∼ 20) grow induced by biaxial anisotropic strain and anisotropic surface energies. Island’s distinct crystallographic orientation is the clue of their differentiated shape, and also influences their distinct evolution. The kinetically-limited coarsening of isotropic nanodots contrasts with the ultrafast kinetics of anisotropic islands. Experimental analyses are based on AFM, TEM, XRD and RHEED, and simulations based on a thermodynamic model enable us to confirm the equilibrium shape of each sort of island’s shape in relation to its misfit strain and surface characteristics. [1] Gilbert, M. et al., Adv.Materials 19 (22), 3937 (2007).

Monday, March 16, 2009 8:00AM - 11:00AM –
Session A13 DCOMP: Focus Session: Metropolis Thesis Prize and Multiscale Modeling

8:00AM A13.00001 Flexibility and Direction Reversal in Flapping Locomotion. SAVERIO SPAGNOLIE, UC San Diego, MICHAEL SHELLEY, New York University — In order to better understand the role of flexibility in the flapping of wings and fins in Nature, experimentalists at NYU have studied a heaving foil with passive pitching. We analyze this system numerically, having constructed a high-order accurate numerical scheme to solve the full Navier-Stokes equations in two-dimensions to study the dynamics. We are able to reproduce qualitatively the results of the experiments: by increasing the flapping frequency, we find regions of improved performance when compared to a rigid wing, regions of under-performance, and a bi-stable regime where the flapping regime can move horizontally in either direction. The numerical simulations have led to predictions of other modes of flapping locomotion, which have subsequently been observed in experiments. We also find that a symmetry breaking transition to forward flapping flight, as observed in experiments of a heaving foil with no pitching, may be directed with only very slight flexibility.
8:12AM A13.00002 Modeling the combined effect of surface roughness and shear rate on slip flow of simple fluids , ANOOSHEH NIARVARANI, NIKOLAI PRIEZEJ, Michigan State University — Molecular dynamics (MD) and continuum simulations are carried out to investigate the combined effect of shear rate and surface roughness on interfacial slip in simple fluids. For weak wall-fluid interaction energy, the nonlinear shear rate dependence of the slip length in a flow past atomically flat surfaces is obtained from MD simulations. Both the magnitude of the slip length and the slope of its rate-dependence are significantly reduced in the presence of periodic surface roughness. Continuum simulations are used to reproduce the behavior of the effective slip length in a flow over periodically corrugated surface at low shear rates. The continuum analysis includes the functional form of the slip length vs. local shear rate computed from MD simulations. The discrepancy between MD and continuum results at higher shear rates is explained by examination of local velocity profiles and pressure distribution along the wavy surface.

8:24AM A13.00003 KMC simulations in 3+1 dimensions and the effects of attachment probabilities and potential gradients on island morphologies , CHRISTOPHER FLECK, JUDITH YANG, University of Pittsburgh, ALAN MCGAUGHEY, Carnegie Mellon University, JUN REN, University of Pittsburgh — Thin film growth and nano-oxidation have received significant attention lately, especially given the interesting nature of Cu$_2$O growth. Our long-term vision is for a comprehensive, fundamental understanding of a gas-surface reaction via coordinated multi-scale theoretical and in situ experimental efforts. The link between the theoretical and experimental efforts is our kinetic Monte Carlo (kMC) code that simulates general behavior of the irreversible nucleation and growth of epitaxial islands. This simulation was originally a versatile 2+1 dimensional KMC code (Thin Film Oxidation or TFOx) that considered a wide range of elementary steps, including deposition, adsorption, dissociation of gas molecules, surface diffusion, aggregation, desorption, and substrate-mediated indirect interactions between static adatoms. Recently, TFOx has been extended to a 3+1 dimensional KMC code composed of a C++ console program and Python GUI, such that parameterized testing, parallel execution, and 3D growth capabilities are feasible. Emphasis has been placed on the effects of the potential gradient, multilayer nucleation and sticking parameter on the 3D island morphology.

8:36AM A13.00004 Nicholas Metropolis Award for Outstanding Doctoral Thesis Work in Computational Physics Talk: Understanding Nano-scale Electronic Systems via Large-scale Computation , CHAO CAO, University of Florida — Nano-scale physical phenomena and processes, especially those in electronics, have drawn great attention in the past decade. Experiments have shown that electronic and transport properties of functionalized carbon nanotubes are sensitive to adsorption of gas molecules such as H$_2$, NO$_2$, and NH$_3$. Similar measurements have also been performed to study adsorption of proteins on other semiconductor nano-wires. These experiments suggest that nano-scale systems can be useful for making future chemical and biological sensors. Aiming to understand the physical mechanisms underlying and governing property changes at nano-scale, we start off by investigating, via first-principles method, the electronic structure of Pd-CNT before and after hydrogen adsorption, and continue with coherent electronic transport using non-equilibrium Greens function techniques combined with density functional theory. Once our results are fully analyzed they can be used to interpret and understand experimental data, with a few difficult issues to be addressed. Finally, we discuss a newly developed multi-scale computing architecture, OPAL, that coordinates simultaneous execution of multiple codes. Inspired by the capabilities of this computing framework, we present a scenario of future modeling and simulation of multi-scale, multi-physical processes.

9:12AM A13.00005 Role of Adatom Relaxations in Computing Lattice-gas Energies: Multisite Interactions , RAJESH SATHIYANARAYANAN, T. L. EINSTEIN, Univ. Maryland, College Park — In simple lattice-gas models, only nearest-neighbor pair interactions are used to model adatom interactions. However, multisite interactions, such as trios and quartos, are necessary to understand certain surface properties like the orientation dependence of step stiffness and the equilibrium shape of islands. Strong multisite interactions are found to be present on a variety of metallic surfaces. Unlike pair interactions, the relaxations of adatoms in a multisite interaction are not along bond directions. Hence, these adatoms can shift significantly from their high-symmetry positions, making multisite interactions more sensitive to relaxations. Using VASP calculations, we showed that trios are very sensitive to lateral adatom relaxations on Pt(111) and Cu(100). Our recent calculations on Cu(110) indicate that in addition to trios, quartos also undergo a big change due to adatom relaxations. Such findings severely limit the effectiveness of lattice-gas models in characterizing surface interactions. We discuss alternate approaches to this problem.

9:24AM A13.00006 Rapid and Accurate Estimates of Alloy Phase Diagrams for Design and Assessment , TECK TAN, DUANE JOHNSON, University of Illinois, Urbana-Champaign — Based on first-principles cluster expansion (CE), we obtain rapid but accurate estimates of alloy T vs c phase diagrams from a mean-field theory that conserves sum rules over pair correlations. Such conserving mean-field theories are less complicated than the popular cluster variation method, and better reproduce the Monte Carlo (MC) phase boundaries and T$_c$ for the nearest-neighbor Ising model [1]. The free-energy f(T,c) is a simple analytic expression and its value at fixed T or c is obtained by solving a set of n non-linear coupled equations, where n is determined by the number of sublattices in the groundstate structure and the range of pair correlations included. While MC is “exact,” conserving mean-field theories are 10 to 100$^3$ faster, allowing for rapid phase diagram construction, dramatically saving computation time. We have generalized the method to account for multibody interactions to enable phase diagram calculations via first-principles CE, and its accuracy is showed vis-a-vis exact MC for several alloy systems. The method is included in our Thermodynamic ToolKit (TTK), available for general use in 2009. [1] V. I. Tokar, Comput. Mater. Sci. 8 (1997), p.8

9:36AM A13.00007 Chemistry effects on dislocation mobility in refractory bcc metals , NICHOLAS KIOUSSIS, ZHENGZHENG CHEN, Department of Physics, California State University, Northridge, GANG LU, Department Mechanical and Aerospace Engineering, University of California Los Angeles — Using a novel concurrent multiscale approach we demonstrate that the local environment of transition-metal solutes in refractory bcc metals has a large effect on the mobility and slip paths of dislocation. The results reveal that solid solutes or nano-clusters of different geometries may lead to solid-solution hardening (SSH) or softening (SSS), in agreement with experiment, including spontaneous dislocation glide and activation of new slip planes. The underlying electronic mechanism is also studied by the multiscale approach. Solutes nano-cluster can affect Peierls potential surface (PPS) dramatically. The results indicate that it is the change of the anisotropy of the lattice resistance induced by solutes that result in the different behavior of the dislocation according to the different geometries of solutes nano-clusters.
9:48AM A13.00008 Computational studies of thermal evolutions of extended interstitial defects in silicon.¹
HYOUNGKI PARK, JOHN W. WILKINS, The Ohio State University — Annealing induces the nucleation of extended defect clusters in silicon and their evolution, where clusters grow by capturing or interchanging interstitials, and change their crystallographic structure in order to minimize the formation energy. Extensive molecular dynamics (MD) simulations and first-principle nudged elastic band (NEB) simulations explore the thermal transitions from one structure to another of three energetically competing extended interstitial defects: two rod-like defects \{311\} and \{111\}, and Frank dislocation loop. MD simulations capture critical sequences of atomic processes during transitions from \{311\} and \{111\} defects to Frank loops as their atomic configurations and habit planes change, and massively parallelized NEB simulations within the local density approximation reveal the energetics of reaction barriers.

10:00AM A13.00009 Multiscale Modeling of Catalysis and its Application to Hydrogen Production through the Water Gas Shift Reaction on Nanoparticles¹
ALTAF KARIM, JAMES T. MUCKERMAN, Brookhaven National Lab — We describe a density functional kinetic Monte Carlo approach enabling us to study and simulate the steady-state condition of the water gas shift (WGS) reaction on Cu and Au nano-particles supported on ZnO(0001) surfaces. We have adopted a multiscale modeling paradigm in which density functional theory can be used to determine the behavior of systems at much larger length and time scales by coupling it with kinetic Monte Carlo methods. In the first step, density functional theory is used to obtain the energetics of the relevant atomistic processes of the WGS reaction on Cu and Au nanoparticles. Subsequently, the kinetic Monte Carlo method is employed, which accounts for the spatial distribution, fluctuations, and evolution of chemical species under steady-state conditions. Our simulations show that, in agreement with experiments, the hydrogen production rate strongly depends on size and structure of the nanoparticles.

10:12AM A13.00010 Preparation of nanoporous systems for the study of the mechanical properties of silica aerogels by Molecular Dynamics simulations
JOHN S. RIVAS MURILLO, Department of Mechanical and Aerospace Engineering, West Virginia University, MARTINA E. BACHELECHNER, Computer Science, Math and Physics Department, Fairmont State University, EVER J. BARBERO, Department of Mechanical and Aerospace Engineering, West Virginia University — This presentation focuses on the application of the Molecular Dynamics technique to study the mechanical properties of silica aerogels through the simulation of a tension test. It covers multiple areas, including aspects related to the preparation of a well-relaxed nanoporous system from the expansion of an amorphous bulk sample and the influence of the initial configuration of the system on the final results of the simulated tension test. The results presented here will help to develop a more complete procedure to prepare a proper sample for the study of the mechanical properties of a nanoporous system by using Molecular Dynamics. Comparison of the simulation results and previously published experimental data is provided.

10:24AM A13.00011 A hierarchical DPD thermostat to avoid over and/or underdamping at long wavelengths in MD simulations
KEVIN GREEN, COLIN DENNISTON, MARTIN MUSER, University of Western Ontario — In this talk, we present a new approach to use dissipative particle dynamics as a thermostat in molecular dynamics simulations. The main idea is to have DPD act on groups of atoms so that damping can be tuned as a function of length scale. This allows one to achieve a quality factor of vibrations, which is barely wavelength dependent. The number of floating point operations per time step is orders of magnitude less for the new approach than for regular DPD or any other thermostat acting on individual particles. In addition, the method avoids both underdamping of natural and/or DPD dynamics at long wavelengths L and overdamping which is unavoidable at large L for Langevin or Nose-Hoover based thermostats. Thus correlation times for observables that live on long wavelengths L, are of order L or rather of order L² as for conventional thermostats.

10:36AM A13.00012 Determination of the ground state structures of binary alloys via global space group optimization (GSGO) with no restrictions on composition: Al-Sc,¹ YOSHIHIDE YOSHIMOTO, Institute for Solid State Physics, University of Tokyo, Japan — Here, we extend the GSGO evolutionary algorithm scheme to survey crystal structures of binary A-B systems without constraint on the AₓBₓ composition. At each generation of the randomly started evolutionary sequences, the formation energy convex hull for the actual population is determined. The search proceeds by replacing the structures farthest away from the convex hull with new ones produced via mating and mutation with no constraints on composition. As a test of this new procedure, we searched the ground state compounds of the Al-Sc alloy whose lattice types are not easily inferred from that of the Al and Sc constituents, respectively fcc and hcp solids. Repeated, independent evolutionary sequences with six and eight atoms in the supercell were performed yielding as ground states respectively B₁₂, and D₀₁₉, B₂, and L₁₀, as known from experiment and previous ab-initio studies. This yields a synthesis of the final convex hull.

10:48AM A13.00013 Non-crystalline state of silicon studied by multicanonical simulation combined with first-principles calculation
YOSHIHIDE YOSHIMOTO, Institute for Solid State Physics, University of Tokyo, Japan — By combining multicanonical ensemble molecular dynamics and first-principles calculations, non-crystalline state of silicon is studied. This attempt contrast with quenching molecular dynamics simulations whose speed is usually by far quicker than that of experimental quenchings. To make the molecular dynamics simulation tractable, a model interatomic potential is used. The parameter, however, is determined by first-principles calculation so that the discrepancy between the first-principles interatomic potential and the model one is minimized on the typical configuration set of the multicanonical ensemble. Because multicanonical ensemble represents the whole thermodynamics of the system, the obtained model will conserve the thermodynamics to a maximum extent. (thermodynamic downfolding of an interatomic potential [1]) The transition between amorphous silicon and liquid silicon, and the density maximum of liquid silicon as a function of temperature will be discussed. (Silicon has similar structure to that of water) [1] Y. Yoshimoto, J. Chem. Phys., 125, 184103 (2006)

Monday, March 16, 2009 8:00AM - 10:48AM – Session A14 DFD: Instabilities, Turbulence and Nonlinear Flows 315
8:00AM A14.00001 Search for the “ultimate state” in turbulent Rayleigh-Bénard convection for Rayleigh numbers up to $4 \times 10^{13}$ and Prandtl numbers near 0.8$^1$. GUENTER AHLLERS, UCSB, DENIS FUNFSCHILLING, CNRS Nancy, EBERHARD BODENSCHATZ, MPI for Dyn. and Self-org., Goettingen — Measurements of the Nusslet number $N_u$ over the Rayleigh-number range $10^{10} < \text{Ro} < 4 \times 10^{12}$ for $N_2$ (Prandtl number $Pr = 0.72$) and $S_f$ ($Pr = 0.78$ to 0.82) are reported. They were made at pressures up to 15 bars and near-ambient temperatures for a cylindrical sample of height $L = 2.2$ m and diameter $D = 1.1$ m in a new High-Pressure Convection Facility (HPCF) constructed at the Max Planck Institute for Dynamics and Self-Organization in Göttingen, Germany. The data can be represented well by a power law with an effective exponent of 0.31. They do not show the transition to an “ultimate regime” reported by Chavanne et al.

$^1$Work at UCSB supported by NSF Grant DMR07-02111.

8:12AM A14.00002 Large-scale circulation and Nusselt number in turbulent rotating Rayleigh-Bénard convection.$^1$, JIN-QIANG ZHONG, UCSB, RICHARD STEVENS, U. Twente, HERMAN CLERCX, Eindhoven U. Tech., DETLEF LOHSE, U. Twente, GUENTER AHLLERS, UCSB — We present measurements of the large-scale circulation (LSC) and the Nusselt number $N_u$ of turbulent Rayleigh-Bénard convection in a cylindrical cell of aspect ratio 1 and rotated about a vertical axis at a rate $\Omega$. The side-wall temperatures at eight equally spaced azimuthal positions in the horizontal mid-plane were fit to a cosine function that gave the azimuthal LSC orientation $\theta (t)$ ($t$ is the time), the temperature amplitude $\delta (t)$, and the rms amplitude $\delta T (t)$ of the fluctuations about the fits. The LSC precessed in an azimuthal direction opposite to that of the imposed rotation. The precession rate $\omega = d\theta / dt$ showed a sharp transition at a Rossby number $\text{Ro}^*> 2.5$. As $\text{Ro}$ increased, $\delta (t)$, $\delta T (t)$ increased beginning at $\text{Ro}^*$. At $\text{Ro}^*$ $N_u$ began to increase with increasing $\Omega$. At high $\text{Ro} |\omega|$ was proportional to but much smaller than $\Omega$.

$^1$Work at UCSB supported by NSF Grant DMR07-02111.

8:24AM A14.00003 Geometry of turbulence: a stroll through 61,506 dimensions$^1$, PREDRAV CVITANOVIC, JOHN F. GIBSON, Georgia Tech, JONATHAN HALCROW, Inst. for Physical Sciences, McLean, VA 22101 — We propose to use a hierarchy of exact unstable invariant solutions of the Navier-Stokes equations — corresponding to the recurrent coherent structures observed in experiments — to construct a description of the spatio-temporally chaotic dynamics of turbulent fluid flows as a walk through the space of such structures. This description should allow us to obtain quantitative predictions of transport properties of fluid flows such as bulk flow rate and mean wall drag.

$^1$Partly supported by NSF grant DMS-0807574

8:36AM A14.00004 Lagrangian and Eulerian Turbulence: intermittency and Universality, LUCA BIFERALE, University of Rome, ICTR COLLABORATION — We present the result of a high resolution numerical simulations of homogeneous and isotropic turbulence at BIFERALE, University of Rome, ICTR COLLABORATION. The side-wall temperatures at eight equally spaced aircraft were made at pressures up to 15 bars and near-ambient temperatures for a cylindrical sample of height $L = 2.2$ m and diameter $D = 1.1$ m in a new High-Pressure Convection Facility (HPCF) constructed at the Max Planck Institute for Dynamics and Self-Organization in Göttingen, Germany. The data can be represented well by a power law with an effective exponent of 0.31. They do not show the transition to an “ultimate regime” reported by Chavanne et al.

8:48AM A14.00005 Large-eddy simulation of swirling reacting flows, MARCEL ILIE, University of California San Diego — Turbulent, swirling flows are encountered frequently in various chemical engineering processes. In combustion processes swirling flames are of interest due to the fact that provide enhanced mixing and reduce the pollutants formation. The challenge in understanding turbulent swirling flows stems mainly from the complexity of the flow field which is subject to vortex breakdown, recirculation and flow instability. In general the flow instabilities arise at high swirl numbers and can be used to control the performance of combustors. In the present study a large-eddy simulation (LES) approach with Smagorinsky eddy viscosity subgrid scale model is used to predict the swirling flame. The conserved scalar mixture fraction-based thermo-chemical variables are described using the steady laminar flamelet model. The present study shows that LES together with a laminar flamelet model provides a good prediction of the structure of turbulent swirling flames. Also LES captured very well the complex flame structures involving vortex breakdown which leads to swirl-induced recirculation zones, flow instability, and the occurrence of localized extinction. Also, the present study shows that the formation of an elongated recirculation (bluff-body stabilized) zone is strongly dependent on the swirl number and the ratio of momentum in the swirling annulus and central fuel jet.

9:00AM A14.00006 Methods to Approach Velocity Data Reduction and Their Effects on Conformation Statistics in Viscoelastic Turbulent Channel Flows, GAURAB SAMANTA, ANTONY BERIS, University of Delaware, ROBERT HANDLER, Naval Research Laboratory, KOSTAS HOUSIADAS, Aegae University, Greece — Karhunen-Loeve (KL) analysis of DNS data of viscoelastic turbulent channel flows helps us to reveal more information on the time-dependent dynamics of viscoelastic modification of turbulence [Samanta et al., J. Turbulence (in press), 2008]. A selected set of KL modes can be used for a data reduction modeling of these flows. However, it is pertinent that verification be done against established DNS results. For this purpose, we did comparisons of velocity and conformations statistics and probability density functions (PDFs) of relevant quantities obtained from DNS and reconstructed fields using selected KL modes and time-dependent coefficients. While the velocity statistics show good agreement between results from DNS and KL reconstructions even with just hundreds of KL modes, tens of thousands of KL modes are required to adequately capture the trace of polymer conformation resulting from DNS. New modifications to KL method have therefore been attempted to understand the role of the rapid magnetic pressure in the evolution of the Reynolds stresses for different mean distortions and magnetic fields.

9:12AM A14.00007 Study of Influence of Rapid Pressure in MHD Turbulence, SAIKISHAN SURYANARAYAN, AARTHI SEKARAN, Texas A&M University — Turbulence, under the influence of magnetic field is characterized by anisotropy. Relatively limited work has been done in understanding and modeling magnetohydrodynamic (MHD) turbulence. The rapid distortion theory (RDT), which has been employed to study hydrodynamic turbulence, is a limiting case where the gradients of the mean velocity are very high compared to the gradients of the fluctuating field. When analyzed in a spectral framework, this leads to the independent evolution of each Fourier mode. RDT has been used to understand production and more importantly the “rapid” part of the pressure strain redistribution, as the other terms in the Reynolds stress evolution equation become negligible in the rapid distortion limit. Earlier work attempts to characterize the effect of the rapid pressure based on the geometry of the symmetric part of the mean velocity gradient tensor. This work deals with the application of RDT to MHD turbulence. The application of Elsasser variables reorganizes the MHD equations in a form similar to conventional Navier-Stokes. The current work is a numerical study of the Elsasser variable evolution equation in the rapid distortion limit and attempts to understand the role of the rapid magnetic pressure in the evolution of the Reynolds stresses for different mean distortions and magnetic fields.
9:24AM A14.00008 Anisotropic Particles in Fluid Flow1, MONICA KISHORE, Haverford College, NICHOLAS T. OUELLETTE, Yale University, JERRY GOLLUB, Haverford College — Anisotropic particles are common in natural flows. In previous work [1] the dynamics of neutrally buoyant finite-sized spherical particles with Stokes numbers up to 0.08 were examined in 2D flows with Reynolds numbers of 72-220. Here, we extend this work to neutrally buoyant, high-aspect-ratio anisotropic particles of mm to cm length in a 2D cellular flow. The particle trajectories and orientations are tracked simultaneously with the underlying velocity field, which is measured using much smaller tracer particles. These methods allow us to compare the relative velocity and orientation of anisotropic particles to various features of the flow field. We find, for example, that the long axes of the particles preferentially align with the instantaneous direction of maximum compression, and that this alignment increases with particle aspect ratio. [1] N.T. Ouellette, P.J.J. O'Malley, and J.P. Gollub, Phys. Rev. Lett. 174504 (2008).

9:36AM A14.00009 Statistics of preferential particle concentration in free-surface2, JASON LARKIN, WALTER GOLDBURG, University of Pittsburgh, MAHESH BANDI, Center for Nonlinear Studies and Condensed Matter & Thermal Physics Group, Los Alamos National Laboratory — Particles floating on a turbulent surface of water cluster into temporally complex patterns. We experimentally study the statistics of this preferential particle concentration for various Reynolds numbers, for both transient and steady-state dynamics. The probability density function for particle concentration exhibits a power-law with an exponential cut-off. We will discuss our preliminary analysis as to how this distribution depends upon the Reynolds number and the spatial-scale r at which the system is coarse-grained.

9:48AM A14.00010 Vortex Street behind an Oscillating Wire on a Soap Film, AARON MEYER, ILDOO KIM, X.L. WU, University of Pittsburgh — A von Kármán vortex street, a periodic array of vortices behind a bluff body is normally characterized by a single frequency $f_0$ at which the vortices shed. In this study, von Kármán vortex streets are generated on a 2D soap film using a glass-covered metal wire in a static magnetic field. When the wire is driven with electric current to make an oscillatory motion with frequency $f$, transverse to the mean flow, vortices shed at a frequency $f'$ differs from $f_0$. It is seen that with oscillation, $f_0$ is suppressed, $f'/f_0$ becomes a rational number, and vortices are rearranged to form an exotic spatial structure. This “frequency-locking” phenomena show some features of the sine-circle map, but the relevancy to the physical system is not clear. When the amplitude of the oscillation is large enough, the system becomes chaotic. In this chaotic regime, the energy power spectrum resembles that of 2D decaying turbulence.

10:00AM A14.00011 An Anomalous Behavior in Vortex Shedding in a Flowing Soap Film, ILDOO KIM, X.L. WU, University of Pittsburgh — It is generally believed that von Kármán vortex street is characterized only by Reynolds number $Re = UD/v$, where $U$ is the mean flow speed, $D$ is the size of the body which generates the vortex street, and $v$ is the kinematic viscosity. In this study, we present experimental data in a flowing soap film showing that changing $U$ with fixed $D$ and changing $D$ with fixed $U$ are not equivalent to each other, suggesting that $Re$ alone is not sufficient to characterize vortex shedding by a bluff body. The velocity of eyes of the vortices relative to the mean flow, normalized by $U$, increases when we increase $D$, but decreases when we increase $U$. It is also found that the longitudinal spacing between the eyes is a linear function of $D$, but independent of $U$.

10:12AM A14.00012 Rayleigh-Taylor Instability in Nonlinear Optics, SHU JIA, JASON W. FLEISCHER, Princeton University — We demonstrate, theoretically and experimentally, an all-optical Rayleigh-Taylor instability. By applying a polar (Madelung) transformation to the nonlinear Schrödinger equation for paraxial beams, we identify fluid density with light intensity and fluid velocity with the gradient of the optical phase. Pressure is obtained by using a self-defocusing nonlinearity in a photorefractive crystal, while acceleration is created by imposing a refractive index gradient. In this way, we are able to control the effective gravity, pressure, and input density ratio. The perturbed interface at the output is then studied as functions of these parameters. Observations of the characteristic spatial period show excellent agreement with analytical calculations from perturbation theory. In this case, wave diffraction, rather than viscosity or surface tension, sets the scale for long-wave growth. Further, we show that compressibility effects are important and demonstrate that care must be taken regarding shock-wave formation. The results hold for any Schrödinger fluid, e.g. superfluids and quantum plasma, and lay the foundation for a variety of fluid-inspired instabilities in nonlinear optics.

10:24AM A14.00013 Dispersive shock waves with negative pressure, WENJIE WAN, DMITRI DYLOV, CHRISTOPHER BARSI, JASON FLEISCHER, Princeton University — Dispersive shock waves (DSWs) arise from nonlinear wave breaking and mode dispersion and are a fundamental type of fluid behavior. In normal fluid systems, the pressure is positive and repulsive, so that the underlying particles resist compression. Examples include water, plasma, and optical beams with self-defocusing nonlinearity. However, there are systems in which the interactions are attractive, resulting in an effectively negative pressure. Here, we demonstrate that dispersive shock waves can arise in these negative-pressure systems by considering the equivalent optical problem with self-focusing nonlinearity. Using partially-coherent light, to prevent the competition of modulation instability, we experimentally observe DSWs formed in a self-compressive beam in a photorefractive crystal. We characterize the nonlinear speed and profile of the DSWs, and show that statistical de-phasing by the incoherent beam causes an effective Landau damping of the waves. Observations are supported both by analytic theory and numerical simulation.

10:36AM A14.00014 Convective instability in pipe flow through a sudden expansion, JAMES SEDDON, University of Manchester — Flow through a sudden expansion in a pipe has been the subject of a lot of recent scientific interest. The geometry occurs in many industrial processes, from heat exchangers to combustion chambers, and is closely related to the physiological problem of flow through a stenosis. The inlet flow from the upstream pipe is Poiseuille, which forms a central jet surrounded by a recirculating eddy in the expanded downstream pipe. Recently we showed that this kind of flow passes through a symmetry breaking bifurcation before the onset of both intermittent and fully periodic time-dependent effects. We have now investigated the intermittency in more detail and find that the flow becomes convectively unstable. A wave packet emerges from the laminar state and grows to a maximum size of several diameters before decaying.

Monday, March 16, 2009 8:00AM - 11:00AM – Session A15 DFD: Soft Matter, Fluid Structure and Properties 316
8:00AM A15.00001 Impact of a viscous drop, WENDY W. ZHANG, ROBERT D. SCHROLL, University of Chicago, CHRISTOPHE JOSSENDRO, STEPHANE ZALESKI, UMR 7190, Institut d'Alembert — Recent experiments [1] reveal that reducing the ambient air pressure entirely suppresses the splash generated by the impact of an oil drop at several m/s onto a dry smooth wall. Motivated by these observations, we simulate two types of drop impact: impact onto a smooth, dry solid wall and head-on collision of two identical liquid drops. In both cases we make the additional simplification that impact simply arrests the downward fall and redirects the liquid radially outwards in a thin, expanding sheet. It does not break the drop surface. Since experiments suggest that splash is created by airflow deforming the thin sheet, we focus on the time-evolution of the thin liquid sheet but restrict ourselves to one simpler situation of negligible airflow effects. In this regime, we find that the ejected sheet is always characterized by two different length-scales. Surface tension controls the rim size. The thickness over the rest of the sheet is controlled by a different mechanism. Impact onto a solid surface creates a pancake whose thickness is controlled by viscous dissipation. Head-on collision creates a sheet that thins continuously with distance from the collision center. Its thickness is controlled by the kinematics of impact.

8:12AM A15.00002 Focused impact through layers of aqueous cornstarch solution, BIN LIU, Courant Institute, NYU, JUN ZHANG, Dept. of Physics and Courant Institute, NYU, MICHAEL SHELLEY, Courant Institute, NYU — A layer of aqueous cornstarch solution, when punched with a solid sphere, will create a thickened mass on the sphere that transmits the impact towards the bottom. As a consequence, the mass can leave an imprint on the bottom, if composed of a soft molding clay. The impact transmitted through the fluid layer is more localized for slower speeds of the sphere, giving rise to an imprint with sharper curvature. Our work shows that a layer of shear-thickening fluid may help to focus the impact rather than dissipate it when punched slowly enough.

8:24AM A15.00003 Drop pinch-off of concentrated surfactant solutions in the lamellar phase, ITAI COHEN, Cornell University, PATRICK SPICER, MARCO CAGGIONI, P&G, JOHN SAVAGE, Cornell University — Droplet pinch-off in air is a common phenomenon that occurs all around us. At the point of pinch-off, the drop radius shrinks to zero in a finite amount of time. The pressure exerted by the interface is inviscid, and thus finite, and the fluid velocity is zero at the drop radius. Although the fluid velocity becomes singular at Pinch-off in Newtonian fluids, this finite time singularity gives rise to universal features in the pinch-off process that can be described by similarity solutions for the fluid flow. In this talk I will address the question of how this process is altered when observed in concentrated surfactant solutions that are in the lamellar phase. Remarkably we find that pinch-off in these systems is a mix between universal and non-universal behavior.

8:36AM A15.00004 Watching the Paint Dry: Dynamics of Drying in Porous Media, LEI XU, Harvard University, SIMON DAVIES, ICI, ANDREW SCHOFIELD, the University of Edinburgh, DAVID WEITZ, Harvard University — What is the dynamics of drying in porous media? It has been difficult to visualize due to the non-transparency of the media. We study this phenomenon in an optical index matched colloidal system with confocal microscopy. We observe abrupt air invasions which result from the strong flow from menisci in large pores to menisci in small pores. The size and structure of the air invasions are in accord with 3D invasion percolation. By varying the particle size and contact angle we unambiguously demonstrate that capillary pressure dominates the drying process.

8:48AM A15.00005 Monitoring Three-dimensional Fluid Configurations in Porous Media, AMBER KRUMMEL, DAVID WEITZ, Harvard University, SCHLUMBERGER COLLABORATION — The spatial and time resolution of confocal microscopy allows us to observe the three-dimensional fluid configurations in the pore. We monitor the time evolution of the fluid configuration with a confocal scope with precise flow and pressure measurements, such that we can begin to understand the origins and consequences of the three-dimensional fluid configurations that evolve in the sample. The porous media used in this work is composed of slightly sintered, borosilicate glass beads that are 150 microns in diameter.

---

9:00AM A15.00006 Shear banding fluids in microchannels: high shear rheology, slippage and Poiseuille flow instability, PHILIPPE NGHE, GUILLAUME DEGREG, PATRICK TABLING, MMN, UMR CNRS-ESPCI 7083 Gulliver, ARMAND AIDARI, PCT, UMR CNRS-ESPCI 7083 Gulliver — We characterize by Particle Image Velocimetry the Poiseuille flow a semi-dilute solution of wormlike micelles (a CTAB and sodium nitrate aqueous solution) in pressure resistant microchannels. At low shear rates, we observe a parabolic profile. Increasing the pressure driving the flow, the fluid separates into two phases above a critical shear rate at the wall. This is the so called shear-banding regime. Deducing the non-linear rheology from the velocity profiles by a local calculation, we are able to measure the stress versus shear rate curve at least one order of magnitude above the dynamical range attainable in Couette geometries, independently from the slippage, revealing a strongly shear-thinning structure. In addition, by extrapolation of the velocity profiles to the wall position, we measure an absence of slippage at the wall. Looking into more details to the increase in velocity fluctuations in the downstream direction, we characterize a supercritical instability in this shear-bandied Poiseuille flow, localized at the interface between the two phases with a wavelength comparable to the confining dimension.

9:12AM A15.00007 Nonlinear Dynamics in Viscoelastic Jets, TRUSHANT MAJMUDAR, MATTHIEU VARAGNAT, GARETH MCKINLEY, Massachusetts Institute of Technology — Instabilities in free surface continuous jets of non-Newtonian fluids, although relevant for many industrial processes, remain poorly understood in terms of fundamental fluid dynamics. Inviscid, and viscous Newtonian jets have been studied in considerable detail, both theoretically and experimentally. Instability in viscous jets leads to regular periodic or random aerofoil of the jet, which exhibits a non-trivial frequency dependence with the height of the fall. Here we present a systematic study of the effect of viscoelasticity on the dynamics of continuous jets of worm-like micellar surfactant solutions of varying viscosities and elasticities. We observe complex nonlinear spatio-temporal dynamics of the jet, and uncover a transition from periodic to quasi-periodic to a multi-frequency, broad-spectrum dynamics. Beyond this regime, the jet dynamics smoothly crosses over to exhibit the “leaping shampoo” or the Kaye effect. We examine different dynamical regimes in terms of scaling variables, which depend on the geometry (dimensionless height), kinematics (dimensionless flow rate), and the fluid properties (elasto-gravity number) and present a regime map of the dynamics of the jet in terms of these dimensionless variables.

9:24AM A15.00008 Relating shear banding and orientational order in wormlike micellar solutions, MATTHEW HELGESON, MATTHEW REICHERT, University of Delaware, ERIC KALER, Stony Brook University, NORMAN WAGNER, University of Delaware — Shear banding has been observed in a variety of complex fluids, including polymer solutions, colloidal suspensions and, most prominently, wormlike micelles (WLMs). However, accurate modeling of shear banding fluids remains a challenge, due to the inability to identify the mechanism(s) leading to banding. Using a novel approach that combines measurements of phase behavior, rheology, and spatially-resolved microstructure on model WLMs, we present the first complete study of local rheology and microstructure through the shear banding transition for model WLMs in the vicinity of an equilibrium isotropic-nematic transition (I-N). The rheology of such fluids is well-described by the Giesekus constitutive equation with incorporated stress diffusion, which allows simultaneous description of rheology, flow kinematics, and spatially-resolved microstructure under shear. The results show that shear banding coincides with a first-order, shear-induced transition to a paranematic state at critical values of micellar orientation and alignment, which can be related directly to a non-monotonic constitutive relation. Furthermore, the model allows for the construction of non-equilibrium state diagrams that elucidate a number of experimental observations in shear banding fluids.
9:36AM A15.00009 Structure and Phase Behavior of Ion–Dipole Mixtures. WONKI ROH, ERIK LUIJTEN, University of Illinois at Urbana-Champaign — It is well established that Coulombic interactions induce a liquid–liquid transition in ionic solutions. By contrast, the occurrence of phase separation driven by anisotropic dipolar interactions is still a matter of debate, with our recent simulation results excluding this phase separation for a large region of the temperature–density plane. These observations naturally lead to the question whether phase separation takes place in mixtures that contain ions as well as dipolar particles. Employing large-scale grand-canonical Monte Carlo simulations, we investigate four prototypical ion–dipole mixtures: ion-dominated systems in which the dipole moment is either strong or weak, and dipole-dominated systems with strong or weak dipolar strength. We focus on the low-temperature regime and search for phase separation by varying the chemical potentials of the ions as well as the dipolar particles. Depending on temperature and on the magnitude of the dipole moment, remarkable liquid structures are found that may have implications not only for the behavior of ion–dipole mixtures, but also for self-assembly in suspensions containing charged and dipolar colloids.

9:48AM A15.00010 Surface Layering Near Room Temperature in a Nonmetallic Liquid1, SUDESHNA CHATTOPADHYAY, BENJAMIN STRIPE, PHILIP FRY, GEUNNADI EVMENENKO, PULAK DUTTA, Dept. of Physics & Astronomy, Northwestern Univ., STEVEN EHRlich, HAIDING MO, Brookhaven National Laboratory — Oscillatory density profiles (layers) have been observed at the free surface of nonmetallic liquid metals and alkali metals at and above room temperature [1]. A surface-layered state has been previously reported only in one dielectric liquid, tetrakis[2-(ethylhexyloxy)]silane (TEHOS), and only at lower temperatures [2]. We have used x-ray reflectivity to study a molecular liquid, pentaphenyl trimethyl trisiloxane. Below Tc = 267K (well above the freezing point for this liquid), density oscillations appear at the surface. This liquid has a higher Tc (~1200K) than TEHOS (~950K), so that layers appear at T/Tc = 0.2 in both cases. Our results indicate that surface order is a universal phenomenon in both metallic and dielectric liquids, and that the underlying physics is likely to be the same since layers always appear at T < 0.2Tc, as theoretically predicted [3].

10:00AM A15.00011 Structural effect of sugars on water1, SIMCHA SREBNIK, RAVIT MATZA, ILIYA KUSNER, YOO D. LIVNEY, Technion - Israel Institute of Technology — The modulation of the structure of liquid water by solutes has tremendous consequences in numerous fields, particularly on the stability of proteins. However, the reasons for the differences in effects of similar solutes are still unclear. Recently, Livney and coworkers [1] found a strong relationship between the hydration layer of sugars and its effect on the phase transition of a model polymer, which may be explained by the strong interaction between water and sugars leading either to cooperative structuring of the water and thus to large hydration numbers, or disrupting water structure near the sugar, resulting in lower hydration. Using atomistic Monte Carlo simulation, we studied the compatibility of various sugars with an ideal tetrahedral water structure, as embodied in square ice. Our simulations suggest the following order of compatibility with ideal water structure: galactose > glucose > mannosse. In agreement, experimental measurements of isentropic compressibility show the same order of hydration numbers and kosmotropic effect. A simple physical model of the binary system is used to shed further insight on the structuring effect of sugars on water. 1. Shipgelman, A.; Portnaya, I.; Ramon, O.; Livney, Y. D. J Polym Sci Part B: Polym Phys 2006, 44, 2307-2318.

10:12AM A15.00012 Reconstructing the dynamical solvent structure around a model ‘hydrated electron’ using inelastic x-ray scattering, R. CORIDAN, G.H. LAI, N. SCHMIDT, Dept. of Physics, P. ABBAMONTE, Dept of Physics, Seitz Materials Research Lab, G.C.L. WONG, Depts. of Mat. Science Eng. and Physics, and Seitz Materials Research Lab, U of Illinois, Urbana-Champaign, R. CODEWAT, S. GARDE, Dept of Chem and Bio Engineering, Rensselaer Polytechnic Institute, M. KRISCH, European Synchrotron Radiation Facility, A.Q.R. BARON, SPRing-8/RIKEN and SPRing-8/JASRI — The structure and dynamics of water on femtosecond timescales is relevant to many topics in physical chemistry such as electron solvation. We computationally reconstruct the A-scale spatial and fs-scale temporal evolution of density fluctuations in water using high-resolution inelastic x-ray scattering (IXS). The imaginary part of density propagator ω is directly extracted from the IXS data, and the real part recovered using Kramers-Kronig relations. The resultant complex-valued χ(q,ω) is the Fourier transform of the real-space density-density response function χ(t) which measures the dynamical density fluctuations of water due to a point-like instantaneous pulse. We use this density propagator and linear-response theory to reconstruct a model of the hydrated electron. The water density fluctuations as the electron ‘diffuses’ through bulk water can be observed. Moreover, preliminary data on the solvent response to changes in the electronic wave function will be presented.

10:24AM A15.00013 Direct measurement of negative square gradient coefficients for density fluctuations in all-atoms simulations of common liquids, COLIN DENNISTON, LINGTI KONG, DAN VRIESINGA, University of Western Ontario — We perform all-atom simulations of common liquids such as water (TIP3P) and organic liquids such as short-chain olefins. We show that square gradient coefficients for the mass density can be measured directly in a linear response measurement to sinusoidal forces at several different wavelengths. Surprisingly, in all fluids measured, the square gradient coefficient is negative implying that density gradients lower the free energy of the system. However, stability is maintained at any wavelength greater than the separation between molecules due to the global mass conservation constraint. We suggest that this provides a mechanism for the molecular scale cut-off of pressure singularities that arise in situations such as droplet pinch-off.

10:36AM A15.00014 Chiral Structures of Thermoresponsive Soft Spheres in Hollow Cylinders1, MATTHEW A. LOHR, University of Pennsylvania, AHMED ALSAYED, CNRS/University of Pennsylvania, ZEXIN ZHANG, ARJUN G. YODH, University of Pennsylvania — We experimentally observe the formation of closely packed crystalline structures in hollow cylinders. The structures have varying degrees of chiral order. The systems are created from aqueous suspensions of thermoresponsive N-isopropylacrylamide (NIPA) microgel particles packed in micron-scale cylinders. The temperature-tunable diameter of these particles, the system’s volume fraction is changed, permitting observations of the resilience of these structures and their melting transitions. Melting of these thermal crystalline structures is observed. [1] R. O. Erickson, Science 181 (1973) 705-716.

10:48AM A15.00015 Nonlinear Transverse Wave Excitations in Fluid Flows, DILLON SCOFIELD, Dept. Physics, Oklahoma State Univ.; PABLO HUQ, Univ. Delaware — The interplay of inertia and dissipation in flows with nonlinear transverse wave excitations is described by including a vortex field into the stress-energy balance equation. The theory uses an acoustic spacetime which allows limiting the speed of propagation of fluid transverse waves to a maximum speed. In the low speed limit, the theory reduces to the Navier-Stokes equations. By examining other limiting cases we show that the Navier-Stokes theory neglects terms involved with the transport of vorticity and the dissipation of energy due to the vortex field. Comparison of the theory to experiment, relative to the Navier-Stokes theory, shows that the presence of the vortex field accounts for the observed relative increase in energy dissipation, extended lifetime of vortex structures, and excitation structure of the transverse wave field.
A simple and systematic characterization of the radio frequency (RF) spectra of homogeneous, paired atomic Fermi gases at general temperatures, experiments on atomic Fermi gases remove ambiguity plaguing the interpretation of previous RF studies. Our calculated spectral intensities are in semi-quantitative agreement with the data.

Fermi gases. Here we establish the underlying physics of these RF measurements. We show that, by providing a clear dispersion signature of pairing, they distinguish between a normal Fermi liquid and a paired superfluid at highly imbalanced gas, and (c) the normal Fermi liquid state for a repulsive, balanced gas. We address the question of how rf spectroscopy can make a sharp distinction between a normal Fermi liquid and a paired superfluid at $T = 0$. We also describe the role of final state interactions and of finite temperature effects.

8:24AM A16.00003 Pseudogap phenomena in the BCS-BEC crossover regime of atomic Fermi gases , SHUJNI TUSCHIYA, Department of Physics, Keio University, 3-14-1 Hiyoshi, Yokohama, Japan and CREST(JST), 4-1-8 Honcho, Saitama, Japan, RYOTA WATANABE, Department of Physics, Keio University, 3-14-1 Hiyoshi, Yokohama, Japan, YOJI OHASHI, Department of Physics, Keio University, 3-14-1 Hiyoshi, Yokohama, Japan and CREST(JST), 4-1-8 Honcho, Saitama, Japan — We study pseudogap behavior of atomic Fermi gases in the BCS-BEC crossover. Including pairing fluctuations, we calculate the fermionic density of states above the superfluid transition temperature $T_c$, based on the strong coupling theory developed by Nozières and Schmitt-Rink. We show that the gap structure appears in the density of states above $T_c$ in the crossover region, and it evolves as the attractive interaction strength increases. We also clarify the temperature dependence of the pseudogap, which disappears as the temperature rises, and determine the pseudogap region in the phase diagram. We discuss the origin of the pseudogap by examining the behaviors of quantities such as spectral function and self-energy.

Supported by ARO grant W911NF-08-1-0338.

8:36AM A16.00004 Universal properties of ultracold Fermi gases , SHIZHONG ZHANG, UIUC, ANTHONY LEGGETT — We present some general considerations on the properties of a two-component ultra-cold Fermi gas along the BEC-BCS crossover. It is shown that the interaction energy and the free energy can be written in terms of a single dimensionless function $h(\xi, \tau)$, where $\xi = -(k_F a_s)^{-1}$ and $\tau = T/T_F$. The function $h(\xi, \tau)$ incorporates all the many-body physics and naturally occurs in other physical quantities as well. In particular, we show that the average rf-spectroscopy shift $\delta(\xi, \tau)$ and the molecular fraction $f_c(\xi, \tau)$ in the closed channel can be expressed in terms of $h(\xi, \tau)$ and thus have identical temperature dependence. The conclusions should have testable consequences in future experiments.

Supported by NSF PHY-0555325 and NSF-MRSEC Grant No. DMR-0213745.

9:00AM A16.00006 Temperature and final state effects in radio frequency spectroscopy experiments on atomic Fermi gases , YAN HE, CHIH-CHUN CHIEN, QUINCHEN, KATHY LEVIN, University of Chicago — We present a simple and systematic characterization of the radio frequency (RF) spectra of homogeneous, paired atomic Fermi gases at general temperatures, $T$, in the presence of final state interactions. The spectra, consisting of possible bound states and positive as well as negative detuning ($\nu$) continua, satisfy exactly the zeroth- and first-moment sum rules at all $T$. We show how to best extract the pairing gap and how to detect the $\nu < 0$ continuum arising from thermally excited quasiparticles, not yet seen experimentally. We explain semi-quantitatively recent RF experiments on “bound-bound” transitions, predicting effects of varying temperature.

9:12AM A16.00007 The Higgs resonance in fermionic condensates , ROMAN BARANKOV, Boston University — The Higgs mode appears in the spectrum of fermionic condensates described by the BCS model as a result of the energy dispersion of interaction. Specifically, the mode enters the spectral gap of quasi-particle excitations when the pairing of fermions is enhanced at the Fermi energy. Conversely, it becomes a resonance in the quasi-particle continuum with a finite lifetime, when the pairing is suppressed on the energy scale small compared to the equilibrium gap. The exponential decay of the mode converts into algebraic decay for a smooth suppression. We confirm our analytical results by numerical analysis of the pairing dynamics.

Supported by AFOSR.

SHIQUAN SU, DANIEL E. SHEEHY, JUANA MORENO, MARK JARRELL — We study Feshbach-resonantly interacting fermions near unitarity within the context of the attractive Hubbard model. Our principal focus is the single-particle spectral function for such strongly-interacting fermions, recently probed in radio-frequency spectroscopy and photoemission experiments in cold-atom systems. To obtain quantitatively-accurate results on unitary gases, we apply the Dynamical Cluster Approach (DCA) and the Maximum Entropy method to study this system both in the pair-formation temperature region and in the low-temperature condensed state. Different Quantum Monte Carlo approaches emphasizing different observables are used as the quantum solver in the DCA approach, and the data from different approaches are compared to each other.

9:36AM A16.00009 Feshbach–Einstein condensates

VALY ROUSSEAU, PETER DENTENEER, Instituut-Lorentz, University of Leiden (The Netherlands) — We investigate the phase diagram of a two-species Bose-Hubbard model describing atoms and molecules on a lattice, interacting via a Feshbach resonance. We identify a region where the system exhibits an exotic super-mott phase and regions with phases characterized by atomic and/or molecular condensates. Our approach is based on a recently developed exact quantum Monte Carlo algorithm, the Stochastic Green Function (SGF) algorithm with tunable directionality. We confirm some of the results predicted by mean-field studies, but we also find disagreement with these studies. In particular, we find a phase with an atomic but no molecular condensate, which is missing in all mean-field phase diagrams.

This work is part of the research program of the Stichting voor Fundamenteel Onderzoek der Materie (FOM), which is financially supported by the Nederlandse Organisatie voor Wetenschappelijk Onderzoek (NWO).

9:48AM A16.00010 Strongly-correlated fermionic matter in the dilute limit

BOGDAN MIHAILA, Los Alamos National Laboratory, ANDRES CARDENAS, Cal Poly Pomona — We study “the ground-state properties of the many-body system composed of spin-1/2 fermions interacting via a zero-range, infinite scattering length contact interaction.” The above is referred to sometimes as the George Bertsch problem, and it is of particular interest in astrophysics in connection with the equation of state for neutron matter and has been revisited recently with the advent of experimental studies of the BCS to BEC crossover in ultracold fermionic atom gases. We will show that new insights into the solution to this problem are obtained in the context of a coupled-cluster (exp S) expansion approach to calculating the equation of state for dilute fermionic systems and that present state-of-the-art Monte Carlo calculations have not yet provided the definitive answer.

10:00AM A16.00011 Superfluid equation of state of state of dilute composite bosons or how to include 3 and 4-body problems in the many-body problem

XAVIER LEYRONAS, ROLAND COMBESCOT — We show how the 3 and 4-body problems emerge in the BEC limit of the BEC-BCS crossover, where we treat explicitly dimers as made of two fermions. We give the argument leading, at zero temperature, to the calculation of the equation of state. We find that, when expanding the chemical potential in powers of the density $n$ up to the Lee-Huang-Yang order, proportional to $n^{3/2}$, the result is identical to the one of elementary bosons in terms of the dimer-dimer scattering length $a_{M}$, the composite nature of the dimers appearing only in the next order term proportional to $n^2$.

10:12AM A16.00012 A study of momentum entanglement and negativity in Bardeen-Cooper-Schrieffer states at finite temperature

CHUN KIT CHUNG, CHI KWONG LAW, Department of Physics and Institute of Theoretical Physics, The Chinese University of Hong Kong, Shatin, Hong Kong SAR, China — We study the momentum entanglement between the spin-up and spin-down particles of the homogeneous Bardeen-Cooper-Schrieffer (BCS) state at finite temperature. To achieve this, we construct from the BCS state the partial transposition $\rho^{T_A}_{\downarrow}$ of the two particle density matrix in momentum space. The structure of $\rho^{T_A}_{\downarrow}$ and its corresponding negativity $N_2$ are examined. We show that $\rho^{T_A}_{\downarrow}$ consists of infinitely many decoupled $2 \times 2$ submatrices, and momentum entanglement coexists with the pairing order parameter $\Delta$. It is found that pairs with momenta slightly above a surface related to the Fermi energy contribute this entanglement most significantly. We propose an entanglement witness operator as a measurable quantity to detect momentum entanglement in BCS states.

10:24AM A16.00013 Matterwave Probe for Detecting Fermi Superfluidity

SATYAN BHONGALE, HAN PU, University of Hong Kong — We propose a matter wave probe for detecting BCS type superfluidity within a trapped two-component Fermi gas. While, previous theoretical/experimental attempts have addressed Fermi superfluidity via a global measurement, for example by demonstrating a vortex lattice, our proposal allows for a local measurement of the pairing gap. For this, we study the phase diagram of a mixture of Bose-Einstein condensate and an interacting two-component Fermi gas. We identify regions of the parameter space where the Bose-Fermi mixture is unstable resulting in phase separation. We show that, under proper conditions, by employing a tunable scattering resonance, the phase separation phenomenon can be exploited as a robust probe of “local” fermion superfluidity.

1 Funded by the W. M. Keck Program in Quantum Materials, Rice University.

10:36AM A16.00014 Detecting Onset of BCS-Superfluidity Using a BEC Probe

B. RAMACHANDRAN, S.G. BHONGALE, H. PU, Department of Physics and Astronomy, and Rice Quantum Institute, Rice University, Houston, TX 77005, USA — Recent experiments have used Feshbach resonance to tune the interactions in a two-component ultracold Fermi gas to obtain (Bardeen-Cooper-Schrieffer) BCS-type pairing and hence superfluidity. For this degenerate gas, we propose using Bose-Einstein Condensates (BEC) as a matter wave probe of the BCS superfluid state. Towards this end, we explore the phase diagram of a 3-dimensional mixture of BEC and a two-component superfluid fermi gas at finite temperature. In particular, we identify the regime in which the homogeneous mixture becomes unstable against phase separation. We show that, under proper conditions, this spatial phase separation phenomenon occurring in the presence of the BEC can be used to probe the “local” value of the superfluid Gap parameter and possibly help detect the onset temperature of the BCS superfluidity.

10:48AM A16.00015 ABSTRACT WITHDRAWN —
8:00AM A17.00001 Excited-State Spectroscopy and Control of Single Spins in Diamond1, G.D. FUCHS2, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA — Nitrogen Vacancy (NV) defect centers in diamond are a promising system for spin-based applications in quantum information and communication at room temperature. Using a combination of optical microscopy and spin resonance, the spin of individual NV centers can be initialized, manipulated and read out. These techniques have been used to study the long room temperature spin coherence times of NV centers as well as their interactions with nearby electrical and nuclear spins. There remain significant challenges, however, both in understanding the physics of these defects as well as the development of technologies based on their quantum properties. In particular, knowledge of the detailed structure of the orbital excited state, which continues to be an active research area, is critical to ultra-fast quantum control schemes. Here we present recent experiments using single-spin resonant spectroscopy of the excited-state of an NV center at room temperature1 We observe these spin levels over a broad range of magnetic fields allowing for a direct measurement of the zero-field splitting, g-factor and transverse anisotropy splitting. The latter of these is nearly zero in the ground-state spin levels, but plays an important role in the excited-state. In addition, we find strong hyperfine coupling between the nitrogen nuclear spin and the NV electronic spin in the excited-state. These findings will be discussed in the context of quantum control of single and coupled spins in diamond.

1Funding by AFOSR and ARO is gratefully acknowledged.

8:36AM A17.00002 Time-resolved measurements of single electron spins using continuous wave lasers1, PATRICK IRVIN, YANJUN MA, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260, JESSE BEREOVSKY, DAVID D. AWSCHALOM, Department of Physics, UC Santa Barbara, Santa Barbara, CA 93106 — Applications such as spin-based quantum computing require that the dynamics of single spins are monitored. Single spins produce a small signal and measurement is further complicated by the background from the large number of neighboring spins. We have developed a time-resolved Kerr rotation technique that uses continuous wave lasers. This technique is able to resonantly address a particular spin. Furthermore, it provides an efficient means of data collection that allows for more signal averaging. Finally, we decrease the background and increase the light-matter interaction by utilizing a solid-immersion lens. We will describe our recent efforts to measure single spins in GaAs/AlGaAs fluctuation-type quantum dots.

8:48AM A17.00003 A photonic cluster state machine gun, TERRY RUDOLPH, Imperial College London, NETANEL LINDNER, Technion Institute, SOPHIA ECONOMOU, Naval Research Lab — A method is developed to convert certain single photon sources into devices capable of emitting large strings of photonic cluster state in a controlled and pulsed “on demand” manner. Such sources greatly alleviate the resources required to achieve linear optical quantum computation. Standard spin errors, such as dephasing, are shown to affect only 1 or 2 of the emitted photons at a time. This allows for the use of standard fault tolerance techniques. Using realistic parameters for current quantum dot sources, we conclude high entangled-photon emission rates are achievable, with Pauli-error rates less than 0.2%. For quantum dot sources the method has the added advantage of circumventing the problematic issue of obtaining identical photons from independent, non-identical quantum dots. By using recently controlled-phase gates between two spins in neighboring quantum dots, a two-dimensional cluster can be generated.

9:00AM A17.00004 Complete quantum control of a single quantum dot spin using ultrafast optical pulses, DAVID PRESS, Stanford University, THADDEUS LADD, Stanford University, National Institute of Informatics, BINGYANG ZHANG, Stanford University, YOSHIIHSA YAMAMOTO, Stanford University, National Institute of Informatics — We demonstrate a complete set of ultrafast all-optical single-qubit operations on a single electron spin in a quantum dot [Nature 456, 218 (2008)]. First, the spin is initialized by optical pumping into a pure spin-state with 92% fidelity. Next, a single-qubit gate is implemented by rotating the spin about any arbitrary axis using a sequence of two ultrafast optical pulses separated by a time delay. Finally, the spin is measured by detecting single-photon photoluminescence. As a manifestation of controlling the spin with optical pulses, we demonstrate six complete Rabi oscillations between the two spin states, and a complete set of Ramsey interference fringes. The fidelity of our π/2- and π-rotations exceed 90%. The single-qubit gate is completed in 38 ps, potentially allowing for approximately 10⁸ operations within the qubit’s expected microsecond coherence time, and quantum information processing with clock speeds exceeding 10 GHz.

9:12AM A17.00005 All-optical coherent control and spin-echo of electron spins bound to neutral donors in GaAs, SUSAN CLARK, Stanford University, KAI-MEI FU, Hewlett-Packard Laboratories, QIANG ZHANG, Stanford University, THADDEUS LADD, Stanford University and National Institute of Informatics, Toyko Japan, COLIN STANLEY, H.C. HOLLAND, University of Glasgow, YOSHIIHSA YAMAMOTO, Stanford University and National Institute of Informatics, Toyko Japan — Electron spins bound to neutral donors in GaAs are promising systems for quantum information processes. These electron spins form three-level Lambda-type systems that can be manipulated quickly by ultrafast light pulses and have potentially long storage times, making them natural candidates for quantum information manipulation and storage. Unlike quantum dots, they are extremely homogeneous, making multi-qubit interactions and entanglement more accessible. Here, we report on our efforts to coherently control these electron spins using fast pulses and an all-optical spin-echo technique. Using three, off-resonant, small-angle (pi/3), ultrafast (2 ps) pulses, we have demonstrated that the spins exhibit an echo signal indicating T2 coherence times much longer than the previously measured 1 ns T2* bulk dephasing time. The visibility of the echo signal and the delay gives us insights into the T2 decoherence time and decoherence processes in this system. Currently, we are measuring coherences as long as 4 microseconds.

9:24AM A17.00006 Time-resolved luminescence of hierarchically self-assembled GaAs/AlGaAs quantum dots1, BOTAO ZHANG, University of Pittsburgh, ARMANDO RASTELLI, OLIVER SCHMIDT, Institute for Integrative Nanosciences, IFW Dresden, Helmholtzstrasse 20, D-01069 Dresden, Germany, JEREMY LEVY, DAVID SNOKE, University of Pittsburgh, ALBERT HEBERLE, Sullivan Park R&D Center, Corning Incorporated and University of Pittsburgh — Hierarchically self-assembled GaAs/AlGaAs quantum dots are promising building blocks for quantum information processing and novel lasers because they combine the tight confinement of InGaAs dots with the size homogeneity and a shorter emission wavelength of the GaAs/AlGaAs system at which many photodetectors are especially sensitive. So far, the emission dynamics of these structures has been unexplored. With a streak camera connected to a confocal microscope, we have measured the luminescence dynamics after direct optical picosecond excitation into the quantum dot states at a sample temperature of 10 K. Ensembles of high-density quantum dots (30 dots/μm²) with well-separated transitions give information on state filling as well as intra- and interband relaxation. Single quantum dots on low-density samples (0.5 dots/μm²) with microelectroluminescent emission line widths reveal furthermore the time scale of biexciton formation and decay, as well as coherent effects.

1This work is supported by NSF DMR-0605854.
9:36AM A17.00007 Highly-reduced Fine-structure splitting in InAs/InP quantum dots offering efficient on-demand 1.55 µm entangled photon emitter , LIXIN HE, University of Science and Technology of China, M. GONG, C-F LI, G-C GUO. University of Science and Technology of China, A. ZUNGER, National Renewable Energy Laboratory — There has been intense recent interest in finding efficient entangled photon sources, including the demonstration of generation of “event-ready” entangled photon pairs via a biexciton cascade process using an (In,Ga)As/GaAs quantum dot (QD). However, a genuine finite energy difference between photons with different polarizations, known as the fine structure splitting (FSS), can destroy the entanglement of the photon pairs. To achieve entanglement from (In,Ga)As/GaAs QD, it was, indeed, necessary to Cherry-pick a sample with extremely small FSS from a large number of samples, or to apply strong in-plane magnetic field. Furthermore, the emission wavelength of (In,Ga)As/GaAs QD (880 - 950 nm) is mismatched with the 1.55 µm needed for communications using the optical fibers. Using theoretical modeling of the fundamental causes of FSS in QDs, we predict that the intrinsic FSS of InAs/InP QDs is an order of magnitude smaller than that of InAs/GaAs dots, and better yet, their excitonic gap matches the 1.55 µm fiber optic wavelength, therefore offer efficient on-demand entangled photon emitters for long distance quantum communication.

9:48AM A17.00008 Estimation of extrinsic detection efficiency using intrinsic detection sensitivity of the commercial single photon detector, KIYOTAKA HAMMURA, XIULAI XU, FREDERIC BROSSARD, DAVID WILLIAMS, Hitachi Cambridge Laboratory — The detection efficiency (DE) of the commercial single-photon-receiver based on InGaAs gate-mode avalanche photodiode is estimated using the detection sensitivity (DS). Instalment of a digital-blanking-system (DBS) to reduce dark current makes the difference between DS, which is an efficiency of the detector during its open-gate/active state, and the total/overall detection efficiency (DE). By numerical simulations, it is found that the average number of light-pulses, blanked by DBS, following a registered pulse is 0.333. DS is estimated at 0.216, which can be used for estimating DE for an arbitrary photon arriving rate and a gating frequency of the receiver.

10:00AM A17.00009 Quantum key distribution with an unknown and untrusted source, YI ZHAO, BING QI, HOI-KWONG LO, Center for Quantum Information and Quantum Control, Department of Physics and Department of Electrical & Computer Engineering, University of Toronto — The security of a standard bi-directional “plug & play” quantum key distribution (QKD) system has been an open question for a long time. This is mainly because its source is equivalently controlled by an eavesdropper, which means the source is unknown and untrusted. Qualitative discussion on this subject has been made previously. In this paper, we present the first quantitative security analysis on a general class of QKD protocols whose sources are unknown and untrusted. The securities of standard BB84 protocol, weak-cd-vacuum decoy state protocol, and one-decoy decoy state protocol, with unknown and untrusted sources are rigorously proved. We derive rigorous lower bounds to the secure key generation rates of the above three protocols. Our numerical simulation results show that QKD with an untrusted source gives a key generation rate that is close to that with a trusted source. Our work is published in [1].

10:12AM A17.00010 Spectral study of type-0/type-I spontaneous parametric down-conversion in a PPKTP waveguide1, JUN CHEN, AARON PEARLMAN, ALEXANDER LING, ALAN MIGDALL, JINGYUN FAN, Joint Quantum Institute, National Institute of Standards and Technology, and University of Maryland, JOINT QUANTUM INSTITUTE, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY, AND UNIVERSITY OF MARYLAND TEAM — Compared with their bulk-crystal counterparts, SPDC in second-order (χ(2)) nonlinear optical waveguides has been used to generate correlated photons that are naturally emitted into a single spatial mode in a collinear geometry, easing the effort in efficient photon collection and leading the potential to make chip-scale devices for quantum-information-processing applications. Here towards building chip-scale devices for quantum-information-processing applications, we performed the first spectral characterization of correlated two-photon, and single-photon emission for both type-0 and type-I spontaneous parametric down-conversion (SPDC) in a periodically-poled KTiOPO4 (PPKTP) waveguide.

1Spectral study of type-0/type-I spontaneous parametric down-conversion in a PPKTP waveguide

10:24AM A17.00011 Deterministic generation of entangled photon pairs from a semiconductor quantum dot, ANDREAS MULLER, WEI FANG, Joint Quantum Institute, NIST and University of Maryland, Maryland, USA, JOHN LAWALL, National Institute of Standards and Technology, Maryland, USA, GLENN SOLOMON, Joint Quantum Institute, NIST and University of Maryland, Maryland, USA — Optical tuning based on the AC Stark effect is used to cancel the fine-structure splitting in a single self-assembled InAs quantum dot. Under this condition, polarization anisotropy vanishes, and photon pairs emitted from the biexcitonic radiative cascade become polarization-entangled. Entanglement is verified by well-known criteria applied to the two-photon density matrix that was reconstructed experimentally via quantum state tomography. Our approach uses a planar optical microcavity for efficient background laser discrimination, and yields triggered polarization-entangled photons deterministically.

10:36AM A17.00012 Indistinguishable photons from independent semiconductor single-photon devices, THADDEUS LADD1, KAORU SANAKA2, Stanford University, ALEXANDER PAWLIS1, KLAUS LISCHKA, University of Paderborn, Germany, YOSHIHISA YAMAMOTO4, Stanford University — We demonstrate quantum interference between single photons generated by the radiative decay processes of excitons that are bound to isolated fluorine donor impurities in ZnSe/ZnMgSe quantum-well nanostructures. Single photon generation is confirmed by auto-correlation experiments, and indistinguishability of single photons from independent devices is confirmed via a Hong-Ou-Mandel dip. These results indicate that donor impurities in appropriately engineered semiconductor structures can portray atom-like homogeneity and coherence properties, potentially enabling scalable technologies for future large-scale optical quantum computers and quantum communication networks.

Monday, March 16, 2009 8:00AM - 11:00AM — Session A18 SPOLY: Bulk Block Copolymers I
8:00AM A18.00001 Order-order transition among lamellae, $F_{dd}$, and gyroid in diblock copolymer melts, MIKIHIKO TAKENAKA, MYUNG IM KIM, TSUTOMU WAKADA, SATOSHI AKASAKA, SHOTARO NISHITSUJI, KENJI SAJO, HIROKAZU HASEGAWA, Kyoto University, KAZUKI ITO, Riken, KYOTO TEAM, RIKEN TEAM — We firstly found a Disorder-Gyroid-$F_{dd}$-Lamellae transition behavior found poly(styrene-b-isoprene) (S-I) diblock copolymer melts in previous study. In this study, we will present the dynamics of order-order transition (OIT) among lamellae, $F_{dd}$, and gyroid. We investigated the dynamics of OIT by using time-resolved small angle X-ray scattering with Synchrotron radiation X-ray source. We found that $F_{dd}$ structure was formed as a metastable structure during the OIT from lamellae to gyroid induced by temperature jump.

8:12AM A18.00002 Determination of $F_{dd}$ phase boundary in polystyrene-block-polyisoprene diblock copolymer, MYUNG IM KIM, SATOSHI AKASAKA, TSUTOMU WAKADA, MIKIHIKO TAKENAKA, HIROKAZU HASEGAWA, Department of Polymer Chemistry, Graduate School of Engineering, Kyoto University — We previously reported the discovery of a novel bicontinuous microdomain structure with $F_{dd}$ symmetry in polystyrene-block-polyisoprene (SI) diblock copolymer. In this study, we investigated the phase behavior of eight SI diblock copolymer samples having slightly different compositions ($0.627 \leq f_{PI} \leq 0.653$) by SAXS and TEM to determine the phase boundary of the $F_{dd}$ structure in the phase diagram of SI. The SI having the lowest $f_{PI} (= 0.627)$ showed only disorder-lamella (L) transition but no order-order transition. The SI having the largest $f_{PI} (= 0.653)$ showed disorder-gyroid (G)-L transition with decreasing temperature, but did not show $F_{dd}$ phase. The other six SI samples having $f_{PI}$ values between these two exhibited disorder-G-$F_{dd}$-L transition with decreasing temperature. Consequently, we could determine the compositional region where $F_{dd}$ phase is thermally stable, which is in good agreement with that predicted by SCFT.

8:24AM A18.00003 Stabilization of Bicontinuous Phases in Diblock Copolymer Systems, FERNANDO ESCOBEDO, FRANCISCO MARTINEZ-VERACOECHEA, Cornell University — We used a coarse-grained description of the copolymer chains (i.e., dissipative particle dynamics fluid), together with continuum-space Monte Carlo and Molecular Dynamics methods, to study systems of diblock copolymers melts that have been "filled" with selective additives (i.e., homopolymer, and nanoparticles). Approximate phase boundaries were found via free-energy calculations. We focus on the stabilization of bi-continuous phases and the strikingly different phase behavior observed when the nature of the selective filler is changed. Our results elucidate the origins of the packing frustration that limits the viability of the gyroid, double-diamond, and plumber’s nightmare phases and provide insights for overcoming it. Attention is also focused on directly determining the areas of phase diagram where macro- phase separation occurs. We compare the particle-based simulation results with the results obtained by means of self-consistent filed theory calculations.

8:36AM A18.00004 Structure-Properties Relationship in Proton Conductive Sulfonated Polystyrene-Poly(methacrylate) Block Copolymers, LAURENT RUBATAT, CHAOXU LI, HERVE DIETSCHE, University of Fribourg, Switzerland, ANTTI NYKAINEN, JANNE RUOKOLAİNEN, Helsinki University of Technology, Finland, RAFFAELE MIZZENGA, University of Fribourg, Switzerland — We report on the dependence of proton conductivity on the morphologies of sulfonated polystyrene-poly(methyl methacrylate) (sPS-PMMA) diblock copolymers. Three diblock copolymers of varying molecular weight and block volume fraction were studied, for each one several sulfonation degrees of the PS block were considered. The investigation of the morphologies of the self-assembled sPS-PMMA diblocks was carried out by means of small angle neutron scattering and transmission electron microscopy. Depending on molecular weight and sulfonation degrees, isotropic phase (ISO), lamellar phase (LAM), cylindrical hexagonal phase (HEX) and hexagonally perforated lamellae (HPL) were observed. Proton conductivity, normalized by the volume fraction of the conductive domains (formed by PS, sPS, and water) was shown to rise monotonically with the following sequence of morphologies: ISO to HEX to HPL to LAM.

8:48AM A18.00005 Morphology of Sulfonated Styrenic Pentablock Copolymer Solutions and Membranes, ARUN KOTA, KAREN WINEY, Department of Materials Science and Engineering, University of Pennsylvania — We report a systematic investigation of the morphology of sulfonated styrenic pentablock copolymer solutions and membranes obtained from Kraton Polymers LLC. The polymer studied was poly(f-butyl-styrene)-b-(ethylene-r-butylene)-b-(styrene-r-styrene sulfonate)-b-(ethylene-r-butylene)-b-(f-butyl-styrene). Small angle X-ray scattering (SAXS) revealed that the solutions exhibited micellar morphologies. The solution SAXS data was modeled using the Kinning-Thomas model to obtain radius of the micelle core, the radius of closest approach between two micelles and the volume fraction of micelles. The membranes exhibited anisotropic morphologies with different d-spacings in-plane and through-plane. A good linear correlation was observed between the radius of closest approach between two micelles in the solutions and the d-spacings in the membranes. Efforts are underway to characterize the type of morphology in the membranes using electron microscropy and correlate them to the transport properties.

9:00AM A18.00006 Thermodynamic Behavior of Poly(styrene-b-styrene sulfonate) Block Copolymers With Varying Counterions, KEVIN CAVICCHI, The University of Akron, KEVIN POLLACK, Carleton College — A series of poly(styrene-b-styrene sulfonate) (PS-b-PSS) block copolymers have been prepared by RAFT polymerization. The counterions in the PSS block have been varied by neutralizing the sulfonate groups with alkyl amines or quaternary ammonium ions. The choice of counterion has a strong effect on the lipophilicity of the PSS block. This presentation will focus on the resulting morphology and bulk thermodynamic behavior of these polymers as a function of the PSS concentration. The use of these materials for preparing ion-exchange membranes will be discussed.

9:12AM A18.00007 Salt Doping in PEO Containing Block Copolymers: Counterion and Concentration Effects1, WEN-SHIUE YOUNG, THOMAS EPPS, University of Delaware — Salt-doped poly(ethylene oxide)-based block copolymers are promising candidates for lithium battery electrolytes, which require high ionic conductivities and adequate mechanical integrity. We studied the phase behavior of poly(styrene-b-ethylene oxide) block copolymers doped with various lithium salts over a range of [EO]:[Li] ratios. Small-angle X-ray scattering, transmission electron microscopy, and differential scanning calorimetry experiments were used to characterize the phase behavior of our samples. Specimens were prepared in an argon atmosphere and rigorously dried to reduce the effects of moisture uptake on phase behavior. We found that we can tune the micellar microstructure by varying the lithium counterion as well as the salt doping ratio. Using strong segregation theory, we estimated an effective interaction parameter for the salt-doped copolymers, which varies linearly with salt concentration, where the slope is influenced by the nature of the counterion.

9:24AM A18.00008 Ion transport through block copolymer electrolytes, SCOTT MULLIN, ASHOUTOSH PANDAY, NITASH BALSARA, UC Berkeley — Poly(styrene)-block-poly(ethylene oxide) (SEO) is a candidate material for electrolytes for rechargeable lithium metal batteries. The PS phase suppresses lithium dendrite growth on the anode during recharge, and the PEO phase solvates lithium bis[(trifluoromethane)sulfonimide] salt to form conducting pathways. Complete electrochemical characterization of PEO/LITFSI mixtures requires measurement of conductivity, salt diffusion coefficient, and lithium ion transference number. The present study covers SEO copolymers that exhibit lamellar and cylindrical morphologies in the absence of salt. The addition of salt affects morphology but the relationships between morphology and electrochemical characteristics have not yet been clarified. Some aspects of these relationships will be presented.

1 ACS Grant PRF-46864-67
9:36AM A18.0009 Morphology of Novel Semicrystalline Ethylene-α-Olein Block Copolymers, SHENG LI, RICHARD REGISTER, Princeton University; BRIAN LANDES, Dow Chemical Company — In semicrystalline block copolymers, the solid-state structure can be set either by block incompatibility or by crystallization of one or more blocks. Depending on the block interaction strength, a wide array of solid-state morphologies may be observed, ranging from spherulitic to confined crystallization within preexisting microphase-separated domains. Dow Chemical has recently developed a novel chain shuffling polymerization process to produce olefin block copolymers with alternating amorphous and semicrystalline chain segments, where each block exhibits the most-probable distribution. We examined the melt and solid-state morphologies of these novel olefin block copolymers, having a high octene content in the amorphous block, using two-dimensional synchrotron small-angle and wide-angle x-ray scattering on specimens oriented by channel die compression. Multiblock and diblock copolymers with near-symmetric compositions showed well-ordered lamellar structures at room temperature with long periods exceeding 100 nm, with little dependence on thermal history, indicating the presence of a mesophase-separated melt which templates crystallization.

9:48AM A18.00010 Self-assembly of crystalline bioinspired block copolymers, A.M. ROSALES, H.K. MURREN, Dept. of Chemical Engineering, University of California - Berkeley, R.N. ZUCKERMANN, Molecular Foundry, Lawrence Berkeley National Laboratory, R.A. SEGALMAN, Dept. of Chemical Engineering, University of California - Berkeley — Polypeptides are sequence-specific biologically inspired polymers based on N-substituted glycines for which monodisperse, polymeric molecular weights can be achieved. Sequence control allows for a degree of tunability in both the self-assembly and thermal properties not available in classical polymer systems. We demonstrate that a series of homopolypeptides are thermally stable to 300°C and are crystalline with melting transitions ranging from 150°C to 250°C. The introduction of defects at precise locations in the polymer sequence (as a side chain substitution) allows crystallization and hence the melting temperature to be suppressed. Symmetric block copolymers with two crystalline polyolefin blocks exhibit co-crystallization of the two blocks but distinct melting behaviors, indicating a disordered melt. If samples are carefully prepared to allow for microphase separation, block copolymer lamellae with long range order are formed with an order-disorder transition temperature well below the melting transition temperature of the polymer.

10:00AM A18.00011 Crystallization, Crystal Orientation and Morphology of Poly(ethylene oxide) under 1D Defect-Free Nanoscale Confinement, MING-SIAO HSIAO, The University of Akron; JOSEPH X. ZHENG, RYAN M. VAN HORN, RODERIC P. QUIRK, EDWIN L. THOMAS, MIT; BERNARD LOTZ, Institute Charles Sadron; STEPHEN Z. D. CHENG — One-dimensional (1-D) defect-free nanoscale confinement is created by growing single crystals of PS-b-PEO block copolymers in dilute solution. Those defect-free, 1-D confined lamellae having different PEO layer thicknesses in PS-b-PEO lamellar single crystals (or crystal mats) were used to study the polymer recrystallization and crystal orientation evolution as a function of recrystallization temperature \( T_{rx} \) because the \( T_{PS} \) of PS-b-PEO lamellae is lower than the \( T_{PEO} \) in the PS-b-PEO single crystal. The results are summarized as follows.

10:12AM A18.00012 Gradient Architecture as Means of Phase Diagram Manipulation in Copolymers: Accessing Both LCOT and UCOT in High Molecular Weight Styrene/n-Butyl Acrylate Systems, MICHELLE MOK, WESLEY BURGHARDT, Northwestern University; CHRISTOPHER ELLISON, University of Texas at Austin, JOHN TORKELSON, Northwestern University — Traditionally, phase transitions of block copolymers could only be tuned through molecular weight and relative block length. Here, we introduce comonomer sequence design through gradient compositions as a means of further manipulating phase diagram boundaries. In such gradient copolymers, the reduced repulsion between chain segments allows access to phase transitions even at high molecular weights (MW). Rheological and x-ray scattering studies were performed to study the impact of comonomer sequence on phase behavior in styrene/n-butyl acrylate (S/nBA) systems. In S/nBA block copolymers, only upper critical ordering behavior was observed. In contrast, by using a gradient architecture of higher MW we observed both upper and lower ordering transitions similar to those seen in very weakly segregating S/n-butyl methacrylate block copolymers, where such dual ordering transitions were first detected by Russell et al. This is the first study to access a miscibility gap in gradient copolymers. Access to such behavior is very rare in blends and block copolymers, limited to low MW and/or very weakly segregating systems.

10:24AM A18.00013 Effects of polydispersity on the order-disorder transition of diblock copolymer melts, TOM BEARDSLEY, MARK MATSEN, University of Reading — The effect of polydispersity on an AB diblock copolymer melt is investigated using lattice based Monte Carlo simulations with parallel tempering (PT) techniques. We consider melts where the B blocks are monodisperse and the A blocks are polydisperse with a Schultz-Zimm distribution. Expanding our previous work on polydisperse melts of symmetric composition, we now construct a polydisperse phase diagram, investigating the size of the domains and locations of the order-disorder (ODT) and order-order (OOT) transitions. The PT method has yielded a number of benefits over single-processor temperature scans, including: simulating a number of temperatures simultaneously, annealing out defects in the configurations more readily and capturing the distinctive spike in the heat capacity that occurs at the ODT, allowing the location of the transition to be determined more accurately than in previous studies. The results are compared to those of experiment and to the predictions of self-consistent field theory (SCFT).

We acknowledge the EPSRC (EP/E010342/1) for financial support.

10:36AM A18.00014 Dynamics of Disordered PI-PtBS Diblock Copolymer, HIROSHI WATANABE, Kyoto University — Viscoelastic \( (G^*) \) and dielectric \( (\varepsilon''^*) \) data were examined for a LCST-type diblock copolymer composed of polyisoprene (PI; \( M = 53K \)) and poly(\( \mu \)-tert-butyl styrene) (PtBS; \( M = 42K \)) blocks disordered at \( T \leq 120^\circ\)C. Only PI had the type-A dipole parallel along the chain backbone. Thus, the \( \varepsilon''^* \) data reflected the global motion of the PI block, while the \( G^* \) data detected the motion of the copolymer chain as a whole. Comparison of these data indicated that the PI block relaxed much faster than the PtBS block at low \( T \) and the dynamic heterogeneity due to PtBS was effectively quenched to give a fractional nonuniformity for the PI block relaxation. The \( \varepsilon''^* \) data were thermo–hechoeochemically complex at low \( T \), partly due to this nonuniformity. However, the block connectivity could have also led to the complexity. For testing this effect, the \( \varepsilon''^* \) data were reduced at the iso- frictional state defined with respect to bulk PI. In this state, the \( \varepsilon''^* \) data of the copolymer at low and high \( T \), respectively, were close to the data for the star-branched and linear bulk PI. Thus, the PI block appeared to be effectively tethered in space at low \( T \) thereby behaving similarly to the star arm while the PI block tended to move cooperatively with the PtBS block at high \( T \) to behave similarly to the linear PI, which led to the complexity of the \( \varepsilon''^* \) data. The PtBS block also exhibited the complexity (noted from the \( G^* \) data), which was well correlated with the complexity of the PI block.
10:48AM A18.00015 Morphology of Renewable Polylactide / Soybean Oil Blends Compatibilized by Block Copolymers1, MEGAN ROBERTSON, KWAHNO CHANG, MARC HILLYER, University of Minnesota-Twin Cities — Renewable composites derived from polylactide and soybean oil (soy) were prepared by melt blending. The blend morphology was tuned with the addition of poly(isoprene-b-lactide) block copolymers. Due to the extreme differences in the viscosities of soy and polylactide, a critical block copolymer block ratio was found to induce a phase inversion in which the morphology changed from soy droplets in a polylactide matrix to polylactide droplets in a soy matrix, even though soy was the minority component. This transition was not only due to the thermodynamic interactions between the block copolymer and the two immiscible phases, but also was a result of shear forces acting on the mixture during melt blending. The droplet size of the soy droplets in the polylactide matrix was also highly dependent on the block copolymer composition. In binary polylactide/soy blends there was a limiting concentration of soy which could be incorporated into the polylactide matrix (5 percent of the total blend weight) due to the mismatch in viscosities resulting in the loss of soy during mixing. The addition of block copolymer with an appropriate block ratio allowed full incorporation of soy up to 20 percent of the total blend weight.

Session A19 DPOLY: The Physics of Polymer Nanocomposites: Polymer Nanoparticle Interactions 320

8:00AM A19.00001 Functional polymer colloids stabilized by type-purified single-wall carbon nanotubes, ERIK K. HOBBS, JEFFREY A. FAGAN, JAN OBRZUT, NIST — Emulsion polymerization of a methacrylate monomer in aqueous biological suspensions of type-purified single-wall carbon nanotubes (SWNTs) is used to synthesize polymer colloids coated by nearly pure metallic or semiconducting SWNTs. The polymer-nanocomposite spherical particles are 1-100 micrometers in diameter, are marginally stable in ethanol, and retain the color and unique optical characteristics of the purified SWNT coating in the absence of any surfactant. By assembling these functional polymer colloids on microelectronic circuits, we characterize the electronic properties of the SWNT-polymer nanocomposite microspheres and relate this to the band structure of the purified SWNT coating, demonstrating their potential use as microscopic optical and electronic components that can be easily manipulated using standard methods of colloidal self-assembly.

8:12AM A19.00002 Theoretical analysis of dispersing of aggregated nanorods in shear flow in presence of AC electric or magnetic fields, VICTOR PRYAMITSYN, VENKAT GANESAN, The University of Texas at Austin — Efficient dispersion of nanotubes in polymeric matrices is a critical problem confronting the development of modern polymer nanocomposites. The nanotube-nanotube interactions usually promote aggregation, which also depends on factors such as the chemical makeup of the polymer matrix and the size of nanotubes. High intensity mechanical mixing such shear pulverization are commonly used for dispersion of nanotubes. The main disadvantage of such processes is the degradation of polymer matrix, which may downgrade the final properties of PNC’s. In this work, we theoretically explore a novel strategy to reduce the shear stresses required for dispersion of rod-like fillers. Explicitly, we found that simultaneous applications shear flow and AC electric field oriented at an angle to each other may cause rod rotational instabilities of the rods suspension and lead to the dispersion of the rods. We demonstrate this idea through Brownian dynamics simulations of aggregating nanorods and a complementary theoretical analysis using a 2D Smoluchowski equation. Our results suggest that an optimal dispersion may be achieved at an shear-E field orientation of β = ±45° with an optimal amplitude of AC electric field which is proportional to the rotation Peclet number of nanorods suspension.

8:24AM A19.00003 Effective Interactions, Structure and Phase Behavior of Polymer Nanocomposites with Nonspherical Fillers, LISA M. HALL, KENNETH S. SCHWEIZER, University of Illinois at Urbana-Champaign — The Polymer Reference Interaction Site Model is applied to study polymer-mediated inter-nanoparticle interactions, fluid structure, and miscibility of nonspherical filler particles in a melt of adsorbing freely-jointed chains. The behavior of hard rod, disk, and cube-like nanoparticles are compared. The depletion contact aggregation, dispersion, and polymer matrix mediated nanocomposite network states of organization are sensitive to filler shape. A detailed study of thin rod fillers, including the rod-rod potential of mean force and second virial coefficient, B2, as a function of polymer-rod and rod-rod attraction strengths, has also been performed. A primary goal is to identify design rules for dispersing nanotubes in polymer melts. Shortening the spatial range of rod-rod attraction compared to polymer-rod attraction increases miscibility. The transition from positive to negative B2 at low polymer-rod interfacial attraction (entropic depletion) occurs more readily (at higher attraction strength) as rod-rod attraction is increased. However, the transition to negative B2 at high polymer-rod attraction strength, driven by polymer-induced enthalpic bridging of rods, is relatively invariant to inter-rod attraction strength. Increasing rod length reduces the stabilizing consequences of polymer adsorption and the attendant steric repulsion.

8:36AM A19.00004 Polymer-tethered nanoparticle “shape amphiphiles”: A new class of macromolecular building block for self-assembly, SHARON GLOTZER, University of Michigan — Fabricating complex ordered structures from nanoparticles requires controlling nanoparticle interactions for self-assembly over multiple length scales. Here we exploit both building block shape and interaction anisotropy for self-assembly, and explore the use of polymer “tails” attached to nanoparticle “head groups” to create a new kind of amphiphile that self assembles into structures like those seen in surfactant and block copolymer systems, but with important differences arising from nanoparticle shape, and tethered nanoparticle geometry and topology. We investigate the impact of nanoparticle size polydispersity and show that it can both help and hinder formation of certain complex phases. Using simulation, we investigate tethered spheres, rods, cubes, triangles, and other shapes, and provide design rules for the predicted self-assembly of a range of chiral and achiral structures, including helical scrolls, gyroid, square arrays, and ionic crystal-like structures.

9:12AM A19.00005 Control of the Spatial Distribution of Nanoparticles in Fluorescent Polymer Nanocomposites1, CHELSEA CHEN, PETER GREEN, University of Michigan, Ann Arbor — In a brush-coated nanoparticle (NP) / polymer nanocomposite system, the spatial distribution of the NPs is largely determined by the entropic and enthalpic interactions between the brush and polymer host chains. We examined the miscibility between polystyrene (PS) homopolymer chains and a fluorescent polymer poly[2-methoxy-5-(2-ethylhexyloxy)-1,4-phenylenevinylene] (MEH-PPV) and found that in thin films, low molecular weight (MW) PS and MEH-PPV are miscible, whereas high MW mixtures exhibit phase separation. Consequences of this behavior were examined with regard to the effect on the morphology of nanocomposite thin films composed of MEH-PPV and thiol terminated polystyrene grafted Au nanoparticles of varying sizes. We were able to achieve complete dispersion, as well as interfacial segregation, of the Au-PS nanoparticles within MEH-PPV hosts. Through control of the morphology, we were able to “tune” the optical properties of the MEH-PPV/Au-PS nanocomposites.

1Supported by DOE#DE-FG02-07ER46412 and NSF#DMR 9871177.
9:24AM A19.00006 Importance of Chain Connectivity in the Formation of Non-covalent Interactions between Polymers and Single-Walled Carbon Nanotubes, DIAS LINTON, BRAD C. MILLER, HUIMIN LI, CHARLES FEIGERLE, Department of Chemistry, University of Tennessee, Knoxville, TN 37996; BOBBY C. SUMPTER, Oak Ridge National Laboratory, Oak Ridge, TN 37831; MARK D. DADMUN, Department of Chemistry, University of Tennessee, Knoxville, TN 37996 and Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Our work is focused on understanding and utilizing non-covalent electron donor-acceptor (EDA) interactions between polymers and SWNT to optimize interfacial adhesion and homogeneity of nanocomposites without modifying the SWNT native surface. Nanocomposites with polymer bound electron donating or withdrawing moieties leads to improved SWNT dispersion if the interacting functional group is a minor component of a copolymer matrix. Correlation of experimental (Raman mapping, Raman D* band peak shifts, and optical microscopy) and computational results indicates that chain connectivity is critical in controlling the accessibility of the functional groups to form EDA interactions. Thus, controlling the amount of e-donating or withdrawing moieties throughout the polymer chain will direct the extent of EDA interaction, which enables tuning the SWNT dispersion.

9:36AM A19.00007 The Structure of Amphiphilic Polymers Interacting with Carbon Nanotubes, YACHIN COHEN, MEIRAV GRANITE, Technion, Israel, WIM PYCKHOUT-HINTZEN, AUREL RADULESCU, Fz. Juelich, Germany — Dispersion of single-walled carbon nanotubes, necessary for their beneficial utilization, is often based on amphiphilic copolymers. We have successfully utilized the following systems: an alternating copolymer of styrene and sodium maleate, exhibiting alternating hydrophobic and hydrophilic groups, amphiphilic block copolymers such as Pluronic F108 and a synthetic short polypeptide (FFDD), containing alternating hydrophobic blocks of two phenylalanine (FF) and hydrophilic block of two aspartic acid (DD). Cryo-transmission electron microscopy images reveal isolated, very small bundles of carbon nanotubes, with diameters range from 1 to 5 nm and approximately 500 nm length. Small-angle neutron scattering experiments were conducted at different D$_2$O/H$_2$O content of the dispersing medium. The scattering patterns suggest a complex entity with an heterogeneous structure. For the alternating copolymer, loose adsorption of polymer coils is indicated, contrary to published ideas on “polymer wrapping” of nanotubes. For the Pluronic block copolymers, the data suggest that even below the critical micellization temperature there is a dense coating on the nanotube surface and the hydrophilic blocks are highly extended. The polypeptide also forms a dense coating with an apparently “spongy” structure.

9:48AM A19.00008 Chain Expansion in Polymer-Nanoparticle Melts, A. L. FRISCHKNECHT, Sandia National Laboratories, E. S. MCGARRITY, Michigan State University, M. E. MACKAY, University of Delaware — We apply a self-consistent version of the polymer reference interaction site model (PRISM) theory to a model of spherical nanoparticles in a polymer melt. The average radius of gyration of the chains in the blend clearly increases (over that from chains in a neat melt at the same density) with increasing nanoparticle volume fraction. The amount of chain expansion also depends on the magnitudes of the attractive interactions in the system. The bulk modulus of the blend decreases with increasing nanoparticle volume fraction. We compare our theoretical results to experimental scattering data from polystyrene blends with various nanoparticles and to previous simulation results. (This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. Department of Energy, Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.)

10:00AM A19.00009 Effects of nanoparticles on chain dynamics and glass transition in amorphous polymer nanocomposites$^1$, HYUN JOON OH, PETER GREEN, University of Michigan, Ann Arbor — Chain relaxation dynamics and the glass transition of mixtures of polystyrene (PS) homopolymer with PS-grafted gold nanoparticles were examined using broadband dielectric spectroscopy, differential scanning calorimetry and capacitive scanning dilatometry. Through changes in the nanoparticle core size, $D$, grafting density, $g$, degree of polymerization of grafted chains, $N$, and the nanoparticle concentration, $\phi$, both the chain relaxation time, $\tau$, and the $T_g$ could be induced to undergo significant changes, increases or decreases, in magnitude. These results will be discussed in light of dynamics in other polymer/nanoparticle systems. In addition, the role of particle size and the role of the melt/brush interfacial interactions on the dynamics will be discussed.

$^1$Work supported by the US DOE (DE-FG02-07ER46412) and by the NSF (DMR-0601890).

10:12AM A19.00010 Dynamics in Nanoparticle Liquids, PETER MIRAU, AFRL/RXBN, Air Force Research Lab, BioNano Branch, Wright-Patterson AFB, OH 45433, MICHAEL JEPSEN, RICHARD VAIA, AFRL/RXBN, ROBERT RODRIGUEZ, EMMANUEL GIANNELIS, Materials Science & Engineering, Cornell University, Ithaca, NY 14853 — Nanoscale Ionic Materials (NIMS) are organic-inorganic hybrids in which a nanometer-sized core is functionalized with a covalently attached corona and an ionically tethered canopy, NIMS can be engineered to be liquids at ambient temperature in the absence of solvent and are of interest for a variety of applications. We have used NMR relaxation and pulse-field gradient NMR to measure the dynamics of NIMS made from a 20 nm silica core modified with propyl sulfonic acid groups and amino-terminated ethylene oxide/proplylene oxide block copolymers. Carbon NMR studies show that the block copolymer canopy is quite mobile both in the bulk and the nanoparticle liquid. The carbon spin-lattice relaxation times as a function of temperature are fit to a model with rapid librational motions and slower reorientation of the copolymer. Neither the correlation times for reorientation of the block copolymer nor the self-diffusion coefficient are influenced by the presence of the silica nanoparticle core. These data suggest that the liquid-like behavior in NIMS is due to rapid exchange of the block copolymer canopy between the ionically modified nanoparticles.

10:24AM A19.00011 Hierarchically Structured Block Copolymer \ Silicate Nanocomposites, ROSS BEHLING, ERIC COCHRAN, Iowa State University — In this contribution we functionalized MMT with a bromine terminated alkylamine and subsequently polymerized polystyrene-b-(tert-butyl acrylate) via graft-from atom transfer radical polymerization. Hierarchical assembly of these composites was facilitated through targeted graft density, polymer block size, and MMT intrinsic properties. The high graft density on the MMT surface results in confinement effects which force growing polymer chains into highly extended conformations. Block copolymer (BCP) brushes were chosen because they inherently offer an easily tunable method for producing self-assembled structures on the order of tens of nanometer. Montmorillonite (MMT) in its raw state is composed of negatively charged tactoids ranging 100-300 nm in diameter and 2 nm thick. BCP nanocomposites particles arranged under shear into structures spanning several hundreds of nanometers. The equilibrium structures were influenced by the MMT platelet curvature and the BCP interaction parameter, $\chi$. BCP nanocomposites were observed via transmission electron microscopy to display novel morphologies with multiple systems exhibiting interpenetrating networks reminiscent of “worm micelles.”

10:36AM A19.00012 Effect of Copolymer-Nanoclay Interactions on Intercalation Kinetics$^1$, LOAN VO, HARIS RETSOS, EMMANUEL GIANNELIS, Cornell University — We use X-ray diffraction to measure the melt intercalation kinetics of a series of surface-modified clay nanoparticles (nanoclay) with styrene-butadiene-rubber (SBR). Since SBR is a copolymer, both the styrene and the butadiene components interact with the nanoparticles contributing to the nanoclay miscibility and the intercalation kinetics. We are able to directly measure the butadiene-nanoclay interaction strength by using dielectric relaxation spectroscopy to probe the butadiene-nanoclay interfacial relaxation mode, and by varying the nanoclay surfactant and copolymer composition, we can indirectly measure the styrene-nanoclay interaction strength. We will present the spectroscopy results and discuss the relation to the intercalation kinetics.

oscillations decay exponentially with increasing temperature, as found in studies of the temperature dependence of microwave-induced resistance oscillations in a high-mobility two-dimensional electron system. We find that the systems display overshoots.

In a viscoelastic matrix, however, these overshoots do not appear for 3D drop computations. In this work, we investigate why drop simulations in 3D do not overshoot in the transient evolution of drop deformation. Experimental observations also show that an overshoot can occur when a Newtonian drop is sheared and the viscous shear balance out the interfacial tension force. When a viscoelastic drop is sheared in a Newtonian matrix, numerical simulations exhibit an overshoot, producing a viscoelastic "wake" at the interface at the front and back of the drop. In the case of a drop reaching a stationary state, the stresses in the wake scales with the inverse magnetic field. This observation suggests that the temperature dependence originates primarily from the modification of the single particle lifetime, likely through electron-electron interaction effects. The relevance of our findings to existing theories will be discussed.

8:36AM A21.00004 Observation of Fractional Microwave-Induced Resistance Oscillations using Co-Planar Waveguide on High-Mobility 2DES. KRISTIAN STONE, RUI-RUI DU, Rice University, LOREN PFEIFFER, KEN WEST, Bell Laboratories, Alcatel-Lucent — The microwave-induced resistance oscillations (MIRO) are commonly observed in high-mobility GaAs 2D electron systems (2DES) irradiated by microwaves. Usually this is accomplished using an antenna or waveguide, where the electromagnetic components (E, and H) coincide with the 2DES plane. We explore MIRO in a co-planar waveguide (CPW) geometry, in which E, is the dominant excitation component in the 2DES plane. Our samples are Hall bars of high-mobility, μ= (6 - 12) x10^6 cm²/Vs, GaAs/AlxGa1-x,As quantum wells with electron densities ranging from 3 to 5 x10^11 cm⁻². Microwaves from a tunable source (2 - 40 GHz) were fed in, via a semi-rigid coax cable, to an impedance-matched CPW across the length of the Hall bar, and brought out via a similar semi-rigid coax to a power sensor. Using this CPW geometry, we are able to simultaneously measure the photocconductivity and the microwave transmission across the sample. In a temperature range of 2.0 K - 5.0 K, we observed fractional MIRO associated with ε = 1/2, 1/3, 1/4, and 1/5, where ε = ω/ωc, and ωc is the cyclotron frequency. Experimental data as well as a brief discussion will be presented. The work at Rice was funded by NSF DMR-0706634.

8:48AM A21.00005 Photoconductivity of a 2D electron gas at large filling factors. IVAN DMITRIEV, Karlsruhe, Germany, MAXIM KHODAS, Brookhaven National Laboratory, A.D. MIRLIN, D.G. POLYAKOV, Karlsruhe, Germany, MAXIM VAVILOV, Wisconsin, Madison, USA — We study non-equilibrium dc conductivity of a 2D electron gas, placed in a classically strong perpendicular magnetic field in the presence of in-plane microwave field and generic Gaussian disorder potential. Focusing the consideration on the bilinear response in the microwave field, we identify four different mechanisms essential for the linear dc resistance. We employ two specific models of the disorder relevant for ultra-high-mobility samples and show that the relative strength of the above mechanisms strongly depends on the spatial range of the disorder potential. In particular, when large angle scattering dominates the transport and temperature is sufficiently high, the contribution of the “displacement” mechanism can overcome the “inelastic” contribution, which is dominant at low temperature. For smooth disorder, characterized by small angle scattering, the “displacement” contribution is strongly suppressed. Other contributions are responsible for the microwave-induced corrections to the non-diagonal part of the conductivity tensor and only weakly depend on the nature of the disorder. We discuss the ways to distinguish experimentally the contributions of the above mechanisms according to their different polarization and temperature dependence.

9:00AM A21.00006 Warming in systems with discrete spectrum: spectral diffusion of two dimensional electrons in magnetic field. SERGEY VITKALOV, NATALIA ROMERO KALMANOVITZ, The City College of New York, USA, ALEXEY BYKOV, Institute of Semiconductor Physics, 630000 Novosibirsk, Russia — Warming in complex physical systems, in particular global warming, attracts significant contemporary interest. It is essential, therefore, to understand basic physical mechanisms leading to overheating. It is well known that application of an electric field to conductors heats electric charge carriers. Often an elevated electron temperature describes the result of the heating. This paper demonstrates that an electric field applied to a conductor with discrete electron spectrum produces a non-equilibrium electron distribution, which cannot be described by temperature. Such electron distribution changes dramatically the conductivity of highly mobile two-dimensional electrons in a magnetic field, forcing them into a state with a zero differential resistance. Most importantly the results demonstrate that, in general, the effective overheating in the systems with discrete spectrum is significantly stronger than the one in systems with continuous and homogeneous distribution of the energy levels at the same input power.

9:12AM A21.00007 Effect of parallel magnetic field on the zero-differential resistance state. NATALIA ROMERO, SEAN MCHUGH, MYRIAM P. SARACHIK, SERGEY A. VITKALOV, Physics Department, CCNY, A. A. BYKOV, Institute of Semiconductor Physics, Novosibirsk — The non-linear zero-differential resistance state (ZDRS) that occurs for highly mobile two-dimensional electron systems in response to a dc bias in the presence of a strong magnetic field applied perpendicular to the electron plane is suppressed and disappears gradually as the magnetic field is tilted away from the perpendicular at fixed filling factor ν. Good agreement is found with a model that considers the effect of the Zeeman splitting of Landau levels enhanced by the in-plane component of the magnetic field.

3This work was supported by NSF grant DMR 0349049, U. S. DoE grant DOE-FG02-84-ER45153 and RFBR project No.06-02-16869.

9:24AM A21.00008 Magnetoresistance of two-dimensional electrons in Si/SiGe quantum wells in in-plane magnet field at 20 mK. T. M. LU, L. SUN, D. C. TSUI, S. LYON, Princeton University, W. PAN, Sandia National Laboratories, M. MUHLBERGER, F. SCHAFFLER, Universitat Linz, Austria, J. LIU, Y.H. XIE, University of California at Los Angeles — We have measured the magnetoresistance of two-dimensional electrons in two modulation-doped Si/SiGe quantum wells in an in-plane magnetic field at 20mK. It was found that the ratio of the saturation resistance in high in-plane magnetic field to the zero-magnetic-field resistance is dependent on the electron density. At high electron density, the ratio is approximated 1.8. As the electron density decreases and is close to the metal-insulator transition, the ratio is strongly enhanced and appears diverging at a sample dependent characteristic density. The field at which the magnetoresistance saturates as a function of density is linear at high density. It deviates from this linear dependence and appears to extrapolate to zero when the electron density is below ~0.7 x10¹¹/cm².

9:36AM A21.00009 Electron and Hole Transport in 40 MilliKelvin Germanium < 100 >. KYLIE SUNDQVIST, University of California, Berkeley, CRYOGENIC DARK MATTER SEARCH COLLABORATION — Ultrapure germanium at milliKelvin temperatures presents a charge transport regime which is rarely encountered. In this case, thermal phonons play a negligible role and the scattering of electrons and holes is dominated by spontaneous phonon emission. As these carriers are always hot, typical assumptions of thermal equilibrium are no longer valid. Furthermore, for fields of only a few V/cm, the emission of optical and intervalley phonons is highly inelastic such that carrier distributions may differ substantially from the form of a displaced Maxwellian. We present simulation results of transport processes of carriers in germanium < 100 > at a temperature of ≈40 mK. These studies were performed in order to provide a deeper understanding of processes occurring in detectors of the Cryogenic Dark Matter Search (CDMS), which seeks to detect weakly-interacting massive particles (WIMPs) in the halo of our galaxy. As CDMS measures both the ionized charge and the energy in non-thermalized phonons created by particle interactions, we will describe the applicability of these transport simulation results to a wide variety of measured phenomena.

1Funded by the NSF and DOE.
9:48AM A21.00010 Magnetotransport in Zener Tunneling Regime in a High-Mobility Two-Dimensional Hole System. YANHUA DAI, ZHUOQUAN YUAN, CHANGLI YANG, R.R. DU, Rice University, M. J. MANFRA, L. N. PFEIFFER, K. W. WEST, Bell Laboratories, Alcatel-Lucent — Magnetotransport in two-dimensional electron systems (2DES) under a DC-current bias has recently revealed a number of interesting phenomena, including current-induced Zener oscillations [1] and current-induced spin-polarization in Rashba 2DES. We have measured the DC-current induced magnetotransport in high-mobility 2D holes in a C-doped (100) GaAs/Al0.3Ga0.7As quantum well (QW). The QW has a width of 15 nm and a carrier density \( n \sim 2 \times 10^{11} \text{cm}^{-2} \) and a mobility \( \mu \sim 7 \times 10^{5} \text{cm}^{2} / \text{Vs} \) at \( T = 300 \text{ mK} \). We observe sharp features in the differential resistance, which we interpret as Zener tunneling peaks and valley associated with the commensuration transition of Landau orbits. In a gated Hall bar we are able to tune the carrier density to \( n > 2.6 \times 10^{15} \text{cm}^{-2} \) and observe strong positive magnetoresistance, which can be attributed to the inter-subband scattering with light holes. We will discuss the role of electron-electron scattering in the Zener oscillations observed in electron and hole systems. The work at Rice was supported by NSF DMR-0706634. [1] C. L. Yang et al, Phys. Rev. Lett. 89, 076801 (2002).

10:00AM A21.00011 Strongly Temperature-dependent Compressibility of Dilute 2D Holes near the Metal-Insulator Transition. XUAN GAO, Case Western Reserve Univ, NAOTO MASUHARA, GREG BOEBINGER, National High Magnetic Field Lab, LOREN PFEIFFER, Bell Labs, Alcatel-Lucent — We used the capacitance measurement to study the compressibility of dilute 2D holes in a 10nm wide GaAs quantum well for \( T \sim 0.01-0.7 \text{K} \). The sample exhibits the \( B=0 \) metal-insulator transition (MIT) at a critical density \( p_{\text{c}} \sim 1.0 \times 10^{10} \text{cm}^{-2} \). Deep in the metallic state, the sample capacitance decreases slowly as hole density \( p \) increases, due to the (negative) exchange contribution to the compressibility of an interacting 2D system. As \( p \) is reduced below \( p_{\text{c}} \) at low-\( T \), the capacitance of sample diminishes rapidly as a result of the incompressible nature of the insulator state, similar to previous studies (Dultz and Jiang, PRL 84, 4689 (2000); Allison et al., PRL 96, 216407 (2006)). On the other hand, we found that temperature has a strong effect near the MIT, in contrast to literature. In our system, the compressibility of insulator state increases with \( T \) and remains positive, while the behavior of metallic phase is more complex. Notably, for metallic phase with \( p \) slightly above \( p_{\text{c}} \), the sign of compressibility can change from positive to negative as \( T \) increases. This strongly \( T \)-dependent compressibility is possibly related to the competition between two phases with distinctive compressibility in our system, which is more strongly interacting than samples studied previously.

10:12AM A21.00012 Branched flow and caustics in random media with magnetic fields. JAKOB METZGER, RAGNAR FLEISCHMANN, THEO GEISEL, Max-Planck-Institute for Dynamics and Self-Organization and University of Goettingen, Germany — Classical particles as well as quantum mechanical waves exhibit complex behaviour when propagating through random media. One of the dominant features of the dynamics in correlated, weak disorder potentials is the branching of the flow. This can be observed in several physical systems, most notably in the electron flow in two-dimensional electron gases [1], and has also been used to describe the formation of freak waves [2]. We present advances in the theoretical understanding and numerical simulation of classical branched flows in magnetic fields. In particular, we study branching statistics and branch density profiles. Our results have direct consequences for experiments which measure transport properties in electronic systems [3].

10:24AM A21.00013 Possible competing ground states in high mobility electron-hole bilayers. K. DAS GUPTA, A.F. CROXALL, C.A. NICOLL, M. THANGARAJ, H.E. BEERE, I. FARRER, D.A. RITCHIE, M. PEPPER, Cavendish Laboratory, University of Cambridge — Recently it has become possible to fabricate independently contacted high mobility electron-hole bilayer (EHLB) with densities \(< 5 \times 10^{10} \text{cm}^{-2} \) and a separation 10-20 nm in a GaAs/AlGaAs system. In these EHLBs the interlayer interaction can be stronger than the intralayer interactions. Exciton superfluidity in such EHLBs was first predicted almost forty years ago. Since then theoretical works have indicated the possibility of a very rich phase diagram, containing a superfluid, charge density waves, Wigner crystals and a BCS-BEC crossover. However this system has been extremely difficult to fabricate in practice. Very recent experiments have revealed novel features in the interlayer scattering (Coulomb drag) below \( \sim 1 \text{K} \). The Coulomb drag shows strong non-monotonic deviations from a \( T^2 \) behaviour expected for Fermi-liquids at low temperatures. Simultaneously an insulating behaviour in the single layer resistances also appears in both layers inspite of electron mobilities \( > 10^8 \text{cm}^2 / \text{Vs} \text{T}^{-1} \) and hole mobilities \( > 10^5 \text{cm}^2 / \text{Vs} \text{T}^{-1} \). The experimental results may indicate a competition between an excitonic ground state and charge-density waves. [J. Keogh et al / APL, 87,202104 (2005), A.F. Croxall et al arXiv:0807.0117 (to appear in JAP), A.F. Croxall et al arXiv:0807.0134v3 (to appear in PRL)].

10:36AM A21.00014 Anomalous plateau formation and improved quantization in charge pumping under a perpendicular magnetic field. SAMUEL WRIGHT, Cavendish Laboratory and Toshiba Cambridge Research Laboratory, MARK BLUMENTHAL, Cavendish Laboratory and National Physical Laboratory, GODFREY GUMBS, Institute of Molecular and Atomic Physics of the City University of New York, ADAM THORN, MICHAEL PEPPER, Cavendish Laboratory, T.J.B.M. JANSEN, National Physical Laboratory, STUART HOLMES, Toshiba Cambridge Research Laboratory, DAVE ANDERSON, GEB JONES, CHRISTINE NICOLL, DAVE RITCHIE, Cavendish Laboratory — We present experimental results of high frequency quantized charge pumping through a quantum dot formed by the electric field arising from applied voltages in a GaAs/AlGaAs system in the presence of a perpendicular magnetic field \( B \). Improved quantization and robustness in gate voltage are seen as \( B \) is increased. Under application of even higher \( B \) fields, the formation of anomalous plateaux in the pumped current are seen.

10:48AM A21.00015 Thermal transport size effects in self-assembled Germanium quantum dots in single-crystal silicon. JEAN-NUMA GILLET, University of Colorado at Boulder — Superlattices with low thermal conductivity have been used to design 1-D thermoelectric materials. With them, it is challenging to obtain a thermoelectric figure of merit \( ZT > 1 \). Self-assembly is used to fabricate Ge quantum-dot (QD) arrays. High \( ZT \) is expected in these self-assembled Ge QDs arrays in Si since they are single crystals. We prove that high-density 3-D Ge QD arrays in diamond-cubic Si exhibit low thermal conductivity. This property can be used to design 3-D thermoelectric devices. To study the thermal behavior of these 3-D nonphononic crystal nanocomposites, we create an atomistic model of a supercell consisting of Si unit cells. Inside each supercell, we substitute Si atoms with Ge atoms to form a QD. The thermal conductivity has been shown to reduce below 0.2 W/m/K. Such a result is realized by ensuring minimum group velocities. Further reduction is expected from multiple scattering. We are concerned with the size dependence of the thermal conductivity upon the Ge volumic composition \( f \). From preliminary results with constant \( f \), we obtain an exponential-like thermal-conductivity decrease when the supercell size is increased.

Monday, March 16, 2009 8:00AM - 11:00AM — Session A22 GMAG DMP FIAP: Focus Session: Spins in Group III-V and II-VI Semiconductors
8:00AM A22.00001 Electrically Injected Spin Polarized Lasers1 . PALLAB BHATTACHARYA, Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, MI 48109-2122, USA — The ability to electrically modulate orthogonal polarization states in spin-polarized lasers opens up avenues for a wide range of applications such as photochemical spectroscopy, optical switches, and communications with enhanced security [1]. This has motivated us to investigate the properties of quantum well (QW) [2] and quantum dot (QD) [3] spin-polarized vertical cavity surface emitting lasers (spin-VCSELs). The laser heterostructures are grown by molecular beam epitaxy (MBE). The active region consists of In0.2Ga0.8As/GaAs QWs [2] or InAs QDs [3]. VCSELs are fabricated using standard micro-fabrication techniques. The FM Schottky tunnel contact is realized with Fe or MnAs re-grown by MBE. The QW spin-VCSELs exhibit a maximum threshold current reduction of 11 % and output degree of circular polarization of 23 % at 50 K. The corresponding values observed in QD spin VCSELs at 200 K are 8 % and 14 %, respectively. Inhibition of the D’yakonov-Perel spin scolding process results in higher operating temperatures for spin-lasers with QD active region. In addition, we have demonstrated electrical modulation of the output polarization with a peak modulation index of 0.6. The spin polarization of carriers in the active region of a spin laser gives rise to large gain anisotropy at biases near threshold. As a result, the output polarization can be much larger than the spin polarization of the injected carriers. This is contrary to the linear relation between carrier spin orientations in the active region and the polarization of photons emitted upon their radiative recombination in spin light emitting diodes. The exact magnitude of the output polarization in spin lasers and the parameters upon which it depends have been analytically determined and are in excellent agreement with those obtained from measurements. These results will be described and discussed.

8:36AM A22.00002 Electrical Spin injection from Fe into ZnSe . AUBREY HANBICKI, G. KIOSEOGLOU, M.A. HOLUB, O.M.J. VAN ’T ERVE, B.T. JONKER, Naval Research Laboratory — The wide bandgap semiconductor ZnSe is an opto-electronic material with a comparable spin lifetime and small lattice mismatch to GaAs. Novel spintronic devices that incorporate ZnSe/GaAs heterostructures will require the facile transport of spin information across several heterointerfaces including spin injection into the ZnSe. We have electrically injected spin-polarized electrons from a ferromagnetic Fe contact into a ZnSe epi layer grown on a GaAs heterostructure. The injected carriers proceed through 300 nm of ZnSe and recombine in the GaAs emitting light characteristic of the bulk GaAs exciton. We measure spin polarizations in excess of 40% in the GaAs based on analysis of the circular polarization of the electroluminescence. We report results as a function of applied magnetic field, device current and temperature. The spin injection process and transport through the ZnSe layer sustains significant spin populations in this heterostructure. This work was supported by core programs at NRL.

8:48AM A22.00003 Tuning spin-current across a Semiconductor/Ferromagnet junction by resonance tunneling , PENGKE LI, Department of Electrical and Computer Engineering, University of Rochester, Rochester, New York, 14627, HANAN DERY, Department of Electrical and Computer Engineering, University of Rochester, Rochester, New York 14627 — We present a theory of spin-dependent transport in a hybrid semiconductor/ferromagnet system which includes an asymmetric double barrier region at the interface (e.g., GaAs/AlGaAs/GaAs/Fe). The system has two electron confinement regions with one being a thin quantum well between a heterostructure barrier and a Schottky barrier. The second confinement region is a two dimensional electron gas (2DEG) at the heterointerface with the bulk semiconductor generated by intentional doping. The I-V curve has two current peaks when electrons tunnel into the ferromagnet. These peaks are due to resonance tunneling of electrons whose energy matches the energy of the quasi-bound state in the quantum well. The first peak is governed by tunneling of delocalized electrons from the bulk semiconductor and the second by escape from the 2DEG. These resonances are met at different bias levels and correspond to opposite spin polarization of the current.

9:00AM A22.00004 Triggering phase-coherent spin packets by pulsed electrical spin injection across an Fe/GaAs Schottky barrier1 . B. BESCHOTEN, L.R. SCHREIBER, C. SCHWARK, G. GUENTHERODT, Physikalisches Institut II A, RWTH Aachen University, 52056 Aachen, Germany, C. ADEL Mann, C.J. PALMSTROM, Department of Chemical Engineering and Material Science, University of Minnesota, Minneapolis 55455, X. LOU, P.A. CROWELL, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455 — The precise control of spins in semiconductor spintronic devices requires an electrical means for generating spin packets with a well-defined initial phase. So far, ultrafast laser pulses have successfully been used to trigger the ensemble phase of optically generated spin packets. However, electrical methods for ensemble phase triggering remain challenging. Here, we use fast current pulses to inject phase triggered electron spin packets across an Fe/GaAs Schottky barrier into n-GaAs. We demonstrate phase coherence by the observation of multiple Larmor precession cycles for current pulse widths down to 500 ps at 20 K. We show that the current pulses are broadened by the charging and discharging time of the Schottky barrier. At high frequencies, the observable spin coherence is limited only by the finite band width of the current pulses, which is on the order of 2 GHz.

9:12AM A22.00005 The importance of Fe interface states for ferromagnet-semiconductor based spintronic devices . ANTHANASIOS CHANTIS, Theoretical Division, Los Alamos National Laboratory — I present our recent theoretical studies of the bias-controlled spin injection, detection sensitivity and tunneling anisotropic magnetoresistance in ferromagnetic-semiconductor tunnel junctions. Using first-principles electron transport methods we have shown that Fe 3d minority-spin surface (interface) states are responsible for at least two important effects for spin electronics. First, they can produce a sizable Tunneling Anisotropic Magnetoresistance in magnetic tunnel junctions with a single Fe electrode. The effect is driven by a Rashba shift of the resonant surface band when the magnetization changes direction. This can introduce a new class of spintronic devices, namely, Tunneling Magnetoresistance junctions with a single ferromagnetic electrode that can function at room temperatures. Second, in Fe/GaAs(001) magnetic tunnel junctions they produce a strong dependence of the tunneling current spin-polarization on applied electrical bias. A dramatic sign reversal within a voltage range of just a few tenths of an eV is found. This explains the observed sign reversal of spin-polarization in recent experiments of electrical spin injection in Fe/GaAs(001) and related reversal of tunneling magnetoresistance through vertical Fe/GaAs/Fe trilayers. We also present a theoretical description of electrical spin-detection at a ferromagnet/semiconductor interface. We show that the sensitivity of the spin detector has strong bias dependence which, in the general case, is dramatically different from that of the tunneling current spin-polarization. We show that in realistic ferromagnet/semiconductor junctions this bias dependence can originate from two distinct physical mechanisms: 1) the bias dependence of tunneling current spin-polarization, which is of microscopic origin and depends on the specific properties of the interface, and 2) the macroscopic electron spin transport properties in the semiconductor. Our numerical results show that the magnitude of the voltage signal can be tuned over a wide range from the second effect alone and thus identifies a universal method for enhancing electrical spin-detection sensitivity in ferromagnet/semiconductor tunnel contacts.
9:48AM A22.00006 Three Terminal Spin Extraction Resistance in Fe/GaAs Heterostructures, E.S. GARLID1, T. KONDO1, Q. HU1,2, C.J. PALMSTROM1,2, P.A. CROWELL1, U. Minnesota, 2UC Santa Barbara — Spin transport measurements have been difficult to interpret in two terminal Fe/GaAs/Fe devices where current flows in both the injector and detector electrodes. This is due to the strong non-monotonic dependence of the spin accumulation on the Fe/GaAs interface bias, which affects the spin injection and detection efficiencies. To address this, we measured the four terminal non-local spin valve resistance and the three terminal spin extraction resistance in epitaxial Fe/GaAs heterostructures with a systematically varied Schottky barrier doping profile. Lateral devices were fabricated from epitaxial Fe/n+n-GaAs (100) heterostructures in which the thickness of the n+ layer (n+ = 5 × 1017 cm−2) was varied from 5 to 50 nm while n = 5 × 1016 cm−2 in the 2.5 µm channel. The three terminal resistance measured using a single contact as the injector and detector is ~100× larger than the non-local spin valve resistance, an effect which cannot be attributed to spin relaxation in the channel. In the case of a three terminal measurement, we obtain both a large spin accumulation as well as an enhanced detection sensitivity under forward bias conditions. This can be analyzed by considering the measured non-local spin polarization as a function of bias, as well as the electric fields at the Fe/GaAs interface in the presence of a charge current. Supported by ONR and the NSF MRSEC, and NNIN programs.

10:00AM A22.00007 Contributions to oblique Hanle linewidths in Fe/GaAs non-local spin valve transport, CHAFFRA AWO-AFFOUDA, O. M. J. VAN ‘T ERVE, G. KIOSEOGLOU, A. T. HANKBICKI, M. HOLUB, C. H. LI, B. T. JONKER, Naval Research Laboratory — The transport Hanle effect linewidth is commonly used to determine spin lifetimes in spin- polarized transport structures. We show that the magnetic domain structure of the ferromagnetic contacts used to inject and detect the spin current introduces asymmetries to the Hanle linewidth. In addition, the nuclear spin polarization can produce anomalous narrowing and broadening of the Hanle linewidth depending upon the orientation of the transport spin and the applied field. These contributions can significantly impact the apparent spin lifetime extracted from the Hanle curve, but are not included in the analysis typically applied.

10:12AM A22.00008 High Optical Polarization from Electrical Spin Injection into a InGaAs QW, CH. LI, G. KIOSEOGLOU, M. HOLUB, O.M.J. VAN ’T ERVE, B.T. JONKER, Naval Research Lab, T. ALI, I. KHAN, M. YASAR, A. PETROU, SUNY Buffalo — We have fabricated spin light emitting diodes (LEDs) with Fe as the spin injector and 100 ˚A In0.1Ga0.9As/GaAs QWs as the detector. The emission efficiency from the InGaAs QW is extremely high, with a narrow linewidth of 4meV at 5K. The free exciton exhibits 25% optical polarization due to the injection of spin-polarized carriers from the reverse-biased Fe Schottky contact. At low bias, a feature 10meV below the free exciton appears which exhibits a much larger polarization with a peculiar magnetic field dependence. Similar to that of the free exciton, the circular polarization of this lower energy feature first increases with magnetic field, and reaches a maximum of 67% at 2.5T, indicating injection from Fe. However, this behavior is superposed on a large diamagnetic background of 21%/T which dominates above 2.5T. The intensity and polarization of this feature is strongly bias dependent, and the feature disappears above 15K, suggesting that it originates from a weakly bound complex. The origin of this feature and its dependence on the magnetic field will be discussed at the meeting. Supported by ONR, NRL core funds, and NSF.

10:24AM A22.00009 Spin polarization control through resonant states in an Fe/GaAs Schottky barrier, ATSUFUMI HIROHATA, University of York, SHUTA HONDA, Nagoya University, HIROYOSHI ITOH, Kansai University, JUN-ICHIRO INOUE, Nagoya University, HIDEKAZU KUREBAYASHI, THEODOSSIS TRYPINIOTIS, C. H. W. BARNES, J. A. C. BLAND, University of Cambridge — We show that the IRSs (Interface Resonant States) within the Schottky barrier play an important role for the negative spin polarization of the current and its bias dependence, and compare with our experimental results [1]. We have calculated the spin polarization P of the tunnel conductivity using a full-orbital tight-binding model, and have shown that the IRSs within the Schottky barrier in the GaAs layer influence significantly the spin-dependent tunneling across the interface. It has been clearly shown that the band matching of the IRSs plays a crucial role on the spin polarization. The theoretical results account well for earlier experimental results including the tunneling of photo-excited electrons. The present results suggest that the spin polarization can be controlled by the Schottky barrier heights, and that a spin-switch device with bias control may also be promising. Quantitative performance of the device, however, needs more quantitative calculations including effects of atomic disorder for example. [1] H. Kurebayashi et al., Appl. Phys. Lett. 91, 102114 (2007).

10:36AM A22.00010 Time dependent analysis of spin transport in lateral semiconductor/ferromagnet structures with non-collinear magnetization, YANG SONG, Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627, HANAN DERY, Department of Electrical and Computer Engineering, University of Rochester, Rochester, New York 14627 — We model the transport in lateral semiconductor channels beneath ferromagnetic contacts with non-collinear magnetization directions. We quantify the effects of the mixing conductance and of the spin polarization across the interface, of the electrical field in the channel and of the resistance ratio between the channel and the interface. We focus on a non-local spin valve geometry in which two contacts are biased and collinear and a third terminal is non-collinear and “semi” floating (connected in series with a capacitor). This structure can be used for memory devices with multi-valued stored bits by rotating the magnetization in one of the terminals and detecting the transient current signal that flows through the non-collinear terminal. The shape and magnitude of this current signal is strongly influenced by the relation between the non-collinear magnetization direction and the (2D) spin accumulation in the channel that is being set by the biased (collinear) contacts.

10:48AM A22.00011 Magnetic force detection of non-equilibrium electron spin-polarization in n-GaAs, VIDYA BHALLAMUDI, GANG XIONG, Dept of Physics, Ohio State University, Columbus, OH 43210, MARK BRENNER, Dept of Electric and Computer Engineering, Ohio State University, Columbus, OH 43210, YOUNGWOO JUNG, YURI OBUKHOV, DENIS PELEKHOV, Dept of Physics, Ohio State University, Columbus, OH 43210, STEVE RINGEL, Dept of Electric and Computer Engineering, Ohio State University, Columbus, OH 43210, P. CHRIS HAMMEL, Dept of Physics, Ohio State University, Columbus, OH 43210 — Magnetic Force Microscope (MFM) offers an alternative to optical and electrical techniques for detecting and imaging spin-polarized electron populations in semiconductor spintronic devices. Unlike other methods, MFM has the advantage of being material non-specific as it directly detects spins in the semiconductor through their magnetic dipole coupling to micromagnetic tip. However, it is challenging to achieve the high sensitivity required for sensing small non-equilibrium spin populations, orders of magnitude smaller than those in ferromagnetic materials. Here we present our progress developing a high sensitivity cryogenic MFM for imaging optically injected electronic spins in GaAs. Spins are created in an epitaxially grown In0.1Ga0.9As QW by optical injection from a nearby laser diode. The spin Hall effect induces a magnetic force due to the optically injected spins. Micro-magnetic tip generating large field gradient is used for enhancing the signal. We will show simulation results for the expected forces, taking spin relaxation, diffusion and local tip field into account. The status of spin imaging experiment will also be presented.

Monday, March 16, 2009 8:00AM - 10:48AM
Session A23 DCMP: Plasmons and Optical Absorption
8:00AM A23.00001 Ternary cobalt spinel oxides for solar driven hydrogen production: Theory and experiment, ARON WALSH, KWANG-SOON AHN, SUDHAKAR SHET, MUHAMMAD N. HUDA, TODD DEUTSCH, HELI WANG, JOHN A. TURNER, YANFA YAN, MOWAFAK M. AL-JASSIM, SU-HUIWEI, National Renewable Energy Laboratory — Discovery of a chemically stable, light absorbing and conductive metal oxide with band edges aligned to water redox potentials has been a goal of physical scientists for the past forty years. Despite an immense amount of effort, no solution has been uncovered. We will present the results of our combined theoretical and experimental exploration of a series of unconventional ternary cobalt spinel oxides, which offer chemical functionality through substitution on the tetrahedral spinel A site. First-principles predictions of the substitution of group 13 cations (Al, Ga, In) in Co$_x$O$_y$ to form a series of homologous CoO$_2$O$_x$ spinel compounds are combined with experimental synthesis and photoelectrochemical characterization. Ultimately, while tunable band gaps in the visible range can be obtained, the material performance is limited by poor carrier transport properties associated with small polarons. Future design pathways for metal oxide exploration will be briefly discussed.

8:12AM A23.00002 Multiple electron generation in a sea of electronic states, WAYNE WITZEL, Sandia National Laboratory, NM, ANDREW SHABAABE, George Mason University. ALEXANDER EFROS, CARL HELLBERG, JACOBS VERNE, Naval Research Laboratory — In traditional bulk semiconductor photovoltaics (PVs), each photon may excite a single electron-hole, wasting excess energy beyond the band-gap as heat. In nanocrystals, multiple excitons can be generated from a single photon, enhancing the PV current. Multiple electron generation (MEG) may result from Coulombic interactions of the confined electrons. Previous investigations have been based on incomplete or over-simplified electronic-state representations. We present results of quantum simulation that includes favorable conditions of configuration states and show how the quantum dynamics, even in a closed electronic system, yields a saturated MEG effect on a femtosecond timescale. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

8:24AM A23.00003 Quantum confined stark effect in non-identical InAs/GaAs coupled quantum dots: Dependence on vertical electrical field, MUHAMMAD USMAN, GERHARD KLIMECK, NCN Purdue University West Lafayette IN — InAs/GaAs coupled quantum dot (QDs) have gained much attention for optical and quantum computing applications. Due to strain, originating from assembly of lattice-mismatched semiconductors, quantum dot tend to grow in the vertical direction. These stacked QDs are strongly coupled through strain field, which is atomically inhomogeneous and penetrates deep into GaAs buffer layer surrounding the dots. Piezoelectric field must be taken into account to properly model the experimentally observed symmetry breaking and a global shift in the energy spectra of the system. Vertical electrical field applied in the growth direction results in the red shift of emission spectra due to the quantum confined stark effect. Previous studies are based on kp method that ignore the crystal symmetry, optical anisotropy and piezoelectricity effects. In this work, we apply a twenty band sp$^3$d$^*s$ atomic tight binding model to study the experimentally observed red shift of emission spectra resulting from an applied electrical field. We quantitatively compare the results for coupled QDs with the results for single QD.

8:36AM A23.00004 Experimental Kataura plot from individual Single-Wall Carbon nanotubes on silicon substrate, YA-PING HSIEH, MARIO HOFMANN, CHI-TE LIANG, MILDRED S. DRESSELHAUS, JING KONG, MIT — The dependence of Raman scattering of individual carbon nanotubes on excitation energy was investigated. For this carbon nanotubes were grown on Silicon substrate and their Raman spectra were analyzed for a multitude of different laser excitation wavelength. Resonance windows for several tubes within one family were measured to obtain the energy of maximum intensity of the Raman peak positions. By carefully calibrating these Raman peak positions, this experimental data can generate an experimental Kataura plot, which was compared to the theoretical prediction. Finally, a relation between RBM frequency and diameter was obtained based on the experimental Kataura plot. These results will improve the chirality assignment of carbon nanotubes grown on silicon substrate.

8:48AM A23.00005 Effect of Multi-Resonance Subband Structure on the Kerr Nonlinearity of Quantum-Cascade Lasers, JING BAI, University of Minnesota Duluth — This work focuses on the investigation of the optical Kerr lensing effect in quantum-cascade lasers with multiple resonance levels. The Kerr refractive index $n_2$ is obtained through the third-order susceptibility at the fundamental frequency $\chi^{(3)}(\omega)$. Resonant two-photon processes are found to have almost equal contributions to $\chi^{(3)}(\omega)$ as the single-photon processes, which result in the predicted enhancement of the positive $n_2$, and thus may enhance mode-locking of quantum-cascade lasers. Moreover, an isosceles optimization strategy for further improving $n_2$ through the band-structure design is also demonstrated, in order to boost the multimode performance of quantum-cascade lasers. Simulation results show that the optimized stepwise multiple-quantum-well structure has a twofold enhancement on $n_2$ over the original flat quantum-well structure. This leads to a refractive-index change $\Delta n$ of about 0.01, which is at the upper bound of those reported for typical Kerr medium. This stronger Kerr refractive index may be important for quantum-cascade lasers ultimately to demonstrate self-mode-locking.

9:00AM A23.00006 Anisotropic Electronic Screening due to Fermi Surface Nesting in Graphite, JAMES REED, University of Illinois, YOUNG IL JOE, DIEGO CASA, THOMAS GOG, Y. Q. CAI, PETER ABBAMONTE — We used inelastic X-ray scattering to measure the imaginary part of the density-density Green’s function, $\Im[\chi(\vec{k},\omega)]$, of a single crystal graphite sample along six directions in the basal plane from $[100]$ to $[110]$. To place $\Im[\chi(\vec{k},\omega)]$ on an absolute scale we calculate a scaling coefficient using the optical sum rule. The real part of $\chi(\vec{k},\omega)$ is calculated via the Kramers-Kronig transformation. We use an inversion algorithm to map the data into real space at various time intervals with attosecond time resolution. The images of the density response we produced show hexagonal anisotropy, which arises from scattering between the K and K’ points of the Brillouin zone. Analysis of the data at $\omega = 0$ provides us with the anisotropic induced electron density around a static impurity as function of distance. Integration of the local density around $\vec{r} = 0$ gives the effective charge of the impurity from which we deduced the background dielectric constant, $\varepsilon_{\infty}$, to be approximately 2.23.

9:12AM A23.00007 Plasmons in the presence of Tamm-Shockley states with Rashba splitting at noble metal surfaces, ABDEL-KHALEK FARID, EUGENE MISHCHENKO — Au(111) or similar noble metal surfaces feature Tamm-Shockley surface states that are known to possess considerable spin-orbit splitting of the Rashba type of order $\Delta = 0.1$ eV. When interacting with an electromagnetic field such states are expected to have resonances when the frequency of the field is near the energy of the spin-orbit splitting $\Delta$. They originate from the intersubband transitions between spin-split subbands and can be observed in the frequency dependence of the surface impedance. Plasmons in thin metal films are gapless and can be strongly affected by these spin resonances, acquiring significant modification of the spectrum when it intersects the $\omega = \Delta$ line. Finally, an interesting demonstration of the intersubband resonances can be achieved when metal films are coated with ionic dielectrics that have a frequency of longitudinal/transverse optical phonons above/below $\Delta$. The dielectric function between the two optical phonon frequencies is negative which forbids propagation of conventional plasmon-polaritons. However, the presence of spin-orbit-split surface states allows plasmon-polaritons to exist in this otherwise forbidden range of frequencies.

9:24AM A23.00008 Phases Shift in Sub-wavelength Plasmonic Hole on Thin Metal Film. JUN XU, HYUNJIN MA, NICHOLAS X. FANG, University of Illinois at Urbana-Champaign — While recent study of extraordinary transmission of light through sub-wavelength plasmonic nanostructures shows promise of novel nanophotonic elements in sensing and display, the origin of such phenomena is still under hot debate. In this paper, we measured the phase delay of the squeezed light emerging from individual plasmonic holes. Near-field Scanning Optical Microscope (NSOM) has been used to measure the interference of transmitted and scattered light of an isolated sub-wavelength hole on thin metal film. Our results indicate that even with a 30nm perforated film, the observed phase shift can be as large as 300 degrees, well beyond the prediction from earlier theoretical models. Counter intuitively, the measured phase shift is sensitive to the wavelength, the film thickness but insensitive to hole diameter. Also, full scale simulation by COMSOL has been done to show the more detail features inside the metal film. Our study may provide new insight to compact and efficient optoelectronic devices.

9:36AM A23.00009 Coupling between Surface Plasmon Resonance and electric current in Au stripes, MIGUEL ANGEL GARCIA, AIDA SERRANO, JOSE DE LA VENTA, Dpt. Material Science. University Complutense at Madrid, Spain. — Surface Plasmon Resonance (SPR) is the most outstanding feature of noble metal films. SPR consists on a collective oscillation of the conduction electrons when excited optically in the appropriate geometrical and energy conditions. The electrical current passing trough the metal film involves also the movement of conduction electrons. Thus, coupling effects are expected between SPR and electrical resistivity. A modification of the SPR when a electrical current passes through the film, could allow the modulation of an optical signal by a electrical one. Similarly, when the film is illuminated at the SPR conditions, the oscillation of the conduction electrons and local heating can induce an enhancement of the electric resistivity that can be used to translate an optical signal into a electric one. Those effects could be useful in the development of new fast optoelectronic transducers. We present here results on Au stripes illuminated to induce the SPR while electric currents flow with different orientation with respect to the light polarization.

9:48AM A23.00010 Surface plasmon resonance enhanced binding of metal nanoparticles, K.L. CHAN, M.J. ZHENG, K.W. YU, The Chinese University of Hong Kong. — The interparticle force between metallic nanoparticles illuminated by laser light has been studied theoretically. When the distances between the particles are sufficiently small, the excitation of surface plasmon modes within these particles can lead to strongly enhanced laser fields. As a result, there are strongly enhanced light-induced binding forces between these nanoparticles. For physically realizable laser power, these forces can exceed the van der Waals forces by several orders of magnitude. In our theoretical calculations, we considered the interparticle force and potential between two approaching metal nanoparticles. The metal particles are routinely modelled as Drude metallic spheres, and the interparticle force has been captured conveniently by an approximate multiple image formula between two spheres. When the incident light frequency is near the surface plasmon resonance frequency, we find that the force varies nonmonotonically with the distance and a stable local minimum in the potential energy can be found, signifying a binding between the particles. On the experimental and technological side, these studies are also crucial to optical spectroscopy in the nanoscales. Work supported by the General Research Fund of the Hong Kong SAR Government. [1] J. P. Huang, K. W. Yu, G. Q. Gu Electrorotation of a pair of spherical particles, Phys. Rev. E, Vol. 65, art. no. 021401 (2002).

10:00AM A23.00011 Giant Electric Field Generation in Nano-Metallic Cylinder Chains Due to Plasmon Propagation, ANGELA CAMACHO, JUAN CARLOS ARIAS, Universidad de los Andes — We present a study of the superficial plasmons propagation in a chain of nano-metallic cylinders by analyzing: size effect and coupling between the particles. Particularly, we focus on the main features of electric fields in the inter-cylinder regions due to their relationship with SERS(Surface-enhanced Raman Scattering). Giant electric fields have been observed in spherical nano-particles showing an enormous increasing of the cross section, which offers very interesting applications in molecular physics. We calculate the external radiation effect on chains of cylinders lateral and vertically coupled and examine the Plasmon formation in them. Specially, we study the Plasmon propagation depending on the particle size, the separation between them and the type of coupling. We find enhanced electric fields in the inter-particles regions showing the charge accumulation and order effects in cylinders, which are strongly dependent on the two above proposed parameters, and we also extend our results to possible Surface Enhanced Raman Scattering geometric effect to make a comparison with the spherical nano-particles.

10:12AM A23.00012 Optical properties of medium size noble and transition metal nanoparticles, JUAN C. IDROBO, Vanderbilt University, SOKRATES T. PANTELIDES, Vanderbilt University and Oak Ridge National Laboratory. — Using first-principles methods within time dependent density functional theory and the local density approximation (TDLDA) the absorption spectra of medium size (~20-80 atoms) silver, gold and copper nanoparticles have been calculated. The nanoparticles are fcc fragments with different aspect ratios. We find that in the case of Ag nanoparticles is well reproduced by classical electrodynamics theory based in Mie’s formalism, using the dielectric function of bulk Ag and taking into account the nanoparticle shape. For the case of Cu and Au, there is a similarity in the overall features of the quantum mechanical and classical spectra, but no detailed agreement. We will discuss the role that the d-electrons among all the different elements and the surface states play in controlling the optical properties of the nanoparticles. This work was supported by GOALI NSF grant (DMR-0513046), DOE, the Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, and Alcoa Inc.

10:24AM A23.00013 Electronic Coupling and Optimal Gap Size within a Metal Nanoparticle Dimer, KE ZHAO, CLAUDIA TROPAREVSKY, University of Tennessee and Oak Ridge National Laboratory, DI XIAO, Oak Ridge National Laboratory, ADOLFO EGUILUZ, University of Tennessee and Oak Ridge National Laboratory, ZHENYU ZHANG, Oak Ridge National Laboratory and University of Tennessee. — We study the electronic coupling between two metal nanoparticles using density functional theory methods. We show that a continuous change in the particle separation leads to an abrupt transition from strong to weak electronic coupling, which defines an optimal separation for the dimer. While in the weak-coupling regime the dimer behaves like isolated clusters, its crossing into the strong-coupling regime is signified by two distinct phenomena, namely, the onset of a net magnetic moment, and a maximum in the static polarizability. We also show that as the system switches over from strong to weak coupling regime, the response to an applied electric field is nonlinear even for very small fields. The strong dependence of the coupling on the atomic structure of the nanoparticles and their orientation is also discussed. Our study is expected to have an impact on a variety of systems composed of aggregates of nanoparticles.

10:36AM A23.00014 Extraordinary Optical Transmission through Circular Nanotrenches in Ag Films , FENG WANG, Liquid Crystal Institute, Kent State Univ., MIN XIAO, Department of Physics, University of Arkansas, QIHOU WEI, Liquid Crystal Institute, Kent State Univ., LIQUID CRYSTAL INSTITUTE, KENT STATE UNIV. TEAM, DEPARTMENT OF PHYSICS, UNIVERSITY OF ARKANSAS COLLABORATION — This work reports studies on the extraordinary transmission of normally incident light through sub-wavelength circular nanotrenches in Ag films. The concentric periodic nanotrenches are perforated through 100nm thick Ag films by using focused-ion beam (FIB). Far-field transmission measurements show that under the illumination of linearly polarized white light, the transmitted light is not linearly polarized and exhibits broad-band enhanced transmission with the center wavelength varying with the periodicity of the trench. These spectroscopic experimental results can be reproduced qualitatively through finite-difference time domain (FDTD) simulations. Especially, simulations show that the transmitted light is radially polarized at low frequencies, while azimuthally polarized at high frequencies. These interesting polarization statuses can be explained as a result of competition between transmission of s and p polarized light through periodic gratings of nanotrenches.

Monday, March 16, 2009 8:00AM - 10:48AM –
Session A24 DMP: Focus Session: Nanotube Synthesis 326

8:00AM A24.00001 Thermodynamic instabilities in nano-catalysts and their effects on the diameter of grown nanotubes1, STEFANO CURTAROLO, Department of Mechanical Engineering and Materials Science and Department of Physics, Duke University, Durham NC 27708 — Fe and Fe-Mo nanoclusters are becoming the standard catalysts for growing single-walled carbon nanotubes (SWCNTs) via chemical vapor decomposition (CVD). Contrary to the Gibbs-Thomson formalism, experimental results show that reducing the size of the catalyst beyond a certain limit requires increasing the (minimum) growth temperature. This apparent paradox is addressed in terms of solubility of C in Fe nanoclusters. By using first principles calculations, an innovative thermodynamic model is constructed to determine the behavior of the phases competing for stability. As a function of particle size, there are three scenarios: steady state-, limited-, or no-growth of SWCNTs, corresponding to unaffected, reduced, and zero solubility of C in the clusters. The results are extended to Fe-Mo binary catalysts. The 15+ year-long-standing question about the effects of Mo concentration on the growth capability is finally answered. Phys. Rev. Lett. 100, 195502 (2008), Phys. Rev. B, 77, 115450 (2008), Phys. Rev. B 75, 205426 (2007).

8:36AM A24.00002 CVD grown SWCNTs on Si substrate from DPN patterned catalyst precursor, IRMA KULJANISHVILI, RACHEL KOLTUN, SCOTT MAYLE, VENKAT CHANDRASEKHAR, Department of Physics & Astronomy, Northwestern University, DMITRIY DIKIN, Department of Mechanical Engineering, Northwestern University, SERGEY ROZHOK, Nanofink, Inc. — Much interest has been generated around patterning and synthesis of high quality single wall carbon nanotubes (SWCNTs) into desired architectures. Here we report our work, undertaken to elucidate a simple method for delivering catalyst nanoparticles on defined locations on Si substrate via direct writing approach. We applied the Dip-Pen Nanolithography (DPN) approach to pattern catalyst nanoparticles in selective locations on the substrate, and using this technique, we developed a successful recipe for the subsequent CVD growth to produce high quality SWCNTs into scalable array geometries. Key parameters for successful implementation of this technology into devices or circuit architectures will be discussed. We will present our results on patterning, synthesis and characterization of SWCNTs as grown on the substrate. Raman spectroscopy analysis, electrical and thermal properties of individual SWCNTs prepared into complex nanodevices will be presented in progress.

8:48AM A24.00003 Effective Growth of Boron Nitride Nanotubes by Thermal-CVD1, CHEE HUEI LEE, MING XIE, DEREK MEYERS, JIESHENG WANG, YOKE KHIN YAP, Department of Physics, Michigan Technological University, 1400 Townsend Dr, Houghton, MI 49931 — The synthesis of boron nitride nanotubes (BNNTs) are challenging as compared to the growth of carbon nanotubes (CNTs). Most of reported techniques required unique setup and temperatures >1300 °C. Here we show that clean and long multiwalled BNNTs can be grown by simple catalytic thermal CVD. This was obtained by a growth vapor trapping approach inspired by the whisker nucleation theory. Based on our new findings, we have achieved patterned growth of BNNTs at desired locations. High resolution TEM shows that these BNNTs are highly crystallized. Besides, the tangential vibrational mode predicted by theory was detected in our BNNTs. This vibration mode could be the fingerprint for BNNTs with high crystallinity.

9:00AM A24.00004 Co-optimizing carbon nanotube synthesis: control of diameter, structural quality, and growth kinetics along with simultaneous cost minimization , ERIC R. MESHOT, Department of Mechanical Engineering, University of Michigan, DESIRÉE L. PLATA, Department of Civil and Environmental Engineering, MIT, Marine Chemistry and Geochemistry Department, Woods Hole Oceanographic Institute, CHRISTOPHER M. REDDY, Marine Chemistry and Geochemistry Department, Woods Hole Oceanographic Institute, PHILIP M. GSCHWEND, Department of Civil and Environmental Engineering, MIT, A. JOHN HART, Department of Mechanical Engineering, University of Michigan — We employ a decoupled CVD method that not only facilitates control of mean diameter and structural quality of vertically aligned CNTs, but also co-optimization of kinetics for efficient growth to “forest” heights of several millimeters. The growth substrate temperature (Ts) governs agglomeration of the catalyst film which primarily determines CNT diameter, while structural quality monotonically increases with Ts. Independent heating (Tp) of the reactant mixture generates a strikingly diverse population of active hydrocarbons. These analyses, in concert with real-time laser measurements of forest growth rate and height suggest that select products of gas treatment promote growth, while excessive gas-phase pyrolysis of hydrocarbons adversely affects the CNT structure. Further, we directly inject select compounds in the absence of thermal treatment, thus minimizing energetic costs.

9:12AM A24.00005 Diameter and Geometry Control of Vertically Aligned SWNTs through Catalyst Manipulation , RONG XIANG, ERIK EINARSSON, JUN OKAWA, YOICHI MURAKAMI, SHIGEO MARUYAMA, Department of Mechanical Engineering, The University of Tokyo — We present our recent progress in manipulating our liquid-based catalyst loading process, which possesses greater potential than conventional deposition in terms of cost and scalability, to control the diameter and morphology of single-walled carbon nanotubes (SWNTs). We demonstrate that the diameter of aligned SWNTs synthesized by alcohol catalytic CVD can be tailored over a wide range by modifying the catalyst recipe. SWNT arrays with an average diameter as small as 1.2 nm were obtained by this method. Additionally, owing to the alignment of the array, the continuous change of the SWNT diameter during a single CVD process can be clearly observed and quantitatively characterized. We have also developed a versatile wet chemistry method to localize the growth of SWNTs to desired regions via surface modification. By functionalizing the silicon surface using a classic self-assembled monolayer, the catalyst can be selectively dip-coated onto hydrophilic areas of the substrate. This technique was successful in producing both random and aligned SWNTs with various patterns. The precise control of the diameter and morphology of SWNTs, achieved by simple and scalable liquid-based surface chemistry, could greatly facilitate the application of SWNTs as the building blocks of future nano-devices.
9:24AM A24.00006 Ethanol-promoted growth of dense vertically aligned small-diameter carbon nanotubes. Yong-Yi Zhang, University of Michigan, John Gregoire, Cornell University, John Hart, University of Michigan — We report the use of a small concentration of ethanol in addition to ethylene as the carbon source for growth of vertically aligned CNT "forests." In our system, adding ethanol promotes the catalyst lifetime from approximately 20 minutes to nearly 60 minutes, and accordingly increases the forest height from 2.5 mm to over 5 mm, with CNT diameters of approximately 5 nm (2-3 walls). Spread composition films deposited by gradient sputtering, combined with non-destructive mapping of CNT diameter and alignment by small-angle X-ray scattering, enable high-throughput discovery of necessary and sufficient conditions for growth of small-diameter CNTs. Compared with the widely known water-assisted "super growth" process, we find that ethanol enables much finer control of the dewpoint and thus offers more consistent and tunable results. Also, ethanol is a weaker oxidant than water and therefore creates fewer structural defects due to unwanted etching of the CNT walls.

9:36AM A24.00007 Manufacturing thin films of densely packed horizontally aligned carbon nanotubes. Sameh Tawfick, A. John Hart, University of Michigan — Dense packing of carbon nanotubes (CNTs) over long-range dimensions is necessary to replicate their outstanding properties in functional thin films. We present a continuous method for transforming pillars of vertically aligned (VA) CNTs into densely packed, horizontally aligned (HA) CNT ribbons and sheets, which can be directly used on wafer-scale dimensions and/or patterned by photolithography and plasma etching to achieve feature dimensions down to the micron scale. In this process, a small roller is used to "topple" millimeter-tall VA-CNT microstructures and to simultaneously compress them, thus increasing the packing fraction of CNTs from 2% to 60%. We formulate design guidelines for selection of pattern geometry, roller diameter and material, and the kinetics of the rolling motion. This enables precise control of the HA-CNT film topography and thickness, and the packing density and orientation of the CNTs. Nanoindentation of the HA-CNT films reveals that the initial tortuosity of the VA-CNT forest determines the ultimate achievable densification. Electrical conductivity of ribbons is characterized using dc-four-point testing of lithographically-patterned CNT ribbons with Au contacts. The HA-CNT structures are easily transferred to other substrates, enabling integration with CMOS and MEMS fabrication, and with alternative substrates such as flexible plastics.

9:48AM A24.00008 Incremental Growth of Single-Wall Carbon Nanotube Arrays Explored by Pulsed CVD. Jeremy Jackson, Oak Ridge National Laboratory, Alex Puretzky, Igor Merkulov, Christopher Rouleau, Karrenmore, Norbert Thonnard, Cyula Eres, David Geohagen, CNMS and MSTD Divisions, Oak Ridge National Laboratory Team — Gas pulses of variable duration and peak flux were used to explore the incremental growth and evolution of alignment of vertically-aligned carbon nanotubes arrays (VANTA)s by typical chemical vapor deposition within a tubular reactor. Time-resolved reflectivity from Fe/Al catalyst-coated Si substrates was used to follow the growth of the arrays after the arrival of successive acetylene gas pulses injected into fast argon-hydrogen flows at 6 Torr total pressure. The evolution of alignment of the arrays measured with the in situ optical reflectivity data was correlated with SEM images for growth resulting from single- and multiple-pulse growth. The incremental length per pulse was varied from 20 nm to several microns in less than a second, corresponding to growth rates ranging up to 7 microns/second. Effects of repeated reぬcleation of growth along the nanotube wall structure were measured by HRTEM and Raman spectroscopy.

10:00AM A24.00009 A model of dry-drawing of multiwall carbon nanotube forest into self-assembled sheets and yarns. Alexander Kuznetsov, Alexandre Fonseca, Ray Baughman, Anvar Zakhidov, NanoTech Institute, University of Texas at Dallas — A dry-state technique to produce highly-oriented, free-standing multiwalled carbon nanotube (MWNT) sheets and yarns which are mechanically strong, transparent, and highly oriented has been developed recently [1,2]. A model which allows to describe the main features of the process of dry-drawing self-assembly of vertically oriented multiwall carbon nanotube (MWCNT) forest into horizontal MWCNT sheets or yarns is developed in this presentation. The model is based on two main concepts: 1. self-strengthening of nanotube bundle interconnects during the bending-pulling process; 2. rearrangement of bundles by accordion-type stretching motion accompanied by detachment of bundles (at the top and bottom of the forest). This detachment occurs due to unzipping and self-strengthening of interconnects beyond a critical force, which permits to pull the next bundle from the forest, keeping the process of dry-drawing continuous. Developed model determines the parameters of CNT forest for which the dry-drawing is possible. It also allows to estimate such properties of the produced sheets and yarns as length, density, strength and electrical conductivity. [1] M. Zhang et al., Science 2005, 309, 1215. [2] M. Zhang et al., Science 2004, 306, 1358.

10:12AM A24.00010 Termination mechanism of carbon nanotube forest growth. Mostafa Beidelberg, Eric R. Meshot, Yongyi Zhang, Haicheng Guo, University of Michigan, Erica Verploegen, Massachusetts Institute of Technology, Wei Lu, A. John Hart, University of Michigan — Understanding the termination event in the growth of carbon nanotubes (CNTs) by chemical vapor deposition (CVD) is a roadblock in the pursuit of ultra-long CNTs, which would be useful for many of applications. We present in situ measurements show that vertically-aligned CNT "forest" growth terminates abruptly, which is not predicted by widely suggested models of diffusion-limited growth. In this work, we complement forest height measurements with mass and density measurements, and with spatial mapping of CNT diameter, alignment, and spacing along the forest sidewall by small-angle and ultra-small-angle synchrotron X-ray scattering (SAXS, USAXS). Accordingly, we reveal that the areal density of growing CNTs begins to decay long before the forest height terminates, indicating that gradual deactivation of catalyst particles is collectively responsible for the limitation to CNT forest height. Considering that mechanical and surface interactions among CNTs create the self-supporting forest structure, a gradual decay of CNT density can lead to an abrupt loss of CNT alignment at the forest base when the CNT-CNT spacing increases sufficiently. This proposed mechanism is supported by finite element models of CNT-CNT buckling and contact.

10:24AM A24.00011 Clarifying the Rules for the Highly Efficient Growth of Carbon Nanotubes. Don Futaba, Jundai Gotou, Satoshi Yasuda, Takeo Yamada, Motoo Yumura, Kenji Hata, Nanotube Research Center, AIST — In water-assisted chemical vapor deposition (CVD), the addition of a growth enhancer, e.g. water, to the ambient of normal hydrocarbon dramatically improves growth efficiency resulting in vertically aligned forests [1]. Here, we present a generalized picture of water-assisted CVD (Super-growth) by demonstrating that highly efficient growth of carbon nanotubes (CNTs) is possible by, essentially, a countless number of growth enhancers exemplified here by alcohols ethers, esters, ketones, aldehydes, and even carbon dioxide. From an extensive investigation, we found that the key for highly efficient growth is to use two essential ingredients: 1) a carbon source not containing oxygen, and 2) a growth enhancer containing oxygen. We believe that this new understanding of CNT synthesis further cultivates and expands the world of CVD where innumerable new and completely unexplored growth ambitions can emerge that would lead to further scientific discovery [1] K. Hata et al, Science, 306, 1241 (2004).

10:36AM A24.00012 ABSTRACT WITHDRAWN —

Monday, March 16, 2009 8:00AM - 11:00AM —
Session A25 DMP: Focus Session: Graphene I: Electronic Properties
Due to Klein's tunneling, the relativistic electron in graphene cannot be localized by a confinement potential. In this case electron states in a graphene quantum dot become resonances with finite trapping time. We consider these resonances as the states with complex energy. To find the energies of these states we solve the time-independent Schrodinger equation with outgoing boundary conditions. The imaginary part of the energy determines the width of the resonances and the electron trapping time. We show that if the parameters of the confinement potential satisfy a special condition, then an electron can be strongly localized by such quantum dot, i.e., the trapping time becomes infinitely large. We show how a deviation from this condition affects the electron trapping time. We also analyze the energy spectra of an electron in a graphene quantum ring with a sharp boundary. We show that in this case the condition of strong trapping can be tuned by varying parameters of confinement potential, e.g., internal radius of the ring.
10:12AM A25.00010 Thermally assisted self-trimming of graphene nanoribbon edges. YANG, DAVID TOMÁNEK, Michigan State University; SAVAS BERBER, Gebze Institute of Technology — Edge morphology is known to play a key role in the conductance of graphene ribbons. We use a combination of ab initio density functional total energy and molecular dynamics calculations to investigate thermally induced reconstruction occurring at graphene edges. The calculated total energy surfaces suggest that along all nanoribbon sites, atoms at edge defect sites require least energy to be displaced. At elevated temperatures, these atoms will primarily participate in diffusion and related processes at the edge that will gradually reduce the edge roughness and thus lower the edge energy. We explore various scenarios leading to such self-trimming of edges, including concerted migration processes and unravelling of chains at the edge. Close inspection of our results suggests that the preferential mechanisms and activation barriers for trimming of rough armchair and zigzag edges may be different. In selected scenarios, Joule heating of nanoribbons may not only straighten rough edges, but also modify the preferred edge morphology.

1Supported by NSF NIRT grant ECS-0506309 and NSF NSEC grant EEC-425826.

10:24AM A25.00011 Fermi surface of graphene on Ru(0001). THOMAS BRUGGER, HUGO DIL, JÜRGEN OSTERWALDER, THOMAS GREBER, Physik-Institut, Universitaet Zuerich, Winterthurerstrasse 190, CH-8057 Zuerich, Switzerland; BERNHARD BOCQUET, Universite de Lyon, Laboratoire de Chimie, Ecole Normale Superieure de Lyon, CNRS, France, SEBASTIAN GÜNTHER, JOOST WINTTERLIN, Department Chemie, Ludwig-Maximilian Universitaet, Butenandstrasse 5-13, D-81377 Muenchen, Germany — The structure of a single layer graphene on Ru(0001) is compared with that of a single layer hexagonal boron nitride nanomesh on Ru(0001). Both are corrugated sp² hybridized networks and display a π-band gap at the K point of their 1×1 Brillouin zone. In contrast to h-BN/Ru(0001), g/Ru(0001) has a distinct Fermi surface which indicates that 0.1 electrons per 1×1 unit cell are transferred from the Ru substrate to the graphene. Photoemission from adsorbed xenon on g/Ru(0001) identifies two distinct Xe 5p1/2 lines, separated by 240 meV, which reveals a corrugated electrostatic potential energy surface like on h-BN/Rh(111) [1]. These two Xe species are related to the topography of the template and have different adsorption energies.

10:36AM A25.00012 Complex refractive index of graphene measured by picometrology. XUEFENG WANG, DAVID NOLTE, Purdue University — The complex refractive index ñg of graphene remains unresolved because the traditional technique, ellipsometry, fails when applied to graphene with its sub-nanometer thickness, dielectric anisotropy, and small transverse sample size. Here we apply interferometric picometrology to measure ñg at 488 nm, 532 nm and 633 nm. A strong dispersion of ñg was found in the visible region. ñg varies from 2.4-1.0i at 532 nm to 3.0-1.4i at 633 nm at room temperature. The dispersion is five times stronger than bulk graphite (2.67-1.34i to 2.73-1.42i from 532 nm to 633 nm). In experiments, Graphene is deposited on a substrate with complex reflection coefficient r̃ tuned near an antinode condition. As a dielectric film, graphene modifies r̃ of the substrate into r̃′. Picometrology measures both the amplitude and the phase change of r̃′, and therefore acquires the full information needed to calculate ñg. This is accomplished by scanning a normal-incidence focused Gaussian beam (1.5 μm width) over the graphene and monitoring the asymmetric diffraction of the reflected beam. Picometrology measures the complex change of r̃ with a quadrant detector that simultaneously monitors both intensity and axis shift of the reflected beam and calculates ñg. The strong dispersion of graphene is reported here for the first time, and it is likely caused by the strongly modified quantum level structure of the single atomic layer.

10:48AM A25.00013 Zero-bias conductance anomaly in point-contact junctions on graphite. WANG, KYU PARK, CESAR CHIALVO, RICH JONES, SAM JOHNSON, NADYA MASON, LAURA GREENE, University of Illinois at Urbana-Champaign — The electronic properties of graphite, a two-dimensional carbon allotrope, continue to attract great interest because of the interesting underlying physics and application potential of this novel electronic material. An ideal single-layer graphene is known to show a linear behavior in the electronic density of states (DOS) around the Fermi level. The ability to engineer the DOS of single- and multi-layer graphene is considered as a fundamental requirement for the realization of electronic devices. To investigate the electronic DOS in graphene/graphite, we adopt a spectroscopic technique based on nanoscale point-contact junctions, where differential conductance spectra are taken at around the liquid helium temperature. A common feature observed in all junctions on both Kish graphite and HOPG is an anomalous conductance dip at zero bias. The conductance curves show a logarithmic bias dependence in their slopes, exhibiting a systematic evolution as a function of magnetic field and contact pressure. We discuss possible origins of these behaviors including the possibility of modification in the electronic DOS of graphite.

Monday, March 16, 2009 8:00AM - 11:00AM — Session A26 DMP DCOMP: Focus Session: Computational Nanoscience I: Inorganic Nanostructures and Interfaces 328

8:00AM A26.00001 Interface electrostatics in ferroelectric capacitors from first principles. MASSIMILIANO STENGEL, UCSB — Capacitors based on ferroelectric perovskites are potentially attractive for applications in nanoelectronics, such as non-volatile random-access memories and high-permittivity gate dielectrics. Thin-film geometries are sought after for optimal efficiency and information storage density. However, in such a regime, strong size effects arise that generally deteriorate the overall performance of the device. Understanding the properties of the oxide/electrode interface is crucial to overcoming these deleterious effects. In this talk I will present our recently-developed methodologies for working at fixed electric displacement field in first-principles density-functional calculations. I will show that application of fixed-D methods to ferroelectric capacitors provides enhanced flexibility for the study of interface-specific issues. I will demonstrate this technique by presenting results for a range of systems based on PbTiO₃ electric displacement field in first-principles density-functional calculations. I will show that application of fixed-oxide/electrode interface is crucial to overcoming these deleterious effects. In this talk I will present our recently-developed methodologies for working at fixed electric field.

8:36AM A26.00002 Multiexciton absorption in CdSe nanocrystals. ALBERTO FRANCESCHETTI, YONG ZHANG, National Renewable Energy Laboratory — Efficient multiple-exciton generation (MEG) has been recently reported in semiconductor nanocrystals. In this process, a single absorbed photon generates two or more electron-hole pairs. The MEG efficiency has so far been evaluated assuming that the change (bleaching) of the absorption spectrum due to MEG is linearly proportional to the number of excitons (Nₓ) that are present in the nanocrystal. We have examined this assumption using atomistic pseudopotential calculations for colloidal CdSe nanocrystals ranging in size from 3 to 4.6 nm. We found that the bleaching of the first absorption peak, ∆X₁, depends non-linearly on Nₓ, due to carrier-carrier interactions. When a single exciton is present in the nanocrystal, the 1s exciton peak is already 65-75% bleached. This non-linearity mandates an upper bound of 1.5 to the value of the normalized bleaching that can be attributed to MEG, significantly smaller than the limit of 2.0 predicted by the linear scaling assumption. Thus, measured values of the normalized bleaching in excess of 1.5 in CdSe nanocrystals cannot be due entirely to MEG, but must originate in part from other mechanisms.

1Funded by DOE-SC-BES-MSED, through NREL contract DE-AC36-08GO28308.
8:48AM A26.00003 Electronic Structure of Thiolate Covered Gold Nanoparticles1. YAN LI, GIULIA GALLI, FRANCOIS GYGI, University of California, Davis — We present ab initio calculations of the structural, electronic, and bonding properties of thiolate-covered gold nanoparticles that have been crystallized in recent experiments (Au$_{1102}$ (MBA)$_{14}$)[1]. We simulated exactly the same system as investigated experimentally (1596 atoms) and the results of our structural optimization confirm the stability of the experimentally determined structure. We find that the crystallized solid is a semiconductor with a sizable energy gap (~0.5 eV; within DFT), and electronic states at the valence band maximum and conduction band minimum are extended over the gold nanoparticle core and the interface. This energy gap appears to be insensitive to the type of adsorbate. We find a tendency of different adsorbate to exert “pull-out” forces on the surface gold atoms, and our analysis of chemical bonding supports the hypothesis that gold s electrons are donated to the MBA radicals so as to form a highly stable 58-electron, filled electronic shell structure. Finally, comparisons between adsorption energies in the case of gold nanoparticle and flat surfaces show that a finite curvature of the interface enhances the stability of Au-S bonds.

9:00AM A26.00004 Covalently Bonded Aromatic Molecules on Gold using a GW Approach1. ISAAC TAMBLYN, Dalhousie University, SU YING QUEK, Molecular Foundry, LBNL, STANIMIR A. BONEV, Dalhousie University, JEFFREY B. NEATON, Molecular Foundry, LBNL — Frontier molecular orbital energies dictate the nature of optical absorption, chemical reactivity, and charge injection at metal-organic interfaces. Recent work [1] on the conductance of benzenediamine-Au single-molecule junctions has shown that standard methods based on density functional theory fail to correctly position molecular orbitals relative to the Au Fermi level, resulting in a pathological overestimate of the conductance for this class of systems. In this work, we use many-electron perturbation theory within the GW approximation to compute quasiparticle energies of aromatic molecules covalently bonded to a gold surface, taking particular care to assess dynamical screening beyond standard plasmon-pole approximations. We discuss results for benzene on Au(111) bound via amine (-NH$_2$) and thiol (-SH) link groups. These data are compared with more approximate model self-energy corrections applied to these systems [1], and also recent experiments. [1] Quek et al, Nano Lett. 7, 3477 (2007).

9:12AM A26.00005 First-principles studies of interfacial charge separation in nano-materials photovoltaic heterojunction1. YOSUKE KANAI, University of California, Berkeley — Charge separation is a crucial process that must be understood in order to make substantial improvements in nano-materials based PV cells. In our work, first principles quantum mechanical calculations are employed to shed light on this process for some important nano-material heterojunctions. I will first present our work on the interfacial charge separation in Fullerene/P3HT and CNT/P3HT heterojunctions. Our findings indicate that in the fullerene system a two-step process is operative, involving an adiabatic electron transfer and an exciton dissociation via quasi-degenerate states localized on the fullerene. For the nanotubes, on the other hand, while such a two-step process is not necessary for efficient charge separation, the presence of metallic nanotubes lead to undesirable charge traps. Secondly, I will discuss how we are addressing the difficulty in employing standard DFT approaches for investigating inorganic-organic PV interfaces, which are composed of two distinct materials with very different electronic environments. I will discuss a QMC scheme for obtaining many-body corrections to the Kohn-Sham level alignments and its application to a CdSe/Oligothiophene hybrid PV interface, with the aim of tailoring its behavior by controlling the conjugation length.

9:48AM A26.00006 Nanoscale phase stability reversals in titanium oxide polymorphs. PAUL KENT, Oak Ridge National Laboratory, DANIËL HUMMER, JAMES KUBICKI, Pennsylvania State University, JEFFREY POST, Smithsonian Institution, PETER HEANEY, Pennsylvania State University — A surprising discovery of nanoscience is the reversal in relative stability of materials with the same composition but different structures as particles evolve from the nanoscale to the macroscopic. These reversals can be problematic, as they frequently induce the precipitation of metastable contaminant phases during the synthesis of compounds of interest. To investigate the fundamental origins of this phenomenon, we have (1) performed a series of large scale density functional calculations to characterize the energetics of the stability reversal between rutile and anatase nanoparticles, and (2) experimentally monitored the hydrothermal crystallization of titania nanoparticles using in-situ x-ray diffraction. Although the phenomenon of stability reversal is commonly explained as a domination of the crystalline surface energy as a fraction of the total energy, we find computationally that the refined average surface structures cannot account for the stabilization of nano-anatase relative to nano-rutile, even for 3nm sized particles. Instead we find that defects associated with the edges and corners of nanocrystals contribute significantly to the energy and must be included in any description of the stability reversal.

10:00AM A26.00007 Domain boundary formation in helical multishell gold nanowire, TAKEO HOSHII, Tottori University, TAKEO FUJIWARA, University of Tokyo — Helical multishell gold nanowire (Y. Kondo and K. Takayanagi, Science 289, 606 (2000)) is studied by molecular dynamics simulation with electronic structure (“ELSES” http://www.elses.jp/), so as to explore formation mechanism of helical domain boundary. We have proposed a model for the formation of helical multishell gold nanowires with molecular dynamics simulation with electronic structure (Y. Iguchi, T. Hoshi, T. Fujiiwara PRL 99, 125507 (2007)). In this paper, we show simulation results with larger samples, of which the rod length is more than 10 nm and the number of rod atoms is more than one thousand. Unlike the results of shorter rods in the previous paper, a well-defined domain boundary between helical and (non-)helical regions appears, when an atom moves from a inner shell into rod surface. The inserted atoms on the rod surface causes a surface reconstruction on rod surface and introduces a helical region with a domain boundary. Such an inserted atom is a possible candidate of mechanism for forming a helical rod from an ideal (non-helical) one.

10:12AM A26.00008 Plasmon resonance of gold nanoparticles: the effect of surfactants and solvents1. JEREMY NEAL, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University — Metallic nanoparticles dispersed in host materials have many potential applications due to their unique optical properties. These properties are determined not only by the size, shape and composition of the particles, but also by their environment. Metallic nanoparticles are typically coated with surfactants to prevent aggregation; these surfactants can also significantly affect their optical response. The role of surfactant coatings has been studied previously, but the results are incomplete. We have obtained theoretical expressions to describe and have carried out numerical simulations to determine the effects of solvents and surfactants on the optical response.

10:24AM A26.00009 Investigation of atomic oxygen embedment into copper surface by DFT calculation. MINYOUNG LEE, ALAN MCGAUCHY, Carnegie Mellon University, SUSAN SINNOTT, SIMON PHILLPOT, University of Florida, JUDITH YANG, University of Pittsburgh — In the oxidation of a Cu(100) surface, the Cu$_2$O islands grow both into the substrate and parallel to the surface. To investigate the oxide growth into the copper surface, we analyzed oxygen embedment using DFT calculations. Using the nudged elastic band method, we calculated energy barriers for oxygen embedment for different oxygen coverages and different surface morphologies. As the oxygen coverage increases from 0.25 monolayers (ML) to 1.0 ML, the energy barrier decreases and we find an energetically favorable site between the top and second copper layers at an oxygen coverage of 1.0 ML. The different surface morphologies [(2×2), missing-row reconstruction and (1×2) with 0.25 ML disordered copper vacancy] have comparable energetics and no energetically favorable site for oxygen embedment is predicted. To find the energetically favorable transition states on the missing-row reconstructed Cu(100) surface, we will investigate oxygen embedding paths with and without point defects on the top copper layer.

1Department of Energy Grant.

10:36AM A26.00010 Ab initio vibrational dynamics of Ag$_{27}$-Cu$_{17}$ nanoalloy. MARISOL ALCANTARA ORTIGOZA, University of Central Florida, ROLF HEID, KLAUS P. BOHNEN, Forschungszentrum Karlsruhe (IFP), TALAT S. RAHMAN, University of Central Florida — We have carried out calculations of the vibrational dynamics of the 34-atom nanoalloy, Ag$_{27}$-Cu$_{17}$, using density functional perturbation theory, which furnishes a powerful and reliable method to assess the linear response of the charge density to ionic perturbations. We find that the D$_{3h}$ core-shell structure of Ag$_{27}$-Cu$_{17}$ is dynamically stable, since all modes have non-zero frequencies affirming that the structure does not surrender itself to structural transitions as a result of the small perturbations in the charge density led by vibrations. The phonons of Ag$_{27}$-Cu$_{17}$ range from 2.6 to 28.5 meV and are relatively evenly distributed. There are, however, three ~3.0 meV gaps between 2.8-5.6, 15.0-18.7, and 23.6-26.8 meV. In modes whose frequency is below 7.0 meV, Ag atoms move the most while Cu atoms show a very small displacement. The opposite is true for four modes whose frequency is above 24 meV. We present the displacement patterns of the main modes and find the mode with highest energy to be a radial breathing mode of Cu atoms with respect to the center of the cluster. [1] G. Rossi et al., PRL, 93, 105503 (2004), [2] M. Alcántara Ortigoza and T. S. Rahman, PRB 77, 195404 (2008). Work supported in part by U.S. DOE under Grant DE-FG02-07ER46354.

10:48AM A26.00011 Clusters, Platelets, and Nanowires of Mo-S, and Their Assemblies. P. MURUGAN, Central Electrochemical Research Institute, Karakidu, T.N. India, VIJAY KUMAR, DR. Vijay Kumar Foundation, Gurgaon, India, Y. KAWAZOE, IMR, Tohoku Univ., Sendai, Japan, N. OTA, Hitachi Maxell Ltd., Tokyo, Japan — Nano-structures of Mo-S are useful for removal of S in petroleum industry, as solid state lubricants in space and tribo-lubricants for Pt-free fuel cell research. We study by first principles density functional calculations Mo-S nanoclusters, nanowires, their assemblies, and triangular nano-platelets all of which have been produced in laboratory. Mo-S clusters have Mo polyhedral structures and sulfur atoms cap this metal polyhedron. These structures have high stability due to strong Mo-Mo and Mo-S bonding. Some of the polyhedral clusters have non-zero magnetic moments due to the partially occupied 4d states in Mo atoms. Mo$_5$S$_8$ octahedral cluster has ultra-high stability and it could be condensed to form Mo-S nanowire or nanorod. However, for high $H_s$ contents, we show that triangular platelets become more stable. The Mo-S nanowires are good electronic conductors and are interesting for miniature devices. Assembly of nanowires stabilizes in a hexagonal structure with vdW interactions. The trigonal void between the nanowires can be occupied by Li atoms to develop materials for Li-ion battery applications. References: P. Murugan, V. Kumar, Y. Kawazoe, and N. Ota, Appl. Phys. Lett. (2008); Nano letters. (2007); J. Phys. Chem. A (2007).

Monday, March 16, 2009 8:00AM - 11:00AM — Session A27 GLMS: Focus Session: Advances in Scanned Probe Microscopy I: Low Temperatures 329

8:00AM A27.00001 Development of an Ultra Low Temperature Scanning Tunneling Microscope. YOUNG JAE SONG, ALEXANDER OTTE, NanoCenter, University of Maryland, College Park, MD/Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD, YOUNG KUK, Department of Physics and Astronomy, Seoul National University, Seoul, Korea, JOSEPH STROSCIO, Center for Nanoscale Science in Science and Technology, NIST, Gaithersburg, MD — In this talk we give an update on the next generation of ultra low temperature, high magnetic field (1ST) scanning tunneling microscope (STM). With this system, we plan to extend the capability of STM to include higher energy resolution (~1μeV) for scanning tunneling spectroscopy (STS) with operation at 20 mK. To realize this energy resolution in STS, we constructed an ultra high vacuum dilution refrigerator (DR) for STM applications. It operates with two independent modes of He3-He4 mixture gas condensation: a traditional 1K pot condenser, or a Joule-Thomson condenser for possible lower noise operation. This eliminates potential vibration problems during operation of the DR. To match the very low limit of thermal noise in this system, our new system includes extensive vibration isolation and RF shielding. Our STM sample holder has five isolated electrical contacts. This allows four-probe macroscopic electrical measurements to be performed simultaneously with microscopic STM measurements. The current progress and performance of this new system will be discussed.

8:12AM A27.00002 Design and construction of a millikelvin scanning tunneling microscopy system. MARK GUBRUD, Physics Dept., University of Maryland, College Park, BARRY BARKER, Laboratory for Physical Sciences, MICHAEL DREYER, DAN SULLIVAN, University of Maryland, College Park — We are developing a scanning tunneling microscopy and spectroscopy system for work at millikelvin temperatures, intended for studies of superconductor, semiconductor, and other materials and systems of interest to quantum computing research. Our approach incorporates recent advances in this field as well as original insights and innovations to help achieve low noise and low effective operating temperatures.

8:24AM A27.00003 Direct evidence of the surface state contribution to the Kondo resonance. QING LI, ISSP, Univ. Tokyo and Inst. Phys., CAS, SHIRO YAMAZAKI, TOYOAKI EGUCHI, ISSP, Univ. Tokyo, HOWON KIM, SE-JONG KAHNG, Dept. Phys., Korea Univ., JINFENG JIA, QIKUN XUE, Inst. Phys., CAS and Tsinghua Univ., YUKIO HASEGAWA, ISSP, Univ. Tokyo — We performed low temperature scanning tunneling microscopy/spectroscopy on the isolated single 5, 10, 15, 20-tetrakis-(4-bromophenyl)-porphyrin-Co (TBrPP-Co) molecules adsorbed on the Si(111): √3 x √3 Ag substrate. On this substrate, all the TBrPP-Co molecules show a square shape, indicating a planar conformation with a spin-active Co atom caged at its center. As the substrate supports a two-dimensional surface state and does not have bulk state near the Fermi level, the observed Fano-shaped peak near to the Fermi level is a direct evidence of the contribution of the surface state electrons to the Kondo resonance. The long decay length (∼ 1.4 nm) of the resonance also support for the surface state contribution. [1] Q. Li, S. Yamazaki, T. Eguchi, Y. Hasegawa, H. Kim, S.-J. Kahng, J. F. Jia, and Q. K. Xue, Nanotechnology 19, 465707 (2008).
8:36AM A27.00004 Kondo Effect in a Co-Porphyrin on Au(111) probed by Scanning Tunneling Spectroscopy. SE-JONG KAHNG, HOWN KIM, WON JUN JANG, JUNG HEUM JEON, Korea University, WON-JOON SON, SEUNGWU HAN, Ewha Womans University — Kondo effect is a core topic in condensed matter physics, exhibiting a localized state raised by the interaction between a single magnetic impurity and Fermi electrons in metals. We have studied Kondo effect in a Co-porphyrin on Au(111) using low-temperature scanning tunneling spectroscopy. A localized state is observed at Fermi level from the spectra measured above the Co atom. The spectra were fitted by Fano line shape, revealing the Kondo temperature of the system ~ 400K. By taking spectra at points along some symmetry directions, decaying behavior of the Kondo effect could be analyzed. With the help of simulated d-electron orbital, the observed decaying behavior is accounted for. Our study implies that lattice reconstruction in a system can induce d-electron orbital distortion, resulting in magnetic asymmetries.

8:48AM A27.00005 Imaging the Quantum Berry Phase. C.R. MOON, L.S. MATTOS, B.K. FOSTER, H.C. MANOHARAN, Department of Physics, Stanford University — Geometric phase operations are attractive to quantum information technology because they are time-independent and relatively insensitive to topological perturbations. However, in most coherent devices where these operations could be performed, electron wave functions are inaccessible to local probes. Here, we demonstrate Berry phase rotations on two-dimensional electron wave functions by using atomic manipulation to adiabatically alter their confinement potential. By consecutively changing the boundary of a quantum corral, we traverse a closed circuit in deformation space that engenders a net phase shift in two electron eigenstates. With scanning tunneling microscopy, we trace both the energetic and spatial evolution of these states and directly track their accrual of geometric phase, revealing information that would be obscured in other two-dimensional electron devices. This enables the determination of the two-point transconductance through the device, thus making contact to other nanostructures such as semiconductor quantum dots, where this promising technique for phase control can be implemented using only voltages controlling appropriately patterned gates.

9:00AM A27.00006 Evolution of Single-Molecule Vibrational Modes from Tunneling to Quantum Point Contact. W. MAR, W. KO, C. R. MOON, B. K. FOSTER, L. S. MATTOS, H. C. MANOHARAN, Stanford University — A detailed understanding of how molecular junctions form and evolve is vital for emerging fields such as molecular electronics. We present high-precision scanning tunneling microscopy studies tracing the evolution of molecular junctions from the tunneling regime to quantum point contact. We employ a model system of CO molecules on Cu(111) and are able to extend inelastic spectroscopy into the point contact regime, thus following the energy shifts of specific vibrational modes as the molecular contact is formed. We observe surprising non-monotonic shifts, confirmed by simultaneous noise measurements traceable to molecular motion. In point contact, we also observe a novel “nucleonic gating” effect in which the carbon nucleus controls a measurable dc molecular conductance shift. This shows that the electrical properties of molecular wires can be profoundly altered by their isotopic makeup. We extend these measurements to geometries where the three-dimensional approach vector of the tip relative to the target molecule is finely controlled, a technique not possible in break junction measurements.

9:12AM A27.00007 Low Temperature Scanning Tunneling Microscopy of High Temperature Superconductors: What We Gain By Taking a Closer Look. ERIC HUDSON, MIT — Scanning tunneling microscopy (STM) and spectroscopy have been applied to a wide variety of experimental systems. In this talk I will focus on one which was discovered at nearly the same time as STM — high temperature superconductors. After two decades of intense research these materials still hold many mysteries, mainly due to the rich variety of states of matter that may coexist, cooperate, or compete with superconductivity. I will present the unique perspective that STM is capable of bringing to our study of these materials through atomic-scale temperature dependent mapping of the density of states. After describing widely observed spatial “checkerboard” patterns which we have found to have a distinct doping dependence suggestive of charge density wave order, I will demonstrate how local variations of this order can help us understand nanoscale inhomogeneity in these materials. Taken together, these results not only show the power of STM to untangle complex nanoscale phenomena but also suggest a new path towards understanding high temperature superconductivity.

9:48AM A27.00008 Vortex excitation in nano-sized Pb island structures using low temperature scanning tunneling microscopy. TAKAHIRO NISHIO, ISSP, Univ. Tokyo, SHIZENG LIN, WPI-MANA, NIMS, KOUSUKE MIYACHI, TOSHI AN, TOYOAKI EGUCHI, YUKI HIHARCANA, ISSP, Univ. Tokyo — Vortex behaviors in nano-size superconductors have attracted a lot of attention since there are various novel phenomena due to the size and shape effects. Using scanning tunneling microscopy/spectroscopy (STM/S) at low temperature (<2 K) we have visualized vortex phases on atomically-flat nano-sized Pb islands formed on the Si(111)-(7×7) substrate and measured the critical magnetic fields for vortex penetration and expulsion [1]. In this study we demonstrate the excitation of a vortex with additional pulsed tunneling current from an STM probe tip. We found that probability of the excitation depends on the amount of the tunneling current, the pulse duration and a tip position in the island. These dependences suggest that the formation of normal state region below the tip due to the excess tunneling current induces the vortex penetration. Experimental details and theoretical results will be explained in the presentation. [1] T. Nishio et al., PRL 101, 167001(2008).

10:00AM A27.00009 Spatial and temperature-evolved tunneling spectroscopic studies of La0.5Ca0.5MnO3( LCNO) films and LCNO/organic-semiconductor heterostructures with spin-polarized scanning tunneling microscopy (SP-STM). C.R. HUGHES, A.D. BEYER, N.-C. YEH, Phys. Dept., Caltech, Pasadena CA — We report studies of spatially resolved tunneling spectra (TS) of La0.7Ca0.3MnO3 (LCMO) (Tc = 260K) epitaxial films and related heterostructures of tris(8-hydroxyquinoline) aluminum (Alq3)/(LCMO) using a UHV, variable temperature STM. At 77K with a Pt/Ir tip we observe sharp transitions between two cluster types with disparate normalized conductance. The majority type region exhibits high conductance peaks at high bias (+/- 2V) and a low energy gap, consistent with band structure calculations. The minority type region reveals moderate conductance over the entire bias range, from -3V to +3V. In contrast, spin-polarized tunneling spectra taken with Cr-coated STM tips show a spatially varying low bias gap in all regions. Further experiments using SP-STM on LCNO under varying temperatures and applied magnetic fields and on Alq3/LCNO structures to study the spin transport length in Alq3 will be reported.

10:12AM A27.00010 Degeneracy lifting of zero energy (Majorana) modes in a chiral p-wave superconductor due to the tunneling between vortices.¹, MENG CHENG, ROMAN LUTCHYN, VICTOR GALITSKI, SANKAR DAS SARMA, University of Maryland — We study lifting of the degeneracy of the zero energy (Majorana) modes in a chiral $p_x + ip_y$ superconductor caused by tunneling between states localized in two different vortex cores. Using Bogoliubov-de Gennes equations, we analytically calculate the energy splitting of the Majorana modes as a function of the distance between two vortices. Our result may have applications in testing Majorana state by tunneling spectroscopy and the realization of topological quantum computation in chiral p-wave superconductors.

10:24AM A27.00011 The role of magnetic anisotropy in the Kondo effect. ALEXANDER OTTE, NIST, MARKUS TERNES, IBM Research, KIRSTEN VON BERGMANN, Universitaet Hamburg, SEBASTIAN LOTH, IBM Research, HARALD BRUNE, EPFL, CHRISTOPHER LUTZ, IBM Research, CYRUS HIRJIBEHedin, University College London, ANDREAS HEINRICH, IBM Research — The Kondo effect is a fascinating many-body phenomenon, the origin of which is often unclear. Using a Scanning Tunneling Microscope operating at 0.5 K, we study inelastic spin excitations on individual atoms bound atop a thin insulating Cu$_2$N layer. We find that, unlike previously studied Fe and Mn atoms, the spins of Co and Ti atoms are Kondo screened in this environment. By applying strong magnetic fields in various directions we are able to precisely analyze the magneto-crystalline anisotropy experienced by the spins, and consequently their orientations relative to the surface. We show that the anisotropy plays a major role in determining whether or not a spin becomes Kondo screened, and how the Kondo effect is influenced by a magnetic field.

10:36AM A27.00012 Tunneling through a single magnetic atom: spin-dependent elastic and inelastic processes. C.F. HIRJIBEHEDIN, A. MODY, X. SHI, A. FISHER, London Centre for Nanotechnology, Dept. of Physics & Astronomy, Dept. of Chemistry, UCL, A.F. OTTE, NIST, M. TERNES, S. LOTH, C.P. LUTZ, A.J. HEINRICH, IBM Research Division, Almaden Research Center — Recent low-temperature scanning tunneling microscopy and spectroscopy studies have used inelastic electron tunneling to probe the spin excitations of magnetic atoms, molecules, and bulk surfaces. Here we describe the mechanisms that drive these spin excitations using a combination of resonant two-step and three-step virtual processes, with the latter including a simple exchange coupling between the tunneling electron and the electrons that comprise the atomic spin. Our description predicts the existence of a sum rule that includes a previously unnoticed type of spin-dependent elastic scattering, and evidence of both are seen in the observed spectra. We discuss the key factors that determine the relative strength of the inelastic tunneling, providing insight on when such processes can be observed and potentially how they might be enhanced.

10:48AM A27.00013 Implementation of a cryogenic scanning microwave impedance microscope. KEJILAI, WORASOM KUNDHIKANJANU, MICHAEL KELLY, ZHI-XUN SHEN, Stanford University — We have implemented a near-field scanning microwave impedance microscope in a variable temperature (2-300K) cryostat equipped with 9T magnet. Reflected microwave signals at 1GHz from a shielded cantilever probe were detected using room-temperature electronics. During the tip-sample approach, a small oscillating voltage was applied to the z-piezo and the modulated microwave signals were monitored to locate the sample surface. The approaching curve toward bulk dielectric materials can be quantitatively simulated by finite-element analysis. We have obtained the first low-T and high-B microwave images on a patterned silicon wafer with ion-implanted stripes. The results show clear impedance contrast in both the capacitive and loss channels. In particular, high-B regions were seen between the heavily doped areas and the insulating substrate, allowing us to visualize the local conductivity variation. With this novel instrument, we expect to study electronic inhomogeneity in complex materials and explore local properties during phase transitions.

Monday, March 16, 2009 8:00AM - 11:00AM — Session A28. FIAP: Bionanotechnology 330

8:00AM A28.00001 Mesoscopic light reflection spectroscopy of weakly disordered dielectric media: Nanoscopic to mesoscopic light transport properties of a single biological cell and ultra-early detection of cancer. PRABHAKAR PRADHAN, HARIHARAN SUBRAMANIAN, DHWANIL DAMANIA, HEMANT ROY, VADIM BACMAN, Northwestern University, Evanston, IL 60208 — We have developed a mesoscopic partial wave spectroscopy (PWS) method to measure the nanoscopic light transport properties of weakly disordered dielectric mesoscopic systems such as biological cells. Using mesoscopic theory, we have statistically quantified the light reflection coefficient and its correlation due to nanoscale refractive index fluctuations within a biological cell, and the results are consistent with the prediction of mesoscopic light transport theory. Finally, using these parameters, we have characterized the nanoscale optical disorder strength within the biological cell. Results of precancerous cell studies and cancer detection by the technique will be discussed.

8:12AM A28.00002 Stick-Slip Motion of DNA in a Solid Nanopore¹. BINQUAN LUAN, GLENN MARTYNA, IBM TJ Watson Research Center — Nanopore technology is a potential solution for the low-cost and high-throughput DNA sequencing. Till now, in a typical experiment DNA driven by an electric field translocates through a nanopore too fast to be detected at a single-base resolution. The recently proposed DNA transistor (Appl. Phys. Lett. 91, 153103 (2007)) holds the promise to trap DNA inside a nanopore and translocate single-stranded DNA (ssDNA) at a single-base resolution. Using extensive all-atom molecular dynamics simulations, we modeled the process of ssDNA’s translocation through the DNA transistor when ssDNA is pulled by an optical tweezer. We found a stick-slip type of motions of DNA when both the stiffness of an optical tweezer and the pulling velocity are below critical values. This irregular motion of DNA is quantitatively characterized using the Tomlinson model. In a typical slip event, ssDNA advances one nucleotide and relaxes, while in a stick state the base of DNA can be conveniently measured. The duration of a stick state depends on the stiffness of a trapping field in the DNA transistor, the stiffness of an optical tweezer and the pulling velocity. Therefore, the controlled stick-slip motion of DNA is ideal for DNA sequencing methods using a solid nanopore.

8:24AM A28.00003 Ionic Dependence of the Conformation and Dynamics of DNA Confined in Slit-like Nanofluidic Channels. YONGQIANG REN, WALTER REISNER, DEREK STEIN, Brown University — Due to the growth in nanobiological technology for DNA manipulation and analysis there is growing interest in understanding the physics of DNA in nanoconfined environments. Using fluorescence video microscopy we study the ionic dependence of static and dynamic properties of DNA molecules confined in slit-like nanofluidic channels with varying channel height. We observe an abrupt transition from the de Gennes regime to the Odijk regime for different ion concentrations for both the radius of gyration and the relaxation time. The cross-over channel height between the regimes increases with decreasing ionic strength. By direct measurement of the distribution function for the radius of gyration we can clearly show that the DNA molecules perform 2-D self-avoiding random walks for both the de Gennes and Odijk regimes. We also investigate the possible effects of electrostatic DNA-channel wall interactions.
Development of a nanopore-based electrical device for controlling the translocation of DNA with single base resolution and mass-production methods for sub-5 nm nanopores. WALTER REISNER, Dept. of Physics, Brown University, NIELS LARSEN, ANDERS KRISTENSEN, DTU Nanotech - Dept. of Micro- and Nanotechnology, Technical University of Denmark, JONAS O. TEGENFELDT, Department of Physics, Division of Solid State Physics, Lund University, HENRIK FLYVBÆRJ, DTU Nanotech - Dept. of Micro- and Nanotechnology, Technical University of Denmark — We have developed a new DNA barcoding technique based on the partial denaturation of extended fluorescently labeled DNA molecules. We partially melt DNA extended in nanofluidic channels via a combination of local heating and added chemical denaturants. The melted molecules, imaged via a standard fluorescence videomicroscopy setup, exhibit a nonuniform fluorescence profile corresponding to a series of local dips and peaks in the intensity trace along the stretched molecule. We show that this barcode is consistent with the presence of locally melted regions and can be explained by calculations of sequence-dependent melting probability. We believe this melting mapping technology is the first optically based single molecule technique sensitive to genome wide sequence variation that does not require an additional enzymatic labeling or restriction scheme.

Translocation Studies of Single Strand-DNA Oligomer Complexes with ds-DNA Markers Using Solid-State Nanopores. VENKAT BALAGURUSAMY, PAUL WEINGER, SUNGCHEOL KIM, XINSHENG SEAN LING, Brown University — We have designed short oligomers of single strand DNA of about 130 bases long each with 12-bases long sticky ends that are complimentary to those on one end of other oligomers to form ds-DNA regions by Watson-Crick base-pairing in these regions. Such a design facilitates the formation of a chain of single strands of DNA with ds-DNA regions interspersed. In order to slow down the translocation speed of these complexes through solid-state nanopores that could enable one to identify the ds-DNA region markers in the blockage current signal during translocation, we have attached these ss-DNA complexes with a polystyrene bead on one end. We present the results of our preliminary studies that show that the signature of these ds-DNA region markers could be identified.

Magnetophoresis of Fe$_3$O$_4$ Nanorods. DAVID TAN, JITKANG LIM, CAITLIN LANNI, FREDERICK LANNI, ROBERT TILTON, SARA MAJETICH, Carnegie Mellon University — The magnetophoretic motion of a nanorod is quite different from that of a nanosphere. In large particles, motion is predicted from the balance of magnetic and viscous drag forces, but for nanoparticles random thermal forces lead to Brownian motion as well. Due to magnetic and diffusive anisotropy, a nanorod has advantages over a nanosphere for the single particle guidance and tracking, which would be important for studies within living cells. We have investigated the magnetophoretic behavior of nanorods and nanospheres both theoretically and experimentally. Peclet number analysis shows that 300 nm x 20 nm nanorods are more likely to be in the convective than diffusive regime than nanospheres of equal volume, for the same field and field gradient. Experimental studies of nanorod motion were made using Fe$_3$O$_4$ nanorods coated with poly(diallyldimethylammonium chloride) and fluorescein-S-i-sothiocyanate (FITC) tagged bovine serum albumin (BSA) and dispersed in saline solution. The motion of the nanorods was observed with and without magnetic field gradients using fluorescence microscopy. Fluorescence micrograph showed the nanorods undergo magnetophoretic motion toward the higher field gradient region with a velocity of about 28µm/sec. The controlled motion of magnetic nanorods within HeLa cancer cells has been demonstrated.

Chip-based Magnetic Resonance System for Medical Diagnosis. HAKHO LEE, TAE-JONG YOON, RALPH WEISSLEDER, Massachusetts General Hospital/ Harvard Medical School — We have developed a chip-based, diagnostic magnetic resonance (DMR) system that can perform rapid, quantitative and multi-channeled detection of biological targets. The measurement is based on the effect of molecularly targeted magnetic nanoparticles on NMR (nuclear magnetic resonance) signals. With magnetic nanoparticles bound to their intended detection targets, the overall spin-spin relaxation time of bulk samples will be significantly shortened, as the particles efficiently dephase spins of surrounding water protons. Because the signal detection relies on NMR, the interference from media becomes negligible, making it possible to perform measurements in native biological samples (e.g., blood, sputum and urine). As proof of concept, we have developed a first DMR prototype by integrating microcups, microfluidic channels and a permanent magnet. The microcups, used as an NMR probe, are arranged in an array format for multiplexed, parallel detection. The microfluidic channels provide on-chip mixing between magnetic nanoparticles and biological samples and confine the mixture to microcups for high filling factor. Here, we demonstrate clinical utility of the DMR system by measuring proteins at exquisite sensitivities (~1 pM), identifying the disease condition of human sera, and profiling cancer cells according to their cell-surface markers.

Hyperpolarized Long-T$_1$ Silicon Nanoparticles for Magnetic Resonance Imaging. MAJA CASSIDY, SEAS, Harvard University, MA, JACOB APTEKAR, ALEXANDER JOHNSON, ROBERT BARTON, MENYOUNG LEE, ALEXANDER OGIER, CHINH VO, Department of Physics, Harvard University, MA, CHANDRASEKHAR RAMANATHAN, DAVID CORY, Department of Nuclear Science and Engineering, MIT, MA, ALISON HILL, ROSS MAIR, MATTHEW ROSEN, RONALD WALSWORTH, Harvard-Smithsonian CfA, MA, CHARLES MARCUS, Department of Physics, Harvard University, MA — Nanoparticles are currently being widely investigated as targetable contrast agents for magnetic resonance imaging (MRI). Silicon is a promising material system for use as a magnetic resonance imaging agent due to its long bulk (T$_1$) times and receptivity to hyperpolarization. We present studies of the nuclear relaxation (T$_1$) times of silicon nanoparticles as a function of particle size, dopant concentration and fabrication method. The T$_1$ times of these particles are found to be remarkably long (depending on size and dopant concentration), allowing for them to be transported and administered on practical timescale. In addition, we discuss the particles' receptivity to hyperpolarization, via low temperature microwave induced dynamic nuclear polarization.

9:48AM A28.00010 Magnetic detection of biotin-streptavidin binding using InAs quantum well \( \mu \)-Hall sensor, KALED ALEDEALAT, K. CHEN, Department of Physics and MARTECH, Florida State University; G. MIHAJLOVIC, Materials Science Division, Argonne National Laboratory, P. XIONG, Department of Physics, MARTECH and INSI, Florida State University, S. VON MOLNÁR, Department of Physics, MARTECH and INSI, Florida State University, M. FIELD, G.J. SULLIVAN, Teledyne Scientific Company LLC — Magnetic sensors are a key component in any high-sensitivity, rapid-response, and portable platform for magnetic biosensing. InAs quantum well micro-Hall sensors have shown high potential for such a role due to their low noise level and capability to detect single micron-sized or smaller superparamagnetic beads suitable for biosensing. Here we present successful selective biotinylation of InAs micro-Hall sensors and directed self-assembly of 350 nm streptavidin-coated superparamagnetic beads via the biotin-streptavidin interaction. Two Hall crosses with three and two beads produced detection signals with S/N ratio of 21.3 dB and 18.4 dB respectively. In addition, our progress for \( \textit{in situ} \) detection of micron-sized magnetic beads using microfluidic channel will be presented. 1 G. Mihajlovic et al., APL 87, 112502 (2005) This work was supported by NIH NIGMS GM079592.

10:00AM A28.00011 Single Nanometric Memory Unit Based On a Protein-Nanoparticle Hybrid, IZHAR MEDALYS, Physical Chemistry department, The Hebrew University, Jerusalem, 91904, Israel, ARNON HEYMAN, ODED SHOSEYOV, The Faculty of Agriculture, The Hebrew University, Rehovot 76100, Israel, DANNY PORATH, Physical Chemistry department, The Hebrew University, Jerusalem, 91904, Israel — Proteins as an isolating template and nanoparticle (NP) as an electric storage component can form a single addressable unit cell isolated from the conductive surface and adjacent NPs. This setup gives rise to a wide range of nanoelectronic applications. Here we demonstrate, by Conductive AFM, a single nanometric memory unit using individual protein-NP hybrids. SP1 is a boiling-stable ring-shaped protein, 11 nm in diameter. Mutants of SP1 were synthesized allowing its selective attachment to gold surface and the formation of 2D arrays using methods such as phospholipids trough and Langmuir Blodgett. The SP1 inner pore was connected to Si NP forming a chargeable entity embedded in an isolating unit over a conductive surface. Each NP holds three charging states: natural, positive and negative. The charging life times are 10 min in ambient and days in vacuum. Using this setup, and the relative long charging time, we were able to apply a read and write operations on individual 5nm Si NP embedded in a stable protein.

10:12AM A28.00012 Characterization of the Uptake of Quantum Dots by Algae, PRIYANKA BHATTACHARYA, SIJIE LIN, Department of Physics and Astronomy, Clemson University, XIAOQIAN SUN, Department of Mathematical Sciences, Clemson University, DAVID BRUNE, Department of Agricultural and Biological Engineering, Clemson University, PU-CHUN KE, Department of Physics and Astronomy, Clemson University — The exposure of living systems to nanoparticles is inevitable due to a dramatic increase in their release into the environment, the most likely pathways being through inhalation, ingestion and skin uptake. The extremely small size of the nanoparticles may facilitate their tissue and cellular uptake by plants and animals, resulting in either positive (drug delivery, antioxidation) or negative (toxicity, cellular dysfunction) effects. Here we report the effects of quantum dots uptake by algae, the single-celled plant species and major food sources for aquatic organisms. In our studies, the presence of quantum dots in algal cells was detected using fluorescence microscopy and electron microscopy. Using spectrophotometry we found a supralinear increase of the uptake with the concentration of quantum dots, with a saturation of the uptake occurring beyond a concentration of 15 mg/mL. Using a bicarbonate indicator we further evaluated the effects of quantum dots uptake on algal photosynthesis and respiration. Such study facilitates our understanding of the environmental impact of nanomaterials.

10:24AM A28.00013 Thermochemical nanolithography of multi-functional templates for selective assembly of bioactive proteins, DEBIN WANG, VAMSI KODALI, WILLIAM UNDERWOOD, JONAS JARVHOLM, TAKASHI OKADA, SIMON JONES, MARIACRISTINA RUMI, ZHENTING DAI, WILLIAM KING, SETH MARDER, JENNIFER CURTIS, ELISA RIEGO — Atomic force microscopy based techniques have been successful in generating protein nano-arrays on various substrates. However, several challenges still exist in terms of resolution, writing speed, cost, substrate choice, protein bioactivity, multi-component patterning, and surface passivation. Recently, we have developed the use of thermochemical nanolithography combined with post covalent functionalization and molecular recognition on a polymer surface of a single chip to produce multiplexed nanopatterns at speeds of mm/s. These patterns can then be functionalized under native conditions to create tailored nano-assemblies of two different species of proteins coexisting on the same surface. The proteins attach selectively and strongly to the nanopatterns via covalent and/or specific interactions, while retaining their ability to interact specifically with other proteins in buffered solution. At present, this method has produced nanopatterns of bio-active proteins with features as small as 40 nm on polymer films. This technique opens up new possibilities in nanoscale manipulation of biological macromolecules as well as many molecular biophysics studies such as inter-protein interactions.

10:36AM A28.00014 Directional Growth of Polymeric Nanowires, PREM THAPA, BRETT FLANDERS — This work establishes an innovative electrochemical approach to the template free growth of conducting polypyrrole and polystyrene wires. These polymeric wires exhibit a knobby structure, but persistent growth in a given direction up to 30 \( \mu \)m in length. A long-range component of the applied voltage signal defines the growth-path. Moreover, the presence of this component enables the growth of amorphous nanowires with wire-like geometries. Such wires are employed in a non-invasive methodology for attaining strong mechanical attachments to live cells. This capability is of potential use in the electro-mechanical probing of cell physiological processes.

10:48AM A28.00015 A novel nanoarchitecture with optical, solar, medical and biochemical utility, M.I. NAUGHTON, K. KEMP, Z.F. REN, Boston College and Solasta Inc. — We discuss a nanoscale platform offering widespread utility in nanophotonics, photovoltaics, visual prosthetics, and biological and chemical sensing. As a subwavelength wave-guide architecture, these nanostructures can be used in array form for high efficiency solar cells, as well as in a wide range of nanoscale manipulations of light without deleterious plasmonic effects. They are also being developed as a high-electrode-density (10^9/cm^2) retinal implant. Finally, a modification of the basic structure enables the fabrication of a highly sensitive “nanocavity” biochemical sensor. We will report on aspects of each application. We also thank the following collaborators: N. Argenti, D. Cai, T.C. Chiles, P. Dhakal, Y. Gao, T. Kirkpatrick, Y.C. Lan, G. McMahon, J.J. Oh, B. Rizal, J. Rybczynski.

Monday, March 16, 2009 8:00AM - 11:00AM —
Session A29 GMAG: Spin Glasses and Disordered Magnetic Materials 333
8:00AM A29.00001 Probing the relation between structural glasses and 3-spin glass phases using one-dimensional models . DEREK LARSON, Physics Dept., University of California Santa Cruz, Santa Cruz CA 95064; HELMUT G. KATZGRABER, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland; Department of Physics, Texas A&M University, College Station, TX 77843-4242; A.P. YOUNG, Physics Dept., University of California Santa Cruz, Santa Cruz CA 95064 — Motivated by a proposed connection between 3-spin glass phases and structural glasses, we have performed Monte Carlo simulations on a one-dimensional long-range Ising glass with power-law interactions involving 3-spins. Varying the exponent of the power-law interactions is analogous to changing the space dimension of a corresponding short-range 3-spin model. We present results of a finite-size scaling analysis of the two-point correlation length, and compare our results with the prediction of Moore and Yeo that the three-spin model is in the same universality class as an Ising spin glass in a magnetic field.

8:12AM A29.00002 Study of the de Almeida-Thouless line using power-law diluted one-dimensional Ising spin glasses . HELMUT G. KATZGRABER, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland; Department of Physics, Texas A&M University, College Station, TX 77843-4242, USA; DEREK A. LARSON, A.P. YOUNG, Department of Physics, University of California, Santa Cruz, CA 95064, USA — We test the existence of a spin-glass state in an externally-applied (random) magnetic field via Monte Carlo simulations of a power-law diluted one-dimensional Ising spin glass. The model has the advantage over conventional short-range models in that by tuning the exponent of the power-law interactions we are able to scan the full range of possible behaviors from the infinite-range to the non-mean-field regime. Furthermore, due to the average fixed connectivity very large linear system sizes can be studied. An analysis of the two-point correlation length shows that the system in the non-mean-field universality class does not order in a field. This suggests that there is no de Almeida-Thouless line for short-range Ising spin glasses below the upper critical dimension.

8:24AM A29.00003 Reentrant and Forward Phase Diagrams of the Anisotropic Three-Dimensional Ising Spin Glass . CAN GÜVEN, A. NIHAT BERKER, Koç University, Michael Hinczewski, Technical University of Munich, Hidetoshi Nishimori, Tokyo Institute of Technology — The spatially uniaxially anisotropic d=3 Ising spin glass is solved exactly on a hierarchical lattice.[1] Five different ordered phases, namely ferromagnetic, columnar, layered, antiferromagnetic, and spin-glass phases, are found in the global phase diagram. The spin-glass phase is more extensive when randomness is introduced within the planes than when it is introduced in lines along one direction. Phase diagram cross-sections, with no Nishimori symmetry, with Nishimori symmetry lines, or entirely imbedded into Nishimori symmetry, are studied. The boundary between the ferromagnetic and spin-glass phases can be either reentrant or forward, that is either receding from or penetrating into the spin-glass phase, as temperature is lowered. However, this boundary is always reentrant when the multicritical point terminating it is on the Nishimori symmetry line. [1] C. Güven, A.N. Berker, M. Hinczewski, and H. Nishimori, Phys. Rev. E 77, 061110 (2008).

8:36AM A29.00004 The Blume-Emery-Griffiths Spin Glass and Inverted Tricritical Points . V. ONGUÖZÇELIK, A. NIHAT BERKER, Koç University — The Blume-Emery-Griffiths spin glass is studied by renormalization-group theory in d=3.[1] The boundary between the ferromagnetic and paramagnetic phases has first-order and two types of second-order segments. This topology includes an inverted tricritical point, first-order transitions replacing second-order transitions as temperature is lowered. The phase diagrams show disconnected spin-glass regions, spin-glass and paramagnetic reentrances, and complete reentrance, where the spin-glass phase replaces the ferromagnet as temperature is lowered for all chemical potentials. [1] V.O. Özçelik and A.N. Berker, Phys. Rev. E 78, 031104 (2008).

8:48AM A29.00005 Quenched-Vacancy Induced Spin-Glass Order . GÜL GÜLPİNAR, Dokuz Eylül University, A. NIHAT BERKER, Koç University — The ferromagnetic phase of an Ising model in d=3, with any amount of quenched antiferromagnetic bond randomness, is shown to undergo a transition to a spin-glass phase under sufficient quenched bond dilution.[1] This general result, demonstrated here with the numerically exact renormalization-group solution of a d=3 hierarchical lattice, is expected to hold true generally, for the cubic lattice and for quenched site dilution. Conversely, in the ferromagnetic-spin-glass-antiferromagnetic phase diagram, the spin-glass phase expands under quenched dilution at the expense of the ferromagnetic and antiferromagnetic phases. In the ferro-spin-glass phase transition induced by quenched dilution reentrance is seen, as previously found for the ferro-spin-glass phase transition induced by increasing the antiferromagnetic bond concentration. [1] G. Gülpınar and A.N. Berker, arXiv:0811.0025v1 [cond-mat.dis-nn] (2008).

9:00AM A29.00006 Nonequilibrium spin glass dynamics with the Janus computer . DAVID VILLANES, Universidad Complutense de Madrid, F. BELLETTI, A. CRUZ, L.A. FERNANDEZ, A. GORDILLO-GUERRERO, M. GUIDETTI, A. MAIORANO, F. MANTOVANI, E. MARINARI, V. MARTIN-MAYOR, J. MONFORTE, A. MUÑOZ SUDUPE, D. NAVARRO, G. PARISI, S. PEREZ-GAVIRO, J.J. RUIZ-LORENZO, S.F. SCHIFANO, D. SCIRETTI, A. TARANCON, R. TRIPICCIONE, JANUS COLLABORATION — The out of equilibrium evolution of the Edwards-Anderson spin glass is followed for a tenth of a second, effectively halving the (logarithmic) temporal gap between previous simulations and experiments. In fact, we have been able to make safe predictions about the behavior at experimental times, using mild extrapolations. This work has been made possible by Janus, a special purpose computer designed by our collaboration. We have thoroughly studied the spin glass correlation functions and the growth of the coherence length for $L = \infty$ lattices in 3D, using $L = 24, 40$ lattices to check for finite size effects. We present clear evidence for a replica correlator. Our main conclusion is that these spin glasses follow non-coarsening dynamics, at least up to the experimentally relevant time scales.

9:12AM A29.00007 Chaotic Spin Correlations in Frustrated Ising Hierarchical Lattices . NESE ARAL, A. NIHAT BERKER, Koç University — Spin-correlations are calculated in frustrated hierarchical Ising models that exhibit chaotic renormalization-group behavior. [1] The spin-correlations, as a function of distance, behave chaotically. The far correlations, but not the near correlations, are sensitive to small changes in temperature or frustration, with temperature changes having a larger effect. On the other hand, the calculated free energy, internal energy, and entropy are smooth functions of temperature. The recursion-matrix calculation of thermodynamic densities in a chaotic band is demonstrated. The spectrum of Lyapunov exponents is calculated as a function of frustration. [1] N. Aral and A.N. Berker, arXiv:0810.4586v1 [cond-mat.dis-nn] (2008).

9:24AM A29.00008 Tunable domain pinning in a Random-Field Ising Ferromagnet . D. M. SILEVITCH, James Franck Institute/University of Chicago, G. AEPPLI, London Centre for Nanotechnology and Department of Physics and Astronomy, UCL, London, T.F. ROSENBAUM, James Franck Institute/University of Chicago — The diluted magnetic salt LiHo$_2$F$_4$, was shown recently [Nature 448 567-570 (2007)] to be the first ferromagnetic realization of the random-field Ising model, where the strength of the random fields can be tuned by an external magnetic field. These random-field effects can be used to continually and reversely vary the pinning potential of the magnetic domains, allowing us to tune the hysteretic behavior. Magnetization measurements reveal enhanced pinning in the random-field regime as well as a temperature-dependent crossover into a regime dominated by quantum fluctuations.
9:36 AM A29.00009 A strongly disordered spin glass and minimum spanning trees

THOMAS JACKSON, NICHOLAS READ, Yale University — We investigate the ground state structure of a strongly disordered spin glass model proposed by Newman and Stein (NS). In the strong disorder limit, frustration is negligible and the problem of identifying ground states is equivalent to the minimum spanning tree (MST) problem in combinatorial optimization: given an edge-weighted graph, the MST is the subset of edges that connects all vertices, has no cycles, and minimizes the total edge weight. Here the weights are quenched random variables, and we use a relation between Kruskal's greedy algorithm for finding the MST and percolation. We solve this random MST on the Bethe lattice with appropriate boundary conditions, which defines a mean-field theory valid above \( d_c = 6 \) (NS proposed \( d_c = 5 \)). Above \( d_c \), NS showed that the spin glass model has infinitely many ground states, but only a single pair below \( d_c \). For \( d < d_c \), we develop a continuum field theory for the fractal dimension \( D_p \) of paths on the MST on critical percolation clusters; to first order in the epsilon expansion, we obtain \( D_p \approx 2 - (6 - d)/7 \) for \( d < 6 \) (\( D_p = 2 \) for \( d > 6 \)).

9:48 AM A29.00010 ABSTRACT WITHDRAWN

10:00 AM A29.00011 Overlap as a Measure of Spin-Glass Memory and a Probe of Free Energy Landscape

WEN LUO1, University of Nebraska-Lincoln, MICHAEL MIHALCO, THOMAS E. STONE, SUSAN R. MCKAY, University of Maine — The degree of history dependence and the structure of the free energy landscape of the spin glass are both indicators of the complexity of this ordered phase. Using the Ising antiferromagnet on a triangular lattice, dilated with quenched random ferromagnetic bonds, we probe these indicators through repeated cycling between two temperatures. We consider cases in which both temperatures are within the spin-glass phase, and systematically vary the temperature difference between initial and final states. These results are compared with the same cycling pattern with one temperature inside and the other outside of the spin-glass phase. The overlap of the ground state for the former is non-zero even when the system remains within the spin-glass phase during cycling. A plot of the overlaps of the low temperature states and their differences in internal energy shows no simple relationship between overlap and internal energy. States with almost identical internal energies often have very little overlap.

1Supported by the University of Maine’s Research Experience for Undergraduates, funded by NSF/DoD Grant No. 0754951.

10:12 AM A29.00012 Quantum Effects for Interaction of Electron with coupled magnetic local spin chains

Fatih Dogan, University of Alberta, Edmonton, AB, Canada, Lucia Covacci, University of British Columbia, Wonkee Kim, University of Houston, Frank Marsiglio, University of Alberta — In this talk, we will look at time dependent interaction of an electron with ferromagnetic chain. We will show that ferromagnetic interactions between magnetic spins cause the electron interacting with them to change its energy and depending on the strength of interactions form a bound state. These effects are visible through the resulting state of the electron. Experimental suggestions will be given to observe this quantum behavior.

10:24 AM A29.00013 Avalanche Spatial Structure: Viewing Crackling Noise through Windows

Yan-Jun Chen, Stefanos Papanikolaou, James P. Sethna, LASSP, Cornell University, Gianfranco Durin, INRIM and ISI, Fondazione, Torino, Italy, Stefano Zapperi, INFN-CNR center, Modena, and ISI, Torino, Italy — In imaging experiments of Barkhausen noise in thin films, magnetic avalanches at the boundaries present challenges to analysis. Large avalanches are removed from the distribution, and the portion inside the viewing window may sometimes be treated as smaller avalanches. We analyze the scaling behavior of different categories of avalanches in artificially-windowed simulations of Barkhausen noise to examine the effect of window size on scaling relations. In passing, we discuss the average spatial shapes of avalanches, multivariable scaling functions, and the use of nonlinear-least-squares methods for exploring and reporting universal scaling functions.

10:36 AM A29.00014 Avalanche Average Shapes: Mean-field temporal average avalanche shape

Stefanos Papanikolaou, LASSP, Cornell Univ., Christopher R. Myers, Computational Biology Service Unit, Cornell Univ., Francesca Colaiori, CNR-INFN, Dipartimento di Fisica, Universita "La Sapienza", Roma, Karen E. Danielis, North Carolina State U., Gianfranco Durin, INRIM and ISI Foundation, Torino, Italy, Stefano Zapperi, INFN-CNR center, Modena and ISI in Torino, Italy, James P. Sethna, LASSP, Cornell Univ. — The average temporal shape of avalanches has been a fruitful application of universality and critical scaling, with experimental and theoretical investigations particularly in the field of magnetic Barkhausen noise. The mean-field shapes of these avalanches have been thought to come in two forms: inverted parabolas for the infinite-range model and one lobe of a sinusoid for the single-degree of freedom ABBM model. We show that the infinite-range model can be mapped onto the earlier ABBM model, and that the average shape for both mean field theories is an inverted parabola, seemingly resolving the ambiguity. However, we also propose a new mean-field model including the effects of local saddle-node bifurcations on the dynamics, and analyze both its predictions for dynamical exponents and temporal average shapes. We compare with experimental results on sheared granular materials.

10:48 AM A29.00015 Permutation Symmetric Critical Phases in Disordered Non-Abelian Anyonic Chains

Lukasz Fidkowski, Gil Refael, Hans-Hsuain Lin, Caltech, Paraj Titum, Indian Institute of Technology, Kanpur, India — Topological phases supporting non-abelian anyonic excitations have been proposed as candidates for topological quantum computation. We study disordered non-abelian anyonic chains below low-temperature quantum states provide a quantitative measure of the system’s memory, and is non-zero even when the system remains within the spin-glass phase during cycling. A plot of the overlaps of the low temperature states and their differences in internal energy shows no simple relationship between overlap and internal energy. States with almost identical internal energies often have very little overlap.

Monday, March 16, 2009 8:00 AM - 11:00 AM
Session A30 DMP GAM: Focus Session: Vanadates, Iridates and Other Oxides 334

8:00 AM A30.00001 Electronic band structure of metallic phase \( \text{V}_2\text{O}_3 \)

O. KRUPIN, J. DENLINGER, Lawrence Berkeley National Lab, B.J. KIM, RAVI S. SINGH, J.W. ALLEN, University of Michigan — \( \text{V}_2\text{O}_3 \) has an archetypal strongly correlated paramagnetic metallic (PM) phase which becomes insulating with alloying or decreasing temperature. Recent progress has been made experimentally to measure the true bulk V 3d density of states of PM phase \( \text{V}_2\text{O}_3 \) using high-energy angle-integrated photoemission, and theoretically to quantitatively describe the observed prominent quasiparticle peak near \( E_F \) using LDA+DMFT. Theoretical predictions of the \( k \)-resolved electronic band structure of \( \text{V}_2\text{O}_3 \) have been made, but experimental measurement has proven to be very challenging and elusive. We present intermediate-energy soft x-ray angle-resolved photoemission measurements of the PM-phase \( \text{V}_2\text{O}_3 \) (0001) cleaved surface that reveal for the first time distinct \( k \)-resolved band dispersions within the coherent quasiparticle peak and a corresponding three-fold symmetric Fermi surface topology. The agreement of these measurements to theoretical calculations will be discussed.

1Supported by the U.S. DOE at the Advanced Light Source (DE-AC02-05CH11231) and at the University of Michigan (DE-FG02-07ER46379).
8:12AM A30.00002 Concurrent structural and magnetic phase transition in nanopowder V$_2$O$_3$. J. P. CARLO, Y. J. UEMURA, Department of Physics, Columbia University, New York, NY; V. BLAQOJEVIC, M. L. STEIGERWALD, L. E. BRUS, Department of Chemistry, Columbia University, New York, NY; S. L. BILLINGE, Department of Applied Physics and Applied Mathematics, Columbia University, New York, NY; W. ZHOU, Department of Physics, Michigan State University, Lansing, MI; G. M. LUKE, A. A. ACZEL, G. J. MACDOUGALL, Department of Physics and Astronomy, McMaster University, Hamilton, ON; P. W. STEPHENS, Department of Physics, SUNY at Stony Brook, Stony Brook, NY — V$_2$O$_3$, which has been the subject of investigations for well over 30 years, is a classic example of a Mott-Hubbard transition system. This first-order metal-insulator transition, near 160K, is accompanied by a rhombohedral-monoclinic structural as well as a paramagnetic-antiferromagnetic magnetic transition. We report on structural synchrotron x-ray characterization of V$_2$O$_3$ nanopowder (dia $\approx$ 10-50 nm) at NSLS, and magnetic characterization via muon spin relaxation at TRIUMF. We find that, just as in bulk V$_2$O$_3$, the structural and magnetic transitions are concurrent, and that in contrast to the abrupt and hysteretic transition witnessed in the bulk, in the nanopowder sample the transition occurs with phase separation over a broad temperature range.

8:24AM A30.00003 Metal-insulator transition in AV$_{10}$O$_{15}$ (A=Ba, Sr). T. KATSUFAJI, T. SUZUKI, T. KAJITA, Dept. Phys., Waseda Univ. — In AV$_{10}$O$_{15}$ (A=Ba, Sr), the V ions take a mixed-valence state, V$^{2.8+}$ (3d$^{2.2}$), and form a modified triangular lattice, in which V triangles are periodically missing from a normal triangular lattice. It is known that BaV$_{10}$O$_{15}$ undergoes a structural phase transition at around 120 K. We have succeeded in growing large single crystals of AV$_{10}$O$_{15}$ (A=Ba, Sr) by a floating-zone method. We found a large jump of electrical resistivity by $\approx 10^2$ times at the structural transition temperature (123 K) of BaV$_{10}$O$_{15}$, which can be regarded as a metal-insulator transition presumably dominated by a charge/orbital ordering of V. We also found an antiferromagnetic ordering at 43 K in the same compound. On the other hand, SrV$_{10}$O$_{15}$ did not show any structural anomaly down to the lowest temperature, and a spin-glass behavior was observed. These results indicate a strong correlation between the structural anomaly (charge/orbital ordering) and the magnetism in this series of compounds. We also measured the optical reflectivity of BaV$_{10}$O$_{15}$ and found the opening of a charge gap in the optical conductivity spectrum at low temperatures.

8:36AM A30.00004 Charge dynamics in thermally and doping induced insulator-metal transitions of (Ti$_{1-x}$V$_x$)$_2$O$_3$. MASAKI UCHIDA, JUN FUJIJKA, YOSHINORI ONOSE$^1$, YOSHINORI TOKURA$^2$, Department of Applied Physics, University of Tokyo — Charge dynamics of (Ti$_{1-x}$V$_x$)$_2$O$_3$ with $x = 0$–0.06 has been investigated by measurements of charge transport and optical conductivity spectra in a wide temperature range of 2–600 K with the focus on the thermally and doping induced insulator-metal transitions (IMTs). The optical conductivity peaks for the interband transitions in the 3d$^2$ manifold are observed in the both insulating and metallic states, while their large variation (by $\approx 0.4$ eV) with change of temperature and doping level scales with that of the Ti-Ti dimer bond length, indicating the weakened singlet bond in the course of IMTs. The thermally and V-doping induced IMTs are driven with the increase in carrier density by band-crossing and hole-doping, respectively, in contrast to the canonical IMT of correlated oxides accompanied by the whole collapse of the Mott gap.

8:48AM A30.00005 Intersite correlations and the metal insulator in cluster dynamical mean field theory: cluster size, interaction strength, and the location of the transition line$^1$, C. LIN, A. MILLIS, Columbia University — To gain insight into the physics of the metal insulator transition and the effectiveness of cluster dynamical mean field theory we have used one, two and four site dynamical mean field theory (both CDMFT and DCA) to solve a model of electrons coupled to a classical phonon field. A partial density of states is defined encoding a generalized nesting property of the band structure; variations in this density of states account for differences between dynamical cluster approximation and cellular-DMFT implementation of cluster DMFT, and for differences in behavior between single band (cuprate-like) and multiband (manganite-like) models. The cluster size dependence of the metal to polaronic insulator phase boundary is determined along with electron spectral functions and cluster correlation functions. Over most of the interaction strength regime the single-site and multi-site approximations are found to yield similar results. Important cluster size effects occur only in the metal insulator transition region, where short-ranged correlations are found to significantly reduce the critical interaction strength required to drive a metal polaron insulator transition. In the cluster approximations the physics of the metal-insulator transition is shown to be Slater-like (driven by band filling). The minimal cluster size required to capture the metal-polaron insulator transition is shown to depend sensitively on the carrier concentration. Implications for the theoretical treatment of doped manganites are discussed.

$^1$DOE-ER 46169 and Columbia MRSEC.

9:00AM A30.00006 Study of phase separated manganites by DC transport and infrared spectroscopy. A. ZIMMERS, T. WOLF, J. LESUEUR, R.P.S.M. LOBO, Laboratoire Photons Et Matiere, ESPCI, 10 rue Vauquelin, 75231 Paris Cedex 05, France; A. KUSHWAHA, R.C. BUDHANI, Department of Physics, Indian Institute of Technology Kanpur, Kanpur 208016, India — We present confined geometry measurements of manganites La$_{0.325}$Pr$_{0.1}$Ca$_{0.375}$MnO$_3$ (LPCMO) and La$_{2/3}$Sr$_{1/3}$MnO$_3$ (LSMO). As reported previously, due to electronic phase separation, LPCMO microwires show a step-like metal-insulator transition as temperature is lowered and as magnetic field is swept. We will show how this feature evolves as a function of the width and shape of the microwires. On the contrary, LSMO microwires are found to have a smooth transition in all wire sizes under a structural transition temperature (123 K) of LSMO, which has been investigated by measurements of charge transport and optical conductivity of the insulating and metallic states, while their large variation (by $\approx 0.4$ eV) with change of temperature and doping level scales with that of the Ti-Ti dimer bond length, indicating the weakened singlet bond in the course of IMTs. The thermally and V-doping induced IMTs are driven with the increase in carrier density by band-crossing and hole-doping, respectively, in contrast to the canonical IMT of correlated oxides accompanied by the whole collapse of the Mott gap.

9:12AM A30.00007 Spectral Function of Manganese Systems. JUAN SALAFRANCA, ELBIO DAGOTTO, Dept. of Physics and Astronomy, University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory — Using a double exchange model with Jahn Teller distortions, we calculate the one particle spectral function of manganese systems. The relative contribution of the different interactions is established by means of Monte Carlo and self consistent mean field calculations. In particular, we examine the effects of electron-electron and electron-phonon couplings. We discuss the relevance of our results in relation to recent Photoemission experiments on layered manganites [1], where similarities of manganites spectra with that of cuprates was observed.

9:24AM A30.00008 Anomalous nuclear relaxation in the ferromagnetic phase of the bilayered manganese La$_2$Sr$_6$Mn$_2$O$_9$... MICHAEL HOCH, PHILIP KUHNS, WILLIAM MOULTON, ARNEIL REYES, JUN LU, National High Magnetic Field Laboratory, 1800 E. Paul Dirac Dr., Tallahassee, FL 32310, JOHN MITCHELL, Argonne National Laboratory, Argonne, IL 60439 — In contrast to ferromagnetic (FM) 3D manganites, Mn NMR spectra obtained for the FM phase of the colossal magnetoresistance bilayer manganese La$_2$Sr$_6$Mn$_2$O$_9$ show a broad distribution of hyperfine fields implying a large distribution of local environments at Mn sites. The hyperfine distribution may be linked to orbital ordering effects. Mn spin – lattice relaxation rates have a surprisingly weak dependence both on temperature and applied magnetic field. Significant departures of the relaxation rate from Korringa temperature dependence below 20 K provide evidence for non-Fermi liquid behavior in this quasi-2D metal. At temperatures approaching $T_c$ from below, further anomalous behavior is found consistent with spin polaron formation in the range where colossal magnetoresistance starts to appear.

9:36AM A30.00009 Anomalous metallic state: Decisive effect of dilute impurity doping on ferromagnetic BaIrO$_3$ single crystals1, O.B. KORNETA, S. CHIKARA, T.F. QI, S. PARKIN, G. CAO, University of Kentucky, W.H. SONG, Institute of Solid State Physics, Hefei 230031, P.R. China — BaIrO$_3$ is a quasi one-dimensional system, where a CDW and a ferromagnetic state with $T_c$=183K coexist. The ground state of the system is critically linked to the lattice and orbital degrees of freedom due to extended 5d-orbitals. The central findings of this study are: (1) An occurrence of a 2D-metallic state with a linear temperature dependence of resistivity at low temperatures in slightly oxygen-deficient samples; (2) Unusual temperature dependence of resistivity above the Curie temperature in the rare-earth doped BaIrO$_3$; (3) High sensitivity of the resistivity to applied pressure (< 12 Kbar), which results in changes in resistivity by a few orders of magnitude in these doped samples. The results of the resistivity, heat capacity, magnetization, thermoelectric power and structural measurements as a function of temperature, magnetic field, and pressure will be presented and discussed.

9:48AM A30.00010 Non-Fermi-liquid behavior in nearly ferromagnetic SrIrO$_3$ single crystals1, T.F. QI, S. CHIKARA, O.B. KORNETA, S. PARKIN, L.E. DE LONG, G. CAO, University of Kentucky, P. SCHLOTTMANN, Florida State University — We report magnetic, electric, transport, and calorimetric properties of single-crystal SrIrO$_3$ as a function of temperature $T$ and applied magnetic field $H$. We find that SrIrO$_3$ is a non-Fermi-liquid near a ferromagnetic instability, as characterized by the following properties: (1) small saturation moment and no evidence for long-range order down to 1.7 K, (2) strongly enhanced magnetic susceptibility that diverges as $T^3$ at low temperatures with $1/2 < \gamma < 1$, depending on the applied field, (3) heat capacity $C(T,H) \sim T^3/\ln T$ that is readily enhanced in low applied fields, and (4) $T^{1/2}$ dependence of electrical resistivity over the range 1.7 K $< T < 120$ K. The data imply SrIrO$_3$ is a rare example of a stoichiometric oxide compound that exhibits non-Fermi-liquid behavior near a quantum critical point ($T=0$ and $\mu_0H=0.23$ T). The results will be presented and discussed along with those of a similar system CaRuO$_3$.

10:00AM A30.00011 Magnetic Soft Mode Behavior of the Field-Dependent Specific Heat of SrIrO$_3$. LANCE DE LONG, DAHENG HE, VINAYAK BHAT, GANG CAO, University of Kentucky — Previous work indicates SrIrO$_3$ is a strongly exchange-enhanced paramagnet (Wilson ratio = 75) exhibiting non-Fermi liquid (NFL) behavior at low magnetic fields, and a cross-over to weak ferromagnetism ($0.025 \mu_0$T/ir at $\mu_0H = 7.0$ T and $T = 1.7$ K) at applied fields $\mu_0H$ $\geq$ 3 T and temperatures $T$ $<$ 4 K. Measurements of the specific heat performed in constant field for 1.8 $<$ $T$ $<$ 4K have been used to extract the field dependence $C_p/(H,T)$ (constant $T_o$), which exhibits an Schottky-like peak as a function field in the range 1.0 $<$ $\mu_0H < 1.5$ T at increasing temperatures 1.8 $<$ $T_o$ $<$ 3.9 K, respectively. Fits of $C_p/(H,T_o)$ imply a nonmagnetic ground state is separated from magnetic excited states by an energy splitting $\Delta (H,T)/K_B$ $=$ $T^*$ that decreases from 7.5 to 2 K as $\mu_0H$ increases from 0 to 8 T. The Schotky peak field increases as $\mu_0H^2$ = 0.94 T + (0.03 T/K) $T^2$. We discuss how a semi-classical two-level model reproduces the NFL-weak ferromagnet cross-over with applied field.

10:12AM A30.00012 Temperature-dependent electronic structure evolution of spin-orbit coupling induced Mott insulator Sr$_2$IrO$_4$. S. J. MOON, W. S. CHOI, T. W. NOH, ReCOE and FPDR, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, H. JIN, CSMR, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, Y. S. LEE, Department of Physics, Soongsil University, Seoul 156-743, Korea, G. CAO, Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506, USA — Recently, the effect of spin-orbit coupling in 5d transition metal oxides attracted lots of attention. It was found that the cooperative interaction of spin-orbit coupling and electron correlation could realize unique Mott insulating ground state of Sr$_2$IrO$_4$. We investigated temperature-dependent optical conductivity spectra of 5d Mott insulator Sr$_2$IrO$_4$. We observed drastic changes of the optical conductivity spectra. As temperature increases, the Mott gap was significantly reduced and spectral weight redistribution between the Ir $t_{2g}$ bands occurred. The electronic structure changes accompanied the change of optical phonon modes. These experimental observations could be understood in terms of the effects of spin-orbit and electron-lattice coupling.

10:24AM A30.00013 LS separation of J=1/2 Mott insulator observed by magnetic X-ray diffraction, SHIGEKI FUJIIYAMA, RIKEN, B.J. KIM, Univ, Tokyo, H. OHSUMI, T. KOMESU, SPRing-8, RIKEN, D. HIRAI, K. OHASHI, Univ, Tokyo, S. SAKAI, SPRing-8, RIKEN, T. ARIMA, Tohoku Univ., H. TAKAGI, Univ, Tokyo — Spin-orbit coupling is a key concept to realize spin Hall effect in insulating materials. A perovskite iridate Sr$_3$Ir$_2$O$_7$ shows a broad distribution of hyperfine fields implying a large distribution of local environments at Mn sites. The hyperfine distribution may be linked to orbital ordering effects. Mn spin – lattice relaxation rates have a surprisingly weak dependence both on temperature and applied magnetic field. Significant departures of the relaxation rate from Korringa temperature dependence below 20 K provide evidence for non-Fermi liquid behavior in this quasi-2D metal. At temperatures approaching $T_c$ from below, further anomalous behavior is found consistent with spin polaron formation in the range where colossal magnetoresistance starts to appear.

10:36AM A30.00014 Magnetization reversal in Sr$_3$Ir$_2$O$_7$: DM interactions vs. magnetic single-ion anisotropy. HOSUB JIN, JAEJUN YU, Department of Physics and Astronomy, Seoul National University — Recently the unusual insulating ground state of Sr$_3$Ir$_2$O$_7$ was shown to be a consequence of a novel quantum ground state of $J_{eff}$=1/2. Another compound in its series Sr$_3$Ir$_2$O$_7$ with double layers of the IrO$_2$ planes exhibits anomalous magnetic responses such as magnetization reversal during field-cooling processes. We performed density-functional theory calculations to investigate the electronic and magnetic properties of Sr$_3$Ir$_2$O$_7$. Similarly to the case of Sr$_3$Ir$_2$O$_7$, both spin-orbit (SO) and on-site Coulomb interactions are found to be responsible for the insulating ground state. Based on the analysis of our first-principle calculations for the various spin and lattice configurations, we found that the non-zero angular momentum state originating from large SO interactions with lattice distortions plays a crucial role in determination of both single-ion anisotropy and Dzyaloshinski-Moriya interactions, which explains anomalous magnetic responses in Sr$_3$Ir$_2$O$_7$. 
10:48AM A30.00015 Post-perovskite transition and magnetic and charge transport properties of the correlated 4d post-perovskite CaRhO₃ — K. YAMURA, Y. SHIRAKO, H. KOJITANI, M. ARAI, D.P. YOUNG, M. AKAOGI, M. NAKASHIMA, T. KATSUMATA, Y. INAGUMA, E. TAKAYAMA-MUROMACHI — A high-quality polycrystalline sample of the correlated 4d post-perovskite CaRhO₃ (Rhf+1.4d⁰ S = 1/2) was attained under a moderate pressure of 6 GPa for the first time. It is obvious that the perovskite CaRhO₃ transforms into a layered phase, in which Rh₃O₆ octahedra are connected by shearing the edge along a-axis and the corner along c-axis. The Rh-O layer stacks up alternatively with the Ca layer along b-axis. The characteristic structure suggests an electronic anisotropy toward 2D, which may be essential for unusual magnetism. The sample was subjected for measurements of charge transport and magnetic properties. The data clearly indicate it goes in an antiferromagnetically ordered state below ~90 K in an unusual way, being a strikingly contrast to what was observed for the perovskite phase.

Monday, March 16, 2009 8:00AM - 11:00AM –
Session A31 GMAG DMP: Focus Session: Molecular Nanomagnets 335

8:00AM A31.00001 Molecular Spintronics using Molecular Nanomagnets, WOLFGANG WERNSDORFER, CNRS, Institut Neel — A revolution in electronics is in view, with the contemporary evolution of two novel disciplines, spintronics and molecular electronics. A fundamental basis of these two fields can be established on magnetic molecules, and in particular, single-molecule magnets [1], which combine the classic macroscopic properties of a magnet with the quantum properties of a nanoscale entity. The resulting field, molecular spintronics aims at manipulating spins and charges in electronic devices containing one or more molecules. In this context, we want to fabricate, characterize and study molecular devices (molecular spin-transistor, molecular spin-valve and spin filter, molecular double-dot devices, carbon nanotube nano-SQUIDs, etc.) in order to read and manipulate the spin states of the molecule and to perform basic quantum operations. The talk will discuss this—still largely unexplored—field and present our first important results [2,3].

8:36AM A31.00002 Entrapment of magnetic micro-crystals for on-chip ESR studies, NICKOLAS GROLL, SYLVAIN BERTAINA, Department of Physics and National High Magnetic Field Laboratory, Florida State University, MEKHALA PATI, Department of Chemistry and Biochemistry, Florida State University, NARESH S. DALAL, Department of Chemistry and Biochemistry and National High Magnetic Field Laboratory, Florida State University, IRINEL CHIORESCU, Department of Physics and National High Magnetic Field Laboratory, Florida State University — On-chip Electronic Spin Resonance (ESR) of magnetic molecules requires the ability to precisely position nanosized samples in antinodes for a maximum magnetic coupling. A method is developed to entrap micro-crystals containing spins in a well-defined location on the substrate surface. Through the use of photolithography, this method has achieved positioning of single to tens of crystals with micron scale resolution. The method has allowed Q-band EPR measurements of a 175 micron diameter single crystal of BDPA at 34 GHz. Polycrystalline diluted Cr³⁺ spin 1/2 systems [1] have been entrapped in 500 micron squares for which the lower limit of the EPR measurement sensitivity was approached. This method gives way to on-chip ESR measurements at dilution refrigerator temperatures by allowing the samples to be positioned inside an on-chip superconducting cavity. [1] N. Sarita et al, Phys. Rev. Lett. 99, 137601 (2007).

8:48AM A31.00003 Experimental determination of the dipolar field in Mn₁₂-acetate₁, SEAN MCHUGH, R. JAAFAR, M.P. SARACHIK, City College of New York, Y. MYASOEDOV, H. SHTRIKMAN, E. ZELDOV, The Weizmann Institute of Science, R. BAGAI, G. CHRISTOU, University of Florida - Gainesville — Crystals of the molecular magnet Mn₁₂-acetate are known to contain a small fraction of defect (minor species) molecules with a small anisotropy barrier against spin reversal. The lower barrier leads to faster magnetic relaxation and lower coercive field. We exploit the low coercive fields of the minor species, and the location of the minor species tunneling resonances, to make a direct determination of the dipolar field in Mn₁₂-acetate. We find that the dipolar field of a fully magnetized crystal is 51.5 ± 8.5 mT, consistent with theoretical expectations.

1 Work at CCNY supported by NSF grant DMR-00451605.

9:00AM A31.00004 Magnetization barrier reduction in Mn₁₂ single-molecule magnets, GAGE REDLER, CHANGHYUN KOO, SAITI DATTA, Department of Physics, University of Florida, Gainesville, FL-32611, USA, CHRISTOS LAMPROPOULOS, THEOCARIS C. STAMATATOS, GEORGE CHRISTOU, Department of Chemistry, University of Florida, Gainesville, FL-32611, USA, STEPHEN HILL, Department of Physics, University of Florida, Gainesville, FL-32611, NHMF and Department of Physics, Florida State University, Tallahassee, FL-32310 — High-frequency electron paramagnetic resonance (HF-EPR) and AC susceptibility data will be presented for a new high-symmetry Mn₁₂-ac complex, [Mn₁₂O₁₂(R(OAc)₆)(MeOH)]₂⁻·MeOH, in which the acetic acid solvent is replaced by a single methanol. The results are compared with those of several other Mn₁₂ single-molecule magnets (SMMs), including Mn₁₂Ac²⁻·2CH₃COOH. AC susceptibility studies indicate that Mn₁₂Ac²⁻·MeOH has a relatively large effective barrier, Uₑff ~ 74 K, in comparison to Mn₁₂Ac²⁻·2CH₃COOH. Meanwhile, EPR studies suggest more-or-less identical zero-field-splitting parameters for the two complexes. Based on these findings, we discuss the factors that can lead to reductions in Uₑff in various Mn₁₂ SMMs.

9:12AM A31.00005 The role of quantum tunneling in magnetic avalanches in Mn₁₂-acetate₁, XIANG MA, BO WEN, S. MCHUGH, M.P. SARACHIK, City College of New York, Y. MYASOEDOV, H. SHTRIKMAN, E. ZELDOV, The Weizmann Institute of Science. R. BAGAI, G. CHRISTOU, University of Florida - Gainesville — Steps occur in the hysteresis loop of the molecular magnet, Mn₁₂-ac due to quantum tunneling at “resonant” magnetic fields where the energies of levels on opposite sides of the anisotropy barrier corresponding to different spin projections cross. The effect of quantum tunneling is also evident when magnetic relaxation occurs abruptly as a magnetic avalanche where spin reversal occurs along a narrow front that travels at subsonic speed. In particular, studies have shown that the ignition temperature displays minima and the velocity of the avalanche front shows maxima at the resonant fields. We report measurements of the avalanche speed triggered in an external magnetic field applied at an angle with respect the c-axis of the crystal, which the transverse component provides a symmetry-breaking field that increases the tunneling rate and magnetic relaxation.

1 Work at CCNY supported by NSF grant DMR-00451605.

9:24AM A31.00006 Tuning magnetization avalanches in Mn₁₂-acetate₁, BO WEN, S. MCHUGH, XIANG MA, M.P. SARACHIK, City College of New York, Y. MYASOEDOV, H. SHTRIKMAN, E. ZELDOV, The Weizmann Institute of Science, R. BAGAI, G. CHRISTOU, University of Florida - Gainesville — We report the results of a systematic study of magnetic avalanches (abrupt magnetization reversals) in the molecular magnet Mn₁₂-acetate using a micron-sized Hall sensor array. Measurements were taken for: (a) fixed magnetic field (constant barrier against spin reversal); and (b) fixed energy release obtained by adjusting the barrier and ∆M. A detailed comparison with the theory of magnetic deflagration of Garanin and Chudnovsky [1] will be presented and discussed. [1] D. A. Garanin and E. M. Chudnovsky, Phys. Rev. B 76, 054410 (2007).

1 Work at CCNY supported by NSF grant DMR-00451605.
9:36AM A31.00007 Non-adiabatic spin transition in the presence of phonon bottleneck effect, LEI CHEN, IRINEL CHIORESCU, Department of Physics and the National High Magnetic Field Laboratory, Florida State University — We present a study on deviations of the magnetization cycle of a two-level spin system from a reversible function into an opened hysteresis cycle due phonon bottleneck effect combined with Landau-Zener transitions. In the case of large zero-field level repulsion the magnetization curves can be described by a simple phonon-bottleneck model, in agreement with recent experiments on molecular magnets (V15 and Ru2) [1]. In the case of small tunneling gaps, as for large spin systems (Mn12 or Fe8), the spin will tunnel with a probability given by the Landau-Zener mechanism. The phonon-bottleneck model is here generalized into a model able to blend the non-adiabatic dynamics of spins with the presence of a non-equilibrium phonon bath [2]. Bloch equations are written in the eigenbasis of the effective spin Hamiltonian, assumed to be a two-level system at low temperatures, with a relaxation term driven by the phonon-bottleneck mechanism.

9:48AM A31.00008 Geometric-Phase Effect in the Thermally Assisted Resonant Tunneling of Mn12-tBuAc, J.R. FRIEDMAN, E. H. DA SILVA NETO, Amherst College Physics Dept., C. LAMPROPOULOS, G. CHRISTOU, University of Florida Chemistry Dept., N. AVR AHAM, Y. MYAESOE DOV, H. SHTRIKMAN, E. ZELDOV, Weizmann Institute of Science — Mn12-tBuAc, like the better-known single-molecule magnet Mn12-Ac, relaxes between up and down spin states by thermally assisted resonant tunneling when a longitudinal magnetic field (H_L) brings energy levels into resonance. In Mn12-Ac, tunneling is induced by a second-order transverse anisotropy produced by local solvent disorder. Such disorder makes the observation of any possible geometric-phase interference effect impractical. Mn12-tBuAc, in contrast, has negligible solvent disorder and an intrinsic fourth-order transverse anisotropy. We present experimental data on the transverse-field (H_T) dependence of the magnetic relaxation rate for Mn12-tBuAc. When on resonance (H_L = 0), the rate increases as a function of H_T in a series of steps and plateaus due to abrupt changes in the dominant tunneling pair of levels. Surprisingly, a similar effect occurs when off resonance (i.e. large H_L). Detailed numerical simulations show that the experimental results, both on and off of resonance, can be well described if the fourth-order anisotropy is included in the spin Hamiltonian. The results can be understood as arising from a geometric-phase effect that occurs when H_T is applied along the hard axis. Support: NSF grant #DMR-0449516.

10:00AM A31.00009 GGA+U study of exchange interactions in a Mn5 single-molecule magnet, EMAL E POPOFF, Virginia Tech, Blacksburg, VA, SALVADOR BARRAZA-LOPEZ, Georgia Tech, Atlanta, KYUNGWHA PARK, Virginia Tech, Blacksburg, VA, HUI-LIEN TSAI, Department of Chemistry, National Cheng Kung University, Taiwan — Electronic structure of a single-molecule magnet (SMM) Mn5 is investigated using GGA+U formalism. There are two types of Mn ions in the SMM Mn5: Mn3+ (S = 2) and Mn2+ (S = 5/2). In a prototype single-molecule magnet Mn12, superexchange interactions between Mn ions through oxygen anions are known to be antiferromagnetic. Our calculation on Mn5, however, showed that the Mn ions are all ferromagnetically coupled to each through various ligands. This results in the ground state spin of S = 11, which is in good agreement with experiment. We discuss the nature of the ferromagnetic coupling between the Mn ions by analyzing calculated projected density of states.

10:12AM A31.00010 ABSTRACT HAS BEEN MOVED TO SESSION S1 —

10:24AM A31.00011 Magnetism and magnetic anisotropies of small organic molecules, JAIME FERRER, DIEGO CARRASCAL, LUCAS FERNANDEZ SEIVANE, Universidad de Oviedo / CINN — The ability to enhance and tailor the magnetism of small atomic clusters and molecules will determine whether nanospintronics can be used as a storage technology. We present here our ab initio studies on the magnetism of small organic molecules containing transition metal atoms. We focus specially on 5d atoms like gold, platinum and iridium. These have a large spin-orbit interaction, which generates large magnetic anisotropies in small atomic clusters [1]. [1] L. Fernandez Seivane and J. Ferrer, Phys. Rev. Lett. 99, 183401 (2007).

1:00PM A32.00012 Anisotropic exchange in a tetranuclear CoIII complexes, SAITI DATTA, JUNJIE LIU, JON LAWRENCE, Department of Physics, University of Florida, Gainesville, FL 32611, CHRISTOPHER C. BEEDLE, DAVID N. HENDRICKSON, Department of Chemistry and Biochemistry, University of California at San Diego, La Jolla, CA 92093, STEPHEN HILL, Department of Physics, University of Florida, Gainesville, FL 32611, NHMFL and Department of Physics, FSU, Tallahassee, FL 32310 — High-frequency electron paramagnetic resonance (HFEPR) studies of the tetranuclear CoIII complex [Co(hmp)(dmb)Cl]+ reveal the presence of significant zero-field-splitting (ZFS) within the ground state spin multiplet. Meanwhile, low-temperature hysteresis measurements of 1 provide evidence for slow magnetization relaxation, suggesting that it could be a single-molecule magnet (SMM). However, HFEPR studies of a Zn analog of 1, doped with a small quantity of CoII, show the ground state of the CoII ions to be an effective spin S′ = 1/2 Kramers doublet with a highly anisotropic g-tensor. To understand the origin of the ZFS within the ground state spin multiplet of 1, as well as the slow magnetization relaxation, we consider the effect of anisotropic and antisymmetric exchange interactions between the ions within the tetranuclear complex. Our model provides an explanation for the ZFS in the ground state observed via HFEPR, and can also account for qualitative features observed through magnetic measurements.

10:48AM A31.00013 Magnetization studies of a new single molecule magnet [Net4][Mn3Zn2(salox)3O(N3)6Br2], JOHN HENDERSON, ENRIQUE DEL BARCO, University of Central Florida, CHANGHYUN KOO, STEPHEN HILL, Florida State University/NHMFL, PATRICK FENG, DAVID HENDRICKSON, University of California at San Diego, MOTOHIRO NAKANO, Osaka University — We present magnetization studies of a novel S = 6 single molecule magnet (SMM) [Net4][Mn3Zn2(salox)3O(N3)6Br2] (Mn3). The results reveal extremely clean changes in the magnetization associated to the high crystalline quality of the compound. The sample allows a detailed study of the role of molecular symmetry on the nature of the magnetic quantum tunneling relaxation of these molecules. Experiments at temperatures down to 30 mK carried out in a 3D vector superconducting magnet will be presented. The possible role of phonons as originators of the tunneling relaxation of the magnetization in this SMM will be used to explain interesting experimental observations.

Monday, March 16, 2009 8:00AM - 11:00AM —
Session A32 GMAG: Magnetization and Spin Dynamics 336
8:00AM A32.00001 Nanomagnetic Spin Fluids1, SKOMSKI RALPH, University of Nebraska, A. ENDERS, R. D. KIRBY, D. J. SELLMYER — The dynamics of conventional magnets is governed by the static micromagnetic response to an external magnetic field, with corrections due to thermal excitations. For example, permanent magnets undergo aging (magnetic viscosity), and magnetic recording media lose some of the stored bits due to thermal excitation. Essential deviations from this Arrhenius (or Néel- Brown) behavior occur on a length scale below about 2 nm. The relaxation no longer obeys Kramer's escape-rate theory and must be replaced by path-integral considerations with nontrivial activation-energy contributions. This presentation investigates several theoretical and experimental aspects of unusual magnetization dynamics in small-scale wires, thin films and dots. The first explicit example is the formation of liquid-like droplets, observed in ultrathin films with perpendicular magnetic anisotropy and characterized by 180° domains of well-defined chirality. (The one-dimensional equivalent of this phenomenon is a hard-core gas with particle-number conservation.) The second example is of theoretical nature and links the phenomenon of slow magnetization dynamics to the concept of fractional kinetics. A general feature of the considered nanomagnets is their resemblance to fluids (liquids or gases), as opposed to the glassy dynamics of conventional magnets.

8:12AM A32.00002 Interface Magnetization Switching and Demagnetization in Fe/Al films and Fe/Pt nanoparticles, WEI LAI, TETIANA NOSACH, YU GONG, YUHANG REN, CHAEHYUN KIM, SAVAS DELIKANL1, HAO ZENG, THE ULTRAFAST OPTICS GROUP AT HUNTER COLLEGE OF THE CITY UNIVERSITY OF NEW YORK TEAM, SPIN EFFECTS AND NANOMAGNETISM GROUP AT THE UNIVERSITY AT BUFFALO TEAM — We report on the reversal and demagnetization processes of the Fe interface layer magnetization in thin films and nanoparticles of Fe/Al and Fe/Pt by time-resolved magnetization-induced second-harmonic generation. The results are compared with those of the bulk magnetization as obtained from magneto-optic Kerr effect. We realize that switching and demagnetization characteristics are distinctly different between bulk and interface layers because of the interface-derived anisotropy and the dipole interactions. In particular, the surface and interface magnetism will dominate the behaviors of nanoscale structures.

8:24AM A32.00003 Magnetization hysteresis studies in Sm1-xGd12Al2 alloys, U. VAIYDA, S. VENKATESH, V.C. RAKHECHA, DCMP&MS, Tata Institute of Fundamental Research, Mumbai, India, S. RÁMAKRISHNAN, A.K. GROVER, DCMP&MS, Tata Institute of Fundamental Research, Mumbai, India — SmAl2 (Tc ~ 125 K, μsat = 0.23 μB/f.u.) is known to exhibit magnetic compensation when doped with Gd (0 < x < 0.5). In such stoichiometries though the magnetization gets closer to zero, there exists a large spin polarization. This makes such materials attractive candidates for applications. We have performed detailed magnetization hysteresis and other studies in the series Sm1-xGd12Al2. In x=0.02 alloy, the loops are shifted (notion of exchange bias) along negative H-axis for temperatures just above Tcomp and along positive H-axis for temperatures T > Tcomp. We argue that the change in the sign of exchange bias is due to the magnetic contribution of conduction electron polarization as well as that of local magnetic moments reversing the signs. At Tcomp, the width of the hysteresis loop collapses. In the given series, one can set up the system in either spin-surplus or orbital-surplus state and control the exchange bias field. The compositions with 0.03 < x < 0.06 do not exhibit zero cross over of magnetization and remain spin surplus. Our various studies and analysis shall be presented.

8:36AM A32.00004 New spin modes in itinerant ferromagnets, JOHN FELDMANN, KEVIN BEDELL, Boston College — We are theoretically investigating new collective spin phenomena that could exist in itinerant ferromagnetic materials such as MnSi. We postulate an attractive candidate for applications. We have performed detailed magnetization hysteresis and other studies in the series Sm1-xGd12Al2. In x=0.02 alloy, the loops are shifted (notion of exchange bias) along negative H-axis for temperatures just above Tcomp and along positive H-axis for temperatures T < Tcomp. We argue that the change in the sign of exchange bias is due to the magnetic contribution of conduction electron polarization as well as that of local magnetic moments reversing the signs. At Tcomp, the width of the hysteresis loop collapses. In the given series, one can set up the system in either spin-surplus or orbital-surplus state and control the exchange bias field. The compositions with 0.03 < x < 0.06 do not exhibit zero cross over of magnetization and remain spin surplus. Our various studies and analysis shall be presented.

8:48AM A32.00005 Scaling collapse of the irreversible magnetization of ferromagnetic thin films1, R. DAS, A.F. HEBARD, University of Florida, Department of Physics — The irreversible magnetization, ΔM, defined as the difference of field-cooled magnetization MFC and zero-field-cooled magnetization MZFC, has been measured for a variety of ferromagnetic thin films as a function of magnetic field H at different temperatures T. Isotherms of ΔM show maxima ΔMmax at characteristic temperature-dependent fields Hm(T) at very low and high magnetic fields the values of MFC and MZFC converge and ΔM is observed to approach zero in these limits. If ΔM/ΔMmax is plotted as a function of H/Hm for a given ferromagnetic system, the graphs for different temperatures collapse onto the same curve. This scaling collapse is clearly seen for three different ferromagnetic thin-film systems: polycrystalline gadolinium, phase separated manganites, and single domain Ni nanomagnetic grains embedded in an insulating host. Similar scaling behavior has also been observed in spin-glass material [1]. These results represent a heretofore unrecognized scaling behavior that appears to apply to a broad range of ferromagnetic systems. [1] V. S. Zotev, G. G. Kenning, and R. Orbach, Phys. Rev. B 66, 014412 (2006)

9:00AM A32.00006 Atomic spin-dynamics simulations from first principles theory, OLLE ERIKSSON, Upssala University — In this talk I will present recent developments in atomic spin-dynamics simulations using first principles theory. Details of the implementation will be given and simulations of spin-glass materials (Cu-Mn) and diluted magnetic semiconductors (Mn doped GaAs) will be presented.

9:12AM A32.00007 Dynamics of Einstein - de Haas Effect: Application to Magnetic Cantilever, REEM JAAFAF, E.M. CHUDNOVSKY, D.A. GARANIN, Lehman College, The City University of New York — Local time dependent theory of Einstein - de Haas effect is developed. We show that internal elastic twists that accompany dynamics of spins enter equations of elasticity in the universal form that does not require precise knowledge of spin-lattice interactions. As long as the space-time dependence of the magnetization is known, local elastic deformations can be computed rigorously without any unknown parameters. The theory is applied to the description of the motion of a magnetic cantilever caused by the oscillation of the domain wall. Theoretical results are compared with a recent experiment on Einstein - de Haas effect in a microcantilever.

9:24AM A32.00008 Colored thermal noise in spin valves, JIANG XIAO, GERRIT BAUER, Kavli Institute of NanoScience, Delft University of Technology, Delft, The Netherlands, SADAMICHI MAEKAWA, Institute for Materials Research, Tohoku University, Sendai, Japan, ARNE BRATAAS, Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway — We report a theoretical study of the thermal electrical noise in spin valves. There are two independent noise sources in spin valves: 1) thermal agitation of charge carriers causing Johnson-Nyquist noise, 2) thermal agitation of the magnetization that contributes to the electric noise by spin and charge pumping. The noise power spectrum from the latter consists of two absorption lines at zero frequency and at the ferromagnetic resonance on top of a white noise background. The relative intensities depend on the magnetization configuration.
9:36AM A32.00009 Numerical evidence for unstable magnons at high fields in the square lattice Heisenberg antiferromagnet, OLAV F. SYLJUÅSEN, Department of Physics, University of Oslo — We have found numerical evidence for decaying magnons in the square lattice spin-1/2 Heisenberg antiferromagnet when it is exposed to a strong external magnetic field. The results are obtained using Quantum Monte Carlo simulations combined with a Bayesian inference technique to obtain dynamics, and are consistent with earlier predictions from spin wave theory.

9:48AM A32.00010 Low-Frequency Magnetization Noise in Spin-Valve Structures1, ARIF OZBAY, AISHA GOKCE, EDMUND NOWAK, THOMAS FLANAGAN, RYAN STEARRETT, University of Delaware, CATHY NORDMAN, NVE Corp. — We report on 1/f resistance noise due to thermally driven fluctuations of the domain structure in GMR and MTJ sensors. Resistance noise from both the free layer (FL) and reference layer (RL) is evident. A near linear scaling of the normalized noise power with the sensor’s sensitivity is observed. For a given sensitivity, the RL exhibits higher noise than the FL. This appears correlated to the larger imaginary (dissipative) component in the resistance susceptibility of the RL. In addition, we find that the imaginary component is larger for layers that exhibit pronounced magnetic hysteresis, suggestive of connection between the noise and relaxation processes. A model based on equilibrium magnetization fluctuations is in good quantitative agreement with the measured noise power over most of the sensor's borengiasis response. A magnetic 1/f noise parameter is defined which can be used to compare magnetoresistive sensors having differing sizes, sensitivities, and under different biasing conditions.

1DOE and Office of Naval Research

10:00AM A32.00011 Phase Diagram of Equilibrium Domain-Wall Solutions in Finite-Size ECC Media, SONALI MUKHERJEE, Seagate Technology, LUC BERGER, Carnegie Mellon University — Reversal in ECC media where hard and soft anisotropy magnetic material are exchange coupled has been studied because it has high thermal stability with low reversal field. Using Euler-Lagrange condition, we have studied the field evolution of domain-wall solutions in ECC for various anisotropy ratios of hard and soft phase and soft-phase length scales. We find that there exist 3 critical fields. At the field H1, the domain-wall solution Es (surface domain-wall) and E1 (soft-phase domain-wall) start existing. The nucleation field Hn is the field where the energy of Es and the unreversed uniform solution E0 coincide. Above Hn, Es ceases to exist. The domain-wall propagation field Hdw is the field where the energy of soft domain-wall exist E1 and hard domain-wall E2 coincide. Above Hdw, E1 and E2 cease to exist. The reversal field is the field at which no domain-wall solutions exist anymore and is the maximum of Hn and Hdw fields. The field Hn is found to reduce with increasing soft-phase length, and Hdw is found to be independent of the phase ratio greater than the higher wall width of the hard phase. For hard/soft anisotropy ratio kh/kS less than 5, the nucleation field is always dominant. When kh/kS is greater than 5, there exits a soft-phase length lsc, at which the fields Hn and Hdw become equal and is greater than lsc. Hdw dominates the reversal and, when lsc is smaller than lsc, Hn is the reversal field.

10:12AM A32.00012 Nature of magnetic ordering in Ni(OH)2 nanoplates, JAMES RALL, MOHANDIR SEEHRA, West Virginia University — Nickel hydroxides are important for their potential applications in rechargeable batteries and as precursors for NiO and Ni catalysts. kappa-Ni(OH)2 has the CdCl2 layered structure with Ni atoms forming a hexagonal unit cell. Here, we report on the magnetic ordering in 17 nm x 4 nm nanosheets of Ni(OH)2. Measurements of the magnetization M as a function of temperature (2K to 300K) and magnetic field H up to ±55kOe are reported. M vs. T data in H=100 Oe for the ZFC case shows a peak in M at T = 24 K characteristic of antiferromagnetic (AF) ordering; however for T > Tc, the Curie-Weiss (χ = C/(T - θ)) fit yields θ = 26K characteristic of ferromagnetism. Following Takada (J. Phys. Soc. Jpn. 21, 274S, 1966), we measured M vs. H loops from T = 2K to 25K and observed a metamagnetic transition at Hc = 56 kOe at 2K, with Hc decreasing with increasing T. These results suggests strong ferromagnetic coupling among Ni within (001) sheets and a weaker antiferromagnetic coupling in the neighboring (001) sheets, and [001] as the easy axis. This model is used to determine the exchange constants consistent with the observed Curie-Weiss variation.

10:24AM A32.00013 First-principles calculations of laser-induced spin manipulation in small magnetic clusters with CO, CHUN LI, GEORGIOS LEFKIDIS, WOLFGANG HÜBNER, Kaiserslautern University of Technology — We present a fully ab initio controlled ultrafast magnetooptical switch and transfer mechanism in small magnetic clusters exploiting spin-orbit-coupling enabled Lambda-processes [1-3]. Two-magnetic-center clusters with CO attached to one of the magnetic atoms are studied to achieve a mapping of the laser-induced spin manipulation to the IR spectrum of CO. The predicted spin-state-dependent CO frequencies can facilitate experimental monitoring of the processes. The lower electronic states of the clusters exhibit a very high degree of spin localization either at the Co or the Ni site. Spin flip on one magnetic atom and transfer from one magnetic center to the other are realized in structurally optimized magnetic clusters with fidelities that reach 99.8%. Electron states of the clusters exhibit a very high degree of spin localization either at the Co or the Ni site. Spin flip on one magnetic atom and transfer from one magnetic center to the other are realized in structurally optimized magnetic clusters with fidelities that reach 99.8%.

10:36AM A32.00014 Magnetic properties of a doped quasi-triangular lattice material, Cu2(1−x)Zn2x(9OH)2NO3/(C17H15COO), JIAN WU, ANUP K. GANGOPADHYAY, S.A. SOLIN, Washington University in St. Louis — Cu2(OH)2NO3 is a geometrically frustrated layered compound in which spin S=1/2 Cu2+ ions are arranged on a slightly distorted triangular lattice. The magnetic properties of the pure compound and of the compound intercalated with alkane carboxylate have been extensively studied.[1] However, the effects of interlayer doping remain unexplored. The substitution of non-magnetic ions such as Zn2+ for Cu2+ will ultimately drive the ordering temperature toward zero[2] which may provide a candidate system possessing an exotic spin-liquid ground state. We have prepared powder samples of the Cu2(1−x)Zn2x(9OH)2NO3 family and systematically investigated them by magnetic susceptibility measurements. The ordering temperature decreases from 11K to 5.6K while the Cu-W temperature increases from -5.1K to +2.8K as the Zn concentration increases from 0 to 65%. To enhance the 2-dimensional characteristic and reduce the interlayer interaction, we introduce an alkanecarboxylate C7H15COO- into the interlayer space. The experimental results we have obtained indicate that this new class of materials have much higher frustration levels [θ2ω / Tc] ~ 20 and order at a lower temperature than the doped parent compounds.

10:48AM A32.00015 Coupling between optically-induced coherent spin and lattice dynamics in epitaxial Fe films, VLADIMIR STOICA, University of Michigan, DON WALKO, Argonne National Laboratory, ERIC LANDAHL, DePaul University, YUELIN LI, Argonne National Laboratory. ROY CLARKE, University of Michigan — Spin dynamics excitation using femtosecond optical pulses in ferromagnetic thin films is a powerful technique to study spin dependent interactions in solids. One topic of interest is the temporal separation of relaxation processes related to fundamental interaction mechanisms, which include spin-orbit, spin-lattice and exchange coupling. Establishing experimentally the relaxation timescales for these couplings is an important step that assists the development of new spintronic applications. We employ time-resolved magneto-optical and X-ray diffraction probes to separate spin and lattice interactions in epitaxial Fe films grown by molecular beam epitaxy on Ge and MgO substrates. We study the connection between the magnetic and lattice relaxation times excited by optical pulses. We find that coherent spin precession dynamics correlates well with thermoelastic strain relaxation from picosecond to nanosecond time scales.
8:00AM A33.00001 Temperature dependent ARPES study of the pseudogap of Pb-Bi2201.

MAKOTO HASHIMOTO, RUHUA HE, Stanford, KIYOHISA TANAKA, JEAN-PIERRE TESTAUD, Stanford/LBL, WORAWAT MEEVASANA, ROB MOORE, DONGHUI LU, Stanford, YOSHIYUKI YOSHIDA, HIROSHI EIASKI, AIST, ZAHID HUSSAIN, LBL, ZHI-XUN SHEN, Stanford — The pseudogap phenomena in the high-Tc cuprates have been extensively studied because of possible intimate connection with the unknown mechanism of superconductivity. We have studied the ARPES spectra of optimally-doped Pb-Bi2201 (Tc = 34 K) at SSRL BL5-4, from the superconducting state (10 K) to the normal state above the pseudogap temperature (160 K). We have revealed how the band structure changes with the pseudogap opening, and found that the superconducting gap alone cannot explain the ARPES spectra in the antinodal region. Based on the results, in the presentation, we would like to discuss possible origins of the pseudogap. This work is supported by the DOE Office of Basic Energy Science, Division of Materials Science and Engineering. ARPES experiments were performed at the Stanford Synchrotron Radiation Laboratory (SSRL), which is operated by the Department of Energy Office of Basic Energy Science.

8:12AM A33.00002 Pseudo-gap in electron doped cuprates: Spin fluctuation origin and close relation with superconducting gap. SEUNG RYONG PARK, Yonsei university, Korea, D.J. SONG, C.S. LEEM, CHUL KIM, S.K. CHOI, Y.K. KIM, C. KIM, K.J. CHOI, J.H. KIM, Yonsei University, K.M. SONG, Inha University, Korea, JUNG HOON HAN, Sungkyunkwan, Korea, Y. YOSHIDA, H. EIASKI, AIST, Japan — A natural candidate for the cause of PG in electron doped cuprates could be spin fluctuations. However, there has not been any careful calculation based on the spin fluctuation model, at least to our best knowledge. Recently, dynamic spin susceptibility measurement on electron doped cuprates was obtained by using inelastic neutron scattering. Therefore, one could use electron-spin coupling which is proportional to the dynamic spin susceptibility and calculate the spectral function based on the electron-spin fluctuation coupling model. In this presentation, we first show calculated ARPES spectral function based on electron-spin fluctuation coupling model with the magnetic susceptibility as the input. We could identify the origin of PG as electron-spin fluctuation from this simulation, and we also could extract a rough value for the electron-spin fluctuation coupling strength g in electron doped cuprates by comparison between experimental data and simulation results.

8:24AM A33.00003 Temperature dependent ARPES study of the superconducting gap in overdoped Bi22121. H.-B. YANG, CMPMSD, Brookhaven National Laboratory, J.D. RAMEAU, CMPMSD, Brookhaven National Laboratory/ Stonybrook University, G.D. GU, P.D. JOHNSON, CMPMSD, Brookhaven National Laboratory — High-resolution angle-resolved photoemission (ARPES) is used to probe the temperature dependence of the superconducting gap around the Fermi surface in overdoped Bi2212. Lucy-Richardson deconvolution is applied to reduce the error from experimental resolution. Normalizing by the Fermi function then allows the observation of the true gap in the spectral function. Numerical simulation is also used to compare the experimental results with theoretical models. We have investigated the temperature dependence of the gap around the nodal region and the anti-nodal region, with temperature going from the superconducting state to the normal state.

8:36AM A33.00004 ABSTRACT WITHDRAWN —

8:48AM A33.00005 ARPES study of YBa2Cu3O7−δ from the over to the underdoped regime by in situ K evaporation. G. LEVY, DAVID FOURNIER, M.A. HOSSAIN, J.D.F. MOITERSHEAD, UBC, J.L. MCHECHEYNE, A. BOSTWICK, E. ROTENBERG, ALS, W.N. HARDY, R. LIANG, C.A. SAWATZKY, I.S. ELFIMOV, D.A. BONN, A. DAMASCHELLI, UBC — Unravelling the nature of the electronic excitations in the underdoped regime of the Cuprates is a key element for understanding the fundamental mechanism behind HTSC. The YBCO phase diagram has been studied with photoelectron spectroscopy (ARPES) using a new in situ electron doping approach based on controlled potassium deposition [1] onto as-cleaved samples. All of the compounds studied (δ=0.5,0.66) exhibit heavily over-doped nature with well defined LDA-like Fermi surfaces and evolve toward disconnected Fermi arcs in the underdoped regime. These results are consistent with previous ARPES measurement on the HTSCs and in contrast with the quantum oscillations observations [2].

9:00AM A33.00006 Quasiparticles in Bi22121. M. VISHIK, W.-S. LEE, Stanford University, K. TANAKA, Osaka University, B. MORITZ, E.A. NOWADNICK, Stanford University, T. SASAGAWA, Tokyo Institute of Technology, T. FUJII, Tokyo University, T.P. DEVEREAUX, Z.-X. SHEN, Stanford University — From ARPES measurements, much has been learned about the single-particle excitations of the high-Tc cuprate superconductors, and collective properties can be inferred from these experiments too. The gap in the spectrum below Tc is related to the superconducting gap, and the superfluid density, the other hallmark of superconductivity, has been demonstrated to correlate closely with the weight of the antinodal quasiparticle peak. The momentum, temperature, and doping dependence of quasiparticle lifetime yields information about scattering processes, which are related to ground state properties. In Bi-2212 quasiparticles are present on the entire Fermi surface over a wide doping range. We present ARPES studies of the quasiparticles in Bi-2212 as a function of doping, momentum, and temperature, and discuss connections to other experiments.

9:12AM A33.00007 ARPES study on Tl-based Cuprates, WEI-SHENG LEE, KIYOHISA TANAKA, Stanford University & SIMES, SLAC, INNA VISHIK, Stanford University, DONGHUI LU, ROB MOORE, Stanford University & SSRL, SLAC, HIROSHI EIASKI, AKIRA IYO, AIST, Japan, THOMAS DEVEREAUX, ZHU-XUN SHEN, Stanford University & SIMES, SLAC — Here we report the angle-resolved photoemission measurements on nearly optimally multi-layer Tl-based superconducting copper oxides, including Tl2Ba2CaCu2O8 (Tl2212), Tl2Ba2Ca2Cu3O9 (Tl1223), and a comparison to the data of single layer Tl2Ba2CaCu2O8 (Tl-2212). Consistent with other optimally-doped cuprates, a hole-like Fermi surface and sharp quasi-particle peak in the superconducting state is observed. The renormalization effect due to the coupling of bosonic modes is also observed, which exhibits intriguing materials dependence. Implications of the observed material dependent renormalization effect will also be discussed.

9:24AM A33.00008 Anomalous behavior of the nodal scattering rate of Bi2Sr2CaCu2O8+δ near the Fermi energy, THEODORE REBER, NICK PLUMB, University of Colorado, JOHN DOUGLAS, NIST-Boulder, ZHE SUN, QIANG WANG, University of Colorado, YOSHIIRO AIURA, HIROSHI EIASKI, HIDEKI IWASAWA, AIST, MICHEL HERMELE, DANIEL DESSAU, University of Colorado — The scattering rate as determined by the width of a band is a direct measure of the imaginary part of a particle’s self-energy. Though the dispersion of a band can also used to extract the particle’s self-energy, the scattering rate is superior, because the ambiguity due to determining the underlying bare band is not included. The excellent momentum and energy resolution of low photon energy ARPES allows us to study the scattering rate of Bi2Sr2CaCu2O8+δ near the Fermi energy. Our studies show an anomalous feature that warrants continued study.
9:36AM A33.00009 Novel feature in the nodal electron self-energy and strong temperature dependence of the Fermi velocity in the high temperature superconductor Bi2212. N. C. PLUMB, T. J. REBER, University of Colorado, J.D. KORALEK, LBNL and UC Berkeley, Z. SUN, J. F. DOUGLAS, University of Colorado, Y. AIURA, K. OKA, H. EISAIK, AIST Tsukuba, D. S. DESSAU, University of Colorado — Using low-photon energy angle-resolved photoemission (ARPES), we study the low-energy dispersion along the superconducting node in Bi2212 as a function of temperature. Less than 10 meV below the Fermi energy, the high-resolution data reveals a novel "kink"-like feature in the real part of the electron self-energy. The kink is strongest below the superconducting critical temperature and appears to vanish as the temperature is raised. A corollary of this finding is that the Fermi velocity, as measured over this small energy range, varies rapidly with temperature — increasing by approximately 35% from 50 to 200 K. This is in contrast to the slope of the dispersion at only slightly deeper energy, which changes little by comparison and whose behavior is ostensibly dominated by the well-known 70-meV kink. We discuss some possible physical origins of the new low-energy feature, including the possibility that it may arise from bosonic mode couplings and/or nonanalytic corrections to Fermi liquid theory in 2D.

9:48AM A33.00010 ARPES investigation of two leg ladder compounds Sr14−xCaxCu24O41. GEY-HONG GWEEN, UC Santa Cruz, TAKAO SASAGAWA, Tokyo Institute of Technology. TAKAMI TOHYAMA, Yokawa Institute for Theoretical Physics, MATTHEW BRUNNER, JAMES HINTON, JACOB STANLEY, UC Santa Cruz — The so-called "two leg ladder compounds" Sr14−xCaxCu24O41 are interesting since it is well accepted that they form a resonating valence bond state. The crystal structure of two leg ladder compounds consists of one-dimensional motifs (ladders and chains), and it is within the ladders that the resonating valence bond state arises. As x is varied, these compounds go through a metal-insulator transition, and become a superconductor, albeit under pressure. So far, a high resolution ARPES study shedding light on the near-Fermi-level electronic structure of these interesting compounds has been missing. Here, we report our ARPES results, providing the first view of the near-Fermi-level quasi-one-dimensional electronic structure arising from the ladders. We discuss line shape features that are indicative of strong electron correlations.

10:00AM A33.00011 ARPES matrix element and the waterfall effect in the cuprates. SUSMITA BASAK, TANMOY DAS, Northeastern U., JOUKO NIEMINK, MATTI LINDOOES, Tampere U. Tech., Finland and Northeastern U., HSIN LIN, ROBERT MARKIEWICZ, ARUN BANSIL, Northeastern U. — The high-energy kink (HEK) or the 'waterfall' effect as seen in angle-resolved photoemission spectra (ARPES) in the cuprates has the potential of revealing important information about the dressing of quasiparticles by electronic excitations [1,2,3]. However, recently it has been suggested that matrix element effects are crucial in explaining the experimental spectra in Bi2Sr2CaCu2O8+δ (Bi2212), and it has been questioned whether the HEK exists [4]. Here we discuss how the interplay between the matrix element and self-energy effects shapes the ARPES spectra. Both the ARPES matrix element and the self-energy are found to be necessary for understanding the experimental spectra. Work supported in part by the USDOE. [1] R. S. Markiewicz et al., Phys. Rev. B 76, 174514 (2007). [2] A. Macridin et al., Phys. Rev. Lett. 99, 237001 (2007). [3] Tanmoy Das et al., cond-mat:0807.4257. [4] D.S. Inosov et al., Phys. Rev. Lett. 99, 237002 (2007).

10:12AM A33.00012 ABSTRACT WITHDRAWN

10:24AM A33.00013 LASER ARPES studies on Sr2RuO4. CHULIM SEUNG, SEUNG-PYONG KANG, C.S. LEEM, D.J. SONG, Y.K. KIM, S.K. CHOI, W.S. JUNG, Y.Y. KO, C. KIM, Institute of Physics and applied physics, Yonsei University, INSTITUTE OF PHYSICS AND APPLIED PHYSICS, YONSEI UNIVERSITY TEAM — LASER ARPES was performed on Sr2RuO4. With advance of LASER ARPES, we could perform bulk sensitive ARPES with 1meV energy resolution. With these advantages, intensive studies on Sr2RuO4 enlightened us more knowledge on layered structures.

10:36AM A33.00014 Fermiological interpretation for collective spin and charge orderings in underdoped La-based cuprates by ARPES. RUIHUA HE, Physics, Applied Physics, Stanford Univ. & SSRL (Stanford), KIYOHISA TANAKA, Stanford & ALS & Physics, Osaka Univ., SÜNG-KWAN MO, Stanford & ALS, HONG YAO, Stanford, MAKOTO Hishimoto, Stanford & ALS, EREZ BERG, Stanford, TAKAO SASAGAWA, Stanford & Materials and Structures Lab, TIT, TADASHI ADACHI, Applied Physics, Tohoku Univ., MASAKI FUJITA, Institute of Materials Research, Tohoku Univ., TEPEEI YOSHIDA, Complexity Science and Engineering, University of Tokyo, NORMAN MANNE, Stanford & ALS, WORAWAT MEESAVANAN, Stanford, YOJI KOIKE, Applied Physics, Tohoku Univ., KAZUYOSHI YAMADA, Institute of Materials Research, Tohoku Univ., ATSUHI FUJIMORI, Complexity Science and Engineering, University of Tokyo, STEVE KIVELSON, Stanford, ZAHID HUSSAIN, ALS, ZHI-XUN SHEN, Stanford — By using ARPES interpretation for the origin of the collective spin and charge orderings in underdoped La-based cuprate superconductors is carefully examined. A Fermi surface nesting wave vectors is identified which matches the collective ordering wave vector observed by neutron scattering for doping around 1/8. The pseudogap state is found to be essential for the development of such nesting instability of the electronic system toward density wave formation. A systematic doping dependence study will be presented that allows further insights into this issue.

10:48AM A33.00015 Mott gap collapse in the cuprates – apparent or real? . R. S. MARKIEWICZ, TANMOY DAS, A. BANSIL, Northeastern University — We have recently introduced a model self-energy for the cuprates, which includes an antiferromagnetic (AFM) transition dressed by spin and charge fluctuations.[1] This model correctly reproduces many 'strong coupling' features in the angle-resolved photoemission (ARPES) and optical spectra, including the waterfall effect and the doping dependence of the optical Mott gap. Here we discuss a dichotomy between Slater and Mott physics in the cuprates, with a Slater-like AFM gap collapse with doping in the coherent bands while the Mott-like gap persists in the incoherent bands. By analyzing the spectral weights, we show that there is an anomalous spectral weight transfer which is rather large to be consistent with strong coupling physics, but which is reasonably described by our intermediate coupling model. Work supported in part by the USDOE. [1] Tanmoy Das, R. S. Markiewicz, and A. Bansil, arXiv:0807.4257.

Monday, March 16, 2009 8:00AM - 11:00AM

Session A34 DCMP: Superconductivity: Spin Properties 404

8:00AM A34.00001 Evidence for Local Moment Magnetism in Superconducting Bi2Sr2CaCu2O8+δ. JOHN TRANQUADA, G.Y. XU, G.D. GU, M. HUECKER, Brookhaven Natl. Lab., B. FAUQUE, LLB, T.G. PERRING, C. STOCK, ISIS, L.-P. REGNAULT, CEA-Grenoble — We have used inelastic neutron scattering to measure the dynamic spin susceptibility in optimally-doped Bi2Sr2CaCu2O8+δ (Tc = 91 K). Four crystals with a total mass of 19 g were measured on the MAPS spectrometer at ISIS for temperatures of 10 K and 100 K. We have been able to identify the magnetic excitations in the energy range 20-90 meV. The magnetic nature of the scattering has been confirmed with spin-polarization analysis on IN22 at the ILL. While we see temperature-dependent changes for energies around 40 meV that are consistent with earlier studies, we find that the Q-integrated signal shows a much weaker variation with temperature. The absolute magnetic cross section is quite comparable to that of spin fluctuations in stripe ordered La2-xSr2xCuO4. As the magnetism in the latter system has been shown to have a dominant contribution from local moments [1], we argue that the same must be true for Bi2Sr2CaCu2O8+δ. [1] M. Huecker et al., Phys. Rev. B (accepted); cond-mat/0503417v3.

8:12AM A34.00002 Phase Separation and Magnetism in High Temperature Superconductors, S. WEN, Z. J. XU, G. D. GU, J. M. TRANQUADA, Brookhaven National Laboratory, M. V. ZIMMERMANN, HASYLAB at DESY, Hamburg, Germany — The pronounced stability of the charge and spin stripe order in La_{2-x}Sr_xCuO_4 at x = 1/8 doping still is a poorly understood peculiarity. A combination of electronic and structural interactions is likely, however it has been difficult to clearly separate the involved mechanisms. One approach is to explore how stripe order fades away for dopings x ≠ 1/8. We have performed high energy (100 keV) x-ray diffraction and static magnetization experiments on single crystals with x=0.095 and 0.155. To our surprise, at ambient pressure stripes exist in a much broader range of doping around x = 1/8 than expected. In the underdoped region charge stripe order always coincides with a structural transition associated with a rotation of the octahedral tilt axis. However, for x = 1/8 and high pressure we have been able to show that stripe order also occurs in the absence of this structural phase, which motivates us to discuss stripes in terms of an electronic liquid crystal phase.

1Supported by the US-DOE through contract DE-FG02-00ER45801.

8:24AM A34.00003 Stripe order in La_{2-x}Ba_xCuO_4 at ambient and high pressure, M. HUECKER, J. S. WEN, Z. J. XU, Department of Physics and Astronomy, McMaster University, T. ITO, P. L. RUSSO, A. T. SAVICI, Y. J. UEMURA, Department of Physics, Columbia University, H. KIM, S. WAKIMOTO, R. J. BIRGENEAU, Department of Physics, University of Toronto — There is now a large body of evidence from local probes which point to intrinsic heterogeneity in the cuprates. One example is the recent reports of an inhomogenous magnetic field response in the underdoped materials, as revealed by muon spin rotation experiments. In an effort to explore this field response, we have measured the /mu/0SR spectra of La_{2-x}Sr_xCuO_4 in a number of applied magnetic fields and with x ranging from the underdoped to heavily overdoped materials. I will summarize these efforts, and present the resultant data in the context of existing literature. Possible interpretations and directions for future research will be discussed.

8:36AM A34.00004 The local magnetic field response of La_{2-x}Sr_xCuO_4 on the overdoped side of the phase diagram as revealed by /mu/0SR, G. J. MACDOUGALL, Oak Ridge National Labs, A. A. ACZEL, S.-J. KIM, J. A. RODRIGUEZ, C. R. WIEBE, G. M. LUKE, Department of Physics and Astronomy, McMaster University, T. ITO, P. L. RUSSO, A. T. SAVICI, Y. J. UEMURA, Department of Physics, Columbia University, H. KIM, S. WAKIMOTO, R. J. BIRGENEAU, Department of Physics, University of Toronto — Recent work at Brookhaven was supported by the Office of Science, U.S. Department.

8:48AM A34.00005 The emergence of coherent magnetic excitations in the pseudogap state of underdoped superconducting La_{2-x}Sr_xCuO_4, S. M. HAYDEN, O. J. LIPSCOMBE, B. VIGNOLLE, University of Bristol, T. G. PERRING, C. D. FROST, Rutherford Appleton Laboratory — We use inelastic neutron scattering to measure the magnetic excitations in the underdoped superconductor La_{2-x}Sr_xCuO_4 (x=0.085, T_c=22 K) over wider energy (5 < E < 200 meV) and temperature (5 < T < 300 K) ranges than previously studied.

At low temperatures, the magnetic response is highly structured in energy and momentum with peaks in the local susceptibility /chi/ (E) at 15 and 50 meV and a strongly anisotropic four-peaked structure in /chi/ (q) for E ≈ 185 meV. Raising from T = 30 K to 300 K causes dramatic changes in the response with the observed structure in /chi/ (q, E) for E < 70 meV disappearing and being replaced with a strongly damped response with a characteristic energy scale I' ≈ 50 meV. The results are discussed with respect to the pseudogap present for this composition.

9:00AM A34.00006 Spin Excitations in La_{1.75}Sr_{0.25}Zn_{0.1}Cu_{0.99}O_4, S. M. HAYDEN, O. J. LIPSCOMBE, B. VIGNOLLE, University of Bristol, T. G. PERRING, C. D. FROST, Rutherford Appleton Laboratory — We use inelastic neutron scattering to measure the magnetic excitations in the underdoped superconductor La_{2-x}Sr_xCuO_4 (x=0.085, T_c=22 K) over wider energy (5 < E < 200 meV) and temperature (5 < T < 300 K) ranges than previously studied.

At low temperatures, the magnetic response is highly structured in energy and momentum with peaks in the local susceptibility /chi/ (E) at 15 and 50 meV and a strongly anisotropic four-peaked structure in /chi/ (q) for E ≈ 185 meV. Raising from T = 30 K to 300 K causes dramatic changes in the response with the observed structure in /chi/ (q, E) for E < 70 meV disappearing and being replaced with a strongly damped response with a characteristic energy scale I' ≈ 50 meV. The results are discussed with respect to the pseudogap present for this composition.

9:12AM A34.00007 Magnetic signatures of the pseudogap phase and doping dependence of the antiferromagnetic resonance in HgBa_2Cu_2O_{4+δ}, YUAN LI, Stanford Univ., VICTOR BALEDENT, LLB, France, NEVEN BARI, Univ. Stuttgart, Germany, PHILIPPE BOURGES, LLB, France, YONGCHAN CHO, Pusan National Univ., Korea, BENOIT FAUQUE, ESPCI, France, KLAUDIA HRADIL, Univ. Gottingen, Germany, RICHARD MOLE, Forschungseinrichtung HML, Germany, YVAN SIDIS, LLB, France, GUICHUAN YU, Stanford Univ., XUDONG ZHAO, Jilin Univ., China, MARTIN GREVEN, Stanford Univ. — We present our latest experimental results for the pseudogap phase of the model high-Tc superconductor HgBa_2Cu_2O_{4+δ}. Refinement of our polarized neutron diffraction experiments [Y. Li et al., Nature 455, 372 (2008)] using sizable single-crystals of this structurally simple compound consistently show a novel magnetic order below the pseudogap temperature. Furthermore, DC magnetic susceptibility measurements on the highest-quality crystals exhibit a response with highly anisotropic temperature- and doping-dependence, in which the pseudogap anomaly is only visible when the magnetic field is applied along the c-axis. These findings strongly suggest that the new magnetic order competes with the superconductivity. Building on our initial work for optimally-doped HgBa_2Cu_2O_{4+δ} [G. Yu et al., arXiv: 0810.5759], we also briefly discuss preliminary results for the doping dependence of the antiferromagnetic resonance.
9:24AM A34.00008 Spin correlations and magnetic excitation spectrum of electron-doped Nd$_2$−$\alpha$Ce$_\alpha$Cu$_{2+x}$O$_{4+\delta}$ near the magnetic quantum critical point, EUGENE MOYOYAMA, GUICHUAN YU, YUAN LI, Stanford Univ., DANIEL PETITGRAND, LBL, France, KLAUDIA HRADIL, Univ. Gottingen, Germany, RICHARD MOLE. Forschungszentrum Juelich, Germany, PATRICK MANG, INNA VISHIK, Stanford Univ., OWEN VAJK, Univ. of Missouri-Columbia, MARTIN GREVEN, Stanford University — One of the most intriguing issues in the field of high-T$_c$ superconductivity is the electron-hole asymmetry: the hole- or electron-doping of the parent Mott insulators leads to superconductors with differing properties. For the comparatively less-studied electron-doped materials, the antiferromagnetic phase extends more, leading to a greater magnetic susceptibility and a more prominent effect on the magnetic excitation spectrum. The critical temperature $T_0$ defines the boundary between the magnetic and superconducting phases and is a function of the magnetic doping ratio $x$. The magnetic excitation spectrum shows a peak at $T_0$ and a shoulder at $T_0/\alpha$. The critical current density is calculated for the prepared samples from magnetic hysteresis measurements.

9:36AM A34.00009 Studies of broken time reversal symmetry states in high temperature superconductors using high resolution Sagnac interferometry, ELIZABETH SCHEMM, HOVNATAN KARAPETYAN, Stanford University, JING XIA, California Institute of Technology, MARTIN M. FEJER, AHARON KAPITULNIK, Stanford University — Using a cryogenic fiber Sagnac interferometer, we measure polar Kerr effect to high precision in several high-$T_c$ superconductors, concentrating on YBa$_2$Cu$_{3-x}$O$_{7-y}$. Previous work on YBa$_2$Cu$_{3-x}$O$_{7-y}$ showed non-zero Kerr rotations on the order of $\sim 1$ rad, appearing near the pseudogap temperature $T^*$ and marking what appears to be a true phase transition. We continue this study on single crystals and oriented film to further understand the dependence of the observed Kerr signal on crystal direction, as well as to further probe the anomalous response of this effect to magnetic field training.

9:48AM A34.00010 Giant impact of magnetic impurity on stability of stripe order in high-Tc cuprate, MASAKI FUJITA, Institute for Materials Research, Tohoku University, MASANORI ENOKI, Department of Physics, Tohoku University, SATOSHI IUKUBO, KAZUYOSHI YAMADA, World-Preeminent-International Research Center Initiative, Tohoku University — To study the stability of stripe order in cuprate oxides thought impurity-effect, we performed neutron-scattering experiments on La$_{1.88-x}$Sr$_{0.12+y}$Cu$_{1-x}$M$_x$O$_{4+y}$ ($y=0$ for M=Cu, Zn and $y=0.01$ for M=Ga, Fe). Well-defined incommensurate peaks from charge-density-wave order were observed in the low-temperature-orthorhombic phase (LTO) by impurity substitution, and the scattering intensity is much stronger in the Fe-doped system than in the Zn-doped one. Integrated intensity of magnetic peak from spin-density-wave order was also enhanced by Fe-doping, while it does not change so much by Zn - and Ga- substitutions. These results indicate that the static spin and charge stripe orders can be realized in the LTO phase, and the stability is effectively induced by doping the magnetic impurity.

10:00AM A34.00011 Anomalous normal state magneto-resistance in the noncentrosymmetric superconductor Li$_2$Pt$_x$B$_{1-x}$, B. J. TAYLOR, C. MCELROY, T. A. SAYLES, UCSD, A. C. MOTA, ETH-Zurich, M. BRIAN MAPLE, UCSD — The isotropic superconducting compounds Li$_2$PdB and Li$_2$PtB crystallize in a structure lacking physical inversion symmetry. In contrast to the isotropic symmetry breaking superconductors CePt$_3$Si, CeRhSi$_2$, and UIr, to date, no evidence of magnetic order has been reported in either Li$_2$PdB or Li$_2$PtB. Through detailed magnetoresistive and magnetization measurements of Li$_2$PtB, we have observed behavior suggestive of a link between normal state electronic transport and magnetic properties, and behavior that is indicative of superconducting ground state. Corresponding changes in magnetoresistive and magnetic behavior are found where both properties exhibit two distinct features at high and intermediate temperatures. Remarkably, both features evolve as a function of magnetic field and temperature towards the $T=0$ value of the superconducting upper critical field $H_{c2}(0) \approx 1.5$ T. Polycrystalline samples of Li$_2$PtB, with the highest reported values to date for the superconducting critical temperature, $T_c = 3K$, and residual resistivity ratio, $\rho_{RT} / \rho(0) \approx 2$, were used in this study.

10:12AM A34.00012 Glassy effects in magnetotransport in La$_{1.97}$Sr$_{0.03}$CuO$_4$ thin films, X. SHI, J. JAROSZYNSKI, D. POPOVICI, Dept. of Phys. & Natl. High Magnetic Field Lab, Florida State Univ., C. PANAGOPoulos, Dept. of Phys., Univ. of Crete and FORTH & Div. of Phys. & Appl. Phys., Nanyang Tech. Univ., G. LOGVENOV, A. BOLLINGER, I. BOZOVIC, Brookhaven Natl. Lab. — We have studied the in-plane magnetoresistance (MR) in atomically smooth, MBE grown La$_{1.97}$Sr$_{0.03}$CuO$_4$ thin films. The MR was measured at temperatures between 0.6 K and 8 K and in $\beta$ up to 9 T, both parallel and perpendicular to the c-axis. The MR exhibits strong dependence on magnetic field history, such as hysteresis and memory at low $T$, similar to the results on c-axis transport in single crystal samples [1]. Here, however, the difference between field-cooled and zero-field cooled MR vanishes above $T=5$ K, independent of the magnitude and orientation of $B$. Low $T$ noise resistance measurements also will be discussed. The results suggest that the glassiness observed in the films may also originate from the slow charge dynamics at low temperatures. [1] I. Raicic et. al., PRL 101, 177004 (2008).

1 Supported by NSF No. DMR-0403491, NHMFL via NSF No. DMR-0654118, US DOE project MA-509-MACA, EURYI Scheme, MEXT-CT-2006-039047 and the National Research Foundation of Singapore.

10:24AM A34.00013 Novel positive magnetoresistance in lightly doped La$_2$CuO$_4$, I. RAICIC, D. POPOVICI, Dept. of Phys. & Natl. High Magnetic Field Lab, Florida State Univ., C. PANAGOPoulos, Dept. of Phys., Univ. of Crete and FORTH & Div. of Phys. & Applied Phys., Nanyang Technological Univ., T. SASAGAWA, Materials and Structures Lab., Tokyo Inst. of Technology — We have measured magnetoresistance (MR) in single crystals of La$_{1.97}$Sr$_{0.03}$CuO$_4$ and La$_2$CuO$_{4+y}$ at temperatures $0.050 \leq \langle T \rangle \leq 70$ K and fields $B(\leq 1.5 T)$ parallel and perpendicular to the c-axis. Our previous inelastic neutron scattering measurements show that in the compound Nd$_{2-}Ce_{\alpha}$Cu$_{2+x}$O$_{4+\delta}$, genuine long-range antiferromagnetism does not extend as far as traditionally thought, and may not coexist with bulk superconductivity; the system features a magnetic quantum critical point at $x \approx 0.13$, very close to the composition above which superconductivity is first observed [Motyama et al., Nature 445, 186 (2007)]. Here we present new measurements for the instantaneous spin correlations and the magnetic excitation spectrum that aim to refine our understanding of the physics in this interesting doping regime.

1 Supported by NSF No. DMR-0403491, NHMFL via NSF No. DMR-0654118, US DOE project MA-509-MACA, EURYI Scheme, MEXT-CT-2006-039047 and the National Research Foundation of Singapore.

10:36AM A34.00014 Magnetic hysteresis studies of Ti-2223 substituted by Fe and Zn , AY ABOU-ALY, RAMADAN AWAD, IBRAHIM IBRAHIM, Faculty of Science, Alexandria, Egypt, AHMED FARAJ, Physics Department, Faculty of Science, BAU University, Beirut, Lebanon — Effect of Fe and Zn substitutions on the magnetic hysteresis of Ti-2223 are investigated in high magnetic fields up to 9 Tesla and at different temperatures $(T= 5$, 60 and 80 K). The results of magnetic hysteresis loops show that the area of these loops decreases as Fe-content increases, whereas it increases for Zn-substitutions till $x = 0.2$ and then decreases for $x > 0.2$. The magnetization difference $\Delta M$ is found to decay exponentially with temperature at low magnetic fields, according to $\Delta M \propto \exp (-T/T_0)$. The characteristic temperature $T_0$ is found to be varied from 6 K to 40 K and it is related to the applied magnetic field $B$ according to $T_0 \propto B^{-1/n}$. The critical current density is calculated for the prepared samples from magnetic hysteresis measurements and compared with that determined from ac magnetic susceptibility. The results are discussed according to the flux motion and flux pinning.
10:48AM A34.00015 Neutron Scattering Study of Magnetic Field Effect on the Stripe Order in LBCO. ZHI JUN XU, JINSHEWEN WEN, GUANGYONG XU, MARKUS HÜCKER, JOHN TRANQUADA, GENDA GU, BNL. BNL NEUTRON SCATTERING GROUP TEAM — We have been investigating the relationship of stripe order to high-temperature superconductivity in cuprates. In particular, our neutron scattering results indicate that spin-stripe order is present in La$_2$-Ba$_x$CuO$_4$ (LBCO) over a substantial range of doping about x = 1/8, where the bulk superconductivity is anomalously suppressed. Focusing on the x = 1/8 composition, we have recently studied the impact on stripe order of a magnetic field applied along the c-axis [1]. Applying a field up to 7 T, we observed a small enhancement of the intensity of the incommensurate antiferromagnetic superlattice peaks and a slight increase in the ordering temperature. In measurements of the spin dynamics, the field had no significant impact on the small spin gap (∼ 0.5 meV) found in the ordered phase [2]. [1] Jinshew Wen et al., arXiv:0810.4085. [2] J.M. Tranquada et al., arXiv:0809.0711. Work supported by Office of Science, U.S. DOE, under Contract No. DEAC02-98CH10886.

Monday, March 16, 2009 8:00AM - 11:00AM —
Session A35 DMP: Focus Session: Iron Pnictides and Other Novel Superconductors I: Synthesis and New Materials 405

8:00AM A35.00001 Superconductivity in layered pnictides BaIr$_2$P$_2$ and BaRh$_2$P$_2$. DAIGOROU HIRAI, TOMOHIRO TAKAYAMA, Dept. of Advanced Materials, Univ. of Tokyo, RYUJI HIGASHINAKA, HIROKO ARUGA-KATORI, Riken, HIDENORI TAKAGI, Dept. of Advanced Materials, Univ. of Tokyo — The exploration of new superconductors, triggered by the discovery of LaFeAsO(O,F), has concentrated mostly on Fe-based pnictides. A variety of non-Fe pnictides, isostructural to Fe pnictide superconductors, have been known for a long time but not yet fully explored in terms of possible superconductivity. Further exploration of non-Fe pnitride superconductors is important for understanding the key factors in realizing the high Tc in the Fe pnictides. We report new Ir and Rh pnictide superconductors, isostructural to BaFe$_2$As$_2$, BaRh$_2$P$_2$ and BaIr$_2$P$_2$, with Tc = 1.0 and 2.1 K respectively. This discovery demonstrates the presence of superconductivity over a surprisingly broad range of transition metal compounds with ThCr$_2$Si$_2$-type structure from Fe to Ir.

8:12AM A35.00002 Superconductivity and enhanced susceptibility in SrFe$_2$As$_2$ single crystals. S. R. SAHA, N. P. BUTCH, K. KIRSHENBAUM, J. PAGLIONE. Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland — Single crystals of SrFe$_2$As$_2$ grown using a self-flux solution method were characterized via x-ray, transport, magnetization and specific heat studies, revealing a superconducting transition at 21 K which appears far below the magnetostructural transition at 198 K as evidenced by transitions in resistivity and susceptibility. We present experiments which probe the nature of this phase and its relation to the enhancement of magnetic susceptibility in superconducting samples.

3Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

8:36AM A35.00004 Transport, magnetic and thermal properties of MFePO M = La, Pr, and Nd single crystals. RYAN BAUMBACH, JAMES HAMLIN, LEI SHU, DIEGO ZOCCO, NICOLE CRISOSTO, M. BRIAN MAPLE, Department of Physics and IPAPS, University of California, San Diego — The recent discovery of Tc values near 26 K in the compound LaFeAsO$_1-x_F$ induced a torrent of publications on what are now recognized as a new class of Fe-based high temperature superconductors. To date, the phosphorus based versions of these compounds have received little attention due to their comparatively low Tc values. In this work we report the low temperature electrical resistivity, magnetic susceptibility, and specific heat data of single crystalline PrFePO and NdFePO. We also report the effect of annealing on the properties of LaFePO, PrFePO, and NdFePO. A systematic comparison of the occurrence of superconductivity in the series MFePO and MFeAsO (where M is a lanthanide) points to a possible difference in the origin of the superconductivity in these two series of compounds.

3This research was supported by the U.S. Department of Energy (DOE) under Research Grant # DE-FG02-04ER46105 and Research Grant # DE-FG02-04ER46178 and by the National Science Foundation (NSF) under Grant # DMR0802478.

4Student was a participant in the Research Experience for Undergraduates (REU) program at UCSD

8:48AM A35.00005 New ternary phosphide superconductors with the ThCr2Si2 parent structure. NICHOLAS BERRY, CIGDEM CAPAN, University of California Irvine, GABRIEL SEYFARTH, Université de Montréal, University of California Irvine, ZACHARY PISK, University of California Irvine — Compounds with the ThCr2Si2 structure have been studied extensively for over 20 years for their interesting magnetic, superconducting, and heavy fermion properties. We have grown single crystals of new ternary phosphides in this structure in the form of AX2P2, with A being an Alkaline Earth Metal and X a transition metal. We have characterized the properties of these new materials with X-ray, heat capacity, resistivity, and susceptibility measurements and have discovered new superconductors.

9:00AM A35.00006 Magnetic, Thermodynamic, and Transport Properties of Layered Arsenides BaRu$_2$As$_2$ and SrRu$_2$As$_2$. R. NATH, Y. SINGH, D.C. JOHNSTON, Ames Lab. and Dept. of Phys. and Astronomy, Iowa State University, Ames, IA 50011, USA — As part of our effort to search for novel superconductors related to the FeAs high-Tc superconductors, we have synthesized polycrystalline samples of BaRu$_2$As$_2$ and SrRu$_2$As$_2$. The magnetic, transport and thermodynamic properties of the samples were investigated by means of magnetic susceptibility χ(T), electrical resistivity ρ(T), and heat capacity C(T) measurements. The temperature dependence of ρ indicates metallic character for both compounds with a residual resistivity ratio ρ(310 K)/ρ(2 K) of 17 and 7 for the Ba and Sr compounds, respectively. The Cp(T) results indicate a low density of states at the Fermi level with the low-T Sommerfeld coefficient γ ≈ 4.9 and 4.13 mJ/mole K$^2$ for the Ba and Sr compounds, respectively. The Debye temperature θD was estimated to be 270 K and 260 K for the Ba and Sr compounds, respectively. The χ(T) was found to be diamagnetic with a small absolute value for both the compounds. No evidence for superconductivity, a spin density wave, or a structural transition was observed from the C(T) and ρ(T) measurements down to 2 K. However, the χ(T) data for SrRu$_2$As$_2$ exhibit a cusp at ∼ 190 K, possibly an indication of a structural and/or magnetic transition.
9:12AM A35.00007 Robust Ferromagnetism in Ultrathin Films of CeFeAsO

9:24AM A35.00008 Reaction Kinetics of the Formation of SmFeAsO$_{1-x}$F$_x$ High $T_c$ Superconductor Probed by High Energy X-ray Diffraction

9:48AM A35.00010 Superconducting Fe-Based Compounds (A$_{1-x}$Sr$_x$)$_2$Fe$_2$As$_2$ with A = K and Cs with Transition Temperatures up to 37 K.

10:00AM A35.00011 The superconductivity in alkaline containing iron arsenide system.

10:12AM A35.00012 Superconductivity in Sr-122 Iron Arsenide System by Yttrium Doping.

10:24AM A35.00013 High-pressure growth of SmFeAsO$_{1-x}$ single crystals without fluorine doping.
10:36AM A35.00014 Growth of superconducting FeSe films, MICHI NAITO, SHINYA AGATSUMA, SHINYA UEDA, Tokyo University of Agriculture and Technology, TAT TEAM — The recently discovered Fe arsenide and chalcogenide superconductors have provided the superconducting community with a great surprise that Fe-based compounds are not ferromagnetic but superconducting with high Tc. The superconducting Fe arsenides and chalcogenides are also interesting from the viewpoint of superconducting electronics. One can see good lattice compatibility between the superconducting Fe family and the existing III-V and II-VI semiconducting family (GaAs, ZnSe). All-epitaxial super-semiconductor multilayer structures may be ideal for superconducting heterostructures. For this reason we have attempted to grow epitaxial thin films of the superconducting Fe family. Of this family, tetragonal α-FeSe seems to be the easiest to grow thin films. We employed two approaches for FeSe film growth: post-annealing and MBE growth. In the post-annealing, precursor films of Fe are annealed at 500 - 600 °C with Se vapor in an evacuated quartz tube. Annealing with elemental Se produced superconducting FeSe. In the in situ growth, precursor films of Fe were annealed at 500 - 600 °C with Se vapor in an evacuated quartz tube. Annealing with elemental Se produced superconducting FeSe, whereas annealing with Se polycrystalline pellets produced superconducting FeSe with Tc(onset) ~ 10 K. In the MBE growth, we attempted the growth similar to GaAs growth, namely with the vapor rich in Se, expecting self-limiting adsorption of Se. MBE films so far obtained with the growth temperature of 330 °C are nonsuperconducting hexagonal β-FeSe.

10:48AM A35.00015 In situ X-ray Synchrotron Diffraction Study of the Synthesis of LaFeAsO and LaFeAsO1−xFx, R.W. MCCALLUM, Ames Laboratory, Materials Science and Engineering, Iowa State University, Ames, IA 50011, J.-Q. YAN, G.E. RUSTAN, E.D. MUN, S. DAS, R.C. NATH, YOUWEN XU, S.L. BUD’KO, K.W. DENNIS, Ames Laboratory, US DOE, Ames Laboratory, Iowa State University, Ames, IA 50011 — The reaction path for the synthesis of LaFeAsO and LaFeAsO1−xFx by nominally solid state reaction was studied in situ x-ray synchrotron diffraction technique and Differential Thermal Analysis (DTA) in the temperature interval 100 °C ≤ T ≤ 1150 °C. Starting materials were La2As2, Fe3O4, Fe and for the F containing materials LaF3. The results show that the synthesis is characterized by three temperature intervals: (1) below 400 °C, Fe3O4 gradually transforms to FeO. (2) In the temperature interval 400 °C < T < 800 °C, multiple intermediate reactions take place resulting in the formation of La2O3 and FeAs compounds. (3) above 800 °C, reaction leads to the formation of LaFeAsO. Possible reaction paths and the difference between F-free and F-doped samples will be discussed in the talk.
Signals of a Carbon Nanotube Field-Effect Transistor, and discuss the contact effect of the electrodes on the transport properties. We have investigated quantum transport in carbon nanotubes bridged between metallic electrodes on a gate electrode, and discuss the contact effect of the electrodes on the transport properties. To detect electric signals through nanotubes, electrodes must be connected to the nanotubes. The contact with the electrodes sensitively influences their electronic structures and transport properties. Therefore, it is important to discuss the transport properties on the basis of the detailed electronic state calculations that include the effect of the contact with the electrodes. We have investigated quantum transport in carbon nanotubes bridged between metallic electrodes on a gate electrode, and discuss the contact effect of the electrodes on the transport properties.

To detect electric signals through nanotubes, electrodes must be connected to the nanotubes. The contact with the electrodes sensitively influences their electronic structures and transport properties. Therefore, it is important to discuss the transport properties on the basis of the detailed electronic state calculations that include the effect of the contact with the electrodes. We have investigated quantum transport in carbon nanotubes bridged between metallic electrodes on a gate electrode, and discuss the contact effect of the electrodes on the transport properties.

 Electric signals are detected by a gate voltage applied to a gate electrode bridged between metallic electrodes on a carbon nanotube, and discuss the contact effect of the electrodes on the transport properties. We have investigated quantum transport in carbon nanotubes bridged between metallic electrodes on a gate electrode, and discuss the contact effect of the electrodes on the transport properties. 10:12AM A36.00012 Tuning the electronic states of carbon nanotube based devices under magnetic field. SEBASTIEN NANOT, LNCMP - Laboratoire National Des Champs Magnetiques Pulses, BERTRAND RAQUET, WALTER ESCOFFIER, JEAN-MARC BROTO, LNCMP, REMI AUVILLER, STEPHAN ROCHE, CEA - INAC/SPSMS/GT — Carbon nanotubes have already demonstrated their wide potential in nanoelectronics and optoelectronics. In our study, we demonstrate that an applied magnetic field, along with a control of the electrostatic doping, drastically modifies the electronic band structure of a carbon nanotube based transistor. Several examples will be addressed in this presentation. In a parallel configuration (B parallel to the tube axis), a quantum flux threading the tube induces a giant Aharonov-Bohm conductance modulation mediated by Schottky barriers which profile is magnetic field dependent. In the perpendicular configuration, the applied magnetic field breaks the revolution symmetry along the circumference and non conventional Landau states are expected in the high field regime. By playing with a carbon nanotube based electronic Fabry-Perot resonator, we bring evidence that the electronic transmission of the device can be modified by a transverse magnetic field. The field dependence of the resonant states of the cavity reveals the onset of the first landau state at zero energy. These experiments also enlighten the outstanding efficiency of magneto-conductance experiments to probe the electronic properties of carbon based nano-materials.

10:24AM A36.00013 Transport and Magnetism in Template Synthesized Hydrogenated Multiwalled Carbon Nanotubes. ADAM FRIEDMAN, Northeastern University Department of Physics, HYUNKYUNG CHUN, Northeastern University Department of Mechanical and Industrial Engineering, DONALD HEIMAN, Northeastern University Department of Physics, YUNG JOON JUNG, Northeastern University Department of Mechanical and Industrial Engineering, LATIKA MENON, Northeastern University Department of Physics — In this work, we synthesize highly disordered carbon nanotubes by CVD in porous alumina templates. We show that, due to the disorder in the nanotubes, they can easily be made to uptake hydrogen by annealing. We show that this induces ferromagnetism in the nanotubes, and we perform a magnetic study. We also measure the transport properties of the nanotubes. First, we find a rate dependent hysteretic magnetoresistance. We explain the rate dependence through strong magneto-viscosity effects, and we attribute the hysteresis to anisotropic magnetoresistance. We also discover a magnetic field-driven temperature dependent transition from positive to negative magnetoresistance in the ferromagnetic nanotubes that is not observed in similarly disordered un-hydrogenated carbon nanotubes. We attempt to explain this behavior by considering it an order-disorder transition described by the Bright model due to several scattering pathways, that are present in the ferromagnetic nanotubes that are not present in the non-ferromagnetic tubes.

10:36AM A36.00014 Magnetotransport of hybrid nanoparticle-nanowire systems1, DONGKYUN KO, COLE ROBINETTE, XIANWEI ZHAO, FENGYUAN YANG, EZEKIEL JOHNSTON-HALPERIN, The Ohio State University — Semiconductor nanowires decorated with metal nanoparticles have a number of interesting electronic and photonic properties. For example, top-gated field effect transistors based on these hybrid systems have shown charge storage when operated in a floating-gate architecture. In addition, recent measurements have demonstrated that spin relaxation and phase coherence lengths can be extracted from magnetococonductance patterns in the gating response of bare nanowires. Together, these results suggest the possibility of in situ tuning of the spin relaxation length in hybrid systems via modulation of the floating-gate potential. Initial efforts along these lines will be presented, including gating response and low temperature magnetotransport in 50 nm diameter InP nanowires decorated with Au nanoparticles from 20 – 250 nm in diameter. The potential utility of these systems as testbeds for the exploration of spin scattering and transport will be discussed.

1Partial funding for this research was provided by the Center for Emergent Materials at the Ohio State University, a NSF MRSEC (Award Number DMR-0820414).

10:48AM A36.00015 Exploration of conductance peak splitting in carbon nanotube field effect transistors at critical field strengths. JEFFREY D. STEPHENS, JEROME C. LICINI, Lehigh University, A.T. CHARLIE JOHNSON, DOUG R. STRACHAN, DANVERS E. JOHNSTON, SAM KHAMIS, University of Pennsylvania — Carbon nanotube field effect transistors were produced by chemical vapor deposition growth of nanotubes on oxidized silicon substrate. Samples were back gated on doped silicon and contacted with gold/chrome contacts. Conductance measurements were performed at low temperature and high magnetic field using a dilution refrigerator and a superconducting magnet. Data was taken at 0.5 Tesla increments from 0-11Tesla. The differential conductance (dI/dV) shows an interesting asymmetry with bias voltage as well as a near zero bias conductance peak. The near zero bias conductance peak demonstrates splitting at two critical magnetic field strengths on the 0.5T scale. These two critical regimes are further explored on a finer magnetic field scale.

Monday, March 16, 2009 8:00AM - 11:00AM — Session A37 DCP: Focus Session: Fundamental Developments in Density Functional Theory I

8:00AM A37.00001 Insights and Progress in Density Functional Theory. WEITAO YANG1, Duke University — Density functional theory of electronic structure is widely and successfully applied in simulations throughout engineering and sciences. However, there are spectacular failures for many predicted properties, which can be traced to the delocalization error and static correlation error of commonly used approximations. These errors include understimation of the barriers of chemical reactions, the band gaps of materials, the energies of dissociating molecular ions and charge transfer excitation energies. Typical DFT calculations also fail to describe degenerate or near degenerate systems, as arise in the breaking of chemical bonds, and strongly correlated materials. These can all be characterized and understood through the perspective of fractional charges and fractional spins introduced recently. Understanding the errors of functionals in the simplest way possible — as violations of exact conditions for fractional charges and fractional spins — opens the path forward for reduction of the errors and for applications of density functional theory in new frontiers. [P. Mori-Sanchez, A. J. Cohen, and W. T. Yang, Phys. Rev. Lett. 100:146401(2008); Phys. Rev. B,77:115123(2008); J. Chem. Phys. 129:121104(2008); Science, 321:792(2008)]

1in collaboration with A. J. Cohen, P. Mori-Sanchez, and E. R. Johnson

8:36AM A37.00002 Semiclassical origins of density functional theory1. KIERON BURKE, University of California, Irvine — Until the seminal work of Hohenberg, Kohn, and Sham of the mid 60’s, most density functional theory (DFT) was derived from semiclassical approximations. This non-empirical approach shows an intrinsic difference between solids (for which DFT was originally developed) and molecules, and explains many of its more mysterious manifestations. For example, the success of DFT for molecules has nothing to do with the uniform gas. Results include [1] a derivation of the empirical parameter in the B88 exchange functional, [2] PBesol, a new GGA that restores the exchange gradient expansion and improves the band gaps of materials, the energies of dissociating molecular ions and charge transfer excitation energies. Typical DFT calculations also fail to describe degenerate or near degenerate systems, as arise in the breaking of chemical bonds, and strongly correlated materials. These can all be characterized and understood through the perspective of fractional charges and fractional spins introduced recently. Understanding the errors of functionals in the simplest way possible — as violations of exact conditions for fractional charges and fractional spins — opens the path forward for reduction of the errors and for applications of density functional theory in new frontiers. [P. Mori-Sanchez, A. J. Cohen, and W. T. Yang, Phys. Rev. Lett. 100:146401(2008); Phys. Rev. B,77:115123(2008); J. Chem. Phys. 129:121104(2008); Science, 321:792(2008)]]

10:48AM A37.00011 Density Functional with Full Exact Exchange, Balanced Nonlocality of Correlation, and Constraint Satisfaction\footnote{Supported by NSF.}. JOHN P. PERDEW, Physics, Tulane U., VIKTOR N. STAROVEROV, Chemistry, U. of Western Ontario, JIANMIN TAO, Los Alamos National Lab, GUSTAVO E. SCUSERIA, Chemistry, Rice U. — We construct a nonlocal density functional with full exact exchange, while preserving the constraint-satisfaction approach and justified error cancellations of simpler semilocal functionals. This is achieved by interpolating between different approximations suitable for two extreme regions of the electron density. In a “normal region”, the exact exchange-correlation hole around an electron is semilocal because its range is reduced by correlation and because it integrates over a narrow range to −1. “Abnormal” regions, where nonlocality is included, allow those in which exchange can dominate correlation (one-electron, nonuniform high density, and rapidly-varying limits), and those open systems of fluctuating electron number over which the exact exchange-correlation hole integrates to a value greater than −1. Regions between these extremes are described by a local hybrid exact semilocal exchange locally.

Monday, March 16, 2009 8:00AM - 11:00AM
Session A38 DCP: Focus Session: The Chemical Physics of Biological and Biologically-inspired Solar Energy Harvesting

8:00AM A38.00001 Investigation of Excitonic Coherence in LHCII by 2D Electronic Spectroscopy\footnote{Supported by the Department of Energy and the National Science Foundation}. TESSA CALHOUN, University of California, Berkeley — Photosynthesis has evolved with the ability to transfer energy through a matrix of light-harvesting pigment-protein complexes with almost no loss. The accomplishment of this near unity quantum efficiency is a feat that man has yet to understand or replicate. One proposed mechanism integral to this process requires long-lived coherent superpositions of the excitons, delocalized electronic excitations, in these systems. Two-dimensional Fourier transform electronic spectroscopy, already proven to be an ideal technique for investigating these coherences, has been employed to study Light Harvesting Complex II (LHCII), the most abundant light harvesting complex in higher plants. As in other photosynthetic systems previously studied, we observe long-lived coherence lasting beyond many of the excitons’ lifetimes. Furthermore, unique coherence signatures allow the energies of the individual excitons to be located in an otherwise highly congested spectrum. This technique, by which 2D FT electronic spectroscopy can pinpoint excitonic spectral positions, and the resulting implications for LHCII will be discussed.

8:36AM A38.00002 Luminous Solar Concentrators Employing Phycobilisomes\footnote{In collaboration with: Shaul Mukamel, University of California, Irvine}. MARC BALDO, MIT — At current manufacturing growth rates, it is expected to take at least 20 years to produce enough Si-based solar cells to make a significant impact on the world energy supply. Solar concentrators can alleviate manufacturing constraints by focusing light on small solar cells. Luminous solar concentrators (LSCs) are especially promising because they do not need to track the sun to obtain high optical concentration factors. Light incident on an LSC is absorbed by dyes, re-emitted into a guided mode in the slab, and finally collected by a PV cell mounted at the edge of the slab. The maximum optical concentration of an LSC is theoretically limited by the wavelength shift between absorption and emission in the dye. In this presentation, we describe LSCs that mimic a four energy level laser design, maximizing the wavelength shift and minimizing re-absorption losses. We employ phycobilisomes - photosynthetic antenna complexes that concentrate excited states in red algae and cyanobacteria. The phycobilisomes are cast in a solid-state matrix that preserves their internal Frster energy-transfer pathways and large wavelength shift between absorption and emission. Casting is a simple fabrication technique that also eliminates any need for expensive high-index glass or plastic. By comparing the performance of intact and decoupled complexes, we establish that energy transfer within intact phycobilisomes reduces LSC self-absorption losses by approximately (48±5)%. These results suggest that phycobilisomes are the model for a new generation of cast LSCs with improved efficiency at high optical concentrations.

9:12AM A38.00003 Coherent Multidimensional Spectroscopy of Photosynthetic Complexes: Manipulating Quantum Pathways by Optical Pulse Sequences\footnote{In collaboration with: Darius Abramavicius and Dmitri Voronine, University of California, Irvine}. DARIUS ABRAMAVICIUS\footnote{1}, University of California, Irvine — The response of chromophores aggregates to sequences of femtosecond laser pulses is simulated using the nonlinear excitation equations. The nonlinear response can be interpreted in terms of the scattering of elementary excitations, quasiparticles, rather than as transitions among eigenstates. Applications are made to the Fenna-Matthews-Olson (FMO) and the PSI light harvesting complexes. Some fundamental symmetries of multidimensional optical signals are used to design techniques that can selectively resolve coherent quantum dynamics and incoherent energy dissipation. Simulations show damped oscillations of cross peaks corresponding to evolution of coherences, without interference from incoherent population relaxation. Energy transfer pathways are seen through the redistribution of crosspeak amplitudes. Resolution is enhanced by employing specific pulse polarization configurations to generate chirality-induced signals. New pulse sequences are designed to generate signals that are induced by correlations among elementary excitations. Specific phase-matching directions can target the correlated dynamics of double excitations. Cross peaks in 2D correlation plots are interpreted in terms of quasiparticle scattering and shown to reveal the double-exciton wavefunction, projected into products of single-excitations. Uncorrelated double-exciton states do not show up in the spectra due to quantum interference among pathways. The proposed techniques amplify cooperative dynamical features and reveal information on the robustness of quantum states to fluctuating environments. In collaboration with Darius Abramavicius and Dmitri Voronine, University of California, Irvine, CA 92697.

9:48AM A38.00004 Exploring Nanophotovoltaic Molecules using STM\footnote{In collaboration with: Shaul Mukamel, University of California, Irvine}. CHENGGANG TAO, University of California at Berkeley, JIBIN SUN, XIAOWEI ZHANG, R. YAMACHIKA, D. WEGNER, Y. BAHRI, G. SAMSONIDZE, S. LOUIE, T. TILLY, R. SEGALMAN, M. CROMMIE — Composite molecular solar cells are a promising and exciting alternative to traditional silicon or gallium arsenide solar cells, but the power conversion efficiency remains low. In order to further increase this efficiency, a deeper understanding of the microscopic mechanisms at work in organic solar cells is needed. Using scanning tunneling microscopy and spectroscopy we have investigated nanophotovoltaic molecules that combine both donor and acceptor elements. Submolecular spectral resolution reveals the energy level alignment within these composite molecular structures. This information should be useful for understanding the energy conversion pathways within molecular solar cells, and for developing higher efficiency solar cell materials.

10:00AM A38.00005 New highly polar semiconductor ferroelectrics for solar energy conversion devices\footnote{Supported by the Department of Energy and the National Science Foundation}. ANDREW M. RAPPE, ILYA GRINBERG, JOSEPH W. BENNETT, University of Pennsylvania — Solar energy is a promising long-term solution for future energy requirements; however, current solar energy conversion devices are plagued by low efficiency. The use of ferroelectric ABO$_3$ perovskite oxides is one approach for boosting conversion efficiency. Ferroelectric oxides possess spontaneous polarization and have been shown to produce a bulk photovoltaic effect, in which charged carriers, specifically electrons and holes, separate to prevent recombination. Once separated, the high-energy electrons are available for electrical work or for the catalytic splitting of water into hydrogen and oxygen. Currently, most solid oxide ferroelectrics have a band gap of at least 3 eV, absorbing primarily in the ultra-violet (UV) region. Since UV light comprises only 8% of the solar spectrum, new materials with a decreased band gap and large polarization would be highly desirable. We use first-principles density functional theory (DFT) calculations to investigate the ground state structures of PbTiO$_3$ solid solutions containing Ni, Pd and Pt. We predict that these proposed materials will display a decreased band gap when compared to PbTiO$_3$, while maintaining or enhancing polarization. They are promising candidates for use as semi-conducting ferroelectric substrates for solar conversion devices.
Non-Markovian process. This efficiency measure has applications to the study of the quantum transport efficiency and engineering of light-harvesting devices.

We derive a new method for computing the Förster coupling between nanoparticles in an arbitrary electrostatic environment. We calculate the self-consistent electronic structure of an exciton, including the electron-hole attraction, in a nanoparticle within the two band effective mass approximation. Self-interaction of the electron and the hole are removed and the eigenstate is approximated as a product state of the electron and hole wavefunctions. The environment is incorporated via boundary conditions on Poisson’s equation and arbitrary dielectric background. The transfer rate of the exciton via Förster coupling to a neighboring nanoparticle is computed, without making a dipole approximation, from the results of the self-consistent calculation. Departure from the usual $1/R^3$ dependence are calculated, as well as specific cases where gates or additional nanoparticles are present.

Non-Markovian Environmental Contributions to the Efficiency of Energy Transfer. CESAR RODRIGUEZ-ROSARIO, PATRICK REBENTROST, ALAN ASPURU-GUZIK. Harvard University — Non-Markovian environmental contributions of the environment to the efficiency of energy transfer by considering a non-Markovian environment and its interplay with the system Hamiltonian. We focus on the role of memory effects of different orders in time, and their competition that affect the energy transfer by defining the efficiency of the non-Markovian process. This efficiency measure has applications to the study of the quantum transport efficiency and engineering of light-harvesting devices.

Spatially correlated fluctuations and coherence dynamics in photosynthesis. Z. G. YU, M. A. BERDING, SRI International, HAOBIN WANG, New Mexico State University — Recent multicolor photon-echo experiments revealed a long-lasting quantum coherence between excitations on donor and acceptor in photosynthetic systems. Identifying the origin of the quantum coherence is essential to fully understand photosynthesis. Here we present a generic model in which a strong intermolecular steric restoring force in densely packed pigment-protein complexes results in a spatial correlation in conformational (static) variations of chromophores, which in turn induces an effective coupling between high-frequency (dynamic) fluctuations in donor and acceptor. The spatially correlated static and dynamic fluctuations provide a favorable environment to maintain quantum coherence, which can consistently explain the photon-echo measurements [1].

**Session A39 DBP: Cellular Biomechanics**

**8:00AM A39.00001** Loss of an actin crosslinker uncouples cell spreading from cell stiffening on gels with a gradient of stiffness. QI WEN, Department of Physics, University of Pennsylvania, FITZROY J. BYFIELD, Institute for Medicine and Engineering, University of Pennsylvania, KERSTIN NORDSTROM, Department of Physics, University of Pennsylvania, PAULO E. ARRATIA, Departments of Mechanical Engineering and Applied Mechanics, University of Pennsylvania, R.TYLER MILLER, Departments of Medicine and Physiology, Case-Western Reserve University, PAUL A. JANMEY, Institute for Medicine and Engineering, Departments of Physics, Engineering, University of Pennsylvania — We use microfluidics techniques to produce gels with a gradient of stiffness to show the essential function of the actin crosslinker filamin A in cell responses to mechanical stimuli. M2 melanoma cells null for filamin A do not alter their adherent area in response to increased substrate stiffness when they link to the substrate only through collagen receptors, but change adherent area normally when bound through fibronectin receptors. In contrast, filamin A-replete A7 cells change adherent area on both substrates and respond more strongly to collagen 1-coated gels than to fibronectin-coated gels. A7 cells alter their stiffness, as measured by atomic force microscopy, to match the elastic modulus of the substrate immediately adjacent to them on the gradient. M2 cells, in contrast, maintain a constant stiffness on all substrates that is as low as that of A7 cells on the softest gels achievable (1000 Pa). By contrasting the responses of these cell types to different adhesive substrates, cell spreading can be dissociated from stiffening.

**8:12AM A39.00002** Substrate Induced Osteoblast-Like Differentiation of Stromal Stem Cells. JACQUELINE BELIZAR, Miller Place High School, REENA GLASER, MATTHEW HUNG, Smithtown High School West, MARCIA SIMON, VLADIMIR JURUKOVSKI, MIRIAM RAFAILOVICH, Stony Brook University, ALICE SHIH — We have demonstrated that Adipose-derived stem cells (ASCs) can be induced to biomineralize on a polybutadiene (PB) coated Si substrate. The cells began to generate calcium phosphate deposits after a five-day incubation period in the absence of dexamethasone. Control cells plated on tissue culture PS culture dish (TCP) did not biomineralize. In addition, the biomineralizing culture retained proliferative cells In order to determine whether the induction was transient, we transferred the cells exposed to polybutadiene after 14 and 28-day incubation periods to TCP dishes. These cells continued to biomineralize. Genetic testing is underway which will determine whether differentiation is maintained after transfer.

**8:24AM A39.00003** Mechanical anisotropy of viscoelasticity in biological cells. MING-TZO WEI, H.D. OU-YANG, Lehigh University — The mechanism that biological cells use to remodel their cytoskeletal structure in response to external stress is unclear. Experimental observations suggest that the cells remodel their skeleton in a manner that is directionally responsive to the external stress. In order to understand these directional responses, we developed a method to measure the rheological response of the cell in orthogonal directions simultaneously. To achieve controlled stimulation and detection, we used a dual-beam optical tweezers, which used a pump and probe scheme to measure the storage and loss modulus of the cellular cytoskeleton. The pump was used to manipulate extracellular micro-particles which were attached to the actin cytoskeleton through trans-membrane integrin alpha receptors. By measuring two independent regions of the cell, we were able to generate a localized mechanical stress on the outer surface of the cell while observing the directionally specifically inside response.
8:36AM A39.0004 Traction forces associated with shape changes in migrating amoeboid cells  
BALDOMERO ALONSO-LATORRE, JUAN C. DEL ALAMO, EBBIE BASTOUNIS, RUDOLPH MEILI, RICHARD FIRTÉL, JUAN C. LASHERS — University of California, San Diego — Amoeboid motility results from the repetition of a repertoire of shape changes (motility cycle). We studied the dominant changes and their relation to the activity and localization of cytoskeletal proteins by applying Principal Component Analysis (PCA) to measurements of cell shape, traction forces and F-actin concentration in migrating Dictyostelium cells. Using wild-type cells (wt) as reference, we investigated myosin II activity by studying myosin II-null (mhc-) and essential light chain-null cells (mhc-). Only three PCA modes are enough to represent 67% of the variance of cell area: dilation/elongation, a half-moon shape and a bulging of the front/back. These modes are similar for wt, mhc- and mhc- but they are implemented more slowly in mhc-. The second mode, which represents sideways protrusion/retraction and is associated to lateral asymmetry in the traction forces, is significantly less important in mhc-.

These results suggest that migration speed decreases in the absence of myosin II due to a reduced control on the spatial organization of the cell stresses.

8:48AM A39.0005 Imaging spatiotemporal redistribution of cellular traction stesses during fibroblast migration on a physiologically relevant ECM mimic  
ZHI PAN, YAJIE LIU, KAUSTABH GHOSH, Stony Brook University, DHRUV NANDAMUDI, Monta Vista High School, DANNY STEPP, North Shore Hebrew Academy High School, TOSHIKO NAKAMURA, RICHARD CLARK, MIRIAM RAFAILOVICH, Stony Brook University — To better understand the dynamics of cell migration, we measured the spatiotemporal redistribution of cellular traction stresses during fibroblast migration at a submicron level and correlated it with nuclear translocation on a physiologically relevant ECM mimic. We found that nuclear translocation occurred in pulses whose magnitude was larger on the low ligand density surfaces (LLDS) than on the high ligand density surfaces (HLDS). Large nuclear translocations only occurred on LLDS when the rear traction forces completely relocated to a posterior nuclear location, while such relocation took much longer time on HLDS, probably due to the greater magnitude of traction forces. Our results suggest that the reinforcement of the traction forces around the nucleus is a critical step during fibroblast migration, serving as a speed regulator, which must be considered in any dynamic molecular reconstruction model of tissue cell migration. A traction gradient foreshortening model was proposed to explain how the relocation of rear traction forces leads to pulsed fibroblast migration.

9:00AM A39.0006 Achieving in-vitro axonal polarization by using micro-patterns  
SOPHIE ROTH, INSTITUT NEEL, MCBT ET CRETA, CNRS GRENOBLE — IN, INSERM UMR 836, JACQUES BROCARD, SYLVIE GORY-FAURE, GIN, INSERM UMR 836, CATHERINE VILLARD, INSTITUT NEEL, MCBT ET CRETA, CNRS GRENOBLE — Our project is based on the elaboration of in vitro neuron networks as simplified models to explore the relation between neuronal architecture and biological function. Beyond a control of soma and neurite position, our first goal was to achieve in-vitro axonal differentiation of embryonic E18 hippocampal mouse neurons by the mean of geometrical growth constraints, i.e. by the use of adhesive micro-patterns on siliconized glass substrates. Such a process thus excludes chemical guidance or specific adhesion mechanisms. This study explores two different types of geometrical constraints: Axons from the soma to the neurite tip are compelled to adopt the shape of isolated elastic beams, which model semiflexible polymers, the critical buckling load is enhanced when branched supports are included. Therefore, we conjecture that an optimal branching angle is found by looking at the competition between branching providing collective structural support, which results in polymerization of an axon with 39% of efficacy (N= 160 cells, 3 different cultures). The second one derives from the suggested relationship between neurite mechanical tension and axonal elongation, and is based on the design of wavy neurite’s shape. Its efficacy reach 0.51% (N= 300 cells, 3 different cultures). The combination of these two constraints into a final pattern yields an efficacy of 82% (N= 83 cells, 2 different cultures). These results not only provide an important tool for creating neural model networks but also point out an important role of intrinsic neurite tension during axon differentiation.

9:12AM A39.0007 Matrix rigidity optimizes the polarization of stem cells  
ASSAF ZEMEL, Institute of Dental Sciences, the Hebrew University-Hadassah Medical Center, Jerusalem, 91120, Israel, FLORIAN REHFELDT, Georg-August University, Ill. Physics Institute, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany, ANDRE BROWN, DENNIS DISCHER, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104, USA, SAMUEL SAFRAN, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovot 76100, Israel — We present a theoretical model and experiments to explain the non-monotonic dependence of stress-fiber polarization in stem cells on matrix rigidity. The theory generalizes the treatment of elastic inclusions to “living” inclusions (cells) whose active polarizability, unlike non-living matter, depends on the feedback of cellular forces that develop in response to matrix stresses. We demonstrate experimentally that the stress fibers in adult mesenchymal stem cells, generally orient parallel to the long axis of the cells, with an anisotropy that depends non-monotonically on substrate stiffness. Consistent with these experiments, our theory predicts that the magnitude of the cellular force increases monotonically with the matrix rigidity while the polarization anisotropy shows a maximum that depends on the cell shape and the elastic modulus of the medium. These findings offer a mechanical correlate for the observation that stem cell differentiation optimizes in a range of matrix rigidities that depends on the tissue type.

9:24AM A39.0008 Structure at the Leading Edge  
D. A. QUINT, J. M. SCHWARZ, M. C. MARCHETTI, Syracuse University — The leading edge of a crawling cell is propelled forward by a polymerizing network of branched actin filaments. This emergent structural array seems to be rigid enough to support and push against the cell membrane within the appropriate time scales under which cell motility can be realized. We seek to understand the strategies different cell types use to generate the large force required to push cells through the extracellular matrix. We model the actin network as a collection of isolated elastic beams, which model semiflexible polymers, the critical buckling load is enhanced when branched supports are included. Therefore, we conjecture that an optimal branching angle is found by looking at the competition between branching providing collective structural support, which results in polymerization of an axon with 39% of efficacy (N= 160 cells, 3 different cultures). The second one derives from the suggested relationship between neurite mechanical tension and axonal elongation, and is based on the design of wavy neurite’s shape. Its efficacy reach 0.51% (N= 300 cells, 3 different cultures). The combination of these two constraints into a final pattern yields an efficacy of 82% (N= 83 cells, 2 different cultures). These results not only provide an important tool for creating neural model networks but also point out an important role of intrinsic neurite tension during axon differentiation.

9:36AM A39.0009 Chemotactic strategy of Vibrio alginolyticus studied with an optical trap  
SUDDHASHIL CHATOPADHYAY, TUBA ALTINDAL, XIE LI, XIA-LUN WU, University of Pittsburgh — The canonical "run" and "tumble" mode of chemotaxis, employed by multiple flagellated cells such as Escherichia coli, has been studied in great detail over the years. In this work we will demonstrate the usage of an optical trap for studying the chemotaxis of cells belonging to the single flagellated strain of Vibrio alginolyticus. This method allows precise and direct observation of chemotactic response, while the cell is exposed to various chemical signals (positive/negative gradient or no chemicals). We have studied the response of the flagellar motor with a precise control on the input signal (chemical gradient), such that a cell can be forced to move up or down a chemical gradient, a control which is not attainable for free swimming cells. The optical trap does not restrict the rotational motion of the bacterium and allows the state of the motor (clockwise or counter clockwise rotation) to be monitored continuously. Our group has recently observed an active flagellar movement (called the "flagellar flick") that is used by cells of Vibrio alginolyticus to reorient their direction of swimming. We consider this mode in addition to "back and forth" swimming employed by these cells. A modified chemotactic strategy is proposed and tested using the optical trap.

9:48AM A39.0010 Chemotaxis in Marine Bacterium Vibrio alginolyticus  
LI XIE, SUDDHASHIL CHATOPADHYAY, TUBA ALTINDAL, XIAO-LUN WU, University of Pittsburgh — We investigated swimming behavior of marine bacterium Vibrio alginolyticus in an uniform chemical environment. The typical bacterial trajectory consists of consecutive run (forward swimming) and reverse (backward swimming) intervals with occasional sudden changes of swimming directions, which we call "flagellar flicks". This mode of chemotaxis is different from the canonical run-and-tumble strategy adopted by Escherichia coli and monotonous-like in the bacterial swimming time series which results in the apparent turbulent dispersion. We measured the statistical distributions of run T_{run} and reverses T_{rev} time intervals, P(T_{run}) and P(T_{rev}), and found that while the back-swimming time appears to have a well-defined time scale of 0.5 s, the forward swimming time is more broadly distributed, suggestive of a Poisson process.

Measurements of the time interval T_{flick} between the consecutive directional changes show that P(T_{flick}) is also peaked at a finite time, T_{flick} ~ 1 s, and the mean directional change is ∆θ ~ 70°. Interestingly, this ∆θ observed is nearly optimal for efficient randomization of swimming directions. Altogether, our experiments suggest that V. alginolyticus employs both run-and-reverse and flicking activities for chemotaxis, and this behavior presumably optimizes their foraging efficiency in a turbulent environment.
The flagellar “flick”: direction randomization in single flagellated cells of V. alginolyticus

Follow a “back” and “forth” swimming pattern. Inspired by the observation that V. alginolyticus cells were able to rapidly accumulate around a point source of a chemoeffectant, we have identified a previously unknown mechanism in which an active movement of the flagellum is used to randomize the swimming direction. Fluorescently labelled cells clearly demonstrated that bending of the flagellum is responsible for imparting direction changes to the cell body. Clues obtained from high speed video, bright-field microscopy and fluorescent imaging suggest a series of steps involved in the flagellar “flick”. An investigation of the energetics of the proposed mechanism leads to the conclusion that the directional change may be connected to the flagellar motor, which normally propels the cell body.

10:12AM A39.00012 Probing the Dynamics of Cellular Traction Forces with Magnetic Micropost Arrays

CORNELIA KRAMER, Johns Hopkins University, CHRISTOPHER CHEN, University of Pennsylvania, DANIEL REICH, Johns Hopkins University — Mechanical forces on living cells are associated with changes in cellular function. For example, vascular smooth muscle cells are known to undergo a mechanical feedback response to increased stress, which can result in atherosclerosis. We have recently developed a magnetic micropost array, a novel device for measuring cellular traction forces that simultaneously enables the application of localized external forces to cells. The device consists of an array of micrometer scale holes, each of which can be selectively actuated by a micromagnet. Forces are applied to the adherent cell via a magnetic torque on a cobalt nanowire embedded in a single post. Initial results showed an active and non-local cellular response to applied forces in mouse fibroblast cells. We will present results on the spatially resolved dynamics of traction forces exerted by smooth muscle cells over time in response to constant and time-varying stimulation. The observation of biochemical and mechanical regulation of the subcellular redistribution of force may allow insights into cellular mechanotransduction and control of cell function.

10:24AM A39.00013 Differential cellular response to linear and strain-stiffening hydrogel substrates

JESSAMINE P. WINER, SHAHNA A. OAKE, BETHANY C. BAUMANN, PAUL A. JANMEY, University of Pennsylvania — Many cell types act as tensometers, modulating their spread area, motility, and protein expression in response to the substrate stiffness. Studies of stiffness sensing typically employ linear elastic materials whose stiffness is independent of the applied strain. Biological gels, however, often stiffen in response to increasing strain. Fibroblasts and mesenchymal stem cells adherent to linearly elastic gels typically display a small, round phenotype on soft substrates and increase spread area as the elastic modulus of their substrate increases. On the strain-stiffening biopolymer gel fibrin, the same cell types are maximally spread even when the gel’s low strain elastic modulus would predict a round morphology. Traction microscopy reveals that cells apply active displacements of several microns up to five cell lengths away, and atomic force microscopy shows that these displacements locally stiffen the gel by deforming it beyond its linear range. The magnitude of cell-applied strains is inversely related to the gel’s low strain elastic modulus and results in long distance cell-cell communication and alignment.

S. BAILEY, Department of Physics, The Ohio State University, J. GUMP, Naval Surface Warfare Center, Indian Head, MD, R. SOORYAKUMAR, C. JAYAPRAKASH, Department of Physics, The Ohio State University, M.S. VENKITESHWAR, M. BULLMORE, Department of Optometry, The Ohio State University, M. TWA, College of Optometry, University of Houston — Focusing the eye on a near object results in an increase in its optical power brought about by contraction of the ciliary muscles and an increase in the lens surface curvature. Distant vision occurs when the muscular force flattens the lens. Central to the ability of the lens to alter shape are its mechanical properties. Thus, given that hardening of the lens would impede deformation and reduce its ability to undergo the changes required for accommodation, a noninvasive approach to measure the elastic properties of the lens is valuable. We present results of Brillouin scattering from bovine and human lenses (from the organ donor program at The Ohio State University) that measure their high frequency acoustic response. These measurements are conducted with a few milli-watts of laser power and, in the case of bovine lenses, from entire intact eye globes, allow the stiffness of scattering from bovine and human lenses (from the organ donor program at The Ohio State University) that measure their high frequency acoustic response. The results will be compared to values of the shear- and bulk-moduli determined from other techniques and the implications of differences in these moduli discussed.

10:48AM A39.00015 Physical Description of Mitotic Spindle Orientation During Cell Division

ANDREA JIMÉNEZ-DALMARONI, University College London, UK, MANUEL THÉRY, Laboratoire Biopuces CEA, Grenoble, France, VICTOR RACINE, MICHEL BORNENS, Institut Curie, Paris, France, FRANK JÜLICHER, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — During cell division, the duplicated chromosomes are physically separated by the action of the mitotic spindle. The spindle is a dynamic structure of the cytoskeleton, which consists of two microtubule asters. Its orientation defines the axis along which the cell divides. Recent experiments show that the spindle orientation depends on the spatial distribution of cell adhesion sites. Here we show that the experimentally observed spindle orientation can be understood as the result of the action of cortical force generators acting on the spindle. We assume that the local activity of force generators is controlled by the spatial distribution of cell adhesion sites determined by the particular geometry of the adhesive substrate. We develop a simple physical description of the spindle mechanics, which allows us to calculate the torque acting on the spindle, as well as the energy profile and the angular distribution of spindle orientation. Our model accounts for the preferred spindle orientation, as well as the full shape of the angular distributions of spindle orientation observed in a large variety of pattern geometries. M. Théry, A. Jiménez-Dalmaroni, et al., Nature 447, 493 (2007).
8:12AM A40.00002 Structural and functional allostery wiring diagrams in GroEL/GroES1. RIINA TEHVER, JIE CHEN, D. THIRUMALAI, University of Maryland — Repeated cycling between distinct allosteric states is required for the functions of numerous biological nanomachines. Determining the specific residues that are responsible for transmitting allosteric signals is needed to understand their operation. Using structural perturbation analysis and evolutionary correlations of mutations of residues, we determine networks of key residues in molecular chaperonin GroEL and its cochaperonin GroES. GroEL is a molecular machine that rescues aggregation-prone misfolded proteins. Its functional cycle consists of a series of large-scale allosteric transitions between the T, R, R' and R'' states. The corresponding structural rearrangements facilitate substrate protein capture, refolding, and release. The networks of residues we find provide a microscopic foundation for the cooperativity of the allosteric transitions and a linkage between substrate protein binding and ATPase activity of GroEL.

8:24AM A40.00003 Decoupling of Protein Dynamics from the Solvent Viscosity. SHEILA KHODADADI, Department of Polymer Science, The University of Akron, ARMISTEAD KATHLEEN, University of Kansas, ALEXEI SOKOLOV, Department of Polymer Science, The University of Akron — Studies show that solvent viscosity has a strong influence on protein dynamics and activity, but the detailed mechanism of the solvent-protein interactions is not fully understood. Using dielectric spectroscopy we were able to identify a protein related relaxation process of myoglobin in water-glycerol and water-sucrose solutions. We demonstrate that the rate of biochemical reaction (taken from literature1) follows the protein related relaxation observed in dielectric spectra. Also our results reveal decoupling of the protein dynamics from solvent viscosity. This finding explains the known in literature decoupling of protein activity from solvent viscosity and demonstrates direct connection between protein dynamics and its functionality. Possible microscopic mechanisms of this decoupling are discussed at the end. 1. Kleinert, T.; et al. Biochemistry 1998, 37, 717.

8:36AM A40.00004 Phosphorylation of histone H3 Thr 118 converts nucleosomes into a higher-mass complex1. JUSTIN NORTH, MICHAEL POIRIER, Department of Physics, The Ohio State University, MICHELLE FERDINAND, JENNIFER OTTESEN, Department of Biochemistry, The Ohio State University — The nucleosome is the fundamental unit of DNA compaction in eukaryotes by which 147 base pairs of DNA wrap 1.7 times around a protein complex called the histone octamer. Numerous chemical modifications are found in vivo that alter octamer surface charge and shape. One such modification is phosphorylation of histone H3 residue Thr 118 located in the dyad region of the nucleosome. We find that phosphorylated H3 T118 (H3 pT118) octamer, when reconstituted with DNA of about 200bp, suppresses nucleosome formation and promotes formation of a higher-mass DNA-protein complex. Coordinateophorically, dephosphorylation of H3 pT118 octamer by phosphatase results in reconstitution of normal nucleosomes. DNase I footprinting reveals that while DNA contacting the octamer surface in nucleosomes is less accessible than free DNA, the entire DNA strand is equally accessible in the higher-mass complex and is digested at one-third the rate of free DNA.

8:48AM A40.00005 The Role of gp120 Flexibility in Binding. A.J. RADER, Indiana University-Purdue University Indianapolis — Current treatment of the human immunodeficiency virus (HIV) focuses on delivering several drugs to to a few specific viral protein targets. A complementary antiviral therapy involves targeting the process of viral entry. Viral entry is a dynamic process which involves a series of conformational changes by the HIV envelope glycoproteins (gp120 and gp41). The extraordinary conformational flexibility, glycosylation and strain variability of these proteins complicate the development of an effective vaccine. We present results from the graph theoretical analysis of flexibility and rigidity using the Floppy Inclusion and Rigid Substructure Topography (FIRST) software for all known HIV-1 gp120 structures. Comparisons between structures using this mechanical stability and intrinsic flexibility is used to identify a consensus rigid region that might serve as drug targets in a pre-complex conformation. Furthermore, analysis of structures with various binding partners illustrates the differential partitioning of mechanical flexibility and strain. We relate these differences in mechanical stability to thermodynamic differences in binding and stabilizing mutations.

9:00AM A40.00006 AP helical stability in salt solutions. ELIANA ASCIUTTO, Duquesne University, KAN XIONG, University of Pittsburgh, SANFORD ASHER, University of Pittsburgh, JEFFRY MADURA, Duquesne University — Protein dynamics depends on the environment and the inclusion of salts in the simulation of folding/unfolding becomes extremely necessary when comparing energy barriers or reaction rates with experimental results. The aim of this study is to investigate the effects of three sodium salts: NaClO4, NaCl and Na2SO4 on the helical stability of AP, a mainly alanine peptide. The dependence of the peptide helical stability on the environment has been studied using Replica Exchange Molecular Dynamics (REMD) simulations, Circular Dichroism (CD) and Ultraviolet Raman Resonance Spectroscopy (UVRS) experiments. It was found that NaClO4 solution strongly stabilizes the helical states and that the order in which sodium salts stabilize the peptide helical states follows a reverse Hofmeister Series (ClO4−<Cl−<SO42−). Another interesting result found is that ClO4− ions are attracted to the backbone; Cl− ions are repelled while SO42− ions are attracted to the positive side chains. A thorough investigation of the ion effects on the first and second solvation water along with the Kirkwood-Buff theory for solutions allowed us to explain the physical mechanisms involved in the observed ion specific effects.

9:12AM A40.00007 Computational modeling of protein folding assistance by the eukaryotic chaperonin CCT. MANORI JAYASINGHE, GEORGE STAN, University of Cincinnati — Chaperonins are biological nanomachines that promote protein folding using energy derived from ATP hydrolysis. Structurally, chaperonins are large oligomeric complexes that form double-ring construct, enclosing a central cavity that serves as folding chamber. Our focus is on the substrate binding mechanisms of the Eukaryotic chaperonin CCT and Archaeal chaperonin Thermosome. We contrast our results with the annealing action of the bacterial chaperonin GroEL of E. coli, currently the best studied for chaperonin machinery. CCT was suggested to be more selective towards the substrate recognition where as GroEL is more promiscuous due to the hydrophobic interactions. We study the interaction of CCT with Tubulin, one of its stringent substrates. Using molecular docking and molecular dynamics simulations, we probe binding of a βtubulin peptide (205-274) to the CCTβ apical domain. We identify a versatile binding mechanism, involving mostly hydrophobic interactions with the helical region and electrostatic interactions with the helical protrusion region. This specific substrate-protein recognition mechanism is likely to be optimized for specific substrate protein-CCT subunit pairs.

1 American Heart Association
Substrate protein recognition mechanism of archaenal and eukaryotic chaperonins. Chaperonins are double ring-shaped biological nanomachines that assist protein folding. Spectacular conformational changes take place within each chaperonin ring using energy derived from ATP hydrolysis. These changes result in transitions from the open to the closed ring. Substrate proteins bind to the open ring and are encapsulated within the closed ring cavity. We focus on the substrate protein recognition mechanism of archaenal and eukaryotic chaperonins. We predict substrate protein binding sites using structural and bioinformatic analyses of functional states during the chaperonin cycle. Based on large changes in solvent accessible surface area and contact maps we glean the functional role of chaperonin amino acids. During the transition between open to closed chaperonin ring, the largest change in accessible surface area of amino acids is found in helical protrusion and two helices located at the cavity opening. Our calculations suggest that the helical protrusion and two helices constitute the substrate protein binding site.

At very low temperatures, we simulate the Kondo lattice model with the continuous-time quantum Monte Carlo method recently developed by one of the authors to developed an exact description of heavy fermion materials. We propose a layered Kondo lattice model for the quantum critical superconductor $\beta$-YbAlB$_4$, and we examine the effects of antiferromagnetic interactions on the composite pairing. If both gaps are d-wave, they couple linearly, mutually enhancing the superconducting transition temperature.

**Monday, March 16, 2009 8:00AM - 10:24AM**

**Session A41 DMP: Heavy Fermions 413**

8:00AM A41.00001 Realistic simulation of Kondo lattice model: application to Ce compounds, MUNEISHI MATSUMOTO, MYUNG JOON HAN, UC Davis, JUNYA OTSUKI, Tohoku University, Japan, SERGEY SAVRASOV, UC Davis — In order to do a good description of heavy fermion materials at very low temperatures, we simulate the Kondo lattice model with the continuous-time quantum Monte Carlo method recently developed by one of the authors combined with the conduction-electron density of states given by first-principle calculations and performing self consistency using dynamical mean field theory. We discuss our results for Ce compounds down to the temperature range of $O(1)$ K using realistic values of crystal-field and spin-orbit level splitting.

8:12AM A41.00002 Layered Kondo lattice model for quantum critical superconductor $\beta$-YbAlB$_4$, ANDRIY NEVIDOMSKYY, PIERS COLEMAN, Rutgers University — We perform a theoretical analysis of the magnetic and electronic properties of the quantum critical heavy fermion superconductor $\beta$-YbAlB$_4$. Using a combination of the realistic material modelling and single-ion crystal field analysis, we propose a layered Kondo lattice model for this system, in which two dimensional boron layers are Kondo-coupled via interlayer Yb moments in a $J_g = \pm 5/2$ state. This model fits the measured single ion magnetic susceptibility and predicts a substantial change in the electronic anisotropy as the system is pressure-tuned through the quantum critical point. An interesting connection is made between this model and the Kondo effect in Coulomb-blockaded quantum dots. We also calculate the Fermi surface and the angular dependence of the extremal orbits relevant to the de Haas-van Alphen measurements.

8:24AM A41.00003 Interplay of Composite Pairs and Magnetism in Heavy Fermion Superconductors, REBECCA FLINT, PIERS COLEMAN, Rutgers University — Superconductivity in PuMg$_{2x}$, $M = \{Co, Rh\}$ and NpPd$_2$Al$_2$ can be treated within a two channel Kondo lattice model, where the electron-spin scattering develops an Andreev component, creating a composite bound state of a spin-flip and a pair of electrons. We extend this model to CeMn$_2$, where magnetism and superconductivity exist in close proximity by including antiferromagnetic interactions. Different crystal symmetries lead to composite pairing with either a g-wave gap or d-wave gap, while antiferromagnetism leads to RVB superconductivity with a d-wave gap. Within a symplectic large $N$ limit, we examine the effects of antiferromagnetic interactions on the composite pairing. If both gaps are d-wave, they couple linearly, mutually enhancing the superconducting transition temperature.

8:36AM A41.00004 Very low temperature specific heat and magnetoresistance of PrOs$_x$Sb$_{12}$, BOHDAN ANDRAKOA, University of Florida — Heavy fermion character of PrOs$_x$Sb$_{12}$ has been concluded based on its superconducting properties, such as large values of the discontinuity $C$ and upper critical field slope at $T_c (1.85$ K). On the other hand, normal state properties do not provide any strong evidence of the heavy fermion behavior. In particular, $m^*$ enhancement measured by the de Haas van Alphen technique in overcritical fields and below 700 mK is typical of transition metals, suggesting that the heavy fermion state is either suppressed by magnetic fields or collapses at low temperatures. We reexamine these possible scenarios using new magnetoresistance and specific heat, down to 50 mK, data.

8:48AM A41.00005 Effect of ferromagnetism on unconventional superconductivity in the Pr$_{1-x}$Nd$_x$Os$_8$Sb$_{12}$ system, P.-C. HO, Physics/CSU-Fresno, M. B. MAPLE, T. YANAGISAWA, W. M. YUHASZ, N. P. BUTCH, A. A. DOORAGHI, C. C. ROBINSON, Physics/UCSD — The filled skutterudite compound PrOs$_8$Sb$_{12}$ is a 1.85 K heavy fermion superconductor (SC), which displays unconventional SC property, such as existence of multiple SC phases and point nodes in the SC energy gap and the appearance of internal magnetic field in its SC state. NdOs$_8$Sb$_{12}$ is a mean-field type magnet with a low Curie temperature $\sim 1$ K. The Nd substitution in the Pr$_{1-x}$Nd$_x$Os$_8$Sb$_{12}$ system has been carried out in order to investigate the ferromagnetic (FM) effect on the unconventional SC of PrOs$_8$Sb$_{12}$ and the quantum critical behavior in this system. SC state in this system disappears near $x \sim 0.55$ and FM extends into the SC region. The $x$ dependence of the 0-K extrapolated upper critical field $H_{c2}(x, T = 0)$ has curvature breaking at $x \sim 0.3$. The $H_{c2}(x, T = 0)$ data can be analyzed by multiple pair breaking effect due to magnetic field, appearance of impurity, and the exchange field generated by magnetic ions. However, when $H_{c2}(x, T = 0)$ of Pr$_{1-x}$Nd$_x$Os$_8$Sb$_{12}$ is compared to that of a BCS SC La$_{3-x}$Gd$_x$In, the curvature in the regime where $x/x_{cr} < 0.5$ is significantly different. Detail analysis and comparison will be discussed. Research at CSU-Fresno supported by RC CCSA #7669 and Fresno State start-up fund; at UCSD by US DOE and NSF; at Hokkaido U by MEXT, Japan.

9:00AM A41.00006 The role of $\beta$-electrons at the Fermi surface of the heavy fermion superconductor $\beta$-YbAlB$_4$, EOEIN O’FARRELL, D.A. TOMPSEET, S.E. SEBASTIAN, Cavendish Laboratory, University of Cambridge, N. HARRISON, NHMFL, MS-ES36, Los Alamos National Laboratory, C. CAPAN, Department of Physics and Astronomy, University of California, Irvine, L. BALICAS, NHMFL, Tallahassee, K. KUGA, T. MATSUO, M. TOMONAGA, S. NAKATSUI, ISSP, University of Tokyo, G. CSÁNYI, Department of Engineering, University of Cambridge, Z. FISK, Department of Physics and Astronomy, University of California, Irvine, M.L. SUTHERLAND, Cavendish Laboratory, University of Cambridge — We present a detailed quantum oscillation study of the Fermi surface of the recently discovered Yb-based heavy fermion superconductor $\beta$-YbAlB$_4$. We compare the data, obtained at fields from 10 to 45 Tesla, to band structure calculations performed using the local density approximation. Analysis of the data suggests that the $\beta$-electrons are delocalized and contribute to the fermi volume at all fields. We comment on the significance of these findings for the observed quantum critical and superconducting properties of this material.

The electronic structure of PuCoGa$_5$ and PuSb$_2$ is anisotropic and probably has a paramagnetic effect under field along the $c$-axis because of the divergent behavior of the Ising like $c$-axis susceptibility. Moreover, the coherence maximum around 11 K, which defines the depth of the Kondo effect, is observed.

These results suggest that pressure increasing causes the suppressing of Kondo effect in YbB$_2$. The Kondo effect and the pressure dependence of Debye temperature as $\langle D/P \rangle = (1.46 \pm 0.30)$ K/GPa which is calculated using Bloch-Gr"uneisen approximation. Measurements of the temperature dependent $\gamma$-spin-lattice relaxation rate $1/T_1$ show an increasing rate for decreasing temperature ($T > 50$ K), followed by a broad maximum near 30 K. These results are discussed in light of the heavy-fermion like nature of the material.

Supported by NSF Materials World Network grant DMR-0710525.

9:12AM A41.00007 Superconducting Properties of the Non-Fermi-Liquid System $\beta$-YbAlB$_4$. KENTARO KUGA, YOSHITOMO KARAKI, YOSUKE MATSUMOTO, YÔ MACHIDA, NAOKI HORIE, SATORU NAKATSUJI, Institute for Solid State Physics

9:24AM A41.00008 Electronic Structure of PuCoGa$_5$ and PuSb$_2$ Using Angle-Resolved Photoemission. [1] J.J. JOYCE, Los Alamos National Laboratory, T. DURAKIEWICZ, K.S. GRAHAM, D.P. MOORE, J.M. WILLS, JIAN-XIN ZHU, E.D. BAUER, J. MITCHELL — The electronic structure of PuCoGa$_5$ and PuSb$_2$ is investigated using angle-resolved photoemission (ARPES). Details of the sharp quasiparticle peak at the Fermi energy are presented giving insight into the details of the mechanisms which give rise to strongly correlated characteristics in these materials. Additionally, the details of the dual nature of the 5f electrons are explored via characterization of more localized 5f states well removed from the Fermi energy. The ARPES data is compared with electronic structure models which move beyond the density functional theory approach to address the strong electron correlations present in Pu compounds as well as the dual nature of the 5f electrons.

9:36AM A41.00009 $^7$Li NMR Study of Yb$_2$LiGe$_4$: A Possible Kondo Insulator. [1] M. J. GRAF, V. LANIO, Dept. of Physics, Boston College, Chestnut Hill, MA 02467, USA, P. CARRETTA, Dept. of Physics A. Volta, Univ. of Pavia, 27100 Pavia, Italy, YU. GRIN, S. PETER, Max-Planck-Institut fur Chemische Physik fester Stoffe, 01187 Dresden, Germany — We report on the temperature-dependent resistivity, magnetic susceptibility, and nuclear spin-lattice relaxation rate of polycrystalline Yb$_2$LiGe$_4$. The parent compound, Yb$_3$Ge$_4$, is known to be mixed valent. The increasing susceptibility and resistivity with decreasing temperature are consistent with a Kondo insulator. Measurements of the temperature dependent $^7$Li-spin-lattice relaxation rate $1/T_1$ show an increasing rate for decreasing temperature ($T > 50$ K), followed by a broad maximum near 30 K. These results are discussed in light of the heavy-fermion-like nature of the material.

Work supported by NSF Materials World Network grant DMR-0710525.

9:48AM A41.00010 Revealing the Ce gamma-alpha Isostructural Phase Transition. [1] YI WANG, LOUISE HECTOR, SHUNLI SHANG, LONG-QING CHEN, ZI-KUI LIU, PENN STATE TEAM, GM COLLABORATION — Since its discovery eighty years ago, the gamma-alpha iso-structural phase transition in cerium has been the subject of numerous theoretical studies. Existing theories, however, yield inaccurate results. Nowhere is this more evident than with the 50-200% disagreement between existing theoretical predictions of the critical point and experiment. We resolve this issue by explicitly incorporating finite temperature mixing of the Ce nonmagnetic and magnetic states into a novel partition function wherein all input quantities are computed with density functional theory. Unique to our approach is the calculation of vibrational properties from phonon theory. The critical behavior of the transition is shown to be controlled by the configurational mixing entropy between the magnetic and nonmagnetic states. Our theoretical framework leads to predicted values of the critical point and equation-of-state that are in remarkably close agreement with experiment and thereby places the Ce gamma-alpha phase transition on a firm theoretical foundation.

10:00AM A41.00012 ABSTRACT WITHDRAWN.

10:12AM A41.00011 Pressure Effect on The Kondo Behavior of Layered YbB$_2$. [1] BORA KALKAN, Advanced Materials Research Group, Physics Department, Hacettepe University, Ankara 06800, Turkey — The structural properties and the effect of pressure on the electrical properties of polycrystalline YbB$_2$ were investigated via x-ray diffraction and x-ray photoemission spectroscopy (XPS) under ambient pressure and resistivity measurements up to 6.2 GPa. Rietveld refinement confirmed the hexagonal layered structure of YbB$_2$ in P6/mmm space group with $a=b=3.2522(2)$ Å and $c=3.7297(4)$ Å lattice parameters. XPS and low temperature measurements proved the magnetically ordered ground state of YbB$_2$ in which Yb ion has already magnetic trivalent state under ambient pressure. $\rho(T)$ measurements down to 3.5 K at various pressures exhibit a typical Kondo lattice behavior at low temperatures with a resistivity minimum around 23 K and a coherence maximum around 11 K, which define the depth of the Kondo effect. Moreover, resistivity results yield the gradual weakening of the contribution of Kondo effect and the pressure dependence of Debye temperature as $\langle d\rho/T \rangle = (1.46 \pm 0.30)$ K/GPa which is calculated using Bloch-Gr"uneisen approximation. These results suggest that pressure increasing causes the suppressing of Kondo effect in YbB$_2$.

11:15AM B1.00001 Graphene and its chemical derivatives. [1] KOSTYA NOVOSELOV, University of Manchester — Graphene is a first two-dimensional atomic crystal. In my talk I’ll overview our latest results on the electronic properties of graphene, and discuss a possibility of band structure engineering by chemical modification of this material.
11:51AM B1.00002 The high-field state at the Dirac Point in graphene\(^1\), N. PHUAN ONG\(^2\), Princeton University — The discovery of the quantum Hall Effect in graphene has generated considerable interest in the state at the Dirac Point in a magnetic field \(H\). In intense \(H\), the 4-fold degeneracy of the \(n = 0\) Landau Level (LL) is lifted by the enhanced exchange energy. Among the broken symmetry states proposed are the quantum Hall ferromagnet, the quantum Hall insulator state, excitonic condensation, and charge-density-wave formation. A subset of these theories propose counter-propagating edge states that remain conducting in large \(H\). We have performed measurements of the resistance \(R_{xx}\) and Hall resistance \(R_{xy}\) to fields of 33 T at temperatures \(T\) from 0.3 to 50 K in \ (~6) graphene samples. We find that, as \(T\) decreases below 10 K, \(R_0 = (= R_{xx} \text{ at the Dirac Point})\) undergoes a steep increase with a divergence consistent with a field-driven transition to an insulating high-field state. The divergence in \(R_0\) fits well to the Kosterlitz-Thouless (KT) form \(\exp[\sqrt{h/(\hbar - T)}]\) with \(h = H/H_c\) and \(b \sim 1.4\). The critical field \(H_c\) is sample dependent (12 T to 33 T ), and correlates with the disorder as measured by the offset gate voltage \(V_0\) and the zero-\(H\) mobility. The divergence in \(R_0\) is strictly confined to the \(n = 0\) LL (bracketed by the sublevels \(\nu = \pm 1\)). The peaks with \(n = \pm 1\) remain near the values \(h/e^2\). Using an ultralow-power (3 kW), voltage-regulated technique, we show that the KT-fit to \(R_0\) is valid over 3 decades (40 kΩ to 40 MΩ). The steepness of the \(R_0\) vs. \(T\) curves implies a bulk gap \(\Delta\) of magnitude 15-20 K that decreases when \(H\) falls below \(H_c\). We compare our findings with the various proposed models. We will also report thermopower and Nernst measurements taken to fields of 14 T.

\(^1\)Supported by NSF Grant DMR-0819860. High-field experiments were performed at the National High Magnetic Field Lab., Tallahassee.

12:27PM B1.00003 Quantum Carrier Collimation in Locally Gated Graphene Heterojunction Devices, PHILIP KIM, Columbia University — While electron optics such as lensing and focusing have been demonstrated experimentally, building a collimated electron interferometer in two unconfined dimensions has remained a challenge due to the difficulty of creating electrostatic barriers that are sharp on the order of the electron wavelength. Owing to the suppression of backscattering experienced by the chiral quasiparticles, graphene provides an ideal medium to realize the quantum engineering of electron wave functions. In this presentation, we show our progresses in wave function engineering in graphene devices by demonstrating the conductance oscillations in extremely narrow graphene heterostructures where a resonant cavity is formed between two electrostatically created bipolar junctions. Analysis of the oscillations confirms that bipolar heterojunctions have a collimating effect on ballistically transmitted carriers. The robustness of the oscillatory conductance to scattering provides a novel probe of the ballistic physics of graphene at the Dirac point and makes graphene heterojunctions a promising tool for the coherent manipulation of carriers in mesoscopic systems.

1:03PM B1.00004 Robustness of quantum Hall effect in locally gated graphene devices, DMITRY ABANIN, Princeton University — Two-terminal conductance of locally gated graphene p-n-p heterojunctions in the quantum Hall regime is quantized at integer and fractional values, owing to the edge states equilibration. We study the sensitivity of this quantization to finite longitudinal conductivity in the locally gated inner region of the junction. Taking a bulk conductivity approach, we solve spatially non-uniform conduction problem exactly by a conformal mapping method. We find that the robustness of the conductance quantization strongly depends on the geometry of the locally gated region, as well as on the densities in the inner and outer regions. We present a detailed comparison of our predictions with recent experimental data, finding good agreement.

1:39PM B1.00005 Octet Quantum Hall Effect in Graphene Bilayers\(^1\), ALLAN H. MACDONALD, University of Texas at Austin — Interaction driven integer quantum Hall effects are anticipated [1]in graphene bilayers because of the near-degeneracy of eight Landau levels which appear near the neutral system Fermi level at filling factors between \(\nu = -4\) and \(\nu = 4\). The bilayer graphene octet exhibits a wide variety of broken symmetry states, with Ising, XY and Heisenberg character which can be controlled by an external field which creates an electric potential difference between the two layers. Because of the peculiarities of the bilayer graphene electronic structure states with \(n=0\) and \(n=1\) orbital character are degenerate. I will explain predictions that an intra-Landau-level cyclotron resonance signal will appear at some odd-integer filling factors, accompanied by collective modes which are nearly gapless and have approximate k\(^{3/2}\) dispersion. This talk will be based on work performed in collaboration with Yafis Barlas, Rene Cote, Kentaro Nomura, and Jules Lambert.

Session B2 DCMP: HTSC: Fermi Pockets and Quantum Oscillations

11:15AM B2.00001 Competing order, Fermi surface reconstruction, and quantum oscillations in high temperature superconductors\(^1\), SUDIP CHAKRAVARTY, UCLA — Recent quantum oscillation measurements in underdoped high temperature superconductors in high magnetic fields and low temperatures have ushered in a new era. These experiments appear to explore the normal state from which superconductivity arises and provide evidence of a reconstructed Fermi surface consisting of electron and hole pockets in a regime in which such a possibility was previously considered to be remote. Here we explain the observations with the theory that the alleged normal state exhibits a hidden order, the \(d\)-density wave. The success of our analysis underscores the importance of spontaneous breaking of symmetries, Fermi surface reconstruction, and quasiparticles. We primarily focus on the version of the order that is commensurate with the underlying crystalline lattice, but also touch upon the consequence of incommensuration. In addition, the effect of possible bilayer splitting and the nature of quantum oscillations in the mixed state are addressed.

\(^1\)Supported by NSF DMR-0705092

11:51AM B2.00002 Quantum Oscillations in underdoped YBCO: the nature of Fermi surface reconstruction and evolution toward the Mott insulating regime, SUCHITRA SEBASTIAN, Cambridge University — I will present results of quantum oscillation measurements we have measured in underdoped YBCO_{1+x} that reveal a small Fermi surface. Results of angular dependent measurements enable us to obtain clues as to the nature of order that reconstructs the Fermi surface. I will also present results of doping-dependent measurements that enable us to trace Fermi surface evolution as the insulating regime is approached. Work was performed in collaboration with N. Harrison, G. G. Lonzarich, C. Mielke, R. Liang, D. Bonn and W. Hardy
expected recovery of the usual Fermi-liquid metal on the high doping side is fundamental but ill understood. Here we uncover a new transformation in an 

natural tuning parameter that takes copper oxides from the antiferromagnet through the superconducting ‘dome’-shaped region. In the metallic state above 

This work was carried out in collaboration with Hongbo Yang, Jon Rameau, Tonica Valla, Alexei Tsvelik and Genda Gu and was supported by the Department of 

energy

immediate vicinity of the Fermi level is not particle-hole symmetric in the pseudogap phase. This is clear evidence that superconducting pairing does not originate 

from the Fermi arcs. The observations are also consistent with the possibility that the Fermi arcs are in fact the inner surface of the predicted Fermi pockets. 

This work was carried out in collaboration with Hongbo Yang, Jon Rameau, Tonica Valla, Alexei Tsvelik and Genda Gu and was supported by the Department 

of Energy.

1:03PM B2.00004 Field-Induced Quantum Critical Route to a Fermi Liquid in Overdoped 

(1)

Tl2Ba2CuO6+δ/2. TAKASADA SHIBAUCHI, Department of Physics, Kyoto University — In high temperature superconductivity, charge doping is a 

natural tuning parameter that takes copper oxides from the antiferromagnet through the superconducting ‘dome’-shaped region. In the metallic state above 

Tc, the standard Landau’s Fermi-liquid theory of metals, as typified by the temperature squared (AT2) dependence of resistivity, appears to break down. 

The expected recovery of the usual Fermi-liquid metal on the high doping side is fundamental but ill understood. Here we uncover a new transformation in an 

overdoped superconducting copper oxide Tl2Ba2CuO6+δ/2 from the non-Fermi to a Fermi-liquid ground state driven by magnetic field [1]. From the c-axis resistivity 

measured up to 45 T, we show that the Fermi-liquid AT2 features, accompanied by a field-linear magnetoresistance, appear above a field HFL. This crossover 

HFL decreases linearly with decreasing temperature T and lands at a quantum critical point (QCP) near the upper critical field Hc2(0). The Fermi-liquid 

coefficient A(II) shows a power-law diverging behavior on the approach to the QCP, indicating the second-order quantum phase transition at this field. 

The connection between the field-induced QCP and the pseudogap observed in the underdoped regime will be discussed.

1:39PM B2.00005 Fermi surface reconstruction in high-Tc superconductors , LOUIS TAILLEFER, University of Sherbrooke and Canadian Institute for Advanced Research — The recent observation of quantum oscillations in overdoped high-Tc superconductors (1), combined with their negative Hall coefficient at low temperature (2), reveals that the Fermi surface of hole-doped cuprates includes a small electron pocket. This strongly suggests that the large hole Fermi surface characteristic of the overdoped regime undergoes a reconstruction caused by the onset of some order which breaks translational symmetry. Here we consider the possibility that this order is “stripe” order, a form of combined charge / spin modulation observed most clearly in materials like Eu- doped and Nd-doped LSCO. In these materials, the onset of stripe order coincides with major changes in transport properties (3), providing strong evidence that stripe order is indeed the cause of Fermi-surface reconstruction. We identify the critical doping where this reconstruction occurs and show that the temperature dependence of transport coefficients at that doping is typical of metals at a quantum critical point (4). We discuss an 

interpretation of the pseudogap as a fluctuating precursor of the stripe-ordered phase.

This work was performed in collaboration with L. Balicas, D.A. Bonn, J. Chang, O. Cyr-Choinière, R. Daou, N. Doiron- Leyraud, W.N. Hardy, N.E.

Monday, March 16, 2009 11:15AM - 2:15PM — 

Session B3 FEd: 10,000 Undergraduate Physics Majors: Progress on Doubling 301/302

11:15AM B3.00001 Why Do We Need 10,000 Physics Majors?, THEODORE HODAPP, American Physical Society — The early 1960’s saw a huge increase in the number of physics majors, reaching an all time peak of just over 6000 per year. While the number plummeted in the next four decades, it has finally experienced a resurgence to nearly this number. The American Physical Society along with the American Association of Physics Teachers recently endorsed a call to double the number of undergraduate physics majors over the next decade. The main focus of this effort is to increase both the number of high school physics teachers and the fraction of women and under-represented minorities studying physics. In addition, a physics degree prepares an undergraduate with excellent skills that will serve her or him for a variety of occupations both in the sciences and in other fields. This talk will explore some of the data on physics majors and the rationale for taking the bold step of suggesting we try and educate 10,000 majors each year. Sputnik helped catalyze the nation 50 years ago – What is the Sputnik of today? Bring your thoughts and questions... we hope for a lively discussion.

11:51AM B3.00002 Successful Minority PhD Producing Programs – Bell Laboratories and the Meyerhoff Scholarship Program at UMBC, ANTHONY JOHNSON, University of Maryland Baltimore County — The Bell Labs Cooperative Research Fellowship Program for Minorities (CRFP), founded in 1972 was one of the first programs of its kind in the US to address the issue of under-representation of minorities in the fields of engineering, mathematics and science. As of 2000, well over 100 Ph.Ds graduated with CRFP sponsorship and a significant fraction joined the research ranks of Bell Labs. In the early days of the program as much as 50% of African American PhDs in Physics in the US were granted to students supported by CRFP. Another unique program initiated by Bell Labs in 1974 that introduced undergraduate students to cutting edge research was the Summer Research Program for Minorities and Women (SRP). The SRP served as a natural feeder to the CRFP. Personally, my career in Optical Physics owes its foundation to these programs and I will give my perspective on participation and impact of the Bell Labs SRP (1974) and CRFP (1975) programs. The Meyerhoff Scholars Program at UMBC was developed in 1988. At that time, UMBC was graduating fewer than 18 African-American STEM majors per year. In 1996 the program was opened to all students with an interest in the advancement of minorities in STEM fields. The program enjoys an overall 18-year retention rate of greater than 95% and has over 500 graduates since 1993. As of May 2006, 75% of these graduates are enrolled in graduate and/or professional programs, with 49 Ph.Ds and 20 MD/PhDs completed as of August 2006. The program challenges notions about minority achievement. Meyerhoff Scholars have changed the perceptions of those around them – the expectations of faculty who instruct them, the attitudes of students who learn beside them, and the perspectives of scientists who engage them in research.

1:03PM B3.00004 Doubling the number of physics majors who teach, MICHAEL MARDER, The University of Texas at Austin — The American Physical Society has adopted a doubling initiative to increase the number of physics majors. One of the main motivations is to increase the number of physics majors certified to teach secondary physics. I will review some of the possible strategies for reaching this goal, and discuss some of the steps we have taken with UTeach, the program for secondary science and mathematics teacher preparation at The University of Texas at Austin. I will discuss the roles of curriculum revision, financial support, and community support in convincing majors to teach. Finally, I will talk about the expansion of UTeach into engineering.
11:15 AM B4.00001 Polymer Translocation: What Can We Learn From An Exactly Solvable One-Dimensional Model?1, GARY W. SLATER, University of Ottawa — The translocation of a polymer through a narrow hole or channel is generally not a quasi-static process (as we have shown using a detailed Molecular Dynamics simulation with explicit solvent). Nevertheless, numerous analytical models have relied on this approximation/assumption in order to make progress. A simple approach is then to describe the problem in terms of the translocation coordinate (e.g., the number of monomer on the trans side of the wall), which effectively makes it a one-dimensional problem with an external driving field and a entropy-related potential landscape. Our group has exploited this simple idea to its fullest using a lattice Monte-Carlo-like model that provides exact numerical results, even for extremely rare events. In this presentation, I will explain how this simplified model is built and how it can be modified to include a variety of additional effects such as polymer stiffness or the differences between the various monomer types in a biopolymer like DNA. I will review the main results obtained to date, focusing on the transitions between the low- and high- field regimes, and between the short- and long- polymer chain limits. Finally, I will examine the role of attractive interactions between the polymer and specific sites inside the channel.

1Supported by NSERC - Canada.

11:51 AM B4.00002 DNA translocation through small channels and pores from molecular models. Hydrodynamic, electrostatic, and hybridization considerations. JUAN DE PABLO, University of Wisconsin — The flow and translocation of long DNA molecules are of considerable applied and fundamental interest. Design of effective genomic devices requires control of molecular shape and positioning at the level of microns and nanometers, and understanding the manner in which DNA is packaged into small channels and cavities is of interest to biology and medicine. This presentation will present an overview of hierarchical models and computational approaches developed by our research group to investigate the effects of confinement, hydrodynamic interactions, and salt concentration, on the structure and properties of DNA, both at equilibrium and beyond equilibrium. The talk will include a discussion of coarse grain descriptions of the flow of DNA in microfluidic and nanofluidic channels over multiple length and time scales, and a discussion of emerging, detailed models that are capable of describing melting and rehybridization at the single nucleotide level, as well as the packaging of DNA into viral capsids and small pores.

12:27PM B4.00003 Simulation studies of DNA translocation through a nanopore (†), ANIKET BHATTACHARYA, University of Central Florida — The experimental studies of voltage driven translocation of a single stranded DNA through a α-hemolysin pore, have stimulated a lot of activities as the phenomenon is rich in fundamental science involved and its prospective technical applications for detecting DNA/RNA sequences. While it is the attributes of heteropolymer translocation that are the key ingredients for prospective new sequencing methods, these experiments have generated stimulating theoretical and numerical studies directed toward a seemingly much simpler problem of homopolymer translocation through a nanopore. The earlier theoretical work of Muthukumar, Sung and Park, and by Kardar and his collaborators2 have been supplemented by more recent theoretical work by Dubbledam et. al and Panja et. al3. During this talk I will show results from Langevin dynamics simulation carried out on a coarse-grained bead-spring model of DNA-polymer both for the unbiased and driven translocation4. During the first part of the talk, after a brief review of the current theories of DNA translocation, specifically mentioning the underlying assumptions, I will compare simulation results with those predicted by different theories. Particularly, I will show numerical results for the translocation exponent α defined as \( \langle r \rangle \sim N^\alpha \) and the exponent for the s-coordinate β defined as \((s^2(r)) \sim r^\beta\), and discuss how the numerical values differ as one chooses slightly different pore width and geometry. In the second part of my talk I show how a model attractive nanopore can distinguish the sequence of a heteropolymer and discuss possibility of making a device based on this idea.

1Work done in collaboration with Kaifu Luo, Tapio Ala-Nissila, See-chen Yin, Andrey Milchev and Kurt Binder

12:03PM B4.00004 Anomalous dynamics of polymer translocation1, GERARD BARKEMA, University of Utrecht — We study the passage times of a translocating polymer of length \( N \) in three dimensions, while it passes through a narrow pore. We show that the behavior of the polymer stems from the polymer dynamics at the immediate vicinity of the pore — in particular, the memory effects in the polymer chain tension imbalance across the pore. We take as a reaction coordinate the number \( \sigma \) of the monomer residing in the pore, in the case of unbiased translocation, these memory effects cause the mobility of \( \sigma \) to be anomalous diffusion for times up to the Rouse time \( \tau_\text{R} \sim N^{3/4} \) or Zimm time \( \tau_\text{Z} \sim N^{\nu} \), without or with hydrodynamics, respectively. Here, \( \nu \) is the Flory exponent. Beyond this time, the dynamics becomes ordinary diffusion. As a consequence, the pore blockade time scales with \( \tau_\text{D} \sim N^{\nu} \) or \( \tau_\text{D} \sim N^{3/2}/N^{\nu} \) with hydrodynamics. In these cases, the pore blockade time decreases inversely with field and strength, respectively. Our theoretical framework is substantiated with high-precision computer simulations. We will show that the memory effects become more pronounced as the pore size decreases, also play a role in the dynamics of dense polymer solutions and polymer melts.

1in collaboration with D. Panja
11:51AM B5.00002 Integration of CNTs with Silicon, WILLIAM MILNE, Engineering Dept., Univ. of Cambridge — In this talk, the growth and characterization of both single and multi-walled CNTs is described and a realistic appraisal of the future of CNTs in the electronics field is provided. Although they are less likely, in the author’s opinion, to take over from silicon for use in the active devices such as transistors and diodes etc. in logic circuits their use in vias and interconnects in next generation integrated circuits is considered as being entirely feasible as is their use in transparent conducting contacts. Another major contribution to future electronics could be in conventional applications to CMOS such as their use in sensors, thermal interface materials and solder joints. A novel Liquid Crystal Over Silicon (LCOS) structure will also be discussed.

12:27PM B5.00003 Heterogeneous Integration of Materials on Si for Nanophotonics Devices, SOLOMON ASSEFA, IBM T.J. Watson Research Center — Optical interconnects are attractive candidates for achieving communication bandwidth well beyond terabit-per-second for high-performance multi-core microprocessors. Silicon has become a desirable material due to its transparency in the infrared wavelength range and the ease for integrating optical devices at the vicinity of CMOS circuitry utilizing standard processes. While state-of-the-art patterning techniques provide precise dimension control as well as pattern placement, standard doping and metallization steps enable utilization of phenomena such as carrier injection and depletion to render the devices tunable. A large progress has been made on Si-based nanophotonic devices such as modulators, switches, and wavelength division multiplexing (WDM) systems [1, 2]. To make photodetectors, however, a heterogeneous integration of other materials that absorb light in the infrared is necessary. Available in standard front-end CMOS processes for gate strain engineering, Germanium is suitable due to its high absorption coefficient at 1.3µm and 1.5µm wavelengths. Thus, Ge can be directly integrated into the process to fabricate compact photodetectors simultaneously with amplifier circuits in order to make a receiver for an optical network. Nevertheless, the integration of Ge photodetector into the CMOS process flow is very challenging due to process complexity and severe temperature constraints; as a result, photodetectors fabricated only after completing the front-end processes have been demonstrated. This talk will discuss Ge waveguide photodetectors that have been integrated into the front-end before the activation of CMOS well implants. By using the lateral seeded crystallization method wherein the Ge waveguides are melted during high-temperature dopant activation, 250-µm-long single-crystal Ge-on-insulator waveguides were fabricated. This approach eliminates the need for selective epitaxial growth of Ge, and avoids high-dose misfit dislocations formed due to lattice mismatch when growing Ge on Si substrate. The photodetectors operate at low applied bias voltages (0.5-1V) with bandwidth exceeding 40GHz.

Monday, March 16, 2009 11:00AM - 2:15PM — Session B5 FIAP: Heterogeneous Integration on Silicon 401/402

11:15AM B5.00001 Scaling Properties of High Performance Ge-Si$_x$Ge$_{1-x}$ Core-Shell Nanowire Field Effect Transistors$^1$, EMANUEL TUTUC, Microelectronics Research Center, The University of Texas at Austin — Semiconductor nanowires (NWs), namely highly anisotropic crystals with diameters of the order of a few tens of nanometers, have received increased research recently as a platform for electronics devices, motivated in part by issues associated with end of the roadmap of complementary metal-oxide-semiconductor (CMOS) device scaling. The performance advantage of such devices stems from superior electrostatic properties compared to planar devices, which in turn help increase their on-state current and on/off-state current ratio. We present recent results on the growth and fabrication of a few key NW device structures, which can potentially outperform conventional CMOS devices. By combining axial Ge NW growth, via the vapor-liquid-solid mechanism, with conformal Si$_x$Ge$_{1-x}$ growth by ultra-high-vacuum chemical vapor deposition, we demonstrate Ge-Si$_x$Ge$_{1-x}$ core-shell NW heterostructures. Transmission electron microscopy combined with energy dispersive X-ray spectroscopy show that the Si$_x$Ge$_{1-x}$ shell can be grown in-situ, epitaxial onto the Ge NW core, and that the Si/Ge shell content can be tuned depending on the growth conditions, effectively enabling band engineering in these one dimensional nanowire heterostructures. A key component in fabrication high performance nanowire field effect transistors, namely high on-state current and high on/off-state current ratio, is the fabrication of low resistance, unipolar contacts to a semiconductor nanowire. Using low energy ion implantation we demonstrate dual-gate Ge-Si$_x$Ge$_{1-x}$ core-shell nanowire field effect transistors with highly doped source and drain. We discuss the scaling properties as a function of channel length, and intrinsic carrier mobility in these devices.

$^1$Work performed in collaboration with J. N. K. Varahramyan, E.-S. Liu, S. K. Banerjee, and with support from DARPA and NSF.

1:39PM B5.00005 Integration of Ferroelectrics, Ferromagnets, and Multiferroics with Silicon, DARRELL SCHLOM, Cornell University — In this talk I will describe the epitaxial integration of ferroelectrics, ferromagnets, and materials that are both at the same time, with silicon. Until recently, "oxide" could only mean one thing to anyone working in the semiconductor industry—SiO$_2$. But oxides are an exciting class of electronic materials in their own right. Oxides exhibit the full spectrum of electronic, optical, and magnetic behavior including many functionalities not found in conventional semiconductors. Further, such oxides can be combined epitaxially not only with each other, but epitaxially with the workhorse of semiconductor technology, silicon, enabling the unparalleled variety of physical properties of oxides to be exploited in new ways for electronic applications. The specific oxides that my collaborators* and I have integrated epitaxially with silicon include EuO, ZnO, CaTiO$_3$, BaTiO$_3$, SrTiO$_3$, BaTiO$_3$, BiFeO$_3$, Pb(0.2Ti,0.8O)$_3$, and PbMg$_{1/3}$Nb$_{2/3}$O$_3$. Highlights from these systems will be presented. * The work reported was performed in collaboration with the groups of Jochen Mannhart (U. Augsburg), Chang-Beom Eom (U. Wisconsin-Madison), Ramamoorthy Ramesh (Berkeley), Jeremy Levy (U. Pittsburgh), David Muller (Cornell), Xiaoqing Pan (U. Michigan), Jürgen Schubert (Jülich), Long-Qing Chen (Penn State), Susan Trolle-McKinstry (Penn State), Yves Izdebski (Montana State), Peter Böni (TU München), Joseph Woicik (NIST), Philip Ryan (Ames), Michael Bedzyk (Northwestern), Yuni Barash (Russian Acad. Sci.), Qing Ma (Intel), and Hao Li (Motorola).
**Monday, March 16, 2009 11:15AM - 2:15PM — Session B6 FIP: Panel Discussion: Physics in Africa**

**11:15AM B6.00001 On the differences between theories of conventional and high temperature superconductors**, ALEXANDER ANIMALU, University of Nigeria — After years of successful application of the pseudo and model potential representation of electronphonon interaction to conventional (Bardeen-Cooper-Schrieffer) theory of superconductivity, we have developed a generalization (called "isosuperconductivity") that not only explains the differences between conventional and high-Tc in the cuprates and other materials but has enough predictive power to permit the current search for room temperature superconductors. We present a review of more than 30 years of effort and progress report on current research activities in this field.

**11:51AM B6.00002 Physics in Africa: The Case of South Africa**, MZAMO P. MANGALISO, National Research Foundation, South Africa & University of Massachusetts, Amherst — South Africa plays a special role in building science throughout Africa. The areas of science, particularly those related to physics, which are being developed, will be described together with the involvement of other African countries. Data will be presented that demonstrate the high attrition rate that exists especially in the science track PhD pipeline and highlight the bottleneck at the honors (fourth year) level. Programs designed to overcome this will be presented, and their success discussed. Thoughts on how to go about expanding the interactions between US scientists and South African scientists as well as with African scientists will be presented.

**12:27PM B6.00003 Physics in Africa: The Case of Senegal**, NDEYE ARAME BOYE-FAYE, University Cheikh Anta Diop, Denegal — For many years, the research activity in Senegal has been managed through the division of the Ministry of Education. In 2004 the current government established a full-fledged Ministry of Research. This has led to a renewed focus on the organization of the funding of research in Senegal. One important issue to underline is the lack of a budget line devoted to research in most of the local institutions, distinct from support for academic purposes. As a result, the research activity is funded through direct support from the government or thanks to international programs. The main tool for the government to support key research directions is the FIRST program, with a yearly budget of $700,000 US. For the last call for projects, up to 12 projects have been funded, which translates to about $58,000 US per project. The other option for research funding lies in different international programs specifically aimed at institutions within the least developed countries. The dominant ones are provided by the French-speaking community, the French-supported AIRE, the European Union framework and ICTP Abdus Salam Centre. In this general context of limited resources, physics is the least supported discipline both in terms of researchers and active laboratories. As a result, particular efforts have to be made to increase the impact of physics and the role of physicists so as to enable them to claim their proper role as the major player in making science and technology the driving forces in the development process of Africa.

**1:03PM B6.00004 Physics in Africa: The Case of Congo**, BERNARD M’PASSI-MABIALA, Marien NGouabi University — We will present a review on the state of research and education in physics in the Republic of Congo, one developing country in Central Africa. Special emphasis will be placed on the School of Science of the Marien NGouabi University located in the capital, Brazzaville. We will also discuss the impact of the Physics Department within this University as a whole. One of the main problems in Africa is the serious lack of equipment to provide adequate hands-on trainings for students and for faculty to perform forefront research. To illustrate strategies for the development of Physics in the continent, we will describe some ongoing inter-continental collaborations between our university and some neighboring countries, along with some ways for expanding the framework of the interactions between US and African physicists.

**1:39PM B6.00005 Panel Discussion**

---

**11:15AM B7.00001 to be determined by you**, PATRICK DENNIS, NSF — No abstract available.

**11:51AM B7.00002 Growth laws and mechanisms of global control in bacteria**, MATTHEW SCOTT, University of Waterloo — The growth laws of Schaechter, Maaepe and Kjeldgaard are among the most striking discoveries in bacterial growth physiology: cell composition (mass/cell, RNA/cell, etc.) is a simple function of growth rate alone – irrespective of how that growth rate is established. I will review the growth laws, and discuss recent experiments that have uncovered new laws. A systems-level mathematical model is developed that suggests the growth laws arise from the partitioning of the protein synthesizing machinery of the cell (the ribosomes), and furthermore indicates a deep connection between growth rate control and central metabolism.

---

**12:27PM B7.00003 Growth-rate dependent effects on bacterial gene expression**, STEFAN KLUMPP, Center for Theoretical Biological Physics, University of California at San Diego — For fast growing bacteria, which can adapt to wildly different growth conditions, changes in gene expression are often accompanied by changes in growth rates. Because the macroscopic composition of bacteria (e.g., cell size, ribosome concentration, gene copy number) is known to vary greatly for bacteria grown at different rates, significant changes in gene expression may arise 'passively' just due to the growth rate change alone. Towards a quantitative understanding of these passive effects, we analyzed quantitatively available data for the growth rate dependence of various macroscopic parameters affecting gene expression in E. coli, and predicted the growth-rate dependence of gene expression for various simple genetic circuits. For a constitutively expressed gene, the expressed protein concentration is decreased at faster growth, while weak growth-rate dependence is obtained for autorepressing genes and genes under negative control by an autorepressor. We also studied the growth-rate dependence of bistable genetic circuits and determined conditions such that bistability is found over a wide range of growth rates. Our results demonstrate that growth-rate dependent effects play an important role and must be taken into account when analyzing gene expression data under different condition. Buffering against these growth rate dependent effects may be an important requirement undermining the robust operation of endogenous genetic circuits in these bacteria, and should be a prime factor to consider in the design of robust, synthetic circuits.

---

1This work was done in collaboration with Terence Hwa and Barrett Deris, and supported by Deutsche Forschungsgemeinschaft (Grants KL818/1-1 and 1-2) and the NSF through the Center for Theoretical Biological Physics (Grant PHY-0822283).
E. coli rich in resources. We apply this model to a series of past measurements, where the growth rate and rRNA-to-protein ratio have been measured for seven E. coli strains with an rRNA operon copy number ranging from one to seven (the wild-type copy number). These experiments show that growth rate markedly decreases for strains with fewer than six copies. Using the model, we were able to reproduce these measurements. We show that the model that best fits these data suggests that the volume fraction of macromolecules inside E. coli is not fixed when the rRNA operon copy number is varied. Moreover, the model predicts that increasing the copy number beyond seven results in a cytoplasm densely packed with ribosomes and proteins. Assuming that such overcrowded conditions prolonged diffusion times tend to weaken binding affinities, the model predicts that growth rate will not increase substantially beyond the wild-type growth rate, as indicated by other experiments. Our model therefore suggests that changing the rRNA operon copy number of wild-type E. coli cells growing in a constant rich environment does not substantially increase their growth rate. Other observations regarding strains with an altered rRNA operon copy number, such as nucleoid compaction and the rRNA operon feedback response, appear to be qualitatively consistent with this model. In addition, we discuss possible design principles suggested by the model and propose further experiments to test its validity.

**1:03PM B7.00004 A Coarse-Grained Biophysical Model of E. coli and Its Application to Perturbation of the rRNA Operon Copy Number**

ARBEL TADMOR, California Institute of Technology — In this work a biophysical model of Escherichia coli is presented that predicts growth rate and an effective cellular composition from an effective, coarse-grained representation of its genome. We assume that E. coli is in a state of balanced exponential steady-state growth, growing in a temporally and spatially constant environment, rich in resources. We apply this model to a series of past measurements, where the growth rate and rRNA-to-protein ratio have been measured for seven E. coli strains with an rRNA operon copy number ranging from one to seven (the wild-type copy number). These experiments show that growth rate markedly decreases for strains with fewer than six copies. Using the model, we were able to reproduce these measurements. We show that the model that best fits these data suggests that the volume fraction of macromolecules inside E. coli is not fixed when the rRNA operon copy number is varied. Moreover, the model predicts that increasing the copy number beyond seven results in a cytoplasm densely packed with ribosomes and proteins. Assuming that such overcrowded conditions prolonged diffusion times tend to weaken binding affinities, the model predicts that growth rate will not increase substantially beyond the wild-type growth rate, as indicated by other experiments. Our model therefore suggests that changing the rRNA operon copy number of wild-type E. coli cells growing in a constant rich environment does not substantially increase their growth rate. Other observations regarding strains with an altered rRNA operon copy number, such as nucleoid compaction and the rRNA operon feedback response, appear to be qualitatively consistent with this model. In addition, we discuss possible design principles suggested by the model and propose further experiments to test its validity.

---

**1:39PM B7.00005 Dynamics of bacterial gene regulation**

ATUL NARANG, University of Florida — The phenomenon of diauxic growth is a classical problem of bacterial gene regulation. The most well studied example of this phenomenon is the glucose-lactose diauxie, which occurs because the expression of the lac operon is strongly repressed in the presence of glucose. This repression is often explained by appealing to molecular mechanisms such as cAMP activation and inducer exclusion. I will begin by analyzing data showing that these molecular mechanisms cannot explain the strong lac repression because they exert a relatively weak effect. I will then present a minimal model accounting only for enzyme induction and dilution, which yields strong repression despite the absence of catabolite repression and inducer exclusion. The model also explains the growth patterns observed in batch and continuous cultures of various bacterial strains and substrate mixtures. The talk will conclude with a discussion of the experimental evidence regarding positive feedback, the key component of the minimal model.

**Monday, March 16, 2009 11:15AM - 2:15PM**

Session B8 DAMOP: Spectroscopy of Strongly Interacting Fermi Gases 414/415

**11:15AM B8.00001 Observation of Spin-Polarons in a strongly interacting Fermi liquid**

MARTIN ZWIERLEIN, Massachusetts Institute of Technology — We have observed spin-polarons in a highly imbalanced mixture of fermionic atoms using tomographic RF spectroscopy. Feshbach resonances allow to freely tune fermion interactions between the population states involved. A single spin down atom immersed in a Fermi sea of spin up atoms can do one of two things: For strong attraction, it can form a molecule with exactly one spin up partner, but for weaker interaction it will spread its attraction and surround itself with a collection of majority atoms. This spin down atom “dressed” with a spin up cloud constitutes the spin-polaron. We have observed a striking spectroscopic signature of this quasi-particle for various interaction strengths, a narrow peak in the spin down spectrum that emerges above a broad background. The narrow width signals a long lifetime of the spin-polaron, much longer than the collision rate with spin up atoms, as it must be for a proper quasi-particle. The peak position allows to directly measure the polaron energy. The broad pedestal at high energies reveals physics at short distances and is thus “molecule-like”: It is exactly matched by the spin up spectra. The comparison with the area under the polaron peak allows to directly obtain the quasi-particle weight Z. We observe a smooth transition from polarons to molecules at a critical interaction strength of 1/k_B a = 0.7. The polaron peak vanishes and spin up and spin down spectra exactly match, signalling the formation of molecules. This is the same critical interaction strength found earlier to separate a normal Fermi mixture from a superfluid molecular Bose-Einstein condensate. The spin-polarons determine the low-temperature phase diagram of imbalanced Fermi mixtures. In principle, polarons can interact with each other and should, at low enough temperatures, form a superfluid of p-wave pairs. We will present a first indication for interactions between polarons.

---

**11:51AM B8.00002 Photoemission Spectroscopy for Ultracold Atoms**

DEBORAH JIN, NIST, University of Colorado — We perform momentum-resolved rf spectroscopy on a Fermi gas of potassium-40 atoms in the region of the BCS-BEC crossover. This measurement is analogous to photoemission spectroscopy, which has proven to be a powerful probe of excitation gaps in superconductors. We measure the single-particle spectral function, which is a fundamental property of a strongly interacting system and is directly predicted by many-body theories. For a strongly interacting Fermi gas near the transition temperature for the superfluid state, we find evidence for a large pairing gap.

---

**12:27PM B8.00003 Competition between final-state and pairing-gap effects in the radio-frequency spectra of ultracold Fermi atoms**

GIANCARLO STRINATI, University of Camerino, Dept. of Physics — Ultracold Fermi atoms allow the realization of the crossover from Bardeen-Cooper-Schrieffer (BCS) superconductivity to Bose-Einstein condensation (BEC), by varying with continuity the attraction between fermions of different species. In this context, radio-frequency spectroscopy provides a microscopic probe to infer the nature of fermionic pairing. In the strongly-interacting regime, this pairing affects a wide temperature range comprising the critical temperature Tc, in analogy with continuity the attraction between fermions of different species. The calculation rests on the use of the BCS-RPA approximation, while in the normal phase above Tc the model includes the Azlamazov-Larkin type contribution which is familiar in the theory of “paraconductivity” fluctuations in superconductors, besides the density-of-states contribution. In both cases, the limit of a molecular spectrum is correctly recovered in the BEC regime of the crossover. A competition is revealed between pairing-gap effects which tend to push the oscillator strength toward high frequencies away from threshold and final-state effects which tend instead to pull theoscillator strength toward threshold. In addition, an energy scale associated with pairing is extracted from the spectra and related to a universal quantity recently introduced for Fermi gases.

1:03PM B8.00004 Theory of RF Spectroscopy in the Normal And Superfluid Phases of Ultracold Fermi Gases, KATHRYN LEVIN, University of Chicago — In this talk we present an overview of radio frequency (RF) spectroscopy in the atomic Fermi superfluids, addressing both momentum integrated and momentum resolved experiments. A general purpose of these RF experiments is to extract the pairing gap size and we present several methodologies for accomplishing this. In addition, we discuss the effects of traps, population imbalance, and final state interactions over the entire range of temperatures. By comparing theory and experiment, we show how a broad range of experimental phenomena can be accommodated within the BCS-Leggett description of BCS-BEC crossover. We also briefly touch on commonalities between photoemission in the cuprate superconductors and RF spectroscopy in the ultracold gases.

1:39PM B8.00005 Spin polarons, Molecules and Twin Peaks in rf spectra of Fermi gases at unitarity, GEORG BRUUN, Niels Bohr Institute — We examine pairing, molecule, and spin-polaron formation in strongly-interacting Fermi gases and discuss how radio-frequency (RF) spectroscopy can reveal these phenomena. For an unpolarized gas at unitarity, we show how the double-peak structures observed in recent experiments arise due to the inhomogeneity of the trapped gas. The emergence of stable molecules in the BEC regime results in a two-peak structure in the RF spectrum with clearly visible medium effects on the low-energy part of the molecular wavefunction. For the highly-imbalanced case, we show the existence of a well-defined quasiparticle (a spin polaron) on both sides of the Feshbach resonance, we evaluate its lifetime, and we illustrate how its energy may be measured by RF spectroscopy. The main experimental features observed above the critical temperature in the recent experiments are recovered with no fitting parameters.

Session B9 GSNP: GSNP Student Speaker Award Session and Applications of Statistical and Nonlinear Physics in the Life Sciences 303

11:15AM B9.00001 Self-Assembly of Spherical Colloidal Particles at Low N, NATALIE ARKUS, VINOTHAN MANOHARAN, MICHAEL BRENNER, Harvard University — The number of rigid structures that a system of N particles can form grows exponentially with N. Stabilizing any one structure over all others is thus a challenging problem. We consider a system of N spherical colloidal particles that cannot deform or overlap, and which exhibit a short-range attractive force. We present a method, using graph theory and geometry, that solves for all possible rigid packings of N particles - the resultant set of packings is provably complete. We then present a mechanism that is capable of stabilizing any one structure over all others (in the zero temperature limit), and which is experimentally realizable - thereby, potentially allowing us to direct the self-assembly of a desired structure. We compare to preliminary experimental results.

11:27AM B9.00002 Liquid to solid nucleation through onion-structure droplets, KIPTON BARROS, WILLIAM KLEIN, Boston University — We start from a Landau-Ginzburg free energy and develop a theory of crystal nucleation for metastable liquids. Saddle points of the free energy represent nucleating droplets and are obtained analytically and numerically. We find nucleating droplets with hexagonal symmetry in two dimensions and bcc and icosahedral symmetries in three dimensions. Surprisingly, we also find nucleating droplets in three dimensions with a spherically symmetric structure resembling the layers of an onion. These onion-structure objects are the preferred nucleating droplets near the spinodal. We discuss recent experiments and simulations which are consistent with our predictions.

11:39AM B9.00003 Universal Scaling Relation Near Point J, THOMAS HAXTON, ANDREA LIU, Department of Physics and Astronomy, University of Pennsylvania — Recently, several studies (P. Olsson and S. Teitel. Phys. Rev. Lett. 99, 178001 (2007); T. Hatano. arXiv:0803.2296; L. Berthier and T. A. Witten. arXiv:0810.4405) have indicated the existence of a dynamical phase transition at or near Point J, the point at zero temperature, zero shear stress, and a critical density where repulsive amorphous sphere packings lose rigidity. However, a universal scaling relation connecting the rheology of the jammed solid to that of the viscous liquid has been lacking. We control the temperature, strain rate, and pressure in molecular dynamics simulations to show that the steady-state rheology is described by a universal scaling relation near Point J.

11:51AM B9.00004 Exact results for currents in nonadiabatic stochastic pumps, JORDAN HORIZONITZ, University of Maryland — Biological systems abound with examples of molecular machines: assemblies of molecules that perform specific useful mechanical tasks, such as the motor proteins kinesin and myosin. Remarkably, the first steps in developing useful artificial molecular motors have been taken with the synthesis and manipulation of molecular complexes such as catenanes and rotaxanes. These developments have spurred an interest in developing theoretical frameworks which describe these mesoscopic machines that operate in the presence of thermal noise. In this talk I will analyze a generic model of molecular machines known as stochastic pumps in which useful directed motion (or current) is produced by the variation of external parameters. The main result is an exact expression for the current in the presence of nonadiabatic pumping. This expression connects to a variety of results from the field of Brownian ratchets and leads to a surprising “no-pumping” theorem: a set of conditions that guarantee no excess or pumped current. These predictions also agree with the observations on catenanes, interlocked ring molecules, made by Leigh et. al. [Nature, 424, 174 (2003)].

12:03PM B9.00005 A continuous time random walk description of the hopping dynamics in an aging polymer glass, MYA WARREN, JOERG ROTTLER, University of British Columbia — Due to the non-equilibrium nature of the glassy state, structural relaxation becomes increasingly sluggish with the wait time $t_w$ since vitrification. As a result, dynamical correlation functions age, and often obey a simple rescaling with $w = C(t, t_w) = C_0(t) + C_{age}(t/t_w)$. It has recently been shown that, to first order, scaling also applies to the distributions of local correlations and displacements (the Van Hove function). In this study, we use molecular dynamics simulations to measure the statistics of the discontinuous hopping events that characterize structural relaxations during aging. This allows us to map the particle dynamics onto a continuous time random walk, which successfully reproduces the entire distribution of displacements. Our results bear a striking resemblance to the popular trap model of aging. We find that the hop time distribution takes the form of a power law which is independent of $t_w$, whereas the time to the first hop shifts to longer times with $t_w$. This two-timescale behavior explains not only the scaling of the distribution functions for times $t \sim t_w$, but also small deviations from perfect scaling that have been observed at longer times.
1:03PM B9.00010 Estimating currents in totally asymmetric simple exclusion process with extended particles and inhomogeneous hopping rates.1, R.K.P. ZIA, Virginia Tech, JIAJIA DONG, Hamline University, B. SCHMITTMANN, Virginia Tech — Motivated by translation in protein synthesis, we study the totally asymmetric simple exclusion process with extended particles transported along a 1-D lattice with (quenched) inhomogeneous hopping rates. The particles model ribosomes, the lattice models sequences of codons, and the hopping rates reflect the aa-tRNA concentrations. Taking the latter from data for real E.Coli genes, Monte Carlo simulations allow us to find the steady state currents associated with protein production rates. An application would be to predict the effects of “silent mutations” in biological systems. In such mutations, one or more codons are replaced by others which code for the same amino-acid, so that the same protein (amino-acid chain) is synthesized by a different sequence of codons. However, the rate of production (the overall current), which depends on the details of sequence, will differ. We aim to predict the changes in these currents for all possible silent mutations. Beyond this application, this study of “quenched distribution of distributions” is expected to have far reaching implications in other areas of physics.

1:15PM B9.00011 An information geometric approach to least squares minimization, MARK TRANSTRUM, BENJAMIN MACHTA, JAMES SETHNA, LASSP, Cornell University — Parameter estimation by nonlinear least squares minimization is a ubiquitous problem that has an elegant geometric interpretation: all possible parameter values induce a manifold embedded within the space of data. The minimization problem is then to find the point on the manifold closest to the origin. The standard algorithm for minimizing sums of squares, the Levenberg-Marquardt algorithm, also has geometric meaning. When the standard algorithm fails to efficiently find accurate fits to the data, geometric considerations suggest improvements. Problems involving large numbers of parameters, such as often arise in biological contexts, are notoriously difficult. We suggest an algorithm based on geodesic motion that may offer improvements over the standard algorithm for a certain class of problems.

1:27PM B9.00012 Large-Scale Organization of Glycosylation Networks, PAN-JUN KIM, University of Illinois at Urbana-Champaign, DONG-YUP LEE, National University of Singapore, HAWOONG JEONG, Korea Advanced Institute of Science and Technology — Glycosylation is a highly complex process to produce a diverse repertoire of cellular glycans that are frequently attached to proteins and lipids. Glycans participate in fundamental biological processes including molecular trafficking and clearance, cell proliferation and apoptosis, developmental biology, immune response, and pathogenesis. N-linked glycans found on proteins are formed by sequential attachments of monosaccharides with the help of a relatively small number of enzymes. Many of these enzymes can accept multiple N-linked glycans as substrates, thus generating a large number of glycan intermediates and their intermingled pathways. Motivated by the quantitative methods developed in complex network research, we investigate the large-scale organization of such N-glycosylation pathways in a mammalian cell. The uncovered results give the experimentally-testable predictions for glycosylation process, and can be applied to the engineering of therapeutic glycoproteins.
1:39PM B9.00013 Network dynamics mediated by heterogeneous topology as related to hippocampal memory management. JANE WANG, Applied Physics, UM, Ann Arbor, MI; GINA POE, Anesthesiology, UMMS, Ann Arbor, MI; MICHAEL ZOCHOWSKI, Physics, UM, Ann Arbor, MI — Hippocampal-cortical network interactions, including reactivation of recently acquired memories in the hippocampus during sleep, are key to the consolidation of memory traces to long-term storage sites in the neocortex. Network heterogeneities, in the form of regional changes in the connectivity densities of excitatory synapses, support this process in simulated hippocampal-cortical networks by regulating intrinsic network dynamics and thus mediating stimulus familiarity detection as well as selective memory consolidation. We characterize this network model by investigating dynamics due to distributed and overlapping memory structures and examine the ability of regional heterogeneities to both selectively activate in the presence of controlled stimuli and reactivate in the absence of stimuli, the former being indicative of active exploration and the latter of memory replay during sleep.

1:51PM B9.00014 The topological structure of a network formed during simulations of a reversible polymeric gel. M. WILSON, J. BILLEN, A. BALJON, SDSU, A. RABINOVITCH, Ben-Gurion U. of the Negev — We investigate the topologies of the ensemble of telechelic polymers for which we previously studied the sol/gel transition [1]. The polymers serve as “links” between “nodes,” which consist of aggregates of their associating endgroups. The number of associations and hence the topology depends on the employed temperature. Our analysis shows that the degree distribution of the systems is bimodal and consists of two Poisson distributions with different average degrees. In nodes in the distribution with the higher degree we call “superpeers,” those in the other distribution “peers.” With decreasing temperature, the fraction of superpeer nodes increases. This increase is steepest at the “jamming” transition. The eigenvalue spectra of the networks reveal that in the jammed state peers are only connected to superpeers, a topology known to be very robust. By contrast, at high temperatures peers are connected to each other as well. Due to the finite size of the polymers, our telechelic network differs from random Erdos-Renyi (ER) bimodal networks. As in many real-world networks, spatial effects play a role. After rewiring the networks obtained in the simulations, we reach the ER limit, that is, the clustering coefficients are equal to those obtained for random ER networks.

2:03PM B9.00015 Generalized fractional Fokker-Planck equation for anomalous diffusion, ALEX VEKSLER, RONY GRANEK, Ben-Gurion University of the Negev, Beer Sheva, Israel — The problem of anomalous diffusion is important for a variety of systems, such as fluids, glasses, polymers, proteins etc. It is characterized by a mean square displacement evolving in time as a power-law (z^2 = 2Dt^α). However, a Fokker-Planck-like equation which could describe a stationary Gaussian process with anomalous-diffusion behavior, such as the one described by the Generalized Langevin equation, is still missing. We propose a generalization for constant force to the fractional Fokker-Planck equation (fFP) [Metzler, R. and Klafter, J., Phys. Rep. 339 (2000), 1-77], based on a series expansion in spatial and fractional time derivatives and powers of the Fokker-Planck operator. The proposed equation, GfFP, recovers the generalized Einstein relation and leads to Gaussian distribution, in particular, for free particle diffusion. We apply GfFP to 1-D first passage time problem. The long-time asymptote of the probability distribution behaves like exp(-t^-α). This contrasts with the power-law behavior of the corresponding solutions of the fFP. We further propose to generalize GFfP for treating other outstanding problems, such as the anomalous diffusion under an harmonic potential and the Kramers’ escape problem.

11:15AM B10.00001 Switching behavior and scaling effects in ferroelectric capacitors, ALEXEI GRUVERMAN, University of Nebraska-Lincoln — In this presentation, we discuss the results of direct time-space resolved studies of domain switching behavior in micrometer capacitors by means of piezoresponse force microscopy (PFM). The PFM approach allows an insight in the mechanism of polarization reversal and its change as a function of the capacitor size and microstructure. Simultaneous visualization of the instantaneous domain configurations arising during polarization reversal and sub-ms transient current measurements allow us to establish direct relationship between the electrically measured polarization reversal signal and domain switching kinetics and determine the relative contribution of nucleation and wall motion mechanisms into polarization reversal as a function of capacitor size. Effect of microstructure on domain switching kinetics has been studied by comparing the switching behavior of polycrystalline and epitaxial capacitors. It is shown that in epitaxial capacitors the domain kinetics can be described by the classical nucleation model. In the polycrystalline capacitors, interaction of moving domain walls with microstructural defects gives rise to a completely different time dependence of polarization due to a wide distribution of local switching times. In this case the domain kinetics can be fitted by nucleation-limited switching model.

11:51AM B10.00002 Resolving Deterministic Mesoscopic Mechanisms of Local Bias-Induced Phase Transitions in Ferroelectric Materials. S.V. KALININ, S. JESSE, M.P. NIKFROV, P. MAKSYMOWYCH, N. BALKE, A. BADDORF, H.J. CHANG, A.Y. BORISEVICH, S.J. PANNYCOOK, S. CHOUDHURY, Y. LI, L.-Q. CHEN, OAK RIDGE NATIONAL LAB TEAM, PENN STATE UNIV. TEAM — Polarization switching in ferroelectric and multiferroic materials is invariably controlled by defects that act as nucleation and pinning sites. Using the synergy of high-resolution spectroscopic Piezoresponse Force Microscopy, materials systems with atomically engineered defects, and phase field modeling, we demonstrate that deterministic mesoscopic mechanisms of polarization switching can be determined. In particular, the artificial bicrystal grain boundary in (100) BiFeO_3 is found to impede ferroelectric switching, but facilitate ferroelastic switching for one of the constituent crystals. The coupling between ferroelastic domain walls and ferroelectric polarization switching is demonstrated and attributed to the kinetic effects. These studies open the pathway for probing kinetics and thermodynamics of local bias-induced phase transitions and dissipation on a single-defect level using field confinement by an SPM tip. The future potential for atomistic studies is discussed.

12:03PM B10.00003 Nanometer/Nanosecond Resolved Domain Dynamics Allowing Mapping of Distinct Nucleation and Growth Activation Energies, BRYAN HUEY, NICHOLAS POLOMOFF, VINCENT PALUMBO, JAMES BOSSE, University of Connecticut, Institute of Materials Science — A high speed variation of AFM is employed to uniquely monitor ferroelectric domain dynamics. Through pump/probe schemes, 20 nanometer resolution and 10 nanosecond temporal resolution is maintained. Consecutive images during switching therefore provide maps of nanoscale times, while domain wall growth velocities as high as 25 m/s are observed. By imaging a specific region repeatedly with several pulse amplitudes, activation energies can also be extracted as a function of position, revealing completely independent energies for nucleation and growth that are sample dependent.
12:15PM B10.00004 Optical crystallography and ferroelectric domain imaging of BaTiO$_3$ nanocrystals with tip-enhanced phonon Raman spectroscopy  
SAMUEL BERWEGER, CATALIN C. NEACSU, Department of Chemistry, University of Washington, Seattle, WA, 98195 — This study focuses on the optical characterization of BaTiO$_3$ nanocrystals, using a combination of optical crystallography and tip-enhanced phonon Raman spectroscopy. The technique allows for the detection of ferroelectric domain structures with high spatial resolution. The study demonstrates the potential of this approach for the investigation of nanocrystal materials.

12:27PM B10.00005 Effects of Surface Modification on Photo-Induced Ferroelectric Nanolithography$^1$.  
YANG SUN, CHI XU, CHIYU ZHU, ROBERT NEMANICH, Arizona State University — This study investigates the effects of surface modification on the photo-induced ferroelectric nanolithography process. The results show that surface modification can significantly affect the ferroelectric properties of the nanolithography patterns, opening new possibilities for controlling the material properties at the nanoscale.

ALEXEI GRIGORIEV, The University of Tulsa — Time-resolved studies of the polarization switching in Pb(Zr,Ti)O$_3$ capacitors reveal that the switching process is highly dependent on the applied electric field and temperature. The study provides insights into the mechanisms governing the polarization switching in these materials.

1:27PM B10.00008 Polarization rotation in epitaxially strained perovskite-oxide superlattices$.  
SERGE NAKHMANSON, Argonne National Lab — This work focuses on the polarization rotation in epitaxially strained perovskite-oxide superlattices, showing how the polarization can be rotated under certain conditions, leading to new possibilities for controlling the material properties.

1:39PM B10.00009 Local polarization discontinuities in perovskite superlattices via compensating heterointerfaces $.  
EAMONN MURRAY, DAVID VANDERBILT, Rutgers University — This study demonstrates how local polarization discontinuities can be compensated using heterointerfaces, leading to materials with enhanced ferroelectric properties.

1:51PM B10.00010 Enhanced piezoelectricity in PbTiO$_3$/BaTiO$_3$ superlattices, VALENTINO R. COOPER, Oak Ridge National Laboratory, KARIN M. RABE, Rutgers University — Short period ferroelectric/ferroelectric PbTiO$_3$ (PTO)/BaTiO$_3$ (BTO) superlattices are studied using density functional theory. Contrary to the trends in paraelectric/ferroelectric superlattices the polarization remains nearly constant for PTO concentrations below 50%. In addition, a significant decrease in the c/a ratio below the PTO values is observed. We predict an enhancement in the $d_{33}$ piezoelectric coefficient peaking at ~75% PTO concentration due to the different polarization-strain coupling in PTO and BTO layers. Further analysis with a superlattice effective Hamiltonian reveals that these trends are bulk properties which are a consequence of the reduced $P$ brought about by the polarization saturation in the BTO layers.

2:03PM B10.00011 ABSTRACT WITHDRAWN —

Monday, March 16, 2009 11:15AM - 2:03PM —
Session B11 DMP: Focus Session: Transport Properties of Nanostructures I: Surface Assemblies and Films 305

11:15AM B11.00001 Following elemental chemical steps by imaging molecular orbitals by STM, PETER LILJEROTH, University of Utrecht — Probing the electronic structure of molecules by STM is complicated by the strong interaction of the molecular orbitals with the metal substrate.[1,2] Adiabatically increasing the ultrathin insulating film alleviates this problem and allows direct imaging of molecular orbitals in real space.[1] This approach will be illustrated by two examples: characterizing the operation of a single-molecule switch and controlling and monitoring the formation of an organometallic complex. The inner hydrogens in the central cavity of a naphthalocyanine molecule can be switched between two equivalent positions.[3] This process (hydrogen tautomerization reaction) can be initiated in a controlled fashion by excitation induced by the inelastic tunnelling current. The tautomerization reaction can be followed by resonant tunnelling through the LUMO of the molecule and is expressed as considerable changes in the conductivity. In addition, we demonstrate a coupling of the switching process so that the charge injection in one molecule induces tautomerization in an adjacent molecule. The other example will consider constructing an organometallic complex from individual organic molecules and metal atoms by STM manipulation on the ultrathin insulating film. The manipulation process and the associated changes in the molecular orbitals (energy, spatial extension, symmetry) can be followed STM imaging and spectroscopy.

1Work in collaboration with Jascha Repp and Gerhard Meyer.

11:51AM B11.00002 Apparent anomaly in electron scattering in Ag nanostructures*, ELLEN D. WILLIAMS, CHENGANG TAO, WILLIAM C. CULLEN, Dept. of Physics, U. of Maryland - College Park — Electron scattering from diffusing atoms can be visualized via the effects of the corresponding force that biases atomic motion, the “electromigration force”. Using a combination of scanning tunneling microscopy and scanning electron microscopy, we investigate electron scattering via the biased motion of monatomic islands and CuO-decorated steps on Ag(111) surfaces in the presence of large current density ($j_{bulk} = 6.7\times10^{9}$ A/m$^2$). For monatomic adatom islands, the biased motion is opposite to the current direction and thus parallel to the direction of momentum transfer (the “wind force” direction), while vacancy islands move oppositely. The measured drift velocity $v$ as a function of the island radius $R$, $vR = 1.9$nm$^2$/s, yields an anomalously large effective force per boundary atom $-0.06$ meV/nm . An effective scattering force of similar magnitude is also observed via current-induced curvature of CuO-decorated line-boundaries. Possible mechanisms for this effect, including current crowding, charge transfer and local heating, will be discussed. 1. A. Bondarchuk, et al. Phys. Rev. Lett. 99, 206801 (2007)

12:03PM B11.00003 Orbital-resolved polaron states in CdSe dots and rods probed by scanning tunnelling spectroscopy, PETER LILJEROTH, ZHIXIANG SUN, INGMAR SWART, University of Utrecht, CHRISTOPHE DELERUE, IEMN-Dept. ISEN, DANIEL VANMAEKELBERGH, University of Utrecht — Despite the extensive knowledge of phonons in semiconductor crystals, the polaron states formed by the coupling between phonons and single electronic orbitals have not been measured directly due to the negligible spacing between the energy levels in conventional semiconductors. This can be overcome in semiconductor nanocrystals that have discrete energy levels due to quantum confinement. Here, we present scanning tunneling spectroscopy results on CdSe dots and rods showing the single- electron polaron energy levels with their phonon replica. We measure the spacing and intensity of the replica, and derive the electron-phonon coupling strength for different orbital symmetries. The effect of multiple added electrons on the coupling strength can be assessed under shell-filling conditions. Our results show the formation of polaron eigenstates arising from Fröhlich coupling of an electron to longitudinal phonons with a coupling strength that depends considerably on the size and shape of the nanocrystals. The results are important for understanding electron transport in zero and one-dimensional semiconductors and the intra-band relaxation of hot carriers in quantum dots.

12:15PM B11.00004 Morphology and transport properties of self-assembled, ligand-exchanged PbSe nanocrystal arrays, CHING-TZU CHEN, IBM Thomas J Watson Research Center, WEON-KYU KOH, CHRISTOPHER MURRAY, Department of Chemistry, University of Pennsylvania, CHANG C. TSUEI, IBM Thomas J Watson Research Center — Self-assembled PbSe nanocrystal (NC) arrays have shown strong potential as a viable candidate for producing large-scale quantum dot superlattices. Such superlattices not only have significant technological implications, but they also serve as a model system for simulating strongly correlated transition-metal oxides. At present, highly-ordered PbSe NC arrays can be reproducibly prepared on structured Si-substrates by drop-casting PbSe solution in controlled environments. The as-grown superlattice films are nearly insulating, and post-processing ligand exchange is necessary to induce conduction. However, the lack of understanding of the ligand exchange processes has been a bottleneck to reliably producing highly-ordered conductive arrays. In this talk, we report on in-depth characterizations of the PbSe NC films treated with various ligand molecules in different solvents. The effect of a range of ligands and solvents on the film morphology will be discussed in details. Preliminary temperature-dependent transport and noise studies will be presented.
12:27PM B11.00005 Tunneling Spectroscopy of Ultrathin Insulating Films: Cu$_2$N on Cu(100)\textsuperscript{1}

CHARLES RUGGIERO, TAEYOUNG CHOI, JAY GUPTA, The Ohio State University — Insulating films of only a few atomic layers offer insight into the evolution of electronic structure at the nanoscale. We report scanning tunneling microscopy (STM) studies of monolayer Cu$_2$N films grown on Cu(100). Our tunneling spectra indicate that Cu$_2$N acts as an insulator, with a band gap that exceeds 4 eV \textsuperscript{1}. We study changes in this electronic structure with size, ranging from few-atom islands to complete films. We find that the conduction band edge first emerges in few-atom islands, and shifts toward lower energy with increasing island size. Images of the local density of states show standing wave patterns consistent with the confinement of electrons to these 2D islands.

Measurements of the tunneling barrier height and image potential states indicate that the Cu$_2$N work function is ~0.9 eV larger than bare Cu. This suggests a significant surface dipole, consistent with charge transfer predicted by theory. http://www.physics.ohio-state.edu/~jgupta

\textsuperscript{1} NSF CAREER (DMR-0645451).

12:39PM B11.00006 Ambipolar Ballistic Electron Emission Microscopy (BEEM) Studies of Gate-field Modified Schottky Barriers(SBs). Y.L. CHE, J.P. PELZ, The Ohio State University — Gate-field modified SBs are important for “Schottky Barrier FETs” \textsuperscript{1}, and could be used to control spin and charge injection into other semiconductor device structures. We have made the first \textit{ambipolar} BEEM measurements on Au/Si SBs that can be changed from effective n-type to p-type by applying a positive or negative back-gate bias, respectively. Samples were fabricated using SIMOX silicon-on-insulator wafers (35nm Si/150nm SiO$_2$/p-Si substrate), with Ti/Au and Pt pads as ohmic contacts for n-type and p-type operation, respectively. The local SB heights at 80K for electrons and holes were measured at the \textit{same location} to be ~0.785eV and ~0.332eV respectively, which correspond to intrinsic SBHs of ~0.84eV and ~0.36eV after accounting for image force lowering. These sum to 1.20eV, close to the ~1.17eV Si bandgap at 80K. We will discuss on-going measurements of the dependence of the local SBH on temperature, back-gate bias, Si film thickness, and bias between the Schottky and ohmic contacts. Future work will investigate local variations of the conduction and valence bands due to local “geometry-induced” electric fields in nanostructured contacts. Work supported by National Science Foundation Grants No. DMR-0505165 and DMR-0909237 \textsuperscript{1}

12:51PM B11.00007 Temperature dependence of lateral hot-electron spreading in Au films using Cross-Sectional Ballistic Electron Emission Microscopy. C. MARGINEAN, J.P. PELZ, The Ohio State University — Cross-sectional ballistic electron emission microscopy (XBEEM) was used to investigate the temperature dependence of hot-electron lateral spreading in metal films. A sequence of GaAs QWs of 1 to 15 nm width (separated by 200nm Al$_{0.3}$Ga$_{0.7}$As barrier layers) were cleaved \textit{ex situ}, and then 10 nm-thick of Au was thermally deposited on the cleaved edge to form Au Schottky barrier (SB) “nanoaperture” contacts \textsuperscript{1}. Previous XBEEM results showed an unexpectedly large hot-electron lateral spreading at room temperature consistent with multiple electron scattering inside the metal film \textsuperscript{2}. If phonon scattering of hot-electrons is significant in Au films (as previously suggested \textsuperscript{3}), then the lateral spreading should increase at lower temperature. However, we found that the lateral spreading at 80K was almost the same as at room temperature, suggesting that electron-phonon scattering is not the dominant scattering mechanism. We will also discuss the temperature dependence of the BEEM current amplitude, as well as Monte-Carlo simulations of the lateral spreading process. Work supported by NSF Grant No. DMR-0505165. \textsuperscript{1} C. Tivarus, \textit{et al}. PRL 94, 206803 (2005) \textsuperscript{2} C. Tivarus et al., APL 87, 182105 (2005) \textsuperscript{3} L. D. Bell, PRL 77, 319007 (1996).

1:03PM B11.00008 Classical size effect in nanometric Cu films: the dominant role of grain boundary scattering. D. CHOI, Dept. of Mater. Sci. and Eng., Carnegie Mellon Univ., Pittsburgh, PA 15213, T. SUN, A. WARREN, B. YAO, AMPAC, Univ. of Central Florida, Orlando FL 32816, A. DARBAL, K. BARMAK, Dept. of Mater. Sci. and Eng., Carnegie Mellon Univ., Pittsburgh, PA 15213, M. TONEY, Standard Synchrotron Radiation Laboratory, Menlo Park, CA 94025, R. PEALE, Dept. of Physics, Univ. of Central Florida, Orlando FL 32816, K. COFFEY, AMPAC, Univ. of Central Florida, Orlando FL 32816 — Surface and grain boundary electron scattering contribute significantly to resistivity as the dimensions of polycrystalline metallic conductors are reduced to, and below, the electron mean free path. In this work, a methodology is reported to independently evaluate surface and grain boundary scattering in encapsulated polycrystalline Cu thin films, with thicknesses of 28-158 nm, grain sizes of 35-466 nm, and interface roughnesses of 0.2-2 nm. The film resistivity, measured at both room temperature and at 4.2 K, is compared for samples having different grain sizes and film thicknesses. The resistivity contribution from grain boundary scattering is found to be dominant in SiO$_2$/Cu/SiO$_2$ and Ta/ SiO$_2$/Cu/Ta/SiO$_2$ films. Resistivity data for a third set of samples, namely SiO$_2$/TaSiN$_x$/Cu/TaSiN$_x$/SiO$_2$, will also be presented.

1:15PM B11.00009 Crystal Orientation Imaging of Nanometric Metal Films in the Transmission Electron Microscope. A. DARBAL, K. BARMAK, N. T. NUHFER, Dept. of Mater. Sci. and Eng., Carnegie Mellon Univ., Pittsburgh, PA 15213, D. J. DINGLEY, G. MEADEN, EBSSD Consultants, Salt Lake City, UT 84105, J. MICHAEL, Sandia National Laboratories, Albuquerque, NM 87185, T. SUN, B. YAO, K. R. COFFEY, AMPAC, Univ. of Central Florida, Orlando FL 32816 — A reliable method for orientation mapping of nanocrystals is crucial to the study of the impact of grain boundaries on resistivity increase of metal films as thickness is reduced (classical size effect). Here we report on the use of the Automated Crystallography (ACT) system for high-resolution grain and orientation mapping in the TEM. The samples for the study were a 50 nm-thick Pt film annealed at 800 °C and a 40 nm-thick Cu film annealed at 450 °C. In ACT, the diffraction pattern for a given point is constructed by analyzing its intensity variation in a series of dark field images obtained using hollow-cone illumination. The reconstructed diffraction pattern for every point is indexed to obtain the orientation map. The sensitivity of the orientation imaging results to details of sample preparation, data acquisition and choice of indexing parameters is discussed.

1:27PM B11.00010 Controlling the assembly and electronic properties of solution processed CNT devices: From large area arrays to individual CNT\textsuperscript{1}. SAIFUL I. KHONDAKER, PAUL STOKES, YODCHAY JOMPOL, SHASHANK SHEKHAR, Nanoscience Technology Center and Department of Physics University of Central Florida, Orlando, FL 32826 — Single walled carbon nanotubes (SWNTs) are considered to be ideal components for nanoelectronic devices because of their exception electronic properties. Integration of these nanostructures into electronic circuits requires the precise positioning of them in different architectures. Here we will summarize our recent progress on the directed assembly of SWNTs using AC dielectrophoresis (DEP). SWNTs are assembled from a surfactant free commercially available aqueous solution using a non uniform electric field. By controlling the electric field strength, frequency, density of solution and novel fabrication techniques, we are able to control the assembly of SWNT from dense arrays mimicking electric flux to single SWNT devices with high yield. Electronic transport properties of field effect transistors and single electron transistors fabricated from such assembly will be discussed.

\textsuperscript{1} This work is partially supported by NSF-CARRER award ECS-0748091.
films. That the PV response of suspended films in vacuum is mainly driven by thermal mechanisms. Finally, we were able to reverse the sign of the PV by changing the doping state of the carbon nanotube films. Thus, monitoring the magnitude of the PV appears as a powerful tool for evaluating the doping state of suspended films.

1:51PM B11.00012 Carrier Type and Transport Characteristics of a-B3C. MARCUS SKY DRIVER, SAAD JANJUA, SUDARSHAN KARKI, DAESUHEUM YEOUN, ANTHONY CARUSO, Dept. of Physics, University of Missouri - Kansas City, CARUSO RESEARCH GROUP TEAM — Boron carbide has many technological applications, including radiation hard semiconducting applications; the most popular of which is volatlic transduction. Structural defects are known to exist, whose implications in defining the majority carrier type is important, yet unclear. Gaining greater insight into the local physical structure and transport character is crucial toward optimizing the volatile behavior. Subsequently, gaining information about the majority carrier and carrier concentration from Hall effect and band structure from photoemission spectroscopy gives insight into the electronic structure and transport of boron-rich carbides. Boron carbides are predominately p-type due to their electron deficiency, but it has been suggested that the electron as a majority carrier may also exist. Preliminary studies including Hall effect, photoemission and extended X-ray absorption fine structure will be discussed within the context of amorphous boron carbides with respect to the carrier properties and physical structure for various growth conditions, within the context of local structural defects.

11:15AM B12.00001 Effects of shadowing and steering in oblique incidence epitaxial growth1. YUNUSIC SHIM, Department of Physics and Astronomy, University of Toledo — Recently the fabrication of novel nanostructures by oblique deposition has drawn much attention due to their potential application in electronic and mechanical devices as well as the interesting morphologies observed in various experiments, such as nanorods, nanocolums, and nanohelicoids. Unlike self-organization by misfit strain in heteroepitaxial growth, oblique deposition provides a relatively direct way of controlling surface structures of growing films. Recent experiments indicate that oblique incidence deposition can significantly alter materials properties such as surface roughness, magnetic anisotropy, optical transmittance, and porosity. After a review of these experimental results, we first show that a series of morphological transitions observed in oblique incidence Cu/Cu(100) growth near room temperature can be explained primarily by geometrical shadowing effects [1]. We then discuss the modifying effects of steering due to short-range and long-range attraction [2] as well as of substrate rotation on the surface morphology. Finally, we present the results of recent multiscale simulations of Cu/Cu(100) growth at lower temperature (T = 160 - 200 K) [3] as well as of parallel accelerated dynamics and molecular dynamics simulations at very low temperature [4]. Based on these simulations we have been able to explain a number of recent intriguing but previously unexplained experimental results including the strong dependence of the surface morphology and roughening behavior on temperature as well as the development of compressive strain in metal thin film growth.

11:51AM B12.00002 Diffusion of two-dimensional Cu islets on Ag(111) studied with the Molecular Dynamics Method. SADAR S. HAYAT, The Islamia University of Bahawalpur, MARISOL ALCANTARA ORTIGOZA, TALAT S. RAHMAN, University of Central Florida — Our molecular dynamics simulations (at 300, 500 and 700 K) of the diffusion of two-dimensional Cu$_n$ islets (1≤n≤9) on Ag(111) using many-body potentials yield an Arrenius behavior. Concentrated motion is seen to dominate the diffusion of smaller islets (2-4 atoms) whereas multiple-atom, shape-adjusting processes control the diffusion of the larger ones. Although the effective energy barrier scales with islet size, the barriers do not change considerably for islands containing 4 to 9 atoms (they are ~220 ± 37 meV). While the diffusion barrier for Cu monomers on Ag(111) is higher than that on Cu(111) (both in experiment and theory), the situation reverses starting from the dimer. Our results for monomer and dimer are in excellent agreement with those extracted from experiments. On comparing our results with those for Cu islets on Cu(111), we find that the comparatively large Ag-Ag bond-length sets the contrast between Cu monomer diffusion on Cu(111) and on Ag(111). The diffusivity of Cu dimer, however, is boosted on Ag(111) by the competition between optimizing the Cu-Cu and the Cu-Ag bonds. For larger islets (3-9 atoms) our results reveal several novel diffusion processes, including those in which an islet-atom climbs atop. Morgenstern et al. PRL93, 056102 (2005). Work supported by NSF-ITR 0428826.

12:03PM B12.00003 Atomic structure determination of the (001) surface of the semimetal Bi by STM and LEED J. SUN, J. WANG, Dept. of Physics, Univ. of New Hampshire; J. WELLS, NTNU, Trondheim, Norway; PH. HOFMANN, Institute for Storage Ring Facilities, University of Aarhus, Denmark; K. POHL, Dept. of Physics, Univ. of New Hampshire — The Bi surfaces differ from the semimetal bulk due to the metallic surface states, induced by the symmetry breaking and strong spin-orbit interaction. All Bi surface states studied are spatially confined to the first layer. Bi(001) is a notable exception with deeply penetrating states, which could have a significant effect on the bulk properties of nanostructures. This work presents surface morphology observation by STM and atomic structure determination by LEED, which are expected to be closely related to the electronic properties. STM shows an unconstructed surface and wide terraces with double-layer step heights of about 3.76 ± 0.02 Å. We also identify the short termination by obtaining unstable single step heights via special sputtering operations. In the LEED analysis, the termination with an intact bilayer also results in a much better agreement between calculated and measured intensities than the broken bilayer. Strong multilayer oscillatory relaxations (about 10%) are found to reach deep into the fifth layer, which can be seen as the structural response to the unusually deep surface state penetration at this surface. The measured relaxations agree well with those from first-principles calculations.
12:15PM B12.00004 Thermal-stability of Pd-Cu surface alloys investigated at the nanometer-scale by LEEM-IV analysis . E. BUSSMANN, Sandia National Labs, NM — Pd-Cu(100) surface alloys are interesting as model systems for metal/metal epitaxy, as well as for their catalytic properties, and as coatings, e.g. for electromigration resistance. We employ the LEEM-IV technique, with 8.5 nm spatial resolution and submonolayer chemical sensitivity, to investigate Pd interdiffusion into the Cu(100) surface. The LEEM-IV technique is sensitive to the layer-by-layer composition down to the fourth subsurface layer. After annealing a 0.4 ML Pd surface alloy at around 540 K, some regions of the surface develop a Cu$_3$Pd structure, a familiar bulk alloy phase. In other regions, the surface Pd concentration becomes dilute due to Pd diffusion into the bulk. We estimate the thermal activation barrier to Pd diffusion from the surface alloy into Cu bulk to be 1.7±0.15 eV. The LEEM allows real-time, real-space, observation of the interdiffusion process, and the concurrent evolution of the surface structure, at the nanometer scale. Sandia is operated by Sandia Corp., a Lockheed Martin Company, for the U. S. DOE’s NNSA under Contract No. DE-AC04-94AL85000. Work at UNH is funded by the NSF under Grant No. DMR-0134933.

12:27PM B12.00005 Bistability of Nanoscale Ag Islands on Anisotropic Si(111)-(4x1)-In Surface Stress Template . MIAO LIU, University of Utah, YAOYI LI, Tsinghua University, DECAI YU, University of Utah, JINFENG JIA, QIKUN XUE, Tsinghua University, FENG LIU, University of Utah, DAYAN MA, Xi’an Jiaotong University, XUCUN MA, Chinese Academy of Sciences — We present a combined experimental and theoretical study of stability of Ag nanofilms grown on Si(111)-(4x1)-In surface. Experiments show the existence of two stability regimes: a conventional regime at low temperature where only one island shape is stable, and an unconventional regime at room temperature (RT) where isotropic compact islands coexist with anisotropic elongated ones. First-principles calculations show the unusual bistability at RT arises from the fact that the Ag nanofilms are under anisotropic stress, further supported by a continuum model of island shape evolution as a function of island size.

12:39PM B12.00006 Impurities in Vacuum Deposition: Effect on Island Nucleation and Surface Morphologies1, 2. ALBERTO PIMPINELLI, Univ. of Maryland, College Park (UM) & U.B.P.Clermont-2 & Science Attaque, French Consulate, Houston, AJMI BH.HAMOUDA, UM & Univ. Monastir, Tunisia, T. L. EINSTEIN, UM — The effect of impurities on epitaxial growth in the monolayer regime is studied using kinetic Monte Carlo simulations of two species solid-on-solid growth model. Both species are mobile, and attractive interactions among adatoms and between adatoms and impurities are incorporated. Impurities can be codeposited with the growing material or predeposited prior to growth. We discuss the peculiar morphologies observed in copper on copper deposition on vicinal surfaces, and argue that only the presence of impurities can explain all observed features3. We also investigate the effect on island morphology using a recently developed approach based on capture zone distributions.

1Work at UM supported by the MRSEC, NSF Grant DMR 05-20471

12:51PM B12.00007 Interface evolution and cluster formation during de-wetting of thin solid films . ADI CONSTANTINESCU, LEONARDO GOLUBOVIC, West Virginia University, ARTEM LEVANDOVSKY, University of California Riverside — Morphology evolution of solid thin films is investigated within a continuum interface dynamics model that incorporates both the interface relaxation and the long range de-wetting interactions. The model is used to explore the cluster formation phenomena seen on the surfaces of polymeric and metallic thin films. Via numerical simulations and analytic arguments, we obtain the scaling laws governing the coarsening growth of these clusters. These scaling laws are found to be super-universal at long time scales: They do not depend on the dimensionality of the film substrate and the nature of the long range de-wetting interactions, as documented by our numerical simulations on 1-d and 2-d substrates with de-wetting interactions of various forms. However, for the physically interesting 2-d substrates, the long range interactions introduce a distinct early time scaling behavior that persists over many decades of time and may be significant for the understanding of the current experimental phenomenology.

1:03PM B12.00008 First-passage time approach to kinetic Monte Carlo simulations of metal(100) growth1, 2. GIRIDHAR NANDIPATI, YUNUSIC SHIM, JACQUES AMAR, University of Toledo — One of the difficulties in carrying out realistic kinetic Monte Carlo simulations is the existence of rapid, repetitive low-barrier processes which can dramatically slow down the simulation. For example, in metal(100) growth the rate for edge-diffusion can be very fast even at moderate temperatures, while the barriers for edge-detachment and corner rounding are relatively high. While one approach to this problem is to artificially reduce the rate of edge-diffusion, such an approach can significantly alter the thin-film evolution. To address this problem while still preserving the relative rates for all processes, we have developed a modified KMC method in which edge-diffusion and corner-rounding are treated using a first-passage time formalism, while the remaining processes are treated as in normal KMC. In simulations of an effective-medium theory (EMT) based model of Cu/Cu(100) growth at T = 200 K and above we find that a speed-up of several orders of magnitude is possible, without sacrificing accuracy. Preliminary results for Cu/Cu(100) growth at high temperatures will also be presented.

1:15PM B12.00009 Growth morphology of ultra-thin Ni films on Pd (100)1, 2. PATRICIO HÄBERLE, CAROLINA PARRA, UTFSM, Valparaiso — A series of thin Ni films with thicknesses between 0.2 ML to 13 ML were deposited on a Pd(100) substrate at room temperature (RT). Growth morphology was investigated using scanning tunneling microscopy (STM). The STM images indicate the existence of three different growth modes. Up to 6.5 ML, Ni films grow pseudomorphically, consistent with a face-centered tetragonal (fct) structure. From 6.5 ML to 10.5 ML a new interlayer distance of 1.0 ± 0.1 Å is established. The new structure is accompanied by the appearance of an arrangement of filaments on the top layer. These filaments are presumably related to a strain relief mechanism of the fct films. Finally above 10.5 ML the Ni films recover their face-centered cubic (fcc) lattice constants. The filaments evolve to form a net-like structure over the whole surface. Preliminary data indicates the magnetic properties of the layers are linked to the evolution of the film’s structure.

1:27PM B12.00010 Dynamical LEED analysis of a quasicrystalline Cu film using periodic approximant structure models . RENEE DIEHL, Penn State University, KATARIINA PUSSI, Lappeenranta University of Technology — Quasicrystalline surfaces pose a challenge to diffraction techniques since they have no periodicity. They do, however, have good long-range order and produce diffraction patterns with sharp peaks. Copper grows on the 5-fold surface of i-Al-Pd-Mn in a layer-by-layer mode. Although its atomic structure cannot be determined by STM, the diffraction pattern from a 5-layer thick film consists of sharp peaks and streaks, the location of which indicate that this film consists of an aperiodic array of rows of periodically-spaced Cu atoms. We have applied the method of periodic approximants in a dynamical LEED analysis of the structure of this quasiperiodic copper film to determine the atomic structure of the Cu film. This analysis indicates that the Cu film has a distorted cubic structure that conforms to the quasiperiodic substrate structure, providing an example of periodic-aperiodic structure matching. This research is supported by NSF-DMR-0505160 and the Academy of Finland.
1:39PM B12.00011 Theoretical Study of Adsorbates-induced Restructuring of Pb flat-top mesa in the Quantum Regime\(^1\), WENGUANG ZHU, University of Tennessee & Oak Ridge National Laboratory, ALEXANDER KHAIJ-TOORIANS, University of Texas at Austin & University of Hamburg, CHIH-KANG SHIH, University of Texas at Austin, ZHENYU ZHANG, Oak Ridge National Laboratory & University of Tennessee — Based on first-principles total energy calculations, we study the adsorption and diffusion of a series of metal adsorbates (Fe, Co and Cs) on flat-top Pb mesas, focusing on their influence on the morphology of the mesas. We found that single Fe and Co atoms can easily dive into the substrate interstitial sites by overcoming a small energy barrier upon deposition onto the mesa top. In contrast, Cs atoms are able to substitute first-layer Pb atoms via a phase exchange process resulting in a surface alloy. This induces a dramatic change on the surface morphology of these mesas as observed in recent experiments. The modification of the transformation is characterized by the emergence of Cs-decorated monolayer-high Pb islands which are predominantly formed on quantum mechanically unstable regions of the Pb mesas. Connections with experimental observations in other related systems will also be discussed.

1:51PM B12.00012 Stress development and relaxation during early stages of oxidation of metals and alloys\(^1\), GUANGWEN ZHOU, CHANGHONG KE, State University of New York, Binghamton, JUDITH YANG, University of Pittsburgh, JEFFREY EASTMAN, JOHN PEARSON, Argonne National Laboratory — It has been long recognized that oxidation of metals results in the generation of stresses and these stresses play an important role in shaping the microstructure of oxide films. However, the mechanism governing the stress development and relaxation during early stages of oxidation of metals and alloys is still to a significant degree unclear. Using a combination of in-situ ultra-high vacuum (UHV) transmission electron microscopy (TEM) and finite element method, we show how oxidation-induced stresses can be used to tailor the initial oxide formation during early-stage oxidation of Cu(100) and Cu-Au(100). From analysis of the observed morphological evolution of Cu\(_2\)O nanoslands, we establish a close relationship between the stresses generated from the oxide growth and the thermodynamic selection of nanoscale morphology of the oxide film. We expect that our results have implications for controlled production of novel oxide nanostructures through controlling the oxidation-induced stresses via oxidation temperature or alloying.

2:03PM B12.00013 Studies of oxidation of the Cu(100) surface using low energy positrons. , W.B. MADDox, N.G. FAZLEEw, A.H. WEISS, Department of Physics, University of Texas at Arlington — Changes in the surface of an oxidized Cu(100) single crystal resulting from vacuum annealing have been investigated using positron annihilation induced Auger electron spectroscopy (PAES). PAES measurements show a large increase in the intensity of the positron annihilation induced Cu M\(_{2,3}\)VV Auger peak as the sample is subjected to a series of Isochroinal anneals in vacuum up to annealing temperature 300° C. The intensity then decreases monotonically as the annealing temperature is increased to ~600° C. Experimental PAES results are analyzed by performing calculations of positron surface states and annihilation probabilities of surface-trapped positrons with relevant core electrons taking into account the charge redistribution at the surface, surface reconstructions, and electron-positron correlations effects. Possible explanation for the observed behavior of the intensity of positron annihilation induced Cu M\(_{2,3}\)VV Auger peak with changes of the annealing temperature is proposed.

Monday, March 16, 2009 11:15AM - 1:51PM — Session B13 SPS Undergraduate Research I 309

11:15AM B13.00001 Introductory Physics Experiments Using the Wiimote , WILLIAM SOMERS, FRANK ROONEY, ROMULO CHOCA, The College of New Jersey — The WII, a video game console, is a very popular device with millions of units sold worldwide over the past two years. Although computationally it is not a powerful machine, to a physics educator its most important components can be its controllers. The Wiimote (or remote) controller contains three accelerometers, an infrared detector, and Bluetooth connectivity at a relatively low price. Thanks to available open source code, any PC with Bluetooth capability can detect the information sent out by the Wiimote. We have designed several experiments for introductory physics courses that make use of the accelerometers and Bluetooth connectivity. We have adapted the Wiimote to measure the variable acceleration in simple motion, centripetal and tangential accelerations in circular motion, and the accelerations generated when students lift weights. We present the results of our experiments and compare them with those obtained when using motion and/or force sensors.

11:27AM B13.00002 Binary Orbital Motion of Electrically Charged Spheres in Weightlessness.\(^1\), LULU LI, BRAD ATKINS, GAVIN FRANKS, JOSHUA FUCHS, CHASE SLIGER, JENNIFER THOMPSON, RHODES BINARY ORBIT TEAM — The similar mathematical forms of Coulombs Law of Electrostatics and Newton’s Law of Gravitation predict that two oppositely charged spheres should be able to move in a binary orbit about their center of mass using only the electric force as the force of attraction. To test this prediction, we conducted an experiment in July 2008 aboard a specialized C-9B aircraft in NASA’s Microgravity University Program which simulates the conditions of weightlessness. We successfully achieved multiple binary orbits between the two spheres. The orbital motion was analyzed using VideoPoint software to measure the orbital interaction of the spheres.

\(^{1}\)NASA; 07-08 SPS undergraduate research grant

11:39AM B13.00003 Dynamics of a charged Kapitza’s pendulum interacting with radiation in thermal equilibrium , JORGE HERNANDEZ GOMEZ, PAULINA PRADLE SOTO, Facultad de Ciencias, Universidad Nacional Autonoma de Mexico — The considered system is a Kapitza’s pendulum that consists of a disk that spins at constant angular velocity, from which edge is attached a massless rigid rod with an electrically charged bob. The system is studied theoretically and experimentally. The motion equations are settled and solved both, analytically under the small oscillation assumption considering the interaction of the system with black body radiation as a perturbation, and in the general case using numerical algorithms. The pendulum’s dynamics is studied varying both initial conditions and parameters in small steps. In order to identify regions of stable and chaotic motion, Lyapunov’s exponents are calculated. Phase and configuration spaces are plotted to notice periodic and erratic behaviors. Poincare sections and fast Fourier transforms are obtained to identify resonance cases.

11:51AM B13.00004 Electrical energy dissipation in superconducting niobium rings\(^1\), E. M. DOWDELL, K. M. CHIOLA, E. T. ROSAURI, J. D. HETTINGER, Department of Physics and Astronomy, Rowan University — Niobium rings were made from films synthesized using sputtering process. Rings and wires were defined in the films using standard photolithographic techniques followed by wet etching. Three rings were fabricated with different diameters and wire widths. One microbridge was created for direct electrical transport measurements. V-I characteristics of the superconducting niobium microbridge were measured at temperatures below 7K and at magnetic fields up to 2T. Dissipation was induced in the superconducting niobium rings by ramping the magnetic field and measuring Faraday’s Law. The current induced was measured through the magnetic moment and the simple expression \(\mu_{edip}=IA\). We will correlate the magnetically induced measurements with those made directly on the microbridge to investigate this method as a technique for extending transport measurements to lower dissipation levels.

12:03PM B13.00005 Surface plasmon enhancement of fluorescence on gold nanogratings. STEPHANIE WIELE, Department of Physics and Astronomy, Trinity University. IURI GAGNIDZE, Department of Engineering Science, Trinity University. JENNIFER STEELE, Department of Physics and Astronomy, Trinity University — This work focuses on using surface plasmons (SPs) excited on gold wire gratings to enhance the yield from fluorescent molecules. SPs enhance fluorescence by amplifying the electromagnetic near-field that excites the fluorophores as well as providing additional decay channels for the fluorophore. Although it has already been shown that SPs excited on metal nanoparticles can enhance fluorescence, SPs excited on gratings offer several advantages over nanoparticles. Because SPs are excited by the diffraction orders of the grating, changing the angle of incidence of light will change the SP wavelength. The SP excited on the grating can then be tuned on a single plasmonic substrate to overlap the absorption and emission spectrum of many different fluorophores. The ability to tune the SP wavelength through both the absorption and emission wavelength of the fluorophores on a single substrate will give greater insight to how SPs enhance fluorescence and how to maximize the fluorescence enhancement for various biosensing applications.

12:15PM B13.00006 Diffusive Behavior of Lipid Rafts in Multicomponent Membranes. MICHAEL G. LESTER, University of Alabama-Birmingham. MOHAMED LARADJI, University of Memphis. P.S. SUNIL KUMAR, IIT-Madras — The diffusion of nanoscale lipid domains (also known as lipid rafts) in multicomponent membranes in the liquid-liquid coexistence region of the phase diagram is investigated via extensive dissipative particle dynamics simulations. In particular we investigated the effect of membrane diameter and shape (curvature) on the diffusivity of the lipid domains. Our results indicate that the domains exhibit Brownian motion, i.e. the center of mass mean square displacement (\(\Delta R^2\)) = 4Dt, with the diffusion coefficient decreasing as the domain radius, \(r\), is increased. More specifically, we found that \(D \sim 1/r\), i.e. the diffusion of the domains is mainly impeded by viscous drag due to solvent surrounding the membrane. Although the data can also be fitted with the logarithmic expression due to Saffman and Delbrück, the later fit is found to be poorer than that with \(D \sim 1/r\).

1 This work is supported by grants NSF-DMR 0755447 and NSF-DMR 0812470.

12:27PM B13.00007 AC Magnetic Susceptibility Probe for Use in a Commercial SQUID Magnetometer. J.D. COHEN, D.M. PAJEROWSKI, M.W. MEISEL, Dept. Physics, Univ. Florida — An AC magnetic susceptibility probe, employing a typical set of mutual inductance coils, has been constructed for operation in a commercial SQUID magnetometer operating down to 1.7 K and up to 7 T. The primary (~1000 turns) and counterwound secondary (each ~1300 turns) coils were wound with 44 AWG Cu wire on a Kapton tube possessing an ID of 6.4 mm. The ensemble of coils is ~30 mm long and has an OD of 8.7 mm, thereby allowing clearance into the sample region of the SQUID magnetometer. One variation of the probe included optical fibers that passed down the center of the stainless steel support rod. The detection electronics involve a lock-in amplifier and the experiment is controlled by LabView software. Typical AC (1 Hz - 1 kHz) fields of ~10 \(\mu\)T afford the study of the temperature, frequency, and dc-field bias dependencies of magnetically interesting samples such as the spin ice material Ho2Ti2O7 [1] and nanoparticles of Prussian blue analogs [2].

12:39PM B13.00008 Recreation of Natural Optical Phenomena. TIFFANY PAONESSA, PETER SHELDON, Randolph College — This project was undertaken to study and fully understand optical atmospheric phenomena. Research was done on the structure and formation of colorful atmospheric phenomena including, but not limited to, primary, secondary, and supernumerary rainbows and halos were created and photographed.

12:51PM B13.00009 Visualization of fracture precursors in vitreous silica: study of under- and over coordinated ions. FRANK JONES, ROMULO OCHOA, DEBORAH KNOX, The College of New Jersey — We have conducted classical molecular dynamics fracture studies of vitreous silica. A new visualization program was designed to observe the fracture process of the sample as a whole. The program also allows users to highlight and focus on the under- and over coordinated oxygen and silicon ions. A BKS potential was utilized to model the ionic interactions. DL-POLY® was the program used to perform simulations. Amorphous silica samples were generated at high temperatures; through a series of quenching and reannealing periods the samples reached room temperature. This method results in samples having, initially, a number of under- and over coordinated ions (less than one percent of all ions) that were randomly distributed. Radial distributions functions were obtained to verify the amorphous structure of the samples. Stress was applied by uniaxially straining the samples at various rates. As a sample was strained there was an increase in under coordinated ions with seemingly no correlation to the region where the sample would break. In all our simulations the under coordinated ions concentrated in the vicinity of the breakage region a few picoseconds before fracture occurred.

1:03PM B13.00010 Determining the Onset of Amorphization of Crystalline Silicon due to Hypervelocity Impact. C. SHANE POLETTI, MARTINA E. BACHLECHNER, Fairmont State University — Atomic simulations were performed to study a hypervelocity impactor striking a silicon/silicon nitride interface with varying silicon substrate thicknesses. Visualization indicates that the crystalline silicon amorphizes upon impact. The objective of the present study is to determine where the boundary between amorphous and crystalline silicon occurs. In the analysis, the silicon substrate is separated into sixty layers and for each layer the average z displacement is determined. Our results show that the boundary between amorphous and crystalline silicon occurs between layers 20 and 22 for an impactor traveling at 5 km/s. This corresponds to a depth of approximately 32 Angstroms into the silicon. More detailed analyses reveals that the z displacement is noticeably larger for the layers that do not have a silicon atom bonded beneath them compared to the ones that do.

1 Funding for this research project was provided by a WV/NASA Space Grant Scholarship.

1:15PM B13.00011 14N (p,p) Scattering with the KN Van de Graff Accelerator. STEPHANIE LYONS, Randolph College. MICHAEL WIESCHER, University of Notre Dame — The 14N (p,p) scattering experiment was performed with the 4 MV KN Van de Graff Accelerator at the Nuclear Structure Laboratory at the University of Notre Dame. The KN experienced many problems throughout the experiment requiring several belt changes, a change of the drive motor bearings, and a resistor check. The first run of data was converted to cross-sections, and normalized to 30°, which was assumed to be completely Rutherford. Resonances were found at 1.06, 1.55, 1.74, 1.80, 2.34, and 2.47 MeV. These values correlated with previous work done. Further experimentation will be required to clarify the resonances and verify that the scattering at 30° is completely Rutherford.
1:27PM B13.00012 Orientation of the adiabatic demagnetization refrigerator in the Micro-X sounding rocket\textsuperscript{1}, KAITLYN YOHA, Duquesne University, TAREK SAAB, University of Florida, TYLOR WHITMER, PATRICK WIKUS, Kavli Institute for Astrophysics and Space Research, Massachusetts Institute of Technology — The Micro-X sounding rocket is a small rocket equipped with an X-ray telescope and will be launched in 2011. For the telescope to function properly, the adiabatic demagnetization refrigerator (ADR) must be aligned with the optics of the X-ray detectors. During the mission, the ADR will move, thus causing errors. A testing prototype was designed and constructed in the lab to simulate the movement the ADR will experience in flight. This method will monitor the orientation of the ADR relative to the detectors, and allow us to counter the resulting measurement errors.

\textsuperscript{1}This work was supported by NSF REU at the University of Florida, and NASA Grant NNX07AK52G.

1:39PM B13.00013 Use of Multivariate Analysis Techniques to Form a Comparison of Mars Odyssey Gamma Ray Elemental Data to Neutron Data\textsuperscript{1}, PAUL ABBAZIA, Department of Physics and Astronomy, Rowan University — The Lunar Reconnaissance Orbiter’s (LRO) primary mission is exploration. Additional science falls to a secondary focus. LRO does not possess a gamma ray spectrometer, but it has the collimated neutron detector LEND (Lunar Exploration Neutron Detector). It is of interest to determine as much as possible about the moon’s elemental composition using LEND. To do so, data from a similar instrument on Mars Odyssey, HEND (High Energy Neutron Detector), was compared to data from Mars Odyssey’s gamma ray spectrometer (GRS). Elemental maps were previously derived from the GRS data, and a relation to HEND would allow for LEND to fulfill this role on LRO. Toward this purpose, different multivariate analysis techniques were used to compare GRS and HEND data, including Principal Components Analysis (PCA), K-means clustering, and Pearson product-moment correlation. Results indicate that two elements well known to affect neutron counts, hydrogen and iron, can be identified by these techniques. Further analysis may find additional relations, which would have benefits to the fields of geochemistry and neutron spectroscopy.

11:15AM B14.00001 Restricted dislocation mobility in crystals of peanut-shaped colloidal particles, ITAI COHEN, Cornell University — Recent advances in colloidal particle synthesis techniques have enabled the production of a variety of anisotropic yet monodisperse particles, including colloidal “peanuts,” which consist of two connected spherical lobes. Since their shape crudely approximates a dimer, colloidal peanut particles constitute a simple but fundamental extension of the classic system of colloidal spheres. Experimental investigations as well as simulations of colloidal peanut monolayers have shown that at high area fractions the particles form a degenerate crystal (DC). In this structure, the peanut particle lobes order into a triangular lattice, much like close-packed spheres, while the connections between lobe pairs are randomly oriented, uniformly populating the three crystalline directions of the underlying lattice. Comparative studies of crystal formation in rapidly compressed monolayers of peanut-shaped versus spherical particles show that DCs harbor many more defects than equivalent crystals of spheres. This suggests that defect annealing may be frustrated by the constraining rigid connections between particle lobes. To elucidate the interactions between the geometric constraints and defect mobility, we directly examine the mechanisms for dislocation nucleation and propagation in DCs. In particular, we show that obstacles formed by certain particle orientations severely limit the range over which dislocations can glide. Furthermore, we observe that transport over longer distances can proceed through dislocation reactions, which switch the direction of propagation and allow dislocations to bypass such obstacles. In this talk I will discuss the impact that these restricted mechanisms have on the macroscopic properties of DCs.

11:51AM B14.00002 Experimental Study of Brownian Dynamics of Bent-core Colloidal Particles, CHUN-ZHEN FAN, BHUWAN JOSHI, Kent State University, JI-PING HUANG, Fudan University, QI-HUO WEI, Kent State University — Bent-core or banana-shaped molecules exhibit a variety of intriguing liquid crystalline mesophases including nematics and smectic phases. We try to develop suspensions of bent-core shaped colloidal particles to mimic the bent-core liquid crystals. This report will focus on the fabrication of bent-core colloidal particle suspension, and optical microscopic studies of the Brownian dynamics of individual bent-core colloidal particles. The bent-core colloidal particles confined between two glass substrates are observed through dark-field optical microscopy, and their orientation and position are obtained through imaging processing. Results on the translational and rotational Brownian dynamics of these type of particles will be reported.

12:03PM B14.00003 Pinch-off Dynamics of Non-Newtonian Fluids, F. M. HUISMAN, P. TABOREK, University of California Irvine — The pinch-off dynamics of a variety of shear-thinning fluids (foams, concentrated emulsions, and slurries) were studied using high speed videography. The pinch was characterized by the variation of the minimum neck radius rmin as a function of the time to pinch t\(_{\text{p}}\). For inviscid fluids, rmin scales as t\(_{\text{p}}\) to the 2/3 power. We found that for all the shear-thinning fluids rmin scales with t\(_{\text{p}}\) to a power in the range 0.2 to 0.5. To study the transition from conventional inviscid pinch, we systematically varied the concentration of a water-bentonite mixture. As the concentration increased the pinch event transitioned from a needle shape resulting in a satellite drop to a symmetric hyperbolic shape with no satellite drop. These results will be compared with the simulations of Suroy and Basaran (J. Non-Newtonian Fluid Mech. 138 (2006) 134-160).

12:15PM B14.00004 Melting Dynamics of 3D Hard Sphere Colloidal Crystals, DENIZ KAYA, N. L. GREEN, Chemical Engineering Department, C. E. MALONEY, Civil and Environmental Engineering Department , M. WIDOM, Physics Department, M. F. ISLAM, Chemical Engineering; Material Science and Engineering Department, Carnegie Mellon University, Pittsburgh, PA 15213 — We use thermally responsive monodisperse micron sized colloidal particles with hard-sphere interactions to study the melting mechanisms in colloidal crystals. As we increase the temperature, these spherical microgel particles decrease in volume, inducing melting in the colloidal crystals. We use video microscopy and image analysis to determine the dispersion relations and the local elasticity near the melting transition. We compare our findings with existing melting and freezing theories. This work has been partially supported by the NSF through Grants DMR-0619424 and DMR-0645596, and by ACS-PRF.
optical tweezers, rather than a potential landscape as most previous studies use. Changing input power can also change the working direction. Thus we need a state diagram to describe the motor behavior of a colloidal particle in this Brownian motor showed reversible behavior: given input power, working direction changes when particle size grows; given a particle bigger than wavelength trapped in optical tweezers relaxes to equilibrium state. To the contrary, we have found experimentally the particle became a Brownian motor. Furthermore, we have calculated the coupled plasmon modes by a tight-binding approach, taking fully multipolar interactions into account. For approaching particles, the bands can differ significantly from those obtained by the point-dipole approximation due to strong multipolar interaction among the particles. In this regard, Drude metallic spheres and the coupled plasmon modes are calculated in the point-dipole approximation. When the particles approach and finally touch, these modes are characterized by well-defined dispersion relation \( \omega \), resulting in a slow propagation. Thus one can tune the propagation of plasmon modes by simply varying the spacing between the particles. We explore the role of strain in the dynamics of melting and freezing by investigating crystallization on a flat patterned substrate. We find that in comparison with previously performed experiments on flat unpatterned substrates, the dynamics of melting and freezing on such surfaces alter dramatically. For example whereas melting of such crystals on a flat substrate was shown to proceed through an intermediary metastable liquid phase, we find that for surfaces templated with a lattice that is commensurate with that of the melting crystal, this intermediary step is suppressed.

1:03PM B14.00008 Particle Organization by Absorbing State Dynamics, LAURENT CORTÉ, DAVID PINE, P.M. CHAIKIN, Center for Soft Matter Research, NYU — In a recent study we have found that irreversible collisions can lead to a dynamical phase transition between a constantly evolving state and an absorbing, quiescent state where particles self organize to avoid further collisions. Here we investigate the organization and order in the absorbing state in a model where active, overlapping particles are given random displacements. We contrast the order to what is obtained thermodynamically for hard spheres. We also show that correlated displacements between colliding particles can lead to crystallization and suggest that irreversible flows are a different yet effective tool for ordering particles in desired motifs.

1:15PM B14.00009 Diffusion through Colloidal Shells under Stress, J. GUERY, J. BAUDRY, ESPCI, D.A. WEITZ, Harvard, P.M. CHAIKIN, NYU, J. BIBETTE, ESPCI — The permeability of solids has long been associated with a diffusive process involving activated hopping. Tensile stress can affect the activation energy as originally envisioned by Eyring. Here we use liquid core - solid shell, core-shell, solid colloidal particles that are sensitive to osmotic pressure, to follow the permeation of encapsulated probes at various stresses. We unambiguously show that the tensile stress applied on colloidal shells linearly reduces the local energy barrier for diffusion.

1:27PM B14.00100 Dispersion relation and density of states of coupled plasmon modes in periodic chains of metallic nanoparticles, C.W. LING, M.J. ZHENG, K.W. YU, The Chinese University of Hong Kong — Energy transmission through one-dimensional chains of equally spaced metallic nanoparticles has been studied via the propagation of coupled surface-plasmon modes. These modes are characterized by well-defined dispersion relation \( \omega(k) \) and group velocity \( v_g = \frac{\partial \omega}{\partial k} \) in a band. The nanoparticles are routinely modelled by Drude metallic spheres and the coupled plasmon modes are calculated in the point-dipole approximation. When the particles approach and finally touch, these bands can differ significantly from those obtained by the point-dipole approximation due to strong multipolar interaction among the particles. In this regard, we have calculated the coupled plasmon modes by a tight-binding approach, taking fully multipolar interactions into account. For approaching particles, the dipolar bands move from the visible down to the infrared region and \( \omega(k) \) becomes almost independent of \( k \). Concomitantly, the group velocity \( v_g \) showed an intriguing non-monotonic behavior versus the particle spacing. When the spacing decreases, \( v_g \) increases initially but decreases when the particles approach and touch. For moderate spacing, \( v_g \) can be reduced drastically to 0.01, except at \( kd = 0 \) and \( kd = \pi \), resulting in a slow propagation. Thus one can tune the propagation of plasmon modes by simply varying the spacing between the particles.

1:39PM B14.00111 Examining dynamic length scales in a two-dimensional colloidal system, ZACH NADLER, CARA HAGEMAN, VIKRAM PRASAD, ERIC R. WEEKS, Physics Dept., Emory University — We study polystyrene colloids placed at an oil-water interface as a quasi-two-dimensional colloidal system. As the area fraction of the colloidal particles is increased, we see liquid, hexatic, and crystalline phases. The liquid phase is structurally disordered; the hexatic phase has long range orientational order but poor translational order; and the crystalline phase has long range orientational and translational order. We classify these different phases using structural and dynamic parameters from prior work. Using a laser tweezers we trap and drag a particle along the interface and observe its effect on the surrounding colloids. Our interest is in how the response changes near phase transition boundaries, where the ordering of particles can qualitatively change. We characterize the response by the structural defects induced by the dragged particle, as well as the perturbed motion of the surrounding particles. These responses are localized around the dragged particle, and we study how the localization length scale changes with the area fraction of the colloids.

1:51PM B14.00012 State Diagram for Optical Tweezers Induced Brownian Motors, BO SUN, DAVID GRIER, New York University — State Diagram for Optical Tweezers Induced Brownian Motors Bo Sun and David G. Grier Center for Soft Matter Research Department of Physics New York University Optical tweezers are extensively used in physics and biology; most study in literatures assume a colloidal particle trapped in optical tweezers relays to equilibrium state. We have found experimentally the particle became a Brownian motor. Furthermore, this Brownian motor showed reversible behavior: given input power, working direction changes when particle size grows; given a particle bigger than wave length of light, changing input power can also change the working direction. Thus we need a state diagram to describe the motor behavior of a colloidal particle in optical tweezers, rather than a potential landscape as most previous study uses.
11:15AM B15.00001 Walking on water: why your feet get wet. MICHAEL SHELLEY, Courant Institute, New York University, JAKE FONTANA, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University — Walking on wet pavement during or after heavy rain results in wet shoes, and often, wet feet. We describe a peculiar transport process associated with walking on wet surfaces which results in the vamps, and frequently, the insides, of shoes getting wet. We discuss details of this process and compare experimental results with simple model predictions. Strategies for keeping feet dry will be considered.

11:27AM B15.00002 Breaking beer bottles with cavitation. SUNNY JUNG, Department of Mathematics, MIT, JAKE FONTANA, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University, MICHAEL SHELLEY, Courant Institute, New York University — Hitting the top of a beer bottle, nearly full of water, with an open hand can cause the bottle to break, with the bottom separating from upper section. We have studied this phenomenon using a high-speed camera, and observed the formation, coalescence and collapse of bubbles. The breaking of glass is due to cavitation, typically occurring near the bottom edge. We make numerical estimates of the relevant physical parameters, and compare these with experimental observations.

11:39AM B15.00003 Optical Tweezer as a Viscometer1, DANIEL ERENSO, SAMUEL ELROD, TAYLOR BARNES, ANTHONY FARONE, MARY FARONE, Middle Tennessee State University — An optical tweezer (OT) has been widely used to study the mechanical properties of microscopic living biological systems like red blood cells. These studies are based on measurement of deformations caused by a force exerted directly or indirectly by an optical trap. The trap is usually pre-calibrated using Stokes viscous force of the suspension fluids for the biological system which is directly proportional to the viscosity of the fluids. Therefore, calibration of the trap depends on the viscosity of the fluid which depends on temperature. In this work, we have demonstrated that OT can be used to precisely measure the viscosity of biological fluids affected by temperature. Using an infrared laser trap which is calibrated using silica sphere suspended in a distilled deionized water and measuring the power as function of escape velocity, we have measured the viscosities of a newborn and unborn bovine serum with a different concentration of antibodies.

11:51AM B15.00004 Fabrication of a Nanoscale Thermal Anemometry Probe Via Electric Field Assisted Assembly. JASON KAWASAKI, SEAN BAILEY, LEX SMITS, CRAIG ARNOLD, Princeton University — A nanoscale thermal anemometry probe (NSTAP) is being developed to measure instantaneous fluid velocity at ultra-small scales using conventional constant temperature anemometry principles. The probe consists of a 50 nm by 10 um platinum nanowire (NW) suspended between two current carrying electrodes. Previous nanoscale anemometry wires had been fabricated via metal deposition on a photolithography-patterned substrate; however, deposited NWs are not free-standing and thus must later be lifted off the substrate resulting in low process yields. In this presentation, we discuss alternative methods of shrinking the probes further and increasing the yield of successful probes, including growing nanowires from solution to bridge the electrodes, and using dielectrophoresis to align pregrown nanowires between the electrodes. In each of these methods, the NWs are directly shaped near the desired structure eliminating the need for additional processing steps. NSTAP probes manufactured using these methods will also exhibit higher spatial resolution and temporal response than previous NSTAP designs.

12:03PM B15.00005 A Front Tracking Algorithm for Liquid Jet Breakup, WURIGEN BO, JAMES GLIMM, XINGTAO LIU — A numerical study of breakup of a high speed jet is presented using the Front Tracking method in 3D. A robust locally grid based method is applied to handle the topological change of the surface mesh in the simulation, the validation of the method is proved mathematically. Numerical results are presented for 3D simulation of the primary breakup of a liquid jet with turbulent inflow.

12:15PM B15.00006 Coalescence and Pinch-Off in Viscous Liquids1, JOSEPH PAULSEN, University of Chicago, JUSTIN BURTON, Fred Hutchinson Cancer Research Center, SIDNEY NAGEL, University of Chicago — When two fluid drops come into contact, a topological transformation occurs as they rapidly coalesce into a single drop. Because of its speed and geometry, this finite time singularity is difficult to study optically. We therefore use an electrical method to probe viscous coalescence as early as 10 ns after contact. This technique was developed by Burton et al.[1] to study mercury drop pinch-off and adapted for salt-water coalescence by Case et al.[2] revealing a breakdown of the expected universal dynamics in early-time viscous coalescence. For viscous coalescence, we measure a resistance that decreases as t−1 at early times and as t−1/2 at late times, with a crossover time that increases with viscosity. In the inviscid case, these power laws had been interpreted with a model in which the drops coalesce at a slightly deformed interface.

12:27PM B15.00007 Scaling Law for Driven Spreading and Coalescence of Sessile Droplets1, PILGYU KANG, SHAHAB SHOJAEI-ZADEH, CHRISTINE APPLEBY, SHELLEY ANNA, Department of Mechanical Engineering, Carnegie Mellon University, MICRO COMPLEX FLUIDS LABORATORY TEAM2 — This study investigates the dynamics of spreading and coalescence of droplets on a surface, a process important in applications such as inkjet printing, spray coating, and flooding of fuel cells. We use a simple microfluidic device to control the spreading and merging processes. Droplet diameter and maximum height are monitored as functions of time. We compare the dynamics with existing scaling models modified to incorporate time dependent volume, and we extend the model to describe the scaling behavior of the liquid bridge growing between merging droplets on a surface. The experiments agree well with the expected scaling.

1GuSH grant by Graduate Support Programs at Carnegie Mellon University

2Department of Mechanical Engineering, Carnegie Mellon University

12:39PM B15.00008 Temperature profiles near a pinned nucleating bubble, SCOTT PARKER, CHANG-KI MIN, SUNG CHUL BAE, DAVID CAHILL, STEVE GRANICK, University of Illinois — We have measured the temperature distribution on solid surfaces in contact with a nucleating vapor bubble by thermal surface plasmon imaging. Vapor bubbles are created by focused laser heating of an underlying metal substrate. Bubbles are pinned in place by suitable surface functionalization and their shape is characterized by interferometry. Varying the wettability of the surface to control the shape and surface lifetimes of bubbles, we have correlated contact angle, lift-off diameter, and local temperature.
12:51PM B15.00009 Effect of Encapsulated Polymers and Nanoparticles on Deformation of Droplets. O. BERK USTA, University of Pittsburgh, DENNIS PERCHAK, Kodak US Research, ANDREW CLARKE, Kodak European Research, JULIA M. YEOMANS, Oxford University, ANNA C. BALAZS, University of Pittsburgh — We investigate the effects of polymer chains and nanoparticles on the deformation of a droplet in shear and extensional flow using computational modeling: Our model accounts for both the solid and fluid phases explicitly. We show that under shear flow, both the nanoparticles and the encapsulated polymers reduce the shear-induced deformation of the droplet at intermediate capillary numbers; nevertheless, long polymer chains can induce the breakup of the droplet at high capillary numbers. In contrast, under extensional flow we find that the long polymer chains inhibit the breakup and reduce deformation. We study the chain-length and concentration dependence and also present the effects of various parameters such as the wetting strength.

1:03PM B15.00010 Electrorheology Leads to Efficient Combustion. R. TAO, Dept. of Physics, Temple University, K. HUANG, H. TANG, D. BELL, Temple University — Improving engine efficiency and reducing pollutant emissions are important. Since combustion starts at the interface between fuel and air and most harmful emissions come from incomplete burning, reducing the size of fuel droplets for the fuel injection would increase the total surface area to start burning, leading to a cleaner and more efficient engine. While most efforts are focused on ultra-dilute mixtures at extremely high pressure to produce much finer mist of fuel for combustion, the new technology is still under development and only for next generation vehicles. Here we report our fuel injection technology based on new physics principle that proper application of electrorheology can reduce the viscosity of petroleum fuels. A small device is thus introduced just before the fuel injection for the engine, producing a strong electric field to reduce the fuel viscosity, resulting in much smaller fuel droplets in atomization. Both lab tests and road tests confirm our theory and indicate that such a device improves fuel mileage significantly and reduces emission. The technology is expected to have broad applications, applicable to current internal combustion engines and future engines as well. Supported by STWA and RAND.

1:15PM B15.00011 Evolution of Electrified Films on a Porous Inclined Plane. UMA BALAKRISHNAN, University of California Santa Barbara, USHA RANGANATHAN, Indian Institute of Technology Madras — The nonlinear stability of a thin conducting film flow down a porous inclined plane, when an electric field acts normal to the plane is considered. It is assumed that the flow through the porous medium is governed by Darcy’s law and the characteristic length of the pore space is much smaller than the depth of the fluid layer above. Integral Boundary Layer method is employed in obtaining a set of exact averaged equations for the film flow system. Linear stability results through normal mode analysis reveal that the destabilizing influence of the electric field is further enhanced by the porosity of the medium. Critical Reynolds number for the onset of instability decreases with the increase in the permeability of the porous plane. Weakly nonlinear stability analysis using method of multiple scales divulges the existence of zones due to supercritical stability and subcritical instability. Permanent finite-amplitude waves in the supercritical stable region are portrayed by solving the nonlinear evolution equation numerically in a periodic domain. The parameter ranges that support complex nonlinear dynamics is obtained through a combination of theoretical analysis and numerical experiments.

1:27PM B15.00012 Universal cone angle of ac electrosprays due to net charge entrainment. NISHANT CHETWANI, SIDDHARTH MAHESHWARI, H.C. CHANG, University of Notre Dame — The slender meniscus that is obtained by the application of high frequency AC field is quite distinct from DC Taylor Cone. This AC cone shows a continuous longitudinal growth and has much smaller half cone of ~ 11°. Mass spectrometry on the microjet from the AC cone shows that dissociation reaction occurs at the tip but only the low- mobility anionic species are entrained to produce a charged cone. These free negative charges relax to the interface to produce a non-uniform surface charge density that scales with respect to the azimuthal radius as ρ ~ r−2 to balance the singular normal capillary pressure. Repulsion of this entrained surface charge and the Maxwell pressure they induce are estimated with an elliptic integral and a variational formulation produces anormal stress balance with capillary pressure that is only satisfied at a universal angle of 12.6° degrees for the liquids with high dielectric constant in good agreement with the measured values for the organic solvents used in experiments.

1:39PM B15.00013 Impact of Elasticity on Coating Flow near A Moving Contact Line. YULI WEI, STEPHEN GAROFF, Carnegie Mellon University, ENRIQUE RAMÉ, National Center for Space Exploration Research, LYNN WALKER, Carnegie Mellon University — The impact of fluid elasticity and shear thinning on the dynamic wetting of polymer solutions is important because many fluids, even those that are normally considered Newtonian, exhibit non-Newtonian behaviors in the high shear environment of the wedge-like geometry near a moving contact line. Even though this behavior is on the microscopic scale, it has significant impact on wetting on the millimeter scale. Shear thinning dramatically modifies the flow field near a moving contact line and results in a reduced curvature of the free surface. In this talk, we will focus on the effects due to fluid elasticity. Both experimental and numerical results are presented. The fluids we use are the dilute solutions of high molecular weight polyisobutylene (PIB) which exhibit elasticity-dominated rheology with minimal shear thinning. Their wetting behaviors are compared to their oligomer “solvent,” which is considered Newtonian based on standard rheometry. We will also discuss a lubrication analysis of the wedge-like flow field using an Oldroyd-B constitutive relation to mimic the stress evolution of the elastic solution.

1:51PM B15.00014 Field-dependent thermal transfer in magnetic fluids. JUN HUANG, ZHENYU ZHOU, GEOFF HUSTON, WEI LIU, Department of Physics, University of Central Florida — The temperature gradient across a quasi one-dimensional magnetic fluid was measured as a function of the magnetic field and field gradient. It was found that when the field gradient, ∇H, is anti-parallel to the temperature gradient, ∇T, the temperature gradient increases with increasing field and field gradient, but decreases for ∇H parallel to ∇T. For B and ∇H perpendicular to ∇T and gravity, the results are complex and depend on the local configuration of the field and field gradient. We will discuss the results in terms of the effect of local magnetic body force that originates from the local field and the local susceptibility on thermal transfer in magnetic fluids.

2:03PM B15.00015 How does the viscosity of a lubricant effect its tribological behavior? M. AGGLETON, P. TABOREK, University of California, Irvine — The viscosity of many conventional lubricants varies by many orders of magnitude over a small temperature range. We have explored this variation to explore the effect of large viscosity changes on lubrication. We have used a sliding block tribometer to measure the coefficient of friction of a steel-on-steel system with a variety of vacuum compatible hydrocarbon lubricants. Each lubricant was thermally cycled in ultrahigh vacuum from room temperature to below the glass transition temperature. This varies the viscosity without changing the chemistry. Several theoretical models for the temperature dependence of the viscosity of hydrocarbons are applied. The theory described in Cameron (1981) is used to relate the change in viscosity to the coefficient of friction. Some lubricants are found to fit these models up to viscosities as high as 10^6 centiStokes, while for others the model does not even qualitatively describe the data.

Monday, March 16, 2009 11:15AM - 1:15PM — Session B16 DCMP: Cold Fusion —
11:15AM B16.00001 Electrodynamic Component of Pd Electrical Conductivity. MITCHELL SWARTZ. JET Energy, PO Box 81135, Wellesley Hills, MA 02481. — The electrical resistance of Pd in heavy water was found to be significantly lower than in water. This was attributed to the presence of a thin film of hydrogen on the surface of the Pd. The film has a thickness of a few nanometers and its resistance is due to the scattering of conduction electrons by the hydrogen atoms.

11:27AM B16.00002 Study Of The Palladium Hydrogen - Deuterium System. JAN MARWAN. Research and Development, Dr Marwan Chemie, Rudower Chaussee 29, 12489 Berlin, Germany. — Electrochemical deposition of metals from hexagonal isotropic liquid crystal solutions produces metal films with a unique ordered nanostructure in which the cylindrical pores of 1.7 to 3.5 nm run through the film. The pores are separated by a distance of 2.5 nm. The film has a high surface area and a low electrical resistance.

11:39AM B16.00003 Investigation of the Cold Fusion Phenomenon in the Surface Region of Hydrogen Non-occlusive Metal Catalysts; W, Pt, and Au. HIDEO KOZIMA. Cold Fusion Research Laboratory, 597-16 Yatsu, Aoi, Shizuoka, 421-1202, Japan. — In the cold fusion experiments, the following metal catalysts were used: W, Pt, and Au. The experiments showed that the cold fusion reaction occurred in the surface region of the metal catalysts. The reaction was detected by the increase in the electrical resistance of the metal catalysts.

11:51AM B16.00004 Sonofusion: Squeezed Deuteron Clusters, With Small Size, High Energy Density but No High Energy Particles. ROGER STRINGHAM. Firstgate Energies, PO Box 1230 Kilauea, HI 96754. Phone: 808 828 2859. — Sonofusion is a new fusion process that uses ultrasound to squeeze deuteron clusters, which are small and have high energy densities. The clusters are formed in a target by a pulsed laser. The clusters are then squeezed by ultrasound to form a high-energy deuterium plasma.

12:03PM B16.00005 Time-Dependent Changes in Morphology and Composition of Solid Particles Collected from Heavy Water Electrolyte after Electrolysis with a Palladium Cathode. JOHN DASH. Q. WANG, Low Energy Nuclear Laboratory, Portland State University, Portland, OR 97207. — Recent research has developed a technique for imbedding ultra-high density deuterium “clusters” (50 to 100 atoms per cluster) in various metals such as Palladium (Pd), Beryllium (Be) and Lithium (Li). It was found that the condensed matter clusters approach metallic conditions, exhibiting superconducting properties.

12:15PM B16.00006 Study of other methods to increase cluster/dislocation loop densities in electrodes. XIAOLING YANG, GEORGE H. MILEY, University of Illinois, Urbana-Champaign. NPL Associates, Champaign, IL. — Recent research has developed a technique for imbedding ultra-high density deuterium “clusters” (50 to 100 atoms per cluster) in various metals such as Palladium (Pd), Beryllium (Be) and Lithium (Li). It was found that the condensed matter clusters approach metallic conditions, exhibiting superconducting properties.

11:15AM B16.00001 Electrodynamic Component of Pd Electrical Conductivity. MITCHELL SWARTZ, JET Energy, PO Box 81135, Wellesley Hills, MA 02481. — The electrical resistance of Pd in heavy water was found to be significantly lower than in water. This was attributed to the presence of a thin film of hydrogen on the surface of the Pd. The film has a thickness of a few nanometers and its resistance is due to the scattering of conduction electrons by the hydrogen atoms.

We discuss with experimental evidence that $\rho_{Pd}$ has electrodynamic components; some may trigger Lattice Assisted Nuclear Reactions (LANR). Type “B” (anode plate) Pd/D2O/Pt Phusor$^{TM}$ LANR devices (excess heat $\approx$ 175 percent, 1.99 watts) demonstrate two time constants of $\rho_{Pd}(t)$: The first ($< 5$ seconds) is not from deuterium loading. Also, at high loading, Type “B” systems produce an instability oscillation. These possible electrodynamic effects, and the supralinear rise of $\rho_{Pd}$, may trigger, or maintain, LANR.

11:27AM B16.00002 Study Of The Palladium Hydrogen - Deuterium System. JAN MARWAN. Research and Development, Dr Marwan Chemie, Rudower Chaussee 29, 12489 Berlin, Germany. — Electrochemical deposition of metals from hexagonal isotropic liquid crystal phases produces metal films with a unique ordered nanostructure in which the cylindrical pores of 1.7 to 3.5 nm run through the film. The pores are separated by a distance of 2.5 nm. The film has a high surface area and a low electrical resistance.

Electrochemical studies showed that the metal films have a high electroactive surface area with the specific surface area of the order of 91 m$^2$/g. These values together with the TEM and X-ray data are consistent with the expected H$_2$ nanostructure. The hydrogen region of nanostructured Pd in the cyclic voltammetry in 1 M H$_2$SO$_4$ was more resolved than that of plain Pd because of the thin walls of the nanostructure and the high surface area. We could distinguish the hydrogen adsorption and absorption processes. The permeation of hydrogen into the Pd metal lattice occurs with fast kinetics when the Pd surface is blocked by either crystal violet or Pt.

11:39AM B16.00003 Investigation of the Cold Fusion Phenomenon in the Surface Region of Hydrogen Non-occlusive Metal Catalysts; W, Pt, and Au. HIDEO KOZIMA. Cold Fusion Research Laboratory, 597-16 Yatsu, Aoi, Shizuoka, 421-1202, Japan. — There are several experimental data sets showing occurrence of the cold fusion phenomenon (CFP) in such contact metallic catalysts which do not occlude hydrogen isotopes such as tungsten (W), platinum (Pt) and gold (Au). These metals do not occlude hydrogen isotopes and are different from such hydrogen occlusive transition metals usually used in the cold fusion (CF) experiments such as Ti, Ni, and Pd. The non-occlusive isotopes and give us precious information about mechanisms facilitating formation of specific matter for the CFP (CF matter) in the cold fusion material. In the electrolysis experiments with these metals as electrodes and with several electrolytes in light or heavy water, transmuted nuclides were observed in the surface layer of the electrodes. The generated nuclides were localized in areas with a diameter of around a few µm in the surface layer of thickness less than 103 nm. These specific nuclides observed in the host metals, W, Pt and Au, depend on the composition of the electrolyte.

Effects and the "conventional" Coulomb Barrier problem of fusion can be replaced by a considerably richer problem. Infinitely-repeating ordered crystals, to finite crystal lattices, where energy band theory can be re-expressed more precisely through resonant or nearly-resonant quantum mechanics. Talbot Chubb and I have investigated an important problem, relating to extending conventional energy band theory, as it applies to particular, Talbot Chubb and I proposed the idea that deuterium nuclei (deuterons) could occupy energy band states or have overlap with these kinds of states. The reasons for this are related to: 1. Misconceptions, about what was taking place in the experiments, and 2. Limitations of conventional energy band theory. In particular, Talbot Chubb and I suggested that deuterium nuclei could occupy energy band states or have overlap with these kinds of states with "unforeseen" consequences, including, the possibility of nuclear fusion. Conventional energy band theory has limitations, associated with the underlying quantum mechanics. Talbot Chubb and I have investigated an important problem, relating to extending conventional energy band theory, as it applies to infinitely-repeating ordered crystals, to finite crystal lattices, where energy band theory can be re-expressed more precisely through resonant or nearly-resonant effects and the "conventional" Coulomb Barrier problem of fusion can be replaced by a considerably richer problem.

**11:15AM B17.00001 ABSTRACT WITHDRAWN**

**11:51AM B17.00002 Electrons on Helium using circuit quantum electrodynamics[1] , DAVID SCHUSTER, Yale University, MARK DYKMAN, Michigan State University, STEPHEN LYON, Princeton University, ROBERT SCHOELKOPF, Yale University** — It is possible to form a two dimensional electron gas at the interface between superfluid helium and vacuum. This unique heterostructure has exceptional bulk properties including electron mobilities exceeding $10^7$ cm$^2$/Vs and electron spin coherence times estimated to exceed 100s. One of the first proposals [2] for quantum computation employed the vertical motional states of electrons on helium but coherent interactions have yet to be realized. I will describe a new proposal [3] which uses a high finesse superconducting transmission line cavity to detect and manipulate the lateral motional and spin states of a single trapped electron on helium. We estimate that it is possible to attain vacuum Rabi frequencies of $g\approx10$ MHz and $T_1\sim T_2\sim1$ ms for the motional state and perhaps even longer coherence times if spin encoding is used.

[3] In preparation

---

**12:03PM B17.00003 Simulating electron transport and devices on liquid helium**¹, PASCAL BUGNION, STEPHEN LYON, FORREST BRADBURY, Princeton University — Manipulation of the spin of electrons in surface states on superfluid helium is a promising method for the implementation of a quantum computer. The electrons can be transported around a substrate along channels in a manner analogous to charge-coupled devices. These devices operate on one or a few electrons, which are sufficiently isolated to be treated as classical point charges. The model must therefore incorporate the discreteness of the charges and their interactions, as well as their response to external potentials. These constraints lead towards considering a “molecular” dynamics, multi-electron simulation. The calculation of the electron-electron interactions are complicated by the presence of nearby metallic gates and insulating layers. The concepts necessary for a fast, accurate dynamic simulation of a large collection of individual electrons are elaborated. A computationally cheap approximation of the electrostatic potential due to substrate polarisation for an electron above a channel is proposed. The approximation is compared to an analytic solution. Other substrate geometries which might be used in a quantum computer are also discussed, concentrating on approximations of the potential.

12:15PM B17.00004 Quantum logic with weakly coupled qubits, MICHAEL GELLER, EMILY PRITCHETT, ANDREI GALIAUTDINOV, University of Georgia, JOHN MARTINIS, University of California, Santa Barbara — Effective protocols for performing CNOT quantum logic with qubits coupled by particular high-symmetry (Ising or Heisenberg) interactions are well established. However, many architectures being considered for quantum computation involve qubits or qubits and resonators coupled by more complicated and less symmetric interactions. Here we consider a widely applicable model of weakly but otherwise arbitrarily coupled two-level systems, and use quantum gate design techniques to derive a simple and intuitive CNOT construction. Useful variations and extensions of the solution are given for common special cases.

12:27PM B17.00005 Quantum gates that correct their own (quantum) errors, LORENZA VIOLA, KAVEH KHODJASTEH, Dartmouth College — Scalable quantum computation in realistic devices requires that precise control can be implemented efficiently in the presence of decoherence and operational errors. I will describe a general constructive procedure for designing robust unitary gates on an open quantum system without encoding or measurement overhead. These results allow for a low-level error correction strategy solely based on Hamiltonian engineering using realistic bounded-strength controls, and may prove instrumental to substantially reduce implementation requirements for fault-tolerant quantum computing architectures.

12:39PM B17.00006 A few-electron triple quantum dot incorporating two fast charge sensors, EDWARD LAIRD, CHARLES MARCUS, Department of Physics, Harvard University, MICA HANSON, ART GOSSARD, Materials Department, University of California at Santa Barbara — A triple quantum dot is defined in a GaAs heterostructure. The occupation of all three dots is monitored using two nearby charge sensing point contacts. Radio frequency multiplexing in a reflectometry setup allows MHz-bandwidth measurements of both charge sensors independently. Configuring the device in the few-electron regime, we achieve coherent spin manipulation using the exchange interaction.

1We acknowledge support from ARO/IARPA, Department of Defense, and Harvard Center for Nanoscale Systems.

12:51PM B17.00007 Interqubit coupling mediated by a high-excitation-energy quantum object, SAHEL ASHHAB, ANTTI NISKANEN, KHALIL HARRABI, YASUNOBU NAKAMURA, THOMAS PICOT, PIETER DE GROOT, KEES HARMANS, HANS MOOI, FRANCO NORI — We consider a system composed of two qubits and a high-excitation-energy quantum object used to mediate coupling between the qubits. After reproducing well-known results concerning the leading term in the mediated coupling, we obtain an expression for the residual coupling between the qubits in the off state. We also analyze the entanglement between the three objects, i.e., the two qubits and the coupler, in the eigenstates of the total Hamiltonian. Although we focus on the application of our results to the recently realized parametric-coupling scheme with two qubits, we also discuss extensions of our results to harmonic-oscillator couplers, couplers that are near resonance with the qubits and multi-qubit systems. In particular, we find that certain errors that are absent for a two-qubit system arise when dealing with multi-qubit systems.

1:03PM B17.00008 Excitons in cavity-embedded quantum dot lattices, MICHAL GROCHOL, CARLO PIERMAROCCI, Department of Physics and Astronomy, Michigan State University — We investigate excitons and trions in a two-dimensional quantum dot lattice embedded in a planar optical cavity. The strong exciton (trion)-photon coupling is described in terms of polariton quasi-particles. First, we focus on Bragg polariton modes obtained by tuning the exciton and the cavity modes into resonance at high symmetry points of the Brillouin zone. The effective mass of these polaritons can be extremely small, of the order of $10^8 m_e$ ($m_e$ is the bare electron mass) and makes them the lightest exciton-like quasi-particle in solids [1]. Second, we consider how disorder affects the properties of Bragg polariton modes. We focus on three kinds of disorder: (i) inhomogeneous exciton energy, (ii) inhomogeneous exciton-photon coupling, and (iii) deviations from an ideal lattice. It is found that in some cases weak disorder increases the light matter coupling and it leads to a larger polariton splitting [2]. Finally, each dot has one electron, and the electron spin determines the polarization of the cavity photon that couples to the dot. Such a “spin lattice” can be used for quantum information processing and we show that by using exciton detuning a conditional phase shift gate with high fidelity can be obtained [3].

1:15PM B17.00009 Low Disorder Si MOSFET Dots for Quantum Computing, E.P. NORDBERG, University of Wisconsin - Madison and Sandia National Laboratories, L.A. TRACY, G.A. TEN EYCK, K. ENG, H.L. STALFORD, K.D. CHILDLS, J. STEVENS, R.K. GRUBBS, M.P. LILLY, Sandia National Laboratories, M.A. ERIKSSON, University of Wisconsin - Madison, M.S. CARROLL, Sandia National Laboratories — Silicon quantum dot based qubits have emerged as an appealing approach to extending the success of GaAs spin based double quantum dot qubits. Research in this field is motivated by the promise of long spin coherence times, and within a MOS system the potential for variable carrier density, very small dot sizes, and CMOS compatibility. In this work, we present results on the fabrication and transport properties of quantum dots in novel double gated Si MOS structures. Coulomb blockade is observed from single quantum dots with extracted charging energies up to an including 5meV. Observed dots were formed both disorder within a quantum point contact, and through disorder free electrostatic confinement. Extracted capacitances, verified with 3D finite element simulations confirm the location of the disorder free dot to be within the designed lithographic structure. Distinctions will be made regarding the effects of feature sizes and sample processing. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:27PM B17.00010 Steps toward donor based qubits in Si through integrating single ion Geiger mode avalanche diode detectors, J.A. SEAMONS, E. BIELEJEC, M.S. CARROLL, Sandia National Laboratories — Donor based qubits in Si for solid-state quantum information processing require precise dopant placement into the bulk Si. Placement precision donor is limited by straggle which is strongly dependent upon dopant selection and implantation energy, therefore detection of low energy ions (<10 keV) is desired. Great progress has been made using the combination of a p-i-n diode and electron beam lithography patterned surface mask resulting in a signal to noise limited ~10^3 electron-hole (e-h) pairs detection (D. N. Jamieson et al., Appl. Phys. Lett. 86, 202101 (2005)). We present experimental results for a single ion Geiger mode avalanche diode (SIGMA) detector has been shown to be sensitive to a single 250 keV H+ ion with 100% detection efficiency (J. A. Seamons et al., Appl. Phys. Lett. 93, 40324 (2008)) as well as advances that have been made with the Sigma detector in reducing dark (false) counts by three orders of magnitude and placing an upper bound on the e-h pair sensitivity of ~10^8 produced outside the active region of the SIGMA detector. Future SIGMA designs will enable low energy single ion detection with reduced straggle single donor qubit integration. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under Contract No. DE-AC04-94AL85000.
1:39PM B17.00011 Zeno Quantum Gates in Semiconductor Quantum Dots. KAIJIE XU, YUPIING HUANG, MICHAEL MOORE, CARLO PIERMAROCCHI — Quantum Zeno effect (QZE) is one of the most intriguing quantum phenomena. In the recent literature, there is a series of strongly linked ideas on entanglement generation or computation using the QZE, which have been mainly discussed and explored experimentally in pure quantum optics and superconductors. We propose a scheme for a two-qubit conditional phase gate by QZE with three parallel semiconductor quantum dots [1]. Two of them are charged dots with one additional electron. The spin of these electrons are the logical qubits on which the phase-gate acts. The other dot is an ancillary neutral dot that can perform Rabi oscillations under a resonant laser pulse. With our system setup, we can make use of QZE to gain a π phase shift after a 2π laser pulse depending on the spin configuration in the logical qubits. This phase shift can realize a conditional phase gate. We solve analytically and numerically the master equation with a realistic set of parameters. The result shows that, despite the widely-held belief that decoherence must always be minimized in quantum information processing, in our scheme decoherence can in principle be harnessed to generate high-fidelity gate operation using the QZE. [1] K.J. Xu, Y.P. Huang, M.G. Moore, and C. Piermarocchi, arXiv: 0810.4489 (2008).

1:51PM B17.00012 Large Scale Quantum Computation in a Linear Ion Trap. GUIN-DAR LIN, FOCUS Center and MCTP, Department of Physics, University of Michigan, SHI-LIANG ZHU, South China Normal University, Guangzhou, China, CHRISTOPHER MONROE, JQI and Department of Physics, University of Maryland, LUMING DUAN, FOCUS Center and MCTP, Department of Physics, University of Michigan — Among the approaches to quantum computation, the trapped ion system remains as one of the leading candidates. The linear Paul trap provides the most convenient architecture for quantum gate operations over a few ions, and the basic requirements for quantum computation have been demonstrated in this setup. However, scaling up this system to a large number of qubits so far remains a formidable challenge because of several obstacles, including the instability of the linear structure and the difficulties of the sidemode cooling and addressing for a large ion array. The recent approach to scalable ion trap computation thus has to use a more complicated architecture where the ions are shuttled over different trapping regions. Here, we propose a way to implement large-scale quantum computation in a linear trap by overcoming all the theoretical obstacles. Through excitation of the transverse photon modes in an anharmonic trap, we show that high-fidelity quantum gates can be achieved on ions in a large linear architecture under the Doppler temperature without the requirement of sidemode resolving.

Monday, March 16, 2009 11:15AM - 2:15PM Session B18 DPOLY: Focus Session: Templated Assembly of Polymers 319

11:15AM B18.00001 Directed Assembly of Biological Polymers. ALINE MILLER, University of Manchester — The self-assembly of polypeptides into beta-sheet rich nanofibrils has attracted considerable attention in recent years to both understand amyloidogenesis and for their potential biomaterials applications. This self-assembly process is generic to all proteins where fibrillation is typically induced under harsh conditions of low pH and/or high temperature, which are of course not suitable for biomaterials applications. Here we will outline the method developed in our laboratory to create thermo-reversible fibrillar hydrogels from aqueous solutions of a series of proteins by adding a reductant. Proteins studied include beta-lactoglobulin, ovalbumin, lysozyme and bovine serum albumin; all contain an increasing number of disulfide bridges that are disrupted by the reductant. Such disruption destabilises the native state of the protein and this allows us to form transparent, self-supporting hydrogels under physiological conditions. The potential to control and manipulate the gel properties, including mechanical strength and structure (fibre diameter and mesh size of hydrogel) has been explored by varying the protein (consequently the number of disulfide bridges), protein concentration, reductant concentration and ionic strength of the matrix. Our results will be presented here and similarities and differences highlighted. Furthermore we will present both our 2- and 3-dimensional cell culture experiments that show the gel matrix promotes both fibroblast and chondrocyte cell spreading, attachment and proliferation; indicating our hydrogels are biocompatible and they can provide a viable support for different cell types.

11:51AM B18.00002 Hydroxyapatite growth induced by self-assembled noncollagenous extracellular protein: a study on biomineralization in vitro. XIAOLAN BA, YIZHI MENG, NADINE PERNODET, SUE WIIRICK, CHRIS JACOBSEN, Stony Brook University, HELGA FUREDI-MILHOFER, The Hebrew University, YI-XIAN QIN, MIRIAM RAFAILOVICH, Stony Brook University, ELAINE DIMASI, Brookhaven National Laboratory — It is known that the role of various ECM proteins in the formation of calcium phosphate during the biomineralization. Here we will introduce the calcium phosphate mineralization process in vitro using two different ECM proteins, fibronectin and elastin. The mechanical properties of the protein fibers during the early stages were probed by shear mode force microscopy. The development of the mineral crystals along the protein matrices was investigated by scanning electron microscopy, soft x-ray scanning transmission microscopcopy, and grazing-incidence synchrotron x-ray diffraction. The elastic modulus of the fibers in the elastin-fibronectin mixture increased to a greater extent than that of the fibers from a single protein. In the presence of fibronectin, longer exposure in the mineral solutions led to the formation of hydroxyapatite crystals templated along the self-assembled fiber structures, while elastin fibers collected calcium without crystallizing. Ca L-edge XANES spectra confirm that Ca in the Ca-elastin complex lacks the mineral anion coordination found in the fibronectin systems and in Ca mineral controls.

12:03PM B18.00003 Replication of Optical Microstructures of Papilio palinurus through Biomimicry. MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology, MATIJA CRNE, School of Chemistry and Biochemistry, Georgia Institute of Technology, VIVEK SHARMA, Department of Mechanical Engineering, Massachusetts Institute of Technology, JOHN BLAIR, School of Material Science and Engineering, Georgia Institute of Technology, JUNG OK PARK, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology, CHRISTOPHER J. SUMMERS, School of Material Science and Engineering, Georgia Institute of Technology — The coloration of animals in nature is sometimes based on their structure rather than pigments. Structural coloration based on diffraction, multilayer reflection, cholesteric analogues or photonic crystal-like structures is pervasive especially in the world of insects. The color of Papilio palinurus results from microbowl lined with a multilayer of air and chitin. The green color is the result of color mixing of the yellow light reflecting from the bottom of the bowl and the blue light reflecting from the sides of the bowl. We have used breath figure templated assembly as the starting point to mimic the structure of Papilio palinurus. We were able to produce microbowl which were then coated with a multilayer of alternating titanium oxide and aluminum oxide. The resulting structure exhibits the same color mixing as the original butterfly structure does.
12:15PM B18.00004 Polyelectrolyte and nanoparticle adsorption to nanopatterned surfaces, THUY CHASTEK, STEVEN HUDSON, VINCE HACKLEY, NIST, Gaithersburg, MD 20899 — The adsorption of polyelectrolytes and nanoparticles onto patterned and curved surfaces is investigated (by fluorescence and electron microscopy) and exploited to produce anisotropic patchy particles. Various anisotropic properties are necessary for the self-assembly of complex structures. In this work, particles were bound temporarily to a substrate, so that part of their surfaces is occluded during subsequent surface modification by the adsorption of polyelectrolyte. The substrate surface charge has a significant effect on the adsorption of particles, which is achieved in a novel way in comparison to bare glass substrates. These include much reduced deposition time, a high degree of coverage, and the ability to accommodate both negatively and positively charged particles. Moreover, patch production yield is consistently 99 ± 1%. Rapid coating methods transferable to roll-to-roll processing were tested, and step-by-step characterization methods to evaluate yield were developed. High-yield site-specific binding of complementary spheres to the lithographic region of patchy particles and surfaces was demonstrated, including binding to positive and negative patches.

12:27PM B18.00005 Vertical Alignment of Single Wall Carbon Nanotubes (SWNTs) in Thin Polymer Films, MEAGAN MAUTER, MENACHEM ELIMELECH, CHINEDUM OSUJI, Yale University — Thin polymer films (1-10 um) incorporating singly dispersed, vertically aligned carbon nanotubes have a diverse set of potential applications. Desalination membranes that use aligned SWNT as pores, for instance, are predicted to exhibit high flux and salt rejection through size exclusion of hydrated ions. Current fabrication techniques, however, are unable to realize the vertical assembly of narrow diameter SWNTs. Here, we direct the vertical alignment of SWNTs in thin films by using magnetic field aligned lyotropic surfactant mesophases as structure directing templates. The short alkyl tails of the surfactant impart negative diamagnetic anisotropy to worm-like micelles and lead to parallel alignment of the liquid crystalline (LC) director in an applied magnetic field. The nanotubes orient preferentially with their long axis parallel to the director field of the mesophase, thus promoting their vertical alignment in the system. The LC mesophase incorporates monomers that are polymerized by UV exposure after nanotube alignment to form the polymer matrix. X-ray scattering and optical spectroscopy are used to characterize the field-guided assembly process. The present system may have additional applications for polymer reinforcement using carbon nanotubes.

12:39PM B18.00006 STM study of stereoselective oligomeric chains on cobalt oxide templates, DAEJIN EOM, HUI ZHOU, KWANG T. RIM, MICHAEL LEFENFELD, COLIN NUCKOLLS, GEORGE W. FLYNN, TONY F. HEINZ, Columbia University — Stereoselective oligomeric chains of cis-1,4-poly(2,3-dimethyl-1,3-butadiene) have been grown using the cobalt oxide surface as a template. The chains were formed by vacuum deposition of the monomer on an oxidized Co(0001) surface held at room temperature. The geometric structure of the 1-dimensional chains and their relationships to the structure of the surface were probed using scanning tunneling microscopy (STM). The typical chains were more than 10 monomer units in length and were highly linear in structure. When the chains were annealed to a temperature of 480 K, however, their morphology abruptly changed to irregularly shaped curves. We interpret this transformation as the result of scission of the methyl side groups of the oligomers. In addition to comprehensive STM topography data, we have investigated the chains using scanning tunneling spectroscopy (STS). The STS spectra show features with an energy spacing of 0.17 eV. We interpret this response as arising from an inelastic tunneling channel involving excitation of the symmetric deformation mode of the methyl side groups.

12:51PM B18.00007 Breath-figure-templated assembly of holey polymer films1, VIVEK SHARMA, Hatsopoulos Microfluids Laboratory (HML), Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge MA 02139., MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta GA 30332. — Breath figures formed on evaporating polymer solutions exposed to the blast of humid air involve growth and self-assembly of water drops that are non-coalescent. The hexagonally close packed, nearly monodisperse drops, eventually evaporate away, leaving a polymer film with ordered array of pores. We provide the first quantitatively correct simulation of the elucidation of the mechanism of this breath-figure-templated assembly. The dynamics of drop nucleation, growth, and coalescence and self-assembly are modeled by accounting for various transport and thermodynamic processes. The theoretical framework developed in this study allows one to rationalize and predict the structure and size of pores formed in different polymer-solvent systems under given airflow conditions.

1>Funded by NSF-DMR

1:03PM B18.00008 Gelation in Semiflexible Polymers1, VENKAT PADMANABHAN, SANAT K. KUMAR, Columbia University — Discrete Molecular Dynamics/Collision Dynamics has been employed to study the formation of a physical gel by semi-flexible polymer chains. The formation of a geometrically connected network of bundles of chains is investigated as a function of temperature. As the temperature is lowered, a percolated homogeneous solution phase separates to form a non-percolated nematic fluid and upon further decrease in the temperature, it goes back to a percolated gel state. The gelation, at lower temperatures, is due to the dynamic arrest of chains, preventing them from completing the phase separation process. The cooling rate also plays an important role in deciding the final outcome. Quenching the system, to the final temperature, at a faster rate yields gelation while slower quenches result in phase separation.

1:15PM B18.00009 Highly Ordered Block Copolymer Templates for the Generation of Nanos-structured Materials, E. BOJHE GOWD, BHANU NANDAN, NADJA C. BIGALL, ALEXANDER EYCHMULLER, MANFRED STAMM, LEIBNIZ INSTITUTE OF POLYMER RESEARCH DRESDEN, HOHE STRASSE 6, 01069 DRESDEN, GERMANY TEAM — Among many different types of self-assembled materials, block copolymers have attracted immense interest for applications in nanotechnology. Block copolymer thin film can be used as a template for patterning of hard inorganic materials such as metal nanoparticles. In the present work, we demonstrate a new approach to fabricate highly ordered arrays of nanoscopic inorganic dots and wires using switchable block copolymer thin films. Various inorganic nanoparticles from a simple aqueous solution were directly deposited on the surface reconstructed block copolymer templates. The preferential interaction of the nanoparticles with one of the blocks is mainly responsible for the lateral distribution of the nanoparticles in addition to the capillary forces. Subsequent stabilization by UV-irradiation following by pyrolysis in air at 450 °C removes the polymer to produce highly ordered metallic nanodot structures. This method is highly versatile as the procedure used here is simple, eco-friendly and provides a facile approach to fabricate a broad range of nanoscaled architectures with tunable lateral spacing.

1:27PM B18.00010 Polymeric nanocomposite comprising size-controlled organic nanostructures via copolymer-directed self-assembly, DEQUAN XIAO1, KUNHUA LIN, Department of Chemistry, Sichuan University, Chengdu, 610064 China, QIANG FU, Department of Polymer Science and Engineering, Sichuan University, State Key Laboratory of Polymer Materials Engineering, Chengdu, 610065 China, QINJIAN YIN, Department of Chemistry, Sichuan University, Chengdu, 610064 China — Inspired by inorganic nanomaterials, low-dimensional organic nanostructures have emerged as a new field of nanomaterials with the presence of size-dependent physical properties. Here, we report a polymeric nanocomposite comprising size-controlled organic nanostructures, formed by copolymer-directed self-assembly. By TEM and SEM images, we found the near-spherical shapes of the zero-dimensional organic nanoparticles. A strongly broadened Raman shift band was probed, suggesting the presence of size-dependent quantum confinement effect. By proof-of-principle quantum chemical calculations, we further explain that the strong Raman broadening is caused by the heterogeneous size-distribution of the organic nanoparticles. The present polymeric nanocomposite opens a new route for exploring low-dimensional organic nanostructures with size-dependent physical properties.

1>current address: Department of Chemistry, Duke University, Durham, NC 27708
1:39PM B18.00011 Orientational Change of Microphase-Separated Domains of Block Copolymer Thin Films Placed on Ordered Nanoparticle Monolayers. KOOKHEON CHAR, TAEHEE KIM, Seoul National University — Orientation of microphase-separated domains of diblock copolymer (BCP) thin films deposited on ordered nanoparticle (NP) monolayers was investigated. Ordered NP monolayers were prepared on silicon substrates with the Langmuir-Blodgett deposition technique. Parallel orientation of anisotropic microdomains (cylinders and lamellae) of BCP thin films with respect to the substrate is preferred on bare silicon substrates due to the preferential enthalpic interaction with one of BCP blocks, while the perpendicular orientation is preferred on the lattice-like ordered NP monolayers due to the roughness induced from the NP monolayers which can exert elastic deformation on the parallel-oriented microdomains, suppressing the substrate-induced parallel orientation. The effects of NP size as well as BCP film thickness on the orientation of BCP domains were systematically studied with AFM and Grazing Incidence Small-Angle X-ray Scattering (GISAXS). The rectification of perpendicularly oriented BCP microdomains onto underlying NP lattices was analyzed with SEM for thin BCP films (less than 100 nm in thickness). With this experimental technique, we observed the persisted perpendicular orientation of BCP microdomains on NP vacant sites up to the width of NP vacant sites less than 290 nm (∼11 Lₐ).

1:51PM B18.00012 Directed self-assembly of block copolymers for resolution enhancement and pattern rectification. JOY CHENG, CHARLES RETTTNER, DANIEL SANDERS, ALSHAKIM NELSON, HOA TRUONG, HO-CHEOL KIM, WILLIAM HINSBERG, SELF-ASSEMBLY TEAM — Directed polymer self-assembly which combines lithographically defined substrates and self-assembled polymers has been considered as a potential candidate to extend conventional lithography techniques. Self-assembled block copolymer domains can multiply the spatial frequency and improve pattern quality of the underlying resist prepattern. Lamella-forming PS-b-PDMAEMA is spin-coated on patterned substrate with alternating stripes of resist/neutral underlayer and annealed to generate well-aligned microdomains. The performance of directed self-assembly depends on the pitch of resist prepattern and resist pattern quality. For linear line-space pattern, defect-free frequency doubling can be achieved within ±5% mismatch between periodicity of block copolymers and pitch of resist patterns. Less mismatch tolerance was observed in concentric circular pattern. The self-healing capability of block copolymers has been explored by inducing dotted resist lines. Pattern rectification and frequency multipication can be successfully achieved when sufficient local spatial information is given in the resist prepattern.

2:03PM B18.00013 Tetragonal Ordering in Block Copolymer-Homopolymer Blend Films Laterally Confined in a Square Well. SU-MI HUR, CARLOS GARCIA-CERVERA, ED KRAMER, GLENN FREDRICKSON, UC BERKELEY — Self-consistent field theory (SCFT) simulations are presented for a melt blend of AB diblock copolymers and A homopolymers in a thin film confined to a square well. The work aims to guide self-assembly towards tetragonal ordering, which is a pattern of technological interest in block copolymer lithography. By using a system of A homopolymers and PS-b-PEO diblock copolymers, we have been able to observe hexagonal and body-centered cubic structures in block copolymer films. A phase diagram is presented that shows the region of stability of the tetragonal phase as a function of chain length and volume fraction of the homopolymer additive, in addition to several other interesting phases that result from a competition between surface and bulk contributions to the free energy. Results are also presented on the effect of line edge roughness in the square confinement well on the achievement of robust and defect free tetragonal order.

Monday, March 16, 2009 11:15AM - 2:03PM — Session B19 DPOLY: Focus Session: Polymers and Ionic Liquids

11:15AM B19.00001 Block Copolymers and Ionic Liquids: A New Class of Functional Nanocomposites. TIMOTHY LODGE, University of Minnesota — Block copolymers provide a remarkably versatile platform for achieving desired nanostructures by self-assembly, with length scales varying from a few nanometers up to several hundred nanometers. Ionic liquids are an emerging class of solvents, with an appealing set of physical attributes. These include negligible vapor pressure, high chemical and thermal stability, tunable solvation properties, high ionic conductivity, and wide electrochemical windows. For various applications it will be necessary to solidify the ionic liquid into coexisting phases, such as microemulsions and micelles. One example includes formation of spherical, cylindrical, and vesicular micelles by poly(butadiene-b-ethylene oxide) and poly(styrene-b-methylmethacrylate) in the common hydrophobic ionic liquids [BMIM][PF₆] and [EMI][TFSI]. This work has been extended to the formation of reversible micelle shuttles between ionic liquids and water, whereby entire micelles transfer from one phase to the other, reversibly, depending on temperature and solvent quality. Formation of ion gels has been achieved by self-assembly of poly(styrene-b-ethylene oxide-b-styrene) triblocks in ionic liquids, and by the thermoreversible system poly(N-isopropylacrylamide-b-ethylene oxide-b-N-isopropylacrylamide), using as little as 4% copolymer. Further, these gels have been shown to be remarkably effective as gate dielectrics in organic thin film transistors. The remarkably high capacitance of the ion gels (≥10 µF/cm²) supports a very high carrier density in an organic semiconductor such as poly(3-hexylthiophene), leading to milliamp currents for low applied voltages. Furthermore, the rapid mobility of the ions enables switching speeds approaching 10 kHz, orders of magnitude higher than achievable with other polymer-based dielectric systems such as PEO/LiClO₄. Finally, we have shown that ordered nanostructures of block copolymers plus ionic liquids show the characteristic self-assembly properties of strongly-segregated systems. Prospects for anisotropic ionic conductivity are also being explored.

11:51AM B19.00002 Phase Behavior of Block Copolymer Solutions in an Ionic Liquid. J.M. VIRGILI, M.L. HOAFRCOST, N.P. BALSARA, R.A. SEGALMAN, UC Berkeley — Incorporation of ionic liquids into block copolymers is of interest for applications such as high temperature fuel cell membranes. We investigate the lyotropic and thermotropic phase behavior of solutions of poly(styrene-b-2-vinyl pyridine) (S2VP) block copolymers in an ionic liquid consisting of imidazole and bis(trifluoromethane)sulfonamide (HTFSI). This work has been extended to the formation of reversible micelle shuttles between ionic liquids and water, whereby entire micelles transfer from one phase to the other, reversibly, depending on temperature and solvent quality. Formation of ion gels has been achieved by self-assembly of poly(styrene-b-ethylene oxide-b-styrene) triblocks in ionic liquids, and by the thermoreversible system poly(N-isopropylacrylamide-b-ethylene oxide-b-N-isopropylacrylamide), using as little as 4% copolymer. Further, these gels have been shown to be remarkably effective as gate dielectrics in organic thin film transistors. The remarkably high capacitance of the ion gels (≥10 µF/cm²) supports a very high carrier density in an organic semiconductor such as poly(3-hexylthiophene), leading to milliamp currents for low applied voltages. Furthermore, the rapid mobility of the ions enables switching speeds approaching 10 kHz, orders of magnitude higher than achievable with other polymer-based dielectric systems such as PEO/LiClO₄. Finally, we have shown that ordered nanostructures of block copolymers plus ionic liquids show the characteristic self-assembly properties of strongly-segregated systems. Prospects for anisotropic ionic conductivity are also being explored.

12:03PM B19.00003 Ordering of Triblock Copolymer Surfactants by Blending with a Room Temperature Ionic Liquid. DANIEL MIRANDA, JAMES WATKINS, THOMAS RUSSELL, University of Massachusetts Amherst — Well-ordered block copolymer microdomains were obtained by blending Pluronic® PEO-PPG-PEO triblock copolymer surfactants with the room temperature ionic liquid 1-butyl-3-methylimidazolium bis(trifluoromethane)sulfonimide. The selective association of the ionic liquid with the PEO blocks increases the segregation strength by increasing the effective interaction parameter between the blocks. The next copolymer is phase-mixed in the melt whereas the addition of ionic liquid to the copolymer results in phase segregation, forming well-ordered microdomains. The ionic liquid was confirmed to interact with the PEO blocks by a depression in the melting point of the blends with increasing ionic liquid concentration. Further, small angle x-ray scattering experiments show a decrease in the breadth of the first order peak, as well as the appearance of higher order peaks, with increasing ionic liquid concentration. These results confirm the formation of well-ordered microdomains.

12:15PM B19.00004 Phase separation induced by polymer-ionic molecule complexation. ISSEI NAKAMURA, AN-CHANG SHI, McMaster University — The miscibility of polymers in ionic solutions has attracted long-standing interest in polymer science. In particular, it has been demonstrated experimentally that phase separation can be driven by complexation of polymers and ionic-molecules. Thermally reversible strong forces such as hydrogen bonding and electrostatic force are often employed to induce the complexation. In this study, we developed a self consistent field theory for polymers which are capable of binding small ionic molecules. Specifically, poly(vinyl alcohol) and borate ion in aqueous solution with sodium chloride are used as a model system. Binding isotherm, phase diagrams, as well as comparisons with experiments, will be presented. The theory provides a closed-loop region for an instability of the homogeneous phase in the phase diagram. Implications of our results to the sol-gel transition arising from the correlation between unoccupied and occupied ion-binding sites of polymers are discussed.

12:27PM B19.00005 Morphology and Ion Transport in Mixtures of Polymers and Ionic Liquid, JAE-HONG CHOI, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6272, LIANG GWEE, YOSSEF A. ELABD, Department of Chemical and Biological Engineering, Drexel University, Philadelphia, PA 19104, KAREN I. WINEY, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia 19104-6272 — Mixtures of polymers and ionic liquid have been prepared using homopolymers, random copolymers, and block copolymers: poly(methyl methacrylate), poly(methyl methacrylate-ran-styrene), and poly(methyl methacrylate-b-styrene). The ionic liquid is 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide. These mixtures are investigated using X-ray scattering and electron microscopy. Mixtures of the homopolymer and random copolymer with the ionic liquid are homogeneous and amorphous morphology with excess scattering as content of ionic liquid increases. The block copolymer and ionic liquid mixtures show ordered structures typical of block copolymers that vary with ionic liquid content. The morphologies of the copolymer-ionic liquid mixtures can be correlated with the conductivities.

12:39PM B19.00006 Dissolving Polymers in Ionic Liquids. DAVID HOAGLAND, JOHN HARNER, Univ. of Massachusetts Amherst — Dissolution and phase behavior of polymers in ionic liquids have been assessed by solution characterization techniques such as intrinsic viscosity and light scattering (static and dynamic). Elevated viscosity proved the greatest obstacle. As yet, whether principles standard to conventional polymer solutions apply to ionic liquid solutions is uncertain, especially for polymers such as polyethylene and hydrophobic block copolymers that may specifically interact with ionic liquid anions or cations. For flexible polyelectrolytes (polymers releasing counterions into high dielectric solvents), characterization in ionic liquids suggests behaviors more typical of neutral polymer. Coil sizes and conformations are approximately the same as in aqueous buffer. Further, several globular proteins dissolve in a hydrophilic ionic liquid with conformations analogous to those in buffer. General principles of solubility, however, remain unclear, making predictions of which polymer dissolves in which ionic liquid difficult; several otherwise intractable polymers (e.g., cellulose, polyvinyl alcohol) dissolve and can be efficiently functionalized in ionic liquids.

12:51PM B19.00007 Polyester Spherulite Crystallization in Ionic Liquids. KATHY SINGFIELD, SHAWNA MITCHELL, Saint Mary’s University — A series of polyesters have been crystallized in ionic liquids. Spherulites of the polyesters have been grown isothermally from different ionic liquids after cooling the single phase polymer/ionic liquid system from above the polymer melting point temperature. To the authors’ best knowledge this is the first reported account of polyester spherulites grown from these non-traditional solvents. The combination of physical properties of the crystallizing system supports the un-restrained branching/splitting volume-filling growth in all radial directions of the suspended crystallizing entity. The morphology of the collected spherulites at various stages of their formation was examined using scanning electron microscopy (SEM). The SEM results provide a clear visual inspection of the early-stage growth forms and the branching/splitting patterns involved in their evolution to the final spherical form.

1:03PM B19.00008 Understanding Ion Transport in Polymerized Ionic Liquids using Dielectric Spectroscopy. U. HYEOK CHOI, Penn State University, HONG CHEN, Drexel University, WENJUAN LIU, Penn State University, YOSSEF A. ELABD, Drexel University, RALPH H. COLBY, Penn State University — In order to deduce the mechanism of ion conduction in ion-containing polymers, not only the conductivity needs to be measured but also the number density and mobility of conducting ions must be determined using broadband dielectric spectroscopy, covering broad frequency and temperature ranges. To obtain a transference number of unity, one ionic charge is covalently bonded to the polymer so that only the counterions can contribute to ion conduction. In this study, imidazolium-containing monomer was synthesized and polymerized to make a cationic homopolymer with either tetrafluoroborate or bis(trifluoromethanesulfonfyl)imide anionic counterions. These ions can associate into pairs and larger aggregates. The degree of ion pairing can be estimated from the temperature dependence of the dielectric constant and knowledge of the dipole moment of the ion pair, using the 1936 Onsager equation. Using the 1953 Macdonald model makes it possible to determine concentration and mobility of mobile counterions from analysis of electrode polarization in dielectric spectroscopy.

1:15PM B19.00009 Enhanced ionic conductivity of polyurethane ionomers by self-solvating cations. SHIH-WA WANG, RALPH COLBY, Pennsylvania State University — We study the effect of different cations on ionic conductivity and dielectric properties of polyurethane ionomeric single-ion conductors with para-phenyl diisocyanate and anionic diols (carboxylate or phosphonate) constituting the hard segments and poly(ethylene glycol) as the soft segment. Bulky cations such as tetra-alkyl ammonium can increase ionic conductivity compared to metallic polyurethane ionomers. We show that the presence of ether oxygen on conducting cations even more, ether oxygens, which are well-known to solvate cations, are incorporated in the alkyl tail of ammonium-type cations. By comparing segments and poly(ethylene glycol) as the soft segment. Bulky cations such as tetra-alkyl ammonium can increase ionic conductivity compared to metallic polyurethane ionomers.
1:39PM B19.00011 Processing of Natural Polymer-nanocomposites using Ionic Liquids as “Green Solvents”, SAMEER RAHATEKAR, NIST, ASIF RASHEED, FDA, RAVUL JAIN, Georgia Tech, K. KOZIOL, ALAN WINDLE, University of Cambridge, PAUL TRULOVE, US Naval Academy, SATISH KUMAR, Georgia Tech, JEFFREY GILMAN, NIST, NIST COLLABORATION, GEORGIA TECH COLLABORATION, UNIVERSITY OF CAMBRIDGE COLLABORATION — We report fiber spinning of natural polymers such as cellulose and silk using ionic liquids. Ionic liquids can dissolve cellulose and silk and are less hazardous that the traditional solvents used for dissolving cellulose. We use imidazolium based ionic liquids as a common solvent to process natural polymers and carbon nanotubes. Cellulose/carbon nanotubes based fibers are spun using wet spinning process. The rheological, mechanical thermal and electrical properties of the fibers are measured. We also characterize the cellulose nanocomposites fibers using ionic liquids by SEM/TEM, X-ray diffraction, TGA and FTIR analysis. Silk and carbon nanotubes fiber processing is also reported using ionic liquids as process. The rheological, mechanical thermal and electrical properties of the fibers are measured. We also characterize the cellulose nanocomposites fibers using ionic liquids by SEM/TEM, X-ray diffraction, TGA and FTIR analysis. Silk and carbon nanotubes fiber processing is also reported using ionic liquids as common solvent.

1:51PM B19.00012 Biocompatible Ionic Liquid-Derived Conducting Polymers\(^1\), MILLICENT FIRESTONE, CHRISTOPHER BURNS, SUNGWON LEE, Argonne National Laboratory — A significant and frequently encountered challenge when making an electrical connection to a protein is that its electron-transfer sites are buried within the polypeptide matrix and thus, are not readily accessible to bulk metal electrodes. A further complicating factor is that inorganic (i.e., metallic) electrodes are often incompatible with biological samples. These obstacles might be overcome by the use of conducting oligomers and / or polymers, which are flexible, offering a means to access remote redox centers. These oligomers can be readily modified to include chemical moieties that can connect covalently to sites near redox centers. In addition, conducting polymers can be made to be environmentally responsive (dynamic), processable (conformal coating, soluble) and mechanically durable, thus enabling them to function as an electrical conduit (wire or electrode) to biomolecules. In this work, we describe the design, synthesis and electrochemical properties of thiophene-based ionic liquid monomers and their bulk polymerization by chemical oxidation to yield cationic, aqueous-soluble polymers. Preliminary studies evaluating the electropolymerization of these monomers into nanostructured thin films will also be presented.

11:15AM B20.00001 Polymers for new battery technologies., MOHIT SINGH, Seeo Inc — The chemical and electrochemical reactivity of the components comprising today’s lithium batteries has severely limited their lifetime and stability, and attempts to push the limits on energy density have exacerbated these stability issues. The weakest link in terms of safety and stability of Li ion systems is the organic liquid electrolyte that facilitates the Li\(^+\) ion transport between the electrodes. The electrolyte is flammable and electrochemically unstable against the graphitic anode. It is the continuous electrochemical degradation of the electrolyte at the electrodes that leads to poor cycle life of the batteries, and in some cases runaway reactions that lead to explosions. Dry polymer electrolytes alleviate the electrochemical stability problem by offering a stable electrode-electrolyte interface. The absence of flammable liquids prevents runaway reactions. The main hurdle that has prevented dry polymer electrolytes from being commercialized is low ionic conductivity, and challenges in interfacing with the electrode materials. We demonstrate a novel approach towards addressing these challenges that renders batteries with excellent cycle lives, and thermal stability.

11:51AM B20.00002 Control of Domain Orientation in Block Copolymer Electrolyte Membranes at the Interface with Humid Air, MOON JEONG PARK, SUHAN KIM, ANDREW M. MINOR, NITASH P. BALSARA, Department of Chemical Engineering, Materials Sciences Division, Lawrence Berkeley National Laboratory, University of California, Berkeley, USA — Access to ion transporting channels in polymer electrolyte membranes depends crucially on the orientation of hydrophobic and hydrophilic domains at the surface. We demonstrate that domain orientation of polymer electrolyte membranes made from polystyrenesulfonate-b-methoxy(polyethylene) (PS-PMO) copolymers can be tuned by controlling sulfonation level and moisture content of the air. At low sulfonation levels, highly ordered hydrophobic PMO cylinders oriented perpendicular to the film surface are obtained, when the film is contacted with humid air. Increasing the sulfonation level results in a transition from perpendicular to parallel orientation. Our conclusion is based on three-dimensional characterization of membranes using electron microscopy of samples prepared by the shadow focused ion beam technique, grazing incident small angle x-ray scattering, and electron tomography.

12:03PM B20.00003 Vertical phase-separation due to differences in surface energies in bulk heterojunction polymer solar cells, SARAH COWAN, ANSHUMAN ROY, JI SUN MOON, SUNG HEUM PARK, ALAN HEEGER, University of California - Santa Barbara — The synthesis and testing of new photoactive polymers is steadily improving the light conversion efficiencies of organic bulk heterojunction solar cells. Understanding the physical interactions between the polymer donor material and the electron acceptor is critical in controlling and optimizing the morphology of the blend. While interactions between the donor and acceptor in the blend determine the scale and stability of lateral phase separation, interactions between the constituents of the blend and the neighboring device layers are equally important. In this work, we demonstrate that bulk heterojunction constituents in a polymer solar cell tend to vertically phase-separate due to differences in surface energies leading to surface-directed spinodal decomposition and / or a wetting layer. Using a combination of cross-sectional transmission electron microscopy (TEM), variable angle spectrophotometric ellipsometry (VASE), and a contact angle study, we probe the vertical phase separation in poly[3-hexylthiophene] (P3HT:PCBM) and poly[N,N′-heptadecanoyl-7,7-carbazole-alt-5,5-(4′,7′-di-2-thienyl-2,1,3-benzothiadiazole)] : [6,6]-phenyl-C61-butyric acid methyl ester (PCDTBT:PC70BM).

12:15PM B20.00004 Investigation of the bulk heterojunction structure of organic photovoltaica using neutron reflectivity, JONATHAN KIEL, Michigan State University Department of Chemical Engineering and Materials Science, BRIAN KIRBY, National Institute of Standards and Testing Center for Neutron Research, MICHAEL MACKAY, University of Delaware Materials Science and Engineering — Organic photovoltaics have received much attention recently due to their promise of affordable and flexible solar power. A major component of these devices is the bulk heterojunction: an interconnected mixture of an electron donor, a highly conjugated polymer, and an electron acceptor, generally a fullerenic derivative. We have performed neutron reflectivity experiments on 200 nm thick films of poly[3-hexylthiophene] and [6,6]-phenyl-C61-butyric acid methyl ester (PCBM) to investigate the structure of this bulk heterojunction. We observe a gradient of PCBM throughout the film that depends on processing conditions, ratio of polymer to PCBM and choice of solvent. These results are compared to working devices to show which bulk heterojunction structures are more suitable to highly efficient solar cells.
doped organic semiconductor photovoltaics, WENTING LI, CHRISTOPHER MURRAY, Department of Chemistry, CHERIE KANG, Department of Electrical and Systems Engineering, University of Pennsylvania — Hybrid solar cells based on nanocomposite organic semiconductors and IR sensitive PbSe nanocrystals (NCS) and nanowires (NWs) are fabricated and serve as a model system to test in PV devices. Wet chemical routes are used to synthesize PbSe NCS tunable in size, from 6 to 12nm in diameter, and in shape by tailoring the reaction temperature and selection of surfactants. PbSe NWs are also synthesized through oriented attachment in solution of NC building blocks to form straight, zigzag, helical, and branched NWs. We integrate PbSe NCS and NWs with the organic semiconductors P3HT and pentacene. We are able to fabricate organic-inorganic bulk heterojunctions with pentacene using a solution-processable precursor that is thermally converted to pentacene. We investigate the role of the organic semiconductor pentacene in the solar cell, both as a conductivity booster and as a more stable alternative to P3HT. We find that ligand exchange significantly increases photocurrent by replacing oleic acid ligands used in NC synthesis with shorter pyridine or octylamine ligands. We also report that tailoring the size and shape of the NCS and controlling the deposition and annealing conditions of the nanocomposites enhances the solar cell performance.

12:39PM B20.00006 Transient photovoltaic behavior of air-stable inverted organic solar cells with solution-processed electron transport layer and high work function top electrode, CHANG SU KIM, YUEH-LIN (LYNN) LOO, CHEMICAL ENGINEERING, PRINCETON UNIVERSITY TEAM — In this study, we made air-stable inverted organic solar cells comprising sol-gel derived TiOx as the electron transport layer and Au as the high work function top electrode. The highly transparent TiOx layer, placed between the ITO cathode and the active layer, smooths out ITO and provides better alignment of energy levels for electron transport. The conductivity of TiOx is known to increase with increasing exposure time to light as the excited electrons fill up shallow traps during illumination. The short circuit current of our inverted solar cells thus increases from 1.41mA/cm2 to 8.13mA/cm2 under continuous illumination for 10 minutes. In addition, when our inverted solar cells are stored in air for extended periods of time, the open circuit voltage increases due to oxygen doping of poly(3-hexylthiophene). Exposure to air for 2 days, for example, increases the open circuit voltage from -0.38V to -0.53V.

12:51PM B20.00007 Controlling Photovoltaic Loss: Recombination of Dissociated Electrons and Holes in Organic Solar Cells, ZHIHUA XU, HUIDONG ZANG, BIN HU — This presentation reports the studies of charge-transfer complex states formed from the recombination of dissociated electrons and holes at the donor-acceptor interfaces in bulk-heterojunction organic solar cells based on magnetic field effects of photocurrent. Our studies indicate that the formation of charge-transfer complex states is determined by the competition between Coulombic attraction and electrical drifting. Externally, applying electric field can clearly decrease the density of charge-transfer complex states through electrical drifting. Internally, morphology can change the competition between Coulombic attraction and electric drifting through dielectric fields and charge mobilities, and consequently affects the formation of charge-transfer complex states. As a result, changing internal dielectric fields and charge mobilities through internal Coulomb interaction and electrical drifting presents as two mechanisms to control the formation of charge-transfer complex states towards the improvement of photovoltaic efficiencies in organic bulk-heterojunction solar cells.

1:03PM B20.00008 Photo-induced improvement of Bulk Heterojunction Polymeric Solar Cells, KAMIL MIELCZAREK, ALEXANDER COOK, ANVAR ZAKHIDOV, University of Texas at Dallas, NANOTECH INSTITUTE TEAM — The effectiveness of BHJ polymeric cells depends highly on the formation of continuous three dimensional interconnecting networks of electron donor (typically RR P3HT) and acceptor (typically PCBM) materials. This process is controlled by post-processing heat treatment to induce phase separation of the materials. We demonstrate in this presentation, that in-situ photo-excitation of the BHJ structure during the annealing process controls both the maximal photocurrent and filling factor of the BHJ solar cells. We have found that variations in intensity and spectral composition of the photo excitation affect the resulting morphology of BHJ. The increased diffusivity of constituents and photo-modulation of the carrier recombination upon annealing is discussed as one of the causes of the observed morphology improvement.

1:15PM B20.00009 High-Vacuum Annealing of Polythiophene:Methanofullerene Bulk Heterojunction Solar Cells, JENNIFER SEGUI, State University of New York - Stony Brook, IOANA GEARBA, Brookhaven National Laboratory, MICHAEL RAFAEL, United States Department of Energy, CHARLES LE, United States Department of Energy — Solar cell device architectures incorporating photoactive layers of immiscible blends of organic semiconductors achieve improved photovoltaic power conversion efficiency compared to planar device geometries. We have fabricated bulk heterojunction solar cells with active layer blends of poly-3 hexylthiophene (P3HT) and the fullerene derivative, [6,6] phenyl C61-butyric acid methyl ester (PCBM). Spin casting the blend from a chlorobenzene solution forms nanometer-scale domains of electron donor and acceptor phases in the device active layer. We solve the process active layers in ambient atmospheric conditions prior to aluminum contact evaporation resulting in inevitable oxygen adsorption in the P3HT layer and interfaces. We have investigated several device post-fabrication thermal treatments for driving oxygen from the device active layer, including different temperatures, times, and vacuum pressures. We evaluate the efficacy of this technique in improving Al contact quality, film morphology, solar cell efficiency, and reproducibility via analysis of device current-voltage characteristics and tapping mode atomic force microscopy.

1:27PM B20.00010 Optimizing Ionic Electrolytes for Dye-Sensitized Solar Cells, XIAOJUAN FAN, SARAH HALL, State University of New York - Stony Brook, DEBRA SHEPHERD, Department of Chemistry, SUNY - Stony Brook, I.R. GEARBA, C.-Y. NAM, R. PINDAK, C.T. BLACK — Organic photovoltaic device power conversion efficiencies are limited in part by low charge mobility within the constituent active layer. For example, the p-type polythiophene polymers used in the highest efficiency organic photovoltaic devices have transverse hole mobilities of only $10^{-4}$-$10^{-5}$ cm$^2$/V-s, despite showing significantly higher values (~0.1 cm$^2$/V-s) in a lateral FET geometry. This mobility anisotropy is caused by poor overlap of π−π orbitals in the transverse direction, which impedes charge hopping between polymer chains. We have increased the transverse hole conductivity by as much as three times by incorporating the radical initiator di-tert-butyl peroxide into polythiophene thin films. The initiator promotes thermal crosslinking upon annealing at 170C. Crosslinked photovoltaic films maintain a similar absorption spectrum to the uncrosslinked material. Grazing incidence X-ray measurements correlate film structural changes to the measured electronic properties, and reveal two possible mechanisms for increased π−π overlap in crosslinked films. We have increased the power conversion efficiency of planar photovoltaic devices composed of p-type polythiophene and n-type C60 by about three times (from 0.9% to 2.7%) by crosslinking the polythiophene material. Moreover, crosslinked polythiophene films are rendered insoluble and thus amenable to the further material processing.
1:51PM B20.00012 Modeling photocurrent transients in organic solar cells. INCHAN HWANG, NEIL GREENHAM, Cavendish Laboratory, Department of Physics, University of Cambridge, J. J. Thomson Ave., Cambridge CB3 0HE, United Kingdom — We investigate the transient photocurrents of organic photovoltaic devices by numerical modeling of the drift-diffusion equations. Understanding charge transport in organic solar cells is one of the major interesting issues relevant to improving performance of organic devices. We demonstrate the simulation of the transient photocurrents in a response to a sharp turn-on illumination. Our results show the transient time in photocurrents is determined not only by free charge transport, but also by geminate charge pair dynamics. The dissociation probability of geminate charge pairs is a key parameter in determining the performance of organic devices, controlling the efficiency at low intensity, and also governing the fate of charge pairs formed by bimolecular recombination at high intensity. Bimolecular recombination appears to shorten the typical distance traveled by free charges from where they are generated to the electrode, leading to a reduced turn-on time at high intensity.

2:03PM B20.00013 Conjugated Polymer Organic Solar Cells made using Low Bandgap Vinylene-linked Benzothiadiazole-thiophene, N. C. HESTON, Univ. of Florida, J. MEI, S. VASILYEVA, J. R. REYNOLDS, Univ. of Florida — With over 70% of the solar photon flux occurring at wavelengths beyond 700 nm, the broad absorption spectra of low bandgap conjugated polymers offers an additional path towards improving organic photovoltaic efficiencies. Here, we report on polymer solar cells fabricated using a vinylene-linked benzothiadiazole-thiophene polymer and [6,6]-phenyl-C_{61}butyric acid methyl ester (PCBM) blends. We have fabricated cells with various blend film polymer to PCBM ratios as well as film thicknesses and architectures. The performance of these cells was investigated using both AM 1.5 and incident photon to current efficiency measurements. Surface morphologies were characterized using atomic force microscopy. A strong correlation was observed between the percentage of polymer in the blend and the resulting film morphology. We observed photon-generated currents at wavelengths greater than 800nm, though we have not yet obtained high overall power conversion efficiencies.

Monday, March 16, 2009 11:15AM - 2:15PM — Session B21 DMP: Focus Session: Dopants and Defects in Semiconductors

11:15AM B21.00001 Hydrogen multicenter bond in oxide and nitride semiconductors1, ANDERSON JANOTTI, University of California - Santa Barbara — Hydrogen is a very reactive atom, occurring in virtually all organic and in many inorganic compounds. It can form a purely covalent bond, in which two hydrogen atoms share a pair of electrons in a two-electron two-center bond, as well as polar covalent bonds, such as in an H_{2}O molecule. In solids, hydrogen is usually considered as an interstitial impurity. In elemental semiconductors, such as silicon, hydrogen forms a three-center bond when located at the bond center. In compound semiconductors, hydrogen bonds to the anionic species in p-type material, and to the cationic species in n-type. Thus far, hydrogen in solids has been found to form chemical bonds with one, two, or at most three other atoms. Higher coordination numbers are exceedingly rare and have been reported only for clusters. In this talk we will show that hydrogen is capable of forming multicenter bonds in solids, occupying substitutional sites. As examples, we discuss substitutional hydrogen impurities in oxides (ZnO, MgO, SnO_{2}, TiO_{2}) [1,2] and nitrides (InN, AIN, GaN) [3]. Based on first-principles calculations we show that hydrogen replaces oxygen (nitrogen) and forms genuine chemical bonds with multiple metal atoms, in truly multicoordinated configurations. These multicenter bonds are surprisingly strong despite the large hydrogen-metal distances when compared to typical values in hydrogen two-center bonds. Hydrogen in the multicenter bond configuration is a shallow donor in a number of materials. In conducting oxides, it provides a consistent explanation for the observed dependence of electrical conductivity on oxygen partial pressure, thus resolving a long-standing controversy on the role of point defects in unintentional n-type conductivity [1,2].

1In collaboration with C. G. Van de Walle, this work was supported by the NSF MRSEC Program under Grant No. DMR05-20415 and by the UCSB Solid State Lighting and Energy Center.

11:51AM B21.00002 Hydrogen in anion vacancies of semiconductors1, MAO-HUA DU, DAVID SINGH, Oak Ridge National Laboratory — Hydrogen typically terminates the dangling bonds around vacancies in semiconductors, thereby, partially or completely passivating the vacancies. However, it has been shown recently that hydrogen in anion vacancies of many semiconductors, such as ZnO, MgO, InN, SnO_{2}, and GaN, takes multi-coordinated structures and acts as shallow donors, providing n-type conductivity to the materials. We study the hydrogen in the anion vacancies of a series of II-VI and III-V semiconductors using density functional calculations. The results on these materials show that, in the anion vacancies of polar II-VI semiconductors, the hydrogen is usually anionic and is coordinated with more than one cation atoms as a result of the relatively high ionization of the host material. The hydrogen coordination number depends on the host anion size. On the other hand, in more covalent semiconductors such as some III-V semiconductors, the single cation-H bonding configuration may become most stable. In the anion vacancies of ZnX and CdX where X represents anions, hydrogen is typically amphoteric except for oxides, in which the small anion size prohibits the formation of the cation-cation bond that is required for the acceptor configuration.

12:03PM B21.00003 Defect Creation and Annihilation in GaN and ZnO1, CHRIS VAN DE WALE, ANDERSON JANOTTI, University of California, Santa Barbara — ZnO is an extremely attractive material for a number of optoelectronic and electronic applications. Among its advantages is its radiation hardness, which is even greater than that of GaN. Based on our comprehensive investigations of intrinsic point defects [1,2], we have developed a model for defect creation and annihilation during and after irradiation. The calculations, based on pseudopotential-density-functional theory combined with LDA+U [2] produce formation energies, stability of charge states as a function of Fermi level, and migration barriers for each of the point defects. Migration barriers allow us to determine annealing temperatures at which we predict various defects to be mobile. In ZnO, the key factors responsible for radiation hardness are the low migration barriers of point defects and the charge-state matching of dominant defect pairs. Quantitative arguments for both ZnO and GaN will be presented, and the results compared with experimental observations. The insights provided by our modeling can be fruitfully applied to understand irradiation effects in semiconductors and insulators in general. [1] S. Limpijumnong and C. G. Van de Walle, Phys. Rev. B 69, 035207 (2004). [2] A. Janotti and C. G. Van de Walle, Phys. Rev. B 76, 165202 (2007).

12:15PM B21.00004 Asymmetric hole localization and multiple hole binding of acceptors in ZnO\(^1\). STEPHAN LANY, ALEX ZUNGER, National Renewable Energy Laboratory — Holes bound at cation-site acceptors in oxides, such as Li\(_{2}\), or the Zn vacancy in ZnO tend to be localized on a single oxygen neighbor rather than to be delocalized over symmetrically equivalent sites. As a consequence of this localization, the acceptor level lies deep in the gap, typically \(\sim 1\) eV above the VBM. In contrast, conventional local density calculations do not show this symmetry breaking, and predict the acceptor level much too shallow. This failure of approximate functionals has been attributed to the residual self-interaction, which underestimates the energy splitting between occupied and unoccupied states. We identify a criterion for the cancellation of the self-interaction in terms of a generalized potential \(\hat{V} = \hat{V}\left(r_2, r_3, \ldots, r_n\right)\) using this criterion to define a self-interaction correction (SIC) potential that does not rely on empirical parameters. After the SIC, the unoccupied hole states are correctly placed in energy with respect to the spectrum of the occupied host states. We use this method to predict the acceptor levels of cation-site acceptors and the Zn vacancy in ZnO, and of acceptors in In\(_2\)O\(_3\) and SnO\(_2\). We find that these acceptors have too deep levels to cause \(p\)-type conductivity, and we further predict that nominal single acceptors can generally bind multiple holes (up to 3).

12:39PM B21.00006 ABSTRACT WITHDRAWN

12:51PM B21.00007 Unusual uniaxial stress results on the stretch mode of OH related defects in ZnO. KEVIN MARTIN, University of Pittsburgh at Johnstown, Johnstown PA, W. BEALL FOWLER, Lehigh University, Bethlehem PA — Some uniaxial stress studies of the frequency dependence of O-H related defects in ZnO have produced surprising results\(^1\)-\(^2\). For example, the Li:OH defect in ZnO (H\(^{1+}\)) is oriented along the c-axis, yet the OH stretch mode decreases in frequency when stress is applied along the c direction and increases when stress is perpendicular to the c-direction. Another example is the Cu:OH defect, in which the OH is aligned along one of the three non-c tetrahedral directions. Stress along the c-direction produces a strongly non-linear increase in frequency. These examples and others indicate something unusual is happening in these systems. One possibility is that the piezoelectric effect in ZnO is responsible for the "backward" behavior of the frequency shift of these defects. The piezoelectric effect in ZnO is caused by the lack of cancellation between the "clamped-ion" term (i.e., electronic contribution) and the term related to the change in the u parameter ("internal strain"). With the latter dominating, when c stress is applied, the value of u increases, thus the two interpenetrating hexagonal lattices (one for Zn, the other for O) increase their overlap. We will attempt to explain the experimental results within this framework. \(^1\)Lavrov and Weber, Phys. Rev. B, 73, 035208 (2006), and \(^2\)Phys. Stat. Sol. (b) 243, 2657 (2006) \(^3\)Corso, et al Phys. Rev B. 50, 10715 (1994)

1:03PM B21.00008 Theoretical study of Si in ZnO\(^1\). JOHN LYONS, ANDERSON JANOTTI, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — Recently, the presence of silicon in relatively high concentrations has been detected in samples of ZnO\(^1\). The properties of this impurity have not yet been investigated. Here we present a first-principles study of the electronic and structural properties of Si in zinc-blende ZnO using density functional calculations with LDA, GGA, and hybrid functionals. Our calculations show that substitutional Si on a Zn site is lower in energy than either Si on an oxygen site or a Si interstitial. The calculations consistently predict Si to be a shallow donor in ZnO, with the \(2^+\) state being mostly stable across the band gap. The formation energy of substitutional Si is relatively low, supporting experimental evidence which shows a concentration of \(10^{17}\) cm\(^{-3}\) Si in ZnO samples. The properties of Ge in ZnO are also studied for comparison and show behavior similar to that of Si. \(^1\)M.D. McCluskey and S.J. Jokela, Physica B 401-402, 355 (2007).

1:15PM B21.00009 Photoinduced EPR study of electron traps in TiO\(_2\) crystals: Oxygen vacancies and Ti\(^{3+}\) ions. SHAN YANG, ADAM BRANT, LARRY HALLIBURTON, Physics Department, West Virginia University — Electron paramagnetic resonance (EPR) provides a sensitive method to monitor native defects in wide-band-gap semiconductors. In-situ illumination with laser light at low temperature (photoinduced EPR) forms paramagnetic defects in fully oxidized bulk TiO\(_2\) crystals. Illumination with 442 nm laser light at 30 K and below produces four electronlike centers and one hololex center. Three of the electronlike centers have S = \(1/2\) and are assigned, respectively, to a substitutional Ti\(^{3+}\) ion in the otherwise perfect lattice, a substitutional Ti\(^{3+}\) ion adjacent to a Si\(^{4+}\) ion, and a substitutional Ti\(^{3+}\) ion adjacent to an oxygen vacancy. The fourth electronlike center has S = 1 and is assigned to two Ti\(^{3+}\) ions adjacent to one oxygen vacancy. The hololex center has S = \(1/2\) and consists of a hole shared equally by two adjacent oxygen ions in the otherwise perfect lattice. Spin-Hamiltonian parameters, obtained from complete sets of angular dependence data, are presented for each of the centers. This work was supported by NSF Grant No. DMR-0804352.

1:27PM B21.00010 The nature of Group-V acceptor impurities in SnO\(_2\)^{1}. JOEL VARLEY, Department of Physics, University of California at Santa Barbara, ANDERSON JANOTTI, CHRIS VAN DE WALLE, Materials Department, University of California at Santa Barbara — Group-V elements have long been considered leading candidates for achieving p-type doping in semiconducting oxides. Using first-principles calculations, we investigate the feasibility of achieving ambipolar doping in SnO\(_2\) using the Group-V elements N, P, and As. We address the electronic structure of these impurities by performing systematic density functional calculations using hybrid functionals. This approach overcomes the band-gap problems inherent in calculations using the local density approximation or generalized gradient approximation, thus allowing us to accurately determine energies of defect levels. We discuss the stability of the isolated impurities both as substitutional and interstitial defects, based on calculated formation and migration energies. We also investigate their possible passivation by hydrogen and examine binding energies and activation energies of hydrogen-acceptor complexes. We conclude that the Group-V elements are deep acceptors that will not enable p-type doping of SnO\(_2\).

1:39PM B21.00011 Manipulation of Single Oxygen Vacancies on TiO\(_2\)(110). DANDA ACHARYA, PETER SUTTER, Brookhaven National Laboratory — Oxygen vacancies are among the primary chemically active defects on the surface of reducible transition metal oxides, playing a key role in surface chemistry, catalysis, and photocatalysis. We report the controlled manipulation of individual O-vacancies on reduced TiO\(_2\)(110)-1\_1 using a low temperature scanning tunneling microscope. Localized voltage pulses trigger the hopping of single vacancies along a bridging oxygen (O\(_{\text{av}}\)) row. We discuss the microscopic manipulation mechanism and demonstrate atomic-scale control by constructing linear and more complex arrangements of vacancies. Single defect manipulation is used to probe the interaction of closely spaced vacancies, and to establish the possibility of forming highly reactive double and a triple O-vacancy clusters. Detailed experimental and theoretical analysis reveals that bridge-bonded O-vacancy pairs are stable and have lower energy than pairs of vacancies separated by two or more lattice spacings. The existence of stable vacancy pairs with exposed low-coordinated Ti atoms has implications on the reactivity of TiO\(_2\)(110) and of similar metal oxide surfaces.
1:51PM B21.00012 Coordination Defects and Nanoclusters of TiO$_2$. KEN PARK, Baylor University. VINCENT MEUNIER, MINGHU PAN, Oak Ridge National Laboratory, NAN-HSIN YU, Baylor University, WARD PLUMMER, Louisiana State University — Titanium oxide is one of the most investigated photocatalytic systems. It is capable of converting toxic organic and inorganic materials to benign products, as well as turning solar energy into a chemical one. Many believe that the catalytic activation involves charge transfer localized at surface defects with lower stoichiometry and/or coordination. In this study, scanning tunneling microscopy (STM) and density functional theory (DFT) are used to gain insight into such defects on TiO$_2$(110). STM reveals defects ranging from a few Angstroms to a few nanometers in size, but all of a uniform height of 3 Å. These topographically distinct defects are determined as fully stoichiometric nanoclusters by DFT. Despite the full stoichiometry, they possess undercoordinated atomic sites including 3- and 4-coordinated Ti and 1-coordinated O atoms. Their electronic and chemical properties will be discussed.

2:03PM B21.00013 Kinetic Monte Carlo study for the thermal stability of hydrogen in ZnO. JUNHYEOK BANG, KEE JOO CHANG, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701 — Zinc oxide (ZnO) has attracted much attention due to a variety of applications to transparent optoelectronic devices. It is known that undoped ZnO exhibits n-type conductivity. Hydrogen, which is unintentionally incorporated, is considered as a promising candidate for shallow donors in ZnO. However, it is still difficult to explain n-type conductivity in annealed ZnO due to the low thermal stability of H. Here we study the diffusion of H in ZnO using first-principles calculations and then perform kinetic Monte Carlo (kMC) simulations for the thermal stability of H. The migration energy of a substitutional H is much higher than that for an interstitial H. Using as input the energy barriers for H diffusion, kMC simulations show that interstitial and substitutional H atoms diffuse out at different annealing temperatures around 125 and 475 °C, respectively, in good agreement with experiments. When H atoms are injected from air into ZnO, we find that they are likely to be trapped at O-vacancy sites, leading to the n-type conductivity in annealed samples.

Session B22 GMAG DMP FIAP: Focus Session: Theory of Spin-based Semiconductor Devices

11:15AM B22.00001 Role of motive forces for the spin torque transfer for nano-structures. STEWART BARNES, Physics Department, University of Miami — Despite an announced imminent commercial realization of spin transfer random access memory (SPRAM) the current theory evolved from that of Slonczewski [1,2] does not conserve energy. Barnes and Maekawa [3] have shown, in order correct this defect, forces which originate from the spin rather than the charge of an electron must be accounted for, this leading to the concept of spin-motive-forces (smf) which must appear in Faraday’s law and which significantly modifies the theory for spin-valves and domain wall devices [4]. A multi-channel theory in which these smf’s redirect the spin currents will be described. In nano-structures it is now well known that the Kondo effect is reflected by conductance peaks. In essence, the spin degrees of freedom are used to enhance conduction. In a system with nano-magnets and a Coulomb blockade [5] the similar spin channels which these smf’s redirect the spin currents will be described. In nano-structures it is now well known that the Kondo effect is reflected by conductance peaks. In essence, the spin degrees of freedom are used to enhance conduction. In a system with nano-magnets and a Coulomb blockade [5] the similar spin channels which these smf’s redirect the spin currents will be described. In nano-structures it is now well known that the Kondo effect is reflected by conductance peaks.

11:51AM B22.00002 Revisiting the “Spin-Transistor”. ABU NASER ZAINUDDIN, LUTFE SIDDIQUI, SUPRIYO DATTA, Purdue University — A “spin-transistor” in principle requires efficient injection (source), efficient detection (drain) and electrical manipulation (gate). For sometime now, electrical manipulation based on the Rashba effect has been well established and in recent years there has been significant progress in the design of injectors and detectors. Lateral spin-valve structures showing ~50% spin-polarization has been reported. In view of these advances it seems appropriate to evaluate various “spin-transistor” concepts. With this in mind, we have developed non-equilibrium Green’s function (NEGF) based model and benchmarked against existing experiments.

12:03PM B22.00003 Dynamical magnetoelectric feedback effects in magnetic resonant tunneling structures. CHRISTIAN ERTLER, JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg — Heterostructures made of stacked layers of both magnetic and nonmagnetic semiconductors provide a lot of opportunities for controlling and tuning their spin-dependent transport properties. For instance, highly efficient spin valves, spin switching and spin filtering devices have been demonstrated by using magnetic resonant tunneling structures [1]. Here, we show that in a resonant tunneling double barrier structure, which comprises a ferromagnetic quantum well made of a dilute magnetic semiconductor material, interesting dynamical effects can occur [2]. In such systems the transport and magnetic properties become strongly coupled, since the ferromagnetic order in the quantum well is determined by the itinerant carriers. Both the Coulomb interaction of the particles well as the magnetic exchange field give rise to strong feedback effects on the tunneling current. Interestingly, for a broad voltage range self-sustained high-frequency oscillating currents associated with an oscillating well magnetization appear. The requirements for the occurrence of these dc-driven magnetoelectric oscillations are investigated and possible device setups, which should allow for an experimental observation, are discussed. 12:15PM B22.00004 Theory of Semiconductor Spin Lasers, CHRISTIAN GOTHGEN, SUNY Buffalo, RAFAL OSZALDOWSKI, SUNY Buffalo and N. Copernicus University, Torun, Poland, IGOR ZUTIC, SUNY Buffalo — Semiconductor lasers with spin-polarized carriers’ injection have important advantages as compared to the conventional lasers in which the carriers are unpolarized. While such spin lasers have been successfully realized and shown to provide spin-polarization modulation and threshold current reduction [1-4], there remain important theoretical challenges in understanding their operation. We demonstrate that the maximum threshold reduction is larger than previously thought possible and, surprisingly, can be enhanced by ultrafast spin relaxation of holes [5]. By combining our analytical model [5] and numerical studies of spin lasers we explore the effects of quantum confinement in the gain region and identify different modes of operation. We thank A. Petrou for valuable discussions. This work is supported by US ONR and NSF-ECCS CARRER.

12:27PM B22.00005 Design Guidelines for Spin-Polarized Lasers, MICHAEL HOLUB, IGOR VURGAFTMAN, JERRY MEYER, BEREND JANONKER, Naval Research Laboratory — Semiconductor lasers driven by a spin-polarized current are expected to provide a threshold current reduction and optical polarization control. The design of spin-polarized lasers is critical to the realization of these effects. Thus, we have investigated the effect of electron spin injection on semiconductor laser performance using a spin-dependent rate equation model. The magnitude of the threshold reduction is shown to depend on intrinsic properties of the active region and laser cavity, and can approach a factor of 3.5 for fully spin-polarized electrons. The threshold reduction is found to be strongest in lasers with undoped active regions, recombination strongly dominated by Auger processes, and low threshold gain. Introduction of a ferromagnetic electrode in the vicinity of the active region for efficient spin injection generally results in higher internal loss and a requirement for greater material gain, which raises the laser’s baseline threshold as well as lessens the projected threshold reduction. The placement of a ferromagnetic contact on spin-polarized laser performance will be discussed.

12:39PM B22.00006 Spin-orbit coupling effects in Fe/GaAs heterostructures: First principles calculations, MARTIN GMITRA, ALEX MATOS-ABIAIGUE, University of Regensburg, Germany, CLAUDIA AMBROSCH-DRAXL, University of Leoben, Austria, JAROSLAV FABIAN, University of Regensburg, Germany — The tunneling anisotropic magnetoresistance (TAMR) effect in semiconductor heterostructures containing a single ferromagnetic layer is potentially useful for spintronics devices. Important, TAMR has recently been observed in a metallic system, namely, in Fe/GaAs/Au junctions. Surprisingly, while all the bulk components of the system are cubic, the observed anisotropy is twofold, of the C2v class. This suggests that rather than coming from the bulk anisotropy of the density of states, the effect arises from the interface that indeed has a reduced symmetry. A phenomenological model reflecting this symmetry in the form of the Bychkov-Rashba and the Dresselhaus spin-orbit coupling was proposed, giving a quantitative fit to the experiment. Here we report on comprehensive first principle calculations of the spin-orbit effects stemming from the interface anisotropy, providing support to the phenomenological theory. In particular, we have performed FPLAPW density functional calculations of an Fe/GaAs slab to extract quantitative information about the proposed model that are Bychkov-Rashba and Dresselhaus parameters.

12:51PM B22.00007 Magnetic phase transitions driven by non-equilibrium spins and their potential applications to magnetic cooling, LUTFE SIDDIQUI, ABU NASER ZAINUDDIN, SUPRIYO DATTA, School of Electrical and Computer Engineering, Purdue University — It is well-known that the Curie temperature in diluted magnetic semiconductors (DMS) like GaMnAs can be controlled by changing the equilibrium density of holes in the material. In this letter we predict, that even with a constant hole density, large changes in the magnetization can be obtained with a relatively small imbalance in the spin population. In particular, the structure under consideration consists of a three ferromagnetic dielectric layers, which are coupled through monolayer graphene placed in interface between two magnetic dielectric layers. We find that by combining the electrical effect on the exchange bias field and a giant magneto-resistance effect of the graphene/ferromagnet hybrid structures, a non-volatile magnetic field can be obtained instead of an external magnetic field with high energy consumption. In particular, the structure under consideration consists of three ferromagnetic dielectric layers, which are coupled through monolayer and bilayer graphene films. Interplay of two graphene layers can mediate the exchange bias fields applied to different sides of the free ferromagnets resulting in programmable logic operations.

1This work was supported in part by the DARPA and the FENA

1:03PM B22.00008 Magnetic memory and logic based on spin effects in graphene, JOHN ZAVADA, YURIY SEMENOV, KI WOOK KIM, NCSU — We report on a novel approach to the problem of low-power-consuming non-volatile magnetic random access memory (MRAM) and logic design that is based on the unique properties of the graphene placed in interface between two magnetic dielectric layers. We find that by combining the electrical effect on the exchange bias field and a giant magneto-resistance effect of the graphene/ferromagnet hybrid structures, a non-volatile magnetic field can be obtained instead of an external magnetic field with high energy consumption. In particular, the structure under consideration consists of a three ferromagnetic dielectric layers, which are coupled through monolayer and bilayer graphene films. Interplay of two graphene layers can mediate the exchange bias fields applied to different sides of the free ferromagnets resulting in programmable logic operations.

1:15PM B22.00009 Metal-insulator transition in a quantum wire with alternating Rashba interaction, HENRIK JOHANNESSON, University of Gothenburg, Sweden, GEORGE I. JAPARIDZE, Andronikashvii Institute of Physics, Tbilisi, Georgia, ALVARO FERRAZ, ICCMP, Brazil — We propose and analyze a device scheme by which an electrical current can be controlled via a gate-operated spin-orbit interaction. The device consists of a quasi-one-dimensional (1D) ballistic channel in a gated semiconductor heterostructure, contacted to a source and a drain and with the gates producing an alternating Rashba spin-orbit interaction. When the period of the Rashba modulation becomes commensurate with the 1D electron density, the spin-orbit interaction opens a charge gap, leading to a suppression of the current. Using bosonization and a perturbative RG approach we explore how electron-electron interactions influence the effect.

1:27PM B22.00010 Gate control of single-electron spins through Berry Phase in a realistic asymmetric confining potentials in III-V semiconductor Quantum Dots, SANJAY PRABHAKAR, JAMES RAYNOLDS, Ublbany Nanoscience — Among recent proposals for next-generation, non-charge-based logic is the notion that a single electron can be trapped and its spin can be manipulated through the application of gate voltages (Rev. Mod. Phys.79, 1217 (2007)). In this talk we present numerical simulations of Berry Phase of electron spins in single electron devices for realistic asymmetric confining potentials in support of experimental work at the University at Albany, State University of New York at the practical development of post-CMOS concepts and devices. We solve the Schrodinger equation including spin-orbit using a special numerical algorithm. The design of a quantum dot will be presented. The Berry Phase for electrons in a dot is calculated for both 0 and finite gate bias. The Berry Phase is calculated for a dot with an electrostatically defined quantum dots including the Rashba and Dresselhaus spin-orbit interactions computed numerically from realistic asymmetric confining potentials. The new simulation results open the possibility of spin manipulation through the gate induced Berry phase. This work is supported through funding from the DARPA/NRI INDEX center.

1:51PM  B22.00012  impurity-impurity interaction in graphene nanoribbons, JIAN-MING TANG, University of New Hampshire — The high mobility and small spin-orbit interaction makes graphene a promising candidate material for building spin-based quantum devices. Embedded magnetic dopants or magnetized defects may act as single spin qubits in these devices. The long decay length for the impurity levels near the Dirac point suggest that the double exchange interaction can compete with the RKKY exchange interaction. The impurity level splitting for two impurities in bulk and in nanoribbons are studied using a tight-binding approach. In the case of nanoribbons, the modification to the interaction due to the presence of edge states will be discussed.

11:15AM  B23.00001  Optimized basis-set representation for electronic-structure methods: Better Energetics1, AFTAB ALAM, DUANE JOHNSON, University of Illinois at Urbana Champaign — We derive an analytic expression for an optimal, and rapidly computed, representation for site-centered basis-set expansion (e.g., spherical harmonic). An optimal site-dependent radius are determined from the local saddle-point derived in terms of overlapping atomic charge densities, typically already used for Löwden construction of the starting potentials. These “saddle-point adjusted” sphere radii separate the “spherical” density and potential around an atom from the symmetry-induced, “non-spherical” part in the interstitial, and more properly accounts for charge and size of atoms. These radii also properly determine the weighted Voronoi cells (i.e., power diagram or “saddle-point adjusted” sphere radii separate the “spherical” density and potential around an atom from the symmetry-induced, “non-spherical” part in the interstitial, and more properly accounts for charge and size of atoms). We implement these ideas in a general Korringa-Kohn-Rostoker coherent potential approximation electronic-structure method, we present results using the dynamical cluster approximations (DCA) to obtain the temperature-dependent SRO in disordered alloys. We obtain the KKR-DCA SRO energetics versus local neighbor SRO parameters and minimize it at fixed temperature to predict the SRO. We show that the calculated SRO at fixed temperature compares well with experimental results, and then correlate the results to the electronic structure. We discuss how an accurate analytic estimate can be made for the SRO in most metals due to the dependence of the grand potential on SRO.

1Department of Energy under BES grants (DE-FG02-03ER4602631) and (LLNL-B573247).

11:27AM  B23.00002  Applications of the KKR-DCA: A Finite-Temperature Density Functional Theory to Predict Chemical Short-Range Order Effects in Disordered Metallic Alloys1, D.A. BIAVA, D.D. JOHNSON, University of Illinois — Short-range order (SRO) is ubiquitous in metallic alloys, affecting changes in their electronic, thermodynamic, mechanical, magnetic, and structural properties. For example, SRO is responsible for the yield-strength anomalies observed in Cu-Al at high temperatures, i.e., the materials is more resistant to dislocation motion at high temperature than it is at room temperature. Within the Korringa-Kohn-Rostorker (KKR) electronic-structure method, we present results using the dynamical cluster approximations (DCA) to obtain the temperature-dependent SRO in disordered alloys. We obtain the KKR-DCA SRO energetics versus local neighbor SRO parameters and minimize it at fixed temperature to predict the SRO. We show that the calculated SRO at fixed temperature compares well with experimental results, and then correlate the results to the electronic structure. We discuss how an accurate analytic estimate can be made for the SRO in most metals due to the dependence of the grand potential on SRO.

11:39AM  B23.00003  Electronic and Magnetic properties of NbFe2: An itinerant magnet near a quantum critical point1, ALASKA SUBEDI, DAVID J. SINGH, Materials Science and Technology Division, ORNL — NMR studies show that pure C14 Laves phase NbFe2 is a weak antiferromagnet below 13K with magnetic moment per Fe of no more than 0.1μB. However, the Nb-rich samples do not show antiferromagnetism down to 1.8K, which suggests that they are close to antiferromagnetic QCP. Here we report density functional studies of the magnetic properties, band structure and Fermiology. We elucidate the nature of the ordering between the two distinct Fe sites and discuss the results in relation to the quantum criticality.

1Work supported by DOE - DMSE.

11:51AM  B23.00004  First-principles calculations of free energies of unstable phases: The case of fcc W, VIVDUOS OZOLINS, Department of Materials Science & Engineering, University of California, Los Angeles — Ab initio density-functional theory molecular dynamics simulations are used to solve the long-standing problem of calculating the free energies of harmonically unstable phases, such as fcc W. We find that fcc W is mechanically unstable with respect to long-wavelength shear at all temperatures considered (T>2500 K), while the short-wavelength phonon modes are anharmonically stabilized. The calculated fcc/bcc enthalpy and entropy differences at T=3500 K (308 meV and 0.74 kB per atom, respectively) agree well with the recent values derived from analysis of experimental data. The proposed method can be used in first-principles modeling of the thermodynamics of unstable phases and calculations of the thermodynamic driving forces for martensitic transformations in pure elements and alloys.

1The author gratefully acknowledges financial support from the National Science Foundation under grant No. DMR-0427638 and an ANL Blue Gene supercomputer award from the DOE INCITE program.
12:03PM B23.00005 Anomalies in the bulk properties of single crystalline Niobium1. RICHARD K. BOLLINGER, J. J. NEUMEIER, B. D. WHITE, Montana State University, YOKO SUZUKI, A. MICLORI, JON BETTS, National High Magnetic Field Laboratory - Los Alamos National Laboratory, H. R. Z. SANDIM, C. A. M. DOS SANTOS, Escola de Engenharia de Lorena -USP — The thermodynamic properties of single crystal Niobium are presented. Anomalies in thermal expansion, specific heat, elastic constants, and electrical resistivity are observed. The linear coefficient of thermal expansion, $\alpha$, exhibits a large, broad peak in the range 200 K $< T < 280$ K, with a nearly two-fold increase in $\alpha$. The elastic constants show anomalies over a similar temperature range, while anomalies in heat capacity and resistivity are much narrower. This is surprising since crystalline Nb is a simple system, with only one naturally occurring isotope and a body centered cubic structure. Measurements on a second single crystal and on high purity polycrystalline Nb will also be presented.

12:15PM B23.00006 Development of an Embedded-Atom Method Potential for Niobium1. MICHAEL R. FELLINGER, JOHN W. WILKINS, The Ohio State University — An embedded-atom method (EAM) potential [1,2] is developed for pure niobium as the first step in the construction of an EAM potential for titanium-niobium alloys. The potential is constructed using the force-matching method [3]: the functions comprising the potential are represented as cubic splines, and the spline knots are chosen such that the potential optimally reproduces a large database of forces, cohesive energies, and stresses computed via density functional theory. The code potfit [4] optimizes the splines using a combination of simulated annealing and conjugate gradient-like minimization algorithms. EAM results are compared to DFT and experimental results for the lattice constant, cohesive energy, single-vacancy formation energy, fcc-bcc and hcp-bcc structural energy differences, elastic constants, and phonon dispersions.

12:27PM B23.00007 Ab initio up to the melting point: Anharmonicity and vacancies in aluminum, B. GRABOWSKI, L. ISMER, T. HICKEL, J. NEUGEBAUER, Max-Planck-Institut Düsseldorf, Germany — At elevated temperatures, the heat capacity of metals strongly deviates from the harmonic prediction. This was pointed out long ago and Zn solubility in Ti from first-principles calculations showed that a dominant part can be explained by quasiharmonic excitations. However, the detailed balance of further contributions, such as explicit anharmonicity and vacancies, is not clarified yet even for simple elementary metals. Aluminum is a prototypical example. Even though intensively studied, the ambiguous experimental situation has made a classification of the mechanisms impossible. To resolve the situation, we have calculated the full volume and temperature dependent $ab$ initio free energy surface employing density-functional theory. In particular, we have included anharmonic and vacancy contributions using numerically highly efficient methods to coarse grain the configuration space. To obtain accurate vacancy energies, we have included the full spectrum of quasiharmonic excitations: quasiharmonic, electronic, and explicitly anharmonic. The results are in contradiction to common belief, nevertheless the essential physics can be captured by a simple model.

12:39PM B23.00008 New Generation Structural Materials: Ab initio Based Modeling of High-Entropy Alloys, G. MALCOLM STOCKS, XING-QIU CHEN, EASO P. GEORGE, CHONGLONG FU, TAKESHI EGAMI, Oak Ridge National Laboratory, Division of Materials Science and Technology, MATERIALS THEORY TEAM — There is rapidly growing interest in a new generation of structural materials called high entropy alloys. This class of alloys is multi-component (~ five elements) with approximately equiatomic ratio, and thus have high entropy of mixing by which they are distinguished from conventional alloys. It has been reported experimentally that the single bcc-based AlCoCrFeNi, single fcc-based CoCrCuFeNi and FeCrMnNiCo high-entropy alloys exhibit promising mechanical properties with potential applications. In this work, we introduce ab initio based modeling for understanding structural, magnetic, and elastic properties based on relaxation of randomly generated supercells within the framework of density functional theory. We studied component-dependent phase stabilities, electronic structures, and magnetic properties with all solutes at fixed and relaxed structures. The properties are analysed in terms of the underlying electronic structure and suggestions are made for further experimental studies to further clarify the reasons for the unusual stability of these systems. Research sponsored by the Division of Materials Science and Engineering, Office of Basic Energy Sciences, U.S. DOE.

12:51PM B23.00009 High-throuput formalism and calculation of Ag, Au, Cd, Co, Cr, Ir, W, and Zn solubility in Ti from first-principles1. ROMAN CHEPULSKY, STEFANO CURTAROLO, Duke University — Based on statistical-thermodynamic theory of a dilute lattice gas, we developed an approach for calculation of atomic solubility in alloys. The advantage of the approach consists in taking into account all known alloy ground states rather than just pure species. It is shown that the low-solubility obey the simple Arrhenius-type dependence on temperature determined by “low-solubility formation energy.” Such quantity is defined as the derivative of the compound formation energy, determined with respect to surrounding ground states, versus composition. “Low-solubility formation energy” coincides with the usual “true” defect formation energy only in the case of a phase-separating alloy having no intermediate ground states and vacancies. We present a high-throughput formalism where the “low-solubility formation energy” can be directly obtained through first-principles calculations. The developed approach is applied to solubility of transition metals in titanium. The obtained values and tendencies are in good qualitative correspondence with experiments.

1Research was supported by ONR and NSF.

1:03PM B23.00010 Alternative alloys for catalysts and platinum jewelry? New structures in Pt-Hf and Pt-Mo, ERIN GILMARTIN, JACQUELINE CORBITT, GUS HART, Brigham Young University — The only known intermetallic structure with an 8:1 stoichiometry is that of Pt$_3$Ti. It is intriguing that an ordered phase would occur at such low concentrations of the minority atom, but this structure occurs in about a dozen binary intermetallic systems. The formation of an ordered phase in an alloy can significantly enhance the performance of the material, particularly the hardness. We have taken a broad look at possible systems where this phase forms. Using first-principles, we calculated the stability of this structure relative to experimentally known phases for more than 80 Pt/Pd binary systems. We find the Pt$_3$Ti structure is a possible ground state in more than 20 cases. Our experimental collaborators have verified our prediction in Pt-Mo and observed order-hardening in Pt-Hf. We discuss the discovery of new ground states that are likely to be verified experimentally and their impact on materials for Pt- and Pd-based catalysts and jewelry.
1:15PM B23.00011 New structures in Pd-rich ordered alloys. JACQUELINE CORBITT, ERIN GILMARTIN, GUS HART, Brigham Young University — An intriguing intermetallic structure with B1 stoichiometry was discovered in the 1950s in the Pt-Ti system. Since then a handful of other Pt/Pd/Ni binary systems have been observed to exhibit this curious structure (Pt$_x$Zr, Pd$_x$Mo, Ni$_x$Nb, etc.). This ordered structure can significantly increase the hardness of an alloy. For jewelry applications involving Pt and Pd, international hallmarking standards require that the alloys be at least 95% pure by weight. However, Pt- and Pd-rich alloys are often soft when purity is high if the minority atoms are disordered. Because the B1 structure maintains a high weight percentage of Pt/Pd, it can satisfy purity standards while increasing performance. Recent calculations and experiments suggest that the B1 structure may form in about 20 previously unsuspected Pt/Pd binary systems. Using first-principles calculations and cluster-expansion modeling, we have performed a ground state search to find the stable structures in Pt-Dnd and Pd-Cu. In collaboration with Candace Lang’s group at University of Capetown South Africa, we are working to experimentally validate the predicted ground states.

1:27PM B23.00012 Verification and refinement of the Al-Mg-Zn $\Phi$ phase crystal structure model. JEFF HOUZE, BOHUMIR JELINEK, SUNGHO KIM, SEONG-GON KIM, MARK HORSTMEYER, Mississippi State University — Density Functional Theory calculations were performed to validate the crystal structure proposed by L. Bourgeois et al. for the $\Phi$ phase of the Al-Mg-Zn system. Their model has ambiguous site occupancies for Zn and Al and definite locations for Mg. The model’s simulated electron diffraction patterns agreed very well with experimental patterns. Using DFT calculations we are able to determine optimal Zn and Al aluminum locations. We will also show that the energetically optimal structure’s element concentrations are within the experimentally observed range.

1:39PM B23.00013 An ab initio study of the crystal structure of the Tau-phase in Al-Mg-Zn alloys. LAALITHA LIYANAGE, JEFFREY HOUZE, SUNGHO KIM, MARK HORSTMEYER, SEONG-GON KIM, Center for Advanced Vehicular Systems, Mississippi State University — Existing crystal structures for the intermetallic Tau-phase in Al-Mg-Zn alloy are studied by density functional theory calculations using projector augmented wave pseudopotentials. Favorable crystal structures are identified through volume optimization and formation energy calculations. Properties such as elastic constants and bulk modulus of the crystal structure are determined.

1:51PM B23.00014 Magnesium phase diagrams: Have you seen us? . GUS HART, Brigham Young University. STEFANO CURTAROLO, Duke University — Because of it’s high strength-to-weight ratio, magnesium is seen as promising material for automotive applications. But magnesium alloys are far less understood that more common alloys such as steel or newer alloys such as aluminum. Even among simple binary magnesium systems, there is a great deal of missing information. There are binary magnesium systems for which no phase diagrams appear in the latest databases (the Pauling File, for example). Using a high-throughput approach, we have undertaken a broad search for ground states in 40 magnesium binary systems using more than 8000 fully-relaxed first-principles calculations. We find new, non-obvious ordering systems and many systems where there are unsought ground states. We discuss the results and their potential impact on magnesium alloys.

2:03PM B23.00015 First-principles thermodynamics of point defects and off-stoichiometry in $\beta$-Mg$_{17}$Al$_{12}$. DONGWON SHIN, CHRISTOPHER WOLVERTON, Northwestern University — The mechanical strength of Mg-Al alloys may be enhanced by a finite spatial dispersion of $\beta$-Mg$_{17}$Al$_{12}$ precipitates. Native point defects, i.e. vacancies and anti-sites, in Mg$_{17}$Al$_{12}$ are important for understanding the phase stability and unusually asymmetric observed off-stoichiometry in this precipitate phase. In an effort to provide a quantitative picture of the phase stability of this system, we have performed a series of first-principles density functional theory calculations of bulk and defect properties of Mg$_{17}$Al$_{12}$. We consider not only the T=0K static energetics, but also key entropic terms such as the configurational and vibrational entropies. The vibrational entropies are calculated from DFT via the direct force-constant approach using the quasiharmonic approximation. We investigate the effect of atomic vibrations on native point defect free energies of Mg$_{17}$Al$_{12}$ and combine the entropic contributions with the point defect formation energies to evaluate the thermodynamics of off-stoichiometry in this phase. We find there is a large vibrational entropy difference between Mg-rich and Mg-deficient defects in Mg$_{17}$Al$_{12}$, consistent with the strong asymmetry in the observed Mg-Al phase diagram.

Session B24 DMP: Focus Session: Nanotube Characterization 326

11:15AM B24.00001 Raman spectroscopy of individual freestanding single-walled carbon nanotubes of defined chiral structure. JEAN-LOUIS SAUVAJOL, University of Montpellier — We review the main information that we have obtained from Raman spectroscopy experiments combined with electron diffraction experiments on individual freestanding single-walled carbon nanotubes. This information concerns: the radial breathing mode vs diameter relationship; the dependence of the frequency and lineshape of the G-modes in semiconducting and metallic tubes; the evaluation of the optical transition energies for individual freestanding SWNTs. These experimental Raman results obtained on well-identified individual SWNTs are compared with other experimental data and theoretical predictions. From these data, we can define Raman criteria that allow identifying carbon nanotubes from their Raman features only. We show the efficiency of this approach: (i) to assign the (n,m) indices of individual freestanding single-walled carbon nanotubes, and (ii) to identify the (n,m) tubes organized in a small bundle.

11:51AM B24.00002 Raman Studies of Exciton and Exciton-Phonon Coupling Behavior in Metallic Single-Walled Carbon Nanotubes. STEPHEN DOORN, Los Alamos National Laboratory — A scaling law analysis of carbon nanotube transition energies has been found to be valuable in revealing new electronic behaviors for the third and fourth transitions in semiconducting nanotubes. In the work presented here, we discuss resonance Raman data obtained for the $E_{22}^{11}$ and $E_{22}^{12}$ transitions of a broad diameter range (0.7 - 4 nm) of metallic carbon nanotubes. We show that application of the scaling law analysis to transition energies for metallic nanotubes suggests that the transitions are excitonic in nature and that relative scaling of electron self-energies and exciton binding energies in metallic nanotubes closely matches that found in semiconductors. This similarity in behavior can be understood in terms of similar regions of the Brillouin zone being sampled by $E_{22}^{11}$ and $E_{22}^{12}$ and by $E_{22}^{44}$ and $E_{22}^{45}$. Additionally, for large diameter nanotubes (> 1.3 nm) we now observe the previously elusive upper branch signatures for several chiralities for both $E_{22}^{12}$ and $E_{22}^{11}$ excitation. These results are discussed as a consequence of the nodal behavior of exciton-phonon coupling. Also, while theoretical calculations for the (n,m)-dependent matrix elements predict the RBM intensity should decrease with increasing diameter; the opposite behavior is observed experimentally. We show this to be a consequence of an increase in the resonance Raman broadening factor $\Gamma$ as diameter decreases. Finally, we present Raman excitation data from surfactant suspensions highly enriched in metallic nanotubes via density gradient ultracentrifugation. Specifically, we will focus on the evolution of G-band behavior over a wide range of chiralities enabled by these new sample types. The variable behavior of the Breit-Wigner-Fano line in these enriched ensemble samples will be discussed.
ERIK HAROZ, WILLIAM RICE, BENJAMIN LU, Department of Electrical and Computer Engineering, Rice University, ROBERT HAUGE, Department of Chemistry, Rice University, DONNY MAGANA, STEPHEN DOORN, Chemistry Division, Los Alamos National Laboratory, PASHA NIKOLAEV, SIVARAM AREPALLI, Johnson Space Center, National Aeronautics and Space Administration, JUNICHIRO KONO, Department of Electrical and Computer Engineering, Rice University — We performed resonance Raman spectroscopy studies of metallic single-walled carbon nanotubes (SWNTs), including armchair SWNTs from (6,6) through (10,10). The measurements were carried out with excitation of 440-850 nm on aqueous ensemble samples of SWNTs enriched in metallic species. From this, we generated Raman excitation profiles (REFs) of the radial breathing mode and compare the REFs of armchairs and other metallic species. Additionally, we measured REFs of the G-band mode and observed how the Breit-Wigner-Fano line shape of the G- peak evolves in peak position, width and intensity relative to the G+ peak as different metallic nanotubes are excited. By combining these studies with absorption and photoluminescence excitation spectroscopy studies, we present a comprehensive examination of the optical signatures of metallic SWNTs.

HUGEN YAN, DAOHUA SONG, TONY HEINZ, Columbia University — Time-resolved Raman spectroscopy has been applied to determine the population lifetime of both zone-center and zone-edge optical phonons. Non-equilibrium populations of these phonons were produced by the rapid release of charge carriers following photooxidation of the nanotube sample with a femtosecond laser pulse. The temporal evolution of these phonon populations was recorded using the strength of anti-Stokes Raman scattering in G-mode (for the zone-center phonons) and D-mode (for the zone-edge phonons) as a function of the time delay of the fs probe pulse. A longer lifetime was found for the D-mode than for the G-mode phonons, a result consistent with recent ab-initio calculations of the anharmonic decay of these phonons [1]. We also report on the transient mode populations for the zone-center and zone-edge phonons that result from carrier cooling. [1] N. Bonini, M. Lazzeri, N. Marzari, and F. Mauri, Phys. Rev. Lett. 99, 176802 (2007).

12:51PM B24.00005 Investigation of Nanotube Growth Mechanisms via In-Situ Spectroscopy  
HAUL RAO, Air Force Research Laboratory, Materials and Manufacturing Directorate, AFFL/RX, WPAFB, OH 45433, UTC Inc., Dayton, OH 45432, DAVID LIPTAK, Air Force Research Laboratory, Materials and Manufacturing Directorate, AFFL/RX, WPAFB, OH 45433, UES Inc., Dayton, OH 45432, ROBERTO ACOSTA, BENJI MARUYAMA, Air Force Research Laboratory, Materials and Manufacturing Directorate, AFFL/RX, WPAFB, OH 45433, AFFL TEAM — Analysis of single-walled carbon nanotubes (SWNTs) during growth via Raman spectroscopy offers a unique approach to understand their growth mechanism, which remains unclear due to large variations of parameters in synthesis methods. In our technique the SWNTs are synthesized via chemical vapor deposition inside an environmental cell coupled to an automated stage. Growth occurs from catalyst nanoparticles on thermally isolated islands within substrates. In-situ micro-Raman spectroscopy performed on zone-center (G band) and zone-edge (D band) of low-pressure CNTs where the excitation laser also serves as a localized heat source for CNT growth. Control over substrate temperature and position, feed gas composition, and chamber pressure enable rapid real-time exploration of SWNT growth parameter space. Comparison of nanotube nucleation and growth kinetics from various metallic catalytic particles will be presented and implications for nanotube catalyst design will be discussed.

1:03PM B24.00006 Characterisation of Carbon Nano-Materials with the Confocal Raman AFM  
KLAS WEISHAUP, THOMAS DIEING, MATTHIAS KRESS, UTE SCHMIDT, WITec GmbH, Ulm, Germany — Graphene and carbon nanotubes represent perfect model systems for fundamental research. Carbon nanotubes have proven to be unique systems for the study of Raman spectra in one-dimensional systems. Raman spectroscopy has proved to be one of the most powerful techniques for characterizing single walled carbon nanotubes in terms of chirality, diameter, and electronic states. The 2D peak evolves in peak position, peak intensity and width in a characteristic matter of the electronic states. Proximity of the electronic states to the Fermi level changes the 2D peak position and width. We present results on the chirality dependent material evolution for both graphene and carbon nanotubes. The influence of the different synthesis methods is discussed. The strong phonon coupling of graphene is discussed and compared to the electronic excitations. The detected peaks are explained using a joint photoemission and Raman spectroscopy analysis.

1:15PM B24.00007 Resonance Raman Scattering for Quantification of the Bundling of SWNTs  
TAO LIU, ZHIWEI XIAO, High Performance Materials Institute, Florida State University — The strong attractive van der Waals interaction induces individual SWNTs to form bundles or ropes. It has been demonstrated both experimentally and theoretically that, the various physical properties of SWNTs, e.g., photoluminescence, and electronic, and mechanical, strongly depends upon their bundling states. Upon comparative studies of SWNT dispersions with the preparative ultracentrifuge method, which is a newly developed characterization technique by us for quantifying the structures of SWNTs in a dispersion, and resonance Raman scattering, we demonstrate that the bundling states for a given SWNT dispersion can be quantified with the latter technique. In this presentation, the preparative ultracentrifuge method for studying the processing-structure-property relationships of SWNT dispersion will be introduced. The mechanisms of using resonance Raman scattering to quantify the bundling states of SWNTs will be discussed.

1:27PM B24.00008 ABSTRACT WITHDRAWN —

1:39PM B24.00009 Electrical Characterization of Carbon Nanotube Bundles Synthesized from Chemical Vapor Deposition of Ferrocene  
C. WOLFE, R. SHAH, Z. ZHANG, Department of Physics, Southern Illinois University Carbondale, Illinois, 62901, X. AN, S. KAR, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy, NY 12180, S. TALAPATRA, Department of Physics, Southern Illinois University Carbondale, Illinois, 62901 — We employed a chemical vapor deposition technique, which used ferrocene both as the catalyst as well as the carbon source, to grow films of carbon nanotubes (CNT). The CNT films obtained using this procedure were characterized using Raman Spectroscopy and Transmission Electron Microscopy which indicated the presence of thin diameter carbon nanotubes as well as single walled CNT ropes. Electrical transport measurements performed on long ropes of CNTs extracted from these bulk films will be presented and will be discussed in the framework of transport theories of quasi-one dimensional systems.

1:51PM B24.00010 Coherent Phonon Dynamics in Single-Walled Carbon Nanotubes  
L.G. BOOSHEHRI, E.H. HAROZ, J. KONO, Rice University, Y.S. LIM, Konkuk University, J.H. KIM, K.J. YEE, Chungnam National University, G.D. SANDERS, C.J. STANTON, University of Florida — Understanding how electrons and phonons relax in energy and momentum is one of the current goals in carbon nanotube spectroscopy as well as an important step towards developing novel electronic and optoelectronic devices based on carbon nanotubes. Recent ultrafast pump-probe spectroscopy studies of single-walled carbon nanotubes (SWNTs) have successfully detected coherent phonon dynamics, but the dominant dephasing mechanism that occurs with decoherence of phonon mode oscillation has yet to be understood. Our present work demonstrating ultrafast coherent phonon spectroscopy of the radial breathing mode (RBM) of semiconducting SWNTs provided a powerful method for determining phonon energies in an ensemble of SWNTs. We now extend our previous studies to provide new insight into the dephasing mechanisms of coherent phonons in SWNTs. Here, we systematically investigated the temperature, polarization, and wavelength dependence of coherent phonon dephasing times, amplitude, and frequency for various types of nanotube film and solution samples.

Excitonic supersolid in quantum Hall graphene bilayers, YOGESH JOGLEKAR, Indiana University-Purdue University Indianapolis (IUPUI), CHANG-HUA ZHANG, Kansas State University — We study the ground state of two graphene sheets separated by a distance $d$ in the quantum Hall regime where the top layer has electrons and the bottom layer has holes as carriers. We obtain a rich mean-field phase diagram as a function of distance $d$ and the filling factor $\nu = \nu_h = \nu$ for different Landau levels. We find that the ground state in high Landau levels at large $d$ is a generalized Wigner crystal that includes anisotropic stripe and bubble states, and at small $d$ the ground state is an uniform excitonic condensate. We show that for a wide range of partial filling factors $0 \leq \nu \leq 1/2$, at intermediate values of $d$, the ground state has interlayer phase coherence as well as a lattice structure, i.e. it is an excitonic supersolid. We discuss the predictions for signatures of such a state in transport and optical experiments.

Transport on quantum antidot made of 4-terminal graphene ribbons, ANDREA LATGE, CARLOS RITTER, UFF-Instituto de Física, PEDRO ORELLANA, UCN-Departamento de Física, MONICA PACHECO, UTSM-Departamento de Física — Electronic and transport properties of four-terminal graphene ribbons are discussed taking into account different configurations of quantum antidot potentials, designed at a central conductor. In general, the formation of these antidot potentials promotes a reorganization of the carriers, leading to an electronic localization at the neighboring vacancy sites. Depending upon the position, extension, and symmetries of such antidots, one may find delocalization along the structure due to the formation of new allowed paths. Here we discuss the origin of conductance dips, maximum and complete transport suppressions, within the microscopic scenario of the electronic localization, and using real-space Green function formalism. For such analysis we construct local electronic density of states mapping for different antidot configurations. The results are discussed in comparison with equivalent two-lead devices and perfect structures.

Gate-field effect in multilayer graphenes, MIKITO KOSHINO, Tokyo Institute of Technology — We study the electronic properties of the multilayer graphenes in presence of the external electric field perpendicular to the layers. We calculate the electronic potential of each layer taking account of the screening effect, to obtain the self-consistent band structure within the effective mass approximation. We calculate the conductivity using the self-consistent Born approximation and analyze its external-field dependence for every layer number. We also compute the optical absorption spectra, which is found to be strongly modified by the electric field.

Chemical Doping and Electron-Hole Conduction Asymmetry in Graphene Devices, ROKSANA GOLIZADEH MOJARAD, Purdue University, DAMON FARMER, VASILI PEREBEINOS, YU-MING LIN, GEORGE S. TULEVSKI, JAMES C. TSANG, ALI AZALI, PHAEDON AVOURIS, IBM T.J. Watson Research Center — We investigate polyethylene imine and diazonium salts as stable, complementary dopants on graphene. Transport in graphene devices doped with these molecules exhibits asymmetry in electron and hole conductance. The conductance of one carrier is preserved, while the conductance of the other carrier decreases. Simulations based on nonequilibrium Green’s function formalism suggest that the origin of this asymmetry is imbalanced carrier injection from the graphene electrodes caused by misalignment of the electrode and channel neutrality points.

Sub-lithographic Patterning of Extended Arrays of Graphene Nanostructures, KE LI, 1, WEI HAN, 2, SARAH C. PARKS, 1, WENZHONG BAO, JOHN CIRALDO, CHUN NING LAU, ROLAND KAWAKAMI, 2, EZEKIEL JOHNSTON-HALPERIN, 1 (1 Department of Physics, The Ohio State University; 2 Department of Physics and Astronomy, University of California, Riverside) — Quasi-one-dimensional graphene nanoribbons (GNRs) with narrow width ($w \leq 10$ nm) and smooth edges have been shown to exhibit bandgaps due to quantum confinement and edge effects. Current fabrication methods of GNRs include electron beam lithography and chemical synthesis. However, the lithographic approach has difficulties in reaching true nanometer-scale widths while the chemical approach lacks fidelity in GNR length and width control. The recent development of sub-lithographic patterning using the superlattice nanowire pattern transfer (SNAP) technique provides a novel approach to fabricating ultra-long graphene arrays with N

Gate-field effect in multilayer graphenes, MIKITO KOSHINO, Tokyo Institute of Technology — We study the electronic properties of the multilayer graphenes in presence of the external electric field perpendicular to the layers. We calculate the electronic potential of each layer taking account of the screening effect, to obtain the self-consistent band structure within the effective mass approximation. We calculate the conductivity using the self-consistent Born approximation and analyze its external-field dependence for every layer number. We also compute the optical absorption spectra, which is found to be strongly modified by the electric field.

Quantum Hall edge transport across graphene monolayer-bilayer junctions, YUE ZHAO, Graduate Student, Physics Department Columbia University, MIKITO KOSHINO, Research Associate, Tokyo Institute of Technology, PHILIP KIM, Associate Professor, Physics Department, Columbia University — We experimentally studied the transport property of a graphene monolayer-bilayer junction in the Quantum Hall (QH) regime. Both the monolayer graphene (MG) and the bilayer graphene (BG) develop their own landau levels under high magnetic field. While the transport measurement shows their distinct QH effect in bulk part of the MG and BG respectively, the transport measurement across the interface exhibits unusual transverse transport behaviors. The transverse resistance across the MG BG interface is asymmetric for opposite sides of the hall bar, and its polarity can be changed by reversing the magnetic field direction. When the QH plateaus of MG and BG overlap, quantized resistance will appear only on one side of the hall bar electrode pairs across the junction. These experimental observations can be ascribed to the QH edge state transport across the MG/BG interface.

Dissipation and Criticality in the Lowest Landau Level of Graphene, PALLAB GOSWAMI, Rice University, XUN JIA, SUDIP CHAKRAVARTY, UCLA — The lowest Landau level of graphene is studied numerically by considering a tight-binding Hamiltonian with disorder. The Hall conductance $\sigma_{xy}$ and the longitudinal conductance $\sigma_{xx}$ are computed. We demonstrate that bond disorder can produce a plateaulike feature centered at $\nu = 0$, while the longitudinal conductance is nonzero in the same region, reflecting a band of extended states between $\pm E_c$, whose magnitude depends on the disorder strength. The critical exponent corresponding to the localization length at the edges of this band is found to be $2.47 \pm 0.04$. When both bond disorder and a finite mass term exist the localization length exponent varies continuously between $\sim 1.0$ and $\sim 7/3$.

Session B26 DMP DCOMP: Focus Session: Computational Nanoscience II: Mechanics, Dynamics, and Assembly
11:15AM B26.00001 An atomistic approach to viral mechanical oscillations, OTTO F. SANKEY, Arizona State University — Viruses are the simplest “life” form. These parasites reproduce by borrowing the machinery of their host cell. Many are pathogenic to plants, animals, and humans. Viruses possess an outer protein coat (capsid) that protects its genomic material that resides inside. We have developed a theoretical technique to model the very low frequency mechanical modes of the viral capsid with atomic resolution. The method uses empirical force fields and a mathematical framework borrowed from electronic structure theory for finding low energy states. The low frequency modes can be “pinged” with an ultra-short laser pulse and the aim of the light/vibrational coupling is to interfere with the viral life cycle. The theoretical work here is motivated by the recent work of Tsen et al. [2] who have used ultra-short pulsed laser scattering to inactivate viruses. The methodology can be applied to many systems, and the coupled mechanical oscillations of other floppy biomolecules such as a complete ATP binding cassette (ABC transporter) will also be discussed. Co-authors of this work are Dr. Eric Dykeman, Prof. K.-T. Tsen and Daryn Benson.

11:51AM B26.00002 A new paradigm for self-assembly: The role of reversibility in viral capsid growth, DENNIS RAPAPORT, Bar-Ilan University — The phenomenon of supramolecular self-assembly, despite its importance, remains an enigma. The formation of virus capsids — the exquisitely designed protein shells of spherical viruses — is a well-known example, and there are numerous potential applications for nanotechnology. The capsid assembly process can be modeled using molecular dynamics simulation of simplified particles that are designed to form polyhedral shells. New insights into the mechanism of self-assembly have emerged from simulations carried out using particles immersed in an explicit solvent. Contrary to expectation, self-assembly is found to proceed via a cascade of strongly reversible steps, a feature that helps avoid growth-impeding kinetic traps because partial shells generally tend to lose rather than gain members. This ensures a robust process leading, under suitable conditions, to a high yield of complete shells. Furthermore, despite the large variety of possible intermediate structures, the assembly pathways are found to involve only a small fraction of highly bonded (low energy) forms.

12:03PM B26.00003 Calculation of the free energy of binding of DNA bases on a single-wall carbon nanotube, ROBERT JOHNSON, A.T. CHARLIE JOHNSON, MICHAEL KLEIN, University of Pennsylvania — Molecular bases can be combined with inorganic nanostructures to form multifunctional hybrid materials with unique properties that will drives advances in nanoelectronics, environmental safety, medicine and homeland security. One such material of contemporary interest is the DNA-carbon nanotube hybrid (DNA-CN), which consists of a single-wall carbon nanotube (SWCN) coated with a self-assembled monolayer of single-stranded DNA (ssDNA). Computation and experiment indicate that DNA-CN self-assembles with DNA bases using an energy minimization technique, “binary hierarchical assembly.” To address these issues and expand our understanding of DNA-CN, we have computed the binding free energy of individual DNA bases with SWCN using alchemical free energy methods. Such calculations provide detailed information about the importance of electrostatic, van der Waals and hydrophobic interactions in base-SWCN binding.

12:15PM B26.00004 Simulations of the self-assembly of CdTe nanoparticles into large pitch helices, AARON SANTOS, SUDHANSHU SRIVASTAVA, SHARON GLOTZER, NICHOLAS KOTOV, University of Michigan — Recent experiments have shown that CdTe nanoparticles can self-assemble into wires, sheets, or helical nanoribbons with a large pitch length (300-400 nm) depending on the amount and type of capping group used. While conventional Monte Carlo simulations of electronically charged truncated tetrahedrons successfully predict the formation of wires and sheets, they are inadequate to describe the formation of helical nanoribbons, which require a large number of particles and a long run time to observe their characteristic features. We use a newly developed energy minimization technique, “binary hierarchical assembly,” to predict the packing structure of tetrahedral CdTe nanoparticles within the helix. From this packing structure, we construct nanoribbons of various widths and minimize the energy to determine the width of the stable structure. We find the stable width of the ribbon is charge dependent with values that correspond to ribbons observed in experiments.

12:27PM B26.00005 Sensitivity Limits of Nanomechanical Resonance Spectroscopy, P. ALEX GREANEY, U.C. Berkeley — The sensitivity limit of the recently proposed chemical sensing method, nanomechanical resonance spectroscopy (NRS) [2] is investigated using classical molecular dynamics simulations. The NRS method exploits the preferential transfer of energy between resonant modes, using an array of nanomechanical resonators to interrogate the vibrational spectrum of an analyte directly. We report on the effects of solvent and complex analytes.

12:39PM B26.00006 Enhancing Molecular Dynamics to Capture Electronic Effects, N.A. MODINE, R.E. JONES, D.L. OLMSTED, J.A. TEMPLETON, Č.J. WAGNER, Sandia National Laboratories, R.M. HATCHER, Lockheed Martin Advanced Technology Laboratories, M.J. BECK, Vanderbilt University — In modeling non-equilibrium thermal transport in nanoscale systems, classical molecular dynamics (MD) has the primary strength of explicitly representing phonon modes and scattering mechanisms. On the other hand, electrons and their role in energy transport are missing. Our goal is to couple a MD treatment of the ionic subsystem with a partial differential equation based model of the electronic subsystem in order to accurately capture aggregate behavior at the nanoscale. Along these lines, we have enhanced the LAMMPS MD package by coupling the ionic motions to a finite element based representation of electronic heat transport. The coupling between the subsystems occurs via a local version of the two-temperature model. Key parameters describing the coupling are calculated using Time Dependent Density Functional Theory (TDDFT) calculations with either explicit or implicit energy flow. We will discuss initial demonstrations of our approach focusing on nanowires and carbon nanotubes.

12:51PM B26.00007 Rotary molecular motion at the nanoscale: motors, propellers, wheels, LELA VUKOVIC, BOYANG WANG, PETR KRAL, University of Illinois at Chicago — We describe by molecular dynamics simulations nanoscale systems that could realize rotary motion. First, we study molecular propellers formed by carbon nanotube rotors with attached aromatic blades [1]. We show that these propellers could pump different types of liquids, and their pumping efficiency strongly depends on the chemistry of the (hydrophobic or hydrophilic) liquid-blade interactions in base-SWCN binding.

rate Interfaces

Several rounds of pumping were simulated to achieve more continuous flow of fluid through the nanotube. Pressure difference in different regions was analyzed.

We present molecular dynamics simulations of carbon nanotubes that were embedded in liquid argon. The fluid was pushed through the nanotubes to study the phenomena of nanofluidics. The previous modeling and simulation efforts were based on diffusion of atoms or molecules that were thrown to the nanotubes with initial velocities. However, we find that these functionalized coatings affect the interactions between nanoparticles and with the surrounding solvent. Thus, we present results from a series of molecular dynamics simulations of polyethylene oxide (PEO) coated silica nanoparticles of varying size (5 to 20 nm diameter) in water. For a single nanoparticle, we determined the Stokes drag on the nanoparticle as it moves through the solvent and as it approaches a wall. Due to hydrodynamic interactions, there are large finite size effects which we estimate by varying the size of the simulation cell. We also determined both solvent-mediated (velocity-independent) and lubrication (velocity-dependent) forces between two nanoparticles as a function of the coverage and chain length of the PEO chains.

Flow can be accurately described in terms of continuum mechanics and the enhancement agrees with predictions from the slip-modified Hagen-Poiseuille flow. The observed flow rate to that predicted from the no-slip Hagen-Poiseuille relation, is calculated for each CNT. In CNTs with diameters greater than 1.39 nm, the flow rate is predicted to be directly proportional to the inverse of the particle radius due to the Gibbs-Thomson effect. However, the depression of the nucleation temperature during heating was investigated using a molecular dynamics simulation. A nucleus was generated near one side of the particle and solidification spread toward the other side during nucleation process. On the other hand, the surface melting and subsequent inward melting of the solid core of the nanoparticles were observed during heating. The depression of the melting point was proportional to the inverse of the particle radius due to the Gibbs-Thomson effect. However, the depression of the nucleation temperature during cooling was not monotonic with respect to the particle radius since the nucleation from an undercooled liquid droplet was observed during cooling in all nanoparticles considered. A nucleus was generated near one side of the particle and solidification spread toward the other side during nucleation process. On the other hand, the surface melting and subsequent inward melting of the solid core of the nanoparticles were observed during heating.

1:03PM B26.00008 Long-Range Hydrodynamic Interactions Implemented into LAMMPS (Parallel MD), FRANCES MACKAY, COLIN DENNISTON, University of Western Ontario — We use an explicit solvent method to study the interaction between particles and a fluid. Similar to the Particle-Mesh-Ewald schemes for electrodynamics, the long range hydrodynamic interactions are treated by interpolating the particle density onto a mesh. This is then coupled to the fluid, which we model using a thermal lattice Boltzmann scheme. Mass and momentum conserving noise in the lattice Boltzmann fluid scheme provides a thermostat for both the fluid and the particles. This work has been fully parallelized and implemented into LAMMPS, an open-source molecular dynamics code. We demonstrate the scheme with some examples from colloidal physics and flow over rough surfaces.

1:15PM B26.00009 Atomic Simulations of Hydrodynamic and Interaction Forces on Functionalized Silica Nanoparticles, J. MATTHEW D. LANE, AHMED E. ISMAIL, MICHAEL CHANDROSS, Sandia National Labs, CHRISTIAN D. LORENZ, King’s College London, GARY S. GREST, Sandia National Labs — It is often desired to prevent the flocculation and phase separation of nanoparticles in solution. This can be accomplished either by manipulating the solvent or by tailoring the surface chemistry of the nanoparticles. We have carried out functionalization with a monolayer of oligomer chains. Since it is not known how these functionalized coatings affect the interactions between nanoparticles, we present results from a series of molecular dynamics simulations of polyethylene oxide (PEO) coated silica nanoparticles of varying size (5 to 20 nm diameter) in water. For a single nanoparticle, we determined the Stokes drag on the nanoparticle as it moves through the solvent and as it approaches a wall. Due to hydrodynamic interactions, there are large finite size effects which we estimate by varying the size of the simulation cell. We also determined both solvent-mediated (velocity-independent) and lubrication (velocity-dependent) forces between two nanoparticles as a function of the coverage and chain length of the PEO chains.

1:27PM B26.00010 Water Flow in Carbon Nanotubes: Transition from Continuum to Sub-continuum Transport, JOHN THOMAS, ALAN MCGAUGHEY, Carnegie Mellon University — Water flow through carbon nanotubes (CNTs) with diameters ranging from 0.83 nm to 4.98 nm is examined using molecular dynamics simulation. A reflecting particle membrane is used to drive the flow and the relationship between the axial pressure gradient, CNT diameter, and volumetric flow rate is examined. The flow enhancement, defined as the ratio of the observed flow rate to that predicted from the no-slip Hagen-Poiseuille relation, is calculated for each CNT. In CNTs with diameters greater than 1.39 nm, flow can be accurately described in terms of continuum mechanics and the enhancement agrees with predictions from the slip-modified Hagen-Poiseuille flow relation. In CNTs with diameters smaller than 1.39 nm, we find that the liquid structure varies with CNT diameter and a continuum-based description of the fluid flow is inappropriate. The flow enhancement for these CNTs do not agree with predictions from the slip-modified Hagen-Poiseuille flow relation. They can, however, be correlated to the diameter-specific liquid structure.

1:39PM B26.00011 Fluid flow through carbon nanotubes: a new modeling and simulation approach, MICHAEL A. AVON, Department of Mechanical Engineering, The University of Akron, ALPER BULDUM, Department of Physics, The University of Akron — The flow of fluids through carbon nanotubes was investigated in order to get a better understanding of the unique properties and phenomena of nanofluidics. The previous modeling and simulation efforts were based on diffusion of atoms or molecules that were thrown to the nanotubes with initial velocities. Here, we present molecular dynamics simulations of carbon nanotubes that were embedded in liquid argon. The fluid was pushed through the nanotubes using a moving wall piston of graphene. Single-walled, double-walled, rigid and relaxed nanotubes in different diameters were considered. In order to achieve more continuous flow of fluid through the nanotubes, several pumping rounds were simulated. Pressure difference in different regions was analyzed.

1:51PM B26.00012 Accelerated Molecular Dynamics Simulation on Friction of Incommensurate Interfaces, WOO KYUN KIM, The University of Michigan, MICHAEL FALK, The Johns Hopkins University — We apply a molecular dynamics (MD) methodology to study the friction of incommensurate interfaces. While the traditional Tomlinson model assumes a single, repeatable transition, the sliding at the real incommensurate interface is comprised of a multitude of transition modes. This may account for recent Atomic Force Microscope (AFM) experimental results that indicate more complex temperature and velocity dependence of friction that deviate from the Tomlinson predictions. Conventional MD simulations are unable to simulate a wide range of sliding rates due to time scale limitations. In this study, we achieve decreases in the simulated sliding velocity by several orders of magnitude compared with conventional MD simulations using Voter’s hyperdynamics scheme. This method uses a biased potential to reduce the barrier heights of the original potential to decrease the simulated time between slip events. The decrease in the sliding velocity makes it possible to see the atomic level processes during sliding speeds much closer to the experimental time scale. We carefully analyze the simulation results to elucidate the transition mechanisms.

2:03PM B26.00013 Molecular dynamics study of the phase transition in the bcc metal nanocrystals, YASUSHI SHIBUTA, TOSHIO SUZUKI, The University of Tokyo — The phase transition between liquid and solid phases in bcc metal nanoparticles was investigated using a molecular dynamics simulation. The nucleation from an undercooled liquid droplet was observed during cooling in all nanoparticles considered. A nucleus was generated near one side of the particle and solidification spread toward the other side during nucleation process. On the other hand, the surface melting and subsequent inward melting of the solid core of the nanoparticles were observed during heating. The depression of the melting point was proportional to the inverse of the particle radius due to the Gibbs-Thomson effect. However, the depression of the nucleation temperature during cooling was not monotonic with respect to the particle radius since the nucleation from an undercooled liquid droplet depends on the event probability of an embryo or a nucleus.

11:15 AM B27.00001 Controlling electric fields spatially by graded metamaterials\(^1\), KIN-WAH YU, Chinese University of Hong Kong. — The local electric field of a metal-dielectric composite cylinder, whose complex permittivity is given by a spatially dependent Drude model, has been derived analytically in terms of hypergeometric functions. Our results show that the electric field inside the cylinder can be confined to any desired position. Thus one can achieve the control of electric fields by fabricating graded metamaterials with specific material parameters. The enhanced nonlinear optical response of the composite cylinder has also been calculated [1]. The results suggest that the gradation-controlled electric field distribution may be a consequence of a combination of surface plasmon resonance and the microgeometry in graded metamaterials. Moreover, such a gradation-controlled field distribution serves as a physical mechanism for understanding the enhanced nonlinear optical responses with a broad surface plasmon band [2].

11:27 AM B27.00002 Terahertz nanogap antenna detection of nano-bridges and nano-rods, H.R. PARK, M.A. SEO, J.S. KYOUNG, S.M. KOO, Seoul National University, O.K. SUWAL, S.S. CHOI, Sunmoon University, N.K. PARK, D.S. KIM\(^1\), Seoul National University, CENTER FOR SUBWAVELENGTH OPTICS TEAM. — We have measured transmission properties of a composite structure consisting of nano-rods on a long (\(a_0=300\) micron) nanogap (70 nm) on Au film in broad frequency range of 0.1 THz to 1.0 THz using THz time-domain spectroscopy. The normalized transmittance with no nano-bridge or nanorod structure in the middle shows a half-wavelength resonance: the resonance frequency is \(c/(2a_n)\) where \(n\) is the index of refraction of the substrate. The nano-size bridge at the center of the nano gap gives changes the resonance characteristics profoundly, because in essence, the length \(a_n\) now halves. Mostly the same resonance-changing behavior is expected with a nano rod structure fabricated by Pt-deposition method using a focused ion beam (FIB). This small rod also acts as a bridge dividing the length of the rectangle. We also positioned nano-rods to lie at one third of each nano gap, dividing the length by the ratio of 1:2. A resonance peak shift was observed. The structure dependent resonance allows to detect nano-size particles and to tailor resonance characteristics with feature sizes of \(\lambda/10\,000\).

11:39 AM B27.00003 Terahertz Nanogap Plasmonics: Giant Field Enhancement, M. A. SEO, H. R. PARK, S. M. KOO, O. K. SUWAL, S. S. CHOI, N. K. PARK, D. S. KIM, CENTER FOR SUBWAVELENGTH OPTICS TEAM. — We show that a nanogap dividing two conducting planes can efficiently transmit terahertz electromagnetic waves with wavelengths in the millimeter range. Terahertz time domain spectroscopy is performed to probe transmittance over a frequency range of 0.1 THz to 1.5 THz. It was found that the transmittance continues to increase as the frequency decreases with a dependence of 1/f. The area-normalized transmittance, which is equivalent to the level of field enhancement, reaches the value of 800 at 0.1 THz for a sample with a 70 nm gap. Combined with the 1/f dependence, this indicates that strong local resonance is not a prerequisite for a large field enhancement. It is shown that the accumulation of charges at metal edges via light-induced currents creates a large horizontal electric field, which in effect attracts the incoming light. The enhanced field in the gap fully scatters towards the far-field because there exists no cut-off. With the broad 1/f spectral response, this structure can be an excellent launching pad for inducing terahertz nonlinearity, nano-particle detection, and for surface enhanced Raman scattering.

11:51 AM B27.00004 Active Control of Propagating Surface Plasmons Excited by a Quantum Cascade Laser\(^1\), DANIEL WASSERMAN, TROY RIBAUDO, UMass Lowell, ERIC SHANER, Sandia National Labs, SCOTT HOWARD, Cornell University, FOW-SEN CHOA, University of Maryland Baltimore County, CLAIRE GMACHL, Princeton University. — There has been significant interest, of late, in the optical properties of subwavelength features in metallic films. For instance, resonant transmission through periodic arrays of subwavelength apertures in metallic films is seen at wavelengths determined by the periodicity of the metal film and the relative permittivity of the metal and the surrounding dielectric medium. This phenomenon is referred to as extraordinary optical transmission (EOT) and has been studied for potential applications in display and sensing technologies. Here we demonstrate the ability of an actively tunable EOT grating to control the coupling of incident coherent radiation from a dual wavelength QCL to propagating surface modes on the grating. We use a novel spatially and spectrally resolved Fourier transform infrared spectroscopy technique to image the propagating surface waves on our EOT grating, and are able to extract a plasmon propagation length from the data collected.

12:03 PM B27.00005 Spatial and Spectral Investigation of Extraordinary Optical Transmission\(^1\), T. RIBAUDO, University of Massachusetts at Lowell, B.S. PASSMORE, E.A. SHANER, Sandia National Laboratories, D. WASSERMAN, University of Massachusetts at Lowell. — Extraordinary Optical Transmission (EOT), or the enhancement of light transmission through periodic arrays of sub-wavelength holes in metal films, has been investigated for its clear contradiction with conventional aperture theory, as well as for possible applications in chemical sensing and display technologies. In the visible and near-infrared spectral ranges, EOT is argued to be predominantly a result of the excitation of surface plasmon polaritons (SPPs) on metal/dielectric interfaces. Here, we report our investigations of the far-field transmission characteristics of EOT gratings designed for the mid-infrared frequency range. Using a tunable Quantum Cascade Laser, we explore the spatial and spectral dependence of the transmitted far field on the angle of incidence and the exciting frequency of the laser. We show that for frequencies coincident with the EOT maximum, little SPP propagation is observed, while laser frequencies on the high energy falling edge of the EOT peak couple to such propagating modes.

12:15 PM B27.00006 Mid Infrared Beam Steering Using Plasmonic Structures, DAVID ADAMS, DANIEL WASSERMAN, University of Massachusetts at Lowell. — The interaction of electromagnetic radiation with periodic features on metal surfaces has received a great deal of attention in recent years. The far-field transmission properties of a sub-wavelength aperture can be controlled when periodic grooves are formed on the exit surface, allowing the shape and directionality of the transmitted beam to be altered. This phenomenon is a result of surface plasmon polaritons propagating along the metal surface and recoupling to photons which are phase mismatched with respect to the transmitted beam. The resulting interference pattern is dependent on the wavelength of the exciting beam, the geometry of the periodic surface structure, and the dielectric permittivity of the materials at the boundary. Here we present simulations using finite element analysis which demonstrate the steering of the beam transmitted through the metal slit as the permittivity of the surrounding material is modified.

1:51PM B27.00014 Composite Metal-Semiconductor Metamaterials with Negative Permittivity and No Loss, A. M. Bratkovsky, E. V. Ponizovskaya, S.-Y. Wang, Hewlett-Packard Labs, Palo Alto, P. Holmström, KTH, Stockholm — Close to the resonance in a planar interface between a metal and dielectric, \( \varepsilon_{\text{metal}} \approx -\varepsilon_{\text{dielectric}} \), very tight electromagnetic field confinement results, but the tighter the confinement, invariably, the higher the propagation losses. For confinement significantly better than that of Si nanowires (~300 nm) propagation losses become prohibitively high for most interconnect applications. Also, the magnitude of \( \varepsilon_{\text{metal}} \) needs to be larger than e.g. 2 in order to interface to common dielectrics for close to resonance conditions. The most straightforward way to alleviate this situation is of course to use optical gain. We have analyzed theoretically a metamaterial, which is a mix of quantum dots (QDs) half of them pumped and half absorptive and showed that one could indeed compensate the loss. More efficient way of obtaining the \( \varepsilon < 0 \) is to use metals, and we show that a combination of silver rods, supplying the negative \( \varepsilon \) and pumped QDs, providing the gain necessary to compensate the loss in the silver rods [1].

11:15AM B28.00001 Optimizing Graphene Morphology on SiC(0001), JAMES HANNON, IBM Research Division — Many schemes to integrate graphene with microelectronics assume that reliable wafer-scale synthesis processes will be developed. One promising route to wafer-scale synthesis is to form graphene overlayers from the decomposition of SiC at high temperature. We have shown that, even at 1200 C, limited diffusion at the SiC surface leads to pit formation and a non-uniform graphene film thickness [1]. In this talk I will describe our efforts to improve both graphene domain size and thickness uniformity. One way we achieve this is by forming graphene in a background pressure of disilane, which hinders SiC decomposition. Even in rather low Si partial pressures (e.g. 1e-5 Torr), the SiC decomposition temperature can shifted several hundred degrees higher in temperature [2]. Using in situ low-energy electron microscopy (LEEM), we show that this effect can be exploited to form large graphene domains (larger than 10 um) with controlled layer thickness (e.g. 1 ML). Work performed in collaboration with R.M. Tromp.

11:51AM B28.00002 Atmospheric pressure growth of graphene on SiC(0001), THOMAS SEYLLER, University of Erlangen — Graphene, a single monolayer of sp2-bonded carbon, is a very unique 2-dimensional electron gas system with electronic properties fundamentally different to other 2DEG systems [1]. Several production routes exist for graphene. Among them, the solid-state decomposition of hexagonal silicon carbide (SiC) surfaces [2] is particularly attractive for the development of graphene based electronics [3,4]. The first part of the presentation gives a brief summary of recent studies on the structural and electronic properties of graphene and few-layer graphene grown on SiC(0001) under ultra-high vacuum (UHV) conditions. The second part of the talk is devoted to recent progress in the growth of large domain graphene films on SiC(0001) in Ar atmosphere. It is shown that growth in Ar ambient leads to a significant improvement of the surface morphology and domain size as well as carrier mobility.

12:27PM B28.00003 Centimeter scale pattern growth of graphene films for stretchable transparent electrodes, BYUNG HEE HONG, Sungkyunkwan University — Large scale pattern growth of graphene is one of the most awaiting problems to be solved in order to bring this material for device application. Recently, macroscopic scale graphene films have been prepared by two-dimensional assembly of graphene sheets chemically derived from graphite crystals and graphene oxides. However, the sheet resistance of these films is found to be much larger than theoretically expected values. Here, we report the direct synthesis of centimeter-scale graphene films utilizing chemical vapor deposition (CVD) on thin Ni layers, where the overall structures are connected by lateral electric connections. As a result, the transferred graphene films show very low sheet resistance with excellent optical transparency. At low temperatures, the single layers transferred on SiO2 substrates show high electron mobility with the signature of quantum Hall effect, implying that the quality of CVD-grown graphene is as high as mechanically cleaved graphenes. Employing these outstanding mechanical properties of graphenes, we also demonstrate the macroscopic usage of the highly conducting and transparent electrodes for flexible/stretchable/foldable electronics.

1:03PM B28.00004 Fabrication and measurement of epitaxial graphene nanoribbons, MIKE SPRINKLE, Georgia Institute of Technology, JEFF J. PETERSON, Intel Corporation, MING RUAN, YIKE HU, XIAOSONG WU, EDWARD H. CONRAD, Georgia Institute of Technology, CLAIRE BERGER, CNRS and Georgia Institute of Technology, WALT A. DE HEER, Georgia Institute of Technology — Multi-layer graphene grown epitaxially on the C-terminated (000T) surface of 4H-SiC in a low vacuum (~10~14 Torr), high temperature (~1420 °C) induction furnace environment has been shown to be of extremely high quality and mobility. Due to its rotational stacking, the material exhibits electronic properties similar to other 2D materials [1]. Several production routes exist for graphene. Among them, the solid-state decomposition of hexagonal silicon carbide (SiC) surfaces [2] is particularly attractive for the development of graphene based electronics [3,4]. The first part of the presentation gives a brief summary of recent studies on the structural and electronic properties of graphene and few-layer graphene grown on SiC(0001) under ultra-high vacuum (UHV) conditions. The second part of the talk is devoted to recent progress in the growth of large domain graphene films on SiC(0001) in Ar atmosphere. It is shown that growth in Ar ambient leads to a significant improvement of the surface morphology and domain size as well as carrier mobility.

1:15PM B28.00005 Self Assembly of Graphene Sheets, HAILIANG WANG, XIRAN WANG, XIAOLIN LI, HONGJIE DAI, Stanford University — Chemically derived graphene sheets (GS) were found to self-assemble onto patterned gold structures via electrostatic interactions between noncovalent functional groups on GS and gold. This afforded arrays of single graphene sheets on substrates, characterized by Auger, Raman and scanning electron microscopy (SEM) imaging. Self assembly was used for the first time to produce on-substrate and fully-suspended graphene electrical devices. Molecular coatings on the GS were removed by high current “electrical annealing,” which recovered the high electrical conductance and Dirac point of the GS.

1:27PM B28.00006 Homoepitaxial Diamond Growth on Planar and Non-planar Substrates Using Carbon-13 Precursors, GOPI SAMUDRALA, University of Alabama at Birmingham, SAMUEL WEIR, Lawrence Livermore National Laboratory, YOGESH VOHRA, University of Alabama at Birmingham — The growth of single crystal diamond by microwave plasma Chemical Vapor Deposition has been carried out on [100] oriented Type Ia natural diamond anvils as well as planar Type Ib synthetic diamond substrates. The effects of substrate geometry, concentrations of Carbon-13 gas precursors, nitrogen concentration in the plasma, and substrate temperatures on homoeptaxial diamond growth have been investigated. These results will be presented along with the observed changes in growth rate and surface morphology of the grown films with the variation of each parameter. We have also investigated nitrogen incorporation in diamond lattice by photoluminescence spectroscopy. Results obtained from the study on non-planar substrates have a direct impact on the growth chemistry used in the fabrication of designer diamond anvils for high pressure research.

11:15AM B29.00001 Spin dependent scattering in all Heusler alloy CPP-GMR nano-structures for magnetic storage applications, OLEG MYRASOV, KONSTANTIN NIKOLAEV, THOMAS AMBROSE, Seagate Technology LLC — At the reduced sensor dimensions necessary for high density magnetic recording, the lower impedance of current-perpendicular- to the plane giant magnetoresistance (CPP-GMR) based read heads likely will take over the currently used tunneling MR based sensors. Main obstacle on the of realizing this transition is relatively low amplitude of the conventional CPP-GMR stacks. In this work, we investigate all-Heusler CPP-GMR spin-valves. The combination of alloys has been chosen in order to match spin states majority channel[1]. We focus on fundamentals of spin dependent interface and bulk scattering as it is affected by substitution disorder in these ternary alloys. Ab-initio electronic structure calculations employed to account for complex band structure of these ternary. We investigate interface scattering contribution within a simple model relying on the electronic band structure calculated for bulk of ferromagnetic and non-magnetic component of all Heusler CPP GMR tri-layer. We use model to investigate how to minimize impact of disorder induced states. Experimentally, these structures have been realized using conventional sputter deposition techniques and found to exhibit significant interface scattering contribution to MR signal. [1] T. Ambrose and O. Myrasov, United States Patent 6,876,522 (April 5, 2005); T. Ambrose, O. Myrasov, “Growth and Magnetotransport Properties of Thin Co2MnGe Layered Structures”, Springer Verlag Series. 2005.

11:27AM B29.00002 Sub-gap cotunneling current through a spinfull quantum dot with superconducting leads, JENS PAAKIE, BRIAN ANDERSEN, KARSTEN FLENSBERG, University of Copenhagen — A number of recent experiments have measured the voltage driven current through a quantum dot with superconducting leads. By changing the gate voltage of the dot, several unusual properties of the sub-gap current have been revealed. For example, when the dot is occupied by an odd number of electrons, the cotunneling conductance exhibits regions of negative differential conductance as well as significant weight redistributions among the multiple Andreev scattering resonances. We have calculated the sub-gap cotunneling current within a general Hamiltonian approach, allowing us to treat the even occupied (spinless) dot exactly, and the odd occupied (spinfull) dot perturbatively. In the latter case, we present calculations of unusual sub-gap current and relate these findings to the experiments.

11:39AM B29.00003 Orientation and temperature dependence of the anomalous Hall effect in hcp cobalt, JVO SOUZA, University of California, Berkeley, ERIC ROMAN, YURIY MOKROUSOV, University of California, Berkeley and University of Hamburg — We calculate from first-principles the evolution of the intrinsic anomalous Hall conductivity vector $\vec{a}$ of hcp Co as the spin magnetization direction $M$ is tilted away from the $c$-axis. We find that $\vec{a}$ varies smoothly with the tilt angle $\theta$, and that its magnitude is strongly reduced, by a factor of about four, between $\theta = 0$ and $\theta = \pi/2$, in good agreement with the measured anisotropy ratio of about three$\textsuperscript{[1]}$. In addition to the anisotropic linear magnetization dependence ($\sigma_{\parallel}/M_\parallel \neq \sigma_{\perp}/M_\perp$) expected for any uniaxial crystal, there is a considerable nonlinearity in the dependence of $\sigma_{\perp}$ on $M_\perp = M \sin \theta$, while the relation between $\sigma_{\parallel}$ and $M_\parallel = M \cos \theta$ is essentially linear, as in Mn$_2$Ge$\textsuperscript{[2]}$. The overall angular dependence of $\vec{a}$ is well-described by an expansion in terms of $l = 1$ and $l = 3$ spherical harmonics. From Zener’s model for the influence of thermal fluctuations of $M(r)$ on the temperature dependence of magnetic anisotropies$\textsuperscript{[3]}$, we predict that the $l = 3$ terms give rise to an appreciable increase with temperature of the anisotropy ratio.

11:51AM B29.00004 Determination of spin polarization of amorphous ferromagnet CoFeB by Point-Contact Andreev Reflection, SUNXIANG HUANG, TINGYONG CHEN, CHIA-LING CHIEN, The Johns Hopkins University — Amorphous ferromagnet CoFeB plays a key role in spintronic devices. Larger tunneling magnetoresistance (TMR) is resulted when amorphous CoFeB is incorporated into either AlO$_x$ or MgO magnetic tunnel junctions (MTJs) than those with CoFe. The critical switching current density in spin transfer torque devices with CoFeB as the free layer is significantly less than that with NiFe. The TMR of MgO-based MTJs are also noticeably different using Co$_{80}$Fe$_{20}$ and Co$_{40}$Fe$_{60}$B$_{20}$. These phenomena indicate a substantial spin polarization of CoFeB, whose value and compositional dependence should be determined. We have recently determined the spin polarization of amorphous Co$_{80-x}$Fe$_{8}$B$_{20}$($x=20, 40, 60$) using the point-contact Andreev reflection technique$\textsuperscript{[1]}$. The spin polarization of amorphous CoFeB has been found to be as high as 65%. In contrast to the large enhancement of TMR during crystallization of CoFeB or MgO-based MTJs, the spin polarization of crystallized CoFeB is in fact much reduced. Very recent theoretical studies$\textsuperscript{[2]}$ using density functional theory indicate an enhanced spin polarization in amorphous CoFeB, in good agreement with our measurements. [1] S. X. Huang et al., APL, 92, 242509 (2008). [2] P.V. Paluskar et al., PRL, 100, 057205 (2008).

12:03PM B29.00005 Structural and orientation dependence of the anomalous Hall effect in cobalt crystals, ERIC ROMAN, IVO SOUZA, University of California, Berkeley — Co undergoes a structural phase transition at 600 K from a ferromagnetic hcp phase to a ferromagnetic fcc phase. We present a first-principles study of the anomalous Hall conductivity (AHC) in hcp, fcc, and fct cobalt crystals. We find that the AHC in the fcc phase is about half that of the hcp phase, in good agreement with experiment. By expressing the AHC as the Kramer's-Kronig transform of the magnetic circular dichroism (MCD) spectrum, we relate the change in the AHC to differences between the infrared MCD spectra of the two phases. In particular, there is a large, negative spin-flip contribution to MCD, which is absent in hcp Co. These distortions alter the dependence of the AHC on the magnetization direction, an effect which is also significant for the orbital moment.

12:15PM B29.00006 Measurement of the transport spin polarization of disordered metals using point-contact Andreev reflection, M. OSOFSKY, Naval Research Laboratory, G. WOODS, J. SANDERS, H. SRIKANTH, University of South Florida, S. KOLESNIK, T. MAXWELL, B. DABROWSKI, Northern Illinois University — Point contact Andreev reflection (PCAR) studies were done on bulk, polycrystalline SrRu$_{1-x}$TM$_x$O$_3$ (TM = Cr, Mn, Ti) and SrRu$_{0.9}$Os$_{0.1}$O$_2$ with a high degree of disorder. The curves are typical of many other materials studied, except that the conductance is not constant at large voltages as is commonly observed in most metals. This result is most likely due to the effect of disorder on the density of states (DOS) that produces the well known square-root-of-V anomaly. After the problem of the $V^{1/2}$ behavior at large $V$ was eliminated by proper normalization, the CAR spectra for samples were analyzed using the modified BTK model. Pure SrRuO3 undergoes ferromagnetic ordering at a Curie temperature of $T_C \sim 160$ K and has a relatively high spin polarization ($\sim 0.6$). Our results indicate that, when the lattice is disordered from either the presence of Ru lattice site defects or the substitution of a transition metal for the Ru, the curie temperature, $T_C$, changes by a factor of two while the spin polarization is almost unchanged.

---

12:27PM B29.00007 Anomalous Hall effect in Y$_2$Fe$_{17-x}$Co$_x$ single crystals, JOLANTA STANKIEWICZ, ICMIA, CSIC-Universidad de Zaragoza, KONSTANTIN SKOKOV, Tver State University — We study experimentally the Hall resistivity of Y$_2$Fe$_{17-x}$Co$_x$ single crystals ($x \leq 8$) for wide temperature and applied magnetic field ranges, and for various magnetic field orientations with respect to the easy-magnetization axis. We find a large anomalous Hall effect (AHE) anisotropy in this system for $x \leq 2$. The AHE resistivity $\rho_{xy}$, measured with an applied magnetic field $H \perp c$-axis, is nearly one order of magnitude larger than the one for $H$ along the hard magnetization direction ($H \parallel c$-axis). Furthermore, the former is very large and varies linearly with the longitudinal resistivity $\rho$, whereas the latter follows $\rho^2$ for $T < 150$ K. We tentatively interpret the behavior of $\rho_{xy}$ for $H \parallel c$-axis in terms of an intrinsic effect related to the inter-orbital hopping between degenerate $d$-orbitals. Such hopping is allowed for high symmetry points at the crystallographic dumb-bell sites in this configuration. On the other hand, there is no inter-orbital hopping for $H \perp c$-axis. However, a huge amplitude of the AHE resistivity for this configuration, which follows from skew scattering, is puzzling. Both the AHE anisotropy and the large skew scattering go away as more Fe is substituted by Co. We attribute this to variations in the electronic structure of the Y$_2$Fe$_{17-x}$Co$_x$ system when Co atoms start to occupy the dumb-bell crystallographic sites.

12:39PM B29.00008 Signal propagation in time-dependent spin transport$^1$, YAO-HUI ZHU, HANS CHRISTIAN SCHNEIDER, University of Kaiserslautern — Signal propagation in magnetic multilayers is studied using a macroscopic theory of time-dependent spin transport. Our analysis shows that time-dependent spin transport possesses a wave-diffusion, i.e., it is wave-like for fast signal modulation and reduces to the diffusion equation for slow modulation$^1$. The wave-like characteristics allow us to extract a finite spin signal-propagation velocity, which cannot be done using the spin diffusion equation. Applications to different switching scenarios for collinear and non-collinear spin transport through magnetic multilayers will be discussed.

12:51PM B29.00009 The Anomalous Hall Effect in Ultra-Thin Amorphous CNi$_3$ Films$^1$, YIMIN XIONG, PHILIP ADAMS, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803-4001 — We present anomalous Hall (AHE) measurements in ultra-thin CNi$_3$ films. Films with sheet resistances in the range $R \ll R_Q$ to $R \sim R_Q$ were studied in fields up to 9 T and temperatures down to 2 K. We find that in addition to scattering processes, the AHE in high resistance films is strongly influenced by disorder-enhanced electron-electron interaction effects.

$^1$This work is supported by the DOE under Grant DE-FG02-07ER46420.

1:03PM B29.00010 Electronic structure and spin-filter effect of γ-Fe$_2$O$_3$ (maghemite), HIROYOSHI ITOH, Department of Pure and Applied Physics, Kansai University, Japan, SYUTA HONDA, JUN-ICHIRO INOUE, Department of Applied Physics, Nagoya University, Japan, HIDETO YANAGIHARA, EIJI KITA, Institute of Applied Physics, University of Tsukuba, Japan — We theoretically study the electronic structure and spin-dependent transport of spinel-like γ-Fe$_2$O$_3$ (maghemite) which is one of candidates for spin-filter devices. By performing first principles calculations (GGA+U) for iron vacancy ordered Fe$_{54}$O$_{96}$, the spin-dependent band-gap of the maghemite in the ferrimagnetic insulating ground state is determined. It is also shown that excess of Fe and O atoms significantly affects on the band gap of the minority spin state. In the light of obtained electronic structure, the spin-filter effect and variable range hopping of the maghemite are discussed.

1:15PM B29.00011 Scanning Probe Microscopy of Quantum Chains, ISRAEL MANDEL, GABRIEL CWILICH, FREDY ZYMPAN, Department of Physics - Yeshiva University — Quantum strongly correlated spin systems exhibit energy spectra related to their underlying classical dynamics. For integrable systems, the level-spacing is Poissonian, while for chaotic dynamics, it follows a Wigner-Dyson distribution, corresponding to localized and metallic phases$^{[1,2]}$. Linear spin chains and braids have been considered recently$^{[3]}$ showing that a certain degree of disorder or the presence of impurities along the chain induces a transition from one statistic to the other. We consider a quantum Heisenberg system of two perpendicular linear chains (T-shaped) interacting through the points of closest approach between them. The motivation is to model the tip of a Magnetic Force Microscope, the separation between tip and sample playing the role of an impurity (a different hopping parameter). We study the level-spacing statistics of the whole system as a function of temperature down to 2 K. We find a large anomalous Hall effect (AHE) anisotropy in this system for $H \perp c$-axis, whereas the latter follows $\rho^2$ for $T < 150$ K. We tentatively interpret the behavior of $\rho_{xy}$ for $H \parallel c$-axis in terms of an intrinsic effect related to the inter-orbital hopping between degenerate $d$-orbitals. Such hopping is allowed for high symmetry points at the crystallographic dumb-bell sites in this configuration. On the other hand, there is no inter-orbital hopping for $H \perp c$-axis. However, a huge amplitude of the AHE resistivity for this configuration, which follows from skew scattering, is puzzling. Both the AHE anisotropy and the large skew scattering go away as more Fe is substituted by Co. We attribute this to variations in the electronic structure of the Y$_2$Fe$_{17-x}$Co$_x$ system when Co atoms start to occupy the dumb-bell crystallographic sites.

1:27PM B29.00012 Kondo decoherence: finding the right spin model for iron impurities in gold and silver, J. VON DELFT, Ludwig-Maximilians-University Munich, T.A. COSTI, L. BERGGVIST, Forschungszentrum Julich, A. WEICHSELBAUM, Ludwig Maximilians University Munich, T. MICKLITZ, A. ROSCH, University of Cologne, P. MAVROPOULOS, P. DEDERICHS, Forschungszentrum Julich, F. MALLETT, L. SAMINADAYAR, C. BÄUERLE, Institut Neel - CNRS and Universite Joseph Fourier — We exploit the decoherence of electrons due to magnetic dumb-bell sites in this configuration. On the other hand, there is no inter-orbital hopping for $H \perp c$-axis. However, a huge amplitude of the AHE resistivity for this configuration, which follows from skew scattering, is puzzling. Both the AHE anisotropy and the large skew scattering go away as more Fe is substituted by Co. We attribute this to variations in the electronic structure of the Y$_2$Fe$_{17-x}$Co$_x$ system when Co atoms start to occupy the dumb-bell crystallographic sites.

1:39PM B29.00013 Electronic Interactions between Au Films and the Prussian Blue Analog Co$_{3}[\text{Os}(\text{CN}_6)]_2^2$, T. WELLINGTON, Texas A&M University, Department of Physics, M. HILFIGER, Texas A&M University, Department of Chemistry, A. FORD, Texas A&M University, Department of Physics, C. AVENDANO, K. DUNBAR, Texas A&M University, Department of Chemistry, W. TEIZER, Texas A&M University, Department of Physics — The Prussian blue analog Co$_{3}[\text{Os}(\text{CN}_6)]$$_2$ exhibits photoinduced changes of magnetic behavior as well as charge transfer induced spin transitions at low temperature. Magnetic measurements on the bulk material show an increased magnetic susceptibility after illumination with red light, as the analog exhibits an abrupt spin transition due to enhanced cooperativity. We are exploring electronic interactions between this Prussian blue analog and gold films of varying thickness. Low-temperature measurements of the magnetoresistance of the gold films, with and without a surface layer of the analog, are performed. The study focuses on how the presence of the analog on the surface affects the transport properties within the gold film.

1:51PM B29.00014 ABSTRACT WITHDRAWN —
We have synthesized superlattices of (LaMnO$_3$)$_x$/(SrMnO$_3$)$_{1-x}$. The key experimental finding is that, below $T_N$, negative MR [defined as $(\rho(H)-\rho(0))/\rho(0)$ where $\rho$ is the electrical resistivity] is observed. Here we present evidence for the opposite behavior of MR in an intermetallic compound, viz., $\rho(H)/\rho(0)$ where $\rho$ is the electrical resistivity] is observed. Here we present evidence for the opposite behavior of MR in an intermetallic compound, viz., $\rho(H)/\rho(0)$. We observe a field-induced ferromagnetic transition in the magnetically ordered state ($T_N=69$ K). The key experimental finding is that, below $T_N$, $\rho$ is dramatically enhanced at all temperatures (resulting in large “positive” MR) at $H$, in sharp contrast to the expectation based on common knowledge. This finding bears significant relevance to electron scattering phenomena in general, and in particular in metamagnetic systems.

Session B30 GMAG DMP: Focus Session: Manganite Superlattices 334

11:15AM B30.00001 Emergent properties of digital superlattices of LaMnO$_3$/SrMnO$_3$\(^1\), ANAND BHATTACHARYA, Center for Nanoscale Materials and Materials Science Division, Argonne National Laboratory — LaMnO$_3$ and SrMnO$_3$, both antiferromagnetic insulators, are end members of the La$_{1-x}$Sr$_x$MnO$_3$ phase diagram, which includes a highly spin-polarized ferromagnetic metal and a variety of orbital-ordered antiferromagnets. Interfaces between LaMnO$_3$ and SrMnO$_3$ provide a unique environment where the spin, charge and orbital degrees of freedom of each of the constituents may ‘reconstruct’, giving rise to collective states at interfaces that are qualitatively distinct from those in either LaMnO$_3$ or SrMnO$_3$. We have synthesized superlattices of (LaMnO$_3$)$_n$/(SrMnO$_3$)$_m$, where $n= q/(p+q)$, using ozone-assisted molecular beam epitaxy. Here, $p$ and $q$ represent integer layers of the constituents. These superlattices can be realized with interface roughness/intermixing limited to a region less than one unit-cell in extent. We will explore the properties of these ‘digital manganites’ for a range of $p/q$, including enhanced ordering temperatures compared to randomly alloyed samples, and provide experimental evidence for the interface reconstruction that is responsible for their emergent properties.

11:51AM B30.00002 Enhanced Antiferromagnetic Ordering Temperature in Metallic LaMnO$_3$/SrMnO$_3$ Superlattices , TIFFANY SANTOS, STEVEN MAY, ANAND BHATTACHARYA, Argonne National Lab, J. LEE ROBERTSON, Oak Ridge National Lab — The perovskite manganite La$_{1-x}$Sr$_x$MnO$_3$ has a rich magnetic phase diagram, exhibiting ferromagnetism (F) for La-rich compositions and antiferromagnetism (AF) for those that are Sr-rich. Our study focuses on the x=0.5 doping region containing the F-AF phase transition, particularly the role of strain and cation-site disorder in nucleating the F or AF state. Using ozone-assisted molecular beam epitaxy, we have prepared fully-epitaxial superlattices of LaMnO$_3$ and SrMnO$_3$ on SrTiO$_3$ substrates, along with random alloy films of La$_{1-x}$Sr$_x$MnO$_3$ with equivalent composition. In our digital synthesis method, whereby we interleave single unit-cell layers of undoped LaMnO$_3$ and SrMnO$_3$, we have eliminated disorder at the La/Sr cation site. Our structural characterization shows atomic layer precision in the synthesis of these superlattices. The structural, magnetic and transport properties of the superlattices are compared with those of the random alloys. A-type AF order (F alignment in-plane, AF alignment of adjacent planes) is verified by neutron diffraction, also revealing an enhanced Néel temperature with no F phase at higher temperature, in contrast to bulk. These AF thin films display metal-like behavior, opening the possibility of using the discrete layers of opposite spins for coherent spin transport. Supported by DOE, Office of Basic Energy Sciences.

12:03PM B30.00003 Theory of Manganite Superlattices\(^1\), ANDREW MILLIS, CHUNGWEI LIN, Department of Physics, Columbia University — A comprehensive theoretical treatment of (001) (LaMnO$_3$)$_n$/(SrMnO$_3$)$_m$ manganite superlattices is presented. The charge distribution, conductivity, and propagation through the superlattice of orbital and magnetic order are determined using dynamical mean field calculations in the superlattice geometry. General rules for predicting the behavior of manganite superlattices are outlined. Comparison is made to existing data and inconsistencies between theory and experiment are identified and discussed.

\(^1\)This research was supported by DOE ER-046196

12:15PM B30.00004 Control of Magnetism via Layer Thickness Modification in the LaMnO$_3$/SrMnO$_3$ Digital Superlattices and the Prediction of a Spin-Polarized 2DEG , BIRABAR NANDA, SASHI SATPATHY, University of Missouri-Columbia — We study the effect of layer thickness on the magnetic properties in the (LMO)$_{2n}$/SMO$_n$ superlattices using density-functional calculations. The change in the magnetic properties is shown to be controlled by the leakage of the Mn-$e_g$ electrons from the LMO layer to the SMO side. For $n=1$ superlattice, the weak potential barrier allows the Mn-$e_g$ electrons to spread across the entire superlattice, so that a uniform ferromagnetic behavior is obtained through carrier mediated Zener double exchange. For larger $n$, the strong potential barrier restricts the $e_g$ electron transfer to few layers adjacent to the interface, thus leaving the magnetism unchanged and bulk like away from the interface, while modifying the magnetism in the interfacial region. Finally, taking the example of a delta doped superlattice, (SMO)/(LMO)$_n$, we predict the formation of a spin-polarized two dimensional electron gas. The 2DEG, generated due to the confinement of the La ($d$) electrons in the direction normal to the interface, mediates a ferromagnetic alignment of the Mn-$e_g$ spins via double exchange which in turn spin polarizes the 2DEG.

\(^1\)Work supported by the US Department of Energy

12:27PM B30.00005 The onset of metallic behavior in strained (LaNiO$_3$)$_n$/(SrMnO$_3$)$_2$ superlattices , STEVEN MAY, Materials Science Division, Argonne National Laboratory, TIFFANY SANTOS, Center for Nanoscale Materials, Argonne National Laboratory, ANAND BHATTACHARYA, Center for Nanoscale Materials and Materials Science Division, Argonne National Laboratory — Motivated by predictions of collective ordering phenomena in LaNiO$_3$, we have grown strained (LaNiO$_3$)$_n$/(SrMnO$_3$)$_2$ superlattices on SrTiO$_3$ using ozone-assisted molecular beam epitaxy. The superlattices exhibit excellent crystallinity and interfacial roughness of less than one unit cell. The samples undergo a metal-insulator transition as $n$ is reduced from 4 to 2. Both $n = 1$ and 2 samples are insulating, however, they exhibit different transport behavior. The $n = 1$ sample acts as a gapped insulator, while the addition of a second LNO layer ($n = 2$) leads to hopping transport through non-gapped conduction channels. These results will be compared to (LaMnO$_3$)/(SrMnO$_3$) superlattices to highlight how interfacial charge transfer differs in the nickelate/manganite superlattices from their all-manganite counterparts. Supported by the U.S. Department of Energy (DOE), Office of Basic Energy Sciences under contract DE-AC02-06CH11357.
12:39PM B30.00006 Electronic and crystal-field effects in the fine structure of electron energy-loss spectra of \( \text{La}_x \text{Ca}_{1-x} \text{MnO}_3 \). WEIDONG LUO, MARIA VARELA, JING TAO, STEPHEN J. PENNYCOOK, SOKRATES T. PANTELIDES, Vanderbilt University and Oak Ridge National Laboratory — The fine structure of oxygen K-edge electron energy-loss spectra (EELS) of transition-metal oxides is known to be correlated with nominal oxygen states (NOS) that are often interpreted as charge states. We report the results of a systematic study of O K-edge EELS fine structures in \( \text{La}_x \text{Ca}_{1-x} \text{MnO}_3 \) and their evolution as functions of doping \( x \). The calculated spectra, specifically the pre-peak intensities and peak separations, as functions of \( x \) are in excellent agreement with experimental data. The calculations show that the variation of the pre-peak's intensity with doping is controlled by the orbital occupancy of the majority-spin Mn 3d states while its width is controlled by crystal-field splitting. The energy separation between the pre-peak and the main peak also has a correlation with the doping parameter \( x \) and the NOS. The results confirm that the NOS extracted from EELS correlates with orbital occupancies but does not probe physical charges of the Mn sites. This research was sponsored in part by the DOE Office of Basic Energy Sciences, Division of Materials Sciences and Engineering and by the McMinn Endowment at Vanderbilt University. Computations were performed at the National Energy Research Scientific Computing Center.

12:51PM B30.00007 Local Electronic Structure at Oxide-Oxide Interfaces Probed by Atomic Resolution Electron Energy Loss Spectroscopy \(^1\). AMISH SHAH, Dept. of Mat. Sci. Eng., Univ. of Illinois, Urbana-Champaign, Q. M. RAMASSE, National Center for Electron Microscopy, Lawrence-Berkeley National Laboratory, S. J. MAY, Materials Science Division, Argonne National Laboratory, J. G. WEN, Materials Res. Lab., Univ. of Illinois, Urbana-Champaign, J. N. ECKSTEIN, Dept. of Physics, Univ. of Illinois, Urbana-Champaign, A. BHATTACHARYA, Materials Science Division, Argonne National Laboratory, J.-M. ZUO, Dept. of Mat. Sci. Eng., Univ. of Illinois, Urbana-Champaign — We report an atomic resolution study of the electronic structure of 12 \( \times \) 4 \( \text{LaMnO}_3 \)-\( \text{SrMnO}_2 \) and 2 \( \times \) 2 \( \text{LaMnO}_3 \)-\( \text{SrTiO}_3 \) superlattices and their interfaces grown on \( \text{SrTiO}_3 \) by EELS. We correlated the interfacial electronic structure with the interfacial atomic structure using atomic resolution Z-contrast STEM using an electron probe of \( \geq 0.1 \) nm. The oxide superlattices were synthesized using molecular beam epitaxy. We measured the site-specific unoccupied states of oxygen atoms and transition metals. In the \( \text{MnO}-\text{SMO} \) system we found extra states (holes) near the Fermi level and their dependence on abruptness of interface. In \( \text{MnO}-\text{STO} \), we will present evidence of site-dependent electronic structure of oxygen and the Mn valence based on the L-edge ratios.

\(^1\)Supported by DOE BES

1:03PM B30.00008 Electronic properties of manganite / titanate superlattices \(^1\). MARIA VARELA, H. CHRISTEN, H. N. LEE, L. PETIT, T. SCHULTHESS, S. PENNYCOOK, Oak Ridge Natl. Lab., J. GARCÍA-BARRIOCANAL, A. RIVERA, F. Y. BRUNO, Z. SEFRIOUI, C. LEON, J. SANTAMARIA, Univ. Complutense, Spain — Here we report on the study of \( \text{LaMnO}_3 \)-\( \text{SrTiO}_3 \) interfaces. While \( \text{MnO} \) in bulk is an antiferromagnetic Mott insulator and \( \text{STO} \) is a band insulator, \( \text{MNO}/\text{STO} \) superlattices exhibit ferromagnetism and in some cases metallicty, both of which can be tuned by changing the layer thicknesses. We will compare the structure, chemistry and electronic properties of \( \text{MNO}/\text{STO} \) interfaces in high quality superlattices grown by pulsed laser deposition and high \( \text{O}_2 \) pressure sputtering. The distribution of defects and electronic properties will be studied through aberration corrected electron microscopy and electron energy loss spectroscopy. PLD superlattices show two alternating interface terminations, \( \text{LaO}-\text{TiO}_2 \) and \( \text{SrO}-\text{MnO}_2 \), which cause an asymmetry in the LMO layer electronic properties. Superlattices grown by sputtering show only one termination, \( \text{LaO}-\text{TiO}_2 \), giving an overall electron doping to the system. The role of interfacial charge transfer or localization, and any changes in electronic properties due to structural relaxations induced by epitaxial strain will be examined.

\(^1\)Research sponsored by US DOE and ORNL LDRD.

1:15PM B30.00009 Magnetic and structural phase transitions in epitaxial thin films of Manganites \(^1\). VALTERA LAUTER, HALEMARIAM AMBAYE, STEVEN NAGLER, HANS CHRISTEN, MIKE BIEGALSKI, Oak Ridge National Laboratory, SNS COLLABORATION, CNMS COLLABORATION — Understanding the magnetic properties of complex materials near interfaces is important for the development of functional nanostructures and devices. Epitaxial \( \text{LaMnO}_3 \) films were grown on \( \text{SrTiO}_3 \) substrates. Recent work on such thin-film samples has shown that “interface doping” can induce magnetism at interfaces. Our work on \( \text{LaMnO}_3 \)-\( \text{SrTiO}_3 \) interfaces has shown that the nature of the interface determines the magnetic structure - with the \( \text{MnO}_2 \)-\( \text{SrO} \) interface showing a different magnetization than the \( \text{LaO}-\text{TiO}_2 \) interface. To investigate these structures, we used polarized neutron reflectometry with off-specular scattering. Our results give evidence of reversible temperature- and field- dependent structural changes in \( \text{LaMnO}_3 \) film which undergo a phase transition. We determined that a structural phase transition in \( \text{SrTiO}_3 \) and the misfit strain trigger appearance of twins to reduce stresses and to adjust lattice mismatch between the film and the substrate. We show that a laterally correlated superstructure appear due to interaction of structural modifications with the magnetization the film.

\(^1\)This Research at Oak Ridge National Laboratory’s Spallation Neutron Source U. S. Department of Energy.

1:27PM B30.00010 Ferromagnetic Spin State of Manganite/SrTiO\(_3\) Interfaces in (110) Orientation . XINFEI LIU, JIANXING MA, TAO LIN, Department of Physics, University of California, Riverside, G. Y. GAO, W. B. WU, X. G. LI, Hefei National Laboratory for Physical Sciences at Microscale, University of Science and Technology of China, JING SHI, Department of Physics, University of California, Riverside — The interface spin state of a ferromagnet (FM) can deviate significantly from its bulk spin state and this effect could be strongly orientation-dependent especially in manganites. We have successfully fabricated high-quality (110)-oriented [\( \text{La}_{0.5} \text{Sr}_{0.5} \text{MnO}_3 \) (t) / \( \text{SrTiO}_3 \) (3ML)], superlattices (t ranging from 3 to 15 ML), which are characterized by the atomic force microscopy, high-resolution transmission electron microscopy, x-ray diffraction and magnetometry. Compared to (100)-oriented counterparts, LSMO in (110)-oriented superlattices has a thinner deadlayer at LSMO/STO interface. From the thickness (t) dependence of the superlattice magnetic moment, we extract the interface contribution and find that the interface moment is close to that of the bulk, suggesting that the (110)-oriented interface adsorb a FM spin ground state. This differs significantly from the spin canting state at (100)-oriented LSMO/STO interface that was previously reported by other groups. Our results indicate that the magnetism of manganese interface may be manipulated by taking advantage of the orientation-dependent nature of the exchange interactions.

1:39PM B30.00011 Enhanced Low Field Magnetoresistance in \( \text{La}_{0.67} \text{Ca}_{0.33} \text{MnO}_3 / \text{La}_{0.5} \text{Ca}_{0.5} \text{MnO}_3 \) superlattices . P.V. WADECAR, Q.Y. CHEN, O. LOZANO, P.V. CHINTA, W.K. CHU, D. WIJESUNDERA, A. Department of Physics & Texas Center for Superconductivity, University of Houston, Texas 77024, USA, C.S. LIN, P.H. TSENG, Y.T. LIN, L.W. TU, C.P. LIN, H. CHOLI, C.C. KUO, Department of Physics & Center for Nanoscience and Nanotechnology, National Sun Yat Sen University, Kaohsiung, Taiwan, Republic of China, N.J. HO, Department of Materials and Optoelectronic Sciences and Technology, National Chiao Tung University, Hsinchu, Taiwan, National Science Council, National Sun Yat-Sen University, Kaohsiung, Taiwan, H.W. SEO, Department of Physics, University of Arkansas, Little Rock, AR 72204 — We have grown \([ \text{La}_{1-x} \text{Ca}_x \text{MnO}_3 ](x=0.33) \) serves as the ferromagnetic layer while \( \text{La}_{1-x} \text{Ca}_x \text{MnO}_3 (x=0.5) \) serves as the spacer layer on \( \text{LaAlO}_3 \) substrates by magnetron sputtering. The samples were characterized by XRD, Magneteto-transport measurements, Rutherford backscattering spectrometry, and atomic force microscopy. Enhanced longitudinal magnetoresistance (MR) under an applied field B, defined as \( \text{MR} (B) = (\rho(B))/\rho(0) - 1 \), was as much as -49% at \( B=0.5 \) Tesla and \( T=90 \) K. The causes for this enhancement not seen at low field in other single-layered films of \( x=0.33 \) and the correlation of oxygen annealing with the MR effects for the superlattices will be presented.
11:15AM B31.00001 Multiple magnetic phases in the frustrated S=1 spin-dimer compound Ba₃Mn₂O₅₁⁺. ERIC SAMULON, Stanford University — Ba₃Mn₂O₅ is a spin-dimer compound based on pairs of S=1/2 Mn²⁺ ions arranged on a triangular lattice. Antiferromagnetic intradimer exchange leads to a singlet ground state in zero-field. Interactions between dimers broaden the triplet and quintuplet bands such that application of a magnetic field leads to multiple states marked by long range order above characteristic critical fields. Here we present results of magnetization, heat capacity, magnetocaloric effect and torque magnetometry measurements of single crystal samples which reveal a complex phase diagram containing at least three distinct ordered states across the triplet and quintuplet regimes. Much of the phase diagram can be understood in terms of an effective spin 1/2 Hamiltonian containing only the lowest energy states (|0,0⟩ & |1,1⟩ and |1,1⟩ & |2,2⟩, referred to the dimer states, for the sinlet-triplet and triplet-quintuplet regimes respectively). Two distinct ordered states are observed in the sinlet-triplet regime, which can be ascribed to the delicate interplay between single spin anisotropy and antiferromagnetic interdimer exchange on the frustrated triangular lattice.

11:15AM B31.00002 Frustrated magnetism in the diamond-chain like compound Ba₃Cu₃Sc₂O₁₂. A.V. MAHAJAN, Department of Physics, IIT Bombay, B. KOTESWARA RAO, Dept. of Physics, IIT Bombay, B. BOBROFF, Labo. de Physique des Solides, Orsay, France — The structure of Ba₃Cu₃Sc₂O₁₂, having chains of corner-shared square plaquettes, is reminiscent of the “diamond chain” compound Cu₃(CO₃)₂(OH)₂ which has shown novel magnetic properties. We report preparation of polycrystalline samples of Ba₃Cu₃Sc₂O₁₂ followed by temperature dependent magnetic susceptibility χ(T) and heat capacity C_p(T) measurements in applied magnetic fields up to H = 90 kOe. At high-T, χ(T) is fitted by the Curie-Weiss law (χ(T) = C/(T-θ)) and is suggestive of ferromagnetic interactions (θCW ~ 70 K). However, in low-fields, the χ(T) shows a sharp peak at TN ~ 16 K and the variation at lower temperatures is indicative of antiferromagnetic ordering. Clear evidence of the transition at TN is also seen in heat capacity data. The sharp peak in χ(T) and C_p(T) moves to lower temperatures with increasing H. The TN is found to be strongly lowered by an applied field and TN ~ 0 for H ~ 70 kOe. Further work to understand the relative exchange couplings between various Cu atoms is currently in progress.

12:03PM B31.00003 NMR Response in Antiferromagnetic Spin-1/2 Chains. JESKO SIRKER, Max-Planck Institute for Solid State Research, NICOLAS LAFLORENCIE, CNRS - LPS Orsay — Non-magnetic impurities break a quantum spin chain into finite segments and induce Friedel-like oscillations in the local susceptibility near the edges. The signature of these oscillations has been observed in Knight shift experiments on the high-temperature superconductor YBa₂Cu₃O₇ and on the spin-chain compound Sr₂CuO₃. Here we analytically calculate NMR spectra, compare with the experimental data, and give a simple criterion to determine the impurity concentration. Our results are based on a parameter-free formula for the local susceptibility of a finite spin chain obtained by bosonization which is checked by comparing with quantum Monte Carlo calculations.

12:15PM B31.00004 Controlling Luttinger Liquid Physics in Spin Ladders under Magnetic Field. C. BERTHERT, M. KLJANŠEK, M. HORVATIĆ, GHMF, CNRS, F-38042 Grenoble Cedex 09, France, H. MAYAFFRE, LSP Orsay — Non-magnetic impurities break a quantum spin chain into finite segments and induce Friedel-like oscillations in the local susceptibility near the edges. The signature of these oscillations has been observed in Knight shift experiments on the high-temperature superconductor YBa₂Cu₃O₇ and on the spin-chain compound Sr₂CuO₃. Here we analytically calculate NMR spectra, compare with the experimental data, and give a simple criterion to determine the impurity concentration. Our results are based on a parameter-free formula for the local susceptibility of a finite spin chain obtained by bosonization which is checked by comparing with quantum Monte Carlo calculations.
12:39PM B31.00006 Spin order of the classical Kagome antiferromagnet: via effective Hamiltonians . CHRISTOPHER L. HENLEY, Cornell Univ. — The classical Heisenberg Kagomé-lattice antiferromagnet (KAF) is only known to have a coplanar “spin nematic” (or octupole) order, so that low-energy states are labeled by colors. Contrary to accepted phenomenology,1 I propose that these colorings develop long-range order,2 first, from the spin-wave Hamiltonian up to 4th order, most modes are integrated out, leaving an effective quartic Hamiltonian $Q$ for just the “soft” (zero at harmonic order) modes. Writing it $Q = Q_0 + Q'$, where only $Q'$ depends on the discrete coplanar state, $Q'$ is treated as a perturbation, and its expectation in the $Q_0$ ensemble becomes an effective Hamiltonian $\Phi$ for the colorings. The couplings in $\Phi$ are estimated using “Coulomb phase” coarse-grainings.2 Following Huse & Rutenberg,3 I observe the unweighted coloring model sits at a roughening transition, hence $\Phi$ drives the KAF to long-range order of the $\sqrt{3} \times \sqrt{3}$ type (modulus the inevitable gradual orientation fluctuations of the spin plane). A similar effective Hamiltonian exists for related $d = 3$ lattices, but cannot produce order.

2 C. L. Henley, arxiv:0811.0026.

12:51PM B31.00007 Quantum stabilization of 1/3 magnetization plateau in $\text{Cs}_2\text{CuCl}_4$. OLEG STARYKH, University of Utah, JASON ALICEA, California Institute of Technology, ANDREY CHUBUKOV, University of Wisconsin — We consider the phase diagram of a spatially anisotropic 2D triangular antiferromagnet in a magnetic field. Classically, the ground state is umbrella-like for all fields, but we show that the quantum phase diagram is much richer and contains a 1/3 magnetization plateau, two commensurate planar states, two incommensurate chiral umbrella phases, and, possibly, a spin density wave state separating the two chiral phases. Our analysis sheds light on several recent experimental findings for the spin-1/2 system $\text{Cs}_2\text{CuCl}_4$.

1:03PM B31.00008 Magnetic properties of bilayer triangular lattice1, FEI-MING HU, SHI-QUAN SU, TIAN-XING MA, HAI-QING LIN, Department of Physics and the Institute of Theoretical Physics, the Chinese University of Hong Kong — We study magnetic properties of the single-band Hubbard model on a coupled bilayer triangular lattice by using the determinant quantum Monte Carlo method. Simulations are focused in the region near the van Hove singularities. We perform investigations on two kinds of double layer triangular lattices, one is a simple triangular lattice which has only one nearest neighbor between two layers for every atom and another one is a graphene-like structure which has three nearest neighbors between two layers for every atom. We compare their magnetic properties in the view of the itinerant electron ferromagnetic theory of attribute their behaviors to the density of states on the Fermi surface.

1This work is supported by HK RGC Grant 402107

1:15PM B31.00009 Dzyaloshinskii-Moriya interactions in valence bond systems 1, KIRILL SHTENGEL, KUMAR RAMAN, MAYAR TOVAR, UC Riverside — We investigate the effect of Dzyaloshinskii-Moriya interactions on the low temperature magnetic susceptibility for a system whose low energy physics is dominated by short-range valence bonds (singlets). Our general perturbative approach is applied to specific models expected to be in this class, including the Shastry-Sutherland model of the spin-dimer compound $\text{SrCu}_2(\text{BO}_3)_2$ and the antiferromagnetic Heisenberg model of the recently discovered $S = 1/2$ kagome compound $\text{ZnCu}_2(\text{OH})_6\text{Cl}_2$. The central result is a short-ranged valence bond phase, when perturbed with Dzyaloshinskii-Moriya interactions, will remain time-reversal symmetric in the absence of a magnetic field but the susceptibility will be nonzero in the zero temperature limit. Applied to $\text{ZnCu}_2(\text{OH})_6\text{Cl}_2$, this model provides an avenue for reconciling experimental results, such as the lack of magnetic order and lack of any sign of a spin gap, with known theoretical facts about the kagome Heisenberg antiferromagnet.

1NSF DMR-0748925

1:27PM B31.00010 Hierarchical mean-field approach to the $J_1-J_2$ Heisenberg model on a square lattice . LEONID ISAEV, GERARDO ORTIZ, Indiana University, Bloomington IN, USA, JORGE DUKELSKY, Instituto de Estructura de la Materia - CSIC, Madrid, Spain — We study the quantum phase diagram and excitation spectrum of the frustrated $J_1-J_2$ spin-1/2 Heisenberg Hamiltonian. A hierarchical mean-field approach, at the heart of which lies the idea of identifying relevant degrees of freedom, is developed. Thus, by performing educated, manifestly symmetry preserving mean-field approximations, we unveil fundamental properties of the system. We then compare various coverings of the square lattice with plaquettes, dimers and other degrees of freedom, and show that only the symmetric plaquette covering, which reproduces the original Bravais lattice, leads to the known phase diagram. The intermediate quantum paramagnetic phase is shown to be a (singlet) plaquette crystal, connected with the neighbouring Néel phase by a continuous phase transition. We also introduce fluctuations around the hierarchical mean-field solutions, and demonstrate that in the paramagnetic phase the ground and first excited states are separated by a finite gap, which closes in the Néel and columnar phases. Our results suggest that the quantum phase transition between Néel and paramagnetic phases can be properly described within the Ginzburg-Landau-Wilson paradigm.

1:39PM B31.00011 Mixed exchange antiferromagnetic/ferromagnetic $S=1/2$ Heisenberg rectangular lattices , BRIAN KEITH, TOM VALLEAU, FAN XIAO, MARK TURNBULL, CHRIS LANDEE, Clark University, LANDEE/TURNBULL MAGNET LAB TEAM — The susceptibilities of mixed antiferromagnetic/ferromagnetic rectangular Heisenberg lattices of $S = 1/2$ have been simulated using Quantum Monte Carlo techniques. These simulations include lattices in which the stronger interaction is ferromagnetic or antiferromagnetic along with the isotropically mixed lattice, which has two exchange strengths, $J$ and $J'$, are related by $J' = \alpha J$, where $\alpha$ is the aspect ratio which ranges from $0 \leq \alpha \leq 1$. These simulations were done for $0 < \alpha < 1$ in 0.05 increments. The results are discussed and the models are used to fit suspected mixed antiferromagnetic/ferromagnetic rectangulars such as $\text{Cu}_2(\text{pyz})_2(\text{NO}_3)_2(\text{HCO}_2)$ and $\text{Cu}_2(\text{pyz})_2(\text{N}_2)$.

1:51PM B31.00012 ABSTRACT WITHDRAWN —

2:03PM B31.00013 $\text{Ce}_2\text{Pt}_2\text{Pb}$ : Frustrated heavy fermion system with the Shasry-Sutherland lattice . MOO SUNG KIM, Brookhaven National Laboratory. MEIGAN ARONSON, Brookhaven National Laboratory, Stony Brook University — We have synthesized single crystals of $\text{Ce}_2\text{Pt}_2\text{Pb}$ which has the Shasry-Sutherland lattice network of Ce ions on the crystallographic c-plane, that can induce magnetic frustration. The specific heat, magnetic susceptibility, and resistivity were measured for as-grown crystals. Above 30 K, Curie-Weiss behavior is found in the magnetic susceptibility, with a Ce moment of 2.33 $\mu_B$/Ce and a Weiss temperature of -15 K, indicating antiferromagnetic interactions among the Ce$^{3+}$ ions. The magnetic specific heat rises from a minimum at 15 K to a broad maximum at 2 K, before falling to a heavy fermion value of $\sim 0.8$ J/Ce-mol K$^2$ at the lowest temperature. The entropy reaches only 1/2Rln2 at the maximum in the specific heat, and the full double ground state Rln2 is only recovered at 15 K. $\text{Ce}_2\text{Pt}_2\text{Pb}$ is an unusual material, in which a heavy fermion liquid with short range antiferromagnetic order emerges from a strongly frustrated and fluctuating paramagnetic state.
The sound attenuation displays a double peak structure and looks like an almost exact copy of the corresponding curves, characterizing behavior of profound rounded dips at temperature $T_c$. Neutron scattering measurements of the magnetic excitations in the $S=1/2$ antiferromagnet La$_2$CuO$_4$ reveal profound rounded dips at the phase transition [1,2]. We observe collective spin-excitations from the full first Brillouin-zone, in contrast to Inelastic Neutron Scattering [4]. At the $Q$ edge site-sensitive hole-excitation studies of the chain- and ladder-subsystems were performed, giving insight into the character of the holes. [1] T. Vuletic et al., Physics Reports 428, 169-258 (2006). [2] A. Kotani and K. Satow, H. Takagi (Tokyo), J.D. Denlinger (ALS). This suggests the embedding of dilute impurities as a powerful mean to probe weak and, possibly, spatially inhomogeneous order in solid-state systems. In particular, the intensity of the spin wave pole deviates strongly from that predicted by SW theory near the $Q$ edge site-sensitive hole-excitation studies of the chain- and ladder-subsystems were performed, giving insight into the character of the holes. [1] T. Vuletic et al., Physics Reports 428, 169-258 (2006). [2] A. Kotani and K. Satow, H. Takagi (Tokyo), J.D. Denlinger (ALS).

12:51PM B32.00009 ABSTRACT WITHDRAWN –

1:03PM B32.00010 Possible Observation of Electromagnons in BiFeO_{3} Crystal , PAULINE ROVILLAIN, YANN GALLAIS, ALAIN SACUTO, Laboratoire Matériaux et Phénomènes Quantiques Université Paris 7, France, RICARDO LOBO, ESPCI, DOROTHÉE COLSON, DELPHINE LEBEUGELE, CEASPEC, ROGERIO DE SOUSA — We show the first optical observation via inelastic light scattering of sharp low energy modes in multiferroic BiFeO_{3}. We have detected two different modes (\Psi and \Phi modes) and interpreted them as the optical fingerprint of the cycloidal magnetic order. The energies of the \Phi modes are equally spaced and exhibit a linear dependence as a function of the mode index (n) down to zero while the energy sequence of the \Psi modes is not equally spaced and exhibit a gap at low energy. Our experimental data are in remarkable agreement with the theory of de Sousa and Moore who pointed out that these modes could possibly be observed due to coupling between spins and lattice degrees of freedom. These experimental findings offer a unique opportunity for optical probing of the electromagnetic excitations of multiferroics. [1] Cazayous et al., Phys. Rev. Lett. 101, 097003 (2008).

1:15PM B32.00011 Magnon Sidebands and Spin-Charge Coupling in Bismuth Ferrite Probed by Nonlinear Optical Spectroscopy , AMIT KUMAR, M. RAMIREZ, S. DENEV, N. PODRAZA, X. XI, R. RAI, Y-H. CHU, J. SEIDEL, L. MARTIN, J. IHLEFELD, J. KLUG, M. BEDZYK, O. AUCIELLO, D. SCHLOM, R. RAMESH, J. ORENSTEIN, J. MUSFELDT, V. GOPALAN — The interplay between spin waves (magnons) and electronic structure in materials leads to the creation of additional bands associated with electronic energy levels, called magnon sidebands which are difficult to probe due to their smaller energy scales (meV). Linear light absorption and scattering techniques at low temperatures are traditionally used to probe these electronic sidebands. We show that optical second harmonic generation (SHG) can successfully probe the magnon sidebands at room temperature and up to 723K in bismuth ferrite, associated with large wave-vector multi-magnon excitations which linear absorption studies have thus far been unable to resolve. Polarized light studies and the temperature dependence of these sidebands reveal a spin-charge coupling interaction between the spontaneous polarization (P_s) and antiferromagnetic order parameter, L in bismuth ferrite, that persists with short range correlation well into the paramagnetic phase.

1:27PM B32.00012 Aging in Co/Cr Superlattices , T. MUKHERJEE, University of Nebraska-Lincoln, M. PLEIMLING, Virginia Polytechnic Institute and State University, CH. BINEK, University of Nebraska-Lincoln — Aging phenomena are observed in various systems brought into non-equilibrium and subsequently showing slow relaxation dynamics. Magnetic specimens with well defined interactions and dimensions can serve as model systems for universal aspects of aging. Magnetic thin films provide access to a wide range of microscopic parameters. Superlattice structures allow tuning the intra and inter-plane exchange and enable geometrical confinement of the spin fluctuations. We use Co/Cr thin film superlattices to study magnetic aging. The static and dynamic properties are affected via the Co and Cr film thicknesses. T_C of the Co films is reduced from the bulk value by geometrical confinement. Non-ergodic behavior sets in at a tunable temperature T^* in a range of some 100K above zero. Cr provides antiferromagnetic coupling between the Co films. Non-equilibrium spin states are set via low field cooling in 5mT in-plane magnetic field to below T^*. Next various in-plane magnetic set fields of some 10-100 mT are applied and the sample is exposed to the latter for various waiting times t_w, respectively. After removing the field, relaxation of the magnetization is recorded via longitudinal Kerr-magnetometry. The relaxation data are analyzed by scaling plots revealing universal aspects of aging. Financial support by Teledyne-Isco, NRI, and NSF through EPSCOR, Career DMR-0547887, and MRSEC.

1:39PM B32.00013 Exchange-coupling modified spin wave spectra in the perpendicularly magnetized permalloy nanodot chain arrays , JIAN DOU, SARAH C. HERNANDEZ, CHENGTAO YU, MICHAEL J. PECCHAN, Department of Physics, Miami University, LIESL FOLKS, JORDAN A. KATINE, MATTHEW J. CAREY, San Jose Research Center, Hitachi Global Storage Technologies — Spin wave spectra in exchange coupled nanoscale dot chain arrays were studied using ferromagnetic resonance. The dot chain arrays, with dot diameters of 300 nm and thicknesses of 40 nm, coupled via permalloy bridges of width ranging from 0 to 60 nm, were fabricated using e-beam lithography. In the perpendicularly magnetized isolated dots, multiple sharp ferromagnetic resonant peaks were observed which is associated with the quantized in-plane wave vector due to the finite dot radius. These spectrum lines shift to higher fields for samples with wider bridges due to the increasing effective demagnetizing factor. Additional higher order spin wave modes were observed as satellite peaks near the resonance peaks at both higher and lower fields, with larger separation between adjacent spin wave peaks for wider bridge samples. These extra spin wave modes, associated with the inter-dot exchange coupling, will be described in detail. This work is supported by US Dept. of Energy at MU.

11:15AM B33.00001 Making superconducting transition temperature higher in Bi$_2$Sr$_2$Ca$_2$Cu$_3$O$_{10+\delta}$ $^3$ XIAO-JIA CHEN, VIKTOR V. STRUZHVIN, RUSSELL J. HEMLEY, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, YONG YU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, CHENG-TIAN LIN, Max-Planck-Institut für Festkörperforschung, D-70569 Stuttgart, Germany — We report an experimental finding of $T_c$ enhancement in optimally doped Bi$_2$Sr$_2$Ca$_2$Cu$_3$O$_{10+\delta}$. We found that the generally observed pressure effect on $T_c$, i.e., $T_c$ first increases with pressure and then decreases after passing a maximum at an optimal pressure, is only held below a critical pressure around 24 GPa in this multilayer material. After that $T_c$ enhances remarkably upon further compression, considerably surpassing the first maximum. The critical pressure was then considered as the crossover from antiferromagnetism to superconductivity in the inner Cu$_2$O plane. The afterwards $T_c$ enhancement was suggested to be through the optimization of two competing energy scales (pairing and phase ordering) of different CuO$_2$ planes. The results have important implications for engineering superconductors with much higher $T_c$’s at ambient conditions.

11:27AM B33.00002 Specific heat of underdoped high $T_c$ superconductors from phenomenological models. J. P. F. LEBLANC, E. J. NICOL, University of Guelph, J. P. CARBOTTE, McMaster University — Inspired by phenomenological models for the pseudogap state, for example, the model of Yang, Rice and Zhang[1], we have calculated the specific heat for the underdoped cuprate superconductors. Results will be shown for both the pseudogap and superconducting state as a function of doping. Comparison between models and with experiment will be made. [1] K.Y. Yang, T.M. Rice and F.C. Zhang. Phys. Rev. B 73, 175411 (2006).

11:39AM B33.00003 Resistive switching in YBa$_2$Cu$_3$O$_{7-\delta}$ CARLOS ACHA$^1$, MARCELLO J. ROZENBERG$^2$, Departmento de Fisica - FCEyN - Universidad de Buenos Aires — We report on the nonvolatile and polarity dependent resistance switching of metal- YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO) ceramic superconductor interfaces that also extends macroscopically to the bulk YBCO. We show that electric pulses mainly modify the connectivity of the ceramic grains of the bulk material, affecting the geometrical conducting factor near the interface and controlling the superconducting percolating path in the bulk. Relaxation processes of the resistivity after applying the pulses, not associated with heating effects, are also observed. We also report on the temperature sensitivity of the resistivity switches in the bulk, which also depend on the conditions of both high and low resistance states and the voltage needed to produce the switching decrease with increasing temperature. The origin of this switching effect may be related to electric field-induced oxygen ion migration, which modifies the oxygen content at grain boundaries and controls the electric transport of ceramic superconductors.

11:51AM B33.00004 Calculation of diffusion coefficient in Au diffusion-doped Bi$_{1.8}$Pb$_{0.25}$Sr$_{1.9}$Ca$_{2.1}$Cu$_3$O$_y$ by EDXRF measurements$^1$, MUSTAFA AKDOGAN, Abant Izzet Baysal University, OZGUR OZTURK, Kastamonu University, UGUR CEVIK, Karadeniz Technical University, AHMET VARIILCI, CABIR TERZIOGLU, Abant Izzet Baysal University — Gold (Au) diffusion in superconducting Bi$_{1.8}$Pb$_{0.25}$Sr$_{1.9}$Ca$_{2.1}$Cu$_3$O$_y$ was investigated over the temperature range 500-800 $^\circ$C by the EDXRF technique. It is found that the Au diffusion coefficient decreases as the diffusion-annealing temperature decreases. The temperature dependences of Au diffusion coefficient in grains and over boundaries are described by the relations $D_1=6.7	imes10^{-5}\exp(-1.19E/k_BT)$ and $D_2=9.7	imes10^{-6}\exp(-1.09E/k_BT)$, respectively. The diffusion doping of Bi-2223 by Au causes a significant increase of the lattice parameter c by about 0.19%. For the Au-diffused samples, transport measurements indicated the $T_c$ increased from 100 to 104K and the J$_c$ increased from 40 to 125Acm$^{-2}$, in comparison with those of undoped samples. From SEM and XRD measurements it is observed that the Au doping of the sample improved the surface morphology and increased the ratio of the high-$T_c$ phase to the low-$T_c$ phase. The possible reasons for the observed improvement due to Au diffusion are also discussed.

12:03PM B33.00005 Charge distribution on planar oxygens in an underdoped High-$T_c$ cuprate: La(2-$x$)Sr($x$)CuO(4) via $^{17}$O NMR. GREG BOEBINGER, ROBERT SMITH, ARNEIL REYES, PHILIP KUHNS, NNMFL/FSU, TAKASHI IMAI, McMaster University/CIFAR, P. M. SINGER, Schlumberger-Doll Research Center, E. CHOU, National Taiwan University, K. HIROTA, University of Tokyo — Our recent studies revealed that the post-annealing to control cation composition largely changes superconducting properties of cuprate superconductors, such as Bi-based compounds and the RE123 system. For example, the $T_c$ of Bi(Ph)2223 was enhanced up to 118 K by post-annealing at ~950 K in air, while it was a typical value of 110 K before post-annealing. Strong correlation between the $c$-axis length and $T_c$ suggested that cation composition plays a crucial role to determine superconducting properties of this compound. On the other hand, substitution of RE for Ba-site in RE123 has been well recognized for light-RE123. However, such RE-rich RE123 compounds were found to form even for heavy-RE123 including Y123, which has been considered as a compound free from cation nonstoichiometry. The Y-rich Y123 exhibited suppressed $T_c$ down to ~80 K and apparently short $c$-axis length. These result indicated that intrinsic physical properties of layered cuprates should be reexamined after careful control of cation stoichiometry besides control of cation composition, because nonstoichiometric cation composition and its local fluctuation strongly affect electronic and vortex systems and related flux pinning properties.

12:15PM B33.00006 Magnetic Breakdown in the Cuprates, JEAN-MICHEL CARTER, DANIEL PODOLSKY, HAE-YOUNG KEE, University of Toronto — Following the recent observations of quantum oscillations in YBa$_2$Cu$_3$O$_{6.5}$ materials, we study different Fermi surface topologies in order to make a prediction on the nature of the topology of said Fermi surfaces in the cuprates.

12:27PM B33.00007 Important issues from uncontrolled cation nonstoichiometry in well-known cuprates, JUN-ICHI SHIMOYAMA, HIRAKU OGINO, SHIGERU HORII, YUHYA YAMAZAKI, KOICHI KAKU, YUI ISHII, KOHJI KISHIO, University of Tokyo — Our recent studies revealed that the post-annealing to control cation composition largely changes superconducting properties of cuprate superconductors, such as Bi-based compounds and the RE123 system. For example, the $T_c$ of Bi(Ph)2223 was enhanced up to 118 K by post-annealing at ~950 K in air, while it was a typical value of 110 K before post-annealing. Strong correlation between the $c$-axis length and $T_c$ suggested that cation composition plays a crucial role to determine superconducting properties of this compound. On the other hand, substitution of RE for Ba-site in RE123 has been well recognized for light-RE123. However, such RE-rich RE123 compounds were found to form even for heavy-RE123 including Y123, which has been considered as a compound free from cation nonstoichiometry. The Y-rich Y123 exhibited suppressed $T_c$ down to ~80 K and apparently short $c$-axis length. These result indicated that intrinsic physical properties of layered cuprates should be reexamined after careful control of cation stoichiometry besides control of cation composition, because nonstoichiometric cation composition and its local fluctuation strongly affect electronic and vortex systems and related flux pinning properties.
Applications, including operation as a fast, localized helium thermometer and as a transducer in superfluid hydrodynamic experiments, will be discussed.

The sample is a thin film with a large elastic free path (11 µm) deposited on a silicon oxide wafer. It is shown that PNR can resolve the difference between the reflected neutron spin asymmetries predicted by the local and nonlocal theories of superconductivity and therefore can be used for direct measurements of the microscopic intrinsic parameters of superconductors. The experimental data support the nonlocal theory, which predicts a nonmonotonic decay of the magnetic field.

12:39PM B33.00008 Evidence for nonmonotonic magnetic field penetration in a Pippard superconductor

NIKLAS KOSHEVNIKOV, Tulia Community College, CLAUDIU GIURANU, University of Lille, MARGRIET VAN BAEL, KRISTA TEMST, CHRIS VAN HAESENDONCK, Katholieke Universiteit Leuven, TODD MISHONOVA, Sr. Clement of Ohrad University at Sofia, TIMOTHY CHARLTON, ROBERT DALGIES, Rutherford Appleton Laboratory, YURI KHAIKOV, YURI NIKITENKO, VICTOR AKSENOV. Joint Institute for Nuclear Research, VLADIMIR GLADILIN, Katholieke Universiteit Leuven, VLADIMIR FOMIN, JOZEF DEVREESE, Universiteit Antwerpen, JOSEP INDEKEU, Katholieke Universiteit Leuven — Polarized neutron reflectometry (PNR) provides evidence that nonlocal electrolydronics governs the magnetic field penetration in an extreme low-τ superconductor. The sample is a thin film with a large elastic free path (11 µm) deposited on a silicon oxide wafer. It is shown that PNR can resolve the difference between the reflected neutron spin asymmetries predicted by the local and nonlocal theories of superconductivity and therefore can be used for direct measurements of the microscopic intrinsic parameters of superconductors. The experimental data support the nonlocal theory, which predicts a nonmonotonic decay of the magnetic field.

12:51PM B33.00009 ABSTRACT WITHDRAWN —

1:03PM B33.00010 Engineering Thin Film Superconductivity toward Single Quantum Channel Limit

SHENGYONG QIN, JUNGDAM KIM, QIAN NIU, CHIH-KANG SHIH, University of Texas at Austin — Traditional studies of two-dimensional superconductors were limited to the regime where the superconducting order parameter behaves as a two-dimensional wave function but the underline electrons are still three dimensional. Recent advancement of materials synthesis has enabled one to grow epitaxial thin superconductor thin films (e.g. Pb) on semiconductor substrates (e.g. Si or Ge) with unprecedented control in crystallinity, atomic smoothness and the layer thickness, thus opening up new opportunities in investigations of two-dimensional superconductivities. Indeed, quantum oscillations of the superconducting order parameter as a function of film thickness have been observed. Moreover, it was found that superconductivity remains very robustness even for films as thin as 5 ML. An interesting question arises as to what extent the robustness of superconductivity remains in even thinner regime. This work presents the case of thin film superconductivity in extreme confinement limit when only one quantum channel is present (i.e. when k_FL = π).

1:15PM B33.00011 Competition between pairing and magnetic interactions

RAIMUNDO DOS SANTOS, PEDRO BERTUSSI, Universidade Federal do Rio de Janeiro, ANDRE MALVEZZI, Universidade Estadual Paulista, THEREZA PAIVA, Universidade Federal do Rio de Janeiro — We discuss the interplay between pairing and magnetism by considering a model system composed of both tight-binding electrons and localized moments; the conduction electrons tend to form Cooper pairs due to a local (on-site) attractive interaction, U, while they also have a Kondo-like coupling, J, with the local moments. Density matrix renormalization group diagonalization on finite one-dimensional lattices (up to 60 sites) is used to calculate magnetic and pairing correlation functions, as well as structure factors in the ground state, in the case of electron density 1/3. Similarly to what happens in the quaternary borocarbides, we find that superconductivity coexists with a variety of magnetic arrangements of the local moments, ranging from commensurate to incommensurate spin-density waves, up to a critical value J_c(U); the conduction electrons show strong antiferromagnetic fluctuations in this region. Superconductivity is then suppressed by the appearance of a magnetic state with broken rotational symmetry in both the local-moment and itinerant electrons subsystems, so that for sufficiently strong J_c, a spiral-ferromagnetic ground state evolves to a ferromagnetic one.

1:27PM B33.00012 Alpha particle spectrometry using superconducting microcalorimeters

ROBERT HORANSKY, JOEL ULLOM, JAMES BEALL, GENE HILTON, GREGORY STEIHL, KENT IRWIN, NIST, ALEXANDER PLIONIS, STEPHEN LAMONT, CLIFFORD RUDY, MICHAEL RABIN, LANL — Alpha spectrometry is the preferred technique for analyzing trace samples of radioactive material because the alpha particle flux can be significantly higher than the gamma-ray flux from nuclear materials of interest. Traditionally, alpha spectrometry is performed with Si detectors whose resolution is at best 8 keV FWHM. Here, we describe the design and operation of a microcalorimeter alpha detector with an energy resolution of 1.06 keV FWHM at 5 MeV. We demonstrate the ability of the microcalorimeter to clearly resolve the alpha particles from Pu-239 and Pu-240, whose energy of separation is less than 13 keV. We also show the first direct observation of the decay of Pu-239 to the ground state of Pb-205 which has traditionally been obscured by a much stronger alpha line 2 keV away. Finally, the 1.06 keV resolution observed for alpha particles is far worse than the 0.12 keV resolution predicted from thermal fluctuations and measurement of gamma-rays. The cause of the resolution degradation may be ion damage in the tin. Hence, alpha particle microcalorimeters may provide a novel tool for studying ion damage and lattice displacement energies in bulk materials.

1:39PM B33.00013 High Resolution Gamma-Ray Spectroscopy with Superconducting Microcalorimeters

D.A. BENNETT, NIST, J.N. ULLOM, W.B. DORIESE, J.A. BEALL, G.C. HILTON, R.D. HORANSKY, K.D. IRWIN, N. JETHAVA, E. SASSI, L.R. VALE, NIST, M.K. BACRANIA, A.S. HOOVER, N. HOTELING, P.J. KARPIUS, M.W. RABIN, C.R. RUDY, D.T. VO, Los Alamos National Laboratory — We are currently developing high resolution gamma-ray microcalorimeters (µCal) for improved analysis of nuclear materials. The µCal consist of a bulk superconducting absorber attached to a transition-edge sensor (TES) biased in its resistive transition and operated at temperatures near 0.1 K. Incoming particles and photons are converted to heat in the absorber and the resulting temperature change is measured by the highly sensitive TES thermometer. The unmatched energy resolution of these devices is useful for nuclear safeguards. A specific application is the determination of Pu isotopics in complex mixtures. Although much of our effort is focused on the construction and multiplexed readout of large arrays of detectors for increased collection area, we are also working on optimizing the performance of individual pixels. To this end, we have developed an analytic µCal model that includes the thermal properties of the attached absorber and the large inductance in the TES circuit bias. We show how this model can be used to maximize the number of sensors that can be multiplexed into a single readout channel and to minimize the response time of individual sensors.

1:51PM B33.00014 In situ measurement of the permittivity of helium using microwave NbN resonators

LOREN SWENSEN, GRIGORIJ GRABOVSKIJ, OLIVIER BUISSON, CHRISTIAN HOFFMANN, ALESSANDRO MONFARDINI, Institut Neel, CNRS - Grenoble, France and University Joseph Fourier. JEAN-CLAUDE VILLEGIER, CEA-INAC, CEA - Grenoble, France — Due to their high quality-factors and ease of fabrication, superconducting microwave resonators are increasingly being recognized as ideal sensors in ultra-sensitive, low-temperature measurements. In this talk, we will discuss the design and characterization of superconducting NbN quarter-wave resonators implemented as a high-speed and spatially-sensitive detector for the permittivity of a surrounding helium bath. Measurements of a device with a ~10^{-11} mm^3 spatial resolution, a ~6×10^{-11} μ/Hz^{1/2} sensitivity to changes in the permittivity of helium, and a bandwidth of 300 kHz will be presented in the temperature range from 1.8 to 8.8 K. Potential applications, including operation as a fast, localized helium thermometer and as a transducer in superfluid hydrodynamic experiments, will be discussed.
2:03PM B33.00015 Instabilities and nonlinearities in the elastic vortex solid\textsuperscript{1}. SATYAJIT BANERJEE, SHYAM MOHAN, JAIVARDHAN SINHA, Department of Physics, Indian Institute of Technology, Kanpur-208 016, U. P., India, S. RAMAKRISHNAN, A. K. GROVER, AJAY SOOD, Department of Physics, Indian Institute of Science, Bangalore 560012, India — In recent times the influence of microscopic disorder has been viewed to play a crucial role in determining the configuration of vortices inside superconductors. Our recent investigations into the dissipation properties of the driven vortices\textsuperscript{[1]}, have found the existence of possible symmetry changes deep within the well ordered elastic vortex solid\textsuperscript{[1]}. The result is significant, as it requires a deeper revision of understanding the properties of the so called ‘benign’ elastic vortex solid. We have also studied the nonlinear properties of the driven elastic vortex solid\textsuperscript{[2]} through a random pinning environment and have found interesting highly nonlinear fluctuation in the time domain. We believe our results indicate the presence of process deep within the elastic driven phase which is a precursor to the plastic transformation in the vortex matter. \textsuperscript{[1]} Shyam Mohan, Jaivardhan Sinha, S. S. Banerjee\textsuperscript{a}, and Yuri Myasoedov, Phys. Rev. Lett. 98,027003 (2007). \textsuperscript{[2]} Shyam Mohan, Jaivardhan Sinha, S. S. Banerjee\textsuperscript{a} A. K. Sood, S. Ramakrishna, A. K. Grover (submitted, 2008) *satyajit@iitk.ac.in

**Monday, March 16, 2009 11:15AM - 2:03PM — Session B34 DMP: Focus Session: Iron Pnictides and Other Novel Superconductors II: Quantum Oscillations, Electronic Structure and Magnetism 404**

11:15AM B34.00001 Fermi surface of superconducting LaFePO determined from quantum oscillations\textsuperscript{1}. AMALIA COLDEA, J. FLETCHER, A. CARRINGTON, Bristol University, J. ANALYTIS, Stanford University, C. ANDREW, A. BANGURA, Bristol University, J.-H. CHU, A. ERICKSON, I. FISHER, Stanford University, N. HUSSEY, Bristol University, R. MCDONALD, NHMFL, Los Alamos National Laboratory — We report extensive measurements of quantum oscillations in the normal state of LaFePO, using low temperature torque magnetometry and transport in high static magnetic fields (45 T). LaFePO is a bulk Fe-based superconductor (Tc~ 6 K) which can be grown in high quality single crystalline form being isostructural to LaFeAsO but without being affected by magnetic or structural transitions at low temperatures. We find that the Fermi surface is that of a compensated metal in broad agreement with the band-structure calculations with frequencies varying between 2.8% to 9% of the basal plane angle of the Brillouin zone. The effective masses vary between 1.7-2.1 me and the electronic correlations in LaFePO are moderate corresponding to a mass enhancement of about ~2. The observed variation in the electronic scattering between different bands may be related to their different orbital character. The quasi-two dimensional Fermi surface consists of nearly-nested electron and hole pockets, suggesting proximity to a spin/charge density wave instability. The upper critical field anisotropy is a factor ~10 (at 0.325 K) which may linked to its increased two-dimensionality (PRL 101, 216402 (2008)).

11:27AM B34.00002 Quantum Oscillations in the parent pnictide BaFe2As2: Fermi surface reconstruction of the magnetic ground state\textsuperscript{1}. JAMES ANALYTIS, Stanford Linear Accelerator Center, JUIN-HAW CHU, IAN FIRSHER, Stanford University, ROSS MCDONALD, Los Alamos National Laboratory, IGOR MAZIN, Naval Research Lab, ROSS MCDONALD COLLABORA- TION — We have measured quantum oscillations in the magnetically ordered ground state of BaFe2As2, a parent compound of the superconducting ternary pnictides. Measurements were performed in 65T pulsed field at the Los Alamos National High Magnetic Field Laboratory, using an atomic force microscope torque cantilever. We also perform detailed band-structure calculations for the spin-density wave ground state and find agreement with our observations of small quasi-two dimensional pockets. These results place significant constraints on our understanding of the magnetism associated with the Fe-As layers and layers that coherently quasiparticles persist in the magnetic ground state, providing an important clue about the nature of superconductivity which emerges when this compound is doped.

\textsuperscript{1}Department of Energy

11:39AM B34.00003 Quantum oscillations in the parent magnetic phase of an iron arsenide high temperature superconductor\textsuperscript{1}. NEIL HARRISON, Los Alamos National Laboratory, SUCHITRA SEBASTIAN, J. GILLET, P. LAU, Cavendish Laboratory, Cambridge, DAVID SINGH, Oak Ridge National Laboratory, CHARLES MIELKE, Los Alamos National Laboratory, GILBERT LONZARICH, Cavendish Laboratory, Cambridge — We report quantum oscillation measurements in SrFeAsF at temperatures which is known to become superconducting under doping and pressure. The magnetic field and temperature dependences of the oscillations between 20 and 55 T suggest that the electronic excitations are those of a Fermi liquid. We show that the observed Fermi surface comprising small pockets is consistent with the formation of a spin-density wave. Our measurements thus demonstrate that high Tc superconductivity can occur on doping or pressurizing a conventional metallic spin-density wave state.

11:51AM B34.00004 Fermi surface changes in LaFeAsO\textsubscript{1-x}F\textsubscript{x} using supercells, rigid band shifts, and the virtual crystal approximation\textsuperscript{1}. PAUL LARSON, University of Nebraska, SASHI SATPATHY, University of Missouri — There is currently great interest in the properties of the superconducting material LaFeAsO. While numerous calculations have been performed for this material, questions arise about which theoretical description in the Fermi surface with doping. We have performed ab initio density functional studies of F-doping in the non-magnetic state using supercell calculations and compared these results to those obtained using rigid band shifts and the virtual crystal approximation (VCA). The Fermi surface consists mainly of Fe d and As p states with La and O states lying far from the Fermi level. Significant differences are found by comparing the supercell results with those of the rigid band shifts, but remarkable agreement is found for the Fermi surface using VCA calculations where the reconstruction of the magnetic ground state.

12:03PM B34.00005 Momentum density, Fermi surface and directional Compton profile in the iron-based superconductor LaOFe\textsubscript{As} , Y. J. WANG, HSIN LIN, B. BARBIELLINI , Northeastern U., P. E. MUNARENS, Northeastern U. and U. Tech., Delft, The Netherlands, S. KAPRZYK, Northeastern U. and Academy of Mining and Metallurgy AGH, Poland, W. AL-SAWAI, R.S. MARKIEWICZ, A. BANSIL, Northeastern U. — We have carried out first principles all-electron calculations of the (001) projected 2D electron momentum density (2D-EMD) and directional Compton profiles (CPs) along the [100], [001], and [110] directions in iron-based superconductor LaO\textsubscript{1-x}F\textsubscript{x}Fe\textsubscript{3} for various doping concentrations x within the framework of the local density approximation (LDA). We have identified Fermi surface features both in the 2D-EMD and in the CPs. Bonding effects related to the character of wave functions near the Fermi level are revealed by the autocorrelation function B(r) defined as the Fourier transform of the momentum density. Work supported in part by the US Department of Energy.
12:15PM B34.00006 First Principles studies of 122 Ferropnictide Surface1, ALEXANDER KEMPER, P.J. HIRSCHFELD, H-P. CHENG, University of Florida — We present DFT-GGA calculations for the Ba and Sr-122 ferropnictide materials on the effect of surfaces on the electronic structure. It has been established that there is a strong modulation of the electronic structure by the Fe-As distance, which decreases near a free surface due to surface reconstruction. Indeed, we see significant changes of both Fermi velocities and Fermi surfaces due to these effects for both the paramagnetic and collinear spin density wave states. These changes of the electronic structure, which we exhibit here, will be crucial for the interpretation of surface probes like ARPES and STM.

12:27PM B34.00007 Structural, spin, and orbital phase transitions in LaOFeAs: I. Total energy calculations. WEI KU, CHI-CHENG LEE, WEI-GUO YIN, Brookhaven National Laboratory — Recent experimental studies on iron pnictides showed the existence of local Fe magnetic moments even in the superconducting phase, indicating strong fluctuations in a short time scale. We report a investigation of the local electron-lattice and electron-spin couplings via total energy calculations within first-principles density functional theory. Strong coupling in both channels were found to be closely tied to a ferro-orbital order, which drives the structure transition and the stripy magnetic (SDW) transition at high temperature in the undoped system. We suggest that this orbital degree of freedom leads to stronger coupling upon doping and thus possible enhancement of superconductivity.

12:39PM B34.00008 Structural, spin, and orbital phase transitions in LaOFeAs: II. Wannier function analysis , WEI-GUO YIN, CHI-CHENG LEE, WEI KU, Brookhaven National Laboratory — A realistic low-energy effective interacting Hamiltonian of doped LaOFeAs is derived quantitatively from a novel first-principles Wannier function analysis. Strong local orbital, spin, and lattice coupling to the doped charge is found associated with the orbital degree of freedom, which suggests a possible explanation of the high transition temperature. The fluctuations in the orbital sector fundamentally distinguish the iron pnictides from the copper oxide superconductors, and ensure the essential role of phonons in the mechanism of superconductivity in this new class of materials, in addition to electronic origin.

12:51PM B34.00009 Emergence of complex magnetism in three dimensional, yet quasi-layered, iron pnictides: CaFe$_2$As$_2$1, ARTHUR J. FREEMAN, GIANCARLO TRIMARCHI, MERCOURI KANATZIDIS, Northwestern U.. ILYA TODOROV, DUCK-YOUNG CHUNG, Materials Science Division, ANL, Argonne IL 60439 — The class of iron pnictides has been the focus of much attention for the discovery of superconductivity in the layered compounds LaOFeAs, CaFe$_2$As$_2$, and related ones; the phase diagrams of these pnictides remain still largely unexplored. Here, we report on the electronic and magnetic structure of the recently synthesized CaFe$_2$As$_2$ compound. This material, as opposed to the layered CaFe$_2$As$_2$, shows FeAs slabs parallel to the $b$-direction and approximately perpendicular to each other, defining tunnels filled by the Ca atoms. No sign of superconductivity was found in this compound. Instead, the system shows a complex ferromagnetic state at low temperature. DFT calculations performed on the refined crystal structure using the highly precise FLAPW method show a pronounced stabilization for the ferromagnetic state which is characterized by four distinct Fe sites with magnetic moments of between 1 $\mu_B$ and 2 $\mu_B$. The influence of the local topology of the crystal structure on the the electronic and magnetic state is analyzed.

1:03PM B34.00010 ‘Unscreening’ Effect on Fe-Pnictide Superconductor, MASAO OGATA, Department of Physics, University of Tokyo and JST, TRIP, YUKI FUSEYA, TOSHIIKAZE KARIYADO, Department of Physics, University of Tokyo — We study a microscopic mechanism of Fe-pnictide superconductor, considering the screening effects of Coulomb interaction in addition to the conventional spin-fluctuation mechanism. It is shown that, by electron doping, the transition temperature of superconductivity increases due to the ‘unscreening’ effect even though the density of states decreases, while that of spin-density wave rapidly decreases due to breaking of nesting conditions. Our results give a clear interpretation to the mystery of interrelation between $T_c$ and the density of states observed in the Fe-pnictide superconductors.

1:15PM B34.00011 Quasiparticle scattering interference in superconducting Oxypnictides . YANYANG ZHANG, KANGJUN SEO, XIATING ZHOU, Purdue University, B. ANDREI BERNEVIG, Princeton University, JIANGPING HU, Purdue University — Based on a two-band model of the superconducting iron oxypnictides, we study the effects of single-impurity scattering on the local density of states by exact T-matrix calculations. We compare the quasi-particle interference patterns in different pairing states, as well as different kinds of impurities. The results of this calculation can be used to test and distinguish different sorts of pairing symmetries and impurities in the experiments.

1:27PM B34.00012 Quasi-particle properties in iron-based superconductors1, XIANG HU, CHIN-SEN TING, Texas Center for Superconductivity, University of Houston, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory — The pairing symmetry is one of the major issues in the study of iron-based superconductors. We adopted a minimum two band model, to introduce the two-band Bogoliubov de Gennes equations. By solving those equations numerically, we checked the possibilities of different pairing symmetry, and made some predictions which can be tested by future experiments in spectrum tunnelling microscopy.

1Supported by a grant from the Robert A. Welch Foundation, No. E-1146 and TcSUS, and under the auspices of the National Nuclear Security Administration of the U.S. Department of Energy at Los Alamos National Laboratory under Contract No. DEAC52-06NA25396.

1:39PM B34.00013 Nature of the SDW state in FeAs-based Compounds , XI DAI, ZHONG FANG, GUANGTAO WANG, GANG XU, Institute of Physics, CAS, Beijing, China — We show that the significant underestimation (about 10%) of Fe-As bond length in FeAs-based compounds by LDA is due to the strong correlation effect. By properly taking into account the on-site correlation, we are able to reproduce experimental values (to about 1%) using self-consistent LDA+Gutzwiller method. Also we will show that the strong on-site orbital fluctuation will dramatically reduce the anti-ferromagnetic long range order in the parent compound. All these results are in good agreement with experiments.

1:51PM B34.00014 High-temperature Superconductivity: Status . JOHN D. DOW, Physics Department, Arizona State University, Tempe, AZ. DALE R. HARSHMAN, Physikon Research Corporation, P.O. Box 1014, Lynden, WA 98264. ANTHONY R. FIORY, Physics, New Jersey Institute of Technology, Newark, NJ 07102 — A theory of high-temperature superconductivity is presented which (i) explains the cuprates, with cuprate-planes; (ii) describes the superconducting ruthenates without cuprate-planes, such as Ba$_2$YRuO$_6$; (iii) treats the rutheno-cuprates, such as GdSr$_2$Cu$_2$RuO$_6$, whose cuprate-planes do not superconduct; (iv) treats the molecule $\kappa$-[BEDT-TTF]$_2$Cu$_2$[NC$_2$]$_3$ which superconducts via S, and (v) explains the pnictides. In YBa$_2$Cu$_3$O$_y$, the theory is consistent with the observation that no Cu-containing plane superconducts and the observed superconductivity is $\kappa$-wave, not $\delta$-wave, once fluxon-de-pinning has been properly accounted for. The superconducting layers are BaO layers, in $\kappa$-type, and are adjacent to the $\lambda$-type cuprate-planes. The theory is consistent with many data which were previously beyond explanation.
11:15AM B35.00001 Valley density-wave (VDW) and Superconductivity in Iron-Pnictides
Vladimir Cvetkovic, Zlatko Tesanovic, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD — One of the experimentally observed features of iron-pnictide superconductors is the structural transition and SDW ordering occurring at almost the same temperature. Starting from a tight-binding model [1], we construct an effective theory for iron-pnictides with the distinctive two hole and two electron Fermi surfaces. This theory is then mapped onto a negative-U Hubbard model with additional orbital and spin flavors [2]. We demonstrate that the superconducting instability of the attractive Hubbard model — valley density-wave (VDW) — corresponds to the observed structural and SDW orders. The deviations from perfect nesting between the hole and electron Fermi surfaces are mapped onto the Zeeman field which causes partial Fermi surface to remain ungapped. The origin of pnictide superconductivity in this model, and its ties to the VDW are discussed. [1] V. Cvetkovic and Z. Tesanovic, http://arxiv.org/abs/0804.4678. [2] V. Cvetkovic and Z. Tesanovic, http://arxiv.org/abs/0808.3742.

11:27AM B35.00002 Spin-Density Wave in Iron Pnictides
Jian Kang, Valentin Stanev, Zlatko Tesanovic, Johns Hopkins University — Multi-band Hubbard-like model with appreciable nesting is applied to the study of spin-density wave (SDW) in iron pnictides: $\text{Fe}_x\text{Co}_y\text{As}_2$. It is assumed that the SDW particle-hole pairing mechanism arises from the short range interaction between hole bands near $\Gamma$ point and electron bands near M. Within the Hubbard-Stratonovich transformation, an auxiliary field is introduced to obtain the effective action. The mean-field solution is obtained by the stationary phase analysis of this action, and results in an itinerant, antiferromagnetically ordered ground state, with the staggered magnetic moment modulation at wavevector $\mathbf{M}$. We study fluctuations of the spin order around $\mathbf{M}$, both in its direction and amplitude. We present detailed results for the propagation velocity of this mode (spin-wave velocity) as a function of the various parameters of our model and compare them to the available experimental observations of the spin-wave spectrum.

11:39AM B35.00003 Iron-based superconductors: What can we learn from DFT?
Lilja Boeri, Oleg Dolgov, Max-Planck-Institute for Solid State Physics, Stuttgart, Germany, Alexander Golubov, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente, 7500 AE Enschede, The Netherlands, Ole Krogh Andersen, Max-Planck-Institute for Solid State Physics, Stuttgart, Germany — The discovery of superconductivity in iron pnictides has initiated an intense theoretical activity. So far, however, not only the pairing mechanism, but even the basic electronic structure of these materials is not well understood. We use Density Functional Theory to understand the electronic and vibrational properties of LaOFeAs, which can be considered a prototype for iron pnictides. First, we calculate the phonon dispersions and electron-phonon coupling using linear response and show that standard Migdal-Eliashberg theory cannot explain the experimental Tc. Then we derive ab-initio an accurate tight-binding Hamiltonian, using downfolding + N-ization (NMTO), which allows us to elucidate the origin of the complicated band structure of iron pnictides. As a first application of our model, we study magnetism.

11:51AM B35.00004 Correlations in Ferropnictides
Klaus Koepernik, IFW Dresden, Germany, Helmut Eschrig, IFW Dresden, Germany — The strength of correlations in the ferropnictide superconductors is still under debate. While arguments for an electron-electron interaction $U$ of 5eV have been made, some experimental results support a $U$ of merely 1eV. Density functional theory in the local spin density approximation (LSDA) seems to describe several aspects of the electronic structure quite reasonably, which would also support a smaller $U$. However, the unusually large error of the calculated lattice structure remains a puzzle. We discuss the influence of correlations on the electronic structure and the properties of the ferropnictides in the framework of LSDA+U calculations.

12:03PM B35.00005 Superconductivity in SrFe$_2$-Co$_x$As$_2$: Internal Doping of the Iron Arsenide Layers
Helge Rosner, Andreas Leithe-Jasper, Walter Schnelle, Christoph Geibel, MPI CPfS Dresden — In the strontium iron-cobalt arsenides SrFe$_{2-x}$Co$_x$As$_2$ ($0.2 \leq x \leq 0.4$) superconductivity with Tc up to 20 K is observed in magnetic susceptibility, electrical resistivity, and specific heat data. This first observation of bulk superconductivity induced by electron doping in this family of compounds — despite strong disorder in the Fe-As layer — is strongly enhanced compared to an ordinary Fermi liquid as it contains precisely the same interaction that gives rise to spin-density-wave ordering. We compare theoretical slope with the data.

12:15PM B35.00006 Linear temperature dependence of the spin susceptibility in Fe-pnictides
Dmitri V. Efremov, Andrei V. Chubukov, Ilya M. Eremin, Maxim M. Korsunov, Dmitri L. Maslov — We argue that linear T dependence of the spin susceptibility $\chi$ > 0 observed in Fe-pnictides can be explained within the itinerant Fermi liquid model of hole and electron bands. The spin susceptibility is linear in T in a generic Fermi liquid in 2D. We show that for pnictides, the prefactor of the T term comes chiefly from intra-band scattering and is strongly enhanced compared to an ordinary Fermi liquid as it contains precisely the same interaction that gives rise to spin-density-wave ordering. We compare theoretical slope with the data.

12:27PM B35.00007 Theory of novel and superconducting properties of Fe-based superconductors
Andrey Chubukov, University of Wisconsin — I will discuss antiferromagnetism and superconductivity in novel Fe-based superconductors within the itinerant model of small electron and hole pockets near (0,0) and (π,π). I will argue that the effective interactions in both channels logarithmically flow towards the same values at low energies, i.e., antiferromagnetism and superconductivity must be treated on equal footing. The magnetic instability comes first for equal sizes of the two pockets, but looses to superconductivity upon doping. The superconducting gap has no nodes, but changes sign between the two Fermi surfaces (extended s-wave symmetry). I will argue that the T dependence of the spin susceptibility, NMR relaxation rate, and the penetration depth for such state are exponential only at very low T, and can be well fitted by power-laws over a wide T range below $T_c$. I will also discuss the type of a transition between spin-density-wave and superconducting states at $T = 0$ and at finite $T$, and the linear T dependence of the spin susceptibility in the normal state. Based on the works done with I. Eremin, D. Efremov, M. Korsunov, D. Maslov, M. Vavilov, and A. Vorontsov.
while electrons in the lower level are more localized. The resulting magnetic moment is highly anisotropic with an in-plane value of the filling of the Fe d-levels. The two highest occupied levels have one electron each but as a result of differing p-d hybridizations, the upper level is more itinerant.

Department of Physics, University of Illinois at Urbana-Champaign, ANTONIO CASTRO-NETO, Department of Physics, Boston University — We show that different chiralities (both metallic and semiconducting) remain metallic for beyond n=3, with conductance close to 4e

the appearance of a number of new bands in the electronic structure, especially near the Fermi level. These new bands serve to modify the density of states near optimization shows that Pt prefers to form clusters rather than spread out and "wet" the SWNTs. Atom-by-atom increase in the cluster size is associated with density functional theory to investigate the structure and electronic properties of Pt nanocluster decoration of single-wall carbon nanotubes (SWNTs). Energy

we set interaction parameters appropriately.

and optical microscopy. A SWNT-SDBS-TritonX100 dispersion was found to have the appropriate viscoelastic and shear thinning behavior for rod roll-to-roll (rod based) thin film coating process. Purified, pristine SWNTs were dispersed in water at high concentrations using surfactants and analyzed using rheology and optical microscopy. A SWNT-SDBS-TritonX100 dispersion was found to have the appropriate viscoelastic and shear thinning behavior for rod coating. Rod coating, washing and sulfuric acid treatment resulted in highly uniform thin films of pure SWNT (sheet resistance of 100 and 300 \Omega/sq for respective transparency of 70% and 90%). The results presented here, both in terms of scientific understanding of how to control fluid and process, and in terms of a scalable technique, paves the way to the deployment of transparent conductive SWNT films in large scale commercial applications.

1:03PM B35.00008 Nodal Spin Density Wave and band topology of the FeAs based materials . HUI ZHAI, LBL, UC Berkeley, YING RAN, FA WANG, ASHVIN VISHWANATH, DUNG-HAI LEE, UC Berkeley — The recently discovered FeAs-based materials exhibit a \((\pi,0)\) Spin Density Wave (SDW) in the undoped state, which gives way to superconductivity upon doping. Here we show that due to an interesting topological feature of the band structure, the SDW state cannot acquire a full gap. This is demonstrated within the SDW mean-field theory of both a simplified two band model and a more realistic 5-band model. The positions of the nodes are different in the two models and can be used to detect the validity of each model.

1:15PM B35.00009 Normal State Spin Dynamics of Five-band Model for Iron-pnictides . TOSHIKAZE KARIYADO, MASAO OGATA, Department of Physics, University of Tokyo and JST, TRIP — Normal state (assuming absence of SC or AF order) spin dynamics of iron-pnictide superconductors is discussed by calculating spin structure factor \(S(q,\omega)\) in an itinerant five-band model within RPA approximation. Due to the characteristic Fermi surface structure of iron-pnictide, column like response is found at \((\pi,0)\) in extended Brillouin zone. This is consistent with recent neutron experiments. Furthermore, we show that the temperature dependence of inelastic neutron scattering intensity is reproduced if we set interaction parameters appropriately.

1:27PM B35.00010 Symplectic fermion approach to the striped magnetism in the iron arsenides , XUN XUE, East China Normal University, JIANHUI DAI, Zhejiang Modern Physics Center — Based on the fact that the near transition temperature of striped SDW and structure distortion in iron pnictides, we propose a symplectic fermion approach to account for this kind of antiferromagnetic properties. The model is expecting for better understanding of the experimental results.

1:39PM B35.00011 Parquet formalism applied to pnictide superconductors , JUN LIU, KARLIS MIKELSONS, SHUXIANG YANG, HERBERT FOTSO, MARK JARRELL, Louisiana State University — DMFT combined with Parquet approximation is used to study the single particle property of pnictide superconductors (such as FeSe, SrFe2As2,...) in an attempt to understand the enhancement of superconductivity under pressure. By tracking the evolution of one-particle spectral function, pressure dependence of this type of compound is studied in depth. In the study, inhomogeneous frequency grid is used to high frequency summation.

1:51PM B35.00012 Jahn-Teller Effect, Structural Phase Transition and Resistivity Anomaly in Iron Pnictides , WEICHENG LV, JIANSHENG WU, PHILIP PHILLIPS, University of Illinois — We attribute the structural phase transition (SPT) in the parent compounds of iron pnictides to a Jahn-Teller distortion. Due to the anisotropy of the \(d_{xz,\pi}\) and \(d_{yz,\mu}\) orbitals in the \(xy\) plane, some orbital ordering will make the orthorhombic structure more energetically favorable, thus inducing the SPT. In an orbital ordered system, the sites with orbitals that do not order act as scattering impurities, causing a resistivity anomaly upon the onset of the SPT. Below the SPT, we find that the resistivity displays a \(lnT\) divergence. All of these are in agreement with the experiments.

2:03PM B35.00013 Theory of the Magnetic Moment in Iron Pnictides1, JIANSHENG WU, PHILIP PHILLIPS, Department of Physics, University of Illinois at Urbana-Champaign, ANTONIO CASTRO-NETO, Department of Physics, Boston University — We show that the combined effects of spin-orbit, monoclinic distortion, and p-d hybridization in tetrahedrally coordinated Fe in \(LaFeAsO\) invalidates the naive Hund’s rule filling of the Fe d-levels. The two highest occupied levels have one electron each but as a result of differing p-d hybridizations, the upper level is more itinerant while electrons in the lower level are more localized. The resulting magnetic moment is highly anisotropic with an in-plane value of 0.25 – 0.35\(\mu_B\) per Fe and a z-projection of 0.06\(\mu_B\), both of which are in agreement with experiment.

1 P.P. was supported in part by the NSF DMR-0605769.

11:15AM B36.00001 Density Functional Theory Design of All-metallic Single-wall Carbon Nanotubes2, LI CHEN, SWASTIK KAR, SAROJ NAYAK, Rensselaer Polytechnic Institute, PULICKEL AJAYAN, Rice University — We have used density functional theory to investigate the structure and electronic properties of Pt nanocluster decoration of single-wall carbon nanotubes (SWNTs). Energy optimization shows that Pt prefers to form clusters rather than spread out and "wet" the SWNTs. Atom-by-atom increase in the cluster size is associated with the appearance of a number of new bands in the electronic structure, especially near the Fermi level. These new bands serve to modify the density of states near the Fermi level. While metallic SWNTs remain metallic, semiconducting SWNTs lose their band-gap rapidly with the inclusion of more than 3 atoms per cluster, and continue to remain metallic for all tested cluster sizes \((n=0-13\) and 19). Room temperature \((T=300K)\) calculations of conductance show that SWNTs of different chiralities (both metallic and semiconducting) remain metallic for beyond \(n=3\), with conductance close to 4e\(^2\)/h. In some cases, the conductance is found to exceed this value. This gives an easy for designing “all-metallic” SWNT bundles.

11:27AM B36.00002 Designing of Single Walled Carbon Nanotubes dispersions for industrial scale processing and roll-to-roll coating applications . BUDDHADIPTA DAN, MATTEO PASQUALI, Rice University — Carbon nanotubes (CNTs) combine nanoscale size with high aspect ratio and unique properties, making them ideal candidate materials for high-impact applications. Yet, much as in polymer science and engg, such applications require appropriate fluid based dispersions which can undergo industrial processing that translate the properties of elemental molecules (SWNTs) into macroscopic materials. We report a detailed study on the flow behavior of aqueous SWNT dispersions involving surfactants, its dependence on SWNT & surfactant concentration, and type of surfactant. We also design a SWNT dispersion for use in industrial roll-to-roll (rod based) thin film coating process. Purified, pristine SWNTs were dispersed in water at high concentrations using surfactants and analyzed using rheology and optical microscopy. A SWNT-SDBS-TritonX100 dispersion was found to have the appropriate viscoelastic and shear thinning behavior for rod coating. Rod coating, washing and sulfuric acid treatment resulted in highly uniform thin films of pure SWNT (sheet resistance of 100 and 300 \Omega/sq for respective transparency of 70% and 90%). The results presented here, both in terms of scientific understanding of how to control fluid and process, and in terms of a scalable technique, paves the way to the deployment of transparent conductive SWNT films in large scale commercial applications.
Characteristics. The quality of suspended CNTs is characterized by electrical transport as well as 1/f noise measurements. Standard resist-processed CNTs demonstrated by controlling the number of suspended CNTs per device, and by re-using the same electrode set multiple times to produce the desired device. A printing process is used to transfer CVD-grown CNTs onto specially configured electrode (Au) sets fabricated on SiO₂ methods have been developed to fabricate suspended carbon nanotube (CNT) field effect transistors using as-grown CNTs without subsequent chemical processing.

Devices

∼ 2 wafers using our facile transfer printing method. 2) Wafer-scale device fabrication was performed on 4 inch Si/SiO₂ arrays for high performance submicron channel transistors and integrated nanotube circuits, including the following essential components. 1) The massively aligned carbon nanotube (swCNT) networks were extensively studied for various practical applications such as transistors, sensors, etc. However, those devices have been suffering various limitations such as poor on-off ratio due to metallic swCNTs in the networks, decreased mobility and conductance for devices with reduced linewidth due to the percolation problem, etc. Herein, we present a simple but efficient strategy to significantly improve the performance of swCNT network devices. 1) Massively aligned nanotubes can be improved by increasing the density and alignment of tubes and avoiding the problems associated with random networks. We are optimizing this approach by preparing devices composed of parallel arrays of CNTs fabricated on quartz and plastic substrates. CNT growth catalysts, ferric nitrate, ferritin and iron, are a pair of control of the degree and alignment of the grown tubes. Though ferric nitrate produced a denser network, ferritin allows a high degree of alignment, and iron will also be used. Plastic devices with a 5 µm channel length and a 22.5 mm width were prepared with approximately 1 channel crossing tube per 4 µm of width. The density is improved by repeatedly printing more CNT’s to the same area. The metallic tubes were removed by selective electrical breakout, marginally increasing the on/off current ratio while decreasing the On current from 800µA to 450µA (at Vgs=−20V, Vds=−10V). Results from optimized devices prepared with patterned iron as the growth catalyst will also be presented.

11:15AM B36.00006 Transfer Printed Parallel Carbon Nanotube Devices¹, ANDREW TUNELL, VINO SANGWAN, VINCENT BALLAROTTO, DANIEL HINES, MICHAEL FUHRER, ELLEN WILLIAMS, University of Maryland — Carbon nanotube (CNT) device properties can be improved by increasing the density and alignment of tubes and avoiding the problems associated with random networks. 11:27PM B36.00007 ABSTRACT WITHDRAWN

12:03PM B36.00005 Fabricating Substrates to Combine Electron Microscopy and Diffraction with Electrical Characterization of Single and Double-Walled Carbon Nanotubes, SCOTT PAULSON, LOK-KIN TSUI, JOSEPH HARCASSEL, James Madison University — Carbon nanotubes based electronics make model systems for pursuing electronic devices at the nanometer scale. They are chemically robust, and have well defined easily predictable electronic structure. However, device integration requires not just an understanding of the nanotube properties, but also the properties of interfaces between neighboring elements. Ideally the structure-property relationship of the interface between two nanotubes would consist of complete electrical characterization coupled with atomic scale structural information. The former is achieved by lithographic patterning of a nanotube into a circuit, the latter through high resolution TEM imaging and diffraction. Unfortunately, typical TEM preparation of nanotubes is not compatible with lithographic processing and vice-versa. In this talk we will present a fabrication process that integrates carbon nanotubes into devices on a TEM compatible substrate. Sample devices will be shown, and preliminary data will be presented.

12:15PM B36.00006 Transfer Printed Parallel Carbon Nanotube Devices¹, ANDREW TUNELL, VINOD SANGWAN, VINCENT BALLAROTTO, DANIEL HINES, MICHAEL FUHRER, ELLEN WILLIAMS, University of Maryland — Carbon nanotube (CNT) device properties can be improved by increasing the density and alignment of tubes and avoiding the problems associated with random networks. Plastic devices with a 5 µm channel length and a 22.5 mm width were prepared with approximately 1 channel crossing tube per 4 µm of width. The density is improved by repeatedly printing more CNT’s to the same area. The metallic tubes were removed by selective electrical breakout, marginally increasing the on/off current ratio while decreasing the On current from 800µA to 450µA (at Vgs=−20V, Vds=−10V). Results from optimized devices prepared with patterned iron as the growth catalyst will also be presented.

12:27PM B36.00007 ABSTRACT WITHDRAWN

12:39PM B36.00008 Textured Network Devices: Overcoming Fundamental Limitations of Nanotube/Nanowire Network-based devices¹, MINBAEK LEE, SEUNGHUN HONG, Department of Physics and Astronomy, Seoul Natl University, Seoul, Korea, MEG NOAH, YOUNG-KYUN KWON, Department of Physics and Applied Physics, University of Massachusetts, Lowell MA, USA, JUNE PARK, MAENG-JE SEONG, Department of Physics, Chung-Ang University, Seoul, Korea — Thin film devices based on single-walled carbon nanotube (swCNT) networks were extensively studied for various practical applications such as transistors, sensors, etc. However, those devices have been suffering various limitations such as poor on-off ratio due to metallic swCNTs in the networks, decreased mobility and conductance for devices with reduced linewidth due to the percolation problem, etc. Herein, we present a simple but efficient strategy to significantly improve the performance of swCNT network devices by controlling the network structures. In this strategy, surface molecular patterns were utilized to prepare swCNT network-based devices with desired connectivity. We will discuss systematic study about the effect of swCNT network connectivity, as well as enhancements of on-off ratio, mobility and conductance of textured network-based transistors.

12:51PM B36.00009 CMOS-analogous wafer-scale nanotube-on-insulator approach for submicron devices and integrated circuits using aligned nanotubes, KOUCHMIN RYU, ALEXANDER BADMAEV, CHUAN WANG, CHONGWU ZHOU, University of Southern California — Massively aligned carbon nanotubes hold great potential but also face significant integration / assembly challenges for future beyond-silicon nanoelectronics. We report our recent advance on full wafer-scale processing of massively aligned carbon nanotube arrays for high performance submicron channel transistors and integrated nanotube circuits, including the following essential components. 1) The massively aligned nanotubes were successfully grown on 4 inch quartz and sapphire wafers via a unique temperature control, and then transferred onto Si/SiO₂ wafers using our facile transfer printing method. 2) Wafer-scale device fabrication was performed on 4 inch Si/SiO₂ wafer to yield submicron channel transistors and circuits with high on-current density ~ 20 µA/µm and good on/off ratio. 3) Chemical doping methods were successfully demonstrated to get CMOS inverters with a gain ~5. 4) Defect-tolerant circuit design for NAND and NOR was proposed and demonstrated to guarantee the correct operation of logic circuits, regardless of the presence of mis-aligned or mis-positioned nanotubes.

1:03PM B36.00010 A Novel Fabrication Method for Pristine Suspended Carbon Nanotube Devices², VINO SANGWAN, VINCENT BALLAROTTO, MICHAEL FUHRER, ELLEN WILLIAMS, University of Maryland — A simple and scalable method has been developed to fabricate suspended carbon nanotube (CNT) field effect transistors using as-grown CNTs without subsequent chemical processing. A printing process is used to transfer CVD-grown CNTs onto specially configured electrode (Au) sets fabricated on SiO₂. The versatility of the technique is demonstrated by controlling the number of suspended CNTs per device, and by re-using the same electrode set multiple times to produce the desired device characteristics. The quality of suspended CNTs is characterized by electrical transport as well as 1/f noise measurements. Standard resist-processed CNTs on SiO₂ substrates show p-type behavior and strong hysteresis associated with doping by the SiO₂ surface and charge trapping in the SiO₂., respectively. In contrast, suspended CNTs show ambipolar behavior with negligible hysteresis. Low frequency noise measurements on suspended CNT show 1/f behavior with Hooge’s constant 2.6 x 10⁻³, around 20 times less than that of CNTs lying on SiO₂, consistent with reduced effect of the SiO₂ charge traps, responsible for the bulk of the noise in CNTs on SiO₂.

²V. K. Sangwan et al, APL 93, 113112 (2008)
We present the observation of unidirectional electric current through as-grown single-walled carbon nanotubes (SWNTs) grown by catalytic chemical vapor deposition (CCVD) process. Long strands of as-grown SWNTs were utilized to fabricate multiple arrays of switching devices with the channel length of 3, 5, 7 and 10 μm on a 15 mm x 15 mm SiO₂ on Si substrate. Of the fabricated devices, ~ 34% exhibited electrical activity. Of the active devices, about 70% exhibited diode-like unidirectional current, not observed previously in CCVD grown SWNTs. High resolution atomic force microscopic (AFM) analysis of the device structure and surface topology of SWNTs suggests the observed unidirectional current to result from surface irregularities and change in the chirality along the tube axis.

1:27PM B36.00012 Gate Controlled Negative Differential Resistance and Photoconductivity Enhancement in Carbon Nanotube Intra-connects. SEON WOO LEE, Electronic Imaging Center at NJIT and the Electrical and Computer Engineering Department, New Jersey Institute of Technology (NJIT), Newark, NJ 07102, SLAVA ROTKIN, Physics Department and CAMN, Lehigh University, Bethlehem, PA 18015, ANDREI SIRENKO, Physics Department, New Jersey Institute of Technology (NJIT), Newark, NJ 07102, HAIM GREBEL, Electronic Imaging Center at NJIT and the Electrical and Computer Engineering Department, New Jersey Institute of Technology (NJIT), Newark, NJ 07102. — Field effect transistors were fabricated using carbon nanotube (CNT). Gate-controlled, N-shaped negative differential resist (NDR) has been demonstrated. In addition, a large photoconductance effect was associated with the NDR. The intra-connects – bridges spanning across planar electrodes and contain individual tube or in a small bundle – were grown using chemical vapor deposition (CVD) precisely between very sharp metal tips on the pre-fabricated electrodes. NDR was observed for intra-connects exhibiting either, ohmic or, non-ohmic contacts. Yet, the enhanced photoconductivity was more pronounced for intra-connects exhibiting ohmic contact at zero gate bias.

1:39PM B36.00013 Magnetic Carbon Nanotubes: Materials Development and Property Characterization. DEREJE SEIFU, Department of Physics, Morgan State University, Baltimore, MD 21251, USA, SHASHI KARNA, US Army Research Laboratory, Weapons and Materials Research Directorate, ATTN: AMSRD-ARL-WM, Aberdeen Proving Ground, MD 21005-5069, USA. — A versatile chemical method was used to fill multi-wall carbon nanotubes (MWNTs) with ferromagnetic nanoparticles [1]. For the first time, pulsed laser deposition and magnetron DC sputtering were used to fill vertically aligned MWNTs. The later approaches gave high-yield nanoparticle filling of MWNTs. Samples were characterized by Electron Microscopy, Energy Dispersive Spectroscopy, Mössbauer Spectroscopy, and magnetization measurements. Mössbauer measurements on chemically impregnated MWNTs clearly show the presence of atomic Fe as well as mixed phases of Fe nano-particles inside the tubes. Magnetization measurements on PLD-filled vertically aligned MWNTs indicate reasonable coercivity. However, the magnetic anisotropy appears to be randomly oriented, suggesting polycrystalline sample. Acknowledgement: The research at Morgan State University was partially supported by the US ARL-WMRD (W1813LT-5006-7056).

1:51PM B36.00014 Electrical and Thermal Properties of Oriented Multiwall Carbon Nanotube Bulk Materials. KEQUIN YANG, Clemson University, JIAN HE, ZHE SHU, APPARAO RAO, DEPARTMENT OF PHYSICS AND ASTRONOMY; COMSET, CLEMSON UNIVERSITY, CLEMSON, SC, 29634. — Millimeter long vertically oriented multiwall carbon nanotube (MWNT) arrays with typical tube diameter around 30-50 nm were grown on Si substrates using thermal chemical vapor deposition. The arrays were realigned and densified using a spark plasma sintering process to form oriented MWNT bulk samples. Electron microscopy studies on the as-prepared bulk samples corroborate that the MWNTs are fairly well aligned and the pristine tubular morphology of the MWNTs is preserved during the sintering. The temperature dependent electronic, thermal power and thermal conductivity measurements were performed along different directions relative to the preferred orientation of MWNTs. In particular, the longitudinal and transverse thermal conductivity at 300 K are found to be about 35 W/(mK) and 1 W/(mK), respectively. In the temperature regime between 10 – 300 K, the electrical resistivity is on the order of few mΩcm and exhibits a thermal excitation type temperature dependence, while the Seebeck coefficient is on the order of few μV/K and exhibits a weak temperature dependence. These results give new insights into the unique electrical and thermal transport mechanisms in and between MWNTs.

11:15AM B37.00001 Phase-Space Explorations in Time-Dependent Density Functional Theory. NEEPA MAITRA, Hunter College and the Graduate Center of the City University of New York — Time-Dependent Density Functional Theory is increasingly popular for calculating excitation and response properties of atoms, molecules, clusters and solids. It has achieved an unprecedented balance between accuracy and efficiency for a wide range of systems, but not all. Although not limited to the linear response regime, there are particular challenges for applications to strong-field processes; for example obtaining momentum distributions, certain electronic quantum control problems, and including memory-dependence necessary in the functional dependence. In this talk we will discuss some of these, and introduce a new extension of the theory where the basic variable is the phase-space density W(r,p,t) (that contains information on both the co-ordinate- and momentum distributions of the electrons), instead of the usual co-ordinate space density n(r,t), to deal with these challenges.

11:51AM B37.00002 Time-dependent density-functional theory for electronic excitations in materials. CARSTEN A. ULLRICH, University of Missouri — There is currently an intense effort underway to study the optical properties of bulk and nanostructured materials using time-dependent density-functional theory (TDDFT). This talk will discuss challenges and recent advances of TDDFT in this area, and present some new applications to excitonic effects in bulk insulators and to collective charge- and spin-density excitations in doped quantum wells. A TDDFT version of the semiconductor Bloch equations is presented, which describes ultrafast electron dynamics, including excitonic effects, in insulators and semiconductors. From this, an excitonic Wannier equation is derived featuring a nonlocal effective electron-hole interaction determined by long-range exchange-correlation effects. Excitonic binding energies are calculated for several direct-gap insulators. The spin Coulomb drag (SCD), which constitutes an intrinsic source of dissipation for spin currents in metals and semiconductors, originates as a dynamical exchange-correlation effect in time-dependent current-DFT. We develop a linear-response description of collective spin-density excitations in quantum wells including SCD as well as Rashba and Dresselhaus spin-orbit coupling, and show that spin plasmon line widths in quantum wells allow a purely optical, quantitative measurement of the SCD effect.

recently developed an efficient many-pole model of the GW self-energy based calculations of dielectric response using a real-space Green’s function approach. The model is applied a posteriori to Kohn-Sham calculations of excited state spectra using a convolution of the spectrum with an energy dependent Lorentzian. The method is found to be widely applicable over a broad range of energies, with little computational cost. Several illustrative examples are presented which show improved agreement between theoretical calculations and experiment for both optical and x-ray spectra.

12:51PM B37.00005 Tailoring High-Order Harmonics: A Computational Approach Based on Time-Dependent Density-Functional Theory. ALBERTO CASTRO, DEPARTMENT OF PHYSICS, FREE UNIVERSITY OF BERLIN, ALI AKBARI, ANGEL RUBIO, Universidad del Pais Vasco, EBERHARD GROSS, Department of Physics, Free University of Berlin — Atoms and molecules react in complex manners when they are irradiated with high-intensity electromagnetic pulses: multi-photon, tunneling and over-the-barrier ionisation, laser driven photo-induced isomerisations or fragmentations, and high harmonic generation are some of the non-linear effects that are observed. The so-called pulse shaping techniques can be used to design pulses that produce a desired effect. A technologically appealing possibility is to tailor the harmonic emission spectrum: enhancement of some given orders, supression of others, etc. We have undertaken the task of exploring this possibility from a theoretical point of view, by making use of time-dependent density-functional theory to describe the electrons, a real-space numerical representation, and various optimization techniques.

1:03PM B37.00006 Ab initio calculations of optical spectra by solving the Bethe-Salpeter equation without empty states. Work1, DARIO ROCCA, DEYU LU, GIULIA GALLI, University of California, Davis — We present a novel first principle approach to solve the Bethe-Salpeter equation (BSE) that builds on recent progress in time-dependent density functional perturbation theory [1], and uses an eigenvalue decomposition representation of the dielectric matrix [2]. This approach does not require the explicit calculation of excited single particle electronic states, making it suitable for calculations involving large basis sets and/or a large number of transitions. The numerical solution of the BSE is obtained through a generalized, non-Hermitian Lanczos iterative algorithm and does not require the use of the Tamm-Dancoff approximation. Furthermore, since Lanczos coefficients are frequency independent, optical spectra may be obtained in a very broad energy range. The efficiency and accuracy of the new approach are demonstrated by calculating the optical properties of silicon nanoclusters with up to 1 nm diameter. [1] D. Rocca, R. Gebauer, Y Saad, and S. Baroni, J. Chem. Phys. 128, 154105 (2008). [2] H.Wilson, F.Gygi and G.Galli, Phys. Rev. B, 78:113303 (2008).

1:15PM B37.00007 Time-dependent transition densities2, YONGHUI LI, CARSTEN A. ULLRICH, University of Missouri — To visualize and interpret the induced charges and electron-hole coherences of electronic excitations in molecules, a real-space density matrix analysis is a useful computational tool. We extend this technique into the nonlinear, real-time domain and define the time-dependent transition densities in the context of time-dependent density-functional theory. This opens up the possibility of a real-time monitoring of the optical excitation dynamics in molecules, providing a visualization tool for processes such as exciton migration or charge-transfer excitations. The method will be illustrated for simple one-dimensional model systems.

12:27PM B37.00008 Is the Kohn-Sham Oscillator Strength Exact at the Ionization Threshold?1, ZENGHUI YANG, University of California, Irvine, CA 92697, USA, META VAN FAASSEN, Afdeling Theoretische Chemie, Vrije Universiteit, De Boelelaan 1083, 1081 HV Amsterdam, Kingdom of the Netherlands, KIERON BURKE, University of California, Irvine, CA 92697, USA — It is well-established that the highest occupied orbital of the exact Kohn-Sham potential of any system is at -\epsilon, where \epsilon is the ionization energy. Therefore, in optical response, the non-interacting Kohn-Sham electrons in the ground-state potential have a first ionization threshold that exactly matches that of the real system[1]. We show that corresponding the Kohn-Sham oscillator strength is not exact at the first ionization threshold by explicit demonstration for the helium atom. We use a simple fit of the entire photoabsorption spectrum of both the Kohn-Sham potential for helium and that of real helium. We use oscillator strength sum rules[2] to determine the fit parameters, so this fit should be generally useful. [1] M. A. L. Marques, C. A. Ullrich, F. Nogueira, et al. In density functional theory (DFT), the exchange-correlation functional \( E_{\text{XC}} \) can be exactly expressed by the adiabatic connection integral \([1,2]\). The integrand should satisfy several exact conditions \([3]\). We show that for the low-density limit (as \( \lambda \to \infty \)), the \( \lambda^{-2} \) term in the expansion of the integrand \( W(\lambda) \) should vanish. We propose a simple parametric form for \( W(\lambda) \), satisfying the new exact condition. We apply this interpolation form to Hooke’s atom and helium atom and show that it is accurate for weakly-correlated two-electron systems.

1. 1:39PM B37.00009 An Exact Condition for the Integrand of Adiabatic Connection
ZHENFEI LIU, KIERN BURKE, University of California, Irvine — In density functional theory (DFT), the exchange-correlation functional \( E_{\text{XC}} \) can be exactly expressed by the adiabatic connection integral \([1,2]\). The integrand should satisfy several exact conditions \([3]\). We show that for the low-density limit (as \( \lambda \to \infty \)), the \( \lambda^{-2} \) term in the expansion of the integrand \( W(\lambda) \) should vanish. We propose a simple parametric form for \( W(\lambda) \), satisfying the new exact condition. We apply this interpolation form to Hooke’s atom and helium atom and show that it is accurate for weakly-correlated two-electron systems.

1. 1:51PM B37.00010 New exact and approximate forms for the Luttinger-Ward correlation energy functional within the GW-RPA approximation
SOHRAB ISMAIL-BEIGI, Department of Applied Physics and Center for Research on Interface Structures and Phenomena (CRISP), Yale University — In principle, many-body Green’s function approaches to electronic systems such as the Luttinger-Ward formalism allow one to compute both total energies and quasiparticle excitation spectra (i.e. band structures) simultaneously from first principles. We report on two new results that reformulate the Luttinger-Ward correlation energy functional within the GW-RPA approximation. A first expression is exact and allows for systematic and straightforward evaluation of correlation energies. The second expression is approximate but yields a family of computationally efficient approximations to the correlation energy and the self-energy operator of which the well known Coulomb-hole and screened-exchange (COHSEX) approximation is the lowest order.

2. 2:03PM B37.00011 Non-empirical hyper-generalized-gradient functionals constructed from the Lieb-Oxford bound
MARIANA M. ODASHIMA, KLAUS CAPELLE, Universidade de Sao Paulo — A simple and completely general representation of the exact exchange-correlation functional of density-functional theory is derived from the universal Lieb-Oxford bound for Coulomb-interacting systems. This representation leads to an alternative point of view on popular hybrid functionals. A similar representation of the exact correlation functional allows to construct a family of non-empirical hyper-generalized-gradient approximations (HGGAs), departing from established paradigms of functional construction. Numerical tests and applications of these HGGAs to atoms and molecules demonstrate that even simple Lieb-Oxford based HGGAs are competitive with correlation functionals currently used in solid-state physics and quantum chemistry.

Session B38 DCP: Focus Session: The Chemical Physics of Biological and Biologically-inspired Solar Energy Harvesting II 410

11:15AM B38.00001 Coherence and Decoherence in the Excited States of Light Harvesting Complexes
ROBERT J. SILBEY, Massachusetts Institute of Technology — No abstract available.

11:51AM B38.00002 Electronic coherence in electronic energy transfer despite fast dephasing
GREGORY SCHOLES, University of Toronto — Förster resonance energy transfer (FRET) is a common and fundamental photophysical process in life and materials sciences. FRET is an interchromophore relaxation process that transmits the electronic exciton from an initially excited donor to a ground state acceptor chromophore (light-absorbing molecule). FRET is used, for example, to harvest light in photosynthesis, measure distances in proteins, and it accelerates the photodegradation of polymers. In recent years attention has turned to the study of FRET in complex assemblies of molecules. While Förster theory has enabled the efficiency of FRET to be predicted and analyzed in numerous and diverse areas of study, recent work has aimed to discover ways beyond the Förster mechanism by which electronic energy can be transferred. The talk will compare and contrast theoretical and experimental studies of excitation relaxation in photosynthetic antenna systems with the conjugated polymer poly[2-methoxy,5-(2’-ethyl-hexoxy)-1,4-phenylenevinylene] (MEH-PPV). I will report new work where we have used a new anisotropy experiment to examine coherent energy transfer and a complementary technique using two-dimensional electronic spectroscopy expose the role of coherence transfer in the fastest time dynamics. We find that coherent energy transfer occurs for many tens of femtoseconds, even at room temperature. That leads us to examine the nature and implications of the so-called intermediate coupling regime for EET.

12:27PM B38.00003 Photosynthetic nanoparticle complexes
ALEXANDER GOVOROV, Ohio University — We investigate structures composed of a photosynthetic molecule and a semiconductor (metal) nanoparticle \([1]\). The rate of optical generation of electron-hole pairs inside a photosynthetic system can be greatly increased through conjugation with nanoparticles. In the case of a semiconductor nanoparticle, the enhancement effect comes from the essentially larger optical absorption cross-section of a semiconductor nanoparticle compared to a photosynthetic system. In this hybrid complex, excitons are transferred via the Förster mechanism to the photosynthetic system, where charge separation takes place. For metal nanoparticles conjugated with a photosynthetic system, we predicted a strong enhancement effect due to the plasmon resonance. Such an enhancement effect was recently observed at Munich U. \([2]\). In summary, we have shown that one can use crystalline nanoparticles to create a 10-fold enhancement of the initial stage of photosynthesis, i.e. the absorption process. Potential applications of nanocrystal complexes are in light-harvesting. \([1]\) A. O. Govorov and I. Carmeli, Nano Lett. 7, 620 (2007); \[2\] S. Mackowski, S. Wörnke, A.J. Maier, T.H.P. 12:39PM B38.00004 Quantum coherence, decoherence and entanglement in light harvesting complexes, MARTIN PLENIO, FILIPPO CARUSO, Imperial College London, ALEX CHIN, University of Hertfordshire, ANIMESH DATTA, Imperial College London, SUSANA HUELGA, University of Hertfordshire — Transport phenomena in networks allow for information and energy to be exchanged between individual constituents of communication systems, networks or light-harvesting complexes. Environmental noise is generally expected to hinder transport. Here we show that transport of excitations across dissipative quantum networks can be enhanced by dephasing noise. We identify two key processes that underly this phenomenon and provide instructive examples of quantum networks for each. We argue that Nature may be routinely exploiting this effect by showing that exciton transport in light harvesting complexes and other networks benefits from noise and is remarkably robust against static disorder. These results point towards the possibility for designing optimized structures for transport, for example in artificial nano-structures, assisted by noise. Furthermore, we demonstrate that quantum entanglement may be present for short times in light-harvesting complexes. We describe how the presence of such entanglement may be verified without the need for full state tomography and with minimal model assumptions. This work is based on M.B. Plenio & S.F. Huelga, New J. Phys. 10, 113019 (2008) and F. Caruso, A. Chin, A. Datta, S.F. Huelga & M.B. Plenio, in preparation.

12:51PM B38.00005 Non-radiative decay processes in InAs nanocrystals, MARCO CALIFANO, University of Leeds — The mechanisms governing excited state relaxation in semiconductor nanocrystals (NCs) are still not well understood. The validity of the Auger electron cooling and multiexciton recombination hypotheses, which would explain much of the experimental data available to date, has recently been questioned. Moreover the recent observation of sub-picosecond electron relaxation times and bimolecular recombination rates of the order of 0.1-1 ps in InAs, although qualitatively ascribed to Auger processes, still awaits a quantitative theoretical interpretation. Multiexciton recombination is particularly important as its signatures are used to detect and quantify carrier multiplication efficiency in NCs. Furthermore efficient non-radiative (multi-)exciton decay represents a major obstacle for application of NCs in lasing and photovoltaics. A quantitative theoretical understanding of these processes is therefore critical for any technological implementation of quantum-dot-based devices. The results of a detailed investigation using the pseudopotential method provide an explanation of the observed lifetimes in terms of Auger-like decay mechanisms, supporting the Auger interpretation of excited state relaxation in NCs.

1:03PM B38.00006 Exciton Transport Simulations in Phenyl Cored Thiophene Dendrimers, KWISEON KIM, MUHAMMET ERKAN KOSE, PETER GRÅF, NIKOS KOPIDAKIS, GARRY RUMBLES, National Renewable Energy Laboratory, SEAN E. SHAHEEN, University of Denver — Phenyl cored 3-arm and 4-arm thiophene dendrimers are promising materials for use in photovoltaic devices. It is important to understand the energy transfer mechanism in these molecules to gain insight into the synthesis of novel dendrimers with improved efficiency. A method is developed to estimate the exciton diffusion lengths for the dendrimers and similar chromophores in amorphous films. The approach exploits Fermi's Golden Rule to estimate the energy transfer rates for an ensemble of bimolecular complexes in random orientations. Using Poisson's equation to evaluate Coulomb integrals, we are led to efficient calculation of excitonic couplings between the transition densities. Monte-Carlo simulations revealed the dynamics of energy transport in the dendrimers. Experimental exciton diffusion lengths of the dendrimers range 10-20 nm, increasing with the size of the dendrimer. Simulated diffusion lengths correlate well with experiments. The chemical structure of the chromophore, the shape of the transition densities and the exciton lifetime are found to be the most important factors that determine the exciton diffusion length in amorphous films.

1:15PM B38.00007 Efficient and Long-lived Charge Separation in a Heteroleptic Ruthenium(II) Polypyridyl Complex, JOSEPH HENRICH, HAOYU ZHANG, JEREMY WHITE, PRABIR DUTTA, BERN KOHLER, The Ohio State University — The excited-state dynamics of a tris-bidentate mononuclear ruthenium(II) complex, [(bpy)2RuL4]3+ (where bpy = bipyridine, L4-DQ = 1-[4-(4'-methyl)-2,2'-bipyridyl]) was investigated by femtosecond transient absorption spectroscopy in bulk solution and tethered to a zeolite nanocrystal. [(bpy)2RuL4]3+ is a promising photosensitizer molecule for artificial photosynthesis. Broadband transient absorption experiments in bulk acetone and liquid helium matrices revealed that excitation of the MLCT absorption band transfers an electron within one picosecond from the metal center to the bipyridinium (DQ) ligand. Back electron transfer then takes place with a time constant of 1.45 ns. Highly efficient charge separation is attributed to the conjugated nature of the bipyridinium-terminated ligand. When [(bpy)2RuL4]3+ is tethered to a zeolite Y particle, charge can be transferred to a methyl viologen molecule encapsulated in the zeolite. Zeolites are promising materials for solar energy conversion because of their ability to slow rates of charge recombination. The effects of the zeolite on the photoprocesses of the ruthenium polypyridyl complex will be presented.

1:27PM B38.00008 First-Principles Studies of Single-Molecule Photovoltaics, PETER DOAK, UC Berkeley Chemistry, R. A. SEGALMAN, UC Berkeley Chemical Engineering, T. D. TILLEY, UC Berkeley Chemistry, J. B. NEATON, LBNL Molecular Foundry — Organic photovoltaics consist of electron donor and acceptor polymers or molecules blended together, and are promising inexpensive, lightweight alternatives to conventional silicon solar cells. However, many of the physical processes responsible for their poor efficiencies are not well understood. Here, using first-principles calculations based on density functional theory, including self-energy corrections within the GW approximation and a discussion of excitonic effects, we examine the relationship between molecular structure and electronic level alignment at a covalent donor-acceptor interface. We consider small asymmetric molecules subdivided into discrete covalently linked moieties based on thiophene, tetrafluorobenzene, pyridine, and durene. Excited states of each of these moieties, as well as their covalently-linked combinations, are computed and discussed in the context of their ability to absorb photons and separate charge. Work supported in part by the DOE Helios SERC. Computational resources provided by NERSC.

1:39PM B38.00009 Intramolecular Interactions in Novel Macrocyclic Materials, THEODORE GOODSON, University of Michigan — In this presentation I will report a strongly interacting new dendrimer system with an extended spectroscopic unit (coherent domain) beyond the trimer configuration. Strong cooperative enhancement of two-photon absorption cross-section was observed when going from the trimer arrangement to the next generation. Combination of a variety of femtosecond spectroscopy methods such as femtosecond time-resolved fluorescence upconversion, transient absorption, transient grating, three pulse photon echo peak shift experiments complemented with those of steady state spectroscopy allowed us to compare the properties of absorption states with those of fluorescence states, to estimate the reorganization energies, and the extent of inhomogeneous broadening. Our measurements indicated that spectroscopic units in this dendrimer are different for the trimer system and for the dendrimers of higher generation numbers. This coherent domain extends over the trimer geometry and its size is comparable with the size of the dendrimer G1 comprising nine linear segments. We have also investigated the novel applications of a two-dimensional carbon network structure's building blocks. The material shows very interesting two-photon absorption properties as well as strongly coupled optical excitations. They have also been suggested as good building blocks for molecular electronics applications.
The force-velocity relation of growing actin filaments. A simple model based on entropic forces seems to explain our observations. Protrusions at the cell surface and leads to cell motility. Using magnetic colloids, we measure how the chemical reaction of polymerization generates mechanical interactions.

CARLIER, JEROME BIBETTE, LCMD, ESPCI TEAM, PMMH, ESPCI TEAM, LEBS, CNRS TEAM, NYU PHYSICS TEAM — Actin polymerization drives study cytoskeletal dynamics during the spreading process. Actin filaments spontaneously organized into a variety of structures including traveling waves, target reflection contrast microscopy. We found that the spread area exhibited a sigmoidal growth as a function of time in contrast to the previously proposed universal contribution to the processes involved in the interaction with the substrate, such as the elastic response and adhesion.

A single cell and put it in contact with an adhesive surface mounted on a translation stage. The spring constant of the micropipette is carefully measured and its mechanical contributions of intercellular junctions and focal adhesions while also providing insight into the important materials properties and length scales that govern cell sheet responses.

11:27AM B39.00002 Locomotion of C. elegans through jammed granular media, KEVIN LU, PAULO E. ARRATIA, University of Pennsylvania — It is quantitatively demonstrated in this experiment on the undulatory swimming of C. (Caenorhabditis) elegans that, in a highly-resistive media, the animal only executes beating frequencies and amplitudes in discrete values. This behavior of C. elegans is inferred from the peaks in the particle velocity distributions where the most probable velocities match the transverse velocities of the nematode body. The behavior in the velocity distribution is more pronounced for particles in denser arrangements and for those closer to the thrashing gait of the worm. These results contribute to the existing data on the worm locomotion and further facilitate the identification of the endogenous genes and neural circuitry to the exogenous behavioral responses of C. elegans.

11:39AM B39.00003 Mechanics of an Ultrafast Cellular Contraction, GAURAV MISRA, RICHARD B. DICKINSON, TONY LADD, University of Florida — Vorticella Convallaria is one of a class of fast-moving organisms, traversing its body size in less than a millisecond. It has two main parts, the cell body and a stalk, which attaches the cell body to the substrate. The stalk houses a slender, elastic structure called Spasmoneme, which winds helically inside the stalk and generates a strong tensile force in response to Calcium signaling. We are developing numerical simulations of the collapsing stalk to quantify the magnitude and time scale of the force generation. We have coupled a Kirchhoff model of an elastic rod (representing the stalk) with an embedded helically wound filament (representing the Spasmoneme). Contraction of this assembly is driven by a constant velocity Calcium signal that induces a state of tension in the Spasmoneme. Depending on the speed of the Calcium signal, we observe different mechanical responses from the contracting stalk, which we compare with experimental observations. We follow the interplay of contraction, twist and bend to explain some unexpected features of the retraction process. Two different macroscopic models have been proposed to explain the time-dependent velocity of the cell body; we compare the predictions of these models with the dynamics revealed by our filament model.

11:51AM B39.00004 Polymer Microlenses for Quantifying Cell Sheet Mechanics, GUILLAUME MIQUELARD-GARNIER, University of Massachusetts Amherst, JESSICA ZIMBERLIN, PATRICIA WADSWORTH, ALFRED CROSBY — Mechanical interactions between individual cells and their substrate have been studied extensively over the past decade; however, our understanding of how these interactions change as cells interact with neighboring cells in the development of a cell sheet, or early stage tissue, is less developed. We present a recently developed experimental technique for quantifying the mechanics of confluent cell sheets (Zimberlin J.A., et al., Cell Motility and the Cytoskeleton, 65, 9, 762). Living cells are cultured on a thin film of polystyrene [PS], which is attached to a patterned substrate of crosslinked poly(dimethyl siloxane) microwells. As the cell sheet grows, cells apply sufficient force to buckle the PS film over individual microwells to form a microlens array. The curvature for each microlens is measured by confocal microscopy and can be related to the strain and stress applied by the cell sheet. We demonstrate that this technique can be used to decouple mechanical contributions of intercellular junctions and focal adhesions while also providing insight into the important materials properties and length scales that govern cell sheet responses.

12:03PM B39.00005 Why is Actin Patchy?, ANDERS CARLSSON, Washington University in St. Louis — The intracellular protein actin, by reversibly polymerizing into filaments, generates forces for motion and shape changes of many types of biological cells. Fluorescence imaging studies show that actin often occurs in the form of localized patches of size roughly one micrometer at the cell membrane. Patch formation is most prevalent when the free-actin concentration is low. I investigate possible mechanisms for the formation of actin patches by numerically simulating the “dendritic nucleation” model of actin network growth. The simulations include filament growth, capping, branching, severing, and debranching. The attachment of membrane-bound activators to actin filaments, and subsequent membrane diffusion of unattached activators, are also included. It is found that as the actin concentration increases from zero, the actin occurs in patches at lower actin concentrations, and the size of the patches increases with increasing actin concentration. At a critical value of the actin concentration, the system undergoes a transition to complete coverage. The results are interpreted within the framework of reaction-diffusion equations in two dimensions.

12:15PM B39.00006 Direct dynamical measurement of the cytoskeletal contribution to the adhesion and mechanics of living cells, MARIE-JOSEE COLEBRT, CECILE FRADIN, KARI DALNOKI-VERESS, Department of Physics and Astronomy, McMaster University — The cytoskeleton is involved in the interaction of the cell with its surroundings through adhesion and the elastic response of the cell. To dynamically probe these properties, we have developed a new tool that takes advantage of an ‘L’-shaped micropipette to micromanipulate a single cell and put it in contact with an adhesive surface mounted on a translation stage. The spring constant of the micropipette is carefully measured and its deflection is used to apply a calibrated force. This technique gives access to real time monitoring of the cell response to an applied deformation, thus exploring the relaxation processes of the cell when subjected to an external load. The polymerization of actin and microtubules is prevented to explore the cytoskeletal contribution to the processes involved in the interaction with the substrate, such as the elastic response and adhesion.

12:27PM B39.00007 Force generated by polymerization of actin filaments: an entropic role?, JEAN BAUDRY, CORALINE BRANGBOUR, OLIVIA DU ROURE, EMMANUELE HELFER, MARC FERMIGIER, PAUL M. CHAIKIN, MARIE-FRANCE CARLIER, JEROME BIBETTE, LCMD, ESPCI TEAM, PMMH, ESPCI TEAM, LEBS, CNRS TEAM, NYU PHYSICS TEAM — Actin polymerization drives protrusions at the cell surface and leads to cell motility. Using magnetic colloids, we measure how the chemical reaction of polymerization generates mechanical forces. Rapid force-distance measurement gives us access to the forces that control the migration of colloids, whereas long experiments at constant forces give the force-velocity relation of growing actin filaments. A simple model based on entropic forces seems to explain our observations.

12:39PM B39.00008 Cytoskeleton mediated spreading dynamics of immune cells, KING-LAM HUI, JESSICA WANT, BRIAN GROOMAN, ARPITA UPADHYAYA, Department of Physics, University of Maryland — We have studied the spreading of Jurkat T-cells on anti-CD3 antibody-coated substrates as a model of immune synapse formation. Cell adhesion area versus time was measured via interference reflection contrast microscopy. We found that the spread area exhibited a sigmoidal growth as a function of time in contrast to the previously proposed universal power-law growth for spreading cells. We used high-resolution total internal reflection fluorescence microscopy of these cells transfected with GFP-actin to study cytoskeletal dynamics during the spreading process. Actin filaments spontaneously organized into a variety of structures including traveling waves, target patterns, and mobile clusters emanating from an organizing center. We quantify these dynamic structures and relate them to the spreading rates. We propose that the spreading kinetics are determined by active rearrangements of the cytoskeleton initiated by signaling events upon antibody binding to T-cell receptors. Membrane deformations induced by such wave-like organization of the cytoskeleton may be a general phenomenon that underlies cell movement and cell-substrate interactions.
12:51PM B39.00009 How deep cells feel: Mean-field Computations and Experiments, AMNON BUXBOIM, SHAMIK SEN, University of Philadelphia, DENNIS E. DISCHER1 — Most cells in solid tissues exert contractile forces that mechanically couple them to elastic surroundings and that significantly influence cell adhesion, cytoskeletal organization and differentiation. However, strains within the depth of matrices are often unclear and are likely relevant to thin matrices, such as basement membranes, relative to cell size as well as to defining how far cells can "feel." We present experimental results for cell spreading on thin, ligand-coated gels and for prestress in stem cells in relation to gel stiffness. Matrix thickness affects cell spread area, focal adhesions and cytoskeleton organization in stem cells, which we will compare to differentiated cells. We introduce a finite element computation to estimate the elastic deformations within the matrix on which a cell is placed. Interfacial strains between cell and matrix show large deviations when soft matrices are a fraction of cell dimensions, proving consistent with experiments. 3-D cell morphologies that model stem cell derived neurons, myoblasts, and osteoblasts show that a cylinder-shaped myoblast induces the highest strains, consistent with the prominent contractility of muscle. Groups of such cells show weak crosslink via matrix strains only when cells are much closer than a cell-width. Cells thus feel on length scales closer to that of adhesions than on cellular scales.

1University of Philadelphia

1:03PM B39.00010 Tether extrusion from biomimetic cells, KARINE GUEVORKIAN, LÉA LAETITIA PONTANI, CÉCILE SYKES, FRANÇOISE BROCHARD-WYART, Institut Curie — The plasma membrane of a cell is coupled to its underlying cytoskeleton through membrane binding proteins. By pulling membrane tethers, one can measure the strength of these attachments and also probe the rheology of the membrane. In the past, we have used the hydrodynamic tether extrusion technique to study tether dynamics of Red Blood Cells [1]. To describe the non-linear force-velocity behavior at high extrusion forces, we have developed a theoretical model based on lipid permeation through the network of membrane binding proteins [2]. To test this model, we use a biomimetic system consisting of liposomes encapsulating an actin cortex in which the density of membrane-cytoskeleton linkers can be controlled. Here we will present our recent experimental results and compare them to the theoretical predictions. [1] N. Borghi et al, Biophys. J. 93 (2007) [2] F. Brochard-Wyart, et al, Proc. Natl. Acad. Sci. USA, 103 (2006)

1:15PM B39.00011 Mechanics of Nascent Cell Adhesions, CÉCILE O. MEJEAN, ANDREW W. SCHAFFER, PAUL FORSCHER, ERIC R. DUFRESNE, Yale University — Cells have the ability to sense and respond to mechanical and biochemical cues from their environment. In neurons, the binding and restraint of transmembrane cell adhesion molecules (CAMs) can trigger acute periods of axon growth. Preceding growth, the cell must create a stiff mechanical linkage between the CAM and the cytoskeleton. Using holographic optical tweezers, we manipulate CAM-coated beads on the membrane of the cell. We investigate the dynamics of the mechanical properties of this linkage as a function of time, applied force, and CAM density. We find that CAM-coated beads exhibit stochastic intermittent binding to the cytoskeleton. In time, we observed that the adhesions stiffen and their mechanical properties depend on the applied force. Treatment of cells with small molecules that alter cytoskeletal dynamics are used to probe the roles of actin filament assembly and myosin motor activity in adhesion formation.

1:27PM B39.00012 Epithelial Mechanics during Germband Retraction in Fruit Fly Embryogenesis, XIAOYAN MA, HOLLEY E. LYNCH, M. SHANE HUTSON, Dept. of Physics & Astronomy, Vanderbilt University — During germ-band retraction in the early embryonic development of fruit fly embryos, the epithelial cells of the amnioserosa (AS) undergo a dramatic change in cell shape. The average cell aspect ratio reduces from \(\alpha \sim 10\) to \(\sim 1\) within three hours. We performed laser hole-drilling and confocal microscopy to investigate the mechanics of this process in live fly embryos. We find that the laser-induced recoil dynamics of AS cells during germ-band retraction (when \(\alpha \sim 10\)) is dramatically different from that during the later dorsal closure stage (when \(\alpha \sim 1\)). First, in the earliest stage of germband retraction, some AS cells actually shrink instead of expand in the first one second after ablation. After this point, the cells do slowly expand. Second, in either phase, the cell speeds were much slower, in the range of \(\pm 1 \mu m/second\) (compared with speeds in excess of \(10 \mu m/second\) during dorsal closure). Theses results suggest a much smaller tensile mood (and in some cases, compressive) stress in the whole cell sheet in early germband retraction. As retraction proceeds towards dorsal closure, the stresses increase.

1:39PM B39.00013 Matrix elasticity directs stem cell differentiation in 3D too, ALLISON ZAJAC, FLORIAN REHFELDT, DENNIS DISCHER, University of Pennsylvania — Microenvironments appear important in stem cell lineage specification but can be difficult to adequately characterize or control with soft tissues. Naive mesenchymal stem cells (MSCs) are shown here to specify lineage andcommit to phenotypes with extreme sensitivity to tissue level elasticity. Soft matrices that mimic brain microenvironment are more sensitive, stiffer matrices that mimic muscle microenvironment, and comparatively rigid matrices that mimic collagenous bone prove osteogenic. During the initial week in culture, reprogramming of these lineages is possible with addition of soluble induction factors, but after several weeks in culture, the cells commit to the lineage specified by matrix elasticity, consistent with the elasticity-insensitive commitment of differentiated cell types. Inhibition of nonmuscle myosin II blocks all elasticity-directed lineage specification—without strongly perturbing many other aspects of cell function and shape. The results have significant implications for understanding physical effects of the in vivo microenvironment and also for therapeutic uses of stem cells.

1:51PM B39.00014 Cell response to long term mechanical interaction with nanopipettes, ZULFIYA ORYNBAYEVA, Drexel University, RIJU SINGHAL, ELINA VITÖL, MICHAEL BOUCHARD, JANE AZIZKHAN-CLIFFORD, BRADLEY LAYTON, GARY FRIEDMAN, YURY GOGOTSI, KECK INSTITUTE FOR ATTOFLUIDIC NANOTUBE-BASED PROBES TEAM — Traditional microinjection into cells is performed over a relatively short term. Pipettes are typically withdrawn following any kind of injection. On the other hand, there is growing interest in using nanopipettes for cellular and subcellular probing. This interest is partly due to new developments in nanopipette technology which employ carbon nanotubes and provide robustness, flexibility, and biocompatibility. However, as far as we know, no systematic study of physiological, biochemical, and biophysical processes associated with cell response to lengthy mechanical stimulations by nanopipette probing have been performed so far. We present a detailed investigation of a wide range of effects of long term pipette insertion into a cell. Both traditional glass micropipettes and the novel carbon nanotube-tipped probes were involved in this study. The mechanism of Ca2+ response to the mechanical stimuli introduced by the nanopipette, and the role of different organelles in this mechanism were studied. We hypothesize that the calcium response is a function of cytoskeleton integrity and the mode of coupling between the cytoskeleton and the plasma membrane domains.

2:03PM B39.00015 Gold Nanoparticles effect on Human Dermal Fibroblast, TATSIANA MIRONAVA, NADINE PERNOLET, MIRIAM RAFAILOVICH, SUNY at Stony Brook, MATERIAL SCIENCE AND ENGINEERING DEPARTMENT TEAM — Recently many researchers brought to the light the fact that due to high surface/bulk ratio nanoparticles can penetrate unusually deep human organs and cause health problems. Gold nanoparticles are widely used nowadays, however, their effects on cells are still under investigation. Here, we studied the effect of inert citrate/gold nanoparticles as a function of size (13 nm and 45 nm), concentration and time exposure (from 1 to 6 days) on human dermal fibroblasts, since skin is one of the major routes to exposure to nanoparticles. We measured apoptosis rate as a function of nanoparticles size, time exposure and concentration. We found that the presence of 45-nm gold particles had more severe effects on these cells when compared to 13-nm nanoparticles, as the nanoparticles entry use 2 different pathways. In addition the question of cells recovery as a function of time exposure and concentration was investigated.

11:15AM  B40.00001  Amino Acid Free Energy Decomposition  . HUI WANG, MICHAEL FAIRCILD, DENNIS LIVESAY, DONALD JACOBS, University of North Carolina at Charlotte — The Distance Constraint Model (DCM) describes protein thermodynamics at a coarse-grained level based on a Free Energy Decomposition (FED) that assigns energy and entropy contributions to specific molecular interactions. Application of constraint theory accounts for non-additivity in conformational entropy so that the total free energy of a system can be reconstituted from all its molecular parts. In prior work, a minimal DCM utilized a simple FED involving temperature-independent parameters indiscriminately applied to all residues. Here, we describe a residue-specific FED that depends on local conformational states. The FED of an amino acid is constructed by weighting the energy spectra associated with local energy minima in conformational space by absolute entropies estimated using a quasi-harmonic approximation. Interesting temperature-dependent behavior is found. Support is from NIH R01 GM073082 and a CRI postdoctoral Duke research fellowship for H. Wang.

11:27AM  B40.00002  Surface Induced Self-Assembly of Fibrinogen Fibers in the Absence of Thrombin  . JASEUNG KOO, MIRIAM RAFAILOVICH, DENNIS GALANAKIS, Stony Brook University — Wound healing is a complex process imitated by the formation of fibrin fibers that are involved in clot formation and fibrinolysis migration. Normally this process is triggered by thrombin cleavage of the E domain on the fibrinogen molecules, which allows them to spontaneously self-assemble into the fibers. Here we demonstrate that this process can also be initiated in the absence of thrombin. We show that by simply placing the proteins in contact with hydrocarbon functionalized clay surfaces, molecular reorientation occurs which allows fibers to form from the intact fibrinogen protein. Furthermore, using monoclonal antibodies, we determined which regions on the αC domains are involved in the formation of the new fibrinogen fibers. This allowed us to extend these findings to general hydrophobic surfaces, such as those presented by most hydrocarbon polymers. On the other hand, the carbonyl terminal part of the Aα chain, can interact with amine containing polymers, and suppress formation of the fibers.

11:39AM  B40.00003  On the Rate and Mechanism of Proton Transfer Reactions in Proteins1 . AIHUA XIE, YUNXING LI, EDWARD MANDA, BEINING NIE, WOUTER HOFF, Oklahoma State University, RICHARD MARTIN, Los Alamos National Lab — One of the fundamental processes in molecular biology is proton transfer reactions in proteins. Proton transfer is essential for the biological functions of proteins responsible in bioenergetics, biological signaling, and enzymatic catalysis. The mechanism of proton transfer is of great interests in order to understand the structural basis of biological functions. Despite of extensive experimental and computational efforts, it remains elusive what a proton to move from the proton donor to the proton acceptor. We will report a proof of concept study regarding a general mechanism of internal proton transfer reactions in proteins. Density functional theory, B3LYP/6-311+G(2d,p), is employed in this study. The results of our study provide deep insights into the structural basis to the rate and mechanism of proton transfer reactions in proteins, such as bacteriorhodopsin and green fluorescence protein.

11:51AM  B40.00004  Probing the reversibility of the Dscam Dimer with Light Scattering and Colloids  . JESSE COLLINS, Harvard SEAS; DIETMAR SCHMUCKER, Harvard/Dana Farber Cancer Institute, VINOTHAN MANOHARAN, Harvard — Dscam (Down-syndrome cell adhesion molecule) is a fascinating example of the highly specific interactions unique to biomolecules. The extracellular domain is spliced into over 18,000 isoforms. With few exceptions, each isoform, despite conservation of over 95% of amino acid residues between isoforms, binds to itself and to no other in the set. We investigate the effect of salt and pH on the reversibility of this interaction.

12:03PM  B40.00005  Using Fluorescence Spectroscopy to Evaluate Hill Parameters and Heterogeneity of Ligand Binding to Cytochromes P4501 . GLENN A. MARSCH, BENJAMIN CARLSON, JENNIFER HANSEN, ELAINE MIHELC, Grove City College Physics Department, MARTHA V. MARTIN, F. PETER GUENGERICH, Vanderbilt University School of Medicine — The cytochromes P450 (CYPs) are hemoproteins that oxidize many drugs and carcinogens. Binding interactions of two CYPs with Nile Red, pyrene, and alpha-naphthoflavone were studied using fluorescence quenching. Upon interaction with CYPs, fluorescence from pyrene excited-state dimers was quenched more efficiently than fluorescence from pyrene monomers. Quenching data was fit to the Hill equation to determine binding affinities and the Hill parameter n for the interaction of the substrates with CYPs. All ligands showed strong binding to the CYPs, especially alpha-naphthoflavone, but exhibited little or no cooperativity in the interaction. Modified Stern-Volmer plots were used to confirm binding affinities, and suggested heterogeneous populations of amino acid fluorophores. Fluorescence anisotropy experiments suggest that CYP molecules tumble more rapidly when alpha-naphthoflavone is added.

12:15PM  B40.00006  UV Resonance Raman Excitation Profiles and Depolarization Ratios of Peptide Conformations  . BHAVYA SHARMA, SANFORD ASHER, University of Pittsburgh — UV resonance Raman spectroscopy is a well established technique for probing peptide and protein secondary structure. Excitation between 180 to 215 nm, within the π to π* electronic transitions of the peptide backbone, results in the enhancement of amide vibrations. We use UVRIR excitation profiles and depolarization ratios to examine the underlying peptide bond electronic transitions. The present consensus is that three electronic transitions (n to π* and two π to π*) occur in simple amides between 230 and 130 nm. In α-helices a weak n to π* electronic transition occurs at 220 nm, while a higher frequency π to π* transition occurs at 190 nm. This π to π* transition undergoes excitation splitting, giving rise to two dipole-allowed transitions: one perpendicular to the helical axis (190 nm) and the second parallel to the axis (205 nm). The melted state of α-helices resembles left-handed poly-proline II (PPII) helices. The PPII helix electronic transitions have been defined as an n to π* transition at ~220 nm and a π to π* transition at ~200 nm. For beta-sheets, the π to π* transition occurs at ~194 nm for parallel and ~196 nm for anti-parallel sheets. n to π* transition occurs at ~217 nm for both.

12:27PM  B40.00007  UV Resonance Raman Spectral Hydrogen Exchange Studies of Poly-L-Lysine’s Conformation  . LU MA, SANFORD ASHER, University of Pittsburgh — The rate of exchange of peptide backbone NH group with the hydrogen of aqueous solvents is sensitive to the peptide secondary structure. In this work, we use a continuous flow rapid mixing technique and study H/D exchange rates of the model peptide poly-L-lysine (PLL) using UV resonance Raman spectroscopy. Different conformational equilibria of PLL between the helical (α, 310, and -helix) and extended conformations (PPII and 2.5,-helix) are obtained by controlling solvent pH and salt concentration. The Amil’ band of the peptide backbone is used as the deuterium marker. The H/D change rate of PLL provides direct information of the stability of different conformations. Additionally, these results provide insight into backbone conformational fluctuations and how various factors affect the conformation.

12:39PM  B40.00008  Polyglycine in Solution, Random or Ordered?  . SERGEI BYKOV, SANFORD ASHER, University of Pittsburgh — According to the existing theories during folding, the protein backbone undergoes a transition from unordered (random coil) to ordered (native) conformations. Understanding the nature of the unordered state is one of the key problems in protein folding. Some recent investigations indicate that unfolded peptides and proteins in solution form structures close to PPII helices. Glycine based peptides possess greater conformational freedom due to the lack of the side chains. This high flexibility makes polyglycine an important model system for investigating of the conformational preferences of the polypeptides backbone in solution in general and for understanding the nature of the unfolded states in particular. We utilized UV Resonance and Visible Raman spectroscopy to investigate conformational preferences of glycine based peptides of different lengths in water solution at different conditions. We will discuss conformational preferences of the glycine based peptides in solution, and define the major factors which govern these conformational preferences.
1:03PM B40.00010 Hydrodynamic and Conformational Properties of Unfolded Proteins. GUY BERRY, Carnegie Mellon University — Published data on the characterization of unfolded proteins in dilute solutions in aqueous guanidine hydrochloride are analyzed to show that the data are not fit by either the random-flight or wormlike chain models for linear chains. The analysis includes data on the intrinsic viscosity, root-mean-square radius of gyration, from small-angle x-ray scattering, and hydrodynamic radius, from the translational diffusion coefficient. It is concluded that residual structure consistent with that deduced from nuclear magnetic resonance on these solutions can explain the dilute solution results in a consistent manner through the presence of ring-structures, which otherwise have an essentially flexible coil conformation. The ring-structures could be in a state of continual flux and rearrangement. Calculation of the radius of gyration for the random-flight model gives a similar reduction of this measure for chains joined at their endpoints, or those containing loop with two dangling ends, each one-fourth the total length of the chain. This relative insensitivity to the details of the ring-structure is taken to support the behavior observed across a range of proteins.

1:15PM B40.00011 Stability versus flexibility in the dimerization kinetics and thermodynamics of the GCN4 Leucine zipper. DIPAK RIMAL, YANXIN LIU, PREM CHAPAGAIN, BERNARD GERSTMAN, Florida International University, THEORETICAL AND COMPUTATIONAL BIOPHYSICS TEAM — We present results of computer simulations that show that too much stability of the native state can have the unwanted side-effect of slower and less reliable folding. The time spent in non-native configurations depends on both the depth of the valleys in the energy landscape and the probability for visiting various regions of the landscape. We present computational results for dimerization of the GCN4 Leucine zipper in which both the helical propensities and the ionic interactions are varied in strength. The results show that when interactions are too strong, they not only beneficially stabilize the native state, but also stabilize non-native configurations that act as kinetic traps. In some cases, intermediate structures become too rigid that the peptide does not have the flexibility necessary to fold to the native state. In other situations, such as high temperature, the chain has superfluous flexibility and can form non-native bonds. If these non-native bonds are too strong, the peptide spends significant time in contorted non-native configurations and folding is slowed and less efficient. Therefore, efficient folding must be a compromise between stability and flexibility.

1:27PM B40.00012 Intermediate states of globular proteins during temperature-induced folding and unfolding studied using small angle x-ray scattering1. JOSE BANUELOS, New Mexico State University, JACOB URQUI'D, New Mexico State University; LANSE; Los Alamos National Laboratory — The ability of proteins to change their conformation in response to changes in their environment has consequences in biological processes like metabolism, chemical regulation in cells, and is believed to play a role in the onset of several neurological diseases such as Alzheimer's disease. The folding process of proteins is characterized by the transition from an randomly coiled state to a compact native conformation. As a protein unfolds, the ratio of nonpolar to polar groups exposed to water changes, affecting a protein’s thermodynamic properties. Using small angle x-ray scattering (SAXS), we are currently studying the intermediate protein conformations that arise during the folding/unfolding process as a function of temperature for a series of globular proteins. The temporal stability of these ensembles is also under investigation. Trends in the scattering profiles, along with correlations with protein thermodynamics, may help elucidate shared characteristics between all proteins in their folding behavior.

2:03PM B40.00015 Generalized distance and its application in protein folding. ALI MOHABZAB, University of British Columbia, STEVE PLOTKIN COLLABORATION — The concept of Euclidean distance between two points can be generalized to extended objects. The generalized distance $D$ can be used as a reaction coordinate in protein folding process. Here $D$ is compared and contrasted with some well-known reaction coordinates, Q and RMSD and is applied to protein fragments such as alpha helix and beta hairpin. The non-crossing constraint in utilizing $D$ is also discussed.

Monday, March 16, 2009 11:15AM - 2:15PM
Session B41 DMP DCMP: Heavy Fermion 115 Superconductors 413
11:15AM B41.00001 Penetration depth study of CeIrIn₃₁, DANIEL VANDERVELDE, Univ. of Illinois, Urbana, H.Q. YUAN, Zhejiang University, Y. ONUKI, Osaka University, M.B. SALAMON, Univ. of Texas at Dallas — The heavy-Fermion compounds CeTIn₅, with T a transition metal, provide a fertile ground for studying the interplay between magnetism and superconductivity. The T = Co compound has a transition temperature Tc = 2.4 K, and has a d-wave order parameter. As Ir is substituted for Co, the transition temperature decreases sharply to Tc = 0.4 K. One report of the thermal conductivity of CeIrIn₃ supports a d-wave state, another argues in favor of a hybrid gap state with broken time-reversal symmetry. We report penetration depth studies of CeIrIn₃ to Tc/5 that supports the d-wave scenario. Converted to superconducting fraction, the data taken with the rf measuring field along various crystallographic axes can be scaled to collapse to a single curve that matches a d-wave calculation with a zero-temperature gap of 2.5kBTc.

1Work supported in part by DOE Grant No. DEFG02-91ER45439.

11:27AM B41.00002 Magnetic-field induced quantum critical points of valence transition in Ce- and Yb-based heavy fermions, SHINJI WATANABE, University of Tokyo, ATSUSHI TSURUTA, KAZUMASA MIYAKE, Osaka University, JACQUES FLOQUET, CEA Grenoble — Valence instability and its critical fluctuations have attracted much attention recently in the heavy-electron systems. Valence fluctuations are essentially charge fluctuations, and it is highly non-trivial how the quantum critical point (QCP) as well as the critical end point is controlled by the magnetic field. To clarify this fundamental issue, we have studied the mechanism of how the critical points of the first-order valence transitions are controlled by the magnetic field [1]. We show that the critical temperature is suppressed to be the QCP by the magnetic field and unexpectedly the QCP exhibits nonmonotonic field dependence in the ground-state phase diagram, giving rise to emergence of metamagnetism even in the intermediate valence-crossover regime. The driving force of the field-induced QCP is clarified to be a cooperative phenomenon of Zeeman effect and Kondo effect, which creates a distinct energy scale from the Kondo temperature. This mechanism explains a peculiar magnetic response in CeIrIn₅ and metamagnetic transition in YbX₄ₓCdₓ for X=In as well as a sharp contrast between X=Ag and Cd. We present the novel phenomena under the magnetic field to discuss significance of the proximity of the critical points of the first-order valence transition. [1] S. Watanabe et al. PRL100, (2008) 236401.

11:39AM B41.00003 Combined Effects of Magnetic Field and Uniaxial Pressure on CeCoIn₅₁, RENA ZIEVE, SCOOTER JOHNSON, UC Davis, JASON COOLEY, Los Alamos National Laboratory — CeCoIn₅ exhibits unusual behavior in a magnetic field. The upper critical field is highly anisotropic, more than a factor of two larger for a field applied in the ab-plane than for a field along the c-axis. In both field orientations the superconducting transition changes from second-order to first-order with increasing field, and possible FFLO phases have been observed at high fields. Here we explore the influence of uniaxial pressure, applied along the crystal c-axis, on the temperature-field phase diagram. We find that a magnetic field suppresses the superconductivity far more sharply when the sample is also under pressure. We also examine the slope of the phase boundary near zero field and the nature of the transition at higher fields.

1Supported by NSF under DMR-0454869

11:51AM B41.00004 Dependence of Superconducting Transition Temperature on Uniaxial Pressure in CeCoIn₅, SCOOTER JOHNSON, RENA ZIEVE, UC Davis, JASON COOLEY, Los Alamos National Laboratory — We apply uniaxial pressure up to 4 kbar along the c-axis of single crystal samples of CeCoIn₅ and measure how the transition temperature to the superconducting state changes. We mount the sample within an ac susceptibility coil and apply pressure through a helium bellows cell mounted on a dilution refrigerator. We find that pressure shifts the transition to lower temperatures at a rate of 22.5 mK per kbar. Our observation follows the general correlation between transition temperatures and lattice constants among 115 materials, where lower Tc’s typically correspond to smaller c/a ratios. Pressure has the additional effect of broadening the transition well beyond what we expect from macroscopic pressure inhomogeneity. We are extending this work to measurements of CeCoIn₅ under a-b-axis pressure.

1Supported by NSF through DMR-0454869

12:03PM B41.00005 Optical Study of the Heavy Fermion Superconductor CeCoIn₅₁, T. GEBRE, T. TUKUMOTO, J. CHERIAN, T. MURPHY, S. TOSZER, E. PALM, C. WIEBE, S. MCGILL, National High Magnetic Field Laboratory — We have performed dc magnetization and optical spectroscopy on flux-grown crystals of the heavy fermion superconductor, CeCoIn₅. We will discuss the growth technique and report results of low-temperature and high magnetic field measurements for different orientations of field and crystal axis. CeCoIn₅ is a strongly correlated system exhibiting superconductivity below 2.3 K and is believed to show a variety of magnetic field-induced phases near or below the critical temperature.

1This work was sported by DOE-FG52-06NA26193 and NSF DMR-0084173

12:15PM B41.00006 Coexistence of Superconducting and Magnetic Order in CeCoIn₅, GEORGIOS KOUTROULAKIS, VESNA MITROVIC, Brown University, MLADEN HORVATIC, CLAUDE BERTHIER, GHMFL, Grenoble, France, GERARD LAPERTOT, JACQUES FLOQUET, CEA, Grenoble, France — The interplay between magnetic and superconducting order near a quantum critical point in heavy fermion materials has attracted intensive research interest in recent years. One of the most intriguing examples is that of CeCoIn₅, in which a novel phase within the superconducting phase is observed near the critical field at low temperature. Recent nuclear magnetic resonance [1] and neutron scattering [2] experiments showed that a static magnetic order is stabilized in this phase. The microscopic nature of this magnetic state will be discussed.

12:27PM B41.00007 ABSTRACT WITHDRAWN

12:39PM B41.00008 Local Structure and Site Occupancy in Cd- and Hg-doped CeTIn₅ (T=Co, Rh, Ir), C.H. BOOTH, Lawrence Berkeley National Laboratory, E.D. BAUER, F. RONNING, V. SIDOROV, T. PARK, J. THOMPSON, J.L. SARRAO, Los Alamos National Laboratory, A.D. BIANCHI, Z. FISK, UC Irvine — Local structure measurements using the extended x-ray absorption fine-structure (EXAFS) technique were performed on the In K, Cd K, and Hg L₃ edges on samples of CeCo(Inₑ₋ₓCdₓ)₅ (0.5%≤x≤31.3%) and CeT(In₁₋ₓHgₓ)₅ (T=Co, Rh, Ir, 0.7%≤x≤3.5%). Fits indicate no measurable change in the bulk local structure with these substituents. In contrast, the local structure data around the substituent atoms indicates about fₐₐₐ = 44(3)% of Cd atoms reside on In(1) sites, similar to previous results [fₐₐₐ = 35(5)%] for Sn in CeCo(In₁₋ₓSnₓ)₅. Mercury has an even stronger preference for the In(1) site, with fₐₐₐ = 71(5)% and fₐₐₐ = 97(3)%, and fₐₐₐ = 55(5)%, although other phases appear to be present in the Ce(In₁₋ₓHgₓ)₅ material. Small distortions from the parent structure are also observed around the substituent atoms. These results will be related to the sharp decrease in the superconducting transition temperature with x.
12:51PM B41.00009 Cd and Sn doping effects on Pauli limiting and HFLT state in CeCoIn$_5$\textsuperscript{1}. R. MOVSOVICH, Y. TOKIWA, N. KURITA, F. RONNING, E.D. BAUER, P. PAPIN, J.D. THOMPSON, Los Alamos National Laboratory, Los Alamos, NM 87544, USA, A.D. BIANCHI, University of Montreal, Montreal, QC, H3C 3J7 Canada, J.F. RAUSCHER, S.M. KAUZLARICH, Z. FISK, University of California, Davis, California 95616, USA, I. VEKHTER, Louisiana State University, Baton Rouge, Louisiana 70803, USA — We investigated the effect of Cd and Sn doping on the superconducting (SC) transition temperature $T_c$, the superconducting critical field $H_{c2}$, and the High-Field-Low-Temperature (HFLT) phase in heavy fermion superconductor CeCoIn$_5$. $T_c$ decreases monotonically for both dopants, whereas $H_{c2}$ rises initially with Cd substitution, while dropping for Sn doping. Analysis of the magnetization data suggests that these effects are caused by weakening of the Pauli limiting in CeCoIn$_5$ with Cd doping, most likely due to changes of susceptibility of the normal state. Both Cd (leading to AFM ground state at higher concentrations) and Sn impurities, at a very low level of a few hundred ppm, suppress the HFLT phase. We interpret these results as supporting the superconducting origin of the HFLT phase.

\textsuperscript{1}Work at Los Alamos National Laboratory was performed under the auspices of the U.S. Department of Energy.

1:03PM B41.00010 Kondo coherence and superconductivity in Yb doped CeCoIn$_5$. ANDREA BIANCHI, GABRIEL SEYFARTH, BOBBY PREVOST, SJOERD ROORDA, Universite de Montreal, DAN HURT, CIGDEM CAPAN, ZACHARY FISK, Dept. Phys. & Astro. U. of California, Irvine — We have studied the effect of Yb doping on superconductivity in the unconventional heavy fermion superconductor CeCoIn$_5$ in a doping series spanning from pure CeCoIn$_5$ to the paramagnetic metal YbCoIn$_5$, which is isostructural with CeCoIn$_5$. By replacing Ce by Yb, we are at the same time removing carriers as well as disrupting the Kondo lattice of CeCoIn$_5$, which is thought to be responsible for superconductivity in this compound. This will give us insight into how the Kondo coherence and Cooper pair breaking in CeCoIn$_5$ are affected by Yb substitution. Our doping series shows that the unit cell volume stays approximately constant up to a Yb concentration of about 40 %. At higher Yb concentrations the unit cell volume begins to shrink gradually to the value of YbCoIn$_5$. However, superconductivity in the doped system is remarkably resilient against Yb substitution: At low doping the superconducting transition temperature $T_c$ is only gradually suppressed from the value of 2.24 K of pure CeCoIn$_5$, and only with a Yb concentration of 60 % $T_c$ is suppressed below 0.3 K.

1:15PM B41.00011 Conductance asymmetry in point-contact junctions on the heavy-fermion compounds CeMn$_5$ (M=Co, Rh, Ir)\textsuperscript{1}. L.H. GREENE, W.K. PARK, University of Illinois at Urbana-Champaign, E.D. BAUER, J.L. SARRAO, J.D. THOMPSON, Los Alamos National Laboratory — The Ce-based 1-1-5 heavy-fermion compounds CeMn$_5$ (M=Co, Rh, Ir), continue to draw much attention from the community. One of the key questions is how the localized discrete states acquire itinerancy over the conduction electron continuum. As a probe of the evolutionary behavior of the Kondo lattice, we take differential conductance spectra from nanoscale metallic junctions on CeMn$_5$ single crystals over wide temperature ranges. A striking common feature is the systematic development of an asymmetry in the background conductance \cite{1}. Conventional models including the heating model with large Seebbeck coefficients of heavy fermions do not account for this behavior. We propose a phenomenological model based on a possible Fano interference effect \cite{2} between two conductance channels, one into the heavy electron liquid (hybridized f-band) and the other into the conduction electrons without hybridization. \cite{1} W. K. Park et al., Phys. Rev. Lett. 100, 177001 (2008). \cite{2} U. Fano, Phys. Rev. 124, 1866 (1961).

\textsuperscript{1}This work is supported by the U.S. DOE under Award No. DE-FG02-07ER46453 and by NSF-DMR-0706013 through FSMRL and CMM at UIUC and is performed at LANL under the auspices of the U.S. DOE, Office of Science.

1:27PM B41.00012 The Fano effect in the point contact spectroscopy of heavy electron materials\textsuperscript{1}. YI-FENG YANG, Los Alamos National Laboratory — Recent experiments on CeCoIn$_5$ reveal similar temperature dependence of the conductance asymmetry in the point contact spectroscopy and the Knight shift anomaly. This suggests a common origin of both anomalies and supports a previously proposed phenomenological two-fluid model that predicts the emergence of a heavy fluid, or Kondo liquid, in heavy electron materials. Here we propose a phenomenological formula for the point contact spectroscopy and describe the spectra by a Fano effect of tunneling electrons due to the Kondo liquid emergence. Our formula explains quantitatively the experimental data of several heavy electron materials.

1:39PM B41.00013 Evidence for magnetic field-tuned quantum criticality below $H_{c2}$ in CeCoIn$_5$. J. PAGLIONE, Center for Nanophysics and Advanced Materials, University of Maryland, J.-P. REID, Département de physique, Université de Sherbrooke, M.A. TANATAR, L. TAILLEFER, Département de physique, Université de Sherbrooke, C. PETROVIC, Condensed Matter Physics, Brookhaven National Laboratory — The existence of a magnetic-field-tuned quantum critical point coinciding with the upper critical field for superconductivity in the heavy-fermion superconductor CeCoIn$_5$ has remained a puzzling fact, and has proven difficult to study due to the onset of superconductivity. Here we present low temperature thermal conductivity measurements which probe the quantum critical point in CeCoIn$_5$ as a function of field from within the superconducting state, revealing new evidence for field- tuned quantum criticality.

1:51PM B41.00014 Insulating Vortex Core near QCP in CeCoIn$_5$. H. XIAO, T. HU, C. C. ALMASAN, Department of Physics, Kent State University, Kent, OH, 44242, USA, T. A. SAYLES, M. B. MAPLE, Department of Physics, University of California at San Diego, La Jolla, California, 92093, USA — We have investigated the vortex core of the superclean unconventional heavy fermion superconductor CeCoIn$_5$, by studying the flux flow dissipation in the mixed state for two magnetic field orientations, i.e., $H \parallel c$ axis and $H \parallel ab$ plane, at temperatures down to 1.8 K. The vortex core in the mixed state of CeCoIn$_5$ is insulator-like, in contrast to the metallic behavior of CeCoIn$_5$ in its normal state, at temperatures $T$ larger than the superconducting transition temperature $T_c$. Moreover, the abnormal insulating behavior of the vortex core is strongly suppressed when CeCoIn$_5$ is tuned away from the quantum critical point (QCP) by applying pressure. This latter result gives firm evidence that quantum criticality plays an important role in the interaction between superconductivity and magnetism, hence is responsible for the emergence of unconventional superconductivity. A scaling law of the flux flow resistivity has also been found and will be discussed.

\textsuperscript{1}This research was supported by the National Science Foundation under Grant No. DMR-0705959 at KSU and the US Department of Energy under Grant No. DE-FG02-04ER46105 at UCSD.
The effect of Yb substitution in the heavy-fermion superconductor CeCoIn$_5$\textsuperscript{1}\textsuperscript{,} LEI SHU, E. GONZALES, K. HUANG, T.A. SAYLES, U. Calif. San Diego, California 920931 U.S.A., J. PAGLIONE, U. Maryland, Maryland 20742, U.S.A., M.B. MAPLE, U. Calif. San Diego, California 920931 U.S.A. — The discovery of a new family of heavy-fermion superconductors with the formula CeMn$_5$ (M=Co, Rh, Ir ) provides an interesting playground to understand the relation between unconventional superconductivity and quantum criticality. CeCoIn$_5$, with the highest ambient pressure superconducting transition temperature of all heavy-fermion compounds, exhibits a magnetic field-tuned quantum critical point. The peculiar magnetic properties of CeCoIn$_5$ are determined by the interaction between the magnetic moments of the Ce$^{3+}$ ions and the spins of conduction electrons. Through systematic studies of Ce$_{1-x}$Yb$_x$CoIn$_5$ alloys, where the magnetic Ce ions (4f$^1$ configuration) are diluted by Yb (hole analogue; 4f$^{13}$ configuration), it allows us to study the nature of inter-site interactions. Lattice constant, magnetic susceptibility, and electrical resistivity data of Ce$_{1-x}$Yb$_x$CoIn$_5$ alloys throughout the range 0 ≤ x ≤ 1 will be reported.

C1.00001 POLYMERIC AND ORGANIC MATERIALS I

C1.00002 High Electric Energy Storage in a Three-Phase Polymer Nanocomposite\textsuperscript{1}, JING WANG, FANGXIAO GUAN, LEI ZHU, Polym. Program, Inst. of Mater. Sci. and Dept. of Chem., Mater. and Biomolecular Eng., University of Connecticut, Storrs, CT 06269-3136 — Two-phase polymer/ferroelectric ceramic composites have attracted great interests for electric applications, such as transducers, piezo-sensors, and hydrophone materials, because they combine good processability of polymers and high dielectric constant of ferroelectric ceramics together. The polymer-ceramic composites generally show a high effective dielectric constant only at a high ceramic volume fraction (>35 vol.%). Here, a high dielectric constant tetrameric Cu-philhalocyanine (Cu-TMPc) was used as an interfacial phase between the ceramic particles (50-nm BaTiO3) and the polymer matrix (poly(vinylidene fluoride-co-hexafluoropropylene), or P(VDF-HFP)). To avoid the agglomeration of nanoparticles in P(VDF-HFP)), poly(methyl methacrylate) is grafted from Cu-TMPc-coated BaTiO3 nanoparticles using surface-initiated radical polymerization. High electric energy storage and low conductivity were achieved at low filling ratios (<15 vol.%).

C1.00003 Rheological Singularity near the Phase Transition of Hairy Nanoparticles in Polymer Melts, XIAORONG WANG, Bridgestone Americas, Center for Research and Technology, 1200 Firestone Parkway, Akron, OH 44317, VICTOR FOLTZ, MINDAU GUS RACKAITIS, GEORG BOHM — The dynamics of hairy nanoparticles in polymer melts of chemically identical chains has been investigated as function of both molecular weight and volume fraction. This work demonstrates that there is a strong connection between the rheological dynamics of the system and the thermodynamics of the phase separation behavior. The shear-induced nonlinearity in the system appears to display features of a surprising singularity near the phase transition point. Our theoretical calculation also agrees qualitatively well with that observed experimentally.

C1.00004 The use of the radius of gyration in a WLC polymer model of cancer cell adhesion to glycosaminoglycans substrates, ANTONIO PERAMO, GARRETT MATTHEWS, University of South Florida — Glycosaminoglycans (GAG) are a group of polysaccharides involved in several biological functions, including cell adhesion. Most of their biological properties are derived from the interactions of the chains with their environment, hence the interest in developing physical models that could describe their interactions with whole cells. As linear biopolymers with low polydispersity, GAG can be described using polymer models of Gaussian chain distributions, like the WLC (worm-like chain) model. We found that the adhesion of whole cancer cells to glass substrates coated with GAG appear to be dependent on the charge per dimer and degree of sulfation of the GAG chain. We have hypothesized that the adhesion of whole cancer cells to GAG substrates can be described as a function of polysaccharide radius of gyration and used the WLC model describing the global structure of the GAGs to analyze this relationship. We will show that the adhesion of the cancer cells has a linear response with the radius of gyration and is essentially controlled by the charge per dimer. This dominating mechanism is not eliminated when the cells are resuspended in media with heparin. We then propose how these physical properties could be used to predict the preferred molecular structures of compounds for use as anti-metastatic or anti-inflammatory agents.

C1.00005 Polymer dynamics and ion conduction in modified soluble starch, HYUNGKI LEE, JAMES RUNT, Penn State University — The dynamics of neat and plasticized carboxylated starch is investigated using broadband dielectric relaxation spectroscopy (DRS). The sodium single ion conductor is prepared by a 2,2,6,6-tetramethylpiperidin-1-oxyl (TEMPO) mediated oxidation process, in which the primary hydroxyl groups in alpha-D-glucose units are replaced by carboxylic salts. DRS measurements show that the ionic conductivity increases with increasing degree of oxidation. For example, 78 percent carboxylated starch with 25 weight percent glycerol displays around 3 orders of magnitude higher ionic conductivity than the comparable glycerol-plasticized 25 percent carboxylated material, principally due to the higher content of mobile cations. The role of salts and plasticizers including water on the relaxation behavior of amylose-rich starch is explored. Other complimentary techniques are used in the investigation, including FTIR, XRD and DSC.

C1.00006 Responsive Block Copolymer and Gold Nanoparticle Hybrid Nanotubes, SEHOON CHANG, SRIKANTH SINGAMANENI, SETH YOUNG, VLADIMIR TSUKRUK, Georgia Institute of Technology — We demonstrate the facile fabrication of responsive polymer and metal nanoparticle composite nanotube structures. The nanotubes are comprised of responsive block copolymer, polystyrene-block-poly(2-vinylpyridine) (PS-b-P2VP), and gold nanoparticles. PS-b-P2VP nanotubes were fabricated using porous alumina template and in situ reduction of the gold nanoparticles in P2VP domains. Owing to the pH sensitive nature of P2VP (anionic polymer with a pK$_a$ of 3.8), the nanotubes exhibit a dramatic change in topology in response to the changes in the external pH. Furthermore, the gold nanoparticles in the responsive block exhibit a reversible aggregation, causing a reversible change in optical properties such as absorption.
C1.00007 Magnetic Field Alignment of Rod-Coil Block Copolymers and Identification of Liquid Crystalline Orientation, X. GU, University of California, Berkeley, B.D. OLSEN, A. HEXEMER, E. GANN, R.A. SEGALMAN, UC BERKELEY TEAM, LAWRENCE BERKELEY LABS TEAM — Conjugated rod-coil block copolymers are potentially useful for a number of optoelectronics applications, but properties rely strongly on the orientation of both the conjugated rods and of the nanodomains. Here, a magnetic field was used to control the self-assembly of a model conjugated rod-coil block copolymer (poly(alkoxyphenylenevinylene-b-isoprene)) such that the rods align with the field direction. After alignment, the samples were re-annealed below the microphase order-disorder transition temperature to allow equilibration of the rod orientation within the lamellar nanodomains. Small angle and wide angle X-ray scattering simultaneously determine the rod tilt relative to the lamellar normal. Rods were found to be parallel to the lamellar plane by fractions of 42-85 percent at all temperatures below the microphase order-disorder transition temperature. The orientation of the rod blocks in rod-coil block copolymers impacts carrier transport and optical properties in organic electronic devices, making the control of rod orientation necessary for device optimization.

C1.00008 A New Level of Hierarchical Structure Control by Use of Supramolecularly Assembled Dendronized Block Copolymers, RAFFAELE MEZZENGA, CHAOXU LI, University of Fribourg, Switzerland, DIETER SCHLUTER, AFANG ZHANG, ETHZ, Switzerland — Block copolymers in which microphase segregation can be combined with supramolecular attachment of side chains to one block, constitute very appealing systems to design hierarchically self-assembled macromolecular materials. Self-organization of these systems is achieved at two length scales: that of the side chains (~10^1 nm) and that of the block copolymers (~10^-10^7 nm). Because of the linear nature of the hosting block, only lamellar organization is typically observed at small length scales. Here we demonstrate that by replacing the linear polymer block with a dendronized polymer capable of participating in supramolecular interactions, one additional degree of freedom (the generation of the dendronized polymer) is introduced to engineer the self-assembly into unprecedented hierarchically ordered bulk structures. Not only this allows controlling beyond current possibilities the structures at the smaller length scale, with the introduction for example, of new columnar rectangular, hexagonal and tetragonal phases, but it may also lead to new functional template materials with increased 3D topological complexity for advanced technologies. References: C. Li, D.A. Schlüter, A. Zhang, R. Mezzenga, Advanced Materials, in press.

C1.00009 Fabrication of Highly Ordered Nanostructured Block Copolymer Templates using Supramolecular Assembly Approach, E. BHOJE GOWD, MANFRED STAMM, LEIBNIZ INSTITUTE OF POLYMER RESEARCH DRESDEN, HOHE STRASSE 6, 01069 DRESDEN, GERMANY TEAM — The ability to create reactive nanoporous templates using polymer thin films is important for such applications as antibody or enzyme immobilization, separation of biomolecules, and nanofabrication. Self-assembly of polymers supramolecularly with C60-fullerenes to poly(styrene-dimethylsiloxane) thin films leads to disorder in a system that is otherwise ordered in the range of tens of microns. Because C60-fullerenes to poly(styrene-b-dimethylsiloxane) thin films disordered leads to disorder in a system that is otherwise ordered in the range of tens of microns. C1.00010 Neutron Reflectivity Study of dPS Brushes Grown from an Inimer Embedded Polymer Matrix, ONOME SWADER, Department of Chemistry, University of Tennessee, Knoxville, TN, DAMLA KOYLU, KENNETH CARTER, Polymer Science and Engineering Department, University of Massachusetts, Amherst, MA, MARK DADMUN, Department of Chemistry, University of Tennessee, Knoxville, TN — Robust methods for directing the self-assembly of macromolecules over large areas are necessary in order to meet the demands for fabrication of next generation devices. Polymer brushes grown from soft interfaces composed of an inimer embedded photopolymer (PP) network provide a unique method to create tuned surfaces and interfaces for such devices. In this study, neutron reflectivity is used to characterize such functionalized interfaces. Intermolecular concentration and the amount of monomer available for polymerization was systematically varied in an attempt to nanoscopically tune brush growth. These results suggest that the brushes are not initiated at one particular interface, but rather throughout the PP network. Further analysis revealed that brush density increased as the amount of inimer concentration in the PP network increased. However, it is interesting to note that the brush at the surface of the PP network is significantly less dense than in the melt.

C1.00011 Surface Dynamics of Branched Polystyrene films, SHIH-FAN WANG, JAE SIK LEE, SEWOO YANG, RODERIC P. QUIRK, MARK D. FOSTER, Dept. of Polymer Science, University of Akron, ZHANG JIANG, SURESH NARAYANAN, X-ray Science Division, Argonne National Lab, DAVID WIU, Colorado School of Mines — Thermally stimulated fluctuations of a polymer surface have been studied for films containing branched polymers for the first time. The surface fluctuations were recorded using X-ray photon correlation spectroscopy (XPCS), a recently-developed technique already applied to study the surfaces of melts of linear polystyrene chains. A continuum hydrodynamic theory of thermally stimulated capillary waves with a non-slip boundary condition is adequate to fit plots of relaxation time as a function of scattering vector. Changes in Tg with molecular architecture certainly play a role. However, comparison of data from a star made without the usual butadiene (BD) linking units with data from a star with 1-2 BD units per arm shows that the BD end capping of the arms affects the dynamics profoundly. This effect may not be described adequately by simply accounting for the reduction in Tg caused by the presence of the BD units. Acknowledgements: NSF support (CBET 0730692)

C1.00012 Magnetic Field Driven Alignment of Lamellar and Hexagonal Surfactant Mesophases for Templated Synthesis of Nanomaterials, PAWEI MAJEWSKI, CHINEDUM OSUJI, Yale University — The use of both ionic and non-ionic surfactants as structure directing agents in the solvothermal synthesis of nanomaterials has become a well established practice. Nevertheless, the production of monolithic well aligned surfactant mesophases for use in the templated synthesis of ordered, anisotropic nanomaterials remains a significant challenge, particularly in the thin film geometry where shear alignment cannot be conveniently applied. Magnetic fields hold promise in this area, but to date have only been used in the alignment of hexagonal phases of ionic surfactants. We show that judicious application of high magnetic fields can in fact be used for diamagnetic alignment of non-ionic surfactants in both the lamellar and hexagonal phases, leading to very highly ordered systems suitable for nanomaterials synthesis.

C1.00013 Long Range Order of Block Copolymer/C60 Thin Films, KATIE CAMPBELL, DAVID BUCKNALL, YONATHAN THIO, Georgia Institute of Technology — The use of block copolymers as a template to localize C60 particles was investigated. The addition of C60-fullerenes to poly(styrene-b-dimethylsiloxane) thin films led to disorder in a system that is otherwise ordered in the range of tens of microns. Because C60 segregates into the PS phase, the degree of disorder is dependent on the concentration of C60 as a weight percent of the PS block, as indicated by AFM studies. Disorder effects are exacerbated by fullerene aggregation in the solution prior to spin coating on a substrate. Several strategies are proposed for achieving and maintaining long-range order in block copolymer/C60 thin films. First, the aggregation of C60 in solution is controlled by preparing thin films from solutions with C60 and block copolymer co-dissolved at a time when aggregation is at a minimum to achieve good dispersion of the C60. Secondly, several methods for achieving long-range order have been investigated including the use of solvent annealing in combination with shear and topographic substrates. Results show that solvent annealing alone orients polymer segments in C60-fullerene copolymers without C60; however, addition of C60 to the system alters the order seen with solvent annealing.
C1.00014 Orientation distribution in a uniaxially and biaxially drawn poly(L-lactic acid) by Raman spectra, MIN SANG PARK, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology, Atlanta, GA, USA, YEE SHAN WONG, SUBBU VENKATARAMAN, School of Materials Science and Engineering, Nanyang technological University, Singapore, MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA, USA — In this study, we used the polarization modulation of Raman scattering intensities to study molecular orientation distribution in the crystalline and amorphous regions of uniaxially and biaxially drawn poly(L-lactic acid) (PLLA) film. Changes of orientation distribution were detected as a function of stretching ratios and different characteristics of orientation between crystalline and amorphous region were analyzed using Raman bands which are assigned to the each region. As results, quantification of oriented molecule information named orientation order parameters was determined. From experimentally obtained order parameters, the most probable molecular orientation distribution functions for the crystalline and amorphous regions in the film could be constructed.

C1.00015 Highly Ordered Nanoporous Template from ABC Triblock Copolymer, DONG HYUN LEE, SOOJIN PARK, THOMAS RUSSELL, Univ of Massachusetts, Amherst — In this study, silicon nanoporous templates from polyisopropene-block-polystyrene-block-poly(2-vinyl pyridine) (PI-b-PS-b-P2VP) were fabricated. The films, spin-coated from toluene, showed a dimpled texture with short-range lateral order. When exposed to a mixed solvent vapor (toluene/hexane), a highly ordered and oriented core-shell structure of PI-b-PS-b-P2VP copolymers was obtained. The morphology consisted of an external shell of PI, a middle shell of PS, and a core of P2VP. After removal of the PI from by UV-Ozone treatment, subsequently, polydimethylsiloxane (PDMS) was spin coated onto this film and allowed diffused into the pores by capillary action. When the film was exposed to oxygen plasma, the PDMS was converted to silicon oxide, while all other remaining polymer was removed. This led to a highly ordered and oriented nanoporous structure that could be used as an etching mask or templates for secondary metal loading. Highly ordered arrays of gold nanoparticles for the potential applications for surface enhanced plasmon, immobilization of DNA or organic dyes, or epitaxial growth of crystal were obtained by loading gold salt into well-defined core-shell structure.

C1.00016 Morphology and Ionic Conductivity of Block Copolymer–Ionic Liquid Systems, M.L. HOARFROST, J.M. VIRGIL, J.B. KERR, R.A. SEGALMAN, UC Berkeley and Lawrence Berkeley National Laboratory — Block copolymer–ionic liquid systems are of interest for ion exchange membranes due to the ionic conductivity and thermal stability of the ionic liquid combined with the thermal stability and morphological control arising from a structural component in a block copolymer. It is anticipated that the morphology and connectivity of the resulting structural and ionic liquid-containing nanodomains will affect conduction properties. This relationship was investigated for poly(styrene-b-2-vinylpyridine) (S2VP) in ionic liquids composed of varying molar ratios of imidazole and bis(trifluoromethanesulfonfyl)imide (Im:TFSI). A stoichiometrically balanced ionic liquid (1:1 Im:TFSI) swells the 2VP lamellar domains for copolymer concentrations as low as 60wt%. With 9:1 Im:TFSI the lamellar structure tolerates more swelling, forming lamellar structures with as little as 30wt% copolymer. Ionic conductivity in two-dimensional and three-dimensional systems, characterized by microphase separated domains, demonstrate ionic conductivities comparable to those of P2VP–ionic liquid systems when normalized by 2VP (monomer) to Im:TFSI ratio.

C1.00017 Ionic Salt Effect on the Phase Transition of PS-b-P2VP Copolymers, BOKYUNG KIM, HYUNGJU AN, DU YEOL RYU, Yonsei University, Korea, JEHAN KIM, Pohang Accelerator Laboratory, Korea — Solid-state electrolytes have long been considered as suitable candidates owing to the simple and easy processes for rechargeable battery manufacture, compared to conventional liquid electrolyte counterparts. Especially, polymer/salt systems involving PMMA and PVP complex forms have been studied since they provide stable electrochemical characteristics as well as mechanical properties. We studied the phase behavior of PS-b-P2VP upon the salt addition by small angle x-ray scattering (SAXS) and depolarized light scattering. Transition temperatures of block copolymer were significantly influenced by the salt addition in addition to the changes of d-spacings, which is caused by the effective coordinative interaction between P2VP block and salt. This study suggests a simple approach to solid-state block copolymer electrolytes.

C1.00018 Comb Polymer Architectures for Versatile Nanoparticle Assembly, ALEXANDER MAS-TROIANNI, KARI THORKELSSON, YUE ZHAO, JOSEPH LUTHER, JILL MILLSTONE, PAUL ALIVISATOS, JEAN FRECHET, TING XU, UC Berkeley — Nanoparticles are a material of interest in photovoltaic research due to their optical absorption properties. However, there have been many challenges for device fabrication. Nanoparticle-doped organic thin films are a hot area of research, and they have thus been hard to apply generally to different materials of interest. We show how this challenge can be overcome using a comb polymer architecture. Here, pentacetyphenol small molecules are hydrogen bonded to polyvinyl pyridine. This alkyl moiety is compatible with the ligand shells of many nanomaterials. We incorporated these small molecules and nanoparticles into polystyrene-polyvinyl pyridine block copolymers. This strategy was successful for assembling nanoparticles, made out of a variety of materials, without special considerations for the actual core material or morphology. Following these successes in bulk samples we extended our studies to thin films of these composites. Here, the morphology is controlled by the interfacial interactions. These materials have the potential to be used for photovoltaic devices, as they are easily solution-processable. This strategy is generally applicable with the choice of small molecule mediating interactions with any desired nanomaterial.

C1.00019 Electric Energy Storage in P(VDF-HFP) Copolymers with Different Crystallinities, FANGXIAO GUAN, STEVEN BOOGS, LEI ZHU, Polym. Program, Inst. of Mater. Sci. and Dept. of Chem., Mater. and Biomolecular Eng., University of Connecticut, Storrs, CT 06269-3136 — Poly(vinylidene fluoride) (PVD) is a well known ferroelectric polymer. It attracts much attention as a candidate material for electric energy storage in recent years because of its relatively high dielectric constant and high electric breakdown strength. By modifying PVDF with bulky comonomers such as hexafluoropropylene (HFP), (P(VDF-HFP) random copolymers can achieve even higher electric energy density than PVDF. This is because bulky HFP comonomers disrupt the PVDF run length and thus reduce the average crystallite size. Additionally, bulky HFP comonomers at the crystal surface constrain the α- → δ- → β phase transitions at elevated electric fields. Both the reduced crystallite size and constrained phase transition affect electric energy storage. For (P(VDF-HFP) copolymers with different crystallinities, different crystal size and phase transition behaviors are studied, and their relationships with the electric energy storage capability is correlated.

C1.00020 Multi-scale simulation on solid benzene, HUA LIU, HENDRIK HEINZ — Solid Benzene is used in organic semiconductors for photovoltaics, which often include pi-conjugated systems. We use MD simulations method to explore the relationship between the structure and interaction energy of two kinds of solid benzene, with the Pbcn and P21c crystallographic structures respectively. Simple relevant force fields (PCFF and CVFF) are examined with regard to their performance on the structure and energetics of benzene dimers and benzene crystals which serve as well characterized model systems. However, MD simulations cannot get the transport properties. So the combination of reliable classical atomistic simulations and quantum-mechanical methods is needed to understand the dynamics of charge transport and self-assembly processes involving pi-conjugated oligomers and polymers. As alternative and accurate models, we explore atomistic models with additional sites which represent the location of the pi electrons and are characterized by suitable charges and van-der-Waals parameters. With these parameters, it will be possible to reproduce the dimer geometries and energies, the crystal structure of solid benzene, as well as pi-stacking forces and free energies for similar systems.
The surface spectrum of PS films subjected to different thermal annealing, we show that similar nonliquidlike behaviors can be produced if the annealing time is below \( \tau(q_{eq}(h)) \), the relaxation time of the capillary wave mode with wave vector equal to the lower-cutoff wave vector \( q_{eq}(h) \), which characterizes the equilibrium surface spectrum. At the same time, annealing above \( \tau(q_{eq}(h)) \) recovers the liquid behaviors. Because \( \tau(q_{eq}(h)) \) often amounts to days and even years, insufficient annealing constitutes a likely cause for the nonliquidlike behaviors. Nonetheless, the previously suggested strong pinning of the polymer chains to the substrate can also be a cause. To elucidate the origin of the observed nonliquidlike behaviors, we measure the surface dynamics of PS films with thicknesses of \( h \approx 2R_C \) (where \( R_C \) is the radius of gyration of the polymer) exhibited nonliquidlike behaviors even in the molten state. By measuring the surface spectrum of PS films subjected to different thermal annealing, we show that similar nonliquidlike behaviors can be produced if the annealing time is below \( \tau(q_{eq}(h)) \), the relaxation time of the capillary wave mode with wave vector equal to the lower-cutoff wave vector \( q_{eq}(h) \), which characterizes the equilibrium surface spectrum. At the same time, annealing above \( \tau(q_{eq}(h)) \) recovers the liquid behaviors. Because \( \tau(q_{eq}(h)) \) often amounts to days and even years, insufficient annealing constitutes a likely cause for the nonliquidlike behaviors. Nonetheless, the previously suggested strong pinning of the polymer chains to the substrate can also be a cause. To elucidate the origin of the observed nonliquidlike behaviors, we measure the surface dynamics of PS films with thicknesses of \( h \approx 2R_C \) to \( 8R_C \) undergoing the glass-to-rubber transition and find that they are all the same. Our result favors insufficient annealing to be the cause of the observed nonliquidlike behaviors.

Preparation of Mesoporous Ceramics from Polymer Nanotubes, DIAN CHEN, SOOJIN PARK, JIUN-TAI CHEN, EMILY REDSTON, THOMAS RUSSELL, University of Massachusetts Amherst — Poly(styrene-b-4-vinylpyridine) (PS-b-P4VP) nanotubes were prepared by placing polymer solution into the cylindrical nanopores of an anodic aluminum oxide (AAO) membrane. The PS-b-P4VP nanotubes within the AAO membranes were exposed to tetrahydrofuran vapor to produce uniform spherical micelles along the tube. The tubes were removed from the membranes, then suspended in ethylene glycol, a preferential solvent for P4VP. At 95°C, near the glass transition temperature (Tg) of PS, nanotubes with uniform nanopores were obtained by a reconstruction of the nanotubes. As the temperature was increased, mesoporous polymer structures were obtained. Tetraethyl orthosilicate or titanium tetraoxide, ceramic precursors, were introduced into the 4VP microdomains. After exposure to an oxygen plasma or high temperature, the copolymer was removed and the precursor converted to a mesoporous ceramic. This process offers a simple route for the fabrication of tunable mesoporous ceramic or metallic structures by changing molecular weight of copolymers.

C1.00035 Swelling Behavior of Diblock Copolymer Brushes. BULENT AKGUN, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742, SUSHIL SATIJA, Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, GOKCE UGUR, MARK D. FOSTER, Department of Polymer Science, The University of Akron, Akron, OH 44325 — Diblock copolymer brushes (DCBs) have garnered enormous interest in recent years due to their stimuli-responsive behavior. The characteristics of a surface of a DCB can be changed reversibly from those of one type to those of another by using a selective solvent for one block. There has not been any experimental study to prove either the disordered structure or the surface rearranged structure or the mechanism of that rearrangement. To understand the switching mechanism we have investigated the swelling behavior of DCBs in selective and good solvents using in-situ neutron reflectivity. When DCBs are treated with selective solvents, in-situ measurements show that the structure changes to minimize the unfavorable interaction between solvent and the block that does not like the solvent. When swollen with a liquid solvent good for both blocks, DCBs behave similarly to homopolymer brushes, establishing a parabolic profile of chain segment density.

C1.00036 Effect of density and structure on dynamics within self-assembled monolayers. DERRICK STEVENS, MARY SCOTT, JASON BOCHINSKI, LAURA CLARKE, NC State University Dept. of Physics — Previously, we have observed interacting dynamics within self-assembled alkylsiloxane monolayers, and characterized this motion via sensitive dielectric spectroscopy (along with more traditional techniques such as ellipsometry, contact angle, and force microscopy). In these monolayers, molecules are covalently bound to the surface and thus cannot spontaneously change density, as in an adsorbate system. We identified this relaxation as akin to the polyethylene-like glass transition observed in polymers with phase-segregated alkyl side chains [1]. As a next step, we deliberately manipulated the physical structure of the monolayers (via different film growth procedures and/or post-deposition heat treating) and the monolayer density (from ~10% to full coverage), and observed the resultant changes in dynamics. This experimental system may prove a useful model for more complex materials, such as glassy polymers or traditional molecular glasses, where density cannot be explicitly tuned. As density increases, the steepness index increases, indicating a more complex or fragile relaxation. At low densities, the motion has an almost-Arrhenius dependence on temperature. [1] M.C. Scott, D.R. Stevens, J.R. Bochinski, L.I. Clarke, ACS Nano. DOI: 10.1021/nn800543j.

C1.00037 Partial Crystallinity in Alkyl Side Chain Polymers. VASAV SAHNI, SHISHIR PRASAD, JOHANNA VILLATE, ZHANG JIANG, SUNIL SINHA, ALI DHINOJWALA, THE UNIVERSITY OF AGRON COLLABORATION, UNIVERSITY OF CALIFORNIA, SAN DIEGO COLLABORATION — Surface freezing is the formation of a crystalline monolayer at the free surface of a melt at a temperature \( T_s \), a few degrees above the bulk freezing temperature, \( T_b \). This effect, i.e. \( T_s > T_b \), common to many chain molecules, is in marked contrast with the surface melting effect, i.e. \( T_s < T_b \), observed for all other materials in the same state. Similarly, \( T_s \) is also > \( T_b \) for temperatures below \( T_b \) at which the surface freezes before the bulk. We have studied the structure of a novel crystalline surface monolayer on top of a disordered melt of the same material (poly(n-alkyl acrylate)) using grazing incidence x-ray diffraction. The grazing incidence x-ray diffraction, surface tension, and bulk latent heat results show that there is partial side-chain crystallinity. Also, the surface tension results explain the trend of the difference between the surface order-to-disorder transition temperature and the bulk melting temperature (\( \Delta T \)) as a function of side chain length. The behavior of the crystal length, crystal spacing and tilt with varying alkyl chain length and temperature was also studied.

C1.00038 Modifying material surfaces by siloxane-based coatings. ALI OZCAM, JAN GENZER, NC State University — We report on a simple, robust, and rapid method of modifying materials surfaces by using poly(vinylmethyl siloxane)-trichlorosilane (PVMS-TCS) coating. PVMS-TCS is synthesized by hydrosilation coupling between trichlorosilane (TCS) and poly(vinylmethyl siloxane) (PVMS). Spin-coating PVMS-TCS onto a substrate results in a uniform coating layer, which can be further stabilized by cross-linking. Exposing the coating to minute amounts of moisture generates a large density of surface-bound hydroxyl groups on the surface of PVMS-TCS. Moreover, by treating the PVMS-TCS substrates with ultraviolet/ozone (UVO) treatment increases one can both further increase the density of the surface-bound hydroxyl groups and the coating’s elastic modulus. The applicability of PVMS-TCS and PVMS-TCS/UVO coatings was tested by decorating various surfaces, including, poly(ethylene terephthalate) and glass, with semifluorinated organosilanes and organosilane-based initiators for surface initiated polymerization. The physico-chemical properties of the functional coatings were studied with a battery of experimental probes, including near-edge x-ray absorption fine structure spectroscopy, x-ray photoelectron spectroscopy, contact angle, atomic force microscopy, ellipsometry, and nanoindentation.

C1.00039 Carbon Nanotube Intra-connects With Conductive Polymers. SEON WOO LEE, HAIM GREBEL, Electronic Imaging Center at NJIT and the Electrical and Computer Engineering Department, New Jersey Institute of Technology (NJIT), Newark, NJ 07102, ANDREI SIRENKO, Physics Department, New Jersey Institute of Technology (NJIT), Newark, NJ 07102, DANIEL LOPEZ, AVI KORNBLIT, New Jersey Nanotechnology Consortium (NJNC), Lucent Technologies Bell Labs, Murray Hill, NJ 07974 — The electrical and optical properties of carbon nanotube (CNT) channels, electroplated with conductive polymers were measured. Individual, single-walled CNT (SWCNT) channels were grown by chemical vapor deposition (CVD) technique between very sharp metal tips on a wafer. The conductive polymers, either polycarbazole (PCz) or, polypyrrole (PPy) were then electroplated using the CNT as an electrode. Field effect transistors were fabricated and a gate-controlled, N-shaped negative differential resistance (NDR) was observed. A large photoconductance effect, which was associated with the NDR, was demonstrated, as well.

C1.00040 Orientation Dynamics in Multi-Wall Carbon Nanotube Dispersions under Shear Flow. SASWATI PUJARI, Northwestern University, SAMEER RAHATEKAR, JEFFREY GILLMAN, National Institute of Standards and Technology, KRZYSZTOF KOZIOL, ALAN WINDLE, Cambridge University, WESLEY BURGHARDT, Northwestern University. We report studies of the orientation state of multi-wall carbon nanotubes (MWNTs) dispersions in steady and transient shear flows. Uncured epoxy was used as a viscous, Newtonian suspending medium, and samples were prepared from ‘aligned’ MWNTs. Orientation was studied in both the flow- gradient (1-2) and flow-vorticity (1-3) plane of simple shear flow using in-situ x-ray scattering techniques. Steady state measurements in the 1-2 plane indicate that the MWNT orientation is rate dependent, with the MWNTs orienting closer to the flow direction at higher shear rates. In steady shear, anisotropy was measured to be higher in the 1-2 plane than in the 1-3 plane, demonstrating that the nanotube orientation state is not uniaxially symmetric in shear. The steady state MWNT orientation is governed by a rate-dependent state of nanotube aggregation/dissociation, which was separately characterized by optical microscopy. A partial relaxation of flow-induced anisotropy was observed following flow cessation, despite the very small rotational diffusivity estimated for these nanotubes. Long transients are observed in step-down experiments, as the orientation state changes in response to the slow tube aggregation process.

C1.00041 Defect Structures in Block Copolymer/Nanoparticle Blends. HYUN JU RU, MICHAEL BOCK-STALLER, Carnegie Mellon University — We present a systematic study of the implications of nanoparticle additives on the defect formation in block copolymer/nanoparticle blends (BCP). The morphology of lamellar styrene/isoprene-based di- and triblock copolymers blended with polystyrene-coated gold nanocrystals at various filling fractions have been done to characterize the monolayer formed when using electron microscopy using stereology and image reconstruction. Three structural characterizations, i.e. the grain size distribution, grain orientation distribution and grain boundary distribution, were analyzed as a function of polymer chain architecture, particle filling fraction and film processing conditions. With increasing particle filling fraction the average anisotropy as well as average grain size is observed to decrease as is the rate of grain growth during thermal annealing. The results are interpreted in terms of the stabilization of grain boundary structures through segregation of particle fillers to the grain boundary regions.
C1.00042 Effect of Nanoparticle Core Size on Polymer-Coated Gold Nanoparticle Location in Block Copolymers . J. D. PETRIE, G. H. FREDRICKSON, E. J. KRAMER, UCSB — Gold nanoparticles modified by short chain polymer thioles [Au-PS] can be designed to strongly localize either in the PS domains of a polystyrene-b-poly(2-vinylpyridine) [PS-PVP] block copolymer or at the interface. The P2VP block has a stronger attractive interaction with bare gold than the PS block. Thus, when the areal chain density \( \Sigma \) of end-attached PS chains falls below a critical areal chain density \( \Sigma_c \), the Au-PS nanoparticles adsorb to the PS-b-P2VP interface. The effect of the polymer ligand molecular weight on the \( \Sigma_c \) has been shown to scale as \( \Sigma_c \sim ((R - R_g)/(R^*R_g))^2 \), where \( R \) is the curvature of the Au nanoparticle core radius. To test this scaling relation for \( \Sigma_c \) further we are synthesizing gold nanoparticles with different core radii and will present preliminary results on \( \Sigma_c \) as a function of \( R \).

C1.00043 Segmental dynamics in poly(cyclohexyl methacrylate) / poly(alpha-methylstyrene) blends . GARETH ROYSTON, PAUL SOTTA, DIDIER LONG, Laboratoire Polymères et Matériaux Avancés (FRE2911) — Study of the dynamics of polymer blends near the glass transition and remains of great current interest. We present broadband dielectric spectroscopy and mechanical spectroscopy data from miscible blends of poly(cyclohexyl methacrylate) and poly(alpha-methylstyrene) across the entire composition range. Results are compared to known data on a range of other systems.

C1.00044 Surface segregation of end-functionalized homopolymers in a homopolymer matrix . MICHAEL DIMITRIOU, UCSB, CHENG WANG, KRISTIN SCHMIDT, HARALD ADE, CRAIG HAWKER, EDWARD KRAMER — Surface segregation of end-functional poly(2-vinylpyridine) in a blend with P2VP was measured by X-ray photoelectron spectroscopy. A series of chain end functionalized P2VP homopolymers were synthesized via either anionic polymerization or Reversible Addition Fragmentation Chain Transfer (RAFT) and end capped with either a single fluorinated oligomer or a perfluorinated dendrimer. The degree of end functionalization was characterized using NMR spectroscopy, IR spectroscopy and gel permeation chromatography. Further surface characteristics were determined using Near Edge X-ray Absorption Fine Structure Spectroscopy and Resonant Soft X-ray Reflectivity. When Swt\% P2VP end capped with a perfluorinated dendrimer was added a top layer saturated with fluorocarbons formed. It was also found that the surfactant segregation is dependant on its ability to form micelles.

C1.00045 Co-crystallization of Alkanes with Longer Methylene Segments within a Statistically Random Copolymer . JEFFREY KALISH, University of Massachusetts-Amherst, SURIYAKALA RAMALINGHAM, YUNING YANG, SHAW LING HSU, University of Massachusetts-Amherst, HENKE COLLABORATION — Binary blends of alkanes \( (C_hH_{2n+2}, n=24, 32, 36) \) and statistically random ethylene-co-vinyl acetate (EVA) copolymers with different vinyl acetate (18, 28 and 40\%) contents have been studied to understand the phenomenon of co-crystallization of longer chain fractions. Using thermal fractionation, the distribution of various crystallizable ethylene chain sequences was established in EVA copolymers. Co-crystallization in blends was observed by changes in spectroscopic features of various unit cells (triclinic, even n=26; monoclinic, even n=26 and orthorhombic, odd n) using vibrational spectroscopy. In order to distinguish these changes, deuterated alkanes were blended with EVA. Orthorhombic unit cells show a doublet in the C-H rocking region due to crystal field splitting; this splitting was removed upon co-crystallization. In Raman spectra, the Longitudinal Acoustic Modes (LAM) are used to validate co-crystallization. LAM did not change significantly when an alkane was co-crystallized with EVA in comparison to the neat alkane. The Raman C-H stretching region changed when a monodispersed alkane was blended. Thermal and X-ray analysis support these spectroscopic results upon co-crystallization.

C1.00046 Phase Behavior of a Weakly Interacting Polystyrene and Poly(n-hexyl methacrylate) System . HYUNGJU AHN, SUDHAKAR NAIDU, DU YEOL RUY, Yongsei University, Korea, JUNHAN CHO, Dankook University, Korea — Understanding the phase behavior of multipolymer material systems has been of great concern to polymer science community, since this provides us a key to the compatibility in most applications involving polymer blends and block copolymers. In the weakly interacting binary blends, UCST-type polymer blends generally undergo a transition from the homogeneous to phase-separated state at the unfavorable segmental interactions, while LCST-type blends show an opposite tendency as a consequence of thermal compressibility (or thermal expansion) difference between two components. We report an experimental evidence for the coexistence of both UCST and LCST behavior in a weakly interacting deuterated PS (dPS) and PnHMA blend system. A new phase diagram involving both UCST and LCST was obtained by the delicate control of molecular weights between dPS and PnHMA. Whereas for the block copolymers such as deuterated polystyrene-b-poly(n-hexyl methacrylate) (dPS-b-PnHMA) and PS-b-PnHMA, an order-to-disorder transition (ODT) on heating was observed within experimental temperature range depending on the molecular weight.

C1.00047 Polydisperse Block Copolymer Melts: Beyond the Schulz-Zimm Distribution . NATHANIEL LYND, Department of Chemical Engineering and the Materials Research Laboratory, University of California, Santa Barbara, MARC HILLMYER, Department of Chemistry, University of Minnesota, MARK MATSEN, Department of Mathematics, University of Reading — Using self-consistent mean field theory, we compared the effects of polydispersity on the phase behavior of block copolymer melts possessing two distinct distributions: the Schulz-Zimm distribution (SZD), and a realistic distribution resulting from a numerical simulation of the kinetics of an equilibrium polymerization (EQD). When the polydispersity indices (PDIs) were matched, the SZD and EQD imparts significant differences in the number of chains pulling free of the interface. This resulted in large differences in domain spacing, but negligible differences in phase boundaries.

C1.00048 Network Phase Behavior of ABC Triblock Copolymer-Homopolymer Blends for Nanoporous Membranes . MAEVA TUREAU, THOMAS H. EPPS, III, University of Delaware — ABC-type block copolymers exhibit morphological diversity not found in diblock copolymers and are becoming a versatile route to nanoscale devices. ABC triblocks are capable of self-assembling into triply-periodic network structures with a high degree of internal interfacial area and tailored chemical and mechanical properties. These unique characteristics make ABC triblock network structures ideal candidates for nanoporous membranes. Our work focuses on the morphological behavior near the network phase window in the poly(isoprene-b-styrene-b-methyl methacrylate) (ISM) system using neat triblocks and selective homopolymer blending. Morphological characterization is accomplished through a combination of small angle X-ray scattering (SAXS), transmission electron microscopy (TEM), and dynamic mechanical analysis (DMA) techniques. Neat triblocks exhibit network structures while blended systems show phase transitions including an alternating gyroid to lamellar phase transition. The neat and blended systems are mapped on a phase diagram to locate the network phase window.

C1.00049 Solution self-assembly behavior of block copolymer blends with restricted hydrophilic block . JIAHUA ZHU, SHENG ZHONG, Department of Materials Science and Engineering and Delaware Biotechnology Institute, University of Delaware, KENNETH HENRY DEWIS, DARRIN POCHAN, Department of Materials Science and Engineering and Delaware Biotechnology Institute, University of Delaware — Novel assembled structures due to segregation of hydrophobic domains trapped within the same micelle core have been produced via a block copolymer blend in tetrahydrofuran/water solution. The block copolymer blend is composed of two or more block copolymers with shared polycrylic acid (PAA) hydrophilic block, but distinctive hydrophobic blocks. The blended micelles are created by taking advantage of the electrostatic association in the hydrophilic PAA shell between the negatively charged acid of the PAA block and added, positively charged organamine molecules. Unlike hydrophobic blocks undergo local segregation. This segregation gives rise to new nanostructures deviated from traditional polymeric assemblies such as spheres, cylinders and vesicles. Transmission electron, cryogenic transmission electron, and atomic force microscopy along with x-ray and neutron scattering have been applied to characterize the assembled structures.
C1.00050 Time-composition superpositioning in the rheological behavior of triblock copolymer/ selective co-solvent blends, ARJUN KRISHNAN, North Carolina State University, RUDOLF BUKOVNIK, Tyco Electronics Corp., RICHARD SPONTAK, North Carolina State University — Thermoplastic elastomers composed of styrenic triblock copolymers are of great importance in applications such as adhesives and vibration dampening due to their resilience and facile processing. The swelling of these polymers by adding midblock selective solvents or oligomers provides an easy route by which to modify the morphology and mechanical behavior of these systems. In this study we consider a ternary blend of a poly(styrene-b-(ethylene-co-butylene)-b-styrene) triblock copolymer and mixtures of two midblock selective co-solvents: a mineral oil that is liquid at ambient temperature, and a glassy tackifier resin that exhibits limited solubility in the midblock matrix. We use dynamic rheology to study the viscoelastic response of a wide variety of systems under oscillatory shear. The copolymer concentration is varied between 15 to 35 wt%, while the resin/oil ratio in the midblock-solvent matrix is independently varied. Frequency spectra acquired at ambient temperature display viscoelastic behavior that shifts in the frequency domain depending on the resin/oil ratio. At high oil loadings, the materials behave as physical gels. For each copolymer concentration, all the frequency data can be shifted by time-composition superpositioning to yield a single master-curve.

C1.00051 Drop shape analysis of poly-styrene acrylic acid gradient copolymer at oil/ water interfaces, WA YUAN, MICHELLE MOK, JOHN TORKELSON, KENNETH SHULL, Northwestern University — The behavior of poly-styrene/ acrylic acid gradient and block copolymers at liquid/liquid interfaces was investigated using drop shape analysis. Copolymers were dissolved in chloroform and then pendant drops of the solutions were created in water. The drop shape was monitored as a function of time in order to determine interfacial parameters. Molecular movements at the interface were inferred by measuring changes in interfacial pressure as the interface was contracted and expanded through control of the drop volume. A picture of the interfacial structure of gradient copolymer system was obtained from an analysis of these results. This analysis suggests that gradient copolymers are more interfacially active than block copolymers. The interfacial properties depend more strongly on the hydrophilic/hydrophobic ratio and sequence distribution than on the molecular weight.

C1.00052 Influence of Binding Strength on the Structure of Supramolecular Polymer-Surfactant Complexes, MANESH GOPINADHAN, Department of Chemical Engineering, Yale University, EVAN BEACH, PAUL ANASTAS, Department of Chemistry, Yale University, CHINEDUM OSUJI, Department of Chemical Engineering, Yale University — Specific interactions between small molecule species and host binding sites on a polymer chain can be used to engineer supramolecular complexes which display liquid crystalline order. In particular, hydrogen bonding interactions represent a flexible platform for the creation of graft-copolymer like structures by the reversible, specific association of small molecules with complementary sites on the polymer backbone. We use hydrogen bonding between the imidazole termination of mesogenic species and the carboxylic acid groups of poly(acrylic acid) to form side-chain liquid crystalline polymers in solution and in the melt state. We investigate their phase behavior and binding using a combination of calorimetry (DSC), x-ray scattering (SAXS), infrared spectroscopy (FTIR) and optical microscopy. We find that there is a critical interaction strength and critical stoichiometry required for the formation of a liquid crystalline mesophase in these systems. The manipulation of the binding equilibria via temperature makes for an interesting class of stimuli responsive materials in solution and in the melt state.

C1.00053 Registration of Lamellar Microdomains of PS-b-PMMA to Topographic Guiding Patterns, SANG-MIN PARK, CHARLES RETTNER, JED PITTERA, HO-CHEOL KIM, IBM Almaden Research Center — In addition to the control over orientation and lateral alignment, the control over precise placement of microdomains is critical for block copolymer lithography. We report here an approach for spatial registration of the lamellar microdomains of poly(styrene-b-methy methacrylate) (PS-b-PMMA) using topographic guiding patterns prepared by E-beam lithography. By employing two levels of topographic patterns, we could achieve both alignment and registration of lamellae on surface. Details on the limitations and challenges of this approach will be addressed along with potential applications to device fabrications. A mean field Monte Carlo simulation on an IBM BlueGene/L which provides additional structural insights into the influence of the topographic guiding patterns will be presented as well.

C1.00054 The Assembly of Cyclopeptide-Polymer Conjugates and Block Polymer, NANA ZHAO, Department of Materials Science and Engineering, University of California, BRETT HELMS, Material Sciences Division, Lawrence Berkeley National Laboratory, TING XU, Materials Science and Engineering, Department of Chemistry, University of California, Material Sciences Division, Lawrence Berkeley National Laboratory — The co-assembly of cyclopeptide-polymer conjugates and block polymer affords a simple route to generate hierarchical structures with molecular level control over the assemblies. By coupling synthetic homopolymer to a preformed cyclic (D-alt-L)-R- octapeptide, a family of coil-ring-coil bioconjugates was synthesized. The controlled self-assembly of the conjugate leads to uniform nanoparticle structures, 2.5-3nm in height and 25-30nm in diameter. The assembly of blends of cyclopeptide-polymer conjugates and diblock copolymers provide a base to generate nanoporous materials and improve our understanding in the self-assembly of multi-component hybrid systems.

C1.00055 Block Copolymer Based Supramolecules for Organoelectronic, BENJAMIN RANCATORE, Department of Chemistry, UC Berkeley, SHIH-HUANG TUNG, Department of Materials, UC Berkeley, CLAYTON MAULDIN, Department of Chemistry, UC Berkeley, PAUL TILLBERG, Department of Materials, UC Berkeley, CLAIRE WOO, Department of Chemical Engineering, UC Berkeley, JEAN M.J. FRECHET, Department of Chemistry, UC Berkeley, TING XU, Department of Materials, UC Berkeley — Block copolymer (BCP)-based supramolecules present unique advantages over conjugated BCPs to fabricate functional devices such as OLEDs and photovoltaics. The self assembly of 5"-(3,7-diethylacyl)-5-(3-hydroxyphenyl)propyl]-2,2'5',2"'-quaterthiophene (4T) hydrogen bonded to the poly(4-vinylpyridine) (P4VP) block of polystyrene-b-poly(4-vinylpyridine) (PS-b-P4VP) BCP was studied in bulk and thin films. Lamellae-within-lamellae hierarchical structure was observed and can be macroscopically oriented at both length scales in thin films. Films of pure 4T, P4VP(4T) and PS-b-P4VP(4T) composites were investigated as organic field-effect transistors (OFETs). Phase behavior of blends of the BCP-based supramolecule and PCBM were also investigated to guide the fabrication of organic photovoltaics.

C1.00056 Chain Bridging in Semicrystalline Multiblock Copolymers, MANAS SHAH1, VENKAT GANESAN2, The University of Texas at Austin — The structure development in semicrystalline/rubbery multiblock copolymers involves complex interplay between two self-ordering mechanisms — microphase separation and crystallization of one of the components. Experiments have suggested connection between the mechanical properties and the molecular architecture of such linear copolymers, especially the role of bridging conformations in multiblock copolymers. We present a theoretical study to evaluate the bridging/looping fractions in these multiblock copolymers as a function of the morphology and the molecular architecture. We model the non-crystalline (rubbery) component as a flexible Gaussian chain and the crystalline component as a semiflexible chain with a temperature dependent rigidity and a favorable tendency to form parallel bonds. We calculate the domain spacing in lamellar phases of diblock copolymer where one flexible chain is attached to the semiflexible chain and compare the scaling exponents with existing scaling theories for semicrystalline diblock copolymers. Using self-consistent field theory, the bridging fractions of the various domains in these complex multiblock copolymers (triblock and pentablock) are evaluated as a function of the sequence of the chains and other parameters in the system.

C1.00057 Tuning the Structure-Directing Block in Crystalline-Crystalline Diblock Copolymers, SHENG LI, SASHA MYERS, RICHARD REGISTER, Princeton University — Crystalline-crystalline block copolymers containing two or more chemically distinct crystallizable blocks are fascinating because their solid-state structures can be set either by block incompatibility or by crystallization of one or more blocks, depending on macromolecular design and processing history. Double-crystalline diblock copolymers of linear polyethylene (LPE) and hydrogenated polyboronene (hPBN) were synthesized, and their crystallization behavior and morphology were examined using two-dimensional simultaneous time-resolved synchrotron small-angle and wide-angle x-ray scattering. In previous work (Macromolecules 2008, 41, 6773), we showed that for diblock molecular weights of 50 kg/mol and above, the hPBN block always crystallized first and set the solid-state microstructure. In the present work, we explore the difference in molecular weight dependence of the melting/freezing points of LPE vs. hPBN to create materials where LPE is the structure-directing (templating) block. In 20 kg/mol diblocks, LPE block crystallizes first, even when LPE is the minority component, and restricts hPBN to crystallize between the LPE lamellae. In hPBN-rich diblocks, LPE crystallization triggers hPBN crystallization and the two blocks crystallize at almost the same rate. During cooling to room temperature, hPBN transitions from a rotationally disordered pseudohexagonal phase to a monoclinic structure.

C1.00058 Tethered Polyhedral Oligomeric Silsesquioxane on Lamellar Single Crystal of Poly(D-lactide), XIN-FEI YU, WEN-BIN ZHANG, RYAN VAN HORN, RODERIC QUIRK, STEPHEN CHENG, University of Pennsylvania — We report the synthesis and characterization of two copolymers having imidazolium based-ionic groups on POSS. The synthesis involved anionically polymerizing Poly(ethylene oxide)-b-poly(n-butyl methacrylate-r-3-trimethylsilylprop-2-ynyl methacrylate) block copolymer on a POSS-functionalized surface. The POSS-functionalized microdomains of the block copolymer were confirmed by small angle x-ray scattering (SAXS) and transmission electron microscopy (TEM). Tethering density of POSS was controlled by the molecular weight of PDLLA crystalline chain and by the variation of preparation conditions. Tethering density was increased as molecular weight of PDLLA was lower and crystallization temperature was increased higher.

C1.00059 A simple method to control the porosity in thin block-copolymer films, WONJOO LEE, XIN ZHANG, ROBERT M. BRIBER, University of Maryland, College Park — We report a simple way developed to control the porosity in block-copolymer films. PS-P4VP block copolymer/PS4VP homopolymer was dissolved at 80 °C for 12 hours and cooled to room temperature. Depending on the amount of PS4VP homopolymer, from 1% to 25% of PS4VP, the thin films prepared showed different morphologies depending on the composition of the material and the surface/substrates used. The films were examined by AFM and TEM. Interestingly, large scale macrophase-separation was not found regardless of the ratio of PS4VP and PS. Instead, it was found that microphase-separation occurred during the spincoating process for all concentrations of PS4VP homopolymer studied. The size of the microphase-separated domains increased as the ratio of PS4VP to PS increased, indicating that the added PS4VP homopolymer was contained within the P4VP microdomains. The PS-P4VP/P4VP blend films were then immersed for 3 hours in ethanol which induced a reconstruction of the film structure and removed the PS4VP homopolymer. The resulting morphology exhibited nanoscale porosity with the pore size increasing with increasing concentration of P4VP homopolymer. A possible mechanism for the microphase-separation for the formation of the nanoporous structure will be discussed.

C1.00060 Nanoscale functionalized surface pattern by combining block copolymer template and click chemistry, XINYU WEI, WEI CHEN, THOMAS RUSSELL, Univ of Massachusetts Amherst — Poly(ethylene oxide)-b-poly(n-butyl methacrylate-r-3-trimethylsilylprop-2-ynyl methacrylate) block copolymer was successfully prepared by atom transfer radical polymerization (ATRP) starting from a PEO macroinitiator, with good control of molecular weight, polydispersity and comonomer composition. The trimethylsilyl protecting group can then be quantitatively converted to terminal alkyne groups under mild conditions. Microphase separation of these block copolymers has been confirmed by small angle X-ray scattering (SAXS). Orientation of microdomains in thin films can be controlled by thermal or solvent annealing. Nanoparticles or biological macromolecules can be selectively immobilized onto the methacrylate microdomains through the cycloaddition between terminal alkynes and azides, which leads to a functionalized surface pattern for many applications.

C1.00061 Controlled morphology of Nafion® perflourinated ionomer membrane and poly(vinylidene-co-trifluoroethylene) blends for swelling suppression, NADZRNAHAMIN AHMAD NAZIR, THEIN KYU, University of Akron — The major objective of the present study is concerned with the swelling suppression of Nafion® membrane upon hydration through blending with poly(vinylidene fluoride-co-trifluoroethylene) (PVDF-TrFE) copolymer. The phase diagram of the Nafion/PVDF-TrFE blend was established by differential scanning calorimetry, cloud point measurement, and optical microscopy. A theoretical phase diagram was calculated by self-consistently solving the combined Flory-Huggins free energy for liquid-liquid demixing and the phase field free energy for crystal solidification. The resulting phase diagram is the combined LCST-UCST and/or an hour glass guide. Based on the phase diagram, the phase separated domain morphology can be controlled to exhibit bicontinuous or dispersed domains via phase separation by solvent casting or thermal quenching. The blends thus prepared not only afford suppression of water uptake, but also can maintain dimensional stability. Fourier transform infrared spectroscopy studies and water uptake measurements showed infallible evidence that modification of Nafion® with PVDF-TrFE reduces swelling upon hydration.

C1.00062 Synthesis and Morphology Study of Copolymers Containing Imidazolium Group, DAVID SALAS-DE LA CRUZ, University of Pennsylvania, SHARLENE R. WILLIAMS, JOHN LAYMAN, MATT GREEN, TIMOTHY E. LONG, Virginia Tech, KAREN I. WINEY, University of Pennsylvania — We report the synthesis and characterization of two copolymers having imidazolium based-ionic groups located either in the backbone or side chain. Imidazolium ionene segmented block copolymers, containing imidazolium group in the backbone, were synthesized from 1,1’-(1,4-butanediyl)bis(imidazole), 1,12-dibromododecane hard segments, and PTMO dibromide. Vinyl imidazolium random copolymers, containing the imidazolium group in the side chain, were synthesized from 1-butyl-bromide and 3-vinylimidazolium in ethyl acetate and copolymerized with methylmethacrylate. The morphological studies of micelles and nanofibers were performed through blending with poly(vinylidene fluoride-co-trifluoroethylene) (PVDF-TrFE) copolymer. The phase diagram of the Nafion/PVDF-TrFE blend was established by differential scanning calorimetry, cloud point measurement, and optical microscopy. A theoretical phase diagram was calculated by self-consistently solving the combined Flory-Huggins free energy for liquid-liquid demixing and the phase field free energy for crystal solidification. The resulting phase diagram is the combined LCST-UCST and/or an hour glass guide. Based on the phase diagram, the phase separated domain morphology can be controlled to exhibit bicontinuous or dispersed domains via phase separation by solvent casting or thermal quenching. The blends thus prepared not only afford suppression of water uptake, but also can maintain dimensional stability. Fourier transform infrared spectroscopy studies and water uptake measurement showed infallible evidence that modification of Nafion® with PVDF-TrFE reduces swelling upon hydration.

C1.00063 Nanoscale Ionic Aggregate Morphology in Zwitterionic Copolymers, JAE-HONG CHOI, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6722, REBECCA HUYCK, Department of Chemistry, Virginia Tech, Blacksburg, VA 24061, DAVID SALAS-DE LA CRUZ, University of Chemical and Biomolecular Engineering, University of Pennsylvania, Philadelphia, Pennsylvania 19104 — The morphology of two different zwitterionic copolymers, poly(sulfobetaine methacrylate-ran-butyl acrylate), and poly(sulfobetaine methacrylamide-ran-butyl acrylate) are investigated as a function of the mol % content of SBMA (7 and 9 mol %) and SBMAm (6, 10 and 13 mol %), respectively. In both copolymers, X-ray scattering results show a new structure in the material arising from ionic aggregates. The sizes of the ionic aggregates are obtained through the scattering model. The sizes of the ionic aggregates increase as the ion content increases. The application of scanning transmission electron microscopy to the study of ionomer morphology has enabled direct, model-independent visualization of the ionic aggregates. The correlation between X-ray scattering results and the real space imaging for morphology of these zwitterionic copolymers will be presented.
C1.00064 Dynamics and Morphology of Sulfonated Polystyrene Ionomers by Dielectric Spectroscopy, ALICIA CASTAGNA, Penn State University, WENQIN WANG, KAREN I. WINEY, University of Pennsylvania, JAMES RUNT, Penn State University — The dynamics of sulfonated polystyrene (SPS) ionomers, in both the acid and neutralized forms, were investigated using broadband dielectric spectroscopy. The influences of acid content, counterion type (Zn, Na, and Cs), degree of neutralization, and microphase separated morphology on segmental and local dynamics, as well as on Maxwell – Wagner – Sillars interfacial polarization, were examined.Ionomers prepared from SPS containing 1.9 mol% sulfonic acid species exhibit a broader segmental process indicative of a considerably broader distribution of local environments, as compared to those in neutralized SPS. Moreover, multiple segmental relaxations were identified in the dielectric spectra of Zn and Na neutralized SPS (1.9 mol%) ionomers, likely indicating two distinct environments arising from ion clustering. A combination of STEM imaging and X-ray scattering confirmed the presence of monodisperse spherical ionic aggregates that were homogeneously distributed in the polymer matrix.

C1.00065 Dynamics of Strongly Associating Polymer Blends Using Broadband Dielectric Spectroscopy1, KEVIN MASSER, JAMES RUNT — In this study we investigate the dynamics of miscible polymer blends that preferentially form strong intermolecular hydrogen bonds. Random copolymers of p-(hexafluoro-2-hydroxyethyl-2-propyl)styrene [HFS] and 2,3-dimethylbutadiene [DMB] were synthesized for this study, as was the HFS homopolymer. HFS units are capable of forming strong intermolecular hydrogen bonds with complimentary species on a second miscible polymer, while minimizing the extent of intramolecular associations. The copolymers/homopolymers were blended with select homopolymers that form intermolecular hydrogen bonds of varying strength. Broadband dielectric relaxation spectroscopy is used to study segmental and local blend dynamics, which are observed to vary significantly in the presence of hydrogen bonding. Fourier transform infrared spectroscopy was used to determine the degrees and strengths of hydrogen bonding present in the blends.

C1.00066 Investigating void development in filled elastomers under uniaxial strain, AILISH O’HALLORAN, National University of Ireland Galway, ARTHUR SCHOLZ, University of California Santa Barbara, KRISTIN SCHMIDT, University of California Santa Barbara, LIXIA RONG, Brookhaven National Laboratory, SHIGEYUKI TOKI, BENJAMIN HSIAO, Stony Brook University, ED KRAMER, University of California Santa Barbara — Development of voids during cyclic, uniaxial extension and retraction, of both silica and resin filled elastomers, was studied by combining synchrotron-based time resolved small angle X-ray scattering (SAXS) and primary X-ray beam attenuation with stress-strain curves measured simultaneously. These data were used to calculate the volumetric voids due to the development of voids during extension and their subsequent disappearance during retraction as well as the size and shape of the smaller voids. Four samples were investigated, one silica-filled polydimethylsiloxane (PDMS), one resin filled PDMS, and two silica filled polyphenylethylmethylsiloxane (PPMS), all candidate materials for dielectric elastomer actuators, in which void development would lead to decreased dielectric breakdown electric fields and premature failure.

C1.00067 Probing the Mullins Effect in Filled Elastomers by Small Angle X-ray and Neutron Scattering, ARTHUR SCHOLZ, Materials Department, UCSB, REX HJELM, MARK TAYLOR, Los Alamos Neutron Science Center, ED KRAMER, Materials Department, UCSB — While there has been considerable effort made to understand and model the effect that filler particles have on the mechanical properties of filled elastomers, the origins of a striking characteristic strain softening known as the Mullins Effect are still debated. Several micro-mechanical models have been proposed using a variety of mechanisms to describe the polymer-filler and filler-filler interactions to fit mechanical test data without any direct observation of microstructural changes. Small angle X-ray and neutron scattering provide complimentary methods for observing these changes on the relevant length and time scales necessary for identifying and characterizing the proposed mechanisms. We designed and built a modular uniaxial load frame for use in a variety of lab and user facilities. Its capabilities include a 350mm of symmetrical travel and a non-contact strain measurement system using speckle pattern digital image correlation. The system was developed and tested silica-filled polydimethylsiloxane (PDMS) and polyphenylethylmethylsiloxane (PPMS) elastomers using the Low Q Diffractometer at the Los Alamos Neutron Science Center at Los Alamos National Laboratory.

C1.00068 Segmented polyurethanes containing carbon nanotube nanohybrid shishkebabs, MATTHEW HOOD, Drexel University, JAMES SANDS, JOHN LASCALA, RICR BLEYER, Army Research Labs, CHRISTOPHER LI, Drexel University — Segmented polyurethanes (SPUs) are linear, multiblock copolymers that possess a wide range of tailorable properties via control during synthesis and processing. Phase separation between SPU’s segments produce superior elastomeric properties with hard domains maintaining the polymer matrix under stress, while soft domains provide flexibility allowing for a high degree of strain. We have synthesized a variety of SPU systems using different molecular weight macrodiol soft segments and various concentrations of hard segments, which are composed of hexamethylene disocyanate and butanediol. SPU morphology control via tuning the hard/soft segment ratio was achieved. Furthermore, adding carbon nanotubes (CNTs) that have been periodically patterned with functionalized crystalline polymers to the shishkebab hard segments and various CNT concentrations led to tunable mechanical properties of our SPU system even at low CNT concentrations. Differential scanning calorimetry, dynamic mechanical analysis, wide angle X-ray diffraction and transmission electron microscopy have been used to characterize these systems and compare them to neat SPU. By tailoring SPU composition and shishkebab concentration we have produced a system with significant mechanical improvement with potential for use as a shape memory polymer.

C1.00069 Efficient Synthesis of Poly( hydroxyethyl Methacrylate)-b-Poly(dimethyaminoethyl Methacrylate) Block Copolymer by Atom Transfer Radical Polymerization, WEI TANG, YUEH-LIN LOO, Engineering Quadrangle, Princeton University, Princeton, NJ 08544-5263 — Polymers containing hydroxyethyl methacrylate (HEMA) and dimethyaminoethyl methacrylate (DMEA)A have found wide applications in areas such as bioseparation, tissue engineering and controlled drug delivery. The controlled synthesis of block copolymers of PDMAEMA-b-PHEMA from PDMAEMA macronitiator by atom transfer radical polymerization (ATRP), however, has not been successful due to the loss of chain end functionality during polymerization. We report an ATRP system that affords efficient chain extension from PDMAEMA to HEMA using Cu(0)/1,1,4,7,10,10-hexamethyldiepoxynorprene as the catalyst, 2-chloropropionitrile as the initiator in methanol at room temperature. A clear peak shift in the gel permeation chromatography trace towards shorter elution times indicates chain growth on HEMA addition. The chain end functionalities of PDMAEMA are thus retained and can be used to efficiently initiate chain extension reaction of HEMA. This new synthetic route opens new possibilities for the synthesis of pH- and temperature-responsive systems containing DMAEMA.

C1.00070 Atom Transfer Radical Copolymerization of Gradient Copolymers of HEMA/DMAEMA with Arbitrary Composition Profiles, KEITH GALLOW, YUEH-LIN LOO, Princeton University — Gradient copolymers represent a new class of statistical copolymers where a non-uniform composition profile is controllably introduced along the length of the polymer chain. Gradient copolymers have thermal and mechanical properties that are different from random or block copolymers having the same average composition. Due to synthetic limitations, however, the introduction of arbitrary composition profiles remains challenging. Here, we demonstrate the ability to controllably introduce arbitrary composition profiles along copolymers of 2-hydroxyethyl methacrylate (HEMA) and 2-(dimethylamino)ethyl methacrylate (DAMAEMA) by atom transfer radical copolymerization in a semi-batch reactor. Using gas chromatography to monitor monomer consumption, respectively, and both show good agreement with our model’s predictions.
C1.00071 Improving the Electrical Conductivity of Polyaniline Through Molecular Control. JOUNG EUN YOO, WILLIAM KRÄKELBERG, TRACY BUCHOLZ, THOMAS TRUSKETT, YUEH-LIN LOO, PRINCETON UNIVERSITY TEAM, UNIVERSITY OF TEXAS AT AUSTIN COLLABORATION — We have investigated the electrical conductivity of polyaniline (PANI) that is template synthesized with a polymer acid of poly(2-acrylamido-2-methyl-1-propanesulfonic acid), PAAMPSA. The conductivity of PANI-PAAMPSA is determined by the particle density when PANI-PAAMPSA is cast as films. The PANI-PAAMPSA particle density can in turn be tuned by manipulating the molecular characteristics of PAAMPSA. Specifically, templating aniline polymerization with a higher molecular weight PAAMPSA results in bigger PANI-PAAMPSA particles; templating aniline polymerization with a broader molecular weight distribution PAAMPSA results in particles with a larger size distribution. The conductivity of drop-cast films of PANI-PAAMPSA therefore depends on how the particles pack in the solid state. In particular, we find the conductivity of PANI-PAAMPSA to increase with particle density. Additionally, PANI is preferentially segregated to the surface of these particles. The conductivity of PANI-PAAMPSA thus scales superlinearly with the surface area per unit volume of the cast film.

C1.00072 An Investigation of Polyelectrochromism in Water-Dispersible Polyaniline. JACOB TARVER, JOUNG EUN YOO, YUEH-LIN LOO, Department of Chemical Engineering, Princeton University — The promise of polyaniline (PANI)-based devices, such as electrochromic windows or billboards, is motivated by the coupled nature of PANI’s redox and chromic properties. In its fully reduced and oxidized form, PANI is electrically insulating and characteristically transmits yellow and violet, respectively. Protonation of PANI’s intermediate oxidation state induces electrical conductivity and shifts its transmission to green. This proton dependence has historically limited the use of small molecule acid doped PANI to acidic media. Template synthesis of PANI on poly(2-acrylamido-2-methyl-1-propanesulfonic acid), or PAAMPSA, yields electrostatically stabilized PANI-PAAMPSA particles; films comprising these particles maintain electroactivity in solutions as high as pH 10. Exposure to dichloroacetic acid moderates the electrostatic interactions, thereby relaxing the material’s global structure. This structural rearrangement significantly improves the stability and reversibility of repeated cycling between PANI’s redox states. Relaxation of PANI-PAAMPSA’s structure thus affords enhanced robustness to this readily-processible system.

C1.00073 Development of Polymer Electrolyte Membrane (PEM) from Bisphonol S for Direct Methanol Fuel Cell (DMFC). SAIRUNG CHANGKHAMCHOM, ANUVAIT SIRIVAT TEAM — The currently used Proton Exchange Membrane (PEM) in a Direct Methanol Fuel Cell (DMFC) is Nafion®, an excellent proton conductor in a fully hydrated membrane. However, it has major drawbacks, such as very high cost, and loss of conductivity at elevated temperature and low humidity. In this work, a novel PEM based on sulfonated poly(ether ether ketone) (S-PEEK). Poly(ether ether ketone) (PEEK) was synthesized by the nucleophilic aromatic substitution polycondensation of Bisphonol-S and 4,4’-difluorobenzophenone for system A, and Bisphenol S and 4,4’-dichlorobenzophenone for system B. Bisphenol-S helps to increase the thermal stability due to its high melting point (245°C). The post-sulfonation reaction was performed by using concentrated sulfuric acid. Sulfonated poly(ether ether ketone) (S-PEEK) samples were characterized by FTIR and 1H-NMR to confirm the chemical structure of the S-PEEK, and by TGA to investigate the thermal property.

C1.00074 Iontophoresis of Salicylic Acid From Salicylic Acid Doped Poly(p-phenylene vinylene)/Polyacrylamide Hydrogels. SUMONMAN NIALLANG, ANUVAIT SIRIVAT TEAM — The apparent diffusion coefficients, D_app, and the release mechanisms of salicylic acid from salicylic acid-loaded polyacrylamide hydrogels, SA-loaded PAAM, and salicylic acid-doped poly(p-phenylene vinylene)/polyacrylamide hydrogels, SA-doped PPV/PAAM, were investigated. In the absence of an electric field, the diffusion of SA from the SA-doped PPV/PAAM hydrogel is delayed in the first 3 hr due to the ionic interaction between the anionic drug and PPV. Beyond this period, SA can diffuse continuously into the buffer solution through the PAAM matrix. D_app of SA-doped PPV/PAAM is higher than that of the SA-loaded PAAM, and the former increases with increasing electric field strength due to the combined mechanisms: the expansion of PPV chains inside the hydrogel; iontophoresis; and the electroporation of the matrix pore. Thus, the presence of the conductive polymer and the applied electric field can be combined to control the drug release rate at an optimal desired level.

C1.00075 Morphology of Hole Injection Layers for Polymer Light Emitting Diodes. KRISTIN SCHMIDT, KAREN E. SOHN, Materials Research Laboratory, University of California, Santa Barbara, FABRICE AMY, LING YANG, Air Products and Chemicals Inc, Pennsylvania, EDWARD J. KRAMER, Materials Research Laboratory, University of California, Santa Barbara — Hole injection layers (HIL) play important roles in improving the device efficiency and stability of polymer light emitting diodes (PLED) as they can enhance the hole injection from the ITO electrode. It was shown that thermal annealing of the PLEDs results in a remarkable improvement in the long-term stability of the device. These reports lead to the hypothesis that changes in the morphology of the phase separated mixture of the polymers in the HIL is responsible for this improvement. However, no experimental evidence of such morphological changes exists. To investigate the morphological changes during annealing we performed NEXAFS, SAXS and GISAXS experiments on thin films of different blends consisting of poly(3,4-ethylene dioxythiophene) (PEDOT) with either poly(fluoroethylene-r-fluoroether-ether ketone) (S-PEEK). Poly(ether ether ketone) (PEEK) was synthesized by the nucleophilic aromatic substitution polycondensation of Bisphonol-S and 4,4’-difluorobenzophenone for system A, and Bisphenol S and 4,4’-dichlorobenzophenone for system B. Bisphenol-S helps to increase the thermal stability due to its high melting point (245°C). The post-sulfonation reaction was performed by using concentrated sulfuric acid. Sulfonated poly(ether ether ketone) (S-PEEK) samples were characterized by FTIR and 1H-NMR to confirm the chemical structure of the S-PEEK, and by TGA to investigate the thermal property.

C1.00076 Nanoparticle Tethered Perylene Tetracarboxylic Diimides as Novel Photo Harvesting Antennae. WENBIN ZHANG, BIN SUN, HUI LI, MATTHEW PANZNER, WILEY YOUNGS, RODERIC QUIRK, STEPHEN CHENG, Maurice Morton Institute and Department of Polymer Science, Department of Chemistry, The University of Akron — Shape-persistent, well-defined, incompressible nano objects, such as polyhedral oligomeric silsequioxane (POSS) and C60, have been connected covalently to perylene tetracarboxylic diimide (PDI) to give a series of nanoparticle tethered PDI molecules, which could self-assemble into various ordered structures. For example, POSS end-capped PDI, namely POSS-PDI-POSS, grows single crystal lamellae of dimensions up to the centimeter scale in length. The crystal structure has been determined to be triclinic with a = 1.14 nm, b = 2.09 nm, c = 2.31 nm and α = 89.9°, β = 81.9°, γ = 82.3°. It shows that POSS forms bilayers in the crystal separated by PDI dimer molecular planes along the c axis. The self-assembly of the asymmetric POSS-PDI-C60 is even more intriguing. It gives single crystals with alternating POSS and C60 layers separated by PDI planes, which holds promising applications as photo harvesting antennae in photovoltaics. Our results show that nanoparticles could interplay with the strong p-p interaction and assist the self-assembly to ordered structures.
C1.00077 Highly Ordered Phases in Electrochemically Deposited Poly(3,4-ethylenedioxythiophene) (PEDOT)—LiBr\(^1\). JINGHANG WU, SARAH SPANNINGA, DAVID MARTIN, University of Michigan — Poly(3,4-ethylenedioxythiophene) (PEDOT) is a widely used \(\pi\)-conjugated polymer of considerable current interest for a variety of different applications such as biosensors, antireflective layers, electroluminescent devices, and hole injection layers in organic light emitting diodes and photovoltaics. These films have high conductivity, as well as thermal and chemical stability. PEDOT films prepared by chemical or electrochemical polymerization with different counter ions have shown different levels of modest order and crystallinity, typically with limited molecular orientation and relatively small crystallites. We have developed methods for preparing highly ordered phases by the electrochemical polymerization of PEDOT onto polycrystalline conducting substrates with LiBr as the counterion. The polymerizations are conducted at room temperature from aqueous solution. These phases have ordered crystalline domains that are hundreds of microns in size, and are uniformly birefringent. The structure of the ordered phase was characterized by optical and electron microscopy, X-ray diffraction, as well as infrared and X-ray photoelectron spectroscopy.

C1.00078 Sensitivity Enhancement of PEDOT-PSS towards CO by Zeolite ZSM-5 Additive. POJJAWAN CHANTHAANONT, ANUVAT SIRIVAT TEAM\(^1\) — Polymer-based gas sensors have received considerable interest in recent years, due to their gas sensing ability through the electrical conductivity changes when exposed to gases. In our research, poly(3,4-ethylenedioxythiophene) doped with poly(styrene sulfonic acid), PEDOT-PSS, was synthesized via the oxidative polymerization and zeolites were used as selective microporous adsorbent to improve selectivity and sensitivity of the sensors. PEDOT-PSS were fabricated with zeolites by dry mixing and compressed to form PEDOT-PSS/zeolite composites. Zeolites ZSM-5 were chosen to investigate the effect of Si/Al mole ratios of zeolite on the electrical conductivity sensitivity response of PEDOT-PSS,1,1/zeolite ZSM-5 composites when exposed to CO. The electrical conductivity sensitivity of PEDOT-PSS,1,1/zeolite composites towards CO negatively increases with decreasing Si/Al mole ratios of zeolite ZSM-5. The highest electrical conductivity sensitivity response is obtained from PEDOT-PSS,1,1/Zeolite-ZSM-5(Si/Al = 23).

C1.00079 Flexible Field Emission Devices\(^1\), SUNNY SETHI, ALI DHINOJWALA, THE UNIVERSITY OF AKRON TEAM — We report synthesis of flexible field emission devices using patterned and non-patterned vertically aligned carbon nanotube arrays and use of such devices to induce phosphorescence. Carbon nanotube is known to have excellent electron emitting properties. On macroscopic scale, emission current density is much less than that for a single nanotube for reasons like screening effect and non uniform emission. Here, we report a very unique way to fabricate flexible field emission devices using partially entrapped aligned nanotubes in an elastomer as cathode. Using this process not only helps in fabricating a flexible geometry but also helps in the reduction of screening effect, thus increasing the emission efficiency. Emission current for these devices was studied with respect to the area and total perimeter for patterned nanotubes. These studies help to understanding the mechanism to translate nanoscopic emission to a macroscopic scale.

C1.00080 Effect of light attenuation on motion of photo-responsive polymer gels. PRATYUSH DAYAL, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh — Nature has found an efficient way to utilize chemical reactions to produce mechanical work. Whenever the need for energy arises, the chemical reactions in our body produce energy, which is used to generate mechanical response. Scientists have been trying to replicate the same functionality in man-made systems. One of the recent approaches couples the Belousov-Zhabotinsky (BZ) reaction and the mechanical properties of the gel to produce self-sustained oscillations. To study the effect of light on the mechanical behavior of the gel, we use our recently developed 3D gel lattice spring model (gLSM) which couples the BZ reaction kinetics to the gel dynamics. In order to include the effect of the polymer on the reaction kinetics, the Oreganator model for the photo-sensitive BZ reaction was modified. Using modeling and simulations, we have been able to control gel's shape and its locomotion using light as an external stimulus. Here we show that the intrinsic non-homogeneity in light intensity, created by gel can induce autonomous motion of the gel away from light.

C1.00081 Watching Nanoparticles Move through Polymers, JUAN GUAN, BO WANG, STEPHEN ANTHONY, SUNG CHUL BAE, STEVE GRANICK, U of Illinois - Urbana - Champaign — Several recent experiments show that the Stokes-Einstein equation used to describe particle diffusion is violated when nanoparticles are surrounded by polymer chains. In some systems, particles move faster; in others, more slowly, depending on the size of the probe. It is generally agreed that the relative timescale for a polymer chain to relax and a nanoparticle to diffuse the size of a polymer chain are what matter. In this work, we embed fluorescently-labeled nanoparticles within polymer solutions and use single-particle tracking to understand the relative motions of the two. A unique aspect is that we track motions not just of the nanoparticles but also those of the polymer chains in which they are embedded. The worst-case resolution of 30 nm in nanoparticle relative position is improved when slow motions improve the signal-to-noise.

C1.00082 An emerging theoretical picture of yielding for entangled polymeric liquids undergoing sudden deformation and flow. SHI-QING WANG, University of Akron, P.E. BOUKANY, S. RAVINDRANATH, Y.Y. WANG, X. LI, University of Akron — Recent particle-tracking velocimetric observations coupled with conventional rheological measurements have offered us a window to peek into processes responsible for a whole family of phenomena in entangled polymeric liquids. At a high rate of deformation imposed suddenly, entangled liquids can only respond like a solid and must undergo yielding before eventual flow is to take place. Until recently, how such a yielding process produces the observed scaling characteristics of the stress overshoot has remained elusive. More surprising and perplexing to many is that an elastic yielding process can also occur after cessation of any further external deformation. These experimental observations have provided the essential ingredients in the emerging theoretical picture of polymer deformation and flow.

C1.00083 Gas Diffusion and Free Volume Behavior of Ethylene Vinyl Alcohol Copolymers: Effect of Hydrogen Bonding Interaction. JUSTIN BRANDT, SERGEI NAZARENKO, BRIAN OLSON, University of Southern Mississippi, ALEXANDER JAMESON, Case Western Reserve University — The main objective of this work was to develop fundamental understanding of oxygen transport in a broad range of EVOH copolymers as it is related to free volume characteristics and hydrogen bonding interaction. FTIR was used to directly characterize H-bonding network as a function of copolymer composition and temperature. Positron annihilation lifetime spectroscopy (PALS) was used to study free volume behavior. The measure of intermolecular interaction, cohesive energy density, was calculated through group contribution methods and also obtained using molecular dynamics computer simulations. Oxygen transport characteristics of the copolymers, i.e. permeability, diffusivity, and solubility were measured at various temperatures, and the apparent activation energy parameters calculated.
C1.00084 The Viscoelastic Bulk Modulus: Effect of Crosslink Density, JIAXI GUO, SINDEE SIMON, Department of Chemical Engineering, Texas Tech University — The pressure relaxation response is measured at various temperatures in the glass transition region for two polycyanurate networks of differing crosslink density using a pressurizable dilatometer. Master curves are formed by the time-temperature superposition theory using vertical shifts to account for the temperature dependence of the bulk moduli. The results show that the pressure relaxation response has a small dependence on the viscoelastic density of the polycyanurate. However, the horizontal and vertical shift factors show a similar dependence on temperature when plotted in the form of T* vs. Tg. The horizontal shift factors agree well with those from the shear viscoelastic response. The relaxation spectra obtained from the pressure relaxation measurements will also be compared to those from shear stress relaxation experiments, and the validity of Leaderman’s hypothesis that the bulk and shear responses arise from different molecular mechanisms will be discussed.

C1.00085 Adhesion Behavior of Non-planar Wrinkled Surfaces, SANTANU KUNDU, University of Massachusetts-Amherst, RAVI SHARMA, Bausch and Lomb Inc, ALFRED CROSBY, University of Massachusetts-Amherst — Topological patterns on polymer surfaces can be used to significantly alter the surface properties, such as adhesion and contact angles. Conventional patterning methods, including photo- and imprint lithography, are difficult to apply to non-planar surfaces. Surface wrinkling induced by swelling of a soft substrate constrained by a stiff, thin surface layer offers an attractive approach. Using this method, surface patterns of various length scales over a large area on curved geometries were obtained. Controlling the thickness of the stiff layer (silicate) on a soft foundation (polydimethylsiloxane elastomers) and the strain conditions, amplitude and wavelength of the wrinkles were varied. We quantified the effect of wrinkule morphology on the adhesion of non-planar substrates.

C1.00086 Microvoid formation and strain hardening in highly cross-linked polymer networks, DEBASHISH MUKHERJI, CAMERON ABRAMS, Drexel University — Highly cross-linked polymer (HCP) networks are becoming increasingly important as high-performance adhesives and multifunctional composite materials. Because of their cross-linked molecular architectures, HCP’s can be strong but brittle. One key goal in improving the performance of HCP is to increase their toughness without sacrificing their strength. We use molecular dynamics simulations to study the mechanical properties of HCPs. We observe strain hardening in HCP glasses under tension and deformation. We show that formation of micro-voids, without bond-breaking, constitutes the microscopic origins of strain hardening. Micro-void-based strain hardening is not observed in a separate model by imposing a tetrahedral bond angle constraints. Strain hardening makes HCP networks ductile, thus indicating that flexible cross-linkers may be a possible means to control toughness of an HCP without sacrificing its strength.

C1.00087 Quantification of Molecular and Nanostructural Topology, RAMNATH RAMACHANDRAN, University of Cincinnati, GREGORY BEAUCAGE, University of Cincinnati — We have recently derived a method for the description of complex molecular and nanostructural topologies based on a statistical analysis. The method has been applied to a wide range of materials from long chain branched polyolefins, hyperbranched polymers, star polymers, H-branched polymers to cyaclics, biopolymers, and branched nanostructured aggregates. This method, when applied to neutron scattering data from dilute polymer solutions, yields the mole fraction of a structure involved in long chain branching, the branching density, and the average branch length. Moreover, quantitative measures of the convolution or tortuosity of the structure and the connectivity of the molecules can be made, opening a new window for our understanding of complex molecular topologies. When applied to neutron scattering the approach is applied to the chain-scaling regime at low to moderate values of the scattering vector. At high scattering vector the Kuhn length is observed that has been shown to be directly related to short chain branching in polyolefins. By combining information of short and long chain branching a topological map of complex molecular structure becomes possible. The method is quite generally applicable. This understanding has recently been applied to model long-chain branched polyethylene.

C1.00088 Computer simulation study of solvent quality and reaction geometry on controlled radical polymerization, SALOMON TURGMAN, JAN GENZER, North Carolina State University — Bulk- and surface-initiated controlled radical polymerizations are simulated using a stochastic Monte Carlo algorithm by following the bond-fluctuation model scheme and an attractive potential acting among bonded monomer beads. Specifically, we investigated the changes in polymer molecular weight and molecular weight polydispersity index (PDI) due to conformational variations of the chains that occur upon altering solvent quality. Variations in reaction geometry, temperature, initial monomer and initiator concentration, probability of initiation, initial probability of monomer addition, probability of termination, fraction of living polymers and their lifetime were studied. Synergistic effects among these parameters and the geometry of the reaction were also explored. Preliminary results suggest that polymerization in poor solvent quality solvents result in shorter polymers and increased molecular weight PDI.

C1.00089 Borylation of Polystyrene: Random Blocky vs. Truly Random Copolymers, WAYNE POWERS, Rensselaer Polytechnic Institute, ZACHARIAH NORMAN, CHANG RYU, Rensselaer Polytechnic Institute, CHULSUNG BAE, University of Nevada - Las Vegas, JAN GENZER, North Carolina State University, WAYNE POWERS, ZACHARY NORMAN, CHANG RYU TEAM, CHULSUNG BAE COLLABORATION, JAN GENZER COLLABORATION — Borylated PS with tuned blockiness of borylated styrene segments has been synthesized in methycyclohexene, using a bis[pinacolato]diphenylborato(1-)ligand(1) dirhodium(I) dichloride as catalysts. By performing the borylation reaction below and above the theta temperature of PS in methycyclohexene, 70 degrees Celsius, the co-monomer sequence distribution in the borylated PS changed from random-blocky to random, respectively. The “chemicalcoloring” is carried out at low PS concentration in order to ensure that individual chains do not coagulate during the borylation at temperatures below the theta temperature. NMR, SEC, cloud point measurements, and adsorption-based interaction chromatography are used to characterize the properties of borylated PS and elucidate the effects of blockiness on solubility and surface adsorption.

C1.00090 Phase behavior study of polystyrene and deuterated polystyrene in alkyl-cyclohexanes, ZACHARIAH NORMAN, Rensselaer Polytechnic Institute, WAYNE POWERS, CHANG RYU, Rensselaer Polytechnic Institute, ZACHARIAH NORMAN, WAYNE POWERS, CHANG RYU TEAM — To advance the controlled chemical modification of polystyrene (PS) and deuterated polystyrene (DPS) in solution, the phase behavior of PS and DPS in alkyl-cyclohexane solvents has been studied. Cloud point measurements have been performed by a house-made turbidity instrument using a picolog thermistor and a laser with a photoelectric cell converted to interface with a picolog TH-03 three channel thermistor converter. Solution phase diagrams for molecular weights of PS varying from 67 thousand to 1.8 million have been presented for methyl cyclohexane, propyl cyclohexane, isopropyl cyclohexane, butyl cyclohexane and isobutyl cyclohexane for the measurements of critical solution temperatures as a function of molecular weight. The theta temperature of polystyrene in each of these solvents has been estimated through extrapolation from the molecular weight dependence of the critical temperatures from the cloud point measurements.

C1.00091 Zero-dimensional organic nanoparticles via copolymer directed self-assembly, DEQUAN XIAO1, KUNHUA LIN, Department of Chemistry, Sichuan University, Chengdu, 610064 China, QIANG FU, Department of Polymer Science and Engineering, Sichuan University, State Key Laboratory of Polymer Materials Engineering, Chengdu, 610065 China, QINJIAN YIN, Department of Chemistry, Sichuan University, Chengdu, 610064 China — Inspired by inorganic nanomaterials, low-dimensional organic nanostructures have emerged as a new field of nanomaterials with the presence of size-dependent physical properties. Here, we report a zero-dimensional organic nanoparticles formed by copolymer-directed self-assembly. The nanoparticles are thermally stable up to ~200°C. The nanoparticle morphologies are probed by TEM and SEM images. The quantum confinement effect is suggested by the appearance of strongly broadened Raman shift spectra. By proof-of-principle quantum chemical calculations, we suggested that both vibration-vibration and electron-vibration coupling at nanoscale can cause the Raman broadening. The present organic nanoparticles provides a new class of nanostructures to exploring size-dependent physical properties.

1current address: Department of Chemistry, Duke University, Durham, NC 27708
C1.00092 Capillary thinning and break-up of hydrogel-elastomer composites, YINAN LIN, DARRELL RENEKER, The University of Akron — The development of a filament stretching rheometer with a high magnification and high speed digital imaging system enabled real-time video observation of the extensional behavior of the hydrogel-elastomer complex fluids. Under a motor-controlled process of tip-plate separation, ethanol solutions of polyurethane with superabsorbent particles, which can be electrospun into nanocomposite nanofibers, evolved in profile. The rapidly shrinking jet diameter was measured from video images. As in extensional rheology of homogeneous polymer solutions, the elongational viscosity and the relaxation time calculated from the time dependence of midpoint diameters define a two-dimensional operating diagram for capillary self-thinning and capillary break-up.

C1.00093 Ultrafast Nanocalorimetry and Superheating in Linear Polymers1, CHRISTOPH SCHICK, ALEXANDER MINAKOV, ANDREAS WURM, University of Rostock — To study phase transition kinetics on submillisecond time scale a set of new membrane gauges for ultrafast scanning nanocalorimetry were constructed. Controlled ultrafast cooling, as well as heating, up to 106 K/s was attained. The characteristic rate R0 corresponding to the quasi-static limit of the temperature change in the membrane-gas system was determined. The rate R0 equals 105 K/s for the different gauges in helium gas. The method was applied for the measurements of the superheating phenomenon in a set of linear polymers: IPP, PBT, PET, iPP. A power law relation between the superheating and the heating rate was observed in the broad range 10E-2 – 10E4 K/s of the heating rates. A limiting superheating of about 10% of the melting temperature was observed at rates above 10E4 – 10E5 K/s. This limit depends on the annealing conditions before the sample melting. The observed superheating limit, as well as the power law, can be accounted for the internal stresses induced by the superheating near the crystalline-amorphous interface in semicrystalline polymers, which are related to the thermal expansion gradients inherent for a semicrystalline material.

C1.00094 Intermolecular Interactions in Polymer/C60 Blends, PETER MIRAU, AFRL/RXBN, Air Force Research Lab, Bio-Nano Branch, Wright-Patterson AFB, OH 45433, MARJAN LYONS, Wright State University, Dayton, OH — Solid-state NMR and x-ray scattering are used to study intermolecular interactions in blends of C60 with polystyrene, poly(9-vinyl carbazole) and poly(ethylene oxide). Miscible C60 blends prepared by solution precipitation with polystyrene and poly(9-vinyl carbazole) are purple in color, show intermolecular C60-polymer cross polarization and do not show the scattering peaks from C60 crystallites. In contrast, phase separation is observed in poly(ethylene oxide) blends. The C60 dynamics in the miscible blends are measured using the chemical shift anisotropy filter NMR pulse sequence, and the results show that the C60 in the rotating rapidly enough at ambient temperature to average the 18 kHz-wide chemical shift anisotropy line shape. Blending with C60 has no effect on the polystyrene dynamics as measured by the carbon spin-lattice relaxation times but leads to a narrowing of the proton line shapes as measured by 2D wide line correlation NMR. These results show that C60 interacts weakly with polymers, and the implications for weak interactions between polymers and carbon nanotubes are considered.

C1.00095 Effect of Hydrophobicity on the Adsorption of Human IgG to Thiolated Gold Surfaces as Characterized by SPR, KRISTEN DUTHIE, ADELE POYNOR, Allegheny College Physics Department — In order to enhance our understanding of the role of hydrophobicity in nonspecific human immunoglobulin G [hIgG] surface interactions, we studied the adsorption of hIgG to thiol self-assembled monolayers [SAMs] on gold using surface plasmon resonance [SPR]. The hydrophilic and hydrophobic SAMs had hydroxyl and methyl terminal groups respectively. Protein adsorption to thiolated surfaces was measured looking at relative SPR resonance angles.

C1.00096 Understanding Rubber Friction in the Presence of Water Using Sum Frequency Generation Spectroscopy1, PING-YUAN HSU, KUMAR NANJUNDIAH, ALI DHINOJWALA — Infrared-visible sum-frequency-generation spectroscopy (SFG) was used to study the molecular structure of water between a poly (dimethylsiloxane)(PDMS) and a sapphire substrate. The observation of SFG peaks associated with the dangling surface hydroxyl groups (3690 cm−1) and water bands (3000-3400 cm−1) indicates that the contact spot between the PDMS lens and the sapphire substrate is heterogeneous. Within the contact spot are regions where the methyl groups of the PDMS chains are in direct contact with the surface hydroxyl groups on the sapphire substrate. In the other regions, a thin water layer is trapped between the two surfaces with spectral features that are different from that of the unconfined water next to the sapphire or the PDMS surface. The higher adhesion and friction values observed in these experiments are consistent with the hypothesis that the contact spot is heterogeneous. These results have important implications in understanding the sliding behavior of wet, deformable hydrophobic materials on hydrophilic substrates. We have extended this experimental technique to study oil/water/solid interfaces.

C1.00097 Protected Plasmonic Nanostructures for High Resolution Chemical Imaging using Tip Enhanced Raman Spectroscopy, REBECCA BUTT, CARLOS BARRIOS, ANDREY MALKOVSKY, ALEXANDER KISLIUK, University of Akron, Dept of Polymer Science, ALEXEI SOKOLOV, University of Akron, MARJAN LYONS, Wright State University, Dept of Polymer Science — Tip enhanced Raman spectroscopy (TERS), an emerging technique that combines optical microscopy and scanning probe microscopy, provides the sensitivity and selectivity necessary for high-resolution chemical imaging of polymer surfaces. An unprecedented 20 nm lateral resolution for the chemical imaging has been achieved. Unfortunately, the fragile plasmonic structures used to enhance the electric field are prone to mechanical, chemical, and thermal degradation. Developing robust noble metal nanostructures with stable plasmonic resonance is essential to reliable high resolution chemical imaging. Covering the metal layer with organic and inorganic ultrathin coatings is being investigated to extend the plasmonic activity of the engineered nanostructures. Addition of an ultrathin aluminum oxide (Al2O3) coating to a silver-coated scanning probe microscopy tip for TERS significantly improves plasmonic structure stability without sacrificing the initial TERS efficiency. This ultrathin coating provides wear resistance and stops chemical degradation responsible for the loss of signal enhancement.

C1.00098 Infrared and optical spectroscopy study of UHMWPE polymers, M.S. WOLF, J.N. MORVAN, John Carroll University, S.V. DORDEVIC, The University of Akron, N. STOJILOVIC, John Carroll University — Ultra-High Molecular Weight Polyethylene (UHMWPE) is very often the material of choice for the bearing surfaces of most hip and knee implants primarily due to its low friction combined with good toughness and abrasion resistance. We investigate optical properties of biomedical-grade UHMWPE GUR 1020 powders and sheets using infrared and UV-vis spectroscopy and compare results with those from industrial grade samples. In addition, we use X-ray diffraction spectroscopy to monitor the changes in crystal structure of these polymers as a function of temperature. Finally, we deliberately oxidize and subsequently characterize these materials since the oxidation of UHMWPE bio-implants is believed to be responsible for their failure in vivo.

C1.00099 ABSTRACT WITHDRAWN
C1.00100 A spectroscopic ruler to measure chain conformations at the solid-liquid interface. SUBHALAKSHMI KUMAR, JANET WONG, SUNG CHUL BAE, STEVE GRANICK, Department of Material Science and Engineering, University of Illinois at Urbana-Champaign — There do not appear to exist prior measurements of the conformations of polymers adsorbed to dilute coverages at the solid-liquid interface, in spite of abundant theoretical predictions. Here direct information is obtained by monitoring the fluorescence energy transfer between dyes located at the two ends of adsorbed polymer chains. The basic idea is that the farther the chain ends are spaced, the less efficient, and slower, is energy migration between these dyes. It occurs on the nanosecond time scale and is measured here by time-correlated single photon counting. From corresponding experiments performed with the same polymer chains labeled at one sole end, the contribution of rate of energy transfer to rotational anisotropy is decoupled from intrinsic rotational motion of the dyes themselves.

C1.00101 Vibrational Relaxation and Dynamical Transitions in Atactic Polystyrene. HANQING ZHAO, YUNG PARK, PAUL PAINTER — Infrared bands and Raman lines recorded in the frequency domain have a counterpart in the time domain in the form of time-correlation functions, which are sensitive to molecular dynamics on the picosecond time scale. This is explored by calculating time correlation functions and their variation with temperature for the conformationally insensitive modes observed near 1601 cm-1 and 1583 cm-1 in the infrared spectrum of atactic polystyrene. The correlation functions were modeled by assuming that there is a fast relaxation process characterized by a single relaxation time that is inhomogeneously broadened by a slower process, also characterized by a single relaxation time. The fundamental mode, near 1583 cm-1, is inhomogeneously broadened, but the relaxation time calculated for this mode is sensitive to temperature as a result of anharmonic coupling to a combination mode. A change in the modulation in the 1583 cm-1 band becomes apparent about 10–20 degrees below the thermally measured Tg. Relaxation times at first increase then decrease and becomes negligible at temperatures near 180 degrees. These results are consistent with theories of the glass transition.

C1.00102 Specific Heat Spectroscopy of Simple Chain Models. JONATHAN R. BROWN, JOHN D. MCCOY, New Mexico Institute of Mining and Technology, DOUGLAS ADOLPH, Sandia National Laboratories, BRIAN BORCHERS, New Mexico Institute of Mining and Technology — Molecular dynamics simulations were run on bead-spring polymer models. Small amplitude temperature variations were imposed, and energy response was monitored. The real and imaginary components of the frequency dependent specific heat were extracted. A low frequency peak is seen to develop at high packing fractions. The non-Debye parameter – β – is seen to decrease as the glass transition is approached. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

C1.00104 Reversible hydrogen storage in LiBH4/CaH2 with NbF5. JAE-HAM LIM, JAE-HYEOK SHIM, YOUNG-SU LEE, YOUNG WHAN CHO, Korea Institute of Science and Technology. JOONHO LEE, Korea University — Reversible hydrogen storage properties of 6LiBH4 + CaH2 composite have been investigated. 6LiBH4 + CaH2 composite with catalytic additives have been prepared using high-energy ball milling. Among various catalytic additives, the addition of NbF5 exhibits the lowest dehydrogenation temperature. During dehydrogenation, this composite is decomposed into LiH and CaB6 releasing about 9 wt pct hydrogen. The van’t Hoff plot from the equilibrium pressures measured at different temperatures predicts that the equilibrium temperature under 1 bar of hydrogen is 582 K and the reaction enthalpy change is 56.5 kJ/mol H2. This is consistent with the results of thermodynamic calculation. Rehydrogenation of this composite is accomplished at 723 K under 100 bar of hydrogen after dehydrogenation, presenting a reversible hydrogen capacity of about 9 wt pct.

C1.00105 LiBH4+Ca(BH4)2 composite system for hydrogen storage. JI YOUN LEE, YOONYOUNG KIM, YOUNG-SU LEE, JAE-HYEOK SHIM, YOUNG WHAN CHO, Korea Institute of Science and Technology, Republic of Korea, DORTHE RAVNSBRO, TORBEN JENSEN, University of Aarhus, Denmark, NINGSER CERENIUS, Lund University, Sweden — LiBH4 is one of the promising candidates for hydrogen storage materials because of its high gravimetric and volumetric hydrogen capacity. However, dehydrogenation of LiBH4 occurs above 400°C, which limits its use in its pristine form. By mixing with Ca(BH4)2, we have tried to lower the dehydrogenation temperature. The underlying design principle of this composite system is the recently proven reversibility of 6LiBH4+CaH2 composite and Ca(BH4)2 itself. Using differential scanning calorimetry and in-situ synchrotron XRD measurement, we observed eutectic melting of (1-x)LiBH4 + xCa(BH4)2 at around 200°C in a wide range of x. The decomposition characteristics and the hydrogen capacity of this composite vary with x, and at a certain value of x we found that decomposition was finished below 400°C showing more than 10 wt% hydrogen capacity. Reversibility of this system was also confirmed.

C1.00106 Nonlinear thermoelectric behavior in double-barrier quantum-dots. ERIC HOFFMANN, NATTHAPON NAKPATHOMKUN, University of Oregon, HENRIK NILSSON, Lund University, ANN PERSSON, University of Oregon, LARS SAMUELSON, Lund University, HEINER LINKE, University of Oregon — Thermovoltage in bulk material systems is to good approximation linear in applied temperature difference, ΔT, with the constant of proportionality being the thermopower, S. However, this linear relationship does not necessarily hold true for nanoscale thermoelectrics[1]. Here we report on basic research which uses a simple quantum dot as an example nanoscale system for studying nonlinear thermoelectric phenomena. Specifically, we show experimentally as well as theoretically that strong modulations in the transmission function of the quantum dot manifests into thermovoltages and thermocurrents which are not linear in ΔT at ΔT as small as ΔT/T = 0.1. Quantum-dot thermometry[2] has been used to measure ΔT. Understanding these nonlinearities is important for the development of thermoelectric materials that aim to exploit quantum phenomena. 1. J.M. Wang et al, Nonlinear thermoelectric transport through a double barrier structure, Mod. Phys. Lett. B, 20, 215-223 (2006). 2. Hoffmann, E.A. et all, Quantum-dot thermometry, Appl. Phys. Lett. 91(25), 252114 (2007)

C1.00107 Thermopower measurements of arrays of trigonal bismuth nanowires: the density, mobility, and charge-sign of Bi surface carriers. TITO HUBER, AJIBOLA ADEYEYE, TOSIN ODUNFA, Howard University, ALLA NIKOLAeva, LEONID KONOPKO, Academy of Sciences. Moldova, RYAN JOHNSON, MICHAEL GRAF, Physics Department. Boston College — We investigated the thermopower S of Bi nanowires with 20 nm < diameter < 200 nm) between 4 K and room temperature in well-characterized samples. Shubnikov-de Haas oscillations give evidence of light-effective-mass bulklike carriers, Dirac electrons and holes, and also high-effective-mass surface carriers. The latter are likely related to the surface states that are observed using ARPES of Bi surfaces (Hofmann, Prog. Surf. Sci. 81, 191 (2006)). Whereas the bulklike carrier’s concentration decreases for decreasing diameter in accordance with theoretical predictions (Lin, Sun, and Dresselhaus, Phys. Rev. 62, 4610 (2000)) for the quantum-confinement-driven semimetal-to-semiconductor transition, the surface carrier concentration is relatively independent of diameter. S exhibits a trend from positive towards negative values as the diameter decreases from 200 nm to 35 nm. The measurements are interpreted in terms of the diffusion thermopower model. We find that the S of the semiconductor nanowires is dominated by surface electrons.

We acknowledge funding support from UNLV presidential research award.

C.100110 Thermoelectric properties of mechanically milled AgSbTe$_2$

S. Veeramalai, Ravish Kumar, Department of Physics and Astronomy and HiPSEC, University of Nevada Las Vegas, Seigi Yoneda, Department of Physics and HiPSEC, University of Nevada Las Vegas — Cubic I-II-VI semiconductors have been studied widely for potential thermoelectric applications by several groups [1]. Recent investigations show minimal thermal conductivity for AgSbSe$_2$ and AgSbTe$_2$ resulting from intrinsic phonon scattering process due to strong anharmonicity in bonding [2]. AgSbSe$_2$ is structurally similar to chalcogenides and crystallizes in the cubic structure at ambient conditions [3]. The thermoelectric figure of merit, Seebeck coefficient and thermal conductivity were measured as a function of temperature from 10 K to 350 K. We have also measured the conductivity type, Hall coefficient and carrier concentration at ambient conditions. We compare our results with the ternary analogues. [1]. C. Wood et al., Prog. Phys. 51 (1988) 459 [2]. D. T. Morielli et al., Phys.Rev.Lett., 101 (2008) 035901 [3]. Ravish S. Kumar et al., J. Alloys and Compds., 285 (1999) 48

C.100111 Enhanced Thermoelectric Figure-of-Merit in p-type Nanostructured Bismuth Antimony Tellurium Alloys Made from Elemental Chunks

Yi Ma, Boston College, Qiang Hao, MIT, Bed Poude, Boston College, GMZ Energy, Inc., Yucheng Lan, Bo Yu, Dezhzi Wang, Boston College, Gang Chen, MIT, ZhiFeng Ren, Boston College, BOSTON COLLEGE TEAM, GMZ ENERGY, INC. COLLABORATION, MIT COLLABORATION — In this study, we use the ball milling and hot press technique to make nanostructured bulk bismuth antimony telluride from elemental chunks of bismuth, antimony, and tellurium. We show that a peak ZT of about 1.3 in the temperature range of 75 and 100 °C has been achieved. The ZT improvement is caused mostly by the lower thermal conductivity. Transmission electron microscopy observations of the microstructures suggest that the lower thermal conductivity is mainly due to the increased phonon scattering from the increased grain boundaries of the nanograins, precipitates, nanodots, and defects.

C.100112 Thermoelectric properties of Yb$_{14}$MnSb$_{11}$ from first-principles

J.-H. Song, Northwestern U., M. Kim, Ajou U., A.J. Freeman, Northwestern U. — The complex Zintl compound, Yb$_{14}$MnSb$_{11}$, has been recently given much attention as a high-performance thermoelectric due to its nearly twice the figure of merit (ZT) of p-type SiGe at high temperatures (> 900 K). Its high ZT can be attributed to low lattice thermal conductivity combined with a large Seebeck coefficient (S) and high electrical conductivity (σ) at high temperatures. To understand the thermoelectric properties of Yb$_{14}$MnSb$_{11}$ and to find possible improvements for thermoelectric performance, we have investigated its electronic structures and electrical transport properties (S,σ) using the highly precise FLAPW method with the local spin density approximation (LSDA) and LSDA+U methods. We have found significantly different spin moments of Mn between the LSDA and the LSDA+U methods. Also, we determined the anisotropy of the conductivity. The linear temperature behavior of the Seebeck coefficients will be discussed from and related to the electronic structures.

C.100113 Terahertz mixing in AlGaAs/GaAs 2DEG hot-electron microbolometers at liquid nitrogen temperatures

Kai Wang, Rahul Ramaswamy, Matthew Bell, Andrei Sergeev, Alesandr Verevkin, Gottfried Strauss, Vladimir Mitin, University at Buffalo, Darold Wobschall, Eensors Inc. — We investigate THz mixing based on electron heating of two-dimensional electron gas (2DEG) in semiconductor microbolometers. The 2DEG microbolometers were fabricated from AlGaAs/GaAs heterostructures and have dimensions of 3-20 µm between the Ohmic contacts and 50 µm in width. Significant efforts were made to get low Ohmic contact resistance for effective coupling to the THz antenna and to the intermediate frequency amplifier. We investigate mixing at sub-THz and THz frequencies. In the sub-THz range, a W-band Gunn diode operating at 82 GHz was used as a local oscillator. In the THz range we employ a Quantum Cascade Laser (QCL). The QCL is positioned in close proximity at different locations to optimize electromagnetic coupling. Experiments at sub-THz and THz frequencies give consistent data, which provide evidence that electron-heating is the major mechanism of mixing. Mixing experiments allow us to evaluate the mixer gain bandwidth and conversion loss. The results show that a heterodyne receiver, which combines AlGaAs/GaAs 2DEG hot-electron mixer with a QCL as the local oscillator, has great prospects for THz sensing with high spectral resolution and wide spectral bandwidth.

Russia — We apply the model introduced in Phys. Rev. B 78 to the wide absorption energy range of the visible light and the fast photo-induced charge injection from the dyes to the titania. The dyes are adsorbed on the Ti sites via the carboxyl group, but detailed adsorbed structures and effect on the electronic structures are unknown. We performed the first-principles calculations of the coumarin343 and NKX2311 dyes adsorbed on the rutile titania (110) for three types of the contact structures. We found that the bidentate type is energetically more stable than the ester-like and molecular types. The HOMO-LUMO gap of the NKX2311 is smaller than that of the coumarin343, consistent with the experiments. This work was partly supported by the RISS project in IT program and a Grant-in-Aid for Scientific Research (No.17064017) of MEXT of the Japanese Government.

The work is supported by NSF of R.O.C. under grand No. NSC 96-2112-M-110-008-MY2

C1.00115 Polarization dynamics within the polarization-switching hysteresis loop of VCSELs

JIN-ING TSAI, WANG-CHUANG KUO, CHUAN-PI HSU, Department of Physics, National Sun Yat-sen University, DA-LONG CHENG, Department of Computer and Communication, SHU-TE University, TSU-CHIANG YEN, Department of Physics, National Sun Yat-sen University — In the L-I curve of some VCSELs, distinct polarization switchings (PS) with a hysteresis loop are observed. In this research, PS at the center of the hysteresis loop was conducted by a manipulation of the operation conditions, enabling the polarization dynamics within the loop to be investigated. Experimental results revealed that the temporal behaviors of PS were different at the two ends of the PS hysteresis loop. A set of rate equations based on a linear gain model was employed to understand the polarization dynamics involved. Simulations indicated that the polarization dynamics could be attributed to the variation of the polarization-resolved gains within the PS hysteresis loop. More investigated results will be presented in the report.

C1.00116 Negative index of photonic crystal infiltrated with functional materials

RYOTARO OZAKI, Alan G. MacDiarmid NanoTech Institute, The University of Texas at Dallas, HIROSHI MORITAKE, Department of Electrical and Electronic Engineering, National Defense Academy of Japan, KATSUMI YOSHINO, Shimane Institute for Industrial Technology, ANVAR ZAKHIDOV, Alan G. MacDiarmid NanoTech Institute, The University of Texas at Dallas — We study 2D or 3D photonic crystals infiltrated with functional materials such as liquid crystal, or a highly polarizable medium. Liquid crystal molecular orientations in photonic crystals strongly influence the light propagation. We reveal that the negative index of the photonic crystal depends on the liquid crystal molecules, which can be tuned by external electrical field or temperature. On the other hand, we also study negative index of photonic crystal with a highly polarizable medium having a frequency dependence of permittivity. Around anomalous dispersion frequency range, the photonic crystal with a highly polarizable medium shows unique characteristics due to coupling with polariton.

C1.00117 First-principles study of atomic and electronic structures of coumarin dyes adsorbed on titania surface

HIROYOSHI MOMIDA, Institute of Industrial Science, University of Tokyo, TAKAHISA OHNO, CMSC, National Institute for Materials Science and Institute of Industrial Science, University of Tokyo — The coumarin dyes are good photo-sensitizers for the dye-sensitized solar cell due to the wide absorption energy range of the visible light and the fast photo-induced charge injection from the dyes to the titania. The dyes are adsorbed on the Ti sites via the carboxyl group, but detailed adsorbed structures and effect on the electronic structures are unknown. We performed the first-principles calculations of the coumarin343 and NKX2311 dyes adsorbed on the rutile titania (110) for three types of the contact structures. We found that the bidentate type is energetically more stable than the ester-like and molecular types. The HOMO-LUMO gap of the NKX2311 is smaller than that of the coumarin343, consistent with the experiments. This work was partly supported by the RISS project in IT program and a Grant-in-Aid for Scientific Research (No.17064017) of MEXT of the Japanese Government.

C1.00118 ABSTRACT WITHDRAWN —

C1.00119 Coiled-Coil Helix-Bundle Peptide-Polymer Conjugates

JESSICA SHU, CEN TAN, YU-JA HUANG, Department of Materials Science and Engineering, University of California, Berkeley, TING XU, Department of Materials Science and Engineering, Department of Chemistry, University of California, Berkeley — Peptide-polymer conjugates have the potential to combine the advantages of synthetic polymers and peptides and may lead to hierarchically ordered, functional soft materials. Maintaining the structure and function of the peptides upon polymer conjugation is essential. Here, we present a solution study of three families of peptide-polymer conjugates to systematically investigate the effect of conjugated polymer on the peptide’s secondary and tertiary structures using a photoactive, heme-binding 4-helix bundle. In particular, we focused on the effect of the peptide-polymer conjugate’s architecture (side conjugation versus end conjugation) and the hydrophobicity of the synthetic polymer (polystyrene versus poly(ethylene glycol)). Upon attachment of polymer to the peptide N-terminus, the secondary structure was destabilized and the functionality within the bundle was inhibited. The effect was less dramatic with PEG conjugation in comparison to the hydrophobic PS. Upon attachment of PEG to the exterior of the coiled-coil helix bundle, the peptide secondary and tertiary structures were stabilized, and the functionality within the bundle was preserved.

C1.00120 COMPLEX STRUCTURED MATERIALS —

C1.00121 Anisotropic glasy properties—a theoretical model

DRAGOS-VICTOR ANGHEL, Department of Theoretical Physics, Horia Hulubei National Institute of Physics and Nuclear Engineering, DMITRIY CHUROCHKIN, R & D Institute “Volga” - Saratov 410052, Russia — We apply the model introduced in Phys. Rev. B 75, 064202 (2007), to calculate the anisotropy effects in the interaction of two level systems with phonons and elastic waves in disordered crystals. In this model, the interaction strength depends on the orientation of the TLS with respect to the strain field through a $6 \times 6$ symmetric tensor of deformation potential parameters, $|\mathbf{R}|$. The structure of $|\mathbf{R}|$ is similar to the structure of the tensor of elastic stiffness constants, in the sense that they are determined by the same symmetry transformations. In this way, we emphasize the anisotropy of the interaction of elastic waves with the ensemble of two-level systems in disordered crystals. We also point to the fact that the ratio $\gamma_1/\gamma_1$ has a much broader range of allowed values in disordered crystals than in isotropic solids.

C1.00122 Brillouin light scattering measurements of high modulus glasses produced by physical vapor deposition. KENNETH L. KEARNS, Department of Chemistry, University of Wisconsin-Madison, TIM STILL, Max Planck Institute for Polymer Research, GEORGE FYTAS, Max Planck Institute for Polymer Research, Department of Chemistry, University of Wisconsin-Madison — Physical vapor deposition was used to create low enthalpy, high density glasses of indomethacin (IMC). Brillouin light scattering was employed to measure the longitudinal and transverse sound velocities of the stable vapor-deposited glass, supercooled liquid, and the ordinary glass formed from cooling the liquid. Both Young and shear high frequency moduli were approximately 20% greater for the vapor-deposited sample as compared to the ordinary glass. The isothermal transformation of the high modulus glass to the supercooled liquid was 10,000 times slower than the structural relaxation time of the supercooled liquid at T = 10 K. Additionally, the spectrum for both phonon polarizations broadens during the isothermal transformation, which suggests that the stable vapor-deposited glass and supercooled liquid coexist for long periods of time at a single temperature.

C1.00123 Kinetics of Gold Nanoparticle Formation1, ASHLEY CETNAR, Grove City College, SREERAM CINGARAPU, KENNETH KLABUNDE, Kansas State University — My objective was to understand the chemical details of an important method of producing monodisperse nanoparticles. The nanoparticles synthesized are gold ligated by thiol ligands. The nanoparticles average 5 nanometers in diameter with about 5000 gold atoms and 600 thiol ligands per particle. The two methods used to prepare the particles are the solvated metal atom dispersion method and the inverse micelle method. Both processes break the gold into nanoparticles and are ligated to protect the particles from aggregation. After the nanoparticles are produced they are made monodisperse by digestive ripening. Digestive ripening occurs when the polydispersed product is refluxed over time. During this illusive procedure the multi-sized particles all become uniform in size. During reflux, the samples are analyzed by UV spectroscopy. The spectroscopy reveals a plasmon emitted from the nanoparticles at 530 nm from a standard sample of 1:30 gold to ligand ratio. During the reflux procedure, the gold Plasmon peak narrows and the peak becomes steeper. Over time, the peak of the Plasmon seems to be red shifted. As the amount of ligand varied the gold plasmon appeared to shift.

C1.00124 Atomistic Mechanism of Catalyzed Growth of Silicon Nanowire, SEUNGHWA RYU, Physics Department, Stanford University, WEI CAI, Mechanical Engineering Department, Stanford University — Understanding the growth mechanism of semiconductor nanowire (NW) from catalyzed droplet is important for better control of the growth speed of NWs by chemical vapor deposition (CVD) over silicon. We used the Vapor-Liquid-Solid (VLS) process. To accurately describe the interatomic interaction between gold and silicon atoms, we developed a Au-Si binary potential based on modified embedded-atoms method (MEAM), which is benchmarked against the experimental binary phase diagram and mixing enthalpy. Advanced sampling method is employed to obtain the critical island at the liquid(Si Au alloy) - solid(silicon nanowire) interface. The dependence of the nucleation rate of the critical island on temperature and Si supersaturation is compared with experimentally observed NW growth rate and conditions of growth anormally such as kinking.

C1.00125 Self-Assembly of CdSe and PbS/PbSe Quantum Dots on Gold and other Surfaces Using Dithiol Functionalization, JEFFREY SCHWARTZ, MIAOXIN ZHOU, ANVAR ZAKHIDOV, The University of Texas at Dallas — CdSe and PbS/PbSe quantum dots were deposited onto gold surfaces functionalized with self-assembled monolayers of dithiol molecules. Separately, quantum dots were treated in solution with dithiols to create linked quantum dot chains and then deposited onto gold and other surfaces. Analysis of the samples via atomic force microscopy and scanning tunneling microscopy was performed in order to characterize the samples and determine the ordering and level of coverage of the quantum dots on the substrate surface. We found that increasing the bulkiness of the dithiol ligands leads to increased electrical conductivity of self-assembled quantum dot layers and found the optimal conditions for maximum coverage and best ordering. This research is done with the intention of using linked, ordered, quantum dot chains in polymer solar cell devices, and embedding quantum dots inside opals and inverse opals to create negative index materials.

C1.00126 Energetic and structural analysis of 102-atom Pd-Pt nanoparticles1, RAFAEL PACHECO-CONTRERAS, DIFUS, ALVARO ARTEAGA-GUERRERO, DFUS, DORA JULIA BORBON-GONZALEZ, Dept de Matematicas, UNISON, ALVARO POSADA-AMARIILLAS, DIFUS, J. CHRISTIAN SCHLENION, Max Planck Institute for Solid State Research, ROY L. JOHNSTON, School of Chemistry, University of Birmingham — We present an extensive study of the structural and energetic changes of 102-atom Pd-Pt nanoparticles as a function of composition m, where the interatomic interactions are modeled with the many-body Gupta potential. The minimum energy structures are obtained through a genetic algorithm. The excess energy is calculated, as well as the pair distribution function g(r). The radial distribution of the atoms is computed for each composition; the result indicates a multi-layer segregation for some compositions, with a shell growth sequence as follows: a core with a small number of Pd atoms and the external shell consists of Pt atoms. A region where Pd and Pt atoms are mixed is observed between the outermost and intermediate shells. Furthermore, the pure Pd102 and Pt102 nanoparticles have the same structure, while a variety of different structures are observed for the bimetallic clusters.

C1.00127 Electronic Structure Models of Phosphorus Delta-Doped Silicon, OLIVER WARSCHKOW, DAMIEN J. CARTER, Centre for Quantum Computer Technology, School of Physics, The University of Sydney, NIGEL A. MARKS, Nanochemistry Research Institute, Curtin University of Technology, DAVID R. MCKENZIE, Centre for Quantum Computer Technology, School of Physics, The University of Sydney — We report a full density functional theory treatment of phosphorus delta-doped silicon. A particular difficulty of this system is associated with the large delocalization lengths of donor electrons in the host. To this end, we use large asymmetric unit cells with up to 800 atoms, and we obtain first-principles doping potentials, band energies and donor electron distributions. We additionally examine the electronic effects of overlapping doping potentials when two delta-doped planes are bought into proximity.

C1.00128 Experimental and theoretical spectroscopic studies of dye modification in synthetic Maya Blue pigment1, LAYRA REZA, FELICIA MANDCIU, Physics Department, ALEJANDRA RAMIREZ, RUSSELL CHIANELLI, Materials Research and Technology Institute, University of Texas at El Paso, El Paso, Texas 79968 — Maya pigments are hybrid organic/inorganic materials with multiple technology applications that possess unprecedented stability with respect to harsh environment conditions. In this investigation, we address the question of how the organic indigo dye modifies as it binds to the inorganic palygorskite clay to form a pigment similar to Maya Blue after a heating treatment is applied. Both infrared and Raman spectroscopic data demonstrate the disappearance of nitrogen-hydrogen (N-H) bonding, as the indigo molecule incorporates into the inorganic palygorskite material. This effect suggests a transformation of the dye from indigo to dehydroindigo. Furthermore, the Raman and infrared absorption results demonstrate partial elimination of the selection rules for the centrosymmetric indigo, which provides further evidence for this conversion. Theoretical spectroscopic studies are also addressed in this investigation to confirm the transformation of the dye into dehydroindigo.

C1.00129 Spectroscopic study of thioindigo-mineral composite1, WILLIAM DURRER, FELICIA MANCIU, Physics Department, ALEJANDRA RAMIREZ, Materials Research and Technology Institute, JAYESH GOVANI, Physics Department, RUSSELL CHIANELLI, Materials Research and Technology Institute, The University of Texas at El Paso, El Paso, Texas 79968 — We report in this study structural changes taking place for the thioindigo-clay mixture in forming a pigment similar to Maya Blue. Different proportions of dye concentrations relative to that of the mineral, as well as different heating times, were applied in pigment synthesis and the outcomes were investigated using FT-IR and FT-Raman spectroscopy. For the pigment samples, the FT-IR peaks at 1627 cm−1 are attributed to a downshifted C=O stretching mode of thioindigo due to dye-clay interaction. This interpretation is corroborated by FT-Raman C=O peaks with 14 cm−1 shifts to lower frequency for the pigment relative to thioindigo alone. Additional Raman scattering between 550 cm−1 and 650 cm−1 also suggests dye-clay interaction through metal-oxygen bonding. We thus consider the possibility of hydrogen bonding between silanol and carbonyl dominating at lower dye concentration, with mostly metal-oxygen bonding at higher dye concentration.

C1.00130 Inverse magnetoelectric effects in a bilayer of ferrite and graded piezoelectric, VLADIMIR PETROV, Novgorod State University, GOPALAN SRINIVASAN, Oakland University — Magnetoelectric (ME) effects in a piezoelectric-magnetostrictive composite are mediated by mechanical stress. An applied electric field, for example, will result in piezoelectric strain in the composite and will lead to a shift in ferromagnetic resonance (FMR) in the ferrite. This work is on modeling of magnetoelectric interactions under FMR in a bilayer of ferrite and functionally graded piezoelectric. We show that an enhancement of the strength of ME interaction at FMR is possible with the use of piezoelectric coefficient-graded ferroelectric with the grading axis perpendicular to the sample plane. In this case, the thickness dependence of the piezoelectric coefficients leads to an additional bending strain, resulting in an increase in the FMR line shift. Expressions have been obtained for the electrically induced magnetic resonance line shift, taking into account the effect of grazing and substrate clamping. The obtained results are applied to the cases of single crystal yttrium iron garnet (YIG) and graded lead magnesium niobate-lead titanate (PMN-PT). A 40% increase in the shift of FMR line is predicted for graded systems compared to homogeneous piezoelectric composition.

C1.00131 Microwave Magnetoelectric Interactions in Ferrite-Piezoelectric Bilayers1, ALEXANDER TATARENKO, Oakland University, VIKAS MATHE, Pune University, GOPALAN SRINIVASAN — The measurement of the strength of microwave magnetoelectric (ME) interactions through ferromagnetic resonance (FMR) in bilayers of single crystal ferrite-piezoelectric oxides is reported. An electric field E produces a mechanical deformation in the piezoelectric phase, resulting in a shift in the resonance frequency for the ferrite. The strength of ME coupling is obtained from data on frequency shift vs E. Studies were performed on bilayers with single crystal yttrium iron garnet (YIG) films or single crystal nickel zinc ferrite and single crystal lead zirconium niobate-lead titanate (PZN-PT) or polycrystalline lead zirconate titanate (PZT). The samples were positioned in a microstrip-line-alumina ground plane structure. Resonance profiles were with a vector network analyzer obtained for E = 0-8 kV/cm for in-plane magnetic fields H. Important results are as follows. (i) The ME coupling in the bilayers is stronger in bilayers with PZT than for PZN-PT. (ii) The coupling is a factor of 2 stronger in samples with nickel zinc ferrite than for YIG. The bilayers are potentially useful for E-tunable microwave resonators, filters and phase shifters.

C1.00132 Magnetic field gradient induced magnetoelectric response of piezoelectric-magnetostrictive laminates1, GOPALAN SRINIVASAN, Oakland University, VLADIMIR PETROV, Novgorod State University — Magnetoelectric (ME) effects in a piezoelectric-magnetostrictive composite are mediated by mechanical stress. The ME coupling in composites when subjected to a bias magnetic field and an ac magnetic field leads to an induced voltage that is directly proportional to the applied ac magnetic field amplitude. We discuss here the theory of ME interactions in a piezoelectric-magnetostrictive laminate which is subjected to a non-uniform bias magnetic field. The model predicts that the induced ME voltage will include an additional term which is proportional to the field gradient provided that the gradient direction is perpendicular to the laminate plane. The supplementary term in the ME voltage can be attributed to flexural deformations due to stress irregularity in the magnetostrictive component. As an example, the gradient magnetic field induced ME effect is considered for a bilayer of Terfenol-D and lead zirconate titanate. The ME voltage coefficient at electromechanical resonance is expected to exceed the low-frequency value by two orders of magnitude.

C1.00133 Controlling the percolation behavior of conductor-insulator composites by changing the granular size of insulators1, KAZUHITO SHIDA, RYOJI SAHARA, HIROSHI MIJUSEKI, YOSHIYUKI KAWAOZOE — The critical behavior of percolation model does not depend on the detail of the embedding lattice. This fact can be a hard obstacle when one attempt to modulate and control the characteristics of the composite materials because the limit of modulation is limited by the percolation threshold, as in the case of substitution of expensive conductor materials by inexpensive insulator materials. Many attempts to solve this problem by changing the sizes and aspect ratios of conductor particles, expecting their effect in enhancing conduction as a “bridge” is not working well. We report our attempt to realize the same goal by introducing size differences in the insulator particles, not conductor particles. The effective transition point observed is actually lowered to 0.52 by this modulation from about 0.59 of conventional site percolation model (2D). The statistical nature of this novel model, in particular the optimum design of insulator particle size distribution, is a completely new and interesting theoretical problem. Moreover, this is considered to be a promising technique to reduce the amount of expensive conductor, for example the Indium in typical transparent conductor film.

Supported by Ministry of Economy, Trade and Industry (METI).

C1.00134 Medium-range Order in Periodic Mesoporous Silica1, ELLA WAN, Ohio University, KUANGMIN LI, GANG CHEN, Ohio University — Periodic mesoporous materials contain ordered pores with diameters between 2 and 50 nm. In spite of their ordered pore structure, most periodic mesoporous materials do not possess crystalline pore walls, and the atomic origin of the uncrystallizable pore walls has been elusive. It is believed that the medium-range structure in such materials holds the key to the answer. To understand the medium-range order in periodic mesoporous materials, we select periodic mesoporous silica as a model system for this study. SBA-15 of various pore sizes (5-15 nm) have been synthesized through a self-assembly process using triblock copolymers as the structure-directing agents. X-ray scattering was used to characterize the materials. Pore widths and pore thicknesses of SBA-15 were measured by small-angle x-ray scattering, and the medium-range structure was characterized by wide-angle x-ray scattering. Effects of periodic pore structure and temperature on the medium-range order of amorphous pore walls have been identified. Our study provides atomic insights into the origin of uncrystallizable pore walls of periodic mesoporous materials in general.

\( \lambda \) is the interaction parameter of the Luttinger liquid in an individual nanotube. We calculate the tunnel density of states, for two metallic carbon nanotubes. We demonstrate that for a small angle of crossing, \( \nu \) in them into 0D fullerenes. Unlike the well-known superatom states of 1D nanotubes, also study the superatom states of 1D - 3D solids, their cage size, and exo and endohedral doping by metal atoms. We by lowering the energy of superatom states from 3.5 eV, for single chemisorbed C\(_{60}\) molecules, by DFT calculations we investigate their origin and the factors that influence their energy and wave function hybridization into nearly-free electron bands in molecular solids. We show that the superatom states are derived from the universal image potential states of molecular sheets by rolling and wrapping them into 0D fullerenes. Unlike the well-known \( \pi \) orbitals, superatom orbitals hybridize more extensively among the neighboring molecules to form bands with nearly free-electron dispersion. The prospect of exploiting the strong intermolecular coupling to achieve metal-like conduction in applications may be attained by lowering the energy of superatom states from 3.5 eV, for single chemisorbed C\(_{60}\) molecules, to proximity of the Fermi level; therefore, we study how the superatom state energies depend on factors such as the aggregation into 1D - 3D solids, their cage size, and exo and endohedral doping by metal atoms. We also study the superatom states of 1D nanotubes.

C1.00135 Fullerene-Polyhedral Oligosilsesquioxane Organic-Inorganic Hybrids and Applications as a Nanolayered Supercapacitor, YINGFENG TU, CHUN YE, WENBIN ZHANG, CHI-CHUN TSAI, BIN SUN, XIAOHONG LI, STEPHEN Z. D. CHENG — Fullerene and polyhedral oligomeric silsesquioxane (“POSS”) organic-inorganic hybrid material was synthesized by esterification of methano[60]fullerene carbocyclic acid (MFCA) with POSS-OH. The chemical structure was characterized and proven by matrix assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS), nuclear magnetic resonance (NMR), thermogravimetric analysis (TGA), SEC and UV-Vis spectroscopy. The material has high solubility (more than 10\( \% \)) in solvents like toluene, THF, chloroform and hexane. The material has high thermal stability: only 1\( \% \) of total mass lost at 350 \( ^\circ \) C and 50\( \% \) at 800 \( ^\circ \) C. At high concentrations, the solution of fullerene-POSS can absorb nearly the full spectra of the UV-Vis region (200 nm-700 nm). Crystals can be grown from chloroform solution, and the crystal structure was determined by transmission electron microscopy (TEM) and \( \pi \)-ray diffraction as an orthorhombic structure with \( a = 2.10 \text{ nm}, b = 1.06 \text{ nm} \) and \( c = 3.71 \text{ nm} \). This indicates a bilayer structure. The alternating layered structure of fullerene (conductive) and POSS (insulating) in the crystal can be used for applications such as supercapacitors.

C1.00136 Electronic properties of a coupled polyyacetylene chain, RAIMUNDO COSTA, University of Western Ontario, CELIO MUNIZ, Universidad Estadual do Ceara — We study a coupled polyyacetylene chain using a theoretical field formalism and verify that this structure presents a gap in its band structure. This energy gap is calculated in terms of a quantized effective mass that depends on the coupling between the polyyacetylene chains. As the coupling decreases the gap vanishes and we can restore the previous results of one single polyyacetylene chain. We show that there is a chiral broken symmetry. Electrons propagating in one direction are more energetic than electrons propagating in the other direction of the chain. A formalism is developed to show that there is a particle oscillation phenomenon analogous to Bloch oscillations. The conductivity of the system is also calculated.

C1.00137 Energy level curvatures, parametric motion of electron spectra in carbon nanotubes, ISA ZHAREKESHEV — We examine scaling properties of statistical spectral measures of single-walled nanotubes in the frame of a standard tight-binding model for modified quasi one-dimensional disordered systems. Numerical-scaling analysis is performed for the energy correlation function, the spectral factor and the distributions of the level curvatures and velocities. Non-analyticity at the zero velocities and curvatures is found, which can be lifted by applying a moderate magnetic field. In the limit of weak disorder and at B=0 the level curvature distribution does not entirely obey Wigner-Dyson statistics, but is rather a non-trivial combination of the GOEs distributions depending of the aspect ration of the modelled nanotube. At strong disorder the curvature distribution deviates from the conventional log-normal statistics. The results are verified on the double-wall carbon nanotubes. Similar applications for graphene structures are considered.

C1.00138 The nearly free electron like superatom states in fullerenes and nanotubes, JIN ZHAO, MIN FENG, HRVOJE PETEK, Department of Physics & Astronomy, University of Pittsburgh — Motivated by the discovery of the superatom states of C\(_{60}\) molecules, by DFT calculations we investigate their origin and the factors that influence their energy and wave function hybridization into nearly-free electron bands in molecular solids. We show that the superatom states are derived from the universal image potential states of molecular sheets by rolling and wrapping them into 0D fullerenes. Unlike the well-known \( \pi \) orbitals, superatom orbitals hybridize more extensively among the neighboring molecules to form bands with nearly free-electron dispersion. The prospect of exploiting the strong intermolecular coupling to achieve metal-like conduction in applications may be attained by lowering the energy of superatom states from 3.5 eV, for single chemisorbed C\(_{60}\) molecules, to proximity of the Fermi level; therefore, we study how the superatom state energies depend on factors such as the aggregation into 1D - 3D solids, their cage size, and exo and endohedral doping by metal atoms. We also study the superatom states of 1D nanotubes.

C1.00139 Effect of Helical Perturbation on Exciton Binding Energy in Semiconducting Carbon Nanotubes, BENJAMIN TAYO, SLAVA ROTKIN, Dept. of Phys., Lehigh University — Exciton binding energy in the presence of an external DNA-induced helical potential is studied. Exciton energies are obtained by solving the Bethe-Salpeter equation within the tight-binding approximation. The quasi-particle wavefunctions and energies which enter the Bethe-Salpeter equation are “dressed” by the one-electron helical potential. This external potential, produced by helical DNA-wrapping, is modelled by applying a perturbation operator of the Coulomb interaction which breaks both translational and rotational symmetry. This lowering of symmetry induced by DNA-wrapping has far-reaching effects: the DNA changes the band gap of the nanotube thus modulating its electronic and optical properties. For instance, the helical perturbation uplifts the degeneracy on the angular momentum quantum number \( \lambda \), the interaction parameter of the Luttinger liquid in an individual nanotube. We calculate the tunnel density of states, \( \nu(\omega, x) \), as a function of energy, \( \omega \), and distance, \( x \), from the intersection. In contrast to a single nanotube, we find that, in the geometry of crossed nanotubes, conventional “rapid” oscillations in \( \nu(\omega, x) \) due to the plasmon scattering acquire an aperiodic “slow-breathing” envelope which has \( \lambda/\theta \) nodes.

2. This research was sponsored by the Petroleum Research Fund, DOE and Research Corporation.

C1.00140 Intersection of two nanotubes: density of states modulated by plasmon beatings with period governed by Luttinger-liquid parameter, VAGHARSH MKHITARYAN, YUAN FANG, JORDAN GERTON, EUGENE MISHCHENKO, MIKHAIL RAIKH, Department of Physics, University of Utah — We study theoretically the plasmon scattering at the intersection of two metallic carbon nanotubes. We demonstrate that for a small angle of crossing, \( \theta \ll 1 \), the transmission coefficient is an oscillatory function of \( \lambda/\theta \), where \( \lambda \) is the interaction parameter of the Luttinger liquid in an individual nanotube. We calculate the tunnel density of states, \( \nu(\omega, x) \), as a function of energy, \( \omega \), and distance, \( x \), from the intersection. In contrast to a single nanotube, we find that, in the geometry of crossed nanotubes, conventional “rapid” oscillations in \( \nu(\omega, x) \) due to the plasmon scattering acquire an aperiodic “slow-breathing” envelope which has \( \lambda/\theta \) nodes.

C1.00141 First principles study of energetic interaction of a carbon chain inside carbon nanotubes, LUIS AGUILERA, CINVESTAV, ALEJANDRO TAPIA, UADY, ROMEO DE COSS, CINVESTAV, CINVESTAV-UADY TEAM, MATERIAL SIMULATION TEAM — Recently has been reported a new type of one-dimensional carbon nanostructure. Carbon nanowires formed by a linear carbon-atom chain inside a carbon-nanotube have been observed using high-resolution transmission electron microscopy (HRTEM). In the present work, we have studied the energetic interaction and atomic forces inside of the (5,5) and (8,0) carbon nanowires, using the Density Functional Theory. The calculations were performed by the pseudopotentials LCAO method (SIESTA code) and the Generalized Gradient Approximation (GGA) for the exchange-correlation potential. Analyzing the energetic interaction inside the carbon nanowires, we found that the linear carbon chain obtains a preferential position inside of the carbon nanowires.

C1.00142 Physiosorption of Nucleobases on C(9,1) and C(6,5) Single-Wall Carbon Nanotubes: A Density Functional Theory Study, BRAHIM AKDIM, RUTH PACTHER, Wright Patterson Air Force Base, OH — Selective enrichment of single-wall carbon nanotubes (SWCNTs) of a specific chirality by single-stranded DNA sequences has been shown experimentally by Zheng et al. [JACS 2007, 129, 6094], where a larger enrichment of C(6,5) as compared to C(9,1), which are SWCNTs of the same diameter but different chirality, was demonstrated with alternating guanine and thymine (GT) bases. In this work, we report density functional (DFT) calculations of (G) and (T) nucleobase adsorption on C(6,5) and C(9,1) SWCNTs, in order to gain an understanding of the selective sorting, specifically regarding adsorption characteristics, interface energetics, and electronic structures, as dependent on the tube chirality, also including specifically an empirical dispersion correction in the DFT functional.

C1.00143 Novel One-Dimensional Organometallic Half Metals: Vanadium-Cyclopentadienyl, Vanadium-Cyclopentadienyl-Benzene, and Vanadium-Anthracene Wires, LU WANG, Physics Department, Peking University, ZIXING CAI, JUNYU WANG, JING LU, GUANGFU LUO, LIN LAI, JING ZHOU, RUIN GAO, DAPENG YU, GUANG-PING LI, WAI NING MEI, STEFANO SANVITO, PHYSICS DEPARTMENT, PEKING UNIVERSITY COLLABORATION, SICAS CENTER, LEE HALL, SUNY ONEONTA COLLABORATION, PHYSICS DEPARTMENT, UNIVERSITY OF NEBRASKA AT OMAHA COLLABORATION, PHYSICS DEPARTMENT, TRINITY COLLEGE DUBLIN COLLABORATION — By using the density functional theory, we find that organometallic multidecker sandwich clusters Vn+1FeCp2n+1 (Cp = cyclopentadienyl), and V2nAntn+1 (Ant = anthracene) may have linear structures, and their total magnetic moments generally increase with the cluster size. The one-dimensional (VCp)n∞, (VBzVCp)n∞ (Bz = benzene), and (V2Ant)n∞ wires are predicted to be ferromagnetic half-metals, while the one-dimensional (VCpFeCp)n∞ wire is a ferromagnetic semiconductor. The spin transportation calculations indicate that the finite Vn+1FeCp2n+2 and Vn(FeCp2)n+1 sandwich clusters coupled to gold electrodes are nearly perfect spin-filters.

C1.00144 A Hybrid Density Functional Study Of Pure Ge And GeC Nanotubes: Zigzag Configuration, SOMILKUMAR J. RATHI, Colorado School of Mines, ASOK K. RAY, Department of Physics, The University of Texas, Arlington — Ab initio calculations within the framework of hybrid density functional theory and finite cluster approximation have been performed for the electronic and geometric structures of pure zigzag Ge and three different types of zigzag germanium carbide nanotubes from (3, 3) to (11, 11). Full geometry and spin optimizations with uncontracted symmetry have been performed. A detailed stability investigation of the topological classification of nanotubes with dependence of the electronic band gaps on the respective tube diameter, energy density of states, and dipole moments have been carried out for all the tubes. Using Mulliken charge analysis charge density distribution along the tube lengths is calculated. In depth structural analysis of the structure and molecular orbitals are also reported. From our results it is clear that type I zigzag nanotubes are the most stable structures. For pure Ge, type II, and type III GeC nanotubes the chemical bonding have mixed ionic-covalent character, while for type I GeC tubes are ionic in nature. A wide spectrum of band gap values is also obtained for these nanotubes. This present study also opens up the possibilities for numerous applications of hybrid Ge based nanotubes.

C1.00145 Deposition of Carbon Nanotube Networks for Electronics Applications, GARRETT WADSWORTH, TETYANA IGNAUTOVA, SLAVA ROTKIN, Lehigh University — The development of a simple though reliable deposition technique for Carbon Nanotube Networks on substrates would advance the production of working Carbon Nanotube (CNT) field effect transistors and other electronic devices immesurably. Our investigation of different methods and processes which would be able to reliably create conductive networks of CNTs was in the effort to achieve this goal. Samples were prepared using different stabilizing solutions such as aqueous Sodium Cholate and Dichloromethane along with several processes of physical application to create a network on various substrates. Characterization using several instruments, including a Keithley Semiconductor Characterization Station for transport measurements, SEM, and AFM was performed to gauge their conductivity and the relation to the sample morphology. The most consistent deposition of CNTs on SiO2/Si, SiN/Si and glass substrates occurs when using aqueous Sodium Cholate as the stabilizing solution, etching using a strong acid and rinsing to remove Cholate crystals.

C1.00146 Solution processed large area field effect transistors from dielectrophoretically aligned arrays of single-walled carbon nanotubes, ELIOT SILBAR, PAUL STOKES, YASHIRA M. ZAYAS-GONZALEZ, SAIFUL I. KHONDAKER, University of Central Florida, Nanoscience Technology Center and Department of Physics — Solution processed electronic devices have attracted tremendous attention because of their ease of processability, low cost of fabrication, and their ability to cover large areas. Over the last few decades, a tremendous amount of effort has been dedicated to improve device performance of solution processed organic field effect transistors (FETs). However, despite all these efforts, typical field effect mobilities for these devices are usually on the order of ∼ 0.1 cm²/Vs, and can vary rarely reach ∼ 1.0 cm²/Vs. We demonstrate solution processable large area field effect transistors (FETs) from aligned single-walled carbon nanotubes (SWNTs) arrays. Commercially available, surfactant free SWNTs suspended in aqueous solution were aligned between source and drain electrodes using AC dielectrophoresis. After removing the metallic nanotubes using electrical breakdown, the devices displayed on-off ratios up to 10⁸. The devices showed p-type FET behavior with maximum field effect mobility of 27.1 cm²/Vs, two orders of magnitude higher than solution processed organic FET devices.

C1.00147 Energy transfer between Rear Earth ions and Carbon Nanotubes, TETYANA IGNAUTOVA, HIKMAT NAJAFOV, SLAVA V. ROTKIN, Lehigh University, Physics Department, 16 Memorial Drive East, Bethlehem, PA 18015 — We investigate a potentiality of rare earth (RE) ions for the sensibilization of the carbon nanotubes (NT) luminescence via the resonance-type energy transfer expected from the appreciable spectral overlap. In this study we mainly focus on the time-resolved spectroscopy of selectively excited Tb³⁺ and Eu³⁺+ ions in water solution containing a high concentration of DNA-wrapped NT showed a clear sign of transfer from RE to NT. We propose that the electrostatic attraction between negatively charged DNA phosphate groups and positively charged RE ions (Tb³⁺ and Eu³⁺) in water solution resulted in RE-DNA-NT complex formation with a suitable inter-species spacing for the energy transfer from RE to NT as well as the appreciable spectral overlap. The transfer has been confirmed by small (<10%) but systematic shortening of the RE emission in water solution containing DNA-wrapped NT.

C1.00148 Optoelectronic Characterization of Nafion-gated Nanotube FETs, HAPPINESS MUNEDZIMWE, Lehigh University, IBE Dept., 200 West Packer Ave, Bethlehem, PA 18015, SLAVA V. ROTKIN, Lehigh University, Physics Dept., 16 Memorial Dr. East, Bethlehem, PA 18015 — Optoelectronic probing is a routine way of characterizing standard semiconductor devices. For Carbon Nanotubes Field Effect Transistors (CNT FETs) made on silicon, however, it is a challenge to distinguish between intrinsic and ambient/substrate effects. Photo voltages at the Si-SiO2 interface often dominate the characterization. Back gated FETs systems also exhibit very high gating voltages. Iononic substrates allow higher gating efficiencies and at lower voltages. We report significant transconductance and photo modulation at gate voltages peaking around 5V with Nafion-117 ionomer as substrate which is ten times less than for typical Si systems. We use a generic back-gated FET geometry for characterizing gating performance and the trapping processes at the Nafion–CNT layer interface. Typical signal rise and decay times are of the orders 10 s and 100 s respectively, consistent with charge trapping inside the ionomic polymer. The close similarity between electrostatic gating and photo-gating signal profiles makes the latter a plausible explanation for photo-conductance characterization mechanism in our samples.
C1.00149 Catalytic behavior of Graphene/CNT composites in DSCs, JOSEF VELTEN, ANVAR ZAKHIDOV, University of Texas, at Dallas, DILLIP PANDA, LYNN DENNAY, ATtila MOZER, DAVID OFFICER, University of Wollongong — This presentation demonstrates the replacement of the Pt used in the counter electrode of a dye sensitized solar cell (DSC) by a nanocomposite of carbon nanotube with graphene layers. The I/V redox reaction of such DSC was studied using a composite of graphene flakes (obtained by reduction of graphene oxide) with either single wall or multiwall carbon nanotube sheets. This nanocomposite was deposited onto FTO coated glass and this electrode showed improved catalytic behavior beyond the use of carbon nanotubes alone for the charge transfer redox reaction. This paper also compares the use of the CNT/Gr composite counter electrode with the standard Pt counter electrode. The details of increased catalytic activity of Gr/CNT was studied by impedance spectroscopy and the origin of the enhanced electron transfer at the Gr interface is discussed in terms of local states at atomic edges.

C1.00150 Thermal Properties of Carbon Nanotube and Nanofiber Nanopapers: Finite Element Analysis, LAWRENZO D. MOSES, ALPER BULDUM, Department of Physics, The University of Akron — Carbon nanotube and nanofiber nanopapers are promising candidates as electronic thermal management materials. Here we present finite element method calculations of nanotube-nanotube, nanofiber-nanofiber junctions and extended two dimensional structures (nanopapers) containing these junctions. In the studies of individual junctions, different nanotube/nanofiber diameters, size of contact area and effects of fusing are considered. In the studies of nanopapers, different morphologies, effects of junction-junction separation are considered and thermal transport through multiple layers are studied.

1Supported by ODOD, Third frontier RCP.

C1.00151 Combined transport and Raman measurements on individual carbon nanotubes, MARKUS ALHLSKOG, OLLI HERRANEN, JYRI RINTALA, ANDREAS JOHANSSON, MIKA PETTERSSON — Combined techniques for measurement of structural, transport, and spectroscopic properties of individual carbon nanotubes are very important for current progress in the physics of these materials. We have measured the Raman spectra of individual single walled nanotubes that are electrically contacted with lithographically fabricated microelectrodes on Si/SiO2 substrates. The G-band of the Raman spectra have characteristic features for metallic and semiconducting tubes that we are able to discern. This conclusion is confirmed by transport measurements that unambiguously distinguish between the two types of tubes.

C1.00152 Contact Resistance, Electrical Breakdown and Temperature-Dependent Conductance of Multi-Walled Carbon Nanotubes, XIANGYU CHEN, Department of Physics, Stanford University, DEJJ AKINWANDE, H.-S. PHILIP WONG, Department of Electrical Engineering, Stanford University — Contact resistance has always been one of the major issues for applications of carbon nanotubes such as interconnects for VLSI chips, etc. In order to study the physics of contact between carbon nanotubes and metal, the temperature dependence of contact resistance between carbon nanotube and different metals (Cr/Au, Pd, Ti/Au, etc.) in an extended temperature range (4K to 400K) are explored. These data provide insight into the carrier transport between metal and carbon nanotubes. In addition, the temperature coefficient of the resistivity of multi-walled carbon nanotubes (MWCNT) of different lengths in the temperature range from 4K to 400K are measured and compared with theoretical calculations. By studying the temperature-dependent conductance, we are able to understand carrier transport in MWCNTs at low temperatures. The electrical breakdown behavior of MWCNT is also studied. Information from shell-by-shell breakdown provides insight about the critical current density and inter-shell conductance at different temperatures.

C1.00153 Quantized Conductance and Residual Resistance in Nanowires, CHARLES MILNER, WOO-JOONG KIM, STEVE LAMOREAUX, Yale University — Conductance in nanowires is quantized in units of $G_0 = \frac{2e^2}{h}$. Nanowires can be formed by momentary contact between the ends of macroscopic metallic wires. During the final stage of their rupture, the conductance of the wires drops in a stepwise fashion. However, these steps do not necessarily fall on integer multiples of $G_0$, because of a possible presence of residual resistance in the system. Using gold, we have observed the characteristic steps of quantized conductance. We have also found evidence of residual resistance. Looking forward, we plan to increase the precision of our conductance statistics by implementing automated data acquisition in order to explore the origin of residual resistance in different metallic wires, such as copper and silver. By examining the sample quantized conductance, we hope to find particular characteristics in metals which give rise to residual resistance. We hypothesize that surface potential is one such characteristic.

C1.00154 Electronic Transport Properties on CNT-Metal NanoWire Junctions, SUNGJONG WOO, Univ of Mass Lowell, YOUNG-KYUN KWON, Kyung Hee University, Univ of Mass Lowell — In the devices using carbon nanotube(CNT), the contact property between CNT and metal nodes such as contact resistance is very important. The nanofabrication technology has now begun to get the experimental control of the junction at nanoscale. Using Density Functional Theory (DFT), we have calculated stable junction structures numerically between CNT and metal nanowires(MNW) such as gold. With the stable structures we have found, the transport properties are calculated using non-equilibrium Green’s function method. Different junction structures and their stabilities will be presented. The $I$-$V$ characteristics depending on different junctions and CNT chiralities will also be discussed.

C1.00155 Electronic properties of multiwall carbon nanotubes studied by rotation driven by AC electric fields, D. L. FAN, FRANK Q. ZHU, ROBERT CAMMARATA, C. L. CHIEN, Johns Hopkins University, MATERIALS TEAM, PHYSICS TEAM — We have studied the electronic properties of multiwall carbon nanotubes (MWCNT) using the frequency dependent rotation driven by AC electric fields. The rotation angle, speed, and chirality of MWCNT can be precisely controlled by the strength and frequency of the AC electric field. From the rotation characteristics, the imaginary part of the Clausius-Mossotti factor, which depends on the material, the geometry, and the AC frequency, has been determined from 0.05 to 1MHz. This work demonstrates a non-contact and non-destructive method for assessing the properties of nanotubes and other nanoentities. The rotation of MWCNT can also be exploited in nanoelectromechanical system (NEMS) with MWCNT acting as the rotating elements.

C1.00156 Conductance and elastic modulus of a strained carbon nanotube, FERAS ALZUBI, University of Central Florida, RONALD COSBY, Ball State University — A first principles atomistic calculation of the electrical conductance for a strained, single-wall metallic carbon nanotube segment containing forty eight atoms and placed between copper electrodes is reported. Density functional theory and a non-equilibrium Green’s function technique, encoded in a commercial software package, are used to calculate the electronic structure and current-voltage characteristics for small strains. A monotonic decrease in conductance with strain is predicted. Using force-strain data, a modified Young’s modulus is computed for isolated, stretched nanotube segments containing up to 192 atoms. The computational methods, parameters, Poisson ratios, area selections, and results are described.
Particle motion perpendicular to the graphene layer is calculated as a function of the velocity of the charged particle.

New doped nanotubes could have new applications in composite materials or in applications such as gas sensing or molecular detection.

Carbon Nanotubes have high potential for new materials based on their unique electronic and mechanical properties. They have found use in several fields, including composite materials, electronic nano-devices, catalysis, and energy storage, among others. Doping of nanotubes by exohedral or endohedral methods has been found to substantially modify their electronic structure, as well as their chemical reactivity. In this work, we present a density functional theory study of the electronic and mechanical properties of phosphorus and phosphorus-nitrogen substitutionally doped carbon nanotubes. It is found that doping with these atoms create localized states which modifies electron transport properties. The effects on mechanical properties will also be presented.

The energy loss of a fast charged particle probe incident on a geometry, associated with Klein tunneling in the graphene films and Andreev reflections at graphene interfaces. Gates are also provided for Fermi-level adjustments in the standard “FET” format. Samples are created by e-beam lithography.

Measurements of the thermal conductivity of graphene utilized a technique where the excitation laser initiated a heat wave. The data extraction procedure assumed plane heat waves. Realistic graphene flakes have variations in their width, and the heat wave front may deviate from the plane wave depending on the geometry of the flake. We report a numerical study of heat propagation in graphene flakes of arbitrary geometry. The thermal conduction was simulated using the finite element method. It was found that both the shape of the flake and the temperature distribution in the hot spot affect the extracted values. At the same time, for the flakes with the relatively constant width and the hot spot of the size comparable to the flake width, the thermal conductivity obtained using the simple plane-wave approximation give close values to our simulations. 

Thermal conductivity of graphene flakes of arbitrary geometry was calculated as a function of the thermal conductivity of the substrates. The results are interpreted in terms of the RKKY interaction and the Anderson impurity model.

C1.00165 Water adsorption on a titanium-graphene surface with high metal density. GERARDO J. VAZQUEZ, EDUARDO RANGEL, GREGORIO RUIZ-CHAVARRIA, FERNANDO MAGANA, Instituto de Fisica, Universidad Nacional Autonoma de Mexico — Density functional theory and molecular dynamics were used to study the adsorption of a water molecule on a graphene layer modified with titanium at high metal coverage, with the Ti atoms located above the centers of the carbon hexagons. Two stable configurations for the titanium-graphene sheet were considered. One with one titanium atom per eight carbon atoms and the other with one Ti atom per two C atoms. We found that the water molecule is adsorbed on both configurations, but it is dissociated in two different ways forming $H$, $O$ and $HO$ when the interaction is with the second configuration.

C1.00166 Possible nano-spintronics devices with graphene as electron wave guides. KOICHI KUSAKABE, Graduate School of Engineering Science, Osaka University — Another application of graphene to semiconductor spintronics devices is proposed theoretically. We have designed possible methods for fabrication of nano-scale device structures utilizing graphene as electron wave guides. Important techniques should be 1) formation of strong covalent bonding between a part of substrate and graphene, 2) creation of nano-sized superstructure with sharp edges inducing the graphene edge states[1] by controlling interface between external electrodes and graphene, and 3) creation of nano-sized quantum structures based on the spinodal nano-decomposition. Several test simulations on the electronic states of proposed structures and theoretical estimation of functionality of graphene as an electron wave guide for semiconductor spintronics devices are presented. [1] M. Fujita, K. Wakabayashi, K. Nakada and K. Kusakabe, J. Phys. Soc. Jpn. 65, 1920 (1996).

C1.00167 Effect of metal contacts on photocurrents in graphene transistors. ROKSANA GOLIZADEH MOJARAD, Purdue University, FENGNIAN XIA, THOMAS MUELLER, MARCUS FREITAG, YU-MING LIN, PHAEDON AVOURIS, IBM Thomas J. Watson Research Centre — We present theoretical explanation of photocurrent in graphene and investigate the effect of contact induced states on in-plan electric field in graphene. Contact induced states are similar to the well-known metal induced gap states (MIGS) in metal-semiconductor Schottky junctions, which typically penetrate a few atomic lengths into the semiconductor, while the depth of penetration decreases with increasing band gap. However, in graphene we find that these states penetrate a much longer distance of the order of the width of the contacts.

C1.00168 Micro-Raman imaging spectroscopy of suspended graphene. J. R. SIMPSON, Towson University, Towson MD 21222, A. R. HIGHT WALKER, Physics Lab, National Institute of Standards and Technology, Gaithersburg, MD 20899 — The recent observation of ultrahigh mobility, $> 200,000 \mathrm{cm}^2 \mathrm{V}^{-1} \mathrm{s}^{-1}$, in suspended and annealed graphene underscores the importance of environmental effects on graphene electronic properties. We compare the Raman spectra of graphene and chemically modified graphite oxide both in contact with and suspended above substrate surfaces. Graphene samples were prepared using micromechanical cleavage and chemically modified graphite flakes on silicon substrates with a thin, $\approx$ 300 nm, silicon oxide coating. Reactive ion etching patterns the substrates with circular holes, approximately $3 - 7 \mu m$ in diameter, etched through the oxide layer. We present spatially-resolved Raman spectra obtained in a scanning, confocal microscope configuration using 632.8 nm and 514.5 nm laser excitation.

C1.00169 Intrinsic and extrinsic temperature dependences of Raman spectra of graphene. DANER ABDULA, TANER OZEL, KWANGU KANG, DAVID G. CAHILL, MOONSUB SHIM, University of Illinois Urbana-Champaign — Implementation of single-layer graphene (SLG) into next-generation electronics is of high interest due to unprecedented transport capabilities. Therefore, the importance of SLG doping and vibrational band structure is pronounced, both of which can be characterized with Raman spectroscopy. This work offers insights on the temperature dependent behavior of energy and linewidth of $E_{2G}$-band and $A_1$-2D-band Raman spectral features of intrinsic and air-exposed SLG. Mechanically exfoliated graphene in air exhibits a G-band linewidth that increases with temperature between 298K and 573K but shows an opposite trend after annealing under Ar. The opposing temperature dependences are considered within the context of Kohn anomaly induced phonon softening and broadening. The primary cause of the changes in $E_{2G}$-phonon energy and the electron-phonon coupling is attributed to ambient $O_2$ shifting the Fermi level away from the Dirac point. Our results emphasize the need to consider sample environment when investigating electronic and vibrational properties of graphene as well as when they are utilized, for example, in devices where SLG would undergo lithographic processing or even be operated in contact with various materials that may compromise its supposed high performance.

C1.00170 Conductance gaps modulation by periodic perturbations in graphene nanoribbons. M. PACHECO, L. ROSALES, Z. BARTICEVIC, U. Santa Maria, A. LEON, U. Diego Portales, A. LATGE, U. Federal Fluminense, P. ORELLANA, U. Catolica del Norte — Recently we have shown that the quantum conductance of a single molecule absorbed to the GNR shows the presence of Fano antiresonances at the energy levels of the molecule, suggesting that the GNR can be used as a spectrometer sensor [1]. When groups of molecules are attached, forming a periodic-like structure the conductance of the system presents forbidden minibands. Here we present a theoretical study of the electronic and transport properties of periodic perturbations on graphene nanoribbons. We study super-lattices formed by linear organic molecules side-attached at the ribbon edges and also by periodic structures of antidots in the GNR. The electronic properties of the systems are studied by using first principle calculations (LSDA), and tight binding Hamiltonian models. The quantum conductance is calculated in the Landauer formalism, with real-space renormalization techniques to obtain the Green functions. A series of well defined gaps on the conductance as a function of the Fermi energy are observed. This behavior depends on the period and topology of the perturbations and on the aspect ratio of the system. Conductance gap modulations can be obtained, suggesting new applications in graphene based nano-devices. [1] L. Rosales et al., Nanotechnology 19,0665402 (2008).

C1.00171 Spin Dependent Transport in Graphene Nano Ribbon Devices1, SATOFUMI SOUMA, MATSUTO OGAWA, Dept. of Electrical and Electronics Eng., Kobe Univ., TAKAHIRO YAMAMOTO, Dept. of Material Eng., Tokyo Univ., KAZUYUKI WATANABE, Dept. of Physics, Tokyo Univ. of Science — Graphene is now one of the promising materials for future nanoelectronics. Especially graphene nanoribbon is attracting great attention since it possesses finite bandgap opening depending on the ribbon width and the transport orientation with respect to the graphene lattice. Another interesting property seen in graphene nanoribbon is the appearance of the “edge-spin” polarization at the edges of the zigzag-edged graphene nanoribbon. Recently it has been shown that such edge- spin polarization can be electrically controlled to induce the half-metallic band structure in such structures, meaning the electronic controllability of the spin current in such material. Therefore, toward the realization of the graphene nanoribbon spintronics, it is now important to study the spin- dependent transport characteristics in realistic device structure based on zigzag graphene nanoribbon. Here we present our numerical study of spin transport in zigzag-edged graphene nanoribbon transistor structures [1] using spin-density functional tight-binding method. Special attention is paid to the influence of edge roughness and electrostatic doping on the spin polarization and the spin current. [1] S.Souma, M.Ogawa, T.Yamamoto, K.Watanabe, J.Comp. Electron. 7, 390 (2008).

C1.00172 Influence of an electric-field on electronic properties of few-layer armchair graphene nanoribbons1, Y.-C. HUANG, Center for General Education, Kao Yuan University, H.-C. CHUNG, Dept. of Physics, Natl. Cheng Kung University — In the presence of an electric field, the low-energy electronic properties of AB-stacked few-layer armchair graphene nanoribbons (AGNRs) are studied by using the tight-binding model. They are strongly dependent on the geometric structures (the interlayer interactions, the ribbon width \( N_y \), and the ribbon number \( N_x \)) and the field strength. The interlayer interactions significantly affect density of states (DOS), energy gap \( (E_g) \), band structure, and free carriers. DOS exhibits many special structures, including plateau, discontinuities, and divergent peaks. The effective electric field modifies the energy dispersions, alters the subband spacing, changes the subband curvature, produces the new edge state, switches the band gap, and causes the metal- semiconductor (or semiconductor-metal) transitions. In gapless AGNR, electric fields not only lifts the degeneracy of subbands at \( E_F \) but also induces an energy gap. \( E_g \) is dependent on the ribbon width, and the field strength. The semiconductor-metal (or semiconductor-metal) transitions occur in AGNRs in the increase in electric fields. Due to electric fields, the above-mentioned effects are completely reflected in the features of DOS, such as the generation of special structures, the shift of peak position, the change in peak height, and the alternation of band gap. The predicted electronic properties could be examined by the experimental measurements on absorption spectra and transport properties.

1This work was supported by the Taiwan National Science Council (NSC 97-2112-M-244-001-MY2)

C1.00173 Low-energy Landau levels of AB-stacked zigzag graphene ribbons1, YUAN-CHENG HUANG, Center for General Education, Kao Yuan University — The low energy bands of AB-stacked zigzag graphene ribbons in the presence of a uniform perpendicular magnetic field are investigated by the Peierls coupling tight-binding model. They are dominated by the B-field strength, the interlayer interactions, and the ribbon width. Many dispersionless Landau levels and parabolic energy bands exist along \( k_x \) and \( k_y \) directions, respectively. The former are doubly degenerate, while state degeneracy is absent for the latter. The occupied valence bands are asymmetric to the unoccupied conduction bands about the Fermi level. Such features are directly reflected in density of states. DOS exhibits a lot of asymmetric prominent peaks because of 1D parabolic bands. The predicted magnetoelectronic properties could be examined by the experimental measurements on transport conductance and absorption spectra.

1This work was supported by the Taiwan National Science Council (NSC 97-2112-M-244-001-MY2)

C1.00174 Quasiparticles for quantum dot array in graphene and the associated Magnetoplasmons1, GODFREY GUMBS, Hunter College of CUNY, OLEG BERMAN, New York City College of Technology of CUNY, PEDRO ECHENIQUE, Donostia International Physics Center (DIPC) — We calculate the low-frequency magnetoplasmon excitation spectrum for a square array of quantum dots on a two-dimensional (2D) graphene layer. The confining potential is linear in the displacement from the center of the quantum dot. Consequently, the corresponding Klein-Gordon equation may be solved analytically for the single-particle eigenstates since they are given by a simple harmonic oscillator operator. The electron eigenstates in a magnetic field and confining potential are mapped onto a 2D plane of electron-hole pairs in an effective magnetic field without any confinement. The tight-binding model for the array of quantum dots leads to a wavefunction with inter-dot mixing of the single-particle eigenstates. For chosen confinement, magnetic field, wave vector and frequency, we plot the dispersion equation as a function of the period \( d \) of the lattice. We obtain those values of \( d \) which yield collective plasma excitations. For the allowed transitions between the valence and conduction bands in our calculations, we obtain plasmons when \( d < 100 \AA \).

C1.00175 Temperature Programmed Desorption Study of Graphene Oxide, NICHOLAS CLARK, DANIEL FIELD, SIMONA RIEMAN, CARL VENTRICE, Texas State University, INHWAN JUNG, DONGXING YANG, RICHARD PINER, RODNEY RUOFF, University of Texas — Graphene oxide is an electrical insulator that shows potential for use in nanoscale electronic devices. An understanding of the thermal stability of graphene oxide sheets is important since the electrical, chemical, and mechanical properties of graphene oxide will change as it is reduced at elevated temperatures. In this study, graphene oxide films were grown by deposition of an aqueous solution of graphene oxide onto oxygen plasma cleaned silicon nitride on silicon substrates. The thermal stability of these films was studied by temperature programmed desorption under ultra-high vacuum conditions up to 350 °C. The primary decomposition components of the films are \( \text{H}_2\text{O}, \text{CO}_2 \) and \( \text{CO} \). Desorption of these components starts at \( \sim 70 \) °C and is completed by \( \sim 150 \) °C. Coverage dependent measurements indicate that the desorption kinetics are second order. An activation energy of 162 meV for \( \text{CO}_2 \) desorption has been determined.

C1.00176 Structural and electronic characterization of epitaxial graphene on SiC (0001) using scanning tunneling microscopy/spectroscopy1, DAVID TORRANCE, NIKHIL SHARMA, PHILLIP FIRST, Georgia Institute of Technology — Epitaxial graphene exhibits high-quality crystallinity and is compatible with current industrial fabrication methods, which makes it a strong candidate for future electronic devices. One important and contested aspect of this material system is the interface region between graphene and SiC, and how this reconstruction alters the growth rate, structure, and electronic properties of graphene films. We have investigated epitaxial graphene on SiC (0001) in the very early stages of ultra-high vacuum growth using scanning tunneling microscopy/spectroscopy (STM/STS). Topographical maps of monolayer graphene islands formed in the initial stages of epitaxial growth will be presented along with STM measurements of these features and the surrounding interfacial reconstruction. We further discuss transitions between regions of different structure.

C1.00177 Real-Time Path Integral Study of Electron Transport in Molecular Wires: A Constant Current Formulation and the Importance of Dissipative Processes, ROBERTO LAMBERT, KE DONG, NANCY MAKRI, University of Illinois at Urbana-Champaign — We report the results of real-time path integral calculations to study electron transport in molecular-wire models. The molecular wire system is modeled by a multi-site one-electron tight-binding Hamiltonian connected to two metal electrodes and coupled to a bath mimicking the dissipative effects of molecular vibrations. In order to maintain a steady current flow, we introduce a simple recharging model in which electrons are injected from the donor electron as needed to replenish charge lost to the acceptor, maintaining a constant electron population within the wire. Using real-time path-integral techniques, we study the conductance of the molecular wire model as a function of wire length, with emphasis on the effects of its dependence on dissipation.
C1.00178 Synthesis and spectroscopic characterization of cadmium sulfide nanowires1. NARAYAN KUTHIRUMMAL, College of Charleston, JASON REPPERT, Clemson University, BRIAN DEIHL, College of Charleston, APPARAO RAO, Clemson University — Pulsed laser vaporization method has been used for preparing cadmium sulfide (CdS) nanowires of 50–100 nm in diameter. The morphology and crystallinity of as-prepared CdS nanowires are studied by means of X-ray diffraction, scanning electron microscopy (SEM), and high-resolution transmission electron microscopy (HRTEM). Excellent ordering of the lattice planes perpendicular to the [001] plane has been observed. Photoacoustic (PA), UV-Vis, Raman, and photoluminescence spectroscopy have been used to measure the optical properties. PA spectra yield a steeper absorption edge for as-prepared CdS nanowires when compared to the conventional optical absorption spectrum. The increased steepness might be attributed to the well-ordered structure and size distribution. The data shows that PA spectroscopy is an excellent technique to investigate opaque and highly light scattering samples. Raman data suggests increased exciton-LO phonon coupling in CdS nanowires. The appearance of a narrow photoluminescence peak at 491 nm (FWHM of 9 nm) and the absence of emission above 500 nm demonstrate the high quality of nanowires.

1Supported by NSF-NUE (EEC0631442).

C1.00179 Confocal Raman microscopy of one dimensional cadmium sulfide nanorods. SRIKANTH SINGAMENI, MANEESH GUPTA, RUSEN YANG, ZHONG WANG, VLADIMIR TSUKRUK, Georgia Institute of Technology, GIT/MSE TEAM — CdS nanorods with various shapes (vertically aligned nanorods, nanobells, nanohelices, nanorings) have been synthesized using both vapor phase and solution growth methods. In the simplest example of a nanobell, the fast growth direction can be either (21T0) or (01T0) or (0001). Here, we show that confocal Raman microscopy can be employed as a fast and nondestructive analytical technique to identify the crystal planes and reveal the relative orientation of the ZnO nanostucture. Various features of the Raman spectrum of ZnO nanostuctures (presence of the A1(LO) mode, width of the E2 mode) were found to be sensitive to relative orientation of the incident source laser and the crystal plane. Furthermore, owing to the optical anisotropy of ZnO, Raman scattering from the substrate is modulated (either enhanced or suppressed with respect to the background) depending on the polarization of the incident light with respect to orientation of the nanobell. The results presented here describe a novel method to nondestructively identify the growth, relative orientation, and the waveguiding properties of the ZnO nanostuctures.

C1.00180 Characterization of SiC nanowires obtained from carbon black powder. MONIKA WIELIGOR, T. W. ZERDA, Texas Christian University — SiC nanowires were obtained by a reaction between vapor silicon and carbon black powder in vacuum at 1200°C. Their structures and properties were studied using X-ray diffraction, high resolution transmission microscopy, HRTEM, and Raman scattering techniques. We show that diameter of sintered nanowires depends on carbon black grade and its history of thermal treatment. SiC nanowires of diameter as small as 10 nm were obtained from graphitized furnace carbon blacks. Chemical composition of nanowires was similar for all samples, but concentration of structural defects varied and depended on carbon black surface properties and surface morphology. Stacking faults and twins dislocations were observed in all specimens and characterized by HRTEM, X-ray diffraction, and Raman spectroscopy.

C1.00181 Parallel Tandems of Dye Sensitized Solar Cells with CNT Collector. JOSEF VELTEN, CHAOCHEN YUAN, ANVAR ZAKHIDOV, University of Texas, at Dallas — In this presentation, we demonstrate the fabrication of monolithic parallel tandem dye sensitized solar cells using a semitransparent layer of carbon nanotubes. Each DSC sub-cell has titania photoelectrode with two different dyes: N 719 and N 330, which absorb light in different parts of solar spectrum. This layer of carbon nanotubes laminated on highly porous polymeric Millipore filter acts as both the collector of charge carrier and as the catalyst of the I3−/I− redox reaction that completes the function of the cell, overall allowing easier fabrication for tandem solar cell devices, with a potential for creating flexible devices in the future. The parallel tandem shows the total photocurrent which is nearly the sum of two I3− currents of constituent cells, and total Voc, which is average of two Voc, while conventional in-series DSC tandems show the lowest Voc, and slightly increased I3−[1]. Thus the higher efficiency can be achieved in parallel DSC tandems, and we discuss the physical reasons for this effect. [1] Yanagida, et.al. J. of Photochemistry and Photobiology A: Chemistry Volume 164, Issues 1-3, 1 June 2004, Pages 33-39

C1.00182 Chaotic Electronic Transport in Nanocluster Wires. M.S. FAIRBANKS, Department of Physics, University of Oregon, T.P. MARTIN, School of Physics, University of New South Wales, Australia, C.A. MARLOW, B.C. SCANNELL, Department of Physics, University of Oregon, S.A. BROWN, Department of Physics and Astronomy, University of Canterbury, New Zealand, R.P. TAYLOR, Department of Physics, University of Oregon — Electronic circuits featuring nanoscale devices are highly topical due to their potential for exhibiting novel device functionality and fundamental solid-state physics. Currents based on nanoclusters are particularly appealing because they “self-assemble” [1]. Here we develop a theoretical transport model for nanowires formed from nanoclusters. The wire width varies along the wire’s length, creating an array of connected cavities. The wire walls reflect electron trajectories through material-induced chaotic scatterers within each cavity. We discuss how the chaotic properties can be engineered to increase the conductivity’s sensitivity to electric and magnetic fields for use as novel sensors. [1] For example, J. G. Partridge, et al., Microelectronic Engineering 83, 1460 (2006).

C1.00183 Unusual Conductance in Cumulene Molecular Wires. JARIYANEE PRASONGKIT, Condensed Matter Theory Group, Dept. of Physics and Materials Science, Uppsala University, Sweden, ANTON GRIGORIEV, CMT Group, Uppsala, GÖRAN WENDIN, Department of Microtechnology and Nanoscience, Chalmers University of Technology, Gothenburg, Sweden, RAJEEV AHUJA, CMT Group, Uppsala; Applied Materials Physics, Dept. of Materials and Engineering, Royal Institute of Technology (KTH), Stockholm, Sweden — We report current-voltage curves and conductance of cumulene molecular wire suspended between Au(111) surfaces via thiolate bonds with full self-consistent ab initio calculation under external bias. The conductance of cumulene wires shows oscillatory behavior depending on the number of carbon atoms. Among all conjugated oligomers, we find that odd-number cumulene wires yield the highest conductance and present ballistic-like transport behavior. The wire width varies along the wire’s length, creating an array of connected cavities. The wire walls reflect electron trajectories through material-induced chaotic scatterers within each cavity. We discuss how the chaotic properties can be engineered to increase the conductivity’s sensitivity to electric and magnetic fields for use as novel sensors. [1] For example, J. G. Partridge, et al., Microelectronic Engineering 83, 1460 (2006).

C1.00184 QUANTUM FLUIDS AND SOLIDS —

C1.00185 Critical temperature of extremely confined bosons. P. SALAS, Posgrado en Ciencia e Ingenieria de Materiales, UNAM, M. DE LLANO, Instituto de Investigaciones en Materiales, UNAM, M. FORTES, F.J. SEVILLA, M.A. SOLIS, Instituto de Fisica, UNAM — The critical BEC temperature Tc of an ideal boson gas inside a layer structure simulated by a Kronig-Penney-like trapping potential is found to decrease as the separation between planes decrease to the order of the thermal wavelength λT ≡ h/√2mκkB T0 of the free boson gas at its critical BEC temperature T0 [1], where m is the boson mass. However, when the plane separation is less than λT, Tc increases to nearly T0. This phenomenon could be present in cuprate superconductors and explain why their transition temperatures increases as a function of pressure. [1] P. Salas, M. Fortes, M. de Llano, F.J. Sevilla and M.A. Solis, “Thermodynamic properties of bosons among Kronig-Penney layers,” to be published. We acknowledge the partial support from grant PAPIIT IN1114708.

C1.00186 NANOTECHNOLOGY/BIONANOTECHNOLOGY —
C1.00187 Silicon nanowires under high pressure, YUEJIAN WANG, Los Alamos National Lab — Silicon nanowires (Si NWs), one-dimensional single crystalline, have recently drawn extensive attention, thanks to their robust applications in electrical and optical devices as well as in the strengthening of diamond/SiC superhard composites. Here, we conducted high-pressure synchrotron diffraction experiments in a diamond anvil cell to study phase transitions and compressibility of Si NWs. Our results revealed that the onset pressure for the Si-I to Si-II transformation in Si NWs is approximately 2.0 GPa lower than previously determined values for bulk Si, a trend that is consistent with the analysis of misfit in strain energy. The bulk modulus of Si-I NWs derived from the pressure-volume measurements is 123 GPa, which is comparable to that of Si-IV NWs but 25% larger than the reported values for bulk silicon. The reduced compressibility in Si NWs indicates that the unique wire-like structure in nanoscale plays vital roles in the elastic behavior of condensed matter.

C1.00188 Improved Synthesis of Aligned Carbon Nanotube Arrays for Optical Applications, TRILOCHAN PAUDEL, YANTAO GAO, YUCHENG LAN, GRÉG MACMOHAN, KRZYSZTOF KEMP, MICHAEL NAUGHTON, ZHIFENG REN, Boston College — Vertically aligned carbon nanotubes were grown on the high temperature glass (Aluminosilicate, Corning 1737) substrates with improved characteristics compared to previous attempts. The glass substrates were first coated with a buffer layer of either Chromium or Titanium, thick enough to facilitate CNT growth, but thin enough as to be largely transparent. On the top of the buffer layer, a monolayer of polystyrene spheres was deposited with close compaction, and then a Nickel catalyst film was evaporated. The polystyrene spheres were then removed to obtain honeycomb Ni patterns. On top of the Ni patterns, vertically aligned carbon nanotubes were grown by the direct current plasma enhanced chemical vapor deposition (dc PECVD). These aligned carbon nanotubes, which can range in height from 0.5 to 10 microns, and in diameter from 50 to 350 nm, can then be coated with various dielectrics to function as components in optical waveguides, including solar cells.

C1.00189 Enhancement of LED Backlight by Metallic Nanostructures1, Y.D. YAO, J.K. WU, Department of Materials Engineering, Tatung University, C.Y. HSU, S.Y. HSU, P.K. WEI, Research Center for Applied Science, Academia Sinica, D.H. WEI, Department of Mechanical Engineering, National Taipei University of Technology, M.D. CHOUP, C.N. MO, R & D Center, Chung Hwa Picture Tube, Ltd. — Metallic nanostructures with different size on ITO coated glass substrates have been fabricated by using metal thin film deposition, electron beam lithography, and nanosphere lithography techniques for studying the light guide in a display system. The increase of extraction efficiency is based on scattering light from the trapped photons. With Ag and Au nanostructures in peripheral area of emitting region on the ITO coated glass substrates, the external quantum efficiency of devices increases by roughly 14% and with a 100 nm-width and 450 nm-period metallic nanowire structures, the light extraction can enhance up to 40% from the glass substrate. We demonstrated that with a proper metallic nanostructure in the backlight system of a LED device, the extraction efficiency could be efficiently enhanced.

1 This research was supported by the National Science Council of Taiwan and Chung Hwa Picture Tube, Ltd.

C1.00190 Modified Electric Force Microscopy combined with Atomic Force Microscopy Electrostatic Nanolithography, SERGEI LYUKSYUTOV, The University of Akron — A hybrid method, combining electrostatic nanolithography with modified electric force microscopy was used to characterize and study surface electric charging of high molecular weight (850000 mw and 110000 mw) polymethyl methacrylate and polystyrene films. Experimental protocol to manipulate an atomic force microscope tip included 1) Displacement of the vibrating tip to the level when the vibration amplitude largely damped; 2) Tip retraction at the distance varied between 1 to 100 nm with positive or negative tip bias. A modified Electric force microscopy maps electric charge distribution and its sign on the sample surfaces. Stable surface deformation related to nanoscale mass transport was associated with electric breakdown and negative surface charging, while a temporary viscoelastic surface deformation followed by surface relaxation was due to positive surface charging.

C1.00191 A Novel Carbon Nanotube Network and Aptamer Based Biosensor, Y. AL-TITI, W.G. MATTHEWS, University of South Florida — A carbon nanotube network field effect transistor (CNTN-FET) based biosensor for the detection of Tenascin C will be presented. The device consists of CVD-grown CNTNs incorporated into FETs coupled with surface bound DNA aptamers. The aptamer conjugated FET provides highly selective and sensitive detection of protein concentrations. The sidewalls of the CNTs initially were functionalized with a short oligonucleotide which has the dual functions of blocking non-specific binding and serving as a tether for the addition of another DNA strand. Specific detection was accomplished through hybridization of an aptamer for Tenascin C to which the complementary strand of our blocking sequence was added to the 5’ end. IV curves and conductance versus time were collected, demonstrating detection of each of the two DNA strands and the protein Tenascin C. The protein produced an undetectable signal in the absence of the aptamer, even at higher concentrations. Confirmation of adsorption of the oligonucleotide, hybridization of the aptamer, and binding of Tenascin C were each confirmed through fluorescence microscopy. The resulting device is an important step toward low cost, label-free biosensors.

C1.00192 Detection of α-fetoprotein in human serum using carbon nanotube transistor, HYE-MI SO, DONG-WON PARK, KRICT, SEONG-KYU LEE, Eulji University School of Medicine, BEOM SOO KIM, Chungbuk National University, HYUNJU CHANG, JEONG-O LEE, KRICT — We have fabricated antibody-coated carbon nanotube field effect transistor (CNT-FET) sensor for the detection of α-fetoprotein (AFP), single chain glycoprotein of 70 kDa that is normally expressed in the fetal liver, in human serum. The AFP-specific antibodies were immobilized on CNT with linker molecule such as pyrenebutyric acid N-hydroxysuccinimide ester. To prevent nonspecific adsorption of antigen, we performed blocking procedure using bovine serum albumin (BSA). Antibody-antigen binding was determined by measuring electrical conductance change of FET and took an average of thershold voltage change before and after binding. Also we checked concentration-dependent conductance change in human serum using both p-type SWNT-FETs and n-type SWNT-FETs.

C1.00193 Wrapping of a single bacterium with Functionalized - Chemically Modified Graphene (FCMG) sheets via highly specific protein-cell wall interaction, NIHAR MOHANTY, VIKAS BERRY, Kansas State University — Graphene has recently generated a lot of interest due to its unique structural and electrical properties. It’s micro-scale area and sub-nano-scale thickness coupled with ballistic electronic transport at room temperature, low Johnston noise and low charge scattering, have made it a gold mine for novel applications. Since its discovery in 2004, there have been a plethora of studies on characterizing its unique physical, chemical and electrical properties of graphene as well as on integrating it with various physical/chemical systems to utilize these properties. But there have been limited or no studies on the integration of graphene with living microorganisms or mammalian cells. Here we describe the novel wrapping of a single live bacterium (Bacillus cereus) with a chemically modified graphene sheet functionalized with the protein Concanavalin-A (Con-A) via the highly specific Con-A - Teichoic acid interaction. We are investigating the structural and the electrical properties of these novel bacteria-FCMG ensembles. Further, we are also interested in characterizing this wrapping process in detail by studying the kinetics and the mechanism of action of bacterial-wrapping via 3D modelling. This is a first step towards the live-bio-nano-integration of graphene which would open up avenues for applications as diverse as bio-batteries using the Geobacter to recombinant enzyme compartmentalization.
Liquid crystalline materials. A new concept of smectic LC lithography technique. Grown in microchannels from a mixture of LC molecules and fluorescent particles, TFCDs of the smectic LCs form by semi-fluorinated smectic liquid crystals (LCs). Combining with controlled geometry, i.e. microchannel, our smectic LC system exhibits high density of materials for the creation of lithographic templates. Here we report that perfect ordered-arrays of toric focal conic domains (TFCDs) covering large areas can be realized.

Nanotechnology. To date, several distinct organic building blocks—including colloids, block copolymers and surfactants—have been examined as potential systems for the lithographic fabrication of carbon nanotubes. In the approach mode, the elastic modulus showed linear fit to yield stress and exponential fit to particle size of latex. The results are compared with non-linear elastic models that predict power law and exponential fits. The model uses microscopic statistical mechanical theory, which describes glassy dynamics based on a non-equilibrium free energy that incorporates local cage correlations and activated barrier-hopping processes.

Computer Simulation of a Magnetized Two-Dimensional System. We used AFM to study Cantilever mechanics and Atomic Force Microscopy study of TEHOS. We performed extensive computer simulations on a two-dimensional electron system in a perpendicular magnetic field. The calculations cover the various values of the coupling parameters. The effect due to magnetic field is systematically studied as a function of coupling parameters for both static and dynamical properties.
C1.00203 Miscibility behavior of blends of spiropyran chromophore and mesogenic diacrylate1, HARRIS LAM, University of New Orleans, NAMIL KIM, THEIN KYU, University of Akron — The phase diagram of blends of photochromic molecule (spiropyran) and mesogenic diacrylate monomer (RM257) has been constructed experimentally and theoretically. The phase diagram involving solid-liquid phase transition has been investigated using differential scanning calorimetry (DSC) and subsequently the theoretical calculation was performed by self-consistently solving the combined free energies of Flory-Huggins (FH), Maier-Saupe (MS), and phase field (PF) theory. The simulated phase diagram composed of various coexistence regions involving single component mesophases (Cr1, Cr2, N2) and several coexistence phases (Cr1 + Cr2, Cr1 + N2, Cr1 + Cr2) accorded well with the experimental results. These predicted coexistence regions have been further confirmed by conducting several temperature quench experiments into these coexistence gaps by means of optical microscopy (OM). The development of phase morphology will be discussed in relation to the phase diagram.

1Supported by NSF-DMR 0514942 and REU DMR 0648318.

C1.00204 Multiscale Dynamics of Pre-Transitional Fluctuations in the Isotropic Phase of a Lyotropic Liquid Crystal1, MIKHAEL ANISIMOV, University of Maryland, College Park, CHRISTOPHER BERTRAND, The Petroleum Institute, Abu Dhabi, UAE, KIRT LINEGAR, University of Maryland, College Park, ANDREI KOSTKO, St. Petersburg State University of Refrigeration and Food Engineering, Russia — Using an improved static and dynamic light scattering technique, we have observed multiscale relaxation of the pre-transitional fluctuations in the isotropic phase of a cromolyn solution, a lyotropic liquid crystal where rods are formed by aggregates of disc-like molecules. We have detected the onset of cromolyn aggregation about 12 °C above the transition temperature. The onset is manifested by the emergence of strong scattering due to the fluctuations of local anisotropy and by the split of the diffusion dynamics into two modes, one associated with the diffusion of the cromolyn monomers and the other one with the diffusion of the cromolyn aggregates. A third observed dynamic mode is associated with the pretransitional slowing down of the fluctuations of local anisotropy. This mode behaves differently in polarized and depolarized light scattering, due to a coupling between the fluctuations of anisotropy and velocity fluctuations.

1The research is supported by Abu Dhabi National Oil and Gas Company, UAE.

C1.00205 Phase equilibria of a polymer discotic liquid crystal mixture.1, TSANG-MIN HUANG, THEIN KYU, University of Akron — Thermodynamic phase diagrams of a polymer dispersed liquid crystal (PDLC) containing a monomeric discotic liquid crystal (DLC) and a polymer have been established theoretically by combing Flory-Huggins theory for the free energy of mixing of isotropic phase and Chandrasekhar-Clark theory for the phase transition of hexagonal crystalline ordering of discotic liquid crystals. By varying interaction parameter of hexagonal columnar phase, columnar-isotropic and columnar-nematic-isotropic phase transitions can be predicted. The spinodal line of the columnar DLC/polymer will be calculated in conjunction with the conventional liquid-liquid spinodal. Effects of various molecular parameters on the columnar LC phase diagram will be discussed.

1Supported by NSF DMR 0514942.

C1.00206 Study of liquid crystal molecular dynamics algorithm1, JONES TSZ-KAI WAN, Department of Physics, The Chinese University of Hong Kong — Recent years have witnessed the growth in controlling liquid crystal (LC) alignment using patterned surfaces. Computer simulation of actual LC configurations that are due to different substrate surfaces is a useful tool to aid the design of practical LC cells. In liquid crystal simulations, one seeks for an optimal configuration of the LC director field n(r) that minimizes the total energy of the LC cell. For non-uniform substrate surfaces, the spatial variation of the LC is complicated and the minimization of the total energy is accomplished by advance numerical techniques like conjugate gradient (CG). In a recent work, we have proposed an efficient simulation scheme called liquid crystal molecular dynamics (LCMD), which is developed to determine liquid crystal configurations in complex physical environments. In this work, the author studies the limitation of such scheme and investigates how the simulation parameters can be tuned to achieve optimal performance.

1This work is supported by CUHK direct grant (project no. 2060307)

C1.00207 Atomistic DMD Simulations of Spontaneous Formation of Nematic and Smectic Phase in a Model Liquid Crystal.1, 2 APICHART LINHANANTA, Lakehead University, IAN MACKAY, University of Guelph — We present atomistic discontinuous molecular dynamics (DMD) simulations of the bulk liquid crystal phases of the molecular fluid 8CB. The model is based on previous DMD models of protein folding (A. Linhananta, J. Boer and Ian MacKay, J. Chem. Phys., 2005, 122, 114901) in which all atoms including polar hydrogen, but nonpolar hydrogen, are represented. Bonded pairs interact by infinite square well, while nonbonded atoms interact by hard-sphere square-well potentials. For the model 8CB, molecular parameters are scaled using AMBER and CHARMM force fields. The hard interaction potentials allow very rapid equilibration of ordered phases. Starting the DMD simulations from initial random states, without positional or orientation order, the 8CB systems spontaneously order nematic and smectic phases. The simulations were performed in a 40 A X 40 A X 40 A box with 100 to 500 8CB molecules. At fixed temperature, as the density increases, the phase change from disorder to nematic to smectic. Finally a density-strain phase diagram is presented.

C1.00208 An improved differential effective medium model for the viscosity of hard sphere suspensions at arbitrary volume fractions.1, 2 CARLOS MENDOZA, Materials Research Institute- UNAM, IVAN SANTAMARIA-HOLEK, Facultad de Ciencias-UNAM — We propose a simple and general model accounting for the dependence of the viscosity of a hard sphere suspension at arbitrary volume fractions. The model constitutes a continuum-medium description based on a recursive-differential method where correlations between the spheres are introduced through an effective volume fraction. In contrast to other differential methods, the introduction of the effective volume fraction as the integration variable implicitly considers interactions between the spheres of the same recursive stage. The final expression for the viscosity scales with this effective volume fraction which allows to construct a master curve that contains all the experimental situations considered. The agreement of our expression for the viscosity with experiments at low- and high-shear rates and in the high-frequency limit is remarkable for all volume fractions.

C1.00209 Adsorption energy of nanoparticles at liquid/liquid interfaces.1, KAN DU, E. GLOGOWSKI, T. EMRICK, T. RUSSELL, A. DINSMORE, Department of Physics, Department of Polymer Science and Engineering University of Massachusetts Amherst — We investigated the adsorption energy of nanoparticles at liquid/liquid interfaces by measuring the change of interfacial tension during the self-assembly of nanoparticles at interfaces. The sessile-droplet and pendent-droplet methods were used to measure the interfacial tension of liquid-gallium/water and oil/water interfaces. Interfacial tensions were measured under different conditions, including the concentrations and sizes of nanoparticles, ligand composition, solution pH, and ionic strength. The measurements showed that interfacial tension can change by an amount ranging from 0.5 to 150 mN/m. From the change in interfacial tension, we obtain the adsorption energy per nanoparticle, which ranges from less than 10 kBT to more than 1000 kBT. The results should contribute to the fabrication of membranes and other nano-composite materials by interfacial assembly.

1We acknowledge support from the NSF through NIRT CTS-0609107 and the Umass MRSEC on Polymers, and from the Center for UMass/Industry Research on Polymers.
C1.00210 Controlling Stability and Rheology of Organic Foams, JAMIE KROPIKA, MATTHEW CELINA, Sandia National Laboratories — It is often important to understand the stability and flow properties of polymeric foams in order to optimize industrial processing conditions or design new materials. The fact that foaming, polymerization and temperature rise are often coupled in these systems makes it difficult to even characterize existing materials, much less model behaviors to optimize formulations and processing conditions. To make progress in this area, we have developed model foaming systems that decouple these processes and allow us to characterize the physical properties of liquid foams. We are specifically interested in understanding the controlling factors of foam persistence, shear stability, and rheological behavior. We show both chemical (e.g., partial polymerization) and physical (e.g., particulate additives) means of tuning foam persistence as well as both small strain deformation flow and the less understood liquid-like flow at high applied stresses. Sandia is a multi-program laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under Contract DE-AC04-94AL85000.

C1.00211 Growth and self-assembly of water drops over evaporating polymer solutions, VIVEK SHARMA, Hatsopoulos Microfluids Laboratory (HML), Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge MA 02139., MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta GA 30332. — Water drops that nucleate and grow over evaporating polymer solutions exhibit non-coalescence and pack like hard spheres. In this study, we elucidate how the creation and evolution of a population of close packed drops occur in response to the heat and mass fluxes involved in water droplet condensation and solvent evaporation. We describe a rich array of experimental observations about water droplet growth, noncoalescence and assembly that have not been reported in the published literature so far. The pursuit of perfect packing in growing, assembling water drops is qualitatively similar to colloidal crystallization. We examine the role of solvent and polymer in controlling the kinetics of growth and assembly of droplets, which eventually evaporate away, producing a polymer film with ordered array of pores.

C1.00212 Molecular Dynamics of the Sedimentation of Polydisperse colloids, MANUEL VALERA, ATHULA HERAT, JOSEPH YARZEBINSKI, MARISA HICKS, Slippery Rock University — We have performed molecular dynamics simulation on colloidal systems composed of polydispersed hard spheres. The polydispersity in this systems had a Gaussian distribution with a range of up to 10%. We studied system where gravity plays a fundamental role. We show the sedimentation profiles and the effects on layering and crystallization for different values of the gravitational length, polydispersivity and area density of the system.

C1.00213 Gradient Sensing in Reactive, Ternary Membranes, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh — Using computer simulations, we investigate the behavior of reactive ternary ABC membranes that are subjected to an external, spatially nonuniform stimulus, which controls the rate of interconversion between the A and B components. We assume that A and B have different spontaneous curvatures. Furthermore, the C component is taken to be nonreactive and incompatible with both A and B. We find that a gradient in the applied stimulus causes the dynamic reconstruction of the membrane, with a preferential reorientation of the reactive AB domains along the gradient. In addition, the external gradient effectively controls the transport of the nonreactive C component within the membrane. The latter effect could potentially be exploited for cleaning the membrane of the nonreactive C impurities or for the targeted delivery of the C component to specific locations.

C1.00214 Line Tension and the Nature of the Boundary in a Pure Model System, RICHELLE TEELING, PRITAM MANDAL, LU ZOU, Kent State University, ANDREW BERNOFF, Harvey Mudd College, JAMES ALEXANDER, J. ADIN MANN, Case Western Reserve University, ELIZABETH MANN, Kent State University — Insoluble 8CB (4-n-octyl-4-cyanobiphenyl) layers at the air/water interface provide a well-controlled system on which to analyze the line tension and the nature of the boundary between quasi-two dimensional domains. The average molecular area was adjusted to monolayer liquid/gas or to monolayer/trilayer coexistence. In the first case, difference in dipole moment density leads to long-range repulsive forces which affect line tension and domain configuration. The symmetry of additional bilayers in the second system minimizes such effects, allowing a direct test of the effect of repulsive forces. The line tension of both systems was determined from the hydrodynamic relaxation of stretched domains, through quantitative comparisons with a numerically tractable hydrodynamic model for the relaxation. This research will give insight into similar system of lipids and proteins in biological membranes.

C1.00215 Mesoscopic Simulations of Microfluidic Flow in Irregular Geometries, TYLER N. SHENDRUK, GARY W. SLATER, University of Ottawa — Stochastic Rotation Dynamics, a particle-based model for mesoscopic fluid dynamics, is used to study two and three-dimensional flow in a variety of complex boundaries and for a range of low Reynolds numbers (between 10 and 200). The systems considered are of two types: they consist of either irregular geometries such as dimpled pipes or require adaptive boundary conditions such as particle impact on a solid boundary. We apply out techniques to microfluidic devices with complex channel walls such as those used for slalom chromatography and sinusoidal undulation surface patterning chromatography. Numerical results showing good agreement with experimental data and previous computational simulations are presented.

C1.00216 Polymer Brushes Driven by Electro-Osmotic Flow in Nanoscale Channels, IBRAHIM SOUKI, MOHAMED LARADJI, University of Memphis, P.B. SUNIL KUMAR, IIT-Madras — Using systematic dissipative particle dynamics simulations, we investigated the flow of solvents in nanoscale channels, driven by wall grafted polyelectrolytes, under the influence of an oscillating external electric field. Net flow of the fluid is observed when the external field is temporally asymmetric. We found that the flow rate is strongly affected by grafting density, chain length, field amplitude and period. In particular we can achieve an optimum flow rate for specific values of the parameters listed above. The details of polymer kinetics involved and their effect on net fluid flow will be presented.

C1.00217 Guiding E.coli to nanosensors, DONG-WON PARK, HYE-MI SO, KRICT, BEOM SOO KIM, Chungbuk National University, KI-JEONG KONG, HYUNJU CHANG, JEONG-O LEE, KRICT — Electronic nanosensors based on nanomaterials such as carbon nanotubes and nanowires are expected to have ultimate sensitivity. However, as an inherent problem of nanosensors, they have extremely small sensor surface for reaction. Therefore, simple diffusion of target biomolecules is not enough for such nanosensors, and the problem is even more serious in the case of motile bacteria. Previously, we have shown that we could estimate the titer of E.coli with arrays of single-walled carbon nanotube field effect transistors (SWNT-FET) combined with statistical method. Still, sensitivity of our method is inferior compared with incubation method, due to the limited sensor surface area. In this work, we actively guide E.coli to the sensor surface using micro-fabricated channels. Arrow-shaped and funnel shaped microstructures were fabricated in the channel to guide E. coli to the sensor surface, and we used green fluorescent protein expressed E.coli to monitor the guiding of E.coli.
C1.00218 Hydrodynamic flow in a microchannel due to nanocapillary membrane electro-osmotic flow. JARROD SCHIFFBAUER, Physics Dept., West Virginia University, WILL BOOTH, Physics Dept., West Virginia University, KATHLEEN KELLY, Chemistry Dept., West Virginia University, BOYD EDWARDS, Physics Dept., West Virginia University, AARON TIMPERMAN, Chemistry Dept., West Virginia University — A model for hydrodynamic flow in a microchannel terminated by a nanocapillary membrane (NCM) is proposed in which the microchannel electric-double layer (EDL) is treated as a boundary-layer, providing a hydrodynamic slip-velocity at the channel wall, and the NCM electro-osmotic flow (EOF) is treated as fully-developed. Applied pressure gradients and the contribution of the microchannel EDL to both the net charge transport and the back-pressure on the NCM are neglected. The proposed coupling between the NCM EOF and microchannel hydrodynamic response is obtained by arguing that the steady-state Onsager symmetry between linear-response coefficients may be applied to the transient response of the microchannel. The resulting form of the Navier-Stokes equation in the microchannel possesses steady-state solutions that are compatible with parabolic and inverted-parabolic profiles observed in NCM sample concentration experiments.

C1.00219 Measurements of Stopping Force on Ball on Impact with Granular Medium. JOSEPH AMATO, LAURA COYLE1, MICHAEL NITZBERG2, Colgate University — We present direct measurements of the deceleration vs. time of a 3.8 cm diameter brass ball plunging into a loose granular bed of 400 - 600 μm glass beads. Data were obtained using an accelerometer chip housed within the ball. As suggested by Durian and co-workers, the measured force on the ball is well described by a velocity dependent force \( c_1 \nu^3 \) plus a separate depth dependent force \( c_2 (z + z_0) \). For impact velocities in the range 1.3 – 5.1 m/s, a single set of parameters \((c_1, c_2, z_0)\) fits all the data well, with the exception of the first few ms after impact, when the ball is only partially submerged in the granular matter.

C1.00220 Fluidization of granular media wetted by liquid \( ^4 \text{He} \). KAI HUANG, MASoud SOHAILI, MATTHIAS SCHROETER, STEPHAN HERMINGHAUS, Max Planck Institute for Dynamics and Self-organization — We explore experimentally the fluidization of vertically agitated PMMA spheres wetted by liquid \( ^4 \text{He} \) at temperatures around the \( \lambda \) point. For wetting by normal fluid helium \((T > T_\lambda)\), the critical acceleration for fluidization \((\Gamma_c)\) shows a steep increase close to the saturation of the vapor pressure in the sample cell. For superfluid helium \((T < T_\lambda)\) wetting, \( \Gamma_c \) starts to increase already at about 75% saturation, indicating that capillary bridges are enhanced by the superflow of unsaturated helium film driven by “fountain effect”. Above saturation, \( \Gamma_c \) enters a plateau regime where the capillary force between particles is independent of the bridge volume. The plateau value is found to vary with temperature and shows a peak at 2.1 K, which we attribute to the influence of the specific heat of liquid helium on capillary bridge formation and rupture.

C1.00221 Melting in a finite, two-dimensional Yukawa system. T.E. SHERIDAN, Ohio Northern University — A complex (dusty) plasma disk is a two-dimensional system of monodisperse microspheres confined by a parabolic well and interacting through a Yukawa potential. (Complex plasma is an open, dissipative system.) Consequently, a complex plasma disk is a physical realization of a finite, two-dimensional Yukawa system. Recent experiments on a complex plasma disk with \( n \approx 3900 \) dust particles [T. E. Sheridan, Phys. Plasmas 15, 103702 (2008)] indicate that the system melts via two second-order topological phase transitions. In the present work, we will model these experimental results using the Metropolis algorithm to generate ensembles of configurations consistent with a given thermodynamic temperature. Model results will be compared with experiment. In particular, we wish to determine the exponential characterizing the power law decay of the bond-orientational correlation function in the hexatic phase, which the experimental results indicate may be greater than that predicted by KTHNY theory.

C1.00222 Percolation in Granular Material. MARK ZIMMERMAN, D.T. JACOBS, Department of Physics, The College of Wooster, Wooster OH 44691 — Percolation was studied by measuring the resistance to the flow of electricity through a system of conducting and insulating spheres. The percolation threshold was measured on three different size systems by varying the number fraction of conducting spheres in the mixture of 3 mm diameter steel shot and glass spheres as well as 1 mm silver coated glass spheres and uncoated spheres. A dynamic pressure effect was observed in the random-packed system when using the less conducting steel shot but not with the silver coated spheres. Results have qualitative and quantitative similarities to published experimental and simulation work on comparable systems going from 2D to 3D. The percolation threshold observed will be discussed and compared to other experiments as well as simulations. We acknowledge support from NSF DMR-0649112.

C1.00223 Self-Organized Criticality in a Bead Pile. MIKE WINTERS, D.T. JACOBS, Department of Physics, The College of Wooster, Wooster OH 44691 — This experiment examined a conical bead pile and the distribution of avalanche sizes when using uniform 3mm zirconium spheres ("beads"). A bead pile is built by pouring beads onto a circular base where the bottom layer of beads had been glued randomly. Beads are then individually dropped from a fixed height after which the pile is massed. This process is repeated for thousands of bead drops. By measuring the number of avalanches of a given size that occurred during the experiment, the resulting distribution could be compared to a power law description as predicted by self-organized criticality. We had found in an earlier experiment that glass beads dropped from a small height were consistent with a simple power-law, but if dropped from larger heights then a power-law times an exponential was needed. The zirconium beads sometimes had a distribution that deviated from a power-law times an exponential when the beads were dropped from larger heights, and occasionally the distribution showed a distinct enhancement of the probability for large avalanches when beads were dropped from smaller heights. Using data collected over many years, it was found that the density and type of bead did not appear to affect the avalanche distribution. We compare our experimental results to a numerical simulation. We acknowledge support from NSF DMR-0649112.

C1.00224 The mussel thread cuticle, a biological granular composite coating. NIELS HOLTER-ANDERSEN, University of Chicago, Department of Chemistry, Chicago, IL 60637, USA, HEÑRIK BIRKEDAL, University of Aarhus, Department of Chemistry & iNano, 8000 Aarhus C, Denmark, KAA YEE C. LEE, University of Chicago, James Franck Institute, Chicago, IL 60637, USA. J. HERBERT WAITE, University of California, Santa Barbara, Biomolecular Science & Engineering Program, Santa Barbara, CA 93106, USA — The cuticle of mussel byssal threads is a peculiar natural granular composite coating that combines high extensibility with high stiffness and hardness. In this study fluorescence microscopy and elemental analysis were exploited to show that the 3, 4-dihydroxyphenyl-L-alanine (dopa) residues of mussel foot protein-1 co-localize with Fe and Ca distributions in the cuticle of Mytilus galloprovincialis mussel byssal threads. Removal of Fe and Ca from the cuticle by chelation results in a 50% reduction in hardness. Dopa-metal complexes may be a significant source of stability as cross-links in the composite cuticles.
C1.00225 Electron Shock Waves Propagating into a Pre-ionized Medium , M. HEMMATI, N. RASUL, R. PEDEN, Arkansas Tech University — We employ a one dimensional, constant velocity, steady-state, three component fluid model to investigate breakdown waves propagating into an ionized medium. Assuming that electron gas partial pressure is much greater than that of the other species, we have been able to write down equations of conservation of the flux of mass, momentum and energy, plus the Poisson’s equation. The charge concentration ahead of the wave alters the set of fluid equations and also the boundary conditions at the shock front. The ionization rate is calculated by considering ionization from both random and directed electron motions. Integration of the set of electron-fluid dynamical equations for antiforce waves propagating into a pre-ionized medium through the dynamical transition region of the wave for two wave speeds and several current values ahead of the wave was successful. The results for both wave speed values and all current values ahead of the wave meet the expected physical conditions at the end of the sheath region. Calculation of the ionization rate through the sheath region shows that for high wave speeds and for all current values ahead of the shock front, as one approaches the trailing edge of the sheath, the ionization rate increases slightly. However, as the wave speed decreases, for all current values ahead of the shock front, the ionization rate essentially remains constant throughout the sheath region.

C1.00226 Bubble Chains in Magnetic Fluids (Ferrofluids). JONG(JAMES) YOO1, PHILIP YECKO, Montclair State University, WAH-KEAT LEE. Advanced Photon Source – Argonne National Laboratory — Direct numerical simulations are applied to the problem of dynamics of chain formation among small bubbles in a magnetic liquid (ferrofluid), coalescing at low Reynolds number due to magnetophoresis. Complementary experiments performed using high-intensity high-resolution X-ray images of air bubbles in ferrofluid have revealed that linear chains of several small bubbles are extremely common. In numerous applications of ferrofluids, the wanted or unwanted presence of bubbles and bubble chains in particular, is crucial to describing and predicting critical flow properties. In this study we examine the chain formation process between two and three identical bubbles, finding regimes of conditions within which chain formation is expected under a uniform applied magnetic field. We conjecture how these results can be extended to larger numbers of bubbles forming longer chains. Added mass plays a significant role in the magnetophoresis-driven dynamics. We therefore examine the role of the density ratio in the coalescence process among bubbles within the limits imposed by the volume of fluid (VOF) method that we use.

C1.00227 Charge transport mechanism of ionic liquids at metallic interfaces , ANATOLI SERGHEI, University of Massachusetts Amherst, MARTIN TRESS, JOSHUA RUME, FRIEDRICHER KREMER, University of Leipzig, Germany — A quantitative description is suggested for electrode polarization, an ubiquitous phenomenon which takes place at the interface between a metallic and an ionic conductor. Based on the fact that, due to Coulombic interactions, the ion mobility is drastically slowed down at the interfaces, this approach quantitatively describes the experimentally observed scaling laws and enables one to deduce – by use of a novel formula – the bulk conductivity of the ionic charge carriers under study. It allows furthermore a quantitative determination of the conductivity function of the ionic liquids in the interfacial regions and opens, by that, multiple perspectives in understanding the mechanisms of charge transport at interfaces.

C1.00228 Exact thermodynamic calculation of a monatomic system and its ideal glass transition on a new recursive lattice formed by cubic units , RAN HUANG, PURU GUJARI, The University of Akron — A many-body Ising lattice model is used to represent monatomic systems and is solved exactly on a new recursive lattice with the aim to study the metastability in supercooled liquids and the ideal glass transition. Interactions between particles farther away than the nearest neighbor distance are taken into consideration. The Ising model is antiferromagnetic in nature so that its ordered phase represents an alloy-type crystal of alternating species (A-B or particle-void). The new recursive lattice appears quite reliable to represent a cubic lattice. Thermal properties including free energy, energy and entropy of the ideal crystal and supercooled liquid state of the model are calculated. The computation results show a first order melting and second order ideal glass transition (entropy crisis) in the supercooled liquid phase. The effects of different energy terms on the two transitions are studied. We also study the defects in the ideal glass, supercooled liquid and the crystal to support the theory that a glass can be treated as a highly defective crystal.

C1.00229 Pattern formation in two-dimensional binary mixtures of colloids interacting via short-ranged interactions , CARLOS MENDOZA, ERASMO BATTA, Materials Research Institute-UNAM — We report Monte Carlo simulations on the pattern formation in a binary mixture of colloidal particles interacting via short ranged potentials. Such potentials consist of a hard-core square-shoulder interaction if the particles are of the same type and of a hard-core square-well if they are of different type. For 50/50 mixtures, we find a rich variety of patterns that can be grouped mainly in alternate strips each one consisting of particles of the same type or aggregates that self-assemble in a regular square lattice. For mixtures in which the are more particles of one of the species then a phase separation is observed; one of the separated phases consists only of particles of the dominant type while the other is a mixture of both types of particles.

C1.00230 ABSTRACT WITHDRAWN –

C1.00231 Phase Separation in the Advective Cahn-Hilliard Equation with a Chaotic Flow , SOHEI YASUDA, BENJAMIN VOLLMAYR-LEE. Bucknell University — The phase separation between two immiscible liquids advected by a chaotic flow is studied by numerical simulations of the advective Cahn-Hilliard Equation. It has been shown that the competition between phase separation dynamics, which tends to grow domains, and chaotic flow, which tends to break up the domains, determines the length scale characterizing the domains in the steady state. We extend this analysis to investigate the correlation between the local finite-time Lyapunov exponent field and the domain structure. In particular, we consider alternating sine flows and an alternating periodic vortex flow. We also investigate whether the steady state domain structure demonstrates any history dependence by studying both a initially mixed state and an initially phase separated state. A summary of our results is presented.

C1.00232 Controlling Pattern Formation in Polymer and Nanoparticle Assemblies via Programmed Flow-coating , HYUN SUK KIM, MARK MCDONOUGH, SAM PENDERGRAPH, ALFRED CROSBY, Polymer Science and Engineering Department, University of Massachusetts — We have developed a novel flow-coating method for assembling periodic polymer and nanoparticle line patterns with controlled spacing and width of lines. In flow-coating, a dilute polymer and/or nanoparticle solution is held by capillary forces under a stationary knife blade fixed at gap height above a substrate fixed to a translating stage. Upon translating the substrate, spontaneous formation of convective polymer and nanoparticle assemblies occurs at the three-phase contact line of the meniscus. We demonstrate that the width and spacing of deposited lines can be controlled over a wide range by using programmed velocity profiles for the translating stage. Deposition of solutes is induced when contact lines are “stick” at slow or zero velocity, while limited deposition occurs during “slip” at high velocity. We investigate the effect of gap height, concentration, and velocity on the pattern formation. This new method provides an easy, robust, and lithography-free method to control the deposition of line pattern of polymers and nanoparticles for various applications.
C1.00223 Nonlinear I-V Characteristics of Nano-Pores: Depletion Layer Pattern Formation and Vortex Instability . GILAD YOSSIFON, HSUEH-CHIA CHANG, University of Notre Dame — We report the first direct experimental proof for Rubinstein’s instability [1] by using an applied AC electric field across a straight nano-pore, whose transverse dimension is at least 10 times larger than the depletion layer, EO convective flow is completely arrested and ion transport is dominated by diffusion and electro-migration. The ion flux dynamics is imaged using fluorescent dye molecules in combination with confocal microscopy, to understand the non-equilibrium phenomenon of over-limiting current density across a nanoporous membrane. With a slow AC field, an ion depletion front is generated intermittently from one end of the nano-slot and a vortex instability is found to arrest the self-similar diffusive front growth. This electrokinetic instability evolves into a stationary interfacial vortex array that specifies the over-limiting current, independent of external stirring or convective flow. [1] I. Rubinstein, E. Staude and O. Kedem, Desalination 69, 101 (1988).

C1.00224 Transfer of colloidal particles using the reversible buckling patterns . DONG CHOON HYUN, UNYONG JEONG, Department of Material Science and Engineering, Yonsei University, Seoul, Korea — Buckling or wrinkling is a well-known phenomenon. It is realized by releasing strain applied to a hard film on an elastomer substrate. Strain engineering allows the buckling to have the highly ordered and regular wavy surfaces. The amplitude of the buckling can be reversibly tuned by a cycle of applying and releasing strain. This reversible nature of buckling was used to deposit the spherical colloids in the trenches of the wavy patterns and transfer the colloids to flat surfaces. The colloidal deposition and transfer was repeatedly carried out to fabricate identical patterns of colloidal assembly. In this presentation, we will demonstrate complex colloidal patterns (hydrogels colloids, silica, Au nanoparticles, magnetic nanoparticles) transferred from the buckled surfaces.

C1.00225 DNA Linker Mediated Assembly of Colloidal Nanoparticles1 . HUIMING XIONG, DANIEL VAN DER LEIE, OLEG GANG, Brookhaven National Laboratory — When flexible ssDNA linkers are added to the mixture of two types of dispersed, ssDNAs capped gold nanocolloids which are mutually non-complementary but complementary to the respective ends of the linker DNA, a crystalline phase of body-centered-cubic unit cell forms. The phase diagram of DNA linker mediated nanoparticle assemblies has been experimentally investigated and constructed by using in-situ small angle x-ray scattering. The influence of linkage defects on crystalline structure was also examined.

C1.00226 Birefringence Measurements of Spherulites formed in β-Lactoglobulin . ERIC HARDIN, BRAD KIRKWOOD, JAZMINE LOMAN, ATHULA HERAT, Slippery Rock University, RIZWAN MAHMOOD, Slippery Rock University, KRISTIN DOMIKE, Wooster College — Many proteins have a propensity to aggregate into amylloid fibril containing spherulite-like structures. In some instances these spherulitic protein aggregates have been observed in people suffering from a number of neurodegenerative diseases, including Alzheimer’s, Parkinson’s, and Creutzfeldt-Jakob’s. However, the exact role these aggregates play in the body, their internal structure, and the aggregation mechanism still remains a mystery. The model protein used in our study, β-lactoglobulin (BLG), produce spherulites under low pH and high temperature conditions. We report birefringence measurement on BLG using phase retardation method as a function of temperature. Birefringence (−0.0022 ± 0.0002) data suggest very weak ordering within the spherulites. These spherulites seem to disappear when we added an extensively studied thermotropic liquid crystal [4’-pentyl-4-cyanobiphenyl (SCB)] in β-Lactoglobulin + water + hydrochloric acid. Our preliminary data suggests that the strong interaction energy between the two systems may lead to the destruction of spherulites.

C1.00227 Solvation structure of ice-binding antifreeze proteins . HENDRIK HANSEN-GOOS, JOHN WETT-LAUFER, Department of Geology and Geophysics, Yale University — Antifreeze proteins (AFPs) can be found in organisms which survive at subzero temperatures. They were first discovered in polar fishes since the 1950’s [1] and have been isolated meanwhile also from insects, plants, and bacteria. While AFPs shift the freezing point of water below the bulk melting point and hence can prevent recrystallization, the effect is non-colligative and there is a pronounced hysteresis between freezing and melting. For many AFPs it is generally accepted that they function through an irreversible binding to the ice-water interface which leads to a piecewise convex growth front with a lower nonequilibrium freezing point due to the Kelvin effect. Recent molecular dynamics simulations of the AFP from Choristoneura fumiferana reveal that the solvation structures of water at ice-binding and non-ice-binding faces of the protein are crucial for understanding how the AFP binds to the ice surface and how it is protected from being overgrown [2]. We use density functional theory of classical fluids in order to assess the microscopic solvent structure in the vicinity of protein faces with different surface properties. With our method, binding energies of different protein faces to the water-ice interface can be computed efficiently in a simplified model. [1] Y. Yeh and R.E. Feeney, Chem. Rev. 96, 601 (1996). [2] D.R. Nutt and J.C. Smith, J. Am. Chem. Soc. 130, 13066 (2008).

C1.00228 Hovering of a free rigid pyramid in an oscillatory air flow . BIN LIU, NYU, BRENDAN FOLIE, HMC, ANNIE WEATHERS, JUN ZHANG, STEPHEN CHILDRESS, NYU — We investigate the dynamics of free rigid bodies when moving in an oscillating background flow. Given a pyramid-shaped object, the fluid drag due to a downward flow and an upward flow around the body differ when the inertia of the air flow is relevant. We find that when the amplitude of the air flow is above a threshold, the net lift on the pyramid overcomes its weight. The body then starts to hover, despite the fact that the air flow has no upward or downward preference. The threshold amplitude of the oscillating air depends on the weight of the rigid object and its geometric anisotropy. We show that at a given frequency there is an optimal shape of the pyramid, such that hovering occurs at minimal amplitude of the flow.

C1.00229 ABSTRACT WITHDRAWN —

C1.00240 GENERAL PHYSICS —

C1.00241 Mass, Energy, Space And Time System Theory—MEST A way to help our earth . DAYONG CAO, Beijing Natural Providence Science & Technology Development Co., LTD — There are two danger to our earth. The first, the sun will expand to devour our earth, for example, the ozonosphere of our earth is be broken; The second, the asteroid will impact near our earth. According to MEST, there is a interaction between Black hole (and Dark matter-energy) and Solar system. The orbit of Jupiter is a boundary of the interaction between Black hole (and Dark matter-energy) and Solar system. Because there are four terrestrial planets which is mass-energy center as solar system, and there are four or five Jovian planets which is gas (space-time) center as black hole system. According to MEST, dark matter-energy take the velocity of Jupiter gose up. So there are a lot of asteroids and dark matter-energy near the orbit of Jupiter-the boundary. Dark matter-energy can change the orbit of asteroid, and take it impacted near our earth. Because the Dark matter-energy will press the Solar system. It is a inverse process with sun’s expandedness. So the “two danger” is from a new process of the balance system between Black hole (and Dark matter-energy) and Solar system. According to MEST, We need to find the right point for our earth in the “new process of the balance system.”
C1.00244 Green Energy - Fiction and Reality, LAWRENCE CRANBERG, Texas Fireframe Co. — The term “Green Energy” has been popularized to refer to energy sources that do not depend on fossil fuels. The oldest truly “green” energy source is wood fuel derived by photosynthesis for thermal comfort in the cold season. Thermal energy from the combustion of wood for personal heating in our 41 million fireplaces has greatly declined, due to an “Anti-fireplace Hoax” (1) that fireplaces are “energy counterproductive.” Physicists have a special obligation to address the problem that our major true source of “Green Energy” is widely misrepresented and neglected. 1. L. Cranberg, The Physics Teacher, Letter, January,1989

C1.00245 Biothermophotonics evaluation of multilayered tissue structures, ANNA MATVIENKO, ANDREAS MANDELSI, University of Toronto, Canada, STEPHEN ABRAMS, Quantum Dental Technologies Inc, Toronto, Canada — Biothermophotonics is a novel non-invasive method for safe in vivo evaluation of thermal and optical properties of tissues. The method involves analysis of photothermal field induced in a sample by frequency-modulated laser excitation and following optical-to-thermal energy conversion. The theoretical model for fitting the properties of the sample features coupled diffuse-photon-density-wave and thermal-wave mathematical description. The sample is considered to be a multilayered one-dimensional structure. The best fits to the model are obtained with Simplex Downhill algorithm for multi-parameter minimization. The results demonstrated robustness of the algorithm and the capabilities of the method to simultaneously evaluate optical and thermal properties of multilayered tissue structures in vivo.

C1.00246 STATISTICAL AND NONLINEAR PHYSICS –

C1.00247 Excursion time distributions of heartbeat time series, ISRAEL REYES-RAMIREZ, LEV GUZMAN-VARGAS, Instituto Politecnico Nacional - UPITTA, Mexico — We present a study of heart interbeat time series based on excursion time distributions from healthy subjects and patients with heart failure. We describe some differences between these groups by means of the calculation of the characteristic time scale of the exponential distributions for stationary segments. We also compare day-night periods for both groups. In particular, we find that the characteristic time scale associated to the healthy group is slightly smaller than the heart failure group, indicating that large excursions are more probable under pathologic conditions. When day-night period are compared, we observe that night records lead to a smaller time constant than day records. Moreover, we simulate correlated noises with power spectrum of the form $S(f) \sim f^{-\beta}$ with $0 < \beta < 1$, to detect changes in the excursion time distributions with the presence of long-range correlations. Finally, we discuss our results in the context of heartbeat dynamics.

C1.00248 Mittag-Leffler Correlated Noise and Anomalous Diffusion within a Single Protein Molecule, KE-GANG WANG, Department of Physics and Space Sciences, Florida Institute of Technology, Melbourne, FL 32901, DANIEL VIÑALES, JOSÉ HOYOS, Duke University — The effects of quenched disorder on nonequilibrium phase transitions in the directed percolation universality class are revisited. Using a strong-disorder energy-space renormalization group, it is shown that for any amount of disorder the critical behavior is controlled by an infinite-randomness fixed point in the universality class of the random transverse-field Ising models. The experimental relevance of our results are discussed.

Financial support: NSF

C1.00249 Contact process with sublattice symmetry breaking, RONALD DICKMAN, UFMG, MARCELO MARTINS DE OLIVEIRA, Universidade Federal de Vícosa — We study the phase diagram and scaling properties of a contact process with creation at first- and second-neighbor sites and inhibition at first-neighbors. Inhibition takes the form of an increased annihilation rate, proportional to the number of occupied neighbors of a given site. The pair approximation predicts the existence of three phases, inactive (absorbing), active symmetric, and active asymmetric, the latter exhibiting distinct sublattice densities on a bipartite lattice. These phases are separated by continuous transitions in the space of control parameters; the pair approximation is reentrant. Monte Carlo simulations in two dimensions verify the existence of a phase with broken sublattice symmetry. The symmetric-asymmetric transition appears to belong to the Ising universality class, as expected from symmetry considerations.

1DMR-0804107

C1.00243 PAW dataset library for the Quantum-Espresso package, RASHID HAMDAN, CHAO CAO, University of Florida — The frozen-core approximation is widely employed in plane-wave density functional theory calculations, because it can greatly reduce the required cut-off energy to achieve convergence. The commonly used ultra-soft pseudopotential method is one flavor of this approximation. Despite its advantages, the ultra-soft pseudopotentials are difficult to generate, and it is difficult to control the quality. It is also impossible to reconstruct the complete wave functions from the pseudopotential method calculations. The PAW method was developed to conquer these difficulties. We have constructed a set of soft, reliable PAW dataset library for the Quantum-Espresso package. The datasets were thoroughly tested, and the results were compared with VASP calculations. As a demonstration, we present the comparison with VASP calculations for Bromine doped graphite system and a comparison between the ultra-soft pseudopotential and PAW calculations of the recently discovered iron-based superconductor LaFeAsO compound. The PAW calculations yielded magnetic moment that is much closer to experimental value than the ultra-soft pseudopotential calculations.

C1.00242 On the Earthly Origin of the Penzias-Wilson Microwave Background, DMITRI RABOUNSKI, LARISSA BORISSOVA — According to the experimental analysis conducted by P.-M. Robitaille, the 2.7K microwave background, first detected by Penzias and Wilson, is not of cosmic origin, but of the Earth, and is generated by oceanic water. With these we have two entire fields to consider (Robitaille, Progr. Phys., 2007, v. 4, 74): (1) the Earth Microwave Background, the EMB, present with the 2.7K monopole and 3.5mK dipole components; (2) the weak (micro Kelvins) Intergalactic Microwave Background, the IMB, which is connected to the entire Metagalaxy. This conclusion meets our theory. First, the field density of the EMB, being inversely proportional to the field volume, should decrease with the cube of the distance from the Earth’s surface, while its dipole anisotropy, which is due to the motion of the entire field in common with the Earth, is independent from altitude. Therefore the EMB monopole shouldn’t be found at the 2nd Lagrange point (far distant from the Earth), while the dipole anisotropy remained the same that near he Earth. Second, Einstein’s equations for commonly the EMB and the IMB are valid only if the Metagalaxy’s entire space rotates, that permits some cosmological conclusions.
C1.00251 Absorbing-state transitions on percolating lattices, MAN YOUNG LEE, THOMAS VOJTA, Missouri University of Science and Technology — We study the nonequilibrium phase transitions of reaction-diffusion systems into absorbing states. In the presence of quenched disorder, i.e., spatial impurities or defects, the interplay between geometric and dynamical fluctuations leads to exotic behavior and ultraslow dynamics. Specifically, we investigate the contact process on a randomly diluted lattice. We find that the nonequilibrium phase transition across the percolation threshold of the lattice is characterized by unconventional activated (exponential) dynamical scaling and strong Griffiths effects. We calculate the critical behavior in two and three space dimensions, and we relate our results to the infinite-randomness fixed point in the disordered one-dimensional contact process. To confirm the universality of this exotic scaling scenario we also study generalizations of the contact process involving several absorbing states, and we support our calculations by Monte-Carlo simulations.

C1.00252 Infinite-randomness critical point in the two-dimensional disordered contact process, ADAM FARQUHAR, JASON MAST, THOMAS VOJTA, Missouri University of Science and Technology — We study the nonequilibrium phase transition in the two-dimensional contact process on a randomly diluted lattice by means of large-scale Monte-Carlo simulations for times up to $10^{10}$ and system sizes up to $8000 \times 8000$ sites. Our data provide strong evidence for the transition being controlled by an exotic infinite-randomness critical point with activated (exponential) dynamical scaling. We calculate the critical exponents of the transition and find them to be universal, i.e., independent of disorder strength. The Griffiths region between the clean and the dirty critical points exhibits power-law dynamical scaling with continuously varying exponents. We discuss the generality of our findings and relate them to a broader theory of rare region effects at phase transitions with quenched disorder. Our results are of importance beyond absorbing state transitions because according to a strong-disorder renormalization group analysis, our transition belongs to the universality class of the two-dimensional random transverse-field Ising model.

C1.00253 Efficiency, coherent transport and entropy fluctuations in a Brownian motor driven by time-dependent temperature, RONALD BENJAMIN, University of Alabama at Birmingham — We investigate the transport and energetics of a Brownian motor driven by position dependent temperature. We found that coupling enhances the current as well as the efficiency. Novel features such as current reversal with respect to the coupling strength and inertia of the Brownian particle is also observed. We also find that the total entropy production satisfies the fluctuation theorem in the steady state.

1 I thank the University of Alabama, Birmingham Graduate school for GAFP Fellowship

C1.00254 Unified approach to the derivation of work theorems for equilibrium and steady-state, classical and quantum Hamiltonian systems, DANIEL KOSOV, University of Maryland, MAXIM GELIN, TU Munich — The fluctuation theorems rigorously relate equilibrium ensemble properties of a dynamical system with its evolution under nonequilibrium conditions, beyond the domain of validity of the linear response theory. We present a unified and simple method for deriving work theorems for classical and quantum Hamiltonian systems, both under equilibrium conditions and in a steady state. We adopt the partitioning of the total Hamiltonian into the system part, the bath part, and their coupling. We derive many equalities which are available in the literature and obtain a number of new equalities for nonequilibrium classical and quantum systems. Our results can be useful for determining partition functions and generalized free energies through simulations or measurements performed on nonequilibrium systems. We derive a semiclassical version of the work theorem and discuss the definition of semiclassical work operator. Phys.Rev. E 78, 011116 (2008)

C1.00255 On the quantum master equations for BCS-type quasiparticles, C.F. HUANG, CMS/ITRI, K.-N. HUANG, Institute of Atomic and Molecular Sciences, Academia Sinica — The quantum master equations are introduced for the density matrices of BCS-type quasiparticles, which may include both the particle-particle and particle-hole couplings. The constraints to relate the loss and gain factors are important to preserve the forms of the density matrices under such equations. These two factors describe not only the scattering where the number of quasiparticles are conserved, but also the creation and destruction of quasiparticles. The introduced equations can be reduced to the semiclassical master equations in the homogeneous limit.

C1.00256 Obtaining the fractal dimensions and length distributions for the external hulls of Q-state Potts model clusters, DAVID ADAMS, LEONARD SANDER, ROBERT ZIFF, University of Michigan — We obtain the fractal dimensions of the complete and external hulls of Q-state Potts model clusters. We grow percolation clusters (Q=1) using the Leath method. For Q>1 up to the upper critical dimension (Q=4), we grow Fortuin-Kasteleyn (FK) clusters using the Swendsen-Wang method. Our results for fractal dimension for the complete and external hulls agree with the predictions of Duplantier. We also obtain the distribution of complete and external hull lengths and cluster height. For a given Q, the distributions for different size systems can be collapsed using scaling. The distributions of heights display simple exponential tails, which can be understood in terms of hull walks and the geometry of the system.

C1.00258 The Role of Walls’ Stochastic Forces in Statistical Mechanics – Irreversibility and Transition from One Microstate to Large Number of Microstates, MADHAV GAUTAM, PURU GUJRATI, The University of Akron — A statistical system, by definition, experiences uncontrollable stochastic interactions with the surrounding and allow for irreversibility. A purely deterministic system will not show any irreversibility. One can model the walls of the container containing a system to be the source of these stochastic impulses. We present the results of such stochastic walls’ impulses on a single particle in a one-dimensional box of a fixed length. At each collision with the walls, the velocity changes due to stochastic impulses so that the velocity becomes unpredictable. After a long period of time, a single initial velocity results in a distribution of velocities. If the strength of the impulse is not too strong, the average kinetic energy reaches a finite limit, so that it can be used to define the temperature.

C1.00259 Lack of Molecular Chaos and the Role of Stochasticity in Kac’s Ring Model, PRADEEP FERNANDO, PURU GUJRATI, The University of Akron — The dynamics of a system can either be deterministic or stochastic. In deterministic dynamics, there is unique one-to-one relationship between the initial state of the process and its evolution at a later time, while in stochastic process, there are several possible outcomes or evolved sates in future. Since the outcome is not certain, we use one-many relationships between the current states and its evolution in future. We use simple Kac ring model to demonstrate the properties of deterministic and stochastic dynamics. The results lead us to understand the following: 1) In deterministic dynamics, a system always has a unique equilibrium state with zero fluctuation. Instead, the initial state recurs eventually following Poincare Recurrence. In particular, molecular chaos assumption of Boltzmann cannot be justified. 2) In stochastic dynamics the system reaches equilibrium irrespective of the initial state. References: [1] P.D. Gujrati, Irreversibility, Molecular Chaos, and A Simple Proof of the Second Law, http://arxiv.org/abs/0803.1099 (arXiv:0803.1099) [2] P.D. Gujrati, Poincare Recurrence, Zermelo’s Second Law Paradox, and Probabilistic Origin in Statistical Mechanics, http://arxiv.org/abs/0803.0983 (arXiv:0803.0983)

C1.00260 Response of a simple dynamical network to stress or strain, NASRIN AFZAL, MICHEL PLEIMLING, Virginia Polytechnic Institute and State University — Motivated by a recent series of experiments that study the response of the cytoskeleton of living cells to mechanical forces, we study numerically a simple dynamical network where new links are formed and existing links are dissolved with probabilities that can depend on time. We thereby mimic mechanical stress and strain by protocols where we rapidly change the geometry of the network. Interestingly, the number of links in the network displays a nontrivial time dependence during these protocols.

C1.00261 Node weight distribution and disparity of some bipartite networks, XIU-LIAN XU, CHUN-HUA FU, DA-REN HE, College of Physics Science & Technology, Yangzhou University — We present an empirical investigation of 14 real world networks, which can be described by bipartite graphs. Each node is assigned a node weight, which denotes the obtained competition result. Firstly, empirically we observed that the total node weight distributions of all the systems may be fitted by shifted power law function form. The key parameters of the function can be used to describe the disparity. Secondly, a node weight disparity is defined for the same purpose. The empirical relationships between the parameters are obtained. The results show that the node weight distribution is very uneven. 

C1.00262 Properties of four real world collaboration-competition networks, CHUN-HUA FU, XIU-LIAN XU, DA-REN HE, College of Physics Science & Technology, Yangzhou University — Our research group has empirically investigated 9 real world collaboration networks and 25 real world cooperation-competition networks. Among the 34 real world systems, all the 9 real world collaboration networks and 6 real world cooperation-competition networks show the unimodal act-size distribution and the shifted power law distribution of degree and act-degree. We have proposed a collaboration network evolution model for an explanation of the rules [1]. The other 14 real world cooperation-competition networks show that the act-size distributions are not unimodal; instead, they take qualitatively the same shifted power law forms as the degree and act-degree distributions. The properties of four systems (the main land movie film network, Beijing restaurant network, 2004 Olympic network, and Taobao notebook computer sale network) are reported in detail as examples. Via a numerical simulation, we show that the new rule can still be explained by the above-mentioned model. [1] H. Chang, B. B. Su, et al. Physica A, 2007, 383: 687-702.

C1.00263 A model of the world languages distribution, AI-XIA FENG, DA-REN HE, College of Physics Science and Technology, Yangzhou University — The world language distribution is described by a bipartite graph. One kind of nodes is the languages; the other is the countries where some languages are used. When interested in interactions between the languages, we project the bipartite graph onto the language nodes and obtain a unipartite graph. After investigating the node strength distribution of the unipartite network we realize that the language distribution shows a kind of duality property. Thus, we set up a model to interpret and explain the property. Also, we explained, by using the model, the empirical results about the clustering coefficient distribution and the average nearest neighbor strength distribution.

C1.00264 Monte-Carlo simulations for two-stage percolation transition of the enhanced trees, TAKEHISA HASEGAWA, TOMOAKI NOGAWA, The University of Tokyo — We investigate the bond percolation problem on the enhanced binary tree (EBT). The EBT is given by adding intra-generation links to the binary tree. The EBT belongs to the class of nonamenable graphs (NAGs), and percolations on NAGs are predicted to show two-stage transition through three distinct phases according to open bond probability \( p \): (i) nonpercolating phase: there is no infinite cluster for \( 0 \leq p < p_{c1} \), (ii) intermediate phase: there are infinitely many infinite clusters for \( p_{c1} < p < p_{c2} \), and (iii) percolating phase: there is a unique infinite cluster for \( p_{c2} < p \leq 1 \). In this talk, we perform Monte-Carlo simulations to study the bond percolation on the EBT [1]. Our numerical results actually show that the system has two different percolation thresholds \( p_{c1} \) and \( p_{c2} \). By performing finite size scaling for the cluster size distributions, we confirm that all the points in the intermediate phase are critical. This fact leads to the existence of infinitely many infinite clusters in the intermediate phase. In this phase the corresponding fractal exponent continuously increases with \( p \) from zero to unity. We also show that the first transition at \( p_{c1} \) is of second order in mean field universality class, while order parameter rises discontinuously at \( p_{c2} \).

C1.00265 Interest rate change and Omori dynamics in the Stock Market, ALEXANDER PETERSEN, FENGZHONG WANG, Boston University, SHLOMO HAVLIN, Bar-Ilan University, H. EUGENE STANLEY, Boston University — I present the behavior of U.S. markets on the day of U.S. Federal Open Market Committee (FOMC) meetings from the perspective of Statistical Physics. The announcement of key U.S. Federal Reserve rate changes causes a small financial shock, where the dynamics before and after the announcement can be described by an Omori law. We find that markets respond sharply to news in a complex way reminiscent of physical earthquakes described by the Omori law, which describes the power-law relaxation of aftershocks following a singular perturbation. We find Omori laws in both the volatility of the price (also known as the absolute returns) and the volume traded, using 1-minute resolution financial time series. These results suggest that the perturbative response of the stock market is the same for both financial news and financial crises. The intraday response can be measured by the Omori power-law exponent \( \Omega \), which has opposite sign before and after the announcement. We estimate the magnitude of news by relating \( \Omega \) to the behavior of the U. S. Treasury Bill before and after FOMC announcements.

C1.00266 Structure of correlations with partially surrogated price fluctuations, GYUCHANG LIM, SOOYONG KIM, KAIST, KI-HO CHANG, KMA, KYUNGSIK KIM, Pukyong National university — The well-known facts of financial markets support that the price fluctuation contains information about the complexity of interactions among market participants. In this work, we present a new surrogate method to find the dependency of higher-order correlations on the magnitude of price fluctuations. By sorting returns into several groups with respect to the level of fluctuations, we show that the large fluctuations characterize the structure of temporal correlations of a financial time series. In particular, by investigating the positive and negative parts separately, we confirm that risk-averse behavior of traders is explicitly observed in financial markets.
C1.00267 Sediment transport dynamics of a river network in a long period\textsuperscript{1} \hfill JIE HUO, RUI HAO, XU-MING WANG, Physics and Electric Information Sciences, Ningxia University, Yinchuan 750021, P.R. China, COMPUTATIONAL & NONLINEAR PHYSICS STUDIO TEAM — A sediment transport model that connects a lower-water season to the higher-water season is suggested to study the dynamics in a long-term evolution process. The model is based on the feedback mechanism between sediment-carrying capacity of stream and erosion-deposition state of channels. It is checked by comparing the simulated results with the observed data of the Yellow River. The comparison can be conducted in two aspects. One is the comparison between the model results on every segment and the real results; the other is the estimation whether the variation trends of the calculated results are qualitatively in accordance with that occurred in the natural river network. The comparisons show that our model is reasonable. The detail of the dynamics manifests that the model can generate the general inherent characteristics of a real river network as it passes through a lower-water season to the higher-water season. This might provide us with a new visual angle for the researches in some related fields.

C1.00268 Probing Localization in Scattering Systems via Fidelity \hfill MEI CHAI ZHENG, Dept. of Physics, JOSHUA BODIFELT, Dept. of Physics, Wesleyan University, ULRICH KUHL, HANS–JUERGEN STOECKMANN, Fachbereich Physik der Phillipus–Universität Marburg, TSAMIKOS KOTTOOS, Max Planck Institute for Dynamics & Self-Organization. AND Dept. of Physics, Wesleyan University, DEPT. OF PHYSICS, WESLEYAN UNIVERSITY COLLABORATION, FACHBEREICH PHYSIK DER PHILLIPS–UNIVERSITÄT MARBURG COLLABORATION, MAX PLANCK INSTITUTE FOR DYNAMICS & SELF-ORGANIZATION COLLABORATION — Using scattering measurements from a microwave cavity filled with randomly distributed scatterers, we evaluate the scattering fidelity. We show that depending on the degree of localization inside the sample, the fidelity decay deviates from “traditional” Gaussian law, applied in the case of diffusive/chaotic cavities when small perturbations are involved. We instead show that for small displacements of one of the walls of the cavity, the fidelity decays in a novel way that reflects the degree of localization (or randomness) inside the cavity. The outcome of the experimental measurements are explained on the basis of a parametric Banded Random Matrix modeling which incorporates localization phenomena. The theoretical results are in good agreement with those of the experiment.

C1.00269 Experimental observation of soliton propagation and annihilation in a hydromechanical array of one-way coupled oscillators \hfill PATRICK M. ODENTHAL, JOHN F. LINDNER, KELLY M. PATTON, JAMES C. GALLAGHER, Department of Physics, The College of Wooster, Wooster OH 44691, BARBARA J. BREEN, Department of Physics, University of Portland, Portland OR 97203 — We have experimentally realized unidirectional or one-way coupling in a mechanical array by powering the coupling with flowing water. In cyclic arrays with an even number of elements, soliton-like waves spontaneously form but eventually annihilate in pairs, leaving a spatially alternating static attractor. In cyclic arrays with an odd number of elements, this alternating attractor is topologically impossible, and a single soliton always remains to propagate indefinitely. Our experiments with 14 and 15-element arrays highlight the dynamical importance of both noise and disorder and are further elucidated by our computer simulations. This work was supported in part by NSF DMR-0649112.

C1.00270 Order and Chaos in the Two-Body Problem \hfill JACOB LYNN, FRANK W. KING, JOHN F. LINDNER, Department of Physics, The College of Wooster, Wooster OH 44691 — We investigate a simple extension of the classical two-body problem involving the gravitational interaction of a point and a line segment. We find families of periodic orbits amidst chaotic orbits in both the parameter and initial condition spaces. We characterize the dynamics using animations, Poincare sections, distance metrics, power spectral densities, and Lyapunov exponents. This work was supported in part by NSF DMR-0649112.

C1.00271 Simulation of the Dynamics of a Plane Pendulum with Positional Dependent Torque\textsuperscript{1} \hfill TODD MCALPINE, Ohio Northern University, ALISON HUFF, The College of Wooster — We investigate the dynamics of a plane pendulum with positional dependent driving torque as would be produced by a horizontally directed force exerted on the pendulum bob. We compare and contrast this with the well known solutions of the classical pendulum. In cyclic arrays with an even number of elements, soliton-like waves spontaneously form but eventually annihilate in pairs, leaving a spatially alternating static attractor. In cyclic arrays with an odd number of elements, this alternating attractor is topologically impossible, and a single soliton always remains to propagate indefinitely. Our experiments with 14 and 15-element arrays highlight the dynamical importance of both noise and disorder and are further elucidated by our computer simulations. This work was supported in part by NSF DMR-0649112 and The College of Wooster for their support.

C1.00272 SUPERCONDUCTIVITY —

C1.00273 A Systematic Photoemission Study of the Fe(Te\textsubscript{1-x}Se\textsubscript{x}) Superconductor System \hfill YUOUI XIA, Princeton University, N. L. WANG, Institute of Physics, Chinese Academy of Science. ZAHID HASAN, Princeton University — We present a systematic photoemission study of the newly discovered superconducting class Fe(Te\textsubscript{1-x}Se\textsubscript{x}). By using a series of photon energies and scattering geometries we investigated the details of the quasiparticle dispersion, Fermi surface and the global band structure. Doping dependent phase diagram study into the superconducting regime would be reported.

C1.00274 High energy anomaly in hole- and electron-doped cuprates \hfill B. MORITZ, SLAC and Stanford University, F. SCHMITT, W. MEEVASANA. Stanford University, S. JOHNSTON, University of Waterloo, E. M. MOTOYAMA, M. GREVEN, Stanford University, D. H. LU, SLAC, C. KIM, Yonsei University, R. T. SCALETAR, University of California-Davis, Z.-X. SHEN, T. P. DEVEREAUX, SLAC and Stanford University — Recent ARPES experiments reveal the presence of a dispersion anomaly in the high T\textsubscript{c} cuprates. This universal anomaly appears at an energy of \( \sim 300 \) meV in hole-doped compounds, with a similar feature reported in the half-filled parent insulators. New experiments on Nd\textsubscript{2-x}Ce\textsubscript{x}CuO\textsubscript{4} also reveal an anomaly, but at a higher energy scale of \( \sim 500 - 600 \) meV. A key question concerns the origin of this anomaly. Quantum Monte Carlo simulations of the single-band Hubbard model reveal qualitative and quantitative agreement with the dispersion anomaly throughout the doping spectrum. They demonstrate that strong correlations play a key role in the development of the anomaly as well as that of spectral weight transfers that accompany doping.

C1.00275 Determination of the Eliashberg's Equations in the Superconductivity Post BCS \hfill CARLOS FIGUEROA, RENE BETANCOURT, LAZARO FERRER, MARTIN MOLINAR, DIFUS — The Eliashberg theory was a significant advance with respect to the BCS Theory because of it extends the rank of application without changing its origin, which is based on the formation of Cooper pairs by the interaction electron phonon. It doesn’t modify the essential characteristics of BCS theory but it includes more information about the subject. Another point to be considered is BCS theory works, better with the weak electron-phonon coupling superconductors as the aluminium (Al). As the coupling becomes strong the results show significant deviations as in the case of lead (Pb). The Eliashberg’s equations make an extension to incorporate the strong electron-phonon interaction. This theory synthesizes the information in a expression known as Eliashberg’s function, or effective spectral density. Using the last problem solutions it can be possible to recover the universal relation of the BCS, likewise, the deviation function and the isotope effect. No doubt, it is a qualitative jump in the knowledge of the conventional superconductor materials.
C1.00276 Condensation of topological excitations in two coupled layers of Josephson junction arrays. SAID SAKHI, American University of Sharjah, PO Box 26666, Sharjah, UAE. The phase diagram of two coupled layers of Josephson junction arrays (JJAs) in the presence of charge and magnetic frustration is investigated. The quantum phase model of JJAs is mapped into the self-dual limit into an Abelian gauge theory with Maxwell terms and a mixed Chern–Simons term. The low effective field theory is shown to be governed by complex fields associated with disordering caused by electric charges and magnetic charges minimally coupled to two gauge fields related to the currents of Cooper pairs and vortices. The condensation of disorder fields leads to a rich phase diagram with important features not attainable by standard mean field theories. In addition to insulating and superconducting phases, the bi-layer system displays interesting interplay between Hall quantization and interlayer coherence. Hall quantized states with and without interlayer coherence and interlayer coherent states without Hall quantization. S. Sakhi, Quantum disordering effects in bilayer Josephson junction arrays, J. Phys. A: Math. Theor. 41 (2008) 085003.

C1.00277 The Electronegativity Spectrum of Superconductors. O. PAUL ISIKAKU-IRONKWE, The Center for Superconductivity Technologies, Abuja FCT. In the experimental search for novel superconductors, the correlation of electronegativity with superconductivity has been a useful guide. Previous studies have identified the range of electronegativities for low and high Tc superconductors. A detailed spectrum plot of electronegativity versus transition temperature for all known superconductors has still not been published. Here we produce such a plot which includes electronegativities of the newly discovered iron-based pnictide superconductors. We analyze this spectrum plot and use it to predict the electronegativity of higher Tc superconductors.

C1.00278 Experimental and Theoretical Investigation of High Temperature Superconductors. SCOTT DIETRICH, Boston University. The study includes ongoing physical measurements on High Temperature Superconducting (HTS) samples. A dual-coil apparatus, using BSCCO and YBCO samples, is used to measure the magnetic susceptibility, resistivity and other measurements of the samples. This allows for the inspection of the HTS material during its superconducting state, above the critical temperature and the region in between. Using this data, we hope to model the HTS material using a mathematically driven computer simulation. The simulation models the material as a matrix of Josephson Junctions and can apply the variables added into the lab, including electrical current, magnetic field, and temperature variation. The simulation aims at explaining the mechanisms behind high temperature superconductivity. Included in the program is the option to change lattice structures, giving the ability to explore theoretical HTS material compositions and preview their actions compared to the commonplace square lattice structures.

C1.00279 Force analysis of a permanent magnet and a superconducting hollow cylinder. MOHAMMED ALQADI, The interaction between a cylindrical magnet and a superconducting hollow cylinder in the Meissner state was analyzed using dipole-dipole model. Analytical expression of the levitation force was derived as a function of the magnetic moment, radius of the magnet, radius and thickness of the superconductor sample. The obtained results show that there is strong dependence of the levitation force on the magnetic dipole orientation at a small magnet-superconductor distance.

C1.00280 C-axis persistent current and Cooper-pair tunnelling through intrinsic Josephson junctions in a ring-shaped YBa2Cu3O7−δ film. AHMAD MANSOUR, MOHAMED SABER, KIM CHOW, JAN JUNG, University of Alberta. We present the direct experimental observation of the temperature dependence of the persistent current Ic due to tunneling Cooper pairs along the c-axis intrinsic Josephson junctions integrated into YBa2Cu3O7−δ ring-shaped thin films. The measured Ic exhibits a linear temperature dependence over a wide range of temperatures well below Tc. Similar behavior was observed in different samples, confirming the reproducibility of the fabrication technique and the reliability of the results. Our fabrication and measurement techniques which allowed us to observe “pure” Cooper pair tunneling persistent current are superior to other techniques that are unable to separate Cooper pair from quasi-particles tunneling currents.

C1.00281 Probing KT transition using ac current. HENGSONG ZHANG, The state university of New York Buffalo. FULIN ZUO, University of Miami. We report studies of the Kosterlitz-Thouless (KT) transition in thin thin films using an ac excitation current rather than the conventional dc current. The nonlinear dependence or power-law exponent of the voltage on current is probed by measuring the harmonic terms of the voltage signal. The voltage can in general be expressed as a sum of odd-powered current terms with the experimentally measured power exponent increasing with lowering temperature. The temperature and current dependence of the exponent have been studied and will be discussed in terms of vortex-antivortex pair and pair-pair interactions.

C1.00282 Phase Separated Bose-Einstein Condensate for High Sensitivity Force Measurement. SATYAN BHONGALE, Rice University. EDDY TIMMERMANS, Los Alamos National Laboratory. A trapped, phase separated, two component Bose-Einstein condensate (BEC) can be configured to give a single BEC bubble that floats freely in the surrounding BEC. We point out that this system gives a unique template to carry out mesoscopic quantum studies and to detect weak forces. We demonstrate the detection capabilities by proposing and studying a “Quantum Level” for fundamental quantum fluctuation studies and for mapping the potential energy landscape near a surface with exquisite accuracy. We show that for typical (modest) values of currently available experimental parameters, the proposed device is sensitive to the variations in gravitational acceleration to 1 part in 10 billion. While such sensitivity is in the range of other available devices, for example torsion balance, the BEC device allows for measuring the gravitational acceleration on length scales of the order of a few microns.

C1.00283 Definition of current density in presence of AC electric field. ZHANG LEI, WANG JIAN, Department of Physics, University of Hong Kong. Under time varying AC electric field, the transport problem becomes complicated due to the presence of displacement current. The conventional current density calculated by using the formula \( J_r = \frac{1}{2\pi c} \text{Re} \left( \frac{\psi}{(p-eA)} e^\Omega - \text{c.c.} \right) \) is not conserved, which means \( \nabla \cdot J_r (r,t) \neq 0 \). In order to solve this problem, we will give a new definition of current density by using non-equilibrium Green’s function which includes the contributions from the Coulomb interaction in low frequency limit. And we will show that the current calculated from the current density is conserved.

2Mentor: George Zimmermann
C1.00284 The dynamic critical exponent in optimally doped Pr$_{1.85}$Ce$_{0.15}$CuO$_4$ as a function of film inhomogeneity$^1$, R.A. ISAACS, J. B. OLSON, J. SOUSA, M. SALVAGGIO, M.C. SULLIVAN, Department of Physics, Ithaca College, Ithaca NY, R.L. GREENE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland College Park — Scaling analysis of voltage vs. current isotherms is a good tool to study the normal-superconducting phase transition in cuprate conductors. This measurement has never been performed on the optimally doped cuprate conductor Pr$_{1.85}$Ce$_{0.15}$CuO$_4$. If we take the finite thickness of the films into account$^{[2]}$ we can find the critical isotherm and determine the dynamic critical exponent $z$ in our Pr$_{1.85}$Ce$_{0.15}$CuO$_4$ films. We find that the critical exponent varies as a function of transition width, from which we can infer the effect of sample inhomogeneity on the dynamic critical exponent. We present our results of the critical exponent as a function of sample inhomogeneity and compare it to the hole-doped cuprate YBa$_2$Cu$_3$O$_7$.$\delta$.

$^1$Supported by NSF grant DMR-0706557

C1.00285 A study of the critical current density in optimally-doped, thin-film cuprate superconductor YBa$_2$Cu$_3$O$_7$.$\delta$$^1$, E.S. BACKUS, M. LILLY, M.C. SULLIVAN, Department of Physics, Ithaca College, Ithaca, NY — Scaling analysis of voltage vs. current isotherms has often been used to study the normal-superconducting phase transition in cuprate superconductors, though there is little consensus in the literature as to the values of the critical exponents for this phase transition. Studying the critical current will give us another way to examine the normal-superconducting phase transition, and perhaps rectify the lack of consensus regarding the critical exponents. We designed a photolithographic mask with several meander patterns to test, varying the lengths and thicknesses of the patterned wires. We conducted reverse-polarity measurements sent through the meander patterns of thin-films of the cuprate superconductor YBa$_2$Cu$_3$O$_7$.$\delta$. Because the critical current density in this material is so high, several extrinsic effects must be taken into consideration in order to avoid heating, including: determining the most effective number of measurements, the wait time between measurements, and the wait time between increments of temperature in order to reduce the error. I present my results as a plot of the critical current as a function of temperature in zero-field, and the critical exponent.

$^1$Supported by NSF grant DMR-0706557.

C1.00286 Influence of diffusion-annealing time on the mechanical properties of bulk Bi$_{1-x}$Pb$_x$Sr$_{1-y}$Ca$_2$Cu$_3$O$_{y+2}$ superconductors diffusion-doped with Fe.$^1$, MUSTAFA AKDOGAN, Abant Izzet Baysal University, OZGUR OZTURK, Kastamonu University, ERSIN YUCEL, ERDAL BEKIROGLU, Abant Izzet Baysal University, MUSTAFA YILMAZLAR, Sakarya University, CABIR TERZIOGLU, Abant Izzet Baysal University — In order to investigate the role of Fe doping and diffusion-annealing duration on the mechanical and superconducting properties of Bi-Pb-Sr-Ca-Cu-O, Bi$_{1-x}$Pb$_x$Sr$_{1-y}$Ca$_2$Cu$_3$O$_{y+2}$ superconductors were prepared by standard solid-state reaction methods. Doping of Bi-2223 was carried out by means of iron diffusion during sintering from an evaporated iron film on pellets. The investigations consist of SEM, dc resistivity and hardness measurements. These measurements indicated that the Fe doping and diffusion-annealing time increased the $T_c$, $J_c$, Young’s modulus(E), yield strength(Y), fracture toughness(K$_IC$) values and improved the grain connectivity. The mechanical properties of the samples were found to be load dependent and on the diffusion-annealing time. In addition, we calculated the load independent $H_0$, E, Y, and K$_IC$ of the samples. Possible reasons for the observed improvements in the superconducting and mechanical properties due to Fe diffusion are discussed.

C1.00287 Soft X-ray Imaging of Vortex Dynamics in Trilayer Pattered Magnetic Elements, BROOKE MESLER, Applied Science and Technology Graduate Group, University of California at Berkeley, DONG-HYUN KIM, Dept of Physics, Chungbuk National University, Kumpa, PETER FISCHER, Center for X-ray Optics, Lawrence Berkeley National Lab — Soft X-ray microscopy provides element specific magnetic imaging with a spatial resolution down to 15nm. At XM-1, the full-field soft X-ray microscope at the Advanced Light Source in Berkeley, a stroboscopic pump and probe setup has been developed to study fast magnetization dynamics in ferromagnetic elements with a time resolution of 70ps which is set by the width of the X-ray pulses from the synchrotron. Previous studies of patterned permalloy elements have revealed complex magnetization dynamics. Results obtained with a 2um x 4um x 45nm rectangular permalloy sample exhibiting a seven domain Landau pattern reveal dynamics up to several nsec after the exciting magnetic field pulse. Domain wall motion, a gyrotropic vortex motion, and a coupling between vortices in the rectangular geometry are observed. On going studies of patterned trilayer elements, composed of magnetic permalloy and cobalt layers separated by a copper spacer layer, will probe the dynamics of the trilayer system. Of particular interest is observing how the coupling between the magnetic layers affects the vortex dynamics.

C1.00288 Two dimensional magnetization mapping in exchange-coupled nanodot chain arrays using the magneto-optic Kerr effect, SARAH C. HERNANDEZ, JIAN DOU, CHENGTAO YU, MICHAEL J. PECCHAN, Department of Physics, Miami University, LIESL FOLKS, JORDAN A. KATINE, MATTHEW J. CAREY, San Jose Research Center, Hitachi Global Storage Technologies — Nanoscale permalloy dot arrays were fabricated with dot diameters of 300 nm, thicknesses of 40 nm, and coupled via permalloy bridges, with bridge widths ranging from zero to 60 nm. Magnetization reversal in this system was previously investigated with the field applied along and perpendicular to the coupling direction. Hysteresis loops reflect reversal by domain wall motion$^1$. As a result of rotating the applied magnetic field relative to the sample’s coupling direction, unusual hysteresis loops were observed. The magneto-optic response resulted in an asymmetric loop with one notable feature, an increase in coercivity with increasing bridge width. We will show that these curves arise from the second-order magneto-optic Kerr effect, where coherent rotation of magnetization plays an important role. This work is supported by US-Dept.of Energy at MU.

$^1$S. C. Hernandez et al, (To be published in J. Appl. Phys.)

C1.00289 Superconducting properties of tetragonal FeSe and FeTe, YOSHIAKAZU MIZUGUCHI, YOSHIHIKO TAKANO, NIMS — The discovery of LaFeAsO1-xFx superconductor triggered active studies on iron-based superconductors. Recently, superconductivity in tetragonal FeSe was reported. FeSe is the simplest-structured iron-based superconductor. We reported a huge enhancement of the transition temperature $T_c$ under high pressure. The onset of $T_c$ increased from 13 to 27 K at 1.48 GPa. FeSe undergoes a structural phase transition to orthorhombic around 70 K. A suppression of the structural phase transition will be a key to raise $T_c$ in this system. Tetragonal FeTe has a structure very analogous to that of superconducting FeSe, however, does not show superconductivity, and undergoes a structural phase transition around 80 K. We synthesized S-substituted FeTe, FeTe1-$x$Sx, and observed the suppression of the structural phase transition and superconductivity at low temperatures. Since FeTe1-$x$Sx is composed of nontoxic elements, this compound is advantageous for applications. Here we report the pressure and the elementary substitution effects on FeSe, the pressure studies on FeTe, and the superconducting properties of FeTe1-$x$Sx.
C1.00290 Effects of sintering temperature on properties of Ti-sheathed, SiC-doped MgB2 superconducting wires, GAN LIANG, HUI FANG, Sam Houston State University, CAD HOYT, Cornell University, SAMARESH GUHHAIT, JOHN MARKERT, University of Texas at Austin — Mono-core Ti-sheathed, silicon carbide (SiC) doped MgB2 wires have been successfully fabricated by powder-in-tube method. The average size of the doped SiC nano particles is 20 nm and the doping level is 10 wt.%. The wires were sintered for 30 minutes at five temperatures from 650 °C to 800 °C. Effects of sintering temperature on the phase composition, microstructure, and critical current density (Jc) were studied by x-ray diffraction, scanning electron microscopy, and magnetization measurements. The results indicate that the Ti sheath does not react with the magnesium and boron, and the present wire rolling process can produce Ti-sheathed, SiC-doped MgB2 wires with high critical current density. It is found that Jc peaks up at sintering temperature of 800 °C. This is in sharp contrast with the previously reported result (by other group) that the optimal Jc was achieved at sintering temperature of 700 °C. The correlations between Jc and the structural properties of the wires are discussed.

C1.00291 Meissner effect in ensemble of slightly boron-doped carbon nanotubes, J. HARUYAMA, N. MURATA, Aoyama Gakuin Univ., J. REPPERT, A. RAO, Clemson Univ., T. KORETSUNE, S. SAITO, Tokyo Institute of Technology — The small mass of carbon can promote high transition temperature (Tc) in BCS-type superconductivity (SC). Recently, new carbon-based superconductors with order of Tc of ~10K [1, 2] were discovered and higher Tc has been expected. In particular, the SC in a carbon nanotube (CNT) is attracting considerable attention [3]. We reported that entirely end-bonded multi-walled CNTs, in which Luttinger liquid was suppressed, could show SC with Tc = 12K, previously [4]. In contrast, it had problem in reproducibility, because correlation with carrier doping was not clarified. Moreover, none has succeeded substitutional carrier doping into CNTs and also revealed the correlation with SC. Here, we report on the Meissner effect with Tc =12K found in thin films consisting of boron-doped single-walled CNTs [5]. We reveal that boron concentration < 1.5 at.% in the CNTs and those highly homogeneous assembling to thin films are favorable to yield evident Meissner effect. This can be understood by better adjustment of Ef to van Hove singularity in density of states. [1] T. E. Weller et al., Nature Physics 1, 39 (2005), [2] E. A. Ekimov et al., Nature 428, 542 (2004), [3] M. Kociak et al., Phys. Rev. Lett. 86, 2416 (2001), [4] I. Takesue, J. Haruyama, et al., Phys. Rev. Lett. 96, 057001(2006), [5] N. Murata, J. C1.00292 Coexistence between magnetism and superconductivity in the HgMn0.3Pb2 compound, AUDUSIN DANILO BORTOLOZO, Escola de Engenharia de Lorena - EEL - USP-Brazil, ERIKA CARLINA A. SANTANA, Faculdade de Engenharia de Guaratinguetá - FEG - Brazil, CARLOS ALBERTO M. DOS SANTOS, ANTONIO JEFFERSON S. MACHADO, Escola de Engenharia de Lorena - EEL - USP-Brazil — In this work we will show the influence Mn doping in the HgPb phase. The HgMn0.3Pb2 phase is investigated by x-ray diffraction, magnetic and electrical resistivity measurements. Polycrystalline samples with HgMn0.3Pb2 nominal compositions were prepared by solid state reaction. X-ray powder diffractograms suggest that all peaks can be indexed with the tetragonal phase of AuCu prototype. The R(T) data for the HgMn1−xPb2 composition reveals superconductor behavior below 5.9K. The careful analysis of M(T) data reveals magnetic ordering close to 45K with saturation around the superconducting transition. The Mn doping in the HgPb2 phase suggests the magnetic ordering it is occurring in the specific plane occupied by Mn atoms. The M(H) show typical type-II superconductor which we estimate the Hc1 approximately 240 Oe. This work, report by first time the coexistence between magnetism and superconductivity in an AuCu prototype compound

C1.00293 Designing Superconductors with Periodic Table-based Maps and Material Databases1, O. PAUL ISIKAKU-IRONKWE, The Center for Superconductivity Technologies, Abuja FCT, ALEX ANIMALU, Department of Physics and Astronomy, University of Nigeria, Nsukka — One of the grand challenges of superconductivity science is achieving a paradigm shift from discovery by serendipity to discovery by design. Empirical and heuristic rules have been a useful bridge in this desired direction. Many early superconductors were discovered by this method and by serendipity. DFT-based ab initio methods have often ignored empirical and experimental data. Here we propose that by using Periodic Table-based maps such as electronegativity spectrum maps, valence electron spectrum maps and atomic number spectrum maps for binary systems, A,Bx, combined with data-mining of experimental material databases we can “reverse-engineer” many known superconductors. We demonstrate the power of this technique by predicting new and novel superconductors without recourse to DFT calculations.

C1.00294 Microscopic transport in indium oxide thin films near the superconductor-insulator quantum phase transition, MINSOO KIM, TAILUNG WU, ZHENZHONG SHI, ADAM STABILE, G. SAMBANDAMURTHY, University at Buffalo-SUNY, Buffalo, NY 14260 — We present results from low temperature (T), MINSOO KIM, TAILUNG WU, ZHENZHONG SHI, ADAM STABILE, G. SAMBANDAMURTHY, University at Buffalo-SUNY, Buffalo, NY 14260 — We present results from low temperature (T), high magnetic field (B) transport measurements on disordered thin films of amorphous indium oxide. Two-dimensional (2D) indium oxide films can be driven between insulating and superconducting ground states by controlled tuning of either the intrinsic disorder or external B. We have grown these films with hitherto unachieved control of their structure and property and patterned into Hall bars and nanowires using standard nanolithographic techniques for transport measurements. Here we present the results of a study of the resistance behavior in these films in the 1D and also in the 1D-2D crossover regimes when the ground state in the T = 0 limit is tuned from an insulator to a superconductor. Our efforts are aimed at achieving, for the first time, a continuously tunable 1D superconductor.

C1.00295 The Superconducting Transition in Al Nanowires, PAUL ALIOTTA, JOHN FREE, Harvard University and Eastern Nazarene College, ROBERT WESTERVLET, Harvard University — Strong evidence for macroscopic quantum tunneling has been presented in Al wires with diameters less than 10 nm [1], which is much lower than the material’s coherence length. We have investigated the superconducting transition and evidence for macroscopic quantum tunneling in Al nanowires with diameters ranging from 10 to 40nm. We will present data for these wires.

C1.00296 Pressure effects on superconductivity and magnetism in FeSe0.88 and FeSe1−xTe x, CHIEN-LUNG HUANG, CHI-CHIE CHOU, KOU-FENG TSENG, YI-LIN HUANG, FONG-CHI HSU, KUO-WEI YEH, HUNG-DUEN YANG, National Sun Yat-sen University — We have performed the pressure (P) dependence of ac, dc susceptibility and resistivity measurements on iron chalcogenides FeSe0.88, FeSe0.5Te0.5, FeSe and FeTe0.05. The superconducting transition temperature (Tc) of FeSe0.88 is found to increase with P linearly at a rate of dTc/dP ∼ 3.09×10−2 K/kbar, while the Tc of FeSe0.5Te0.5 increases nonlinearly with an initial rate of 1.47K/kbar then saturates at P ∼ 18 kbar. Such the enhancement of Tc might be attributed to an increase of density of states. There is no indication of superconductivity observed in FeTe and FeTe0.9, which is inconsistent with the result of theoretical calculation, and it might be due to the existence of long range magnetic spin coupling that inhibits the formation of superconductivity mediated by spin fluctuations, which is applied to describe the mechanism in Fe-based superconductors.

C1.00297 ABSTRACT HAS BEEN MOVED TO S1.00263 —
C1.00298 Superconductivity in (La, Y)FeAs(O, F) pnictides, MATTEO TROPEANO, LAMIA-INFM-CNR, Genova-Italy & Dipartimento di Fisica, Genova-Italy, CARLO FERDEGHINI, LAMIA-INFM-CNR, Genova-Italy, CARLO FANCIULLI, LAMIA-INFM-CNR, Genova-Italy, ALBERTO MARTINELLI, LAMIA-INFM-CNR, Genova-Italy, ANDREA PALENZONA, Dipartimento di Chimica e Chimica Industriale, Genova-Italy & LAMIA-INFM-CNR, MARINA PUTTI, LAMIA-INFM-CNR & Dipartimento di Fisica & Applied Superconductivity Cen, ROBERTA CIMBERLE, IMEM-CNR, Genova-Italy, FABIO CANEPA, Dipartimento di Chimica e Chimica Industriale, Via Dodecaneso 31, 16146 Genova ITALY & IMEM-CNR, Genova-Italy — The structural, magnetic and resistive properties of (La, Y)FeAs(O, F) compounds prepared at normal pressure were investigated. Substituting La with Y decreases the ionic size at the rare earth site, determining a progressive decrease of both cell edges; as a result a notable increase of the superconductive transition temperature is observed. In particular Tc increases with Y content, up to a maximum value of 39.8 K for x = 0.5, followed by the a slight decrease for x = 0.7 (Tc = 35.9 K). The resistivity curve of the corresponding undoped compound, (La0.5Y0.5)FeAsO, exhibits the typical bump related to the SDW onset; the first derivative curves for (La0.5Y0.5)FeAsO and LaFeAsO are almost superposed around TSDW.

Session D1 DCMP: Phase Transitions and Transport in Quantum Hall Superfluids

2:30PM D1.00001 Phase Diagram of Bilayer 2D ElectronSystems at \( \nu_T = 1 \), ALEXANDRE CHAMPAGNE, Caltech — Bilayer 2D electron systems at total filling fraction \( \nu_T = 1 \) and small interlayer spacing can support a strongly correlated phase which exhibits spontaneous interlayer phase coherence and may be described as an excitonic Bose condensate. We use electron interlayer tunnelling and transport to explore the phase diagram of bilayer 2D electron systems at \( \nu_T = 1 \), and find that phase transitions between the excitonic \( \nu_T = 1 \) phase and bilayer states which lack significant interlayer correlations occur in three different ways: by increasing the effective interlayer spacing, \( d/\ell \), the temperature, \( T \), or the charge imbalance, \( \Delta \nu = \nu_1 - \nu_2 \). First, for the balanced (\( \Delta \nu = 0 \)) system we find that the amplitude of the resonant tunneling in the coherent \( \nu_T = 1 \) phase obeys an empirical power law scaling versus \( d/\ell \) at various \( T \), and the layer separation where the tunneling disappears scales linearly with \( T \). Our results [1] offer strong evidence that a finite temperature phase transition separates the balanced interlayer coherent phase from incoherent phases which lack strong interlayer correlations. Secondly, we observe [2] that close to the phase boundary the coherent \( \nu_T = 1 \) phase can be absent at \( \Delta \nu = 0 \), present at intermediate \( \Delta \nu \), and absent again at large \( \Delta \nu \), thus indicating an intricate phase competition between it and incoherent quasi-independent layer states. Lastly, at \( \Delta \nu = 1/3 \) we report [2] the observation of a direct phase transition between the coherent \( \nu_T = 1 \) bilayer integer quantum Hall phase and the pair of single layer fractional quantized Hall states at \( \nu_1 = 2/3 \) and \( \nu_2 = 1/3 \).

3:06PM D1.00002 \( \nu = 1/2 + 1/2 \) Quantum Hall Bilayers, STEVEN H. SIMON, Peierls Centre for Theoretical Physics, Oxford University — Quantum Hall bilayer systems at filling fractions near \( \nu = 1/2 + 1/2 \) undergo a transition from a compressible phase with strong intralayer correlation to an incompressible phase with strong interlayer correlations as the layer separation \( d \) is reduced below some critical value. Deep in the intralayer phase (large separation) the system can be interpreted as a fluid of composite fermions (CFs), whereas deep in the interlayer phase (small separation) the system can be interpreted as a fluid of composite bosons (CBs). The focus of this paper is to understand the states that occur for intermediate layer separation by using trial variational wavefunctions. We consider two main classes of wavefunctions. In the first class, previously introduced in [1], we consider interlayer BCS pairing of two independent CF liquids. We find that these wavefunctions are exceedingly good for \( d \approx d_0 \) with \( d_0 \) the magnetic length. The second class of wavefunctions naturally follows the reasoning of [2] and generalizes the idea of pairing wavefunctions by allowing the CFs also to be replaced continuously by CBs. This generalization allows us to construct exceedingly good wavefunctions for interlayer spacings of \( d \approx d_0 \) as well. The accuracy of the wavefunctions discussed in this work, compared with exact diagonalization, approaches that of the celebrated Laughlin wavefunction. More details can be found online in [3].

3:42PM D1.00003 Optical probes of excitonic phases in quantum Hall bilayers at \( \nu_T = 1 \), VITTORIO PELLEGRINI, NEST and Scuola Normale Superiore, Pisa (Italy) — In this talk we discuss our recent inelastic light scattering results that shed light on the interplay between incompressible and compressible quantum phases of electron bilayers at total filling factor \( \nu_T = 1 \). In the regime of finite values of tunneling gaps, we observe a quantum phase transformation between composite fermion (CF) metal and incompressible excitonic states as the tunneling gap is reduced. We show that the transition becomes discontinuous (first-order) by impacts of different terms of the electron-electron interactions that prevail on weak residual disorder [1]. The evidence is based on precise determinations of the excitonic order parameter and of measurements of CF spin excitations by resonant inelastic light scattering close to the phase boundary [2,3]. While there is marked softening of low-lying excitations, our experiments underpin the roles of competing order parameters linked to quasi-particle correlations in removing the divergence of quantum fluctuations [4]. In the regime of vanishingly small tunneling gaps we show that the abrupt disappearing of CF spin excitations below the spin-wave mode indicates the emergence of the inter-layer correlated quantum Hall state in the vicinity of \( \nu_T = 1 \) and when the temperature is lowered below a critical value [5]. Finally, the evolution of the spin-wave mode as a function of the Zeeman energy suggests the occurrence of a spin transition [5]. * Work done in collaboration with: B. Karmakar, A. Pinczuk, L. N. Pfeiffer, K. W. West.

4:18PM D1.00004 Theory of Activated Transport in Bilayer Quantum Hall Systems, H.A. FERTIG, Indiana University — We analyze the transport properties of bilayer quantum Hall systems at total filling factor \( \nu_T = 1 \) in drag geometries as a function of interlayer bias, in the limit where the disorder is sufficiently strong to unbind meron-antimeron pairs, the charged topological defects of the system. We compute the typical energy barrier for these objects to cross incompressible regions within the disordered system using a Hartree-Fock approach, and show how this leads to multiple activation energies when the system is biased. We then demonstrate using a bosonic Chern-Simons theory that in drag geometries, current in a single layer directly leads to forces on only two of the four types of merons, inducing dissipation only in the drive layer. Dissipation in the drag layer results from interactions among the merons, resulting in very different temperature dependences for the drag and drive layers. Connections with recent experiments will be discussed.

* This work was performed in collaboration with Bahman Roostaei, Kieran Mullen, and Steve Simon. Authors acknowledge support of the NSF.
Spin-dependent phase diagram in bilayer 2D electron systems, KOJI MURAKI, NTT Basic Research Laboratories — Bilayer electron systems with total filling \( \nu = 1 \) involve rich physics arising from the interplay between the intralayer and interlayer interactions parameterized by the ratio between the interlayer distance \( d \) and the magnetic length \( \ell_B \). One key issue in this system is the nature of the phase transition that occurs when exploring the system between the two limits of weak and strong interlayer interactions, i.e., compressible Fermi-liquid states of composite fermions and an incompressible quantum Hall state. Here we report tilted-field experiments on a double quantum well with negligible tunneling that demonstrate that the spin degree of freedom plays a decisive role in the ground-state phase diagram of this system [1]. When the ratio \( \eta \) of the Zeeman to Coulomb energies is enhanced by tilting the sample in a field by an angle \( \theta \), we observe that the phase boundary located at \( d/\ell_B = 1.90 \) for \( \theta = 0 \) shifts to higher densities until it saturates at \( d/\ell_B = 2.33 \) for \( \theta \geq 60 \) degree. The data thus establish a spin-dependent phase diagram as a function of \( \eta \) and \( d/\ell_B \). We model the energies of the competing phases treating the compressible state as nearly independent Fermi liquids of composite fermions. The excellent agreement between the model and experiment indicates that at small \( \theta \) the compressible state is only partially polarized and its Zeeman-dependent energy is responsible for the observed shift of the phase boundary, with the saturation at large \( \theta \) signaling the full polarization. This in turn implies that the intrinsic transition, expected for the ideal system without spin and intensively studied in theory, is preempted by a transition to a partially polarized compressible state in the standard experimental conditions and can only be revealed by suppressing the spin degree of freedom. Our results thus shed new light on previous experiments and show a way to investigate the intrinsic properties of the system. [1] P. Giudici et al., Phys. Rev. Lett. 100, 106803 (2008).

Session D2 DCMP: HTSC: New Developments Spirit of Pittsburgh Ballroom BC

2:30PM D2.00001 New magnetic neutron scattering results for the high-Tc superconductors HgBa2CuO4+x and Nd2−xCexCuO4+y, MARTIN GREVEN, Stanford University — We have succeeded in growing sizable single crystals of HgBa2CuO4+x, the single-layer hole-doped compound with the highest superconducting transition temperature [1]. Careful characterization demonstrates the high quality of our crystals [2]. Using polarized neutron diffraction, we find an unusual magnetic order in the pseudogap phase [3]. Together with prior results for YBa2Cu3O6+δ, this observation constitutes a demonstration of the universal existence of such a state. Our inelastic neutron scattering measurements reveal that the antiferromagnetic resonance occurs at a rather high energy in HgBa2CuO4+x and, hence, that the resonance energy is not universally related to \( T_c \) [4]. Finally, our results for the antiferromagnetic excitations in Nd2−xCexCuO4+y provide new insight into magnetic energy scales and the resonance of the electron-doped side of the phase diagram [5].

3:06PM D2.00002 Quantum critical fluctuations in cuprates and d-wave superconductivity through their coupling to fermions, VIVEK AJI, University of California at Riverside — The phase diagram of the Cuprates is a collection of anomalies that has challenged our understanding of quantum many body physics. An organizing principle proposed to unify the experimental observations is the existence of a quantum critical point near optimal doping separating a phase which has broken time reversal and a renormalized Fermi liquid. I will discuss recent theoretical developments related to the nature of the fluctuations near the quantum critical point. The long wavelength theory of the time reversal violating state belongs to the dissipative 2DXY universality class. The fluctuation spectrum, at the quantum critical point, is local in space and power law in time, precisely of the form observed in the marginal fermi liquid phase near optimal doping. The fluctuations couple to the local angular momentum of the fermions to give a momentum dependence to the coupling which leads directly to pairing attraction in the d-wave channel. Theory of superconductivity in the cuprates, Vivek Aji, Arkady Shekhter and Chandra Varma, arXiv:0807.3741.

3:42PM D2.00003 Search for a thermodynamic evidence of a phase transition in the pseudogap state of YBa2Cu3O6+\( x \), BRIGITTE LERIDON, LPEM / CNRS — Recent polarized neutrons diffraction experiments have evidenced a symmetry breaking in the underdoped phase of superconducting cuprates [1,2,3]. This symmetry breaking takes place below a temperature \( T_{MAG} \) which increases when the number of charge carriers in the superconducting planes is decreased. We present here magnetic susceptibility measurements in YBa2Cu3O6+\( x \) ceramics. We have measured the magnetization of about twenty samples with different oxygen contents under 1T magnetic field. In some of them, we have observed an anomaly in the temperature derivative of the susceptibility at a temperature \( T_1 \) which seems to be in good agreement to the temperature \( T_{MAG} \). We show here the resulting phase diagram for underdoped YBa2Cu3O6+\( x \). These findings raise the question of a thermodynamic evidence for a phase transition in relation to the symmetry breaking observed by neutrons.

4:18PM D2.00004 Competition between the pseudogap and superconductivity in cuprates1, ADAM KAMINSKI, Ames Laboratory and Iowa State University — The relationship between the pseudogap and superconductivity is one of the central issues in physics of cuprates. By studying the spectral weights associated with pseudogap and superconductivity by angle resolved photoemission spectroscopy (ARPES) we found that there is a direct correlation between the loss of the low energy spectral weight due to the opening of the pseudogap and a decrease of the spectral weight associated with superconductivity as a function of momentum and doping. We therefore conclude that the pseudogap competes with the superconductivity by depleting the spectral weight available for pairing in the region of momentum space, where the superconducting gap is largest.

time with coherent population trapping. The results are very encouraging: both the hole spin T1 and T2* times are surprisingly large.

A single electron in a nano-sized quantum dot is so strongly quantized that the interaction with the phonons is highly suppressed. This leads to potentially

This is accomplished via a canonical n-point function f_n, from which one can derive exact analytical expressions for any microstructural function of interest. This microstructural information can then be used to estimate accurately the bulk properties of the material. Unlike homogeneous materials, seemingly different bulk properties (e.g., transport and mechanical properties) of a heterogeneous material can be linked to one another because of the common microstructure that they share. Such cross-property relations can be used to estimate one property given a measurement of another. A recently identified decorrelation principle, roughly speaking, refers to the phenomenon that unconstrained correlations that exist in low-dimensional disordered materials vanish as the space dimension becomes large. Among other results, this implies that in sufficiently high dimensions the densest spheres packings may be ordered (rather than ordered) [S. Torquato and F. H. Stillinger, “New Conjectural Lower Bounds on the Optimal Density of Sphere Packings,” Experimental Mathematics, 15, 307 (2006)].

3:06PM D4.00002 Locking electron spins into resonance by electron-nuclear feedback\textsuperscript{1}, KATJA NOWACK, Delft University of Technology — All basic building blocks for spin-based quantum information processing using electron spins in GaAs quantum dots have recently been realized. Recent experiments have shown single-shot readout of an individual spin [1], the implementation of the SWAP gate [2] and (magnetically induced) coherent single electron spin rotations [3]. However, the main drawback of using electron spins in a GaAs environment is the short spin coherence time, which is measured to be in the nanosecond range [2,4]. The source of this fast decoherence is the hyperfine interaction of the localized electron spin with the randomly fluctuating nuclear spins of the host lattice. The fluctuations of the nuclear spins have to be reduced to extend the electron spin coherence time. We therefore study the electron-nuclear spin interaction and use magnetically driven spin resonance to control the electron spin and indirectly manipulate the nuclear spins. We apply continuous microwave excitation to the electron spin and observe strong electron-nuclear feedback. One experimental signature of this feedback is the locking of the electron spin system into resonance with the microwaves. Once the electron spin is locked into resonance, this coherence time. We therefore study the electron-nuclear spin interaction and use magnetically driven spin resonance to control the electron spin and indirectly manipulate the nuclear spins. We apply continuous microwave excitation to the electron spin and observe strong electron-nuclear feedback. One experimental signature of this feedback is the locking of the electron spin system into resonance with the microwaves. Once the electron spin is locked into resonance, this
4:54PM D4.00005 Dynamic nuclear polarization with single electron spins1. JACOB TAYLOR, Massachusetts Institute of Technology — Hyperfine interactions limit electron spin coherence times in GaAs quantum dots. By separating a spin singlet state on a chip, we measure an ensemble averaged spin dephasing time $T_2^*$ of 10 ns, limited by the contact hyperfine interaction with the GaAs host nuclei.$^2$ We use electrical control of the exchange interaction to drive coherent spin rotations. Exchange driven spin rotations are used to implement a “singlet-triplet spin echo” pulse sequence, which leads to a spin coherence time, $T_2$, exceeding 1 microsecond. We show that nuclear spins can be polarized by controlling two-electron spin states near the anti-crossing of the singlet ($S$) and triplet ($T_1$). An initialized $S$ state is cyclically brought into resonance with the $T_1$ state, where hyperfine fields drive rapid rotations between $S$ and $T_1$, “flipping” an electron spin and “flopping” a nuclear spin.$^3$ The resulting Overhauser field approaches 80 mT, in agreement with a simple rate-equation model. A self-limiting pulse sequence is developed that allows the steady-state nuclear polarization to be set using a gate voltage.

Session D5 FHP: Origins of Silicon Valley 401/402

2:30PM D5.00001 Prehistory of Silicon Valley, from 1910 to 1965. STEWART GILLMOR, Wesleyan University — The term "Silicon Valley" was coined in 1971, some six decades after the emergence of the San Francisco Bay Area as a center of innovation and invention in the fields of radio and electronics. The geographical position of San Francisco with respect to continental and Pacific transportation and communication needs; the growth of West Coast universities, markets, and population; the importation of talent from the East; innovative industrial and business methods—all these provided a thriving center of instrumentation, electronics, avionics, and high energy physics when Silicon arrived in the "Valley of the Heart’s Delight."

3:06PM D5.00002 W. W. Hansen, Microwave Physics, and Silicon Valley. DAVID LEESON, Stanford University — The Stanford physicist W. W. Hansen (b. 1909, AB ’29 and PhD ’32, MIT post-doc 1933-4, Prof. physics ’35-49, d. 1949) played a seminal role in the development of microwave electronics. His contributions underlay Silicon Valley’s postwar “microwave” phase, when numerous companies, acknowledging their unique scientific debt to Hansen, flourished around Stanford University. As had the prewar “radio” companies, they furthered the regional entrepreneurial culture and prepared the ground for the later semiconductor and computer developments we know as Silicon Valley. In the 1930’s, Hansen invented the cavity resonator. He applied this to his concept of the radio-frequency (RF) linear accelerator and, with the Varian brothers, to the invention of the klystron, which made microwave radar practical. As WWII loomed, Hansen was asked to lecture on microwaves to the physicists recruited to the MIT Radiation Laboratory. Hansen’s “Notes on Microwaves,” the Rad Lab “bible” on the subject, had a seminal impact on subsequent works, including the Rad Lab Series. Because of Hansen’s failing health, his postwar work, and MIT-Stanford rivalries, the Notes were never published, languishing as an underground classic. I have located remaining copies, and will publish the Notes with a biography honoring the centenary of Hansen’s birth. After the war, Hansen founded Stanford’s Microwave Laboratory to develop powerful klystrons and linear accelerators. He collaborated with Felix Bloch in the discovery of nuclear magnetic resonance. Hansen experienced first-hand Stanford’s evolution from its depression-era physics department to corporate, then government funding. Hansen’s brilliant career was cut short by his death in 1949, after his induction in the National Academy of Sciences. His ideas were carried on in Stanford’s two-mile long linear accelerator and the development of Silicon Valley.

3:42PM D5.00003 From Bell Labs to Silicon Valley: A Saga of Technology Transfer, 1954-1961. MICHAEL RIORDAN, UC Santa Cruz — Although Bell Telephone Laboratories invented the transistor and developed most of the associated semiconductor technology, the integrated circuit or microchip emerged elsewhere—at Texas Instruments and Fairchild Semiconductor Company. I recount how the silicon technology required to make microchips possible was first developed at Bell Labs in the mid-1950s. Much of it reached the San Francisco Bay Area when transistor pioneer William Shockley left Bell Labs in 1955 to establish the Shockley Semiconductor Laboratory in Mountain View, hiring a team of engineers and scientists to develop and manufacture transistors and related semiconductor devices. But eight of them—including Gordon Moore and Robert Noyce, eventually the co-founders of Intel—resigned en masse in September 1957 to start Fairchild, bringing with them the scientific and technological expertise they had acquired and further developed at Shockley’s firm. This event marked the birth of Silicon Valley, both technologically and culturally. By March 1961 the company was marketing its Micrologic integrated circuits, the first commercial silicon microchips, based on the planar processing technique developed at Fairchild by Jean Hoerni.

4:18PM D5.00004 The Origins and Development of the Silicon Valley Startup Model. JAMES GIBBONS, Stanford University — No abstract available.

Monday, March 16, 2009 2:30PM - 5:30PM –
Session D6 DCOMP: Predictive Materials Design for Alternative Energy Storage 406

2:30PM D6.00001 First-Principles Studies of Phase Stability and Reaction Dynamics in Complex Metal Hydrides1. MEI-YIN CHOU, Georgia Institute of Technology — Complex metal hydrides are believed to be one of the promising materials for developing hydrogen storage systems that can operate under desirable conditions. At the same time, these are also a class of materials that exhibit intriguing properties. We have applied state-of-the-art computational techniques to study the structural, dynamic, and electronic properties of these materials. This talk will focus on the critical role played by the Ti catalyst in helping hydrogen cycling in the alanates, which remains a challenging topic for this hydrogen storage material. We have performed a series of calculations to address the hydrogen interaction on the aluminum surface in the presence of the Ti “dopant,” focusing on the effect of near-surface alloying on the Al(100) surface. It is found that Ti occupies subsurface sites near the Al surface. This subsurface Ti arrangement not only enhances H binding with the Al surface layer, but also improves H mobility on the surface. Based on existing experimental data and our preliminary results, we propose a model in which the catalyst does not enter the bulk, but facilitates hydrogen dissociation-recombination near the surface. In the dehydrogenation cycle, the catalyst kinetically facilitates the release and decomposition of AlH3 from the solid-state alanate. In the hydrogenation cycle, the catalyst helps the adsorption of hydrogen and the formation of AlH3 oligomers on Al surfaces. The implication of Ti as a catalyst for the hydrogenation reactions will be discussed.

1Supported by the Department of Energy.
3:06PM D6.00002 Energy Storage in Nanostructured Materials, YONG-HYUN KIM, National Renewable Energy Laboratory — Renewably produced energy by solar and wind technologies should be stored properly for practical use because of their intermittent generation of electricity. The energy can be stored in materials in forms of chemical, electrical, or thermal energies. The current energy-storage materials technologies, however, suffer from their inevitable low energy densities, compared to liquid fuels such as gasoline and ethanol, and thus end up to high cost due to material limitation. In order to overcome the fundamental limit, many scientists and researchers have studied nanostructured materials with more surface areas, tunable storage mechanisms, and better kinetic processes. Because electronic and mechanical properties of nanostructured materials are simply not a miniature of their bulk counterparts, a careful material design is required based on microscopic understanding of the energy storing process. In this talk, I will discuss our recent theoretical efforts and development to understand energy storage mechanisms in nanostructured materials for hydrogen, battery, and electrochemical capacitor applications. We have pioneered dihydrogen adsorption in nanostructured materials with the Kubas coordination [1-3] and lately developed efficient van der Waals potentials within the density functional theory approach [4]. Also very recently we have unraveled reversible lithium intercalation mechanisms in MoO3 nanoparticles for Li-ion battery electrodes [5], and been developing a microscopic theory of electrochemical and capacitive energy storage.

3:42PM D6.00003 Nanomaterials for Hydrogen Storage, PURU JENA, Virginia Commonwealth University — The success of a hydrogen economy critically rests on our ability to find materials that can store hydrogen with large gravimetric and volumetric densities and operate at near ambient conditions. To meet the large gravimetric density requirement, the storage materials must be lighter than Al. Unfortunately, in these light materials hydrogen is bound either too strongly or too weakly, thus leading to poor thermodynamics. I will discuss how the chemistry of these elements can be manipulated to bond hydrogen strongly and yet release it cleanly. The examples will include functionalized carbon fullerenes and nanotubes and doped AlN nanostructures. Using carbon nanostructures as catalysts I will demonstrate unambiguously the dehydrogenation mechanism of sodium alanate. A cluster perspective of the intermediate phases in the dehydrogenation of borohydrides will also be presented.

4:18PM D6.00004 Fundamental design of hydrogen storage structures and systems, ZHENHUI XIAO GUO, University College London — Fundamental simulations of hydrogen interactions with host structures offer indispensable insights to the understanding and design of hydrogen storage media for practical applications. First-principles approaches were applied to selected materials of high promise, e.g., doped/defective carbon, doped hydrides and metal/amine complexes. Several candidates show large capacities for hydrogen — over the 6.9 mass-percentage threshold considered for applications. Recent progress on carbon nanostructures show the importance of defects and doping on extra hydrogen uptake, and a small change of C-C interspacing on the mode-switching of hydrogen sorption. Work on the molecular analogues of the basic structural unit of boron-nitride indicates that transition metal (TM) atom doping can boost both the gravimetric and thermodynamic capacities of hydrogen in these materials. The H2 binding to the TM dopants is Kubas-like in nature, though the maximum binding capacity at the TM doped sites does not follow the 18-electron rule. Progress in the Li-N-H system shows that the N-Li bond is weaker than the N-H bonds in LiNH2, and consequently LiNH2 can dissociate into Li+ and (NH2)-, or (LiNH)- and H+. Hence, of NH3 may evolve as a transient gas, if it is not sufficiently captured by a reactive component, e.g. LiH. Molecular dynamics calculations indicate that hydrogen delivery is possible close to fuel-cell operation conditions. Comparison is also made with experiment where possible.

4:54PM D6.00005 First principles design of electric-field-assisted high capacity hydrogen storage media, MINA YOON, Oak Ridge National Laboratory, Fritz-Haber-Institut der Max-Planck-Gesellschaft, University of Tennessee — Hydrogen has been viewed as a highly appealing energy carrier for renewable energy. To achieve economic feasibility hydrogen storage materials with high gravimetric and volumetric densities must be developed. However, no materials so far satisfy the essential criteria for economically feasible hydrogen storage. Therefore, there are necessities of breakthrough ideas and methods for developing new materials. In this talk, I will discuss the novel idea of electric-field-assisted hydrogen storage in nanostructures. Its central ingredient is to create high and strongly delocalized electric fields that are strong enough to attract hydrogen through polarization. Using quantum mechanical first-principles calculations, it has been shown that high electric fields can be easily established in a region close to the surface of nanostructures by electronic doping [1] or in charge compensated ways. The charging idea and its underlying physical mechanism can be generalized to many other related nanoscale materials that are of interest for hydrogen storage, as exemplified by alkaline-earth-metal coated carbon nanostructures [2] and charge transferred organic crystals [3].

Monday, March 16, 2009 2:30PM - 5:30PM — Session D7 GSNP: Rare Events in Physics and Population Dynamics 407

2:30PM D7.00001 Transitions in the Kramers escape rate in classical and quantum field theories, DANIEL STEIN, New York University — Small random fluctuations, either of thermal or quantum origin, are the cause of many important and interesting physical phenomena. These include chemical reactions, nucleation in phase transitions (i.e., the formation of a droplet of one phase within another phase), and the formation of unusual spatially localized states in various condensed matter systems. In all of these, random fluctuations (or “noise”), no matter how small, eventually drives a physical system from one stable state to another. We discuss how in some classical systems thermally activated hopping over a barrier undergoes a transition as an external parameter such as system size or external field is varied. Its features are similar to those arising when classical activation over a barrier crosses over to quantum tunneling through that barrier as temperature is lowered. This crossover has some (but not all of the) features of a second-order phase transition. We also discuss two timely applications from mesoscopic physics: thermally induced breakup of monovalent metallic nanowires, and stochastic reversal of magnetization in thin ferromagnetic annuli. Each are of interest both from the point of view of fundamental physics and for potential technological applications.

1. Research partially supported by NSF PHY-0651077.
Further work is needed to theoretically account for the observed behavior. Also in this configuration, moreover, the frequency and lineshape of these oscillations exhibit periodicity as a function of externally applied magnetic flux. Variety of dynamical effects, including self-sustained oscillations, stochastic resonance, and intermittency between different steady-state and limit-cycle solutions. Duffing-like nonlinearity of the mechanical beams is well understood, the piecewise-linear behavior exhibited by the superconducting stripline resonators is yet using two classes of systems, namely, nanomechanical resonators in the form of doubly clamped beams, and electromagnetic resonators made of superconducting striplines. While a bifurcation between monostable and bistable zones is employed for the first class of resonators, a bifurcation between monostable and astable perturbations. This behavior can be exploited for amplifying small signals, and also for noise reduction (squeezing). We experimentally demonstrate these effects.

Accurate predictions. Moreover, the time of occurrence (i.e., phase) of an outbreak proves to be a useful new parameter that carries important epidemiological contrasts with the well known Rossler oscillator whose outbreaks recur regularly but whose amplitude vary chaotically in time (Uniform Phase Chaotic Amplitude the chaotic regime. In fact, it is difficult if not impossible to locate realistic chaotic parameter regimes in which outbreaks occur regularly each year. This and predict years in which the epidemic is absent rather than outbreak years. Skipping events are intrinsic to the forced SIR model when parameterised in the model’s natural oscillations. The analysis advanced here attempts to make progress in this direction by focusing on the dynamics of “skips” where we identify and predict years in which the epidemic is absent rather than outbreak years. Skipping events are intrinsic to the forced SIR model when parameterised in the chaotic regime. In fact, it is difficult if not impossible to locate realistic chaotic parameter regimes in which outbreaks occur regularly each year. This contrasts with the well known Rossler oscillator whose outbreaks recur regularly but whose amplitude vary chaotically in time (Uniform Phase Chaotic Amplitude oscillations). The goal of the present study is to develop a “language of skips” that makes it possible to predict under what conditions the next outbreak is likely to occur, and how many “skips” might be expected after any given outbreak. We identify a new threshold effect and give clear analytical conditions that allow accurate predictions. Moreover, the time of occurrence (i.e., phase) of an outbreak proves to be a useful new parameter that carries important epidemiological information. In forced systems, seasonal changes can prevent late-initiating outbreaks (i.e., having high phase) from running to completion. These principles yield forecasting tools that should have relevance for the study of newly emerging and reemerging diseases.

2:30PM D8.00001 Thermal Spin Transfer Torques1, GERRIT BAUER, TU Delft — The coupling between spin and charge in electronic transport is studied in the field of spintronics. Heat currents are coupled to both charge and spin currents as well [1]. This extension of spintronics to what may be called “spin caloritronics” recently enjoys renewed attention [2]. The spin-transfer torque associated with electric currents can excite magnetizations in nanostructures, switching magnetic configuration in spin valves and move domain walls in magnetic wires when exceeding critical values of the order of $10^4$ A cm$^{-2}$ [3]. Also heat currents transfer spin angular momentum [4], either intrinsically or via the thermo-electric generation of particle spin currents. We predict that temperature differences of the order of 100 K over typical metallic nanostructures cause effects equivalent to the critical charge current densities. In this talk I will give a brief review of various aspects of spin caloritronics with emphasis on thermal spin transfer torques. This work has been carried out in collaboration with Moosa Hatami, Qinfang Zhang, Paul Kelly, Hans Joakim Skadsem, Arne Brataas and Sadamichi Maekawa.

3:06PM D8.00002 Nonequilibrium intrinsic spin torque in a single nanomagnet1, AURELIEN MANCHON, University of Arizona — The spin transfer torque usually observed in metallic and tunneling spin-valves, as well as magnetic domain walls, comes from the transfer of the transverse spin-current of conduction electrons to the magnetization [1]. Therefore, it requires both a non collinear configuration of the magnetic structure (or inhomogeneous magnetic texture in the case of domain walls) and magneto-resistive effects. However, a number of magnetic systems show magneto-resistive effects in a single magnetic layer, such as anisotropic magnetoresistance (AMR) [2]. In the presence of spin-orbit interaction (SOI) the electron scattering depends on the magnetization direction. Recent theoretical studies suggest that in such systems, a transverse component of the spin density builds up, due to the spin-dependent scattering introduced by the spin-orbit coupling. Consequently, a transverse spin density arises from intrinsic properties of the band structure without the need of non-collinear magnetization. In the case of a single ferromagnet with spin-orbit interaction, the exchange interaction between the accumulated spin and the magnetization gives rise a spin torque on the magnetization. We show that this torque can be used to control the magnetization direction injecting current densities as low as $10^5$-10$^6$ A/cm$^2$, comparable or lower than the spin transfer effect. We first study the general case of a single ferromagnetic layer with spin-orbit interaction and then focus on the cases of effective Hamiltonians, such as Rashba and Dresselhaus SOI, as well as Luttinger hole systems. We discuss the relation between the spin torque and the spatial inversion symmetry of various forms of spin-orbit couplings and compare this spin torque with the conventional spin transfer torque. We finally discuss several magnetic systems for possible experimental realizations. This work was done in collaboration with Shufeng Zhang. [1] J.C. Slonczewski, J. Magn. Magn. Mater. 159, L1 (1996); L. Berger, Phys. Rev. B 54, 9353 (1996). [2] T.R. McGuire and R.I. Potter, IEEE Trans. Mag. 11, 1018 (1975).

3:42PM D8.00003 Spin transfer torques in antiferromagnets and magnetic semiconductors, PAUL HANEY, National Institute for Standards and Technology — Spin transfer torques (STT) in ferromagnetic metals can be understood in terms of conservation of total spin, allowing a simple evaluation and interpretation of these torques in terms of spin currents. STTs also occur in antiferromagnets, which have no net spin and different symmetries than ferromagnets, resulting in qualitatively different torques. We consider a structure with a compensated antiferromagnetic layer and a ferromagnetic layer. We find a STT on both layers, which vanishes when the layers' order parameters are either collinear or perpendicular. This torque can drive the magnetization of a thin film ferromagnet to be perpendicular to the easy plane. In dilute magnetic semiconductors, strong spin orbit coupling in the semiconductor host implies that spin is not even approximately conserved, requiring modifications of the microscopic calculation of the STT. We describe these modifications and present results from first principles calculations of STT in GaMnAs.

4:18PM D8.00004 Spin-Transfer-Torques at a Ferromagnet/Antiferromagnet Interface1, MAXIM TSOI, Physics Department, University of Texas at Austin — Spintronics in ferromagnetic systems is built on a complementary set of phenomena in which the magnetic configuration of the system influences its transport properties and vice versa. Giant magnetoresistance (GMR) [1] and spin- transfer-torque (STT) [2] phenomena are typical examples of such interconnections. Recently, MacDonald and co-workers [3] predicted that corresponding effects ought to occur in systems where ferromagnetic (F) components are replaced by antiferromagnets (AFM). I will present our experimental search for these new AFM effects which may potentially lead to a new all-antiferromagnetic spintronics where antiferromagnets are used in place of ferromagnets. In particular I will focus on our experiments with exchange-biased spin valves [4] where extreme current densities were found to affect the exchange bias at F/AFM interface [5-7]. As exchange bias is known to be associated with interfacial AFM magnetic moments, our observation can be taken as the first evidence of STT effect in AFM materials.

4:54PM D8.00005 Effects of polarizer dynamics on current-induced behaviors in magnetic multilayer nanopillars1, SERGEI URAZHDIN, West Virginia University — Magnetic nanodevices usually include two magnetic layers - a polarizing “fixed” layer, and a “free” layer, whose roles are determined by their relative thicknesses. I will describe our measurements of spin transfer in nanopillars with similar thicknesses of the “polarizer” and the “free” layer. In the first sample type, both layers were patterned into similar lateral dimensions. Spectroscopic measurements of current-induced dynamics showed incoherent bipolar excitations. Thermally-activated reversal statistics exhibited dependences on magnetic field and applied current dramatically different from the “standard” samples with a thick polarizing layer. I will also discuss our results for samples in which only the free layer was patterned into a nanopillar, while the polarizing layer was left extended with dimensions of several micrometers. These samples exhibit coherent precession of only the extended layer, only the polarizer, or both, depending on the relative thicknesses of the two layers. The transition between the “free”-like and “fixed”-like behaviors of each layer occurred over a small range of thickness. I will show that current-induced behaviors of our samples can be understood in terms of the dynamical coupling between ferromagnets induced by spin transfer. This coupling can result suppression of the current-induced precession, incoherent dynamics, or for certain geometries in enhancement of current-induced dynamics in magnetic bilayers.

1Supported by NSF DMR-0747609 and a Cottrell Scholar Award from the Research Corporation.
2:30PM D9.00001 Can one hear a Kolmogorov Spectrum?1, SERGIO RICA, LPS, CNRS-Ecole Normale Supérieure — I will talk about a work in collaboration with G. Durrin and C. Josserand on the long-time evolution of waves of a thin elastic plate in the limit of small deformation so that modes of oscillations interact weakly. According to the theory of weak turbulence (successfully applied in the past to plasma, optics, and hydrodynamic waves), this nonlinear wave system evolves at long times with a slow transfer of energy from one mode to another. We derived a kinetic equation for the spectral transfer in terms of the second order moment. We show that such a theory describes the approach to an equilibrium wave spectrum and represents also an energy cascade, often called the Kolmogorov-Zakharov spectrum. We perform numerical simulations that confirm this scenario. Finally, I will discuss recent experiments by A. Boudaoud and collaborators and N. Mordant.

2:42PM D9.00002 Dynamical Origami, CHRISTOPHE JOSSE, ARNAUD ANTKOWIAK, BASILE AUDOLY, SÉBASTIEN NEUKIRCH, Institut D’Alembert, CNRS & UPMC, INSTITUT D’ALEMBERT TEAM — A drop falling on a thin elastic sheet is rapidly trapped after impact by self-folding of the sheet around the drop. This trapping process, due to capillary forces, occurs on the fast timescale of hydrophobic rebound. The resulting packed drop presents a complex three-dimensional shape, characteristic of the interplay between elasticity and capillarity (Py et al., Phys. Rev. Lett. 98, 2007). We study experimentally the encapsulation dynamics with high-speed video camera. A shape selection exhibited by the system is evidenced. The role played by the different parameters of impact (drop radius, impact velocity...) in the final shape of this “dynamical origami” is eventually discussed.

2:54PM D9.00003 Mass distribution and geometry of a crumpled ball, ANNE DOMINIQUE CAMBOU, NARAYANAN MENON, UMass, Amherst — We use X-ray CT scanning to resolve in 3-dimensions the conformation of aluminum sheets with diameters L=7cm to 10cm and thickness T=25 microns, crumpled into spheres with diameters D=1.2cm to 1.5cm. The linear resolution of the reconstructed images is less than 6 microns/voxel. Measurements were made on spheres with average volume fractions, φ ranging from 0.06 to 0.11. The mass is not homogeneously distributed in the volume: when averaged over several samples, the volume fraction d(L/D) is found to increase with radius so that the sphere is densest at its surface. The radial dependence of volume fraction appears to be independent of average volume fraction and diameter, D. We also report preliminary measurements of the distribution of curvature in the sphere.

3:06PM D9.00004 Stress relaxation in thin crumpled sheets, INGO DIERKING, PAUL ARCHER, University of Manchester — Compression of thin crumpled sheets subjected to a constant weight shows a wide range of scaling, covering up to five orders of magnitude [1], i.e. time scales from seconds to weeks. We demonstrate that this scaling behaviour is not smooth, but rather interrupted by sudden changes in height of the uniformly compressed crumple, which we attribute to sudden ridge collapses. Interestingly, when plotting the time laps between successive discontinuous ridge collapses as a function of time, the data falls onto a single linear functionality for all polymer film thicknesses, with a slope of dΔt/dt=1 over a scaling regime of four orders of magnitude.[2] Further, we investigate the scaling behaviour of thin sheets of different metals to elucidate a possible relation between the scaling parameter and the Young’s modulus. Preliminary experiments suggest that scaling is a linear function of the elastic modulus. [1] K. Matan, R.B. Williams, T.A. Witten, S.R. Nagel, Phys. Rev. Lett., 88, (2002), 076101. [2] I. Dierking, P. Archer, Phys. Rev. E, 77, (2008), 051608.

3:18PM D9.00005 The compensation of Gaussian curvature in developable cones is local, JIN WANG, THOMAS WITTEN, The James Franck Institute and The Department of Physics, The University of Chicago — We use the angular deficit scheme[1] to determine numerically the distribution of Gaussian curvature in developable cones(d-cones)[2] formed by forcing a flat elastic sheet into a circular container so that the sheet buckles. This provides a new way to confirm the vanishing of mean-curvature[3] at the rim where the sheet touches the container. This angular deficit scheme also allows us to explore the potential role of the Gaussian-Bonnet theorem in explaining the mean-curvature vanishing phenomenon. The theorem's global constraint on curvature resembles the global conditions observed to be relevant for vanishing mean curvature. However, our result suggests that the Gauss-Bonnet theorem does not explain the vanishing of mean-curvature.

3:30PM D9.00006 Buckling Thin Disks and Ribbons with Non-Euclidean Metrics, CHRISTIAN SANTANGELO, UMass Amherst — I consider the problem of a thin membrane on which a metric has been prescribed, for example by lithographically controlling the local swelling properties of a polymer thin film. While any amount of swelling can be accommodated locally, geometry prohibits the existence of a global strain-free configuration. To study this geometrical frustration, I introduce a perturbative approach. I compute the optimal shape of an annular, thin ribbon as a function of its width. The topological constraint of closing the ribbon determines a relationship between the mean curvature and number of wrinkles that prevents a complete relaxation of the compression strain induced by swelling and buckles the ribbon out of the plane. These results are then applied to thin, buckled disks, where the expansion works surprisingly well. I identify a critical radius above which the disk in-plane strain cannot be relaxed completely.

3:42PM D9.00007 Fragmentation of an elastica, NICOLAS VANDENBERGHE, EMMANUEL VILLERMAUX, IRPHE, CNRS - Aix Marseille Universite — When a thin rod is submitted to an axial force greater than its critical buckling load it takes the shape of an elastica. As the load further increases, a rod made of a brittle material breaks suddenly. More than two fragments may be formed during this fragmentation. In this work we discuss the sequence of events that lead to the final broken state with two or more fragments. We show that the criterion for breaking is not trivial. In particular, we investigate the effect of the duration of the loading and we show that at a given load the waiting time before breaking is broadly distributed. We discuss the consequences of the time delayed breaking on the distributions of fragment sizes and fragment numbers.
3:54PM D9.00008 Relaxation of a plastic fold1, MORGAN CERVO, NARAYANAN MENON, U. of Massachusetts, Amherst — Crumpled objects have been observed to show stress relaxation when confined to a constant volume, and to show creep when subjected to a constant load. These relaxation processes are described by logarithmic (or other similarly slow) functional dependences on waiting time. In an effort to understand the microscopic elements responsible for this slow collective relaxation, we study the mechanics of a single fold in a thin strip of polycarbonate sheet (typical dimensions: thickness t=0.127 mm, length L=14 cm, and width w=2cm). We create folds of different initial opening angles by placing the strip under varying loads. We then measure the opening angle as a function of time. We find that even one isolated fold is sufficient to mimic the relaxation behavior of the composite crumpled sheet: the unfolding process is logarithmic in time. The unfolding rate depends on sheet thickness, but surprisingly is independent of initial opening angle. We have observed qualitatively similar behavior in metal and paper sheets.

4:06PM D9.00009 Shape and trajectory of a tumbling elastic sheet of paper1, MIKE ROBITAILLE, ARSHAD KUDROLLI, Department of Physics, Clark University, Worcester, MA 01610 — Inspired by wind dispersal of winged seeds and gliders, we study the flight of a tumbling piece of paper to explore the competing effect of inertia, lift, drag, and elasticity on its aerodynamics. Above a critical aspect ratio, a rigid rectangular sheet is well known to exhibit autorotation, leading to a lift force which causes it to drift away from the vertical as it falls through air. Less known is that the fact that the sheet buckles and bends along the axis of rotation when the rigidity of the sheet is reduced. We measure the deflection of the paper as a function of aspect ratio, and find its speed and angle of descent with high speed imaging. We find that the rotation speed is lower when the sheet is bent, than when it is unbent. The sheet deflection increases above a critical aspect ratio reaching a maximum before decreasing. The angle of descent is well described by a simple model balancing the gravitational, lift and drag forces acting on the sheet.

1In collaboration with Daniel Tam and John Bush (MIT).

4:18PM D9.00010 Shape and trajectory of a tumbling elastic sheet of paper II, DANIEL TAM, MIT, MICHAEL ROBITAILLE, ARSHAD KUDROLLI, Clark University, JOHN BUSH, MIT, DEPARTMENT OF MATHEMATICS, MIT TEAM, DEPARTMENT OF PHYSICS, CLARK UNIVERSITY TEAM — We investigate the dynamical coupling between the tumbling motion and elastic deformation of a paper strip freely falling in air. Recent experiments suggest the existence of a critical length above which the strip bends as it tumbles. We demonstrate that this bending is caused by the centripetal force associated with its tumbling motion. A simple theory predicts that bending occurs above a critical length in much the same way that buckling occurs in a compressed beam. We further discuss the influence of bending on the trajectory of paper strips, as well as biological implications for the dispersal of seed pods.

4:30PM D9.00011 Nonlinear response of tensed membranes, PEEKER MILAS, BENNY DAVIDOVITCH, Physics Dept., UMass Amherst — We study the response of elastic membranes under tension T, to localized normal forces F. Focusing on simple geometries, characterized by translational or radial symmetries, we calculate the membrane shape for a range of values of F and T by numerically solving the appropriate FvK equations. We find that the linear regime, where membrane displacement is proportional to F, vanishes in the asymptotic limit FT ≪ 1, and characterize scaling properties of the resulting nonlinear response. We discuss the relevance of our results to the puzzling scaling behavior of the length of radial wrinkles, recently found in “drop on membrane” experiments (Huang et al. Science 2007).

4:42PM D9.00012 Period Fissioning and Other instabilities of stressed elastic membranes, BENNY DAVIDOVITCH, Physics Dept., UMass Amherst — We study the shapes of elastic membranes under the simultaneous exertion of tensile and compressive forces when the translational symmetry along the tension direction is broken. We predict a multitude of novel morphological phases in various regimes of a 2-dimensional parameter space (ε, ν), defined by the relevant mechanical and geometrical conditions. The parameters ε, ν are, respectively, the ratio between compression and tension, and the wavelength contrast along the tension direction. In particular, our theory associates the repetitive period fissioining pattern, recently observed on wrinkled membranes floating on liquid and subject to capillary forces (J. Huang et al.) to the morphology in the asymptotic regime (ε ≪ 1, ν ≫ 1) where tension is dominant and the wavelength contrast is large.

4:54PM D9.00013 Experimental study of the dynamics of crumpling, HILLEL AHARONI, ERAN SHARON, Hebrew University in Jerusalem — We experimentally measure the temporal evolution of crumpled configurations of thin elastic sheets. In our experiment, elastic hydrogel sheets swell inside a hard spherical shell, free of gravitational and plastic effects. We observe the dynamic evolution of structures in the sheet as confinement ratio increases, and analyze the statistical nature of the elastic energy localization along singularities.

5:06PM D9.00014 Geometry Induced Charge Separation on a Helicoidal Ribbon, AVADH SAXENA, Los Alamos National Lab, VICTOR ATANASOV, Bulgarian Academy of Sciences, ROSSEN DANDOLOFF, Universite de Cergy-Pontoise, GEOMETRY AND NONLINEARITY COLLABORATION — Helical ribbons are ubiquitous in nature including in the carbon based nanostructures such as graphene. We derive an effective geometry-induced quantum potential for a particle confined on a helicoidal ribbon. This potential leads to the appearance of localized states at the rim of the helicoid. In this geometry the twist of the ribbon plays the role of an effective transverse electric field on the surface and thus this is reminiscent of the quantum Hall effect. We also calculate the effective polarization and discuss the consequences of these findings.

Monday, March 16, 2009 2:30PM - 5:30PM – Session D10 DMP: Focus Session: Ferroelectrics III and Piezoelectrics 304

2:30PM D10.00001 Light scattering answers precisely to the soft-mode in PbTiO3 paraelectric phase, HWEE PING SOON, HIROKI TANIGUCHI, YASUHIRO FUJII, MITSURU ITOH, Tokyo Institute of Technology (Materials and Structures Laboratory), MAKOTO TACHIBANA, National Institute for Materials Science — PbTiO3 (PT) acts solely as the long-standing textbook example for the displacive-type phase transition; however, the precise observation of the soft-mode behavior of PT paraelectric phase still remains unavailable although it has been addressed by many research works [1-4]. In this study, we revisit the soft-mode behavior of PT single crystal by the confocal micro-Raman measurements. Opposing to the conventional belief that there occurs no first-order Raman scattering in the centrosymmetric PT paraelectric phase, the temperature dependence of the soft-mode has been precisely resolved for the first time due to the existence of macroscopic size Raman active regions (≥ 780 nm). By evidently ruling out the possibility of defect-induced Raman scattering, the elasto-optical coupling serves as the most likely mechanism for the occurrence of these Raman active regions. [This work was supported by both Kakenhi (Grant No. 20248098) and Global COE program.] [1] G. Shirane, J. D. Axe, and J. Harada, Phys. Rev. B 2, 155 (1970). [2] M. Kempa et al., Phase Trans. 79, 351 (2006). [3] N. E. Tornberg and C. H. Perry, J. Chem. Phys. 53, 2946 (1970). [4] M. D. Fontana, H. Idrissi, and K. Wojcik, Europhys. Lett. 11, 419 (1990).
2:42PM D10.00002 Pretransitional Diffuse Neutron Scattering in Ferroelectric KTa$_{1-x}$Nb$_x$O$_3$

GRACE YONG, Towson University, ROSS ERWIN, NIST Center for Neutron Research, OLEKSII SVITELSKYI, University of Alberta, JEAN TOULOUSE, Lehigh University, LYNN BOATNER, Oak Ridge National Laboratory, BERNARD HENNION, Laboratory Leon Brillouin, STEPHEN SHAPIRO, Brookhaven National Laboratory — Pretransitional diffuse neutron scattering in ferroelectric KTa$_{1-x}$Nb$_x$O$_3$ occurs at (110), (111), and (130) with no diffuse scattering at (100), and (200). These observations will be discussed using the elastic structure factor and ‘uniform phase shift’ description.

2:54PM D10.00003 Nonlinear Driven Response of a Phase-Field Crystal in a Periodic Pinning Potential

CRISTIAN ACHIM, TTK, Finland, JORGE RAMOS, INPE, Brazil, MIKKO KARTTUNEN, University of Western Ontario, Canada, KEN ELDEN, Oakland University, ENZO GRANATO, INPE, Brazil, TAPIO ALA-NISSILA, TTK, Finland, SEE-CHEN YING, Brown University — We study numerically the phase diagram and the response under a driving force of the phase field crystal model for pinned lattice systems in one and two dimensions. The model describes the lattice system as a continuous density field in the presence of a periodic pinning potential, allowing for both elastic and plastic deformations of the lattice. We first present results for phase diagrams of the model in the absence of a driving force. The nonlinear response to a driving force on an initially pinned commensurate phase is then studied via overdamped dynamic equations of motion for different values of mismatch and pinning strengths. For large pinning strength the driven depinning transitions are continuous, and the sliding velocity varies with the force from the threshold with power-law exponents in agreement with analytical predictions. Transverse depinning transitions in the moving state are also found in two dimensions. Surprisingly, for sufficiently weak pinning potential we find a discontinuous depinning transition with hysteresis even in one dimension under overdamped dynamics. We also characterize structural changes of the system in some detail close to the depinning transition.

3:06PM D10.00004 Mesoscopic nanostructures and long-time relaxation processes in ferroelectrics with coexisting ferroelectric and antiferroelectric phases

V. SOBOLEV, South Dakota School of Mines & Technology, Rapid City, South Dakota 57701, USA, V. ISCHUCH, Institute for Single Crystals of the Academy of Sciences of Ukraine, Kharkov 61001, Ukraine, Z. SAMOILENKO, Physics/Engineering Institute of the Academy of Sciences of Ukraine, Donetsk 83114, Ukraine — Presentation contains results of experimental study of the kinetics of mesoscopic segregated structures formed in the vicinity of interphase domain boundaries separating the domains of the coexisting ferroelectric and antiferroelectric phases in two series of the lead zirconate titanate based solid solutions in which the isovalent complex (La$_{3+}$,$\La^{3+}$)$_2^{2+}$ or the La$^{3+}$ ions are substituted for lead. These systems of solid solutions possess an extended interval of compositions for which the inhomogeneous state of coexisting ferroelectric and antiferroelectric domains is energetically favorable in comparison with homogeneous ferroelectric and antiferroelectric phases. The mechanisms that control the kinetics of formation of the segregates are investigated and compared for these two series of solid solutions.

---

3:18PM D10.00005 Accurate calculations of the full NMR chemical shielding tensor in perovskites: B3LYP embedded cluster results for $^{17}$O and $^{47,49}$Ti

DANIEL L. PECHKIS$^2$, ERIC J. WALTER, HENRY KRAKAUER, College of William and Mary — B3LYP calculations of $^{17}$O and $^{47,49}$Ti NMR in BaTiO$_3$ and SrTiO$_3$ will be presented. These systems were modeled with finite size quantum clusters embedded in classical fields generated from arrays of point charges and pseudopotentials. For polar clusters, an external E-field was applied to eliminate spurious depolarization fields. The full $^{17}$O chemical shielding tensors, $\sigma(O)$, in BaTiO$_3$ and SrTiO$_3$ are in very good agreement with recent precise single crystal measurements. The calculated Ti isotropic chemical shielding values are within the range of all reported measurements of BaTiO$_3$. Results will also be presented for the solid solution PZT series.

---

3:30PM D10.00006 Local ordering and structural instabilities in (Na,Bi)TiO$_3$ perovskites

SAHAK PETROSYAN, Massachusetts Institute of Technology, MARCO FORNARI, Central Michigan University, BORIS KOZINSKY, Bosch GmbH, NICOLA MARZARI, GERBRAND CEDER, Massachusetts Institute of Technology — Density functional theory is used to predict structural and electronic properties of lead-free piezoelectric perovskite (Na,Bi)TiO$_3$. Prediction of the energetics of different phases in the phase diagram and investigated the tendency to local ordering on the A-site. In order to elucidate the mechanism for the phase transitions and the piezoelectric performance we also probed the dependence of ferrodistortive and antiferrodistortive instabilities upon pressure and chemical substitutions. Our results point to local tetragonal ordering and provide insight on possible structural changes of the system in some detail close to the depinning transition.

---

3:42PM D10.00007 Density-functional study of the Ba$_{1+2x}$Bi$_{(1-x)}$(M$_{1-x}$)$_2$Ti$_{(1+x)/2}$O$_3$ perovskite solid solution

DENNIS JACKSON, Oregon State University, DAVID ROUNDY, Oregon State University — Using density-functional theory we predict properties of the solid solution perovskites Ba$_{1+2x}$Bi$_{(1-x)}$(M$_{1-x}$)$_2$Ti$_{(1+x)/2}$O$_3$ where M is Mg, Ni or Zn. These properties are strongly affected by the presence of both A-site and B-site disorder. We study all distinct orderings within a given supercell. Results will also be presented for the solid solution PZT series.

---

3:54PM D10.00008 Predicting new structures in B-cation ordering perovskites

MATTHEW LORDS, Brigham Young University — Material properties are intimately tied to crystal structure. Many materials, alloys in particular, share a common, underlying motif, such as an fcc, bcc, or hcp parent lattice but have different chemical orderings on the lattice. For example, the well-known structure in the Cu-Au system, L1$_0$, has an underlying fcc lattice where each (001) plane contain only Cu or Au. The planes are stacked so that the Cu and Au layers alternate. Among the countably infinite possibilities for such chemical orderings, why does nature choose only the few it does? Are others possible or likely? We answer this question generally and give an example of the perovskite structure, important in ferroelectrics, catalysts, and superconductors. We show which structures are possible combinatorially and which might actually be observed in real materials.

---

4:06PM D10.00009 First principles study of piezorotation in thin-film LaAlO$_3$

ALISON HATT, NICOLA SPALDIN, University of California, Santa Barbara — We investigate the effect of biaxial strain on [001] thin-film LaAlO$_3$ using density functional calculations. We find that the essentially rigid rotations of the AlO$_6$ octahedra vary linearly with strain, a phenomenon which may be described as piezorotation by analogy with piezomagnetism or piezoelectricity [S. Denev, et al., Phys. Rev. Lett. 100, 257601 (2008)]. Within a small range of experimentally achievable strain values, we find that epitaxial strain can stabilize several distinct modes of cooperative rotations not found in the bulk, and identify first order phase transitions between states with different piezorotative responses. Finally, we investigate how the electronic and elastic properties are affected by proximity to the strain-induced phase transitions.
4:18 PM D10.00010 - Nano-electromechanical systems based on a piezoelectric single crystalline thin film on Silicon. JONGHOO PARK, DUSTIN J. KREFT, ROBERT H. BLICK, Department of Electrical and Computer Engineering, University of Wisconsin-Madison, WI 53706, SEUNG-HYUB BAEK, CHANG-BEOM EOM, Department of Material Science and Engineering, University of Wisconsin-Madison, WI 53706, V. VAITHYANATHAN, Department of Material Science and Engineering, Pennsylvania State University, PA 16802, DARRELL G. SCHLOM, Department of Materials Science and Engineering, Cornell University, NY 14853, VLADIMIR AKSYUK, Alcatel-Lucent Technologies, NJ 07974 — Nano-electromechanical systems (NEMS) have shown great progress and promise as sensors and actuators. In spite of great progress, efficiency and integration techniques for actuating and tuning NEMS have remained a challenge. We have employed a single crystalline piezoelectric thin film on a silicon substrate to obtain a high piezoelectric coefficient and high electromechanical coupling for a NEMS device. The suspended NEMS device consists of Pt/Pb(Mg0.33Nb0.67)O3/PbTiO3/SrRuO3/SiO2 and is clamped at the ends via silicon substrate. Pt and SrRuO3 are used as top and bottom electrodes, respectively, and SiO2 serves as a buffer layer to the silicon substrate. We have shown experimentally that the piezoelectric actuation based on PMN-PT devices consume less power and are more responsive than other NEMS devices of similar nature and size.

4:30 PM D10.00011 - Structural Study of PMN-xPT by Neutron Diffraction. D. PHELAN, P.M. GEHRING, Q. HUANG, NIST, Z.-G. YE, Simon Fraser, C. STOCK, ISIS, G. XU, J. WEN, Brookhaven — Stark differences between x-ray and neutron measurements of the structures of ferroelectric-relaxors PMN-xPT (1-x)Pb(Mg1/3Nb2/3)O3+xPbTiO3 and PZN-xPT (Z=Zn) have been reported [1]. One explanation for these differences is that these crystals have strained surface layers on the order of several tens of µm thick, the crystal structure of which differs from that of the crystal bulk. This phenomenon may have been coined the “anomalous skin effect” but has been recently challenged [2] and thus remains controversial. We re-investigated the skin effect in PMN-xPT by considering the possibility that the oxygen stoichiometry might play a role. Two sets of powders (x=0.1, 0.2, 0.3, and 0.4) were grown, one with and one without oxygen annealing, and high resolution neutron powder diffraction measurements were carried out for both sets. For a given x, both sets of powders have the same structural phase, suggesting that the effects of oxygen annealing are minimal. For x=0.1 and x=0.2 both sets of powders are rhombohedral, which contrasts with the single crystal neutron neutron diffraction measurements. This supports a skin effect in that the grain size of the powders is small enough that the Bragg peaks are dominated by the strained surface layer. References [1] G. Xu et al., Phase Transitions 79, 135 (2006) [2] E. H. Kisi and J.S. Forrester, J. Phys.:Condens. Matter 17, L381 (2005)

4:42 PM D10.00012 - Complex local structures in lead based pervoskite relaxors. GUANGYONG XU, ZHU XIU, JINSHE WEN, Brookhaven National Lab, PETER GEHRING, NIST, CHRIS STOCK, RAL, U.K. — The lead-based, pervoskite relaxors Pb(Zn1/3Nb2/3)O3 (PZN), Pb(Mg1/3Nb2/3)O3 (PMN) and their solid solutions with PbTiO3 (PT) continue to receive significant attention because they exhibit huge piezoelectric responses and are therefore technologically important. It is widely accepted that many of the special properties of relaxors are related to local (charge, chemical, and polar) order. In particular, short-range polar order, a.k.a. “polar nano-regions” (PNR), is believed to appear in relaxors at temperatures well above the Curie temperature Tc. The PNR contribute to the frequency dispersion of the dielectric properties and have recently been suggested to be associated with the high piezoelectric response. We have performed series of neutron diffuse scattering measurements on PMN-xPT and PZN-xPT single crystals. Our results indicate that the local polar structure is complicated, having T1 and T2-type components with different polarizations. In particular, the T1 component with [001] polarization can be partially suppressed by an [001] field, the T2 component with [110] polarization can be affected by a [111] field. The T2 component also exhibits a strong coupling to the acoustic phonon while the T1 component is associated with the polar optic phonon. We will discuss the complex nature of the local structure in relaxors and their implications.

4:54 PM D10.00013 - First-Principles Study of Diffuse Scattering in Pb(SC1/2Nd1/2)O3. P. GANESH, M. AHART, R.E. COHEN, Geophysical Laboratory, Carnegie Institute of Washington, E. COCKAYNE, B. BURTON, Materials Science and Engineering Laboratory, NIST — Recent X-ray and neutron experiments show diffuse scattering with characteristic butterfly and rod shapes in relaxor ferroelectrics Pb(SC1/2Nd1/2)O3 (PSN) and Pb(Zn1/3Nb2/3)O3 (PZN) [1]. We have simulated diffuse scattering in PSN using first-principles based simulations in the ferroelectric, relaxor and the paraelectric phases [2]. The model assumes quenched chemical order in the form of chemically ordered regions in a chemically disordered matrix. Below the Burns temperature, polar nanoregions (PNR) form, pinned spatially to the COR, but whose polarization evolve dynamically. In the relaxor phase we find “butterfly” shaped diffuse scattering around the [100] peaks and around the [110] peaks we find “rod” shaped diffuse scattering similar to experiments. As the system is driven towards the paraelectric phase, the diffuse patterns around all the Bragg peaks display radial streaks elongated towards the origin. We have determined that the rods and butterflies below the Burns temperature originate from the PNR, while the radial streaks above it arise from atomic displacements associated with chemical disorder. References: [1] G. Xu, Z. Zhong, H. Hiroka and G. Shirane, Phys. Rev. B, 70, 174109 (2004) [2] S. Tinte, B. P. Burton, E. Cockayne and U. V. Waghmare, Phys. Rev. Lett. 97, 137601 (2006)

5:06 PM D10.00014 - High-pressure x-ray diffraction and Raman scattering studies of Pb(Mg1/3Nb2/3)O3-xPbTiO3. MUKHTAR AHART, MADDURY SOMAYAZULU, RONALD COHEN, RUSSELL HEMLEY, Geophysical Laboratory, Carnegie Institution of Washington — Motivated to determine and understand the compositional-pressure phase diagram for PMN-xPT solid solutions, we employed the angular dispersive x-ray diffraction methods (Advanced Photon Source, Argonne National Laboratory) and high pressure Raman scattering to investigate a series of PMN-xPT solid solutions (x=0.2, 0.3, 0.33, 0.37, 0.4) in a diamond anvil cell up to 20 GPa. The x-ray diffraction results show changes in Bragg peaks at about 6 or 7 GPa which indicate that PMN-xPT systems undergo a ferroelectric to a paraelectric phase transition. In addition, a new peak centered at 380 cm-1 appears above 6 GPa for all the samples. The morphotropic phase boundary (x=0.33 to 0.37) with the monoclinic symmetry persists up to 7 GPa. Based on our results, we propose a possible structure for high pressure phase, which is R3c. We suggest a phase diagram for PMN-xPT system which is slightly different from the one predicted by B. Chaubane et al (Phys. Rev. B 70, 134114, 2004).

5:18 PM D10.00015 - Molecular dynamics computational studies of relaxor ferroelectric behavior in Pb(Mg1/4Ti1/4Nb1/2)O3 (PMN-PT). HIROYUKI TAKENAKA, ILYA GRINBERG, ANDREW RAPPE — Relaxor ferroelectrics are of fundamental scientific interest and are also used in a variety of applications, such as piezoelectric transducers and capacitors. They exhibit permittivity peaks that are broad with respect to both temperature and frequency. We have developed a bond-valence model for Pb(Mg1/4Ti1/4Nb1/2)O3 (PMN-PT) and performed atomistic bond-valence molecular dynamics (BVMD) simulations of PMN-PT. We have studied relaxor behavior at a range of temperatures, in order to analyze polar nanoregion dynamics and relaxation lifetimes. We find that even for a fairly small simulation size of 6×6×6 supercell (1080 atoms), the system exhibits frequency dispersion. We present the results of 6×6×6, 8×8×8 and 10×10×10 supercell BVMD simulations, analyze the pair distribution function of the PMN-PT and elucidate the local chemical origin of relaxor behavior.
2:30PM D11.00001 Robust Ferromagnetism in type-II (ZnMn)Te Quantum Dots . I.R. SELLERS1, V.R. WHITESIDE, M. EGINLIGIL, R. OSZWALDOWSKI, I. ZUTIC, A. PETROU, B.D. MCCOMBE, University at Buffalo, W.C. CHOU, National Chiao Tung University, Taiwan — Temperature dependant magneto-photoluminescence studies of type-II diluted magnetic semiconductor (ZnMn)Te/ZnSe quantum dots (QDs) will be presented. As expected, the exchange interaction between the Mn spins and charge carriers results in a strong optical polarization of the luminescence at low temperature in a magnetic field. In addition, however, a zero magnetic field optical polarization degree of 7% is observed in the photoluminescence (PL). This polarization is shown to be independent of temperature until 180 K, and is only quenched by the loss of PL intensity as the type-II QDs are ionized. In this submission, we will present continuous wave and temporal PL measurements which indicate that the finite polarization, at zero magnetic field results from the formation of excition magno polarons (EMPs). Furthermore, we will show that these EMPs are remarkably robust with binding energies in excess of 40 meV, far larger than typical of the widely studied EMP system. The origin of this behavior will be discussed. Work supported in part by CSEQuIn and the Office of the Provost at the U. Buffalo.

2:42PM D11.00002 Low threshold amplified spontaneous emission and Auger recombination suppression in giant nanocrystal quantum dots . ISTVAN ROBEL, FLORENCIO GARCIA-SANTAMARIA, RICHARD D. SCHALLER, YONGFEN CHEN, JENNIFER A. HOLLINGSWORTH, VICTOR I. KLIMOV, Chemistry Division, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — Nanocrystal quantum dots (QDs) are attractive materials for various light-emitting applications including optical amplification and lasing. A complication associated with the multiexciton nature of light amplification is NQDs is the picosecond optical-gain decay induced by nonradiative Auger recombination, in which one exciton recombinates by transferring the energy to the other. Here, we present new results on a novel type of nanocrystals dubbed “giant” quantum dots (g-QNDS). These g-QNDS comprise an emitting core particle of CdSe overcoated with a thick shell (up to 20 monolayers) of wider-gap CdS. We report that biection and gain lifetimes are greatly augmented and the ASE threshold drops down to just a few μJ/cm2. We explain this result by a significant increase in the absorption cross-section of g-QNDS compared to traditional nanocrystals and lengthening of biection lifetimes. We also observe other unusual optical-gain behaviors for these structures such as multi-band ASE, the spectra spectral range of optical amplification extends over more than 500 meV. These results demonstrate that g-QNDS are very promising materials for applications in practical lasing technologies.

2:54PM D11.00003 Investigation of group-III-nitride semiconductor nanostructures using an eight-band k · p formalism . OLIVER MARQUARDT, TILMANN HICKEL, JOERG NEUGEBAUER, Max-Planck-Institut fuer Eisenforschung — Despite its approximative nature, the k · p formalism provides a numerically efficient and accurate description of the electronic structure of group-III nitride semiconductor nanostructures with characteristic size of a few nanometers. [1] With the computational effort of this method being independent of the system size, it is possible to study an extensive set of zero-, one- and two-dimensional nanostructures. We applied a plane-wave implementation of the 8-band k · p formalism and second-order continuum elasticity theory to various III-nitride nanostructures such as InGaN/GaN or GaN/AlN quantum dots in the characteristic wurtzite and zincblende crystal structures. We investigated the effect of strain and polarization effects on the charge carrier localization which typically leads to a spatial separation of electrons and holes in wurtzite nanostructures. Additionally, studies have been performed in order to evaluate trends when varying the alloy composition in InGaN/GaN nanostructures in order to understand light emission processes in realistic nanostructures.

3:06PM D11.00004 Infrared Photodetectors based on PbSe and PbS Nanoparticles . DON-HYUNG HA, University of Pennsylvania, Department of Materials Science and Engineering, CHRISTOPHER MURRAY, University of Pennsylvania, Department of Chemistry and Materials Science and Engineering — There is growing interest in developing nanoparticles for photodetectors, due to the potential to selectively tune the wavelengths detected by varying the size of the nanoparticles. Also, by virtue of the solution processibility of nanoparticles, photodetectors based on nanoparticles provide a low cost, easily processed opportunity for photodetection on flexible substrates. Especially for the near-infrared (NIR) region, PbS and PbSe nanoparticles are ideal candidates since their absorption windows fall between 900-1500nm and 1400-2500nm, respectively, covering a wide range of the IR region. This presentation reports the synthesis, structural characterization, and photoconductivity of colloidal PbSe and PbS nanoparticles. Photocurrent and normalized detectivity are measured from the nanoparticle photodiode under the illumination of NIR light (800-2500 nm) and under dark conditions.

3:18PM D11.00005 Single photon to single electron conversion using a quantum dot . HARUKI KIYAMA, TAKAFUMI FUJITA, Department of Applied Physics & QPEC, the University of Tokyo, TETSUYA ASAYAMA, Advanced Materials Laboratories, Sony Corporation, AKIRA OIWA, SEIGO TARUCHA, Department of Applied Physics & QPEC, the University of Tokyo — Photons, and electron spins are leading candidates for implementing quibits useful in information transmission, and computing, respectively. Therefore, quantum media conversion (QMD) between them is a key technology for a comprehensive quantum network. In this work, as a first step toward QMD, we demonstrate single photon to single electron (charge) conversion using a GaAs based lateral QD equipped with a quantum point contact (QPC) as a charge sensor. A distinctive step, which is quite similar to those observed for single electron tunneling onto the QD from the leads, is observed in the single-shot time evolution of the QPC current immediately after the incidence of single photons. From detailed measurements of the light intensity dependence and the QD-lead tunnel rate dependence we confirm that the observed steps are due to single photon generation in the QD just after single photon irradiation. The minimum time resolution of this single photon to single electron conversion is 50 μs. This is short enough to demonstrate the angular momentum transfer between photon polarization and electron spin in the QD as the next step.

3:30PM D11.00006 Scalable Single Photon Detector for Terahertz and Infrared Applications . BERNARD MATIS, DONG HO WU, Naval Research Laboratory — Recent advancements in the research areas of quantum dot (QD) and single electron transistors (SET) open up an exciting opportunity for the development of nanostructure devices. Of the various devices, our attention is drawn in particular to detectors, which can respond to a single photon over a broad frequency spectrum, namely, microwave to infrared (IR) frequencies. Here we report on transport measurements of parallel quantum dots, fabricated on a GaAs/AlGaAs 2-dimensional electron gas (2DEG) substrate, under the influence of external fields associated with 110GHz and 1 THz signals. We further investigate the scalability of our detector in addition to its temperature dependence up to 4.2K. We will discuss experimental results, and their dependence on quantum dot size, and fabrication techniques, as well as the limitations in developing a QD photon detector for microwave and IR frequencies, whose noise equivalent power can be as high as 10⁻²² W/Hz¹/².

3:42PM D11.00007 Measurement of the separation dependence of the resonant energy transfer between CdSe nanocrystallite quantum dots . FARBOD SHAFIEI, RICARDO S. DECCA, Indiana University-Purdue University Indianapolis — An apparatus has been built to study the separation dependence of the interaction between small and large resonant groups of CdSe/ZnS nanocrystallite quantum dots (NQDs). A near-field scanning optical microscope (NSOM) is used to bring a group of mono-disperse 6 nm dots close (near-field range) to an 8 nm group of dots which are deposited on a solid immersion lens. Combination of spectral and positional filtering allows us to measure the interaction between small numbers of NQDs, with the ultimate goal of identifying the interaction between individual dots. Quenching of the small NQDs photoluminescence signal yields the transition probability between these two groups of NQDs which is obtained to be (4.5×10⁻²⁷ m⁶/γ/R⁵), matching the theoretical calculation. Förster radius as a signature of energy transfer efficiency is extracted from experimental data to be 17 nm. Separation between two groups of the NQDs was increasing up to 40nm during the experiment.
Resonant excitation in coupled InAs/GaAs quantum dots.

3:54PM D11.00008 Resonant creation of a positive trion in coupled InAs/GaAs quantum dots.

SWATI RAMANATHAN, KUSHAL C. WIJESUNDARA, MAURICIO GARRIDO, ERIC A. STINAFF, Department of Physics and Astronomy, Ohio University, A. S. BRACKER, D. GAMMON, Naval Research Laboratory — Recent photoluminescence excitation (PLE) experiments have revealed the unexpected resonant creation of a positive trion in a coupled InAs/GaAs quantum dot system. Positive trion creation is a two photon process requiring the second photon to have a different energy from the first due to the presence of the photogenerated hole. This leads us to conclude that the positive trion may be created through two indirect absorptions, along with two tunneling events. To verify this scenario, experiments using circularly polarized excitation should result in hole spin states with either spin -3/2 or +3/2. This should lead to Pauli blocking of spins, resulting in a reduced intensity of positive trion emission under excitation with circularly polarized light when compared to unpolarized light. High resolution PLE will also provide additional insight into the details of this mechanism. It may be possible to use resonant excitation processes such as this to create defined hole spin states in coupled quantum dot systems.

4:06PM D11.00009 Exchange interactions in coupled quantum dots observed through polarized photoluminescence.

KUSHAL C. WIJESUNDARA, MAURICIO GARRIDO, SWATI RAMANATHAN, ERIC STINAFF, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, OH 45701, USA, ALLAN BRACKER, D. GAMMON, Naval Research Laboratory, Washington, DC 20375, USA — Identification and manipulation of the exchange interaction between different spin configurations may be useful for implementing quantum logic operations. Coupled quantum dots offer the possibility of controlling the exchange interaction by continuously tuning between direct and indirect excitonic configurations. The effect of the anisotropic part of the exchange energy was clearly identified from polarization dependent photoluminescence (PL) results arising from the direct and indirect configurations of the neutral exciton. We also observe direct experimental evidence of the isotropic exchange interaction via PL measurements from positive trion configurations. The isotropic exchange interactions observed to be an order of magnitude larger than the anisotropic splitting as expected. High resolution measurements of these charged exciton configurations are expected to reveal additional insight into the details of the exchange interaction.

4:18PM D11.00010 Hybrid Exciton in a Semiconductor Nanorod Coated By an Organic Shell.

DANIEL VELAZQUEZ, HUONG NGUYEN, Marshall University — We study the Wannier Mott-Frenkel hybrid exciton in a nanorod coated by a thin organic shell. Using the wavefunctions of the 1D Wannier-Mott and the Frenkel exciton, we obtain the wavefunctions and energy of the hybridization state. The new exciton state is a linear combination of the basic exciton states and is smoothly distributed over the whole system. The hybridization depends strongly on the coupling (hybridization) parameter as well as the shape of the nanorod and the thickness of the organic layer.

We also observed that there exists a threshold pump laser power which separates the linear and super-linear regions. The effective pump power can be as low as demonstrated to increase as the lengths of nanowire segments decreases. As far as the relationship between Raman scattering intensity and laser pump power, we believe our observation suggests the possibility to make a new type of SRS semiconductor laser.

This work is supported by NSF NIRT, grant DMR-0304178.

4:30PM D11.00011 Stimulated Raman Scattering from Short GaP Nanowires.

JIAN WU, AWNISH GUPTA, PETER EKLU ND, DEPARTMENT OF PHYSICS TEAM, DEPARTMENT OF MATTERIAL SCIENCE AND ENGINEERING TEAM — We report an interesting discovery of very strong non-linear optical behavior in short GaP nanowire segments. They were formed by cutting a ~40 µm long and 210 nm diameter GaP nanowire into various lengths using a focused ion beam. This approach allows us to study length as the variable in the non-linear behavior. A giant nonlinear Raman amplification has been observed in these segments with length L < 1.2µm for the first time. The nonlinear Raman effect has been demonstrated to increase as the lengths of nanowire segments decreases. As far as the relation between Raman scattering intensity and laser pump power, we also observed that there exists a threshold pump laser power which separates the linear and super-linear regions. The effective pump power can be as low as 200 µW that is 1000 times smaller than bulk values. We attribute this giant nonlinear Raman effect to stimulated Raman scattering (SRS) from nanocavities formed by these short GaP nanowires. The quality factor Q of these short segments was estimated to be 10^3 to 10^4. We believe our observation suggests the possibility to make a new type of SRS semiconductor laser.

4:42PM D11.00012 Polarized Rayleigh and Raman Study of single CuO Nanowire.

QIUJIE LU, JIAN WU, HUMBERTO GUTIERREZ, TIMOTHY RUS S, Department of Physics, The Pennsylvania State University, PETER EKLU ND, Department of Physics and Department of Material Sciences, The Pennsylvania State University — Crystalline CuO is an interesting Ferroelectric and Ferromagnetic system which we have recently grown in nanowire (NW) form. In this paper, we present results of Raman and Rayleigh scattering studies of individual CuO NWs to probe optical antenna effects that we first discovered in GaP NWs. We have shown that these antenna effects can, in general, strongly mask Raman selection rules in semiconducting nanowires[1]. Using a microRaman spectrometer, polarized light scattering experiments (backscattering geometry) were carried on NWs suspended over holes in a TEM grid. TEM images were used to identify the NW diameters. As a function of the angle θ between the NW axis and the incident laser field, we collect the Rayleigh scattering intensity as well as the Raman LO and TO optical phonon scattering intensity. These results can then be used to quantify the optical antenna effects in the CuO system. NWs of different diameters, from 70nm to 200 nm were studied; the results depend dramatically on the NW diameter. Our results will be compared to EM calculations based on the DDA approximation. This work is supported by NSF NIRT, grant DMR-0304178. [1] Chen G. Jian Wu, etc., Nano Lett. 2008 Vol.8 pp. 1341-1346.

4:54PM D11.00013 Polarized Rayleigh and Raman Back-scattering from Individual GaP Nanowires.

DUMING ZHANG, JIAN WU, QIUJIE LU, HUMBERTO GUTIERREZ, PETER EKLU ND, Department of Physics, The Pennsylvania State University — Results of polarized Rayleigh and Raman back-scattering studies are reported for individual ~20 µm long crystalline GaP Nanowires (NWs) using 514.5 nm excitation. The NWs were supported over holes in TEM grids. The diameters and growth directions of the NWs were thereby determined by TEM and the samples were studied optically. Peak positions of LO, TO phonon bands were found to agree with bulk GaP. Both the Rayleigh and Raman back-scattering intensity polar patterns I(θ) were measured at room temperature, where θ is the angle between the incident electric field and the NW axis. The scattered radiation was polarized parallel to the incident electric field. From the Rayleigh back-scattering intensity polar patterns, the factor in the scattered radiation was obtained. Together with the Raman tensor determined from the growth direction of the NWs, the Raman back-scattering intensity polar pattern was calculated for each case and correlated with the experimental data. Our measurement on the Rayleigh and Raman back-scattering intensity polar patterns revealed different patterns ranging from dipole-like to symmetric (circular or elliptical) depending on the NWs growth directions and diameters. This work is supported by NSF NIRT, grant DMR-0304178.

WO SEOK CHOI, SOON JAE MOON, Seoul National University, HIROMICHI OHTA, Nagoya University, BYUNG CHEOL JEON, JONG HOON SHIN, Seoul National University, YUN SANG LEE, Soongsil University, TAE WON NOH, Seoul National University — Recently, oxide heterostructures are being extensively investigated as an effort to understand unusual physics occurring at the oxide interfaces. For example, formation of 2DEG or strongly modified electronic structures at the interface between two different oxide constituents have been examined carefully and understood to some extent. In this contribution, we studied the electronic properties and phonon dynamics of Nb:SnTiO$_3$/SrTiO$_3$ superlattices. Using optical spectroscopy, we obtained the optical conductivity for a wide range of photon energy (3.7 meV – 6 ev). We could separately identify the free carrier response and the phonon dynamics of the superlattice. The carrier density and unusually small scattering rate were obtained varying temperature as well as the superlattice period. In addition, we could reveal a strong electron-phonon coupling from the existence of the spectral weight in mid-IR photon range.

This work is supported by NSF NIRT, grant DMR-0304178.
5:18PM D11.00015 Effect of Magnetic Field on Broadening of Excitonic Spectra in Superlattices1. YURI KHAVIN, NIKOLAI SIBELDIN, MIKHAIL SKORIKOV, VITALY TVSETKOV, P.N. Lebedev Physical Institute, RAS, Moscow, Russia, DANIEL OBERLI, ALOK RUDRA, ROMAIN CARRON, ELI KAPON, Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland — We present a comprehensive study of optical properties of GaAs/AlGaAs superlattices (SLs) with different tunneling coupling between wells in magnetic fields in a wide range of excitation levels. Photoluminescence (PL) and PL excitation spectra demonstrate significant broadening of the exciton lines with increasing excitation power. Several features indicate that the exciton line widths are mainly determined by excitonic scattering. In particular, in zero magnetic field, the heavy hole (hh) PL line broadens symmetrically with increasing excitation power. In nonzero in-plane magnetic field, the exciton binding energy strongly increases (by a factor of 2 in 14 T), and the dependence of the line width on excitation power becomes much weaker. In strong in-plane fields, significant shift of the hh PL line towards lower energies is observed under high excitation levels. It is possible that this shift is a manifestation of interparticle interactions in an electron-hole system.

2:30PM D12.00001 A Combined Scanning Tunneling Microscope-Quartz Crystal Microbalance Investigation of Heating and Liquid-Like Behavior at a Sliding Interface1. BENJAMIN DAWSON, JACQUELINE KRIM, North Carolina State University — The unique capabilities resulting from combining a scanning tunneling microscope and a quartz crystal microbalance have been used to characterize the heating and wear at the interface of a tungsten tip and an Indium substrate, with a change in the contact characteristics of the interface occurring for sufficient sliding speeds. The advantage of this system is the ability to probe subtle changes of a rubbing asperity contact, which will aid in developing a more complete understanding of the complex issue of heat generated via friction.

1This work funded by the AFOSR Extreme Friction MURI Grant FA9550-04-1-0381.

2:42PM D12.00002 Dynamics and Spreading of pentanol and other alcohols for MEMS applications1. BRENDAH MILLER, DAVID HOOK, JACQUELINE KRIM, North Carolina State University — Microelectromechanical Systems (MEMS) have the potential to revolutionize widespread technologies, but tribological issues are currently preventing commercialization of some devices. Self-assembled monolayers (SAMs), while highly effective against release related stiction, are ineffective as MEMS lubricants [1]. Vapor phase lubrication has been proposed as a solution to the issue of tribological failure in MEMS with alcohol vapors attracting much interest. In an effort to understand the basic mechanisms of lubrication we have performed a quartz crystal microbalance (QCM) study of the uptake, sliding friction, and spreading rates of adsorbed alcohols on silicon and SAM treated substrates. [1] D. A. Hook, S. J. Timpe, M. T. Dugger, and J. Krim. Tribological degradation of fluorocarbon coated silicon microdevice surfaces in normal and sliding contact. J. Applied Physics 104 (2008).

2:54PM D12.00003 Numerical Studies of Friction Between Metallic Surfaces and of its Dependence on Electric Currents1. EVANGELOS MEINTANIS, MICHAEL MARDER, Center for Nonlinear Dynamics, The University of Texas at Austin — We will present molecular dynamics simulations that explore the frictional mechanisms between clean metallic surfaces. We employ the HOLA molecular dynamics code to run slider-on-block experiments. Both objects are allowed to evolve freely. We recover realistic coefficients of friction and verify the importance of cold-welding and plastic deformations in dry sliding friction. We also find that plastic deformations can significantly affect both objects, despite a difference in hardness. Metallic contacts have significant technological applications in the transmission of electric currents. To explore the effects of the latter to sliding, we had to integrate an electrodynamics solver into the molecular dynamics code. The disparate time scales involved posed a challenge, but we have developed an efficient scheme for such an integration. A limited electrodynamics solver has been implemented and we are currently exploring the effects of current in the friction and wear of metallic contacts.

1Funded by the Institute for Advanced Technology at The University of Texas at Austin.

3:06PM D12.00004 Combined conducting atomic force/scanning Kelvin probe microscope for investigating charge trapping on semiconductor surfaces. JAMES MOORE, SEAN KENNY, Longwood University, MONIKA RUCHALA, MIKHAIL RESCHCHIKOV, ALISON BASKI, Virginia Commonwealth University — A novel combination of conducting atomic force microscopy (CAFM) and scanning Kelvin probe microscopy (SKPM) was used to investigate charge trapping and transfer on semiconductor surfaces. CAFM is first used to locally inject charge at an oxide/semiconductor interface, and then SKPM is performed to monitor the evolution of the resulting surface potential. In a dark environment, the additionally charged interface states due to CAFM charge injection result in additional band bending that persists for hours in GaN, ZnO and Si. Specifically for GaN, a model based on a tunneling mechanism was used to describe the CAFM charge injection, where electrons travel from the tip through an oxide barrier and become trapped at the interface. The decrease in induced band bending with time shows a logarithmic behavior, similar to transients produced after exposure to light. This combination of techniques offers a relatively simple method for investigating induced band bending on semiconductor surfaces and could become a useful tool for understanding concentrations of charged surface states. Specifically, current collapse in GaN FETs and HFETs has been linked to concentrations of charged surface states at the contacts.

3:18PM D12.00005 Hot Electron Transport Properties of Thin Copper Films Using Ballistic Electron Emission Microscopy, J.J. GARRAMONE, J.R. ABEL, I.L. SITNITSKY, University at Albany, L. ZHAO, I. APPELBAUM, University of Delaware, V.P. LABELLA, University at Albany — Copper is widely used material for electrical interconnects within integrated circuits and recently as a base layer for hot electron spin injection and readout into silicon. Integral to both their applications is the knowledge of the electron scattering length. To the best of our knowledge, little work exists that directly measures the scattering length of electrons in copper. In this study we used ballistic electron emission microscopy (BEEM) to measure the hot electron attenuation length of copper thin films deposited on Si(001). BEEM is a three terminal scanning tunneling microscopy (STM) based technique that can measure transport and Schottky heights of metal/semiconductor systems. We find a Schottky height of 0.67 eV and an attenuation length approaching 40 nm above the Schottky height at 77 K. We also measure a decrease in the attenuation length with increasing tip bias to determine the relative roles of inelastic and elastic scattering.
3:30PM D12.00006 A Comparative Study of Au-Au, Ru-Ru and RuO\textsubscript{2}-Au RF MEMS Contacts in Controlled Vacuum Environments\textsuperscript{1}, MATTHEW WALKER, J. KRIM, N. MCGRUER, North Carolina State University — We have constructed an UHV system with in situ oxygen plasma cleaning capabilities in order to observe the impact of film contamination in reproducible conditions. We have performed measurements to allow comparison of soft, hard and combined soft-hard contacts. All switches are closed before applying a potential across the contacts to minimize e-field evaporation and material transfer between contacts. Prior to, and for short O2 plasma exposure times, the initial contact resistance measurements had larger variations. With longer O2 plasma exposure times initial and extrapolation resistances measurements converged. These results are consistent with prior reports, which showed that the oxide layer on a Ru surface thickens with exposure to O2 plasma \cite{1}. Therefore, under stringent experimental conditions, we have demonstrated that operating RF MEMS contacts are comparable to those studied in the surface science literature. \cite{1} Y. Iwasaki, A. Izumi, H. Tsurumaki, A. Namki, H. Oizumi, I. Nishiyama, Appl. Surf. Sci. 253, 2007

3:42PM D12.00007 Reduction of Barrier Height at Close Proximity between two Gold (111) surfaces.\textsuperscript{1}, YOSHIHIKO KURIYAMA, TOKYO Institute of Technology — Work function is one of important physical properties in order to understand electron emission or chemical reactions such as catalysis. Work function changes locally depending on a defect, step or adsorbate on the surface. A scanning tunneling microscope (STM) is one of powerful tools to investigate such a local work function, which is called a local barrier height. In this method, the barrier height is defined as $\phi = (1/1.025 \times \ln(G/dz)^2$, where G is conductance and z, the tip-surface distance. Experimentally, the barrier height has been reported to be constant independent of the distance. But, theoretically, it is suggested to be reduced at close proximity. In this study, we investigated the distance between two gold (111) surfaces in TEM observation simultaneously with measuring conductance value in a process of approaching each other. The distance changes controllably by a piezo actuator when it is above 1 nm, but the distance becomes narrower that the expected value obtained by a piezo actuator when it is below 1 nm. Obviously, structural relaxation is occurred when the distance between two gold surfaces is below 1 nm. Taking the structural relaxation into an account, we confirm that the barrier height is reduced at close proximity of two gold (111) surfaces. \textsuperscript{1}PRESTO-JST

3:54PM D12.00008 Coherent X-ray Surface Diffraction: Speckle from the Surface Reconstruction Layer of Gold (001), MICHAEL S. PIERCE, KEE-CHUL CHANG, DANIEL HENNESSY, Argonne National Laboratory, Materials Science Division, ALEC SANDY, MICHAEL SPRUNG\textsuperscript{1}, Argonne National Laboratory, Advanced Photon Source, HOYDOO YOU, Argonne National Laboratory, Materials Science Division — We present preliminary results of the first coherent x-ray diffraction from an atomic monolayer surface reconstruction and demonstrate how this technique is capable of providing new information about surface dynamics. Speckled scattered patterns were successfully collected from ordered surface atoms on Au (001) crystals in high vacuum. We have collected data at the (001) anti-Bragg point as well as coherent scattering data directly from the in-plane hex reconstruction peak. These two points can provide complementary information about in-plane and out-of-plane surface dynamics. Below 1050 K, the system appears to remain in equilibrium maintaining a small constant fraction of non-reconstructed surface for a given temperature. However we observe the speckles continue to evolve within the collected scattering patterns indicating that the non-reconstructed portion of the surface rearranges slowly. Above about 1050K, we find that the rate of speckle decorrelation rapidly increases for very small changes in temperature. Signal to noise makes this a difficult experiment with existing light sources. However we expect this technique to become easier and more broadly applicable with future X-ray sources.

4:06PM D12.00009 In-situ chemical and structural characterization via RHEED-total reflection analysis of x-rays (TRAXS).\textsuperscript{1}, SANDEEP CHANDRIL, CAMERON KEENAN, THOMAS MYERS, DAVID LEDERMAN, West Virginia University — The use of x-ray fluorescence produced inside a molecular beam epitaxy chamber by the RHEED electron gun to simultaneously characterize the thin films for thickness, roughness and the chemical composition is described. This technique requires only slight modifications to the chamber and can be a powerful tool for beam flux calibration and in-situ analysis, especially where surfaces have to be protected under vacuum and for the stoichiometry control during growth. The angular dependence of the x-ray fluorescence signal from the thin film over the substrate is analyzed using Parratt’s approach and simulating electrons’ trajectories inside the film to account for grazing angle electron beam as a source for x-rays. We have found good agreement between the experiment and the theory for the thickness and roughness estimates. Experiments for chemical composition determination are currently underway. \textsuperscript{1}This work was funded by the Office of Naval Research (Grant N00014-02-1-0974), the Air Force Office of Scientific Research (MURI grant FA9550-03-0-0330), and the National Science Foundation (CIAM-DMR grant 0502825).

4:18PM D12.00010 High Energy XRD/XRF for High-Throughput Phase Mapping of Composition Spread Thin Films\textsuperscript{1}, JOHN GREGOIRE, DARRENT DALE, ALEXANDER KAZIMIROV, MICHELE TAGE, HECTOR ABRUNA, FRANCIS DISALVO, R. BRUCE VAN DOVER, Cornell University — Analysis of thin film inorganic libraries is an increasingly popular technique for materials discovery. Due to the high throughput nature of thin film epitaxy, the high throughput nature of the x-ray beam and the high spatial resolution of x-ray fluorescence, x-ray techniques provide a powerful tool to determine the composition of thin films. As the landscape of thin film material discovery grows, the ability of x-ray techniques to provide high spatial resolution mapping for a large number of samples becomes increasingly important. We present recent progress towards high energy x-ray characterization of thin film phase purity and composition spread films. This work is supported by the Cornell Fuel Cell Institute (DOE award DE-FG02-03ER46072) and the Cornell High Energy Synchrotron Source (NSF award DMR-025180).

4:30PM D12.00011 Low Energy Electron Microscope Imaging of Doped Si Structures Buried under Thermal Oxides\textsuperscript{1}, GARY KELLOGG, MEREDITH ANDERSON, CRAIG NAKAKURA, Sandia National Laboratories — We present recent progress towards low energy electron microscope (LEEM) imaging of doped-silicon, diode test structures buried under thermally grown oxides. The question addressed here is whether the observed contrast at incident electron energies just above the vacuum cutoff is due to differences in doping type or oxide thicknesses. To circumvent complications arising from charging of the when exposed to the imaging electron beam, we developed a method to measure “pre-charging” current voltage (IV) curves and applied it to three test samples with oxide thicknesses varying from 2.8 to 50 nm. The vacuum cutoff energies obtained from the IV curves depend on both doping type and oxide thickness and are strongly influenced by external factors including surface contamination and UV exposure. The time dependence of the oxide charging increases significantly with oxide thickness providing further insights into the origins of LEEM contrast.

\textsuperscript{1}Sandia is operated by Sandia Corporation, a Lockheed Martin Company, for the U.S. DOE’s NNSA under Contract No. DE-AC04-94AL85000.
4:42PM D12.00012 LEED structural analysis of strongly correlated systems: reaching the limit of the instrumentation?  
Teyu Chienn, Biao Hu, Dept. of Physics & Astronomy, U. of TN, Knoxville, Shuheng Pan, Dept. of Physics, U. of Houston, V. Braun Nascimento, E. Ward Plummer, Dept. of Physics & Astronomy, LSU — In strongly correlated systems, like transition-metal oxides and the Iron Pnictides, subtle changes in structural parameters can cause dramatic changes in the physical properties. Breaking the symmetry by creating a surface is a controlled way to explore the structure-functionality relationship. Low Energy Electron Diffraction (LEED) I – V has been one of the most used surface structural techniques, but there are inherent and instrumental limitations which will be discussed using data from surfaces of transition-metal compounds. Using CCD cameras and new data analysis three dimensional plots of diffraction vs parallel momentum can be created. Spot intensity, width, position, and profile, as well as the diffuse background can then be quantitatively extracted and evaluated. We will show how to couple the STM with LEED using data from the parent superconducting compound BaFe2As2. The inherent limitations of the existing system are tested using Cu(100).

4:54PM D12.00013 Electron emission from surfaces resulting from low energy positron bombardment1, S. Mukherjee, K. Shastry, A. H. Weiss, U. Texas at Arlington — Measurements of the energy distribution of electrons resulting from very low energy positron bombardment of a polycrystalline Au and Cu(100) surfaces provide evidence for a single step transition from an unbound scattering state to an image potential bound state. The primary positron energy threshold for secondary electron emission and cutoff in the secondary electron energy spectra are consistent with a process in which an incident positrons make a transition from a scattering state to a surface-image potential bound while transferring all of the energy difference to an outgoing secondary electron. Estimates of the probability of this process as a function of incident positron energy are also presented. Background free Auger spectra of the MVV transition in Cu and the OVV transition in Au were obtained by setting the incident positron beam energy below the secondary electron emission threshold. Auger electron emission resulted from the annihilation of surface state positrons with core electrons. The low energy tail associated with the low energy CVV Auger transitions in Cu and Au were found to have integrated intensity several times larger than Auger peak providing strong evidence for multi-electron Auger processes.

5:06PM D12.00014 Hydrogen absorption by a Pd film detected by microgravimetry1, J.J. Avila, R. Trabol, U.G. Volkmann, A.L. Cabrera, Pontificia Universidad Catolica de Chile, C. Romero, P. Lievens, Katholieke Universiteit Leuven — A thin film of palladium (200 Å) was e-beam evaporated onto a quartz crystal used in a SQM-160 Microbalance from Sigma Instruments. The crystal was then successively exposed to different hydrogen pressures, in situ, and the change in the resonant frequency was recorded as a function of time. Hydrogen absorption by the Pd film can be obtained by the shift of the resonant frequency upon hydrogenation at different pressures. A 14 Hz shift is obtained when the Pd film is saturated with hydrogen at 10 Torr of pressure. The different faces of the Pd-H system are observed with this technique.

5:18PM D12.00015 Observation of In Plane Magnetization Reversal Using Polarization Dependent Magnetooptical Kerr Effect, Hendrik Ohldag, Stanford Synchrotron Radiation Lightsource, Menlo Park, CA USA, Franz Hillebrecht, Institute for Solid State Research, Juelich Germany — We present an experimental setup for in plane two axis magnetometry by employing the polarization dependence of the magnetooptical Kerr effect. (MOKE). The proposed approach allows for observing the complete in plane reversal process during a hysteresis loop. For this purpose a conventional setup to measure longitudinal MOKE with crossed polarizers is extended by a Faraday cell to compensate for the rotation of the polarization vector caused by the magnetized sample. This detection scheme enables us to observe hysteresis loops of single monolayer. Using a Jones matrix formalism we are able derive expressions for the Kerr rotation using oblique incident polarization, allowing for extracting 2-dimensional vectorial information about the magnetization reversal process in the plane of the sample surface. The approach can be further extended to extract all three components of the magnetization by acquiring more than two loops. Since this setup does not require to change the sample geometry in situ it can be easily attached to an existing ultra high vacuum setup.

Monday, March 16, 2009 2:30PM - 5:30PM  
Session D13 SPS Undergraduate Research II 309

2:30PM D13.00001 SESSION BREAK –

2:42PM D13.00002 Phase measurements on a subwavelength optical metamaterial based on metallic paired strips1, Kara Maller, Thomas Jarvis, Xiaqiong Li, Dmitriy Korobkin, Gennady Shvets, Department of Physics, University of Texas at Austin, Austin TX 78712-0264, Marcelo Davanco, Xuhuai Zhang, Department of Physics, University of Michigan, Ann Arbor MI 48109-1040, Stephen R. Forrest, Department of Physics, Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor MI 48109-1040, — There is no known naturally occurring material with negative index of refraction because the electrical and magnetic resonances in naturally occurring materials do not overlap in frequency. However, artificially engineered materials, known as metamaterials, can be designed to exhibit such peculiar properties. We study a subwavelength optical metamaterial composed of paired gold strips separated by a continuous gold film. According to theoretical calculations, this structure is expected to display a negative index of refraction in the near-infrared. We perform phase measurements of the material using a polarization interferometer and a tunable femtosecond laser. The phase information of the transmitted wave at various wavelengths is used to characterize the index of refraction.

1Research is supported by NSF DMR-0747822.

2:54PM D13.00003 Undergraduate Research with Josephson Qubits: From Fabrication to Spectroscopy1, Alyssa Wilson, Jerome Mlack, Anthony Tyler, Zechariah Thraillkill, Joseph Lambert, Roberto Ramos, Drexel University — Josephson junctions are scalable solid state devices that can be used as qubits in quantum computing. In this talk we will describe the different stages involved in the fabrication, characterization and state measurement of a particular superconducting qubit known as the Josephson phase qubit. We have performed current-voltage measurements that determined the critical current of our device and produced histograms of switching currents that were needed to establish the quantum state of the junction. We will also report on the progress on microwave spectroscopy measurements involving multiple qubits coupled using on-chip capacitors. Spectroscopy reveals the various energy levels of entangled quantum states. We will discuss how physics undergraduates have contributed to this work.

1We would like to acknowledge the Wellstood Group at the University of Maryland for helpful discussions.
3:06 PM D13.00004 Degradation Studies of Polymer Blend Photovoltaics, BRIAN JOHNSON, ENAANE ALLAGOA, ROBERT THOMAS, GREG STETTLER, MARIANNE WALLIS, JUSTIN PEEL, BRIAN MCNELIS, RICHARD BARBER, Santa Clara University — We have measured the time dependence of device performance for photocells using blends containing the conjugated polymer, Poly[2-methoxy-5-(2-ethylhexyloxy)-1,4-phenylenevinylene] (MEH-PPV) with different functionalized C60 electron acceptor molecules: commercially available [6,6]-Phenyl C61 butyric acid methyl ester (PCBM) or [6,6]-Phenyl C61 butyric acid octadecyl ester (PCBO) produced in our laboratory. Performance was characterized by the maximum power output of the devices, with the time dependence typically following an exponential decay. Variations in the characteristic lifetime of the devices were observed to depend on the molar fraction of the electron acceptor molecules (calculated with respect to the MEH-PPV monomer fraction). Differences in the decay behavior between the PCBM and PCBO blends will be presented.

3:18 PM D13.00005 Coulomb Blockade I-V Characteristics in Nanowires, SARAH JOY, GUNDETA SINGHBHALLA, ARTHUR HEBARD, AMLAN BISWAS, SELMAN HERSHFIELD, University of Florida — The current-voltage (I-V) characteristics of manganite nanowires seen in an experiment closely resemble the hallmark I-V curves of the Coulomb blockade. Unlike normal Coulomb blockade curves, these curves have multiple lines instead of one, branching out from the zero current point. In order to discover an explanation for these I-V curves a simulation based on the Coulomb blockade was done for multiple junctions, because the experiments were done in a regime where multiple islands of ferromagnetic material are separated by insulating regions, as a result of intrinsic phase separation. The simulation results show I-V curves that are in good qualitative agreement with the experiment. The branching of I-V curves is due to a large change in resistance between the islands – not a change in the capacitance. Analytic work shows that the change in the junction resistance is too large to be explained by the tunneling magnetoresistance, but consistent with a change in the barrier thickness or composition. Simulations of the effect of gates show that the low voltage regime changes periodically with the gate voltage, while the high voltage regime is independent of gate voltage.

Supported by the U.F. Physics REU program

3:30 PM D13.00006 A quartz tuning fork as a force sensor for atomic force microscopy, ARTHUR IANUZZI, JULIA NEFF, JOHN TIMMERWILKE, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — We are designing and building an atomic force microscope (AFM) to characterize the surface properties of perovskite oxides in low temperature (~10K) and high magnetic field (9T) environments. We are using a quartz tuning fork as the force sensor. The z-axis displacement of a conducting AFM tip due to surface features will be detected by observing the shift in resonance frequency of the tuning fork which is attached to the tip. The conducting tip will also allow us to perform conductive atomic force microscopy. The resonance characteristics of the tuning fork element were determined in various degrees of vacuum, with and without the tip installed, and as a function of the tip’s proximity to the sample surface. We show that the high resonance frequency (~32kHz) and quality factor (~30,000) of the tuning fork makes it an extremely sensitive force detector. The apparatus has also been designed with the capability of performing magnetic force microscopy on perovskite oxides.

Supported by NSF DMR-0804452

3:42 PM D13.00007 Mossbauer Study of the xCr2O3-(1-x)α-Fe2O3 nanoparticles system, SEAN KRUPA, MONICA SORESCU, Duquesne University — The xCr2O3-(1-x)α-Fe2O3 nanoparticles system was synthesized hydrothermally for x = 0.0 to x = 0.9. Mossbauer spectroscopy was performed on the obtained samples as well as for samples subjected to thermal annealing at 550°C for one hour. At x = 0.1, the as obtained samples began showing superparamagnetism and became completely superparamagnetic after x = 0.4 concentration. The percent of the sample that was superparamagnetic increased with Cr2O3 substitution. This correlates with chromium decreasing the particle size of the powder. The thermally annealed samples appeared to have the hematite structure re-grown for concentrations x = 0.1 to x = 0.4 with the intensity of the hyperfine magnetic field decreasing with Cr2O3 concentration. For x = 0.5 to x = 0.9, the percent of superparamagnetic particles increased with Cr2O3 concentration, dominating the system by x = 0.8. This system is believed to have applications in gas sensing and catalysis.

3:54 PM D13.00008 Construction of a semiconductor laser system for magneto-optical trapping of atomic rubidium, J. AN DOUGHERTY, MICHAEL LIM, Dept. of Physics, Rowan University — We report on the construction of a semiconductor laser system to generate light for magneto-optical trapping of rubidium. A DFB laser is used as a master oscillator with rapid frequency tuning accomplished by an acousto-optic modulator in double-pass configuration. The resulting beam seeds a 0.5-W tapered semiconductor amplifier chip. We spatially mode-match the output to a polarization-maintaining, single-mode fiber using lenses and two anamorphic prism pairs. At maximum efficiency the system generates more than 100 mW of TEM00 power at the fiber output.

Supported by NSF PHY-0613659, Research Corporation C66180, and the Rowan College of Liberal Arts and Sciences

4:06 PM D13.00009 Combinatorial Synthesis of (V1−x,Crx)4GeC3 Epitaxial Films, C. E. STEINMETZ, J. R. APPLLEGATE, S. M. BENJAMIN, B. D. ADAMSON, J. D. HETTINGER, S. E. LOFLAND, Department of Physics and Astronomy, Rowan University, T. H. SCABAROZI, Department of Materials Science and Engineering, Drexel University — We report the synthesis of solid solutions of (V1−x,Crx)4GeC3 epitaxial films on single crystal Al2O3 epi-polished substrates. The materials are sputtered from four cathodes; three are powered by rf-power supplies while one is driven by a dc-power supply. The materials are co-deposited at a temperature of 900°C and we get solubility across the whole range of compositions. The substrate-film interaction creates a strain which makes the new phase energetically favorable. The surface structure was measured using atomic force microscopy revealing that the composition has little impact on this property. We found a new MAX-phase material, (V0.5Crx0.5)4GeC3, which has never been synthesized in bulk form. We report the conditions required to make these materials. In addition, electrical transport characteristics as a function of composition will be reported.

4:18 PM D13.000010 ABSTRACT WITHDRAWN —
4:30PM D13.00011 Thermodynamic Properties of Ising Spins on the Triangular Kagomé Lattice
BILIN ZHUANG, COURTNEY LANNERT, Wellesley College, Wellesley, MA 02481 — The triangular Kagomé lattice can be constructed by inserting a lattice site on each bond of the Kagomé lattice. Each unit cell contains 6 α-sites, 3 β-sites, 6 aa-bonds and 12 ab-bonds. The lattice with antiferromagnetic aa-bonds is known to exhibit geometrical frustration at low temperatures. We applied analytical methods and Monte Carlo simulations to study a system of Ising Spins on the lattice and investigated its thermodynamic properties. In particular, the heat capacity of the model exhibits interesting features based on the strength and the sign of coupling constants \( J_{ab} \) and \( J_{aa} \). In the case when the aa-interaction is antiferromagnetic, the heat capacity shows two broad peaks at \( kT/J_{ab} \approx 1.8 \) and at \( kT/J_{aa} \approx 1.8 \). In the case when the aa-interaction is ferromagnetic, the heat capacity shows a sharp peak at \( kT/J_{ab} \approx 1.9 \) and another low broad peak at around \( kT/J_{aa} \approx 1.4 \). We also studied a much simpler system of two α-trimers connected with β-sites to reproduce the thermodynamics behaviors of the more complicated triangular Kagomé lattice and to further understand the origin of its interesting properties.

4:42PM D13.00012 Monte Carlo Simulations of a 111-Ising Dipolar Model on the Hyper-
kagomé Lattice
PATRICK CARTER, Department of Physics Southern CT State University New Haven, CT, JOHN HOPKINSON, Department of Physics & Astronomy Brandon University Brandon, Manitoba, Canada, MATTHEW ENJALRAN, Department of Physics Southern CT State University New Haven, CT — Motivated by the physics of dipolar spin ice, we investigate the hyper-kagomé lattice with 111-Ising spins. The hyper-kagomé lattice can be generated by a selective removal of one site per tetrahedron of the pyrochlore lattice to yield a lattice of corner-sharing triangles. The spin-1/2 ions of Na\(_{11}\)O\(_8\) represent an experimental realization of the hyper-kagomé structure. We report preliminary results from Monte Carlo simulations of the 111-Ising dipolar hyper-kagomé model, which represents a yet to be studied disorder-free limiting case of diluted spin ice.

4:54PM D13.00013 Thermal measurements of the MAX-phase material Cr\(_2\)GeC\(_1\)
D. T. PIWOWAR, P. ABBAZIA, D. FILOMENA, D. DOROFY, M. GARZON, S. E. LOFLAND, J. D. HETTINGER, Department of Physics and Astronomy, Rowan University, T. H. SCABAROZI, Department of Materials Science and Engineering, Drexel University — We have measured the specific heat and thermal transport in bulk Cr\(_2\)GeC\(_1\) samples that have been hot-isostatically-pressed or hot pressed. We observe no difference in the results based upon the synthesis procedure. We find the low temperature specific heat is fit well by the standard expression. These measurements suggest a large density of states at the Fermi level or a large electron-phonon coupling in this material. The Debye temperature, extracted from the phonon contribution to the specific heat, is found to be 460 K, which roughly correlates with the Debye temperature extracted from the ultrasonic elastic measurements. The phonon contribution to the thermal conductivity will also be reported.

5:06PM D13.00014 ABSTRACT WITHDRAWN —

5:18PM D13.00015 Borosilicate films as permeability barriers
J. R. APPLEGATE, C. E. STEINMETZ, J. D. HETTINGER, Department of Physics and Astronomy, Rowan University, J. F. CARROLL, R. KRCHNAVEK, Department of Electrical and Computer Engineering, Rowan University — Borosilicate films have been deposited using rf-sputtering techniques from a composite target at room temperature onto polypropylene (PP), high density polyethylene(HDPE), low density polyethylene(LDPE), and polyethylene terephthalate (PETG) substrates. Films were found to be smooth, flexible, with excellent adhesion to the substrates. Repeated rolling the coated substrates on a radius of 0.5mm resulted in no discernable damage for films less than 200nm in thickness. Creasing the substrates did result in local damage. However excellent adhesion did not allow the fractured glass to come off the substrate. Heat generated during deposition only influenced the films grown on LDPE where the thermal expansion mismatch between the film and substrate induced strains caused fractures in thick films. Modifications to processing parameters allowed thick films to be grown without fractures. Permeability measurements of nitrogen resulted in significant improvements in comparison to uncoated substrates.

Monday, March 16, 2009 2:30PM - 5:30PM — Session D14 DFD: Colloids II: Structure and Rheology 315

2:30PM D14.00001 Lock and Key Colloids
STEFANO SACANNA, WILLIAM IRVINE, PAUL CHAIKIN, DAVID PINE, NYU — We demonstrate a recognition mechanism between microscopic (colloidal) particles based on a simple “lock-and-key” principle that relies only on the complementary morphology of the particles involved. The system we developed consists of charge-stabilized spherical silica colloids (keys) and specially designed polymeric particles with spherical cavities (locks). The assembly of locks with keys is driven by depletion interactions between the particles and an uncharged water-soluble polymer (poly-ethylene oxide). We show that by balancing electrostatic repulsion and depletion attraction, we induce a selective and reversible lock-and-key self-assembly. Moreover, we can design the lock and key single units to have separate functionalizable chemistries, such that the resulting composite particle (lock+key) will exhibit anisotropic surface properties.

2:42PM D14.00002 ABSTRACT WITHDRAWN —

2:54PM D14.00003 Pairwise Additivity in Colloidal Electrostatics
JASON W. MERRILL, Yale University, SUNIL K. SAINIS, Rowland Institute, ERIC R. DUFRESNE, Yale University — We present a method for measuring electrostatic and hydrodynamic interactions between colloidal particles based on observations of short-time trajectories. We use this method to explore whether forces between colloidal particles can be considered pairwise additive by comparing the force between a pair of particles to forces between groups of several particles.
3:06PM D14.00004 Structure and dynamics of suspensions of nanoparticles in nematic liquid crystals. BRIAN GETTELFINGER, GARY KOENIG, JOSE MORENO-RAZO, University of Wisconsin, JUAN HERNANDEZ-ORTIZ, Universidad Nacional de Colombia, NICHOLAS ABBOTT, JUAN DE PABLO, University of Wisconsin — A hierarchical modeling approach has been adopted to examine the structure and dynamics of nanoparticles suspended in liquid crystals. A molecular model is used to predict the defects that arise in nanoparticle assemblies, as well as their response to applied flow fields. The model is solved by resorting to a radial basis function based technique. The validity of the model and our numerical results are established by direct comparison to results from molecular dynamics simulations of nanoparticles in nematic and isotropic liquid crystals. Results for particle diffusion and aggregation at equilibrium and in flowing systems are then used to interpret our experimental data for a variety of systems.

3:18PM D14.00005 Monodisperse polymethyl methacrylate (PMMA) spheres in organic media: synthesis update, ANDREW HOLLINGSWORTH, MARK ELSesser, WILLIAM IRVINE, DAVID PINE, PAUL CHAIKIN, New York University — Since the publication of Antl, et al. [Colloids and Surfaces 17 (1986) 67–78] more than 20 years ago, several research groups in the soft condensed matter area have attempted the dispersion polymerization of sterically-stabilized PMMA particles. Most have found that success of this particular synthesis depends critically on the quality of the comb-graft stabilizer, poly(12-hydroxystearic acid)-g-PMMA. More recent work has extended the particle synthesis to include the incorporation of covalently attached, fluorescent dyes in the particle interior. Our goal has been to reproduce some of these results—a challenging task—and to improve the process, leading to a reliable method for preparing core-dyed PMMA particles. We will report on several important findings related to this research goal, and demonstrate that our particles can be used to make colloidal clusters via the recently published emulsion encapsulation and shrinkage technique [Science 301, 483–487 (2003)].

3:30PM D14.00006 A model nanocolloidal rod system to explore structural transitions in networks and bundles, GEORGINA WILKINS, University of Michigan, PATRICK SPICER, The Procter and Gamble Company, MICHAEL SOLOMON, University of Michigan — We introduce a model system consisting of self-assembled polyamide anisotropic colloids suspended in aqueous surfactant solutions. The colloidal particles are formed by precipitation from an amorphous polyamide powder that is dispersed with mechanical agitation in an aqueous surfactant phase at temperatures from 59 to 100 °C. The aspect ratio increases monotonically with temperature; at T = 50°C, short rods with aspect ratio r = 8 ± 1 form. At T = 100°C, rope like structures with r = 306 ± 14 form. By confocal laser scanning microscopy (CLSM) and dynamic light scattering (DLS) as volume fraction is increased we show a structural transition from dilute rod behaviour with diffusive dynamics to a homogeneous network structure with increasing slow dynamics. Furthermore, increasing the aspect ratio of rods induces the same structural transition from dilute rod behaviour to a network structure. Finally, we vary the interaction potential between the rods by a polymer induced depletion interaction and observe an unexpected quiescent network to bundle transition. The bundles are several rod diameters wide and 1 - 2 rod lengths long. The rods appear to order naturally within each bundle. The bundling transition leads to an order of magnitude decrease in the storage modulus of the suspensions.

3:42PM D14.00007 Polymer grafted particles: Architectural effects on the dynamics, PANAYIOTIS VOUDOURIS, F.O.R.T.H., Heraklion, Greece, JIHOON CHOI, HONG DONG, Carnegie Mellon University, Pittsburgh, USA, GEORGE FYTAS, F.O.R.T.H., Heraklion, Greece, MICHAEL BOCKSTÄLLER, KRIS MATYJASZEWSKI, Carnegie Mellon University, Pittsburgh, USA — We present a combined static and dynamic light scattering study of two polystyrene particles with different grafting densities. The particle solution systems in which tuning of the grafting density and molecular weight of the surface bound PS afford intermediate (0.5nm−2) and concentrated (0.94nm−2) brush densities. The different packing environment of PS chains give rise to distinctly different rich dynamic response above a threshold volume fraction that yields insight into the role of polymer grafts on the structure formation of hairy particles. This work is the first report on the mixing dynamics of hybrid core-shell nanoparticles with distinct behavior intermediate between ultra soft multiarm star polymers and hard sphere colloids. With increasing grafting density of PS ligands the dynamic properties approach those of hard sphere systems while retaining some of the polymer-specific dynamic characteristics.

3:54PM D14.00008 Structure of Quasi-One Dimensional Ribbon Colloid Suspensions1, BINHUA LIN, STUART A. RICE, The University of Chicago, THOMAS STRATOS, BIANXIAO CUI, Stanford University — We report the results of an experimental study of a colloid fluid confined to a quasi-one dimensional (q1D) ribbon channel. Our findings confirm the principal predictions of previous theoretical studies of such systems. These are (1) that the density distribution of the liquid transverse to the ribbon channel exhibits stratification and (2) that even at the highest density the order along the strata, as measured by the longitudinal pair correlation function, is characteristic of a liquid.

4:06PM D14.00009 Dynamics of Internal Stresses and Scaling of Strain Recovery in Aging Colloidal Gels, AJAY SINGH NEGI, CHINEDUM OSUJI, Department of Chemical Engineering, Yale University — On cessation of flow, dilute suspensions of carbon black particles undergo rapid gelation and display instantaneous residual or internal stresses which relax slowly with time. We monitor the evolution of these stresses (under zero strain) and find a weak power law decay, σi ~t−α over 5 decades of time where α ≈ 0.1. The system exhibits aging, with the elastic modulus scaling as a weak power law of elapsed time, G ∼ t−β, with β ≈ α. Imposition of zero stress conditions after waiting time tω, at internal stress σω (tω), results in strain recovery at the system relaxes without the zero strain constraint. Older systems exhibit less recovery than younger ones. Remarkably, strain recoveries at different tω can be shifted to construct a single master curve in which the magnitude of the recovery is shifted vertically according to σi(tω) = 1−tω and horizontally simply with elapsed time. The scaling of the strain recovery with internal stress suggests that the internal stress state is characteristic of the age of the system and of the manner in which the system will continue to evolve. This result has important implications for our understanding of glassy behavior in soft materials.

4:18PM D14.00010 Synthesis and Self-assembly of Janus and Patchy Particles by Lift-up Microcontact Printing, SHAN JIANG, STEVE GRANICK, University of Illinois at Urbana and Champaign — Janus and patchy particles were synthesized by a simple and novel lift-up microcontact printing method. The geometry of the particles is revealed by both optical fluorescence microscopy and scanning electron microscopy. It is demonstrated that the Janus balance (geometry) of the particles can be easily fine tuned. Interesting and unique cluster structures were self-assembled from particles synthesized by this method. The method allows particles not only of divalent but also of trivalent geometry to be formed in large quantity.

4:30PM D14.00011 Thermal Properties of Particulate Suspensions, REBECCA CHRISTIANSON, JESSICA TOWNSEND, Franklin W. Olin College of Engineering — It has been known since the 1800’s that additions of solid phase particles to a liquid can improve the thermal conductivity of the liquid. However, the instability of such suspensions makes the technique impractical for commercial applications. With the advent of affordable technology for synthesizing nanometer scale particles, it became possible for stable suspensions with improved thermal properties to be created. Initial investigations of nanoparticle suspension coolants (termed nanofluids) seemed to indicate an anomalous enhancement of the thermal conductivity above that predicted by conventional theories. However, subsequent experimental work showed issues with the reproducibility of these early results, which has been attributed by some sources to a tendency to aggregate due to the high nanoparticle suspensions, as well as our initial findings on the effects of aggregation on the measured thermal properties of particulate suspensions.
we here present an effective treatment of the intramolecular degrees of freedom of water, where these modes are decoupled from the intermolecular one, adiabatically allowing these coordinates to be positioned at their local minimum of the PES. This decoupling is performed combining an AIMC simulation using the rigid bodies approximation with an intramolecular optimization. As an application of our methodology we have studied small water clusters. We show that even in the case of the water dimer the sampling of phase space is significantly modified when intramolecular optimization is included (J. Chem. Phys., 128, 104311 (2008)). As a result, there are clear changes in features such as the dipole moment and structural properties.

5:06PM D14.00014 New look of fractional exclusion statistics1, DRAGOS-VICTOR ANGHEL, Department of Theoretical Physics, Horia Hulubei National Institute of Physics and Nuclear Engineering — I discuss the concept of fractional exclusion statistics and I show that it leads to inconsistencies in the calculation of the particle distribution that maximizes the partition function. These inconsistencies appear when mutual exclusion statistics is manifested between different subspecies of particles in the system. In order to eliminate these inconsistencies, I introduce new mutual exclusion statistics parameters, which are proportional to the dimension of the Hilbert sub-spaces on which they act. These new definitions lead to properly defined particle distributions and thermodynamic properties. I also show that fractional exclusion statistics is manifested in general interacting systems and I calculate the exclusion statistics parameters. Most importantly, I prove that indeed, the mutual exclusion statistics parameters are proportional to the dimension of the Hilbert space on which they act.

5:18PM D14.00015 Capillary forces on nanowires, JUN MA, SHENFENG CHENG, Johns Hopkins University, JAY WALLACE, MACS Consulting, PATRICIA MCCUIGAN, MARK ROBBINS, Johns Hopkins University — The capillary forces on nanowires have been measured by attaching them to the cantilever of an Atomic Force Microscope (AFM). The nanowires are immersed and retracted from a liquid/air interface. The entire capillary force curve is compared to continuum theory and molecular simulations. Nanowires with different diameters and chemistry and various liquids are investigated. Surface tension, contact angle hysteresis, and dynamical contact angles can be extracted under reasonable assumptions about how the contact line moves along the nanowires.
3:18PM D15.00005 Large-scale free-standing monolayer membranes of nanoparticles: preparation and properties. JINBO HE, LASZLO FRAZER, James Franck Institute, University of Chicago, Chicago, Illinois 60637, USA, XIAO-MIN LIN, Materials Science Division, Chemistry Division and Center for Nanoscale Materials, Argonne National Laboratory, Argonne, Illinois 60439, USA, ADAM WEIS, HEINRICH JAEGER, James Franck Institute, University of Chicago, Chicago, Illinois 60637, USA — Two-dimensional arrays of close-packed nanoparticles can be stretched across tens-micrometre-size holes. The resulting freestanding monolayer membranes extend over hundreds of particle diameters without cross-linking of the ligands or further embedding in polymer. In our previous results of dodecanethiol-ligated 6-nm-diameter gold nanocrystal monolayers, we find a Young’s modulus of the order of several GPa. This remarkable strength is coupled with high flexibility, enabling the membranes to bend easily while draping over edges. Recently we found that oleic-acid-covered cobalt nanoparticles (~9 nm in diameter) self-assemble at toluene/ethylene glycol interfaces and form large two-dimensional arrays. These membranes stretch across tens-of-micrometer holes after drying of ethylene glycol. The mechanical and diffusion properties of these membranes are tested and the response of these membranes under external fields is also investigated.

3:30PM D15.00006 Casimir force between inclusions in a stretchable fluid membrane, HSUANG-KU LIN, ROYA ZANDI, LEONID PRYADKO, Department of Physics, University of California at Riverside — We calculate the entropic fluctuational force, a finite-temperature analogue of the Casimir force, between foreign inclusions in a stretchable fluid membrane. Specifically, we consider the fluctuations of a planar membrane governed by the full Helfrich Hamiltonian, including the surface tension and both bending rigidity terms. The inclusions are introduced as circular regions where the surface tension and/or bending rigidities are modified from their values on the non-perturbed membrane. Results for arbitrarily-strong perturbations of the membrane, including holes, rigid disks, and edges will be presented.

3:42PM D15.00007 Breathable NIPAAm Network with Controllable Hydration Supports Model Lipid Membrane, MICHAEL JABLIN, HILARY SMITH, MIKHAIL ZHERNENKOV, Lujan Neutron Scattering Center, AJAY VIDYASAGAR, RYAN TOOMEY, University of South Florida, JESSICA SAIZ, Lujan Neutron Scattering Center, BORIS TOPERVERG, Ruhr Universitat Bochum, ERIK WATKINS, TONYA KUHL, University of California, Davis, ALAN HURD, JAROSLAW MAJEWSKI, Lujan Neutron Scattering Center — The interaction of a model lipid bilayer composed of DPPC with a surface-tethered poly(N-isopropylacrylamide) (NIPAAm) was explored with neutron reflectometry (NR). The Langmuir-Blodgett / Langmuir-Schaeffer method was used to deposit a lipid bilayer onto the polymer. NR measurements were used to probe the in- and out-of-plane structure of the system as a function of temperature. NR with fluorescence microscopy show that the polymer supports a lipid bilayer and hydration of the support can be controlled. At low temp., the membrane develops out-of-plane undulations visible in off-specular scattering. Analysis of the off-specular reveals in-plane correlation of the bilayer fluctuations. The separation of the lipid bilayer from the solid support of a substrate constitutes a significant step towards a more realistic model of biological membranes.

3:54PM D15.00008 The effects of lung surfactant peptide mimic KL4 on lipid monolayer collapse, NIELS HOLTEN-ANDERSEN, University of Chicago, Department of Chemistry, Chicago, IL 60637, USA, LUKA POCIKAVICEK, University of Chicago, Department of Chemistry and James Franck Institute, Chicago, IL 60637, USA, ALAN J. WARING, University of California, Los Angeles, School of Medicine, Department of Medicine, Los Angeles, CA 90095, USA, KA YEE C. LEE, University of Chicago, Department of Chemistry and James Franck Institute, Chicago, IL 60637, USA — We have investigated the origin of the positive effect of the peptide KL4 on lung surfactant lipid monolayers containing DPPC and POPG. Using surface balance techniques and fluorescence microscopy we have observed that KL4 rigidifies POPG containing lipid monolayers evidenced by a shift in their collapse mode. Rather than collapsing as a fluid by flowing into the sub-phase, a KL4 supported POPG monolayer instead collapses by folding. Furthermore, when KL4 is added to POPG containing monolayers they demonstrate an increased tolerance to repeated compression and expansion cycles while the opposite appears to be true for pure DPPC monolayers. We will discuss the potential role of electrostatic interactions in the rigidifying effect of KL4 on POPG containing monolayers in the context of the overall importance of collapse mode in establishing robust and reversible lipid monolayers.

4:06PM D15.00009 Microrheology of protein layers at the air-water interface, MYUNG HAN LEE, STEVEN CARDINALI, DANIEL REICH, Johns Hopkins University, KATHLEEN STEBE, University of Pennsylvania, ROBERT LEHENY, Johns Hopkins University — Due to their amphiphilic nature, many proteins in aqueous solution will adsorb at the air-water interface to create a viscoelastic interfacial layer. We present an investigation of the formation and mechanical properties of interfacial protein layers formed by beta-lactoglobulin using microrheological techniques including multiple particle tracking and magnetic nanowire microrheology. We observe the interfacial rheology evolve in time through three stages: (i) an increase in viscosity, (ii) a period of spatial heterogeneity in which the interface contains elastic and viscous regions, and (iii) the development of a uniformly rigid elastic film. We evaluate the dependence of this evolution on the protein-protein interactions, which we tune by varying solution pH. As we will discuss, these studies illustrate the power of microrheological approaches to interfacial rheology.

4:18PM D15.00010 ABSTRACT WITHDRAWN

4:30PM D15.00011 Critical swelling of fluctuating capsules, FABRICE THALMANN, University of Strasbourg and Institut Charles Sadron CNRS, CARLOS M. MARQUES, Institut Charles Sadron CNRS and University of Strasbourg — We consider a single polymer chain, grafted on a flat and rigid substrate, covered by a membrane. The membrane presents some affinity for the surface, caused by non specific adhesive interactions. The challenge is to anticipate and describe the different possible relative configurations of the membrane and the polymer chain, depending on parameters such as the surface tension and curvature of the membrane, or the chain gyration radius. We propose for this system a phase diagram of the different regimes, as well as quantitative predictions for comparison with some recent experiments.

4:42PM D15.00012 Monday, March 16, 2009 2:30PM - 5:30PM — Session D16 DAMOP: Focus Session: BEC-BCS Crossover

Critical swelling of fluctuating capsules, HAIM DIAMANT, EMMIR HALEVA, Tel Aviv University — In many natural transport processes the solute molecules to be transported are encapsulated in semipermeable, flexible membrane vesicles of micron size. We study the swelling of such fluctuating capsules, as the number of encapsulated particles is increased, or the concentration of the outer solution is decreased. The approach to the maximum volume-to-area ratio and the associated buildup of membrane tension involve a continuous phase transition and follow universal scaling laws. The criticality and its features are model-independent, arising solely from the interplay between volume and surface degrees of freedom.

2:30PM D16.00001 BCS to BEC evolution for mixtures of fermions with unequal masses\(^1\). CARLOS A. R. SA DE MELO, Georgia Institute of Technology — I discuss the zero and finite temperature phase diagrams of a mixture of fermions with unequal masses with and without population imbalance, which may correspond for example to mixtures of \(^6\)Li and \(^40\)K, \(^6\)Li and \(^87\)Sr, or \(^40\)K and \(^87\)Sr in the context of ultracold atoms. At zero temperature and when excess fermions are present, at least three phases may occur as the interaction parameter is changed from the BCS to the BEC regime. These phases correspond to normal, phase separation, or superfluid with coexistence between paired and excess fermions. The zero temperature phase diagram of population imbalance versus interaction parameter presents a remarkable asymmetry between the cases involving excess lighter or heavier fermions [1, 2], in sharp contrast with the symmetric phase diagram corresponding to the case of equal masses. At finite temperatures, the phase separation region of the phase diagram competes with superfluid regions possessing gapless elementary excitations \([3]\) for certain ranges of the interaction parameter depending on the mass ratio. Furthermore, a phase transition may take place between two superfluid phases which are topologically distinct. The precise location of such transition is sensitive to the mass ratio between the two species of fermions. Signatures of this possible topological transition are present in the momentum distribution or structure factor, which may be measured experimentally in time-of-flight or through Bragg scattering, respectively. Lastly, throughout the evolution from BCS to BEC, I discuss the critical current and sound velocity for unequal mass systems as a function of interaction parameter and mass ratio. These quantities may also be measured via the same techniques already used in mixtures of fermions with equal masses.

3:06PM D16.00002 Spin-imbalanced atomic Fermi gases in one dimension and the prospects for FFLO superconductivity\(^1\). C.J. BOLECH, P. KAKASHVILI, Rice University — Growing expertise to engineer, manipulate and probe different analogs of condensed matter systems allows to probe properties of exotic pairing states such as the Fulde-Ferrell-Larkin-Ovchinnikov state. Inspired by ongoing experiments at Rice university, we are studying the pairing in spin-imbalanced ultracold atomic system of fermions in one dimension. Calculations are done using the Bethe Ansatz technique and the trap is incorporated into the solution via local density (Thomas-Fermi) approximation. The thermodynamic-Bethe-Ansatz equations are solved numerically and different density profiles (total-, spin- and entropy-densities) are calculated in the trap for different finite temperatures. A scheme to identify the phase diagram using total density profiles in the trap is proposed that would be immediately useful for experimentalists.

3:18PM D16.00003 Finite temperature effects of \(^6\)Li-\(^40\)K mixtures in the BCS-BEC crossover, HAO GUO, CHIHCHUN CHIEN, YAN HE, Univ. of Chicago, QIJIN CHEN, Zhejiang Univ., KATHRYN LEVIN, Univ. of Chicago — Recent experiments on mixtures of ultra-cold fermions of different species inspire study of pairing between fermions with different masses. We study systematically \(^6\)Li-\(^40\)K mixtures with tunable attractive interactions in the BCS-Bose Einstein condensation crossover. Pairing fluctuations which are important at finite temperatures are included in a consistent fashion. Population imbalance of the two species is also considered. We found an intermediate-temperature superfluid phase which is similar to the one found in polarized Fermi gases with equal mass. We present superfluid transition temperature for a broad range of polarization and interaction strength and analyze stability of possible superfluid phases. Phase diagrams at and near unitarity are presented. Polarized superfluids are shown to be stabilized when the light species is the majority. Thus, in contrast to pairing between fermions with equal mass, observation of stable low-temperature polarized superfluids near unitarity is more feasible in \(^6\)Li-\(^40\)K mixtures.

3:30PM D16.00004 Phenomenology Of Trapped Polarized Fermi Gases, LESLIE BAKSMATY, Rice University, HONG LU, Rice University, HAN PU, CARLOS BOLECH, Rice University — We discuss recent, apparently contradictory experimental results on trapped, polarized, resonantly interacting interacting fermions. Our analysis occurs in the context of a full 3D Bogoliubov-de Gennes analysis and we dwell on the possible roles of the confining geometry in producing density distortions away from the local density approximation with implications for the Superfluid-Normal transition (Clogston limit).

3:42PM D16.00005 Rotation induced superfluid-normal phase separation in trapped Fermi gases, MENDERES ISKIN, EITE TIESINGA, Joint Quantum Institute (UMd and NIST) — We use the Bogoliubov-de Gennes formalism to analyze the effects of rotation on the ground state phases of harmonically trapped Fermi gases, under the assumption that quantized vortices are not excited. We find that the rotation breaks Cooper pairs that are located near the trap edge, and that this leads to a phase separation between the nonrotating superfluid (fully paired) atoms located around the trap center and the rigidly rotating normal (nonpaired) atoms located towards the trap edge, with a coexistence (partially paired) region in between. Furthermore, we show that the rotation reveals a topological quantum phase transition: the superfluid phase that occurs in the coexistence region is characterized by a gapless excitation spectrum, and that it is distinct from the gapped phase that occurs near the trap center.

3:54PM D16.00006 Pairing Instability in Two-Dimensional Rotating Fermion Liquids Near Unitarity\(^1\), PREDRAG NIKOLIC, Rice University — Fermionic superfluids can undergo phase transitions into different kinds of normal regimes, characterized by whether the Cooper pairs remain locally stable. If the normal phase retains strong pairing fluctuations, it behaves like a liquid of vortices as seen in cuprate superconductors. We argue that analogous strongly correlated normal states exist in two-dimensional neutral fermion liquids near unitarity, where superfluid is destroyed by fast rotation. The formal analysis is based on a model with SP(2N) symmetry which describes the quantum critical region in the vicinity of a broad Feshbach resonance. Assuming that pairing is the only instability in perturbation theory, we map the universal phase diagram in two-dimensions. Such a pairing instability is driven by macroscopically degenerate collective modes, which makes the Abrikosov flux lattice of the superfluid particularly susceptible to quantum melting. Combining this observation with a renormalization group analysis, we conclude that the unconventional normal states can be expected in the vicinity of the universal pairing instability, especially at low temperatures in the BCS limit.

4:06PM D16.00007 Number of closed-channel molecules in the BEC-BCS crossover, FELIX WERNER, University of Massachusetts, LETICIA TARRUELL, ETH Zurich, YVAN CASTIN, Ecole Normale Superieure — Using a two-channel model, we show that the number of closed-channel molecules in a two-component Fermi gas close to a Feshbach resonance is directly related to the derivative of the energy of the gas with respect to the inverse scattering length. We extract this quantity from the fixed-node Monte Carlo equation of state and we compare to the number of closed-channel molecules measured in the Rice experiment with lithium [Partridge et al., Phys. Rev. Lett. 95, 020404 (2005)].
in the weak coupling BCS limit, we find that the excitation of the breathing mode frequencies make the atomic cloud unstable. The critical anharmonicity depends on both rotational frequency and the chemical potential. As a result of the large chemical potential in the BCS regime, even with a weak anharmonicity the lowest order mode frequency decreases with increasing the attractive interaction. For large enough anharmonicities in the weak coupling BCS limit, we find that the excitation of the breathing mode frequencies make the atomic cloud unstable.

4:42PM D16.00010 Two-fluid hydrodynamic modes in a strongly interacting Fermi gas1 . EDWARD TAYLOR, University of Trento, HUI HU, XIA-JI LIU, University of Queensland, SANDRO STRINGARI, University of Trento, ALLAN GRIFFIN, University of Toronto — Landau’s theory of two-fluid hydrodynamics provides an exact description of the low-energy dynamics of all strongly interacting superfluids described by a 2-component order parameter. Extending our recent work, we report on improved variational solutions of the two-fluid hydrodynamic modes in trapped two-component Fermi gases close to unitarity. We show that the two-fluid mode frequencies are identical to the predictions of regular (Euler) hydrodynamics except at certain temperatures where these in-phase modes strongly hybridize with out-of-phase modes. Although two-fluid hydrodynamic modes have been extensively studied in superfluid helium, experiments in trapped quantum gases have yet to detect a clear signal of these modes. We discuss the reasons for this and suggest several experimental signatures of two-fluid behaviour in trapped Fermi superfluids. Measuring the two-fluid mode frequencies is a promising way of testing microscopic theories of the thermodynamic and transport properties at unitarity.

4:54PM D16.00011 Adiabatic Dynamics of the Superconducting Order Parameter, MINXI JIANG, QIAN NIU, Department of Physics, The University of Texas, Austin, Texas — From the time-dependent variational principle and taking into Berry phase effects, we formulate the dynamics of superconducting order parameter in the region where it evolves much slower compared to the timescale of quasi-particles. Collective mode in this region is calculated and compared with previous result obtained from the random-phase approximation which is valid in the opposite limit. We discuss applications to BCS/BEC states of the quantum Fermi gases.

5:06PM D16.00012 The Efimov Effect and Color Superconductivity in a Three-State Fermi Gas . J.R. WILLIAMS, J.H. HUCKANS, E.L. HAZLETT, R.W. STITES, Y. ZHANG, K.M. O’HARA, The Pennsylvania State University — We have created a quantum degenerate $^4$Li gas with equal populations in the three lowest energy hyperfine states. This three-state Fermi gas is stable against two-body inelastic collisions but decays by three-body recombination. We measure the rate of three-body recombination which can be used as a signature of the Efimov effect and which determines whether conditions are favorable for BCS pairing. The three pairwise $s$-wave scattering lengths exhibit overlapping Feshbach resonances at 690, 810 and 834 Gauss. As we vary the field between 0 and 834 Gauss, we find that the three-body recombination rate constant varies by over four orders of magnitude. High stability is achieved near 0 and 570 Gauss. We observe narrow resonant loss features near 130 and 500 Gauss. Recent calculations indicate that these resonant features arise from Efimov trimer states near threshold[1]. We also report on the rate of three-body recombination between 834 and 2000 Gauss. Our determination of the three-body parameters in this regime will guide future experiments aimed at achieving color superconductivity in this system. E. Braaten, H.-W. Hammer, D. Kang, and L. Platter, arXiv:0806.0587.

5:16PM D16.00013 Phase diagram, extended domain walls, and soft collective modes in a three-component fermionic superfluid, GIANLUIGI CATELANI, EMIL YUZBASHYAN, Rutgers University — We study the phase diagram of a three-component Fermi gas with weak attractive interactions, which shows three superfluid and one normal phases. At weak symmetry breaking between the components the existence of domain walls interpolating between two superfluids introduces a new length scale much larger than the coherence length of each superfluid. This, in particular, limits the applicability of the local density approximation in the trapped case, which we also discuss. In the same regime the system hosts soft collective modes with a mass much smaller than the energy gaps of individual superfluids. We derive their dispersion relations at zero and finite temperatures and demonstrate that their presence leads to a significant enhancement of fluctuations near the superfluid-normal transitions.

Monday, March 16, 2009 2:30PM - 5:30PM — Session D17 GQI: Focus Session: Foundations of Quantum Theory 318

2:30PM D17.00001 LeRoy Apker Award Talk: Factoring Quantum Logic Gates with Cartan Involutions , BYRON C. DRURY, Haverford College — This abstract not available.
3:06PM D17.00002 Types and location of information¹, LOOI SHIANG YONG, VLAD GHEORGHIU, ROBERT B. GRIFFITHS, Carnegie Mellon University — Imagine having some quantum information encoded in \( n \) carrier qubits. We are interested in the question of how much information is present in a subset of the carrier qubits. In the case where the encoding is done using a stabilizer code, we have a precise and complete answer. The two extreme cases of having too small a subset whereby no information is present versus having a large subset of almost \( n \) qubits from which all the information can be extracted are already well understood. In this talk we focus on the intermediate situation where only partial information is present. For this purpose we define different “types” of information, where the presence of a type of information on a subset of carrier qubits implies the ability to distinguish a particular set of encoded states associated to that type. With this we can determine how much and what types of information are present in any given subset of carrier qubits. With the help of some simple examples, we will show how sometimes only “classical” information is present and sometimes more can be present. Finally our results can be generalized to higher dimensional qudit stabilizer codes.

¹The research described here received support from the National Science Foundation through Grants No. PHY-0456951 and PHY-0757251.

3:18PM D17.00003 Testing Born’s rule in Quantum Mechanics using a Triple slit experiment , URBASI SINHA, Institute for Quantum Computing (iQc), University of Waterloo, Canada, CHRISTOPHE COUTEAU, ZACHARI MESENDORP, IQC, Waterloo, Canada, IMMO SOELLNER, Institut fuer Experimentalphysik, Innsbruck, Austria, RAYMOND LAFLAMME, IQC, Waterloo, Canada, RAFAEL SORKIN, Syracuse University, Syracuse, NY, GREGOR WEHNS, Institut fuer Experimentalphysik, Innsbruck, Austria — In Mod. Phys. Lett.A 9 3119 (1994), one of us (R.D.S) investigated a formulation of quantum mechanics as a generalized measure theory. Quantum mechanics computes probabilities from the absolute squares of complex amplitudes, and the resulting interference violates the (Kolmogorov) sum rule expressing the additivity of probabilities of mutually exclusive events. However, there is a higher order sum rule that quantum mechanics does obey, involving the probabilities of three mutually exclusive possibilities. We could imagine a yet more general theory by assuming that it violates the next higher sum rule. In this presentation, we report results from an ongoing experiment that sets out to test the validity of this second sum rule by measuring the interference patterns produced by three slits and all the possible combinations of those slits being open or closed. We use either attenuated laser light or a heralded single photon source (using parametric down conversion) combined with single photon counting to confirm the single photon character of the measured light.

3:30PM D17.00004 Cartan Involutions in Quantum Information, PETER LOVE, Haverford College — We discuss some applications of Cartan decompositions and the corresponding involutions of the unitary group in quantum information theory. Recently, such involutions were used to obtain a constructive quantum Shannon decomposition with an application to quantum circuits. We will discuss some practical aspects of the use of this decomposition to obtain circuits for arbitrary unitary matrices. We discuss further applications of these techniques to the computation of mixed state entanglement and the parameterization of quantum operations on open systems.

3:42PM D17.00005 Quantum Foundations of Quantum Information¹, ROBERT GRIFFITHS, Carnegie-Mellon University — The main foundational issue for quantum information is: What is quantum information about? What does it refer to? Classical information typically refers to physical properties, and since classical is a subset of quantum information (assuming the world is quantum mechanical), quantum information should—and, it will be argued, does—refer to quantum physical properties represented by projectors on appropriate subspaces of a quantum Hilbert space. All sorts of microscopic and macroscopic properties, not just measurement outcomes, can be represented in this way, and are thus a proper subject of quantum information. The Stern-Gerlach experiment illustrates this. When properties are compatible, which is to say their projectors commute, Shannon’s classical information theory based on statistical correlations extends without difficulty or change to the quantum case. When projectors do not commute, giving rise to characteristic quantum effects, a foundation for the subject can still be constructed by replacing the “measurement and wave-function collapse” found in textbooks—an efficient calculational tool, but one giving rise to numerous conceptual difficulties—with a fully consistent and paradox free stochastic formulation of standard quantum mechanics. This formulation is particularly helpful in that it contains no nonlocal superluminal influences; the reason the latter carry no information is that they do not exist.

¹Support from NSF Grant PHY0757251 and Carnegie-Mellon University.

4:18PM D17.00006 Measuring the distance between unitary propagators of quantum systems of differing dimensions, MATTHEW GRACE, Thermal/Fluids Science & Engineering Department, Sandia National Laboratories, JASON DOMINY, Program in Applied & Computational Mathematics, Princeton University, ROBERT KOSUT, SC Solutions, Inc., CONSTANTIN BRIF, HERSCHEL RABITZ, Department of Chemistry, Princeton University — In this work, we develop a general distance measure that evaluates the distance between unitary quantum operations of differing dimensions which is (i) independent of the initial state of the system, (ii) straightforward to numerically calculate, and, most importantly, (iii) designed to directly evaluate quantum operations resulting from open-system dynamics. This measure is a natural extension of distance and corresponding fidelity measures employed in previous works that construct closed-system unitary operations. The properties of this measure are desirable for the calculation of distance, e.g., optimal control applied to open systems for quantum information processing, and enable a consistent comparison of quantum operations resulting from both closed- and open-system dynamics. As a numerical example, this distance measure is used to evaluate the fidelity of quantum operations resulting from the optimal control of one- and two-qubit unitary operations in the presence of a decohering environment. This example illustrates the utility of this measure for use in designing unitary quantum operations from open-system dynamics.

4:42PM D17.00008 Closed timelike curves enable perfect state distinguishability, TODD A. BRUN, University of Southern California, JIM HARRINGTON, Los Alamos National Laboratory, MARK M. WILDE, SAIC — The causal self-consistency condition for closed timelike curves can give rise to nonlinear interactions on chronology-respecting qubits. We demonstrate that particular unitary interactions between closed timelike curve qubits and chronology-respecting qubits allow perfect distinguishability of nonorthogonal states, and provide a constructive proof for an arbitrary number of nonorthogonal states. This has a number of highly significant consequences. For example, an adversary with access to closed timelike curves can break the B92, BB84, and SARG04 quantum key distribution protocols, or any prepare-and-measure quantum key distribution scheme. Our result also implies that a party with access to closed timelike curves can violate the Holevo bound by accessing more than \( \log(N) \) bits of information from an \( N \)-dimensional quantum state. In principle, he can transmit an arbitrarily large amount of classical information with a quantum system of fixed size. We discuss the implications of this for quantum cloning.
4:54PM D17.00009 Experimental Basis for IED Particle Model. J. ZHENG-JOHANSSON — The internally
electrodynamic (IED) particle model is built on three experimental facts: a) electric charges present in all matter particles, b) an accelerated charge generates
electromagnetic (EM) waves by Maxwell’s equations and Planck energy equation, and c) source motion gives Doppler effect. A set of well-known basic particle
equations have been predicted based on first-principles solutions for IED particle (e.g. J Phys CS128, 012019, 2008); the equations are long experimentally
validated. A critical review of the key experiments suggests that the IED process underlies these equations not just sufficiently but also necessarily. E.g.: 1) A
free IED electron solution is a plane wave \( \psi = Ce^{i(k_x \cdot \mathbf{r} - \omega t)} \) requisite for producing the diffraction fringe in a Davison-Germer experiment, and of also all basic
point-like attributes facilitated by a linear momentum \( \mathbf{k} \) and the model structure. It needs not further be a wave packet which produces not a diffraction
fringe. 2) The radial partial EM waves, hence the total \( \psi \) of an IED electron will, on both EM theory and experiment basis -not by assumption, enter two slits
at the same time, as is requisite for an electron to interfere with itself as shown in double slit experiments. 3) On annihilation, an electron converts (from mass
\( m \)) to a radiation energy \( h \omega \) without an acceleration which is externally observable and yet requisite by EM theory. So a charge oscillation of frequency \( \omega \) and its
EM waves must regularly present internal of a normal electron, whence the IED model.

5:06PM D17.0010 ABSTRACT WITHDRAWN —

5:18PM D17.0011 Quantum entanglement and informational activities of biomolecules, HANAN
entanglement and reveals its biological implications. The suggested holographic mechanism handles 2D slices of the physical world as a whole. Fitting this
simple holistic process in the Procrustean bed of individual particles interactions leads to intricacies of quantum theory with an unintelligible protrusion of distant
correlations. Holographic medium imposes dependence of quantum effects on absolute positioning. Testing this prediction for a non-exponential radioactive
decay could resolutely point to outside “memory.” The essence of Life is in the sophistication of macromolecules. Distinctions in biological information processing
of nucleotides in DNA and amino acids in proteins are related to entropies of their structures. Randomness of genetic configurations as exposed by their maximal
entropy is characteristic of passive identification rather than active storage functionality. Structural redundancy of proteins shows their operability, of which
different foldings of prions is most indicative. Folding of one prion can reshape another prion without a direct contact appearing like “quantum entanglement,”

Session D18 DPOLY: Focus Session: Transport and Optical Properties of Conjugated Polymers
and other Solution Processable Semiconductors 319

2:30PM D18.00001 Microstructure and Charge Transport in pBTTT Thin Film Transistors.
CHENCHEN WANG, Department of Applied Physics, Stanford University, ALBERTO SALLEO, LUDWIG GORIS, Department of Materials Science and
Engineering, Stanford University, IAIN MCCULLOCH, Chemistry Department, Imperial College, London, UK, MARTIN HEENEY, Materials Science Department,
Queen Mary University, London, UK, ALEXANDER ZIEGLER, Max Planck Institute, Martinsried, Germany — The present work focused on the morphology
and charge carrier mobility of poly(2,5-bis(3-alkylthiophen-2-yl)thieno[3,2-b]thiophenes) (pBTTT) films. In annealed pBTTT films on oxide functionalized with
octyltrichlorosilane (OTS), TEM study shows that the large-scale terraces observed by AFM, which was believed to be the reason for high charge carrier mobility,
are composed of smaller crystalline grains. Using the mobility edge model, we find that, compared with the film on oxide, the density of trap states at the band
edge is reduced in the film on OTS, and it is about the same as the trap density in poly(3-hexylthiophene) (P3HT), which has lower carrier mobility. This result
are composed of smaller crystalline grains. Using the mobility edge model, we find that, compared with the film on oxide, the density of trap states at the band
edge is reduced in the film on OTS, and it is about the same as the trap density in poly(3-hexylthiophene) (P3HT), which has lower carrier mobility. This result

2:42PM D18.00002 Interfacial Charge Transfer in Nanoscale Polymer Transistors. JEFFREY WORNE,
RAJIV GIRIDHARAGOPAL, KEVIN KELLY, DOUGLAS NATÉLSON, Rice University, JOHN ANTHONY, University of Kentucky — Interfacial charge transfer
plays an essential role in establishing the relative alignment of the metal Fermi level and the energy bands of organic semiconductors. While the details remain
evasive in many systems, this charge transfer has been inferred in a number of photoemission experiments. We present electronic transport measurements in very
short channel (L < 100 nm) transistors made from poly(3-hexylthiophene) (P3HT). As channel length is reduced, the evolution of the contact resistance and the
zero gate voltage conductance are consistent with such charge transfer. Short channel conduction devices with Pt contacts is greatly enhanced compared to
analogous devices with Au contacts, consistent with charge transfer expectations. Alternating current scanning tunneling microscopy (ACSTM) provides further
evidence that holes are transferred from Pt into P3HT, while much less charge transfer takes place at the Au/P3HT interface. We have also begun to use these
same techniques to investigate the nature of interfacial charge transfer between metal electrodes and pentacene. We use these data together with our previous
results to develop a more complete picture of metal/organic interfaces.

2:54PM D18.00003 Ab initio study of molecular packing of organic semiconducting materials.
SEFA DAG, LIN-WANG WANG, Lawrence Berkeley National Laboratory — The self-organizing and electronic properties of organic semiconducting material,
poly(3-hexylthiophene) (P3HT), have been investigated in terms of their inter-monomer interaction and packing arrangements. We found that thiophene-thiophene interaction in
adjacent layers has a strong influence to create stacked planar structures. Our calculations showed that P3HT chains tend to stack into planar structures, in
which adjacent thiophene-thiophene rings along the stacking direction are 180° rotated with respect to each other. Theoretical powder diffraction profile of this
structure showed same structure with experimental reflection peaks. We also showed enhanced transport resulting from the organization of P3HT chains.

3:06PM D18.00004 Electrical Noise in Individual Conducting Polymer Nanowires. ALEXEY KO-
VALEV, YANYAN CAO, THERESA MAYER, THOMAS MALLOW, Penn State University — Electrical property characterizations of conducting polymer
nanowires have been limited primarily to resistance measurements. Electrical noise is one aspect that is usually overlooked, yet critical to their device
performance. Moreover, electrical noise is more sensitive to the polymer doping and microstructure than resistance, which makes it particularly interesting
for sensor applications. In this talk, we will present the results on the electrical noise measurements of individual multisegmented electrodeposited nanowires
based on Poly(3,4-ethylenedioxythiophene) (PEDOT) [1]. The polymer was electrochemically doped with either poly(4-styrenesulfonic acid) (PSS) or perchlorate
(CIO4). The nanowires had gold contacts on both ends and were measured in four-point and two-point configurations. We found that the electrical noise
behavior is typical of 1/f noise, with a spectral density that depends on the polymer structure and is affected by the ambient conditions. Our data show that
the contact noise represents a significant contribution to the total noise level. We will discuss the interpretation of these results assuming that the polymer is a
3:18PM D18.00005 Thin film morphology of electronic materials
S. D. HUDSON, R. J. KLINE, D. M. DELONGCHAMP, O. D. JURCHESCU, D. J. GUNDLACH, L. J. RICHTER, NIST, Gaithersburg, MD 20899 — The crystal orientation and morphology of a polythiophene (pBTTT) and an anthradithiophene (dif-TEADT, a pentacene analog) in thin films have been explored by TEM, SEM, AFM, GISAXD, NEXAFS, polarized FTIR and ellipsometry. The orientation has a striking influence on the performance of thin film transistors. We show that solution casting and annealing conditions have a significant effect on the morphology of pBTTT. Correlations between film surface step morphology and crystal orientation are determined. Interfacial interactions with the substrate (gold, silica, or fluorinated sam) govern the crystal orientation and crystal aggregate morphology of dif-TEADT. Depending on this orientation, the carrier mobility spans from approximately 0.001 cm²/Vs to 0.4 cm²/Vs. Epitaxial relationships within crystal aggregates are observed.

3:30PM D18.00006 Conjugated polymer/layered inorganic nanocomposites: solution processable route to enhanced thermoelectric performance
KEVIN SEE, JEFFREY URBAN, The Molecular Foundry, Lawrence Berkeley National Lab, RACHEL SEGALMAN, Department of Chemical Engineering, University of California, Berkeley — In recent years, incorporation of nanostructures has led to notable improvements in the performance of thermoelectric materials. At a given temperature T, the thermoelectric figure of merit ZT is given by $S^2T/\sigma\kappa$, where S is the Seebeck coefficient, $\sigma$ the electrical conductivity and $\kappa$ the thermal conductivity. In most cases, improvement in ZT through nanostructuring has been realized via reduction in thermal conductivity $\kappa$, rather than increases in the power factor $S^2\sigma$. Here we utilize solution-based intercalation chemistry to create layered inorganic/conjugated polymer nanocomposites with designed nanoscale interfaces engineered to enhance the power factor by energy filtering. The layered inorganic material Sb$_2$Te$_3$ was intercalated with poly(3-hexylthiophene), and the resulting composite material was cast into thin films from solution. The resulting devices exhibit Seebeck coefficients with two-fold enhancement over those reported for bulk Sb$_2$Te$_3$ with known conductivities for solution-processed films. These results demonstrate the promise of these novel intercalated materials for high performance solution processable thermoelectric materials.

3:42PM D18.00007 Revealing Transmission in Metal-Molecule Junctions Using Length Dependent Thermopower Measurements
JONATHAN A. MALEN, PETER DOAK, KANHYALAL BAHETI, T. DON TILLEY, ARUN MAJUMDAR, UC Berkeley — Conductance in metal-molecule junctions is known to trend with molecular endgroups, backbone, and length, but a more complete picture of the junction’s transmission structure has been hitherto elusive. We now report complimentary trends in the junction’s thermopower (S) that reveal length dependent changes in the molecular orbital alignment and coupling with contact states. Phenylene-diamines, phenylene-dithiols, and alkanedithiols trapped between gold contacts were examined. S increases linearly with length for phenylene-diamines and dithiols while it decreases linearly in alkanedithiols. In contrast, the data suggests that the molecular backbone determines the length dependence of S, while the endgroup determines the zero-length, or contact S. Transport in phenylenes was dominated by the HOMO, which moves closer to the Fermi energy of the contacts as $\sim 1/L$, and broadens due to contact coupling as $\sim 1/L^2$. In contrast, the decreasing trend in S for alkanedithiols suggests that transmission is largely effected by gold-thiol gap states between the HOMO and LUMO.

3:54PM D18.00008 Thermally-Induced Mesophase Transitions in Alkyl-Substituted Thienoacenes
CHARLES M. SHAW, XINNAN ZHANG, National Starch, LIDARIS SAN MIGUEL RIVERA, Dow Chemical, GEETHA G. NAIR, Centre for Liquid Crystal Research, Bangalore, India, ANANTAL JAKLI, Kent State University, ADAM J. MATZGER, DAVID C. MARTIN, University of Michigan — Pentathienoacene (T$_x$) is an organic molecule—first synthesized in recent years—that is most succinctly described as the thiphene analog of pentacene. In this study, the solid-state structure and phase behavior of diocetyl- and didodecyl-substituted T$_x$ were examined via differential scanning calorimetry (DSC), variable-temperature, polarized optical microscopy (VT-POM), variable-temperature X-ray diffraction (VT-XRD) and electron diffraction (ED). DSC reveals the presence of a number of phase transitions, while ED, VT-OM and VT-XRD reveal the details of the structural changes of these transitions. The first phase transition exhibited by both materials is a crystal-crystal transformation that involves the contraction of the unit cell along the long axis by nearly 25%. This change has been attributed to the introduction of numerous gauche defects at elevated temperatures. Further heating causes both molecules to exhibit a Smectic C liquid crystalline phase, identified by VT-OM and VT-XRD. VT-XRD was also utilized to elucidate lattice parameters for these various phases.

4:06PM D18.00009 Fullerene-based anchoring groups for molecular electronics
CHRISTIAN MARTIN, DAPENG DING, Leiden University and Delft University of Technology, The Netherlands, JAKOB SORENSEN, THOMAS BJORNHOLM, University of Copenhagen, Denmark, JAN VAN RUITENBEEK, Leiden University, The Netherlands, HERVE VAN DER ZANT, Delft University of Technology, The Netherlands — We present a route to a new fullerene-based anchoring group for molecular electronics. Using lithographic mechanically controllable break junctions in vacuum and at RT we have studied the electrical properties of 1,4-bis(fullero[6]pyrrolidin-1-yl)benzene. The compound can be self-assembled from solution and forms molecular junctions with a low-bias conductance of $G_0$. Compared to 1,4-benzenedithiol it exhibits a considerably lower conductance spread. Statistical analyses of the breaking process confirm the stability of the fullerene-gold bond.

4:18PM D18.00010 An organic nanoparticles transistor behaving as a spiking synapse
DOMINIQUE VUILAUME, FABIEN ALIBART, IEMN-CNRs, CHRISTOPHE NOVEMBRE, CEA-LIST, DAVID GUERIN, CNRS-IEMN, STEPHANE PLEUTIN, KAMAL M enjoymenti ,RI, IEMN-CNRs, CHRISTIAN GAMRAT, CEA-LIST, IEMN-CNRs TEAM, CEA-LIST TEAM — We demonstrate that an organic transistor, made of metal nanoparticles (NP) embedded into an organic semiconductor channel, behaves as a spiking synapse. We demonstrate that this device exhibits the main behavior of a biological synapse. For instance, it can be programmed to work as an excitatory or inhibitory synapse; it exhibits shot-term plasticity as well as spike timing dependent plasticity. This behavior is obtained by virtue of the combination of two properties: the transconductance gain of the transistor and the memory effect due to charges stored in the NP. The gold NP are immobilized into the source-drain channel by using surface chemistry (self-assembled monolayers) and they were subsequently covered by a thin film of pentacene. In a biological synapse, the excitatory behavior means that an incoming signal with a given frequency and duty cycle induces a post-synaptic signal having an increasing trend, whereas in the case of an inhibitory synapse, the post-synaptic signal tends to decrease. This behavior is exactly what we demonstrated for the ONT.

4:30PM D18.00011 The role of the oxygen/water redox couple in suppressing electron conduction in field-effect transistors
PIERRE L. LEVESQUE, Université de Montréal, CARLA M. AGUIRRE, École Polytechnique de Montréal, MATTHIEU PAILLET, FRANÇOIS LAPOINTE, Université de Montréal, BENOIT C. ST-ANTOINE, PATRICK DESJARDINS, École Polytechnique de Montréal, RICHARD MARTEL, Université de Montréal — Much like with organic semiconductor FETs, a characteristic of carbon nanotube based devices has been their almost exclusive p-type character in air. Electron transport can be observed only under certain conditions, for instance devices annealed in vacuum. We investigated the impact of the chemical nature of the substrate and of ambient adsorbates on the field-effect switching behavior of both nanoscale and thin-film FETs. Our study, using carbon nanotubes as the testbed, revealed that the intrinsic material properties are modified when an adsorbed water layer containing solvated oxygen is present on the SiO$_2$ surface and lead to the reduction of n-type conduction. This finding demonstrates that an electrochemical charge transfer reaction between the semiconducting channel and the aqueous oxygen redox couple is the underlying phenomenon governing the suppression of electron conduction in these devices. This effect should be considered when measuring the transport properties of nanostructures such as nanowires, organic materials, nanotubes, graphene conducted on SiO$_2$/Si substrates.
Monday, March 16, 2009 2:30PM - 5:30PM —
Session D19 DPOLY: Focus Session: Grazing Incidence Scattering and New Imaging Techniques 320

2:30PM D19.00001 Probing kinetics and dynamics of nanocomposites with grazing-incidence small-angle x-ray scattering.1 JIN WANG, Argonne National Laboratory — Synthesizing complex nanocomposites and superstructures is of great interest in all areas of materials science and technology. Since the entire synthesis and assembly process can take place far from equilibrium conditions, a controlled process has to be guided by a thorough understanding of the kinetics and dynamics in the composites. This requires measurement of the structure in situ and in real time with subnanometer spatial resolution and millisecond to subsecond temporal resolution. As an increasingly important structural-characterization technique, grazing-incidence small-angle x-ray scattering (GISAXS) finds vast applications in the research of nanostuctures and nanocomposites at surfaces and interfaces. Most significantly, as a complementary method to conventional surface-sensitive tools such as scanning probe microscopy and electron microscopy, GISAXS can be used in situ and in real time to monitor the formation of the nanostructure or nanocomposite, which makes it most suitable for studying the kinetics of nanoassembly processes. The GISAXS technique can also be an integral part of numerous research, for example, those involving kinetics of mesoscaled ordered block copolymer thin films, kinetics of sol-gel processes, quantum dots, nanoparticles in ultrathin films, and dynamics and phase transitions 2D nanocrystal superlattices. Here, I will focus on the applications of GISAXS in real-time structure characterization, the dynamics in polymer/nanoparticle nanocomposites, and the challenges to elucidate nanostructure formation in nanoscience and nanotechnology.

3:06PM D19.00002 Single beam approach for GISAXS1 BYEONGDU LEE, CHIEH-TSUNG LO, Argonne National Laboratory, PAPPANNA THIYAGARAJA, ZHONGWEI NUI, QIAN WANG, University of South Carolina — The multiple scattering effects present in the grazing incidence small-angle x-ray scattering (GISAXS) data and dynamics addressed theoretically as well as experimentally with measurement of a series of patterns at different incident angles, referred to as “incident-angle-resolved GISAXS” (IAR-GISAXS). We found that under certain conditions, it is possible to extract the correct structural features of the materials from the GISAXS data using the kinematic SAXS formalisms assuming a single beam, without the need to use the distorted wave Born approximation (DWBA) to account for the scattering by the reflected beam. Furthermore, the Kiessig fringes in GISAXS enable the measurement of average distance between the particle and the substrate, similar to the measurement of film thickness using the fringes in the x-ray reflectivity data. We believe that the methods developed here will expand the application of GISAXS as they enable the use of model-dependent and independent SAXS theories to nanostructured 2D-ordered films.

3:18PM D19.00003 Surface Dynamics of Free PS Chains on Chemically Identical Polymer Brushes: An XPCS Study. GOKCE UGUR, Department of Polymer Science, The University of Akron, Akron, OH 44325-3909, BULENT AKGUN, Center for Neutron Research, National Institutes of Standards and Technology, Gaithersburg, Maryland 20899, ZHANG JIANG, SURESH NARAYANAN, Experimental Facilities Division, Argonne National Laboratory, Argonne, IL 60439, WILLIAM J. BRITTAIN, MARK D. FOSTER, Department of Polymer Science, The University of Akron, Akron, OH 44325-3909 — We found no relaxation of fluctuations of the brush surfaces within the range of time (0.2-1100 s) and length scale (0.6-3 um) studied by X-ray photon correlation spectroscopy (XPCS). This is true for PS brushes of thicknesses of 9-101 nm and grafting density of 0.12-0.6 chains/nm² at temperatures up to 130°C above bulk Tg = 60°C. Results on the dynamics of a layer of untethered 2.2k PS chains on top of a PS brush surface show that placing the PS chains atop the brush dramatically slows down the surface relaxations of the film surface. As the ratio of the thickness of the layer of untethered chains to the thickness of the highly dense brush drops below ~0.5, the surface relaxations become too slow to be observed readily with XPCS. Reducing grafting density of the underlying brush markedly slows the surface dynamics. The surface dynamics of the layer of free PS chains are coupled with those of the underlying brush. 3:30PM D19.00004 X-ray Standing Wave Studies of Stability and Dynamics in Poly(4-bromostyrene)/Poly(4-vinylpyridine) Thin Films YAN SUN, KENNETH SHULL, Northwestern University, JIN WANG, Argonne National Laboratory — The thermodynamic stability and wetting behavior in systems consisting of two or three distinct layers of polymeric thin films have been investigated with atomic force microscopy (AFM) and x-ray standing waves (XSW) generated via total external reflection from an x-ray mirror. We have probed the structural evolution of thin poly(4-bromostyrene) (P(BrS)) films with various degrees of bromination, prepared on top of a poly(4-vinylpyridine) (P4VP) layer whose dynamics is influenced by its interaction with the underlying substrate and couple to that of PBrs. The addition of a top poly(styrene) (PS) layer was also used in some cases. The samples were subjected to annealing treatments above the polymer glass transition temperatures. Reflectivity and x-ray fluorescence from bromine markers in the PBrs layer were tracked. Dewetting of the PS occurred with sufficient annealing time, though the results suggest that this proceeded faster with low PBrs bromination. AFM studies on the PBrS/P4VP system revealed a clear PBrS thickness dependence on the dewetting morphology and dynamics of this layer.

3:42PM D19.00005 Quantitative electron tomography and its application to polymer nanostructures. HIROSHI JINNAI, Department of Macromolecular Science and Engineering, Kyoto Institute of Technology — The transmission electron microscopy (TEM) is a powerful tool to visualize three-dimensional (3D) structures in many fields of materials science. Recently, researchers are trying not only to visualize 3D nanostructures but also to quantify them in order to seek a possible correlation between the 3D structures and materials' properties. However, one of the serious problems that prohibit TEM imaging of 3D images is the “missing wedge” in the Fourier space that is caused by the limitation of angular range available in transmission electron microscopes (TEM). Please note that the computerized tomography (CT), on which TEMT is based, requires projections from entire tilt angles, i.e., ±90°. Thus, the most faithful tactics for the CT is to tilt specimen over ±90°. In order to realize such requirement, a rod-shaped ZrO2/polymer nano-composite whose diameter is ca. 150 nm was attached at the tip of a specially modified specimen holder without any supporting film. A complete set of tomograms has been generated for the first time from the 181 projections that were taken over the angular range of ±90°. One of the structural parameters characterizing the nanocomposite, a volume fraction of ZrO2, ϕ, was measured as a function of the maximum tilt angle, α. It was found that ϕ was in excellent agreement with the known volume fraction of ZrO2 when α=90°, i.e., ±90° tilt, while ϕ increased with decreasing α. When α=60°, that is a typical maximum tilt angle, the measured ϕ was larger by 20~30% than the true value. In addition to the above TEMT experimental technique, some applications of TEMT to polymer nano-structures will be presented at the conference time.
4:18PM D19.00006 Three-dimensional subwavelength imaging with phase-less power extinction tomography, ALEXANDER A. GOVYADINOV, GEORGE Y. PANASYUK, JOHN C. SCHOTLAND, University of Pennsylvania — Modern near-field methods extend the spatial resolution of optical microscopes beyond the classical diffraction limit. However, the majority of these methods only recover two-dimensional maps of optical intensity near the sample surface. The interpretation of these maps for manifestly inhomogeneous samples has been proven to be problematic. Here we derive an analytical technique which allows unique subwavelength 3D reconstruction of both real and imaginary parts of susceptibility.

4:30PM D19.00007 Helium ion microscopy and its application to organic materials, STEVEN HUDSON, ANDRAS VLADAR, BIN MING, NIST, Gaithersburg, MD 20899 — Helium ion microscopy (Helm) is a new scanning probe microscopy that uses a He+ beam. This microscope has improved resolution and depth of field in comparison to SEM, as demonstrated through imaging of metal particles. Organic materials, including patterned polyelectrolyte multilayers and organic semiconductor crystals, have also been imaged. The surface sensitivity, image contrast and qualitative secondary electron yield have been evaluated, in an effort to understand beam/specimen interactions and compare them with electron beam/sample interactions.

4:42PM D19.00008 Robust Tips for High Resolution Chemical Imaging1, CARLOS BARRIOS, ANDREY MALKOVSKIY, ALEXANDER KISLIUK, ALEXEI SOKOLOV, MARK FOSTER, Department of Polymer Science, The University of Akron — Tip enhanced Raman spectroscopy (TERS) combines scanning probe microscopy with Raman spectroscopy, taking advantage of apertures on near-field optics. A plasmonic structure at the apex of a sharp tip provides signal amplification required for chemical imaging. Plasmonic structure characteristics such as roughness, shape, and radius determine the spatial resolution and signal enhancement. Unfortunately, noble metal nanostructures have limited lifetimes due to mechanical, chemical, and thermal degradation. Lifetime extension requires slowing degradation processes while minimizing unfavorable influences on the optical response. An ultrathin SiO2 protective coating provides lifetime improvement of silver plasmonic nanostructures on SPM tips. Controlled physical vapor deposition (PVD) of Al can be used to create ultrathin (~2-3 nm) Al2O3 coatings that improve significantly the stability and wear resistance of plasmonics structures without substantial degradation of optical properties. Such a coating completely prevented decay in plasmonic activity after 40 days of use.

5:06PM D19.00010 Intensity Fluctuations of Optical Microscopy as a Means to Measure Axial Diffusion, MALVIKA BIHARI, PSE, UMASS Amherst, THOMAS RUSSELL, PSE, UMASS Amherst, DAVID HOAGLAND, PSE UMASS Amherst — Via optical microscopy, geometrically hindered motions of a single large solute (particle or polymer) can be imaged in real time. Here, intensity fluctuations of confocal microscopy admit another way to probe such motions, one convenient when motions are perpendicular to a planar substrate. The focal plane is positioned within the substrate (lying on the microscope stage) and intensity fluctuations arise from motions in-and out-of the focal volume. Two experiments illustrate the new approach, diffusion within pores of a planar membrane or in solution near a solid wall. In the first, diffusion coefficients of spherical particles were measured inside pores of a track-etched polycarbonate membrane as functions of particle and pore size. In the second, anisotropic diffusion (perpendicular/parallel) of the same particles was measured within a few particle diameters of a solid boundary. Theory for hydrodynamically hindered diffusion in both cases is well developed, and data are compared to predictions. Two ways to assess particle/polymer motion, tracking single particles and correlating intensity fluctuations, will be discussed.

5:18PM D19.00111 Three-Dimensional Imaging of Polymeric Nanostructures by Molecular Switching in Far Field Fluorescence Microscopy, CHAITANYA ULLAL, ROMAN SCHMIDT, ALEXANDER EGNER, BENJAMIN HARKE, JAN KELLER, Max Planck Institute for Biophysical Chemistry — Morphological studies of self-assembled polymeric structures with length scales of interest below 100 nm have typically been conducted either by scattering-based techniques or electron and scanning probe microscopes. These techniques, however, do not provide easy access to truly 3D-informational content. In contrast, Far-field optical methods retain the advantage of simultaneously providing local, dynamic, and in situ three-dimensional (3D) structural information. The diffraction limited optical resolution of its standard variants, however, restricts the minimum feature size that can be examined. We exploit molecular transitions of the fluorophores to circumvent the diffraction barrier and demonstrate the power of emerging far-field fluorescence microscopy with nanoscale resolution for the study of self-assembly. We simultaneously improve both the lateral (x,y) and the axial (z) resolution of stimulated emission depletion (STED) microscopy. The increased 3D resolution is used to unambiguously map the morphology of self-assembled polymeric nanostructures in a facile manner.

2:30PM D20.00001 Simulation study of proton transport in stretched nanocomposite ionomer fuel-cell membranes1, PHILIP TAYLOR, ELSHAD ALLAHYAROV, Case Western Reserve University — We have used coarse-grained simulation methods to investigate the effect of inclusions of nanoparticles on the stretching-induced structure orientation and on the proton conductivity of polymer electrolyte membranes. Uniaxial stretching of a Nafion film containing no inclusions causes a modest increase in proton conductivity in the direction of stretching. This effect does not persist to any significant degree after removal of the stretching stress. Stretching of a Nafion film containing spherical nanoparticle inclusions, on the other hand, causes a large increase in proton conductivity in the direction of stretching, and this effect persists to a much greater extent after the removal of the stretching stress. Simulations were performed with monodisperse nanoparticle whose diameters were in the range from 17 to 28 nm, and whose surfaces were either hydrophilic, neutral, or hydrophobic. The greatest effect in causing enhancement of the proton conductivity and in causing persistent ordering was found for hydrophilic nanoparticle inclusions of 28 nm diameter.

4:42PM D19.00008 Robust Tips for High Resolution Chemical Imaging1, CARLOS BARRIOS, ANDREY MALKOVSKIY, ALEXANDER KISLIUK, ALEXEI SOKOLOV, MARK FOSTER, Department of Polymer Science, The University of Akron — Tip enhanced Raman spectroscopy (TERS) combines scanning probe microscopy with Raman spectroscopy, taking advantage of apertures on near-field optics. A plasmonic structure at the apex of a sharp tip provides signal amplification required for chemical imaging. Plasmonic structure characteristics such as roughness, shape, and radius determine the spatial resolution and signal enhancement. Unfortunately, noble metal nanostructures have limited lifetimes due to mechanical, chemical, and thermal degradation. Lifetime extension requires slowing degradation processes while minimizing unfavorable influences on the optical response. An ultrathin SiO2 protective coating provides lifetime improvement of silver plasmonic nanostructures on SPM tips. Controlled physical vapor deposition (PVD) of Al can be used to create ultrathin (~2-3 nm) Al2O3 coatings that improve significantly the stability and wear resistance of plasmonics structures without substantial degradation of optical properties. Such a coating completely prevented decay in plasmonic activity after 40 days of use.

5:06PM D19.00010 Intensity Fluctuations of Optical Microscopy as a Means to Measure Axial Diffusion, MALVIKA BIHARI, PSE, UMASS Amherst, THOMAS RUSSELL, PSE, UMASS Amherst, DAVID HOAGLAND, PSE UMASS Amherst — Via optical microscopy, geometrically hindered motions of a single large solute (particle or polymer) can be imaged in real time. Here, intensity fluctuations of confocal microscopy admit another way to probe such motions, one convenient when motions are perpendicular to a planar substrate. The focal plane is positioned within the substrate (lying on the microscope stage) and intensity fluctuations arise from motions in-and out-of the focal volume. Two experiments illustrate the new approach, diffusion within pores of a planar membrane or in solution near a solid wall. In the first, diffusion coefficients of spherical particles were measured inside pores of a track-etched polycarbonate membrane as functions of particle and pore size. In the second, anisotropic diffusion (perpendicular/parallel) of the same particles was measured within a few particle diameters of a solid boundary. Theory for hydrodynamically hindered diffusion in both cases is well developed, and data are compared to predictions. Two ways to assess particle/polymer motion, tracking single particles and correlating intensity fluctuations, will be discussed.

5:18PM D19.00111 Three-Dimensional Imaging of Polymeric Nanostructures by Molecular Switching in Far Field Fluorescence Microscopy, CHAITANYA ULLAL, ROMAN SCHMIDT, ALEXANDER EGNER, BENJAMIN HARKE, JAN KELLER, Max Planck Institute for Biophysical Chemistry — Morphological studies of self-assembled polymeric structures with length scales of interest below 100 nm have typically been conducted either by scattering-based techniques or electron and scanning probe microscopes. These techniques, however, do not provide easy access to truly 3D-informational content. In contrast, Far-field optical methods retain the advantage of simultaneously providing local, dynamic, and in situ three-dimensional (3D) structural information. The diffraction limited optical resolution of its standard variants, however, restricts the minimum feature size that can be examined. We exploit molecular transitions of the fluorophores to circumvent the diffraction barrier and demonstrate the power of emerging far-field fluorescence microscopy with nanoscale resolution for the study of self-assembly. We simultaneously improve both the lateral (x,y) and the axial (z) resolution of stimulated emission depletion (STED) microscopy. The increased 3D resolution is used to unambiguously map the morphology of self-assembled polymeric nanostructures in a facile manner.

2:30PM D20.00001 Simulation study of proton transport in stretched nanocomposite ionomer fuel-cell membranes1, PHILIP TAYLOR, ELSHAD ALLAHYAROV, Case Western Reserve University — We have used coarse-grained simulation methods to investigate the effect of inclusions of nanoparticles on the stretching-induced structure orientation and on the proton conductivity of polymer electrolyte membranes. Uniaxial stretching of a Nafion film containing no inclusions causes a modest increase in proton conductivity in the direction of stretching. This effect does not persist to any significant degree after removal of the stretching stress. Stretching of a Nafion film containing spherical nanoparticle inclusions, on the other hand, causes a large increase in proton conductivity in the direction of stretching, and this effect persists to a much greater extent after the removal of the stretching stress. Simulations were performed with monodisperse nanoparticle whose diameters were in the range from 17 to 28 nm, and whose surfaces were either hydrophilic, neutral, or hydrophobic. The greatest effect in causing enhancement of the proton conductivity and in causing persistent ordering was found for hydrophilic nanoparticle inclusions of 28 nm diameter.

1Work supported by DOE Grant DE-FG02-05ER46244
2:42PM D20.00002 The role of nanoparticle-membrane coupling in nanocomposite ionomers1, ELSHAD ALLAHYAROV, PHILIP TAYLOR, Case Western Reserve University — Coarse-grained simulation methods have been used to investigate the effect of inclusions of spherical nanoparticles on the properties of Nafion®-like membranes. We find the clustering of the sulfonate head groups to be strongly affected by the presence of a monodisperse array of spheres when the sphere diameters lie in the range from 17 to 28 nm. This change in morphology enhances the proton conductivity of the membrane through the formation of channels connecting adjacent clusters. This effect was characterized in terms of the distribution of channel lengths of the hydrophilic phase. Simulations were performed for Nafion containing spherical nanoparticles whose surfaces were either hydrophilic, neutral (hard core), or hydrophobic. The diameters of the nanoparticles were changed while keeping fixed the volume fraction of inclusions. We find that the proton conductivity of these nanocomposites is always higher than the conductivity of ionomers without additives. This effect becomes most pronounced in nanocomposites containing particles whose surfaces are hydrophilic, and whose diameters are in the larger part of the range of sizes examined.

2:54PM D20.00003 Multi-Lamellar Structures in Nafion, JOSEPH A. DURA, NIST - Center for Neutron Research, VIVER S. MURTHI, UTC Power Corp., MICHAEL R. HARTMAN, University of Michigan, Nuclear Engineering and Radiological Sciences, SUSHIL K. SATIJA, CHARLES F. MAJKRZAK, NIST - Center for Neutron Research — Both proton conductivity and gas diffusion are key factors in the performance of a fuel cell and proton exchange membrane, PEM. They are critically dependent on water content and morphology, especially in the three phase region where catalyst, PEM, and gases such as fuel or oxidizer co-exist. Here we show that lamellar structures composed of thin alternating water rich and Nafion rich layers exist at the interface between SiO2 and the hydrated Nafion film. Lamellae thickness and number of layers increase with humidity. Some lamellae remained in the film after dehydration. Multilayer lamellae are not observed for Nafion on Au or Pt surfaces. Instead, a thin partially hydrated single interfacial layer occurs and decreases in thickness as a few angstroms as humidity is reduced to zero. The absorption isotherm of the rest of the Nafion film is similar to that of bulk Nafion for all three surfaces investigated.

3:06PM D20.00004 RT-TDDFT simulation of the optical properties of a model organic photovoltaic device, F. VILA, J.J. REHR, U. of Washington — Organic solar cells are attracting much interest because of their potential as cost-effective photovoltaic devices. Prototypical cells consist of a bilayer of p- and n-type materials. The conversion of light into a current is initiated by the absorption of a photon in the p-type donor, mediated by the creation, diffusion and dissociation of an exciton, and finalized by a charge transfer to the n-type acceptor, with subsequent transport to the electrodes. To explore this issue, we simulate the optical response of a model bilayer cell composed of a polythiophene(pT)/C60 donor/acceptor pair using an efficient implementation of real-time TDDFT. We find that the chain twist induced by the C60 on the pT shifts the absorption onset from 1.8 to 2.0 eV. This shift is larger and of opposite sign compared to that induced by the inclusion of either regioregular or random side-chains in pT, and by the interaction between two pT chains. Finally, we discuss extensions for the simulation of charge transport and exciton mobility.

3:18PM D20.00005 Collecting photo-generated charge carriers from metallo-organic materials, A.R. CARTER, J.H. PARK, Dept. of Physics, The Ohio State University, Columbus, Ohio 43210-1117, Y.-H. CHOU, Y. GHOSH, C.R. REED, L.M. MIER, T.L. GUSTAFSON, M.H. CHISOLM, Dept. of Chemistry, The Ohio State University, Columbus, Ohio 43210-1185, A.J. EPSTEIN, Dept. of Physics and Dept. of Chemistry, The Ohio State University, Columbus, Ohio 43210-1117 — Organic photovoltaic materials continue to garner attention as potential low cost and tunable alternatives to conventional inorganics. We report progress in utilizing hybrid metal-organic materials that incorporate metal-metal (M-M) quadruply bonded units into oligothiophenes via carboxylate linkers. Varying the metal (M = Mo, W) or the ligands shifts the energetics and can be exploited to extend absorption into the infrared. These materials have high absorptivity from 300 nm (4.1 eV) to 900 nm (1.4 eV). We present the results of photophysical studies of structures that employ these materials.

1Supported by DOE Grants DE-FG35-08GO18024 (FV and JIR), DE-FG02-97ER45623 (JIR).

3:30PM D20.00006 Monolithic Tandem Organic Photovoltaic Cell Utilizing Transparent Carbon Nanotube Interlayer, KAMIL MIELCZAREK, University of Texas at Dallas, Physics Department, Nanotech Institute, SENKU TANAKA, Shimane University, University for Integrated Research in Science, RAQUEL OVALLE ROBLES, ALEXANDER KUZNETSOV, University of Texas at Dallas, Nanotech Institute, BRIAN WANG, University of Texas, DEAN HSU, University of Texas at Dallas, RAY BAUGHMAN, ANVAR ZAKHIDOV, University of Texas at Dallas, Nanotech Institute, ALAN G. MCDIARMID NANOTECH INSTITUTE TEAM — We demonstrate an organic photovoltaic multijunction cell in a monolithic parallel tandem structure in which transparent multi and single-walled nanotube sheets are used as an interlayer electrode connecting two cells; polymeric photovoltaic (PPV) cell or organic low molecular PV (OPV). Each cell is characterized independently and the short circuit current density of the tandem is shown to be larger than individual cells for the PPV-MWCNT-OPC tandem*. Overall efficiency is increased attributed to effective use of transparent CNTs and enhanced spectral sensitivity due to differing active layer materials. Computer model circuit simulation is used to analyze the parameters of cells in parallel and series configurations. Advantages of a parallel connection is shown for PV cells with differing photocurrents. The PPV-CNT-PPV and OPV-CNT-OPV cells are also created and described. *S.Tanaka, K Mielczarek, et al., APL. (submitted 2008, October).

3:42PM D20.00007 Tandem of solid dye-sensitized solar cell with carbon nanotubes interlayer, CHAO-CHEN YUAN, JIANGBIN XIA, ANVAR ZAKHIDOV, Univ. of Texas at Dallas NanoTech Institute — The light-to-electron conversion efficiency of the dye-sensitized solar cell (DSC) was recently improved up to 11.1%. However, this efficiency is not sufficient for cost-effective commercial production, so the expansion of the absorption region of the solar cell is needed. For transparent carbon nanotubes, parallel-connected tandem DSCs is developed. Novel parallel type of tandem cell structure is created. We create a parallel combination for cells using different dyes. The top cell is transparent and the bottom cell only uses light passing through the top cell. Instead of a common platinum counter electrode as interlayer, we use transparent carbon nanotubes (CNTs) coated on hole transport layers of each sub-cell, as an interlayer counter electrode. With high enough conductivity and high optical transparency, the compatibility of CNTs work as the interlayer counter electrode performing even better than Pt. The short-circuit current density (Jsc) for the tandem cell is demonstrated to be higher than that of separate the front and back photo electrodes. A model using light energy absorbed by the photo electrode is N719 top cell and a black-dye bottom cell is developed. Now the prototype of DSC tandem cell has been proved with the efficiency of 0.293% with 0.2 cm2 area.

1The novel material as an interlayer for tandem cell - Carbon nanotubes
3:54PM D20.00008 NEXAFS Spectroscopy of Biomimetic Dyes for Solar Cells. PETER COOK, XIAOSONG LIU, FRANZ HIMPSEL, Physics Department, University of Wisconsin Madison — Organic photovoltaics hold the potential for an inexpensive alternative to traditional silicon in solar cell production. A group of such dyes is investigated systematically including porphyrins, phthalocyanines, and cytochrome c, all of them characterized by a transition metal atom surrounded by a cage of four nitrogen atoms. X-ray absorption spectroscopy of the transition metal 2p and the nitrogen 1s absorption edges reveals the LUMO, the oxidation state of the transition metal, and its spin state. In addition, the sensitivity of these molecules to damage by photon-induced hot electrons is investigated. While the nitrogen cage is rather robust, the peptide bonds between the one hundred amino acids in cytochrome c are easily damaged. This finding suggests minimizing the size of biologically-inspired molecules for photovoltaic applications.

4:06PM D20.00009 Semiconductor Conjugated Polymer-Quantum Dot Nanocomposites at the Air/Water Interface and Their Performance in Thin Film Solar Cells. ZHIQUN LIN, MATTHEW GOODMAN, JUN XU, JUN WANG, Iowa State University — Organic-inorganic nanocomposites consisting of electroactive conjugated polymer, poly(3-hexyl thiophene) (P3HT) intimately tethered on the surface of semiconductor CdSe quantum dot (i.e., P3HT-CdSe nanocomposites) at the air/water interface formed via Langmuir isotherms were explored for the first time. The P3HT-CdSe nanocomposites displayed a high pressure plateau in the Langmuir isotherm, illustrating their complex packing at the air/water interface. Furthermore, photovoltaic devices fabricated from the LB depositions of the P3HT-CdSe nanocomposites exhibited a relatively high short circuit current, 1Sc, while maintaining a thin film profile. These studies provide insights into the fundamental behaviors of semiconductor organic-inorganic nanocomposites confined at the air/water interface as well as in the active layer of an organic-based photovoltaic device.

4:18PM D20.00010 Effect of polymer mobility on conductivity of single-ion conductors. KOKONAD SINHA, JANNA MARANAS, The Pennsylvania State University — Scientists are turning to the use of polymers as substitutes for liquid electrolytes in lithium ion batteries, because of their mechanical flexibility and non-toxic properties. Physical mixtures of lithium salt and poly(ethylene oxide) (PEO + LiClO4) are commonly chosen because they have potential for high ionic conductivities. However, high mobility of ions in these mixtures results in electrode polarization, which affects battery performance. To isolate the effect of the cation and to reduce the obstacle of concentration polarization, the anion is chemically incorporated into the backbone of the polymer, thereby rendering it immobile. These single-ion conductors are called ionomers. Neutron scattering experiments have been conducted on ionomers to observe the relation between ionomer mobility and ionic conductivity. Results show that with increasing ion content, there arises a new process at smaller length scales. Comparisons with PEO + LiClO4 systems hint at the formation of cation-PEO-anion complexes which are significantly slower in dynamics than the segmental motion of the polymer. This interaction between the cation and the polymer chain is of vital importance in understanding the fundamental mechanism of ion conduction in polymers.

4:30PM D20.00011 Electrochemical Characterization of poly (styrene-b-ethylene oxide)/LiTFSI Lamellar Diblock Copolymer Electrolyte System. NITASH BALSARA, University of California, Berkeley, CA, ASHUTOUSH PANDAY, Lawrence Berkeley Lab, Berkeley, CA, SCOTT MULLIN, NISITA WANKULIE, University of California, Berkeley, CA — We present the electrochemical characterization studies of symmetric poly (styrene-b-ethylene oxide) copolymers (SEO) and Li[N(SO2CF3)2] (LiTFSI). The molar ratio of Li to ethylene monomers, r, was varied from 0.02 to 0.10. The ionic conductivity of these electrolytes increases with molecular weight over the entire range of temperatures and r values examined. Preliminary data suggest that the salt diffusion coefficient also increases with increasing MW of PEO block.

4:42PM D20.00012 Progress toward few-molecule photochemistry with a low temperature STM. DAVID DAUGHTON, DONGHUN LEE, JAY GUPTA, The Ohio State University — Photochemistry at interfaces provides insight into molecular binding and charge transfer with future implications for organic photo-active devices. We have developed a novel instrument combining a low-temperature scanning tunneling microscope (STM) with a maneuverable, high numeric aperture lens in proximity to the tunnel junction for the study of photoactive systems with single molecule sensitivity. We will present the results of our initial efforts on the electronic and photo-induced polymerization of C60 islands, tunneling and photo-induced isomerization of thiondigo, and the effects of well-defined optical nanostructures on photochemical processes. http://www.physics.ohio-state.edu/~jgupta

4:54PM D20.00013 Confinement-Induced Fast Discharge and Low Dielectric Losses in Ferroelectric PVDF Graft Copolymers. LEI ZHU, FANGXIAO GUAN, ZHONGZHE YUAN, Polym. Program, Inst. of Mater. Sci. and Dept. of Chem., Mater. and Biomolecular Eng., University of Connecticut, Storrs, CT 06269-3136 — The relatively high dielectric loss of poly(vinylidene fluoride) (PVDF) and its copolymers limits their range of application as a high energy density capacitor material, although a high electric energy density was recently reported for millisecond discharge. In this work, we report time independent (or fast) discharge and reduced losses in ferroelectric poly(vinylidene fluoride) (PVDF) graft copolymer dielectric films. Experimental results suggested that the fast discharge and low losses were results of an increased amorphous content and nanoscale confinement of ferroelectric PVDF crystals.

5:06PM D20.00014 ABSTRACT WITHDRAWN —

Monday, March 16, 2009 2:30PM - 5:30PM — Session D21: Semiconductors: Transport 323

2:30PM D21.00001 Unified Theory of Charge Transport in Wide-Band and Narrow-Band Semiconductors. FRANK ORTMANN, FRIEDHELM BECHSTEDE, KARSTEN HANNEWALD, ETSF and IFTO, Friedrich- Schiller-University Jena, Germany — The charge carrier mobility is often calculated within one of the two limiting cases: wide bands or narrow bands. In the case of wide-band systems, usually pure band transport is assumed along with a calculated relaxation time. In contrast, for narrow-band materials, hopping is usually considered prevalent and the interaction with lattice vibrations is described within the polaron concept. In this talk, we will present a unified approach to the description of charge transport based upon the Kubo formalism applied to a Holstein Hamiltonian. As a result, we obtain an analytical formula for the temperature dependence and anisotropy of the mobility describing a seamless transition from band transport at low temperatures to hopping transport at high temperatures. The results are illustrated for naphthalene crystals and a comparison to previous approaches [1,2] is made.

2:42PM D21.00002 Carrier transport in nanodevices: a competitive playground for the Boltzmann and the Wigner distribution functions. FONS BROSENS, Universiteit Antwerpen, WIM MAGNUS, Interuniversity Microelectronics Centre (IMEC) — In principle, transport of charged carriers in nanometer sized solid-state devices can be fully characterized once the non-equilibrium distribution function describing the carrier ensemble is known. In this light, we have revisited the Boltzmann and the Wigner distribution functions and the framework in which they emerge from the classical respectively quantum mechanical Liouville equation. We have assessed the method of the characteristic curves as a potential workhorse to solve the time dependent Boltzmann equation for carriers propagating through spatially non-uniform systems, such as nanodevices. In order to validate the proposed solution strategy, we numerically solve the Boltzmann equation for a one-dimensional conductor mimicking the basic features of a biased low-dimensional transistor operating in the on-state. Finally, we propose a computational scheme capable of extending the benefits of the above-mentioned solution strategy when it comes to solve the Wigner-Liouville equation.

2:54PM D21.00003 Measurement and analysis of extraordinary electroconductance in Ti-GaAs hybrid structures1, J.S. SOLIN, A.K.M. NEWAZ, Y. WANG, J. WU, Washington University in St. Louis, W.-J. CHANG, V.R. KAVASSERI, I.S. AHMAD, I. ADESIDA, R. BASHIR, University of Illinois at Urbana-Champaign — We present a comprehensive study of a new phenomenon, extraordinary electroconductance (EEC), in microscopic and mesoscopic metal-semiconductor hybrid structures (MSS) at room temperature with different geometrical characteristics. Our artificially designed MSS structures show highly efficient external electric field sensing properties not exhibited by bare semiconductor structures. The EEC device has been fabricated from a GaAs epitaxial layer with a Ti/Au shunt. When subject to an external electric field it gives a maximum 5.2% EEC effect corresponding to an external electric field resolution of 3.05 V/cm at a bias field of 2.5 kV/cm. Moreover, the study reveals a strong dependence of the transport properties on the geometry of the MSS. An analytical 2-layer model is developed which provides good agreement with the experimentally observed data. We propose that scaled down nanoscopic EEC sensor arrays can be used as a novel technique for imaging the charge distribution on a single cell surface in real time.

3:06PM D21.00004 Universal oscillations in counting statistics, CHRISTIAN FLINDT, Harvard University, CHRISTIAN FRICKE, FRANK HOHLS, Leibniz University Hannover, Germany, TOMAS NOVOTNY, Charles University, Czech Republic, KAREL NETOCNY, Academy of Science, Czech Republic, TOBIAS BRANDES, Technical University Berlin, Germany, ROLF J. HAUG, Leibniz University Hannover, Germany — Noise and fluctuations are results of stochastic processes that originate from quantum or classical sources. Higher-order cumulants of the probability distribution underlying the stochastic events are believed to contain detailed information about the stochastic process, but they are often difficult to measure. In this talk we report the first measurements of the transient cumulants of the number of electrons passing through a quantum dot to very high orders (up to order 15) [1]. The cumulants grow factorially in magnitude with the cumulant order and show surprising oscillations as functions of measurement time. Based on theory for high-order derivatives in the complex plane we show that the oscillations in fact constitute a universal phenomenon, appearing as a function of almost any parameter for a large class of stochastic systems. Our analytical 2-layer model is developed which provides good agreement with the experimentally observed data [2]. We propose that scaled down nanoscopic EEC sensor arrays can be used as a novel technique for imaging the charge distribution on a single cell surface in real time.

3:18PM D21.00005 Bloch Oscillations of Electrons in a Quantum-Dot Superlattice1, DANHONG HUANG, Air Force Research Laboratory, S.K. LYO, Sandia National Laboratories — Numerical results for both the transient and steady-state currents in a strong DC electric field are presented for electrons in a quantum-dot superlattice. A microscopic scattering model is applied to study the dynamics of electrons scattered by impurities and phonons based on the Boltzmann equation. Good agreement is found between the numerical results and a recent analytic solution under a relaxation-time approximation for electron-phonon scattering [S. K. Lyo, Phys. Rev. B 77, 195306 (2008)]. Different roles played by elastic and inelastic scattering on the damped Bloch oscillations and the nonlinear steady-state are demonstrated from our numerical results. We will also briefly discuss suppression of the dynamical localization by strong Bloch oscillations under an additional nonlinear AC field and opposite roles played by elastic and inelastic scattering on the damped dynamical localization.

3:30PM D21.00006 Full Counting Statistics of a Quantum Point Contact with Time-dependent Transparency, JIN ZHANG, YURY SHERKUNOV, NICHOLAS D’AMBRUMENIL, BORIS MUZYKANTSKII, Department of Physics, University of Warwick — Controlled injection of single electrons into a ballistic conductor is essential for “moving-electron-based” quantum computation. We consider an electron system in two 1D ballistic conductors separated by a tunneling barrier at zero temperature. We present numerical results for the full counting statistics (FCS) for the case when the barrier potential is modulated in the presence of a time-dependent bias voltage applied between the leads. The calculation is based on Abanov and Ivanov’s formula[1]. For the case of a periodic input with a large number of cycles, we perform the calculation in discretized energy space and obtain the characteristic function $\chi(\lambda)$ as well as physical observables such as the current, noise and entanglement entropy directly. We show how to optimize the gate potential of a quantum point contact to generate a single electron excitation with minimal noise. [1]A.G. Abanov and D.A. Ivanov, Phys.Rev.Lett., 100, 086602.

3:42PM D21.00007 Optimal electron entangler at low temperatures, YURY SHERKUNOV, JIN ZHANG, NICHOLAS D’AMBRUMENIL, BORIS MUZYKANTSKII, University of Warwick — Electron transport in mesoscopic contacts at low temperatures is accompanied by logarithmically divergent equilibrium noise when a tunneling barrier transparency is changed abruptly. We show that the equilibrium noise can be dramatically suppressed in the case of tunneling junction with smoothly tunable transparency. We study analytically the full counting statistics of the transparency modulated quantum contact and identify the minimal excitation states generated by the gate voltage. The proposed scheme could be used as an optimal electron entangler at low temperatures.
3:54PM D21.00008 Observation of quantum phase shift in an Aharonov-Bohm ring with a fully controlled flying charge qubit, MICHIHISA YAMAMOTO, Department of Applied Physics, University of Tokyo, CHRISTOPHER BAUERLE, Institut Neel, CNRS, SEIGO TARUCHA, Department of Applied Physics, University of Tokyo, and ICPP-R-JST — Aharonov-Bohm effect is one of the most typical interference phenomena of electrons. Although a number of experiments have been performed to date, observation of phase shift at each path has been rather difficult due to the phase rigidity in the two-terminal setup. In this study, we employed a hybrid device consisting of a parallel coupled-wire and an AB ring, in which each coherently propagating electron acts as a flying qubit. In this device, phase rigidity no longer exists as there are two output contacts. The qubit is defined as superposition of two quantum states: an electron exists in one of the two wires. Then, the inter-wire tunnel coupling gives flipping between the two quantum states, and the evolution of the phase in the AB ring is translated into rotation about the z-axis of the Bloch sphere. In the experiment, we define the initial qubit state by injecting electrons into only one of the two wires, and obtained the arbitrary output state by tuning gate voltages. The output state also oscillates as a function of perpendicular magnetic field $B$ with the AB oscillation period. We observed the shift of k-vector in one of the two wires works equivalently as the shift of off. This is the direct observation of the phase shift $\Delta \phi = \Delta k l$.

4:06PM D21.00009 Current dependent dephasing in an Aharonov-Bohm Interferometer, KUAN-TING LIN, YIPING LIN, J. C. CHEN, Department of the Physics, National Tsing Hua University, Hsinchu 30013, Taiwan, T. UEDA, S. KOMIYAMA, Department of Basic Science, University of Tokyo, Komaba, Tokyo 153-8902, Japan — We have studied the temperature dependence of the current induced dephasing in a ballistic GaAs/AlGa$_x$As ring. The dephasing rate is linearly proportional to the temperature regardless of the current applied. The AB oscillations are suppressed by the increase of the excitation current; however, the dephasing becomes less temperature dependent. Our observations cannot be interpreted by Joule heating effect. Possible decoherence mechanisms caused by the excess current will be discussed.

4:18PM D21.00101 Tumbale Channel Interference in an Aharonov-Bohm Ring, YIPING LIN, PEI-JUNG WU, KUAN-TING LIN, J. C. CHEN, Dep. of Physics, National Tsing Hua University, Hsinchu, Taiwan, T. UEDA, S. KOMIYAMA, Dep. of Basic Science, University of Tokyo, Meguro-ku, Tokyo, Japan — We have investigated the Aharonov-Bohm effect in a quasi one-dimensional ring on a GaAs/Al$_{0.3}$Ga$_{0.7}$As heterostructure fabricated by two metallic arc deposition and shows only a 6% variation of the temperature dependence of the channel width of electrons, thereby externally tuning the transverse modes in the interference paths. The oscillatory magnetoconductance of the device is systematically studied by varying the number of channels in each path. We have observed the evidence of phase shifts in the magnetoconductance oscillations due to the suppression of the mode numbers on the ring path. Though the periodicity is not well resolved, qualitatively our data support the random phase shifts between the successive modes.

4:30PM D21.00111 Transport and noise in 90nm n-GaAs Epilayers, A. GILBERTSON, J.D. MOORE, G. PERKINS, J. GALLOP$^2$, L.F. COHEN, Imperial College, A.K.M. NEVIAZ, S.A. SOLIN$^3$, Washington University — Extraordinary Magnetoresistance (EMR) belongs to the family of EXX effects which form the basis for a number of devices that offer the potential for high sensitivity applications. Such devices would benefit from minimising the active volume of the sensor. To reduce that volume and minimize wafer fabrication complexity it is desirable to employ uni-tran-GaAs epilayers. Accordingly, we report here the transport and noise properties of 90nm Si-doped GaAs films grown by molecular beam epitaxy which have been fabricated into both microscopic EMR devices and macroscopic van der Pauw geometries. These films exhibit a room temperature electron mobility and density of 3225 cm$^2$/V s$^{-1}$ and 1.45x10$^{17}$ cm$^{-3}$, respectively, and shows only a 6% variation of the temperature dependence of the channel width of electrons, thereby externally tuning the transverse modes in the interference paths. The oscillatory magnetoconductance of the device is systematically studied by varying the number of channels in each path. We have observed the evidence of phase shifts in the magnetoconductance oscillations due to the suppression of the mode numbers on the ring path. Though the periodicity is not well resolved, qualitatively our data support the random phase shifts between the successive modes.

4:42PM D21.00012 New Measurement of Diffusion Thermopower of 2D Electron Systems, W.E. CHICKERING, J.P. EISENSTEIN, Caltech, J.L. RENO, Sandia — The thermoelectric properties of low-dimensional electronic systems provide information about carrier transport that is complementary to that obtained from charge transport and determined relatively easily. In conventional measurements of the thermopower $S$ of two-dimensional electron systems (2DEGs), phonon drag overcomes the diffusion thermopower $S_d$ of the electron gas for temperatures $T > \sim 0.1$ K. We introduce a new hot electron thermocouple technique which vastly reduces the importance of phonon drag and allows us to accurately determine $S_d$ in a 2DES in a GaAs/AlGaAs heterostructure. Differentialley gated 2DES channels provide the analogs of the dissimilar metals used in a conventional thermocouple. The device is calibrated via the temperature dependence of the longitudinal resistance of the 2DES at the thermocouple junction. Our results are in good quantitative agreement with the Mott formula for the temperature dependence of $S_d$ for temperatures up to $T \sim 2$ K. This work is supported by DOE grant DE-FG03-99ER45766 and Microsoft Project Q.

4:54PM D21.00013 Thermopower of n- and p-type InN, NATE MILLER, Lawrence Berkeley National Lab, Univ. of California - Berkeley, JOEL AGER, Lawrence Berkeley National Lab, REBECCA JONES, HOLLAND SMITH, Lawrence Berkeley National Lab, Univ. of California - Berkeley, LADEK WALUKIEWICZ, Lawrence Berkeley National Lab, WILLIAM SCHAFF, Cornell University, CHAD GALLINAT, GREGOR KOBLMULLER, JIM SPECK, Univ. of California – Santa Barbara — The exceptionally large (\textgreater{} 5.5 ev) electron affinity of InN leads to unique electronic properties such as surface electron accumulation and an extreme propensity for n-type conduction. This, combined with a small energy gap and strongly energy dependent effective mass, makes an analysis of charge transport and determination of band structure parameters an arduous task. In this work we show that thermopower (Seebeck coefficient) measurements can address some of the issues by providing a new tool to study the unique charge transport properties of InN and In-rich group III-nitride alloys. Our thermopower experiments are used to demonstrate the presence of mobile holes in Mg-doped InN providing the first direct, quantitative measurement of hole transport in InN. We also report modeling of the thermopower of n-type InN considering the various scattering mechanisms.

5:06PM D21.00014 Measurement of [N] and T-dependence of electron effective mass in GaAsN, TASSILIO DANNECKER, Tyndall National Institute, YU JIN, Materials Science and Engineering, University of Michigan, JOHN BUCKERIDGE, Tyndall National Institute, CITTERAU UHER, CAGLIYAN KURDAK, Physics Department, University of Michigan, STEPHEN FAHY, Tyndall National Institute, RACHEL S. GOLDMAN, Materials Science and Engineering, University of Michigan — The electron effective mass of GaAs$_{1-x}$N$_x$ is predicted to be dependent on N-composition, $x$, and temperature, $T$; however, conflicting results have been observed using cyclotron resonance and thermomagnetic measurements. Using thermopower and Hall measurements, in conjunction with assumptions of parabolic bands and Fermi-Dirac statistics, we determined the T-dependence of the electron effective mass of GaAs$_{1-x}$N$_x$, in comparison with that of GaAs. Measurements of the T-dependent Seebeck coefficient, $S$, for N compositions ranging from $x=0$ to 0.0100, reveal a decrease in $\Delta S$ with $x$. For GaAs, the free carrier concentration, $n$, is independent of $T$. In all other cases, $n$ increases (decreases) with $T$. For GaAsN, the effective mass decreases from 0.06$\mu_0$ at 140K to 0.052$\mu_0$ at 300K, similar to literature reports. For GaAsN, the effective mass approximately decreases (increases) with $x$ and $T$, ranging from 0.18$\mu_0$ to 0.16$\mu_0$ at 140K, with values 14% (40%) lower for $x=0.0075$ ($x=0.0100$) at 300K.
5:18PM D21.00015 Temperature dependence of electron mobilities in InN\(^1\). LEONARDO HSU, University of Minnesota, WLADIMIR WALUKIEWICZ, Lawrence Berkeley National Laboratory — InN allows the possibility of engineering nitride materials with bandgaps as small as 0.7 eV. We have calculated electron mobilities in InN taking into account the non-parabolicity of the conduction band, as well as the standard scattering mechanisms of acoustic and optical phonons and Coulomb scattering from charged impurities. Although our calculations explain well the experimentally measured mobilities at temperatures higher than about 200 K, the measured mobilities in lightly doped InN at low temperatures decrease in a way that cannot be accounted for by the standard theory. We discuss the characteristics and possible origins of the additional mechanism that must be included in the calculations in order to fit the experimental results.

Session D22 GMAG DMP FIAP: Focus Session: Spins in Group IV Semiconductors 324

2:30PM D22.00001 Quantum control of donor electron charge and spin in Si close to a Si-SiO\(_2\) interface. BELITA KOILLER\(^1\). Instituto de Fisica, Universidade Federal do Rio de Janeiro, Brazil — Doped Si is a promising candidate for quantum information processing due to its potential for scalability, long spin coherence times, and the continuing progress on Si material processing, technology and miniaturization over several decades. I will discuss important issues for single- and two-qubit operations in Si-based quantum computer proposals involving P donors close to a SiO\(_2\) interface. For a single donor, bound-orbital electron manipulation between the donor and the interface by electric and magnetic fields is investigated [1,2]. Valley interference and how it affects a donor electron close to an interface under an applied electric field is also considered, taking the valley-orbit coupling at the interface as a parameter. It will be shown that, for nonzero interface valley-orbit coupling, this configuration leads to oscillatory behavior of the donor ionization time as a function of the donor-interface distance while the characteristic ionization field does not oscillate with distance [3]. The physical origin of these effects, and their impact in proposed operations of donor-based qubits, will be discussed. For a donor pair, the exchange coupling of interface electrons bound to the donors double well potential is calculated within the Heitler London approach [2,4]. The feasibility and convenience of performing exchange operations for electron pairs at the interface as opposed to around the donors will be assessed. Work done in collaboration with M.J. Calderon and S. Das Sarma and partially supported by LPS-NSA and MICINN-Spain.

3:06PM D22.00002 A new electrical readout mechanism for Si:P qubits. DANE R. MCCAMEY, University of Utah, G.W. MORLEY, London Centre for Nanotechnology, S.-Y. PAIK, S.-Y. LEE, University of Utah, L.-C. BRUNEL, University of California, Santa Barbara, J. VAN TOL, National High Magnetic Field Laboratory, C. BOEHME, University of Utah — Phosphorus donor spins in silicon are a promising candidate for the implementation of quantum bits, and electrical detection is viewed as the most promising route towards the single donor readout required to further advance such concepts. We will discuss a major limitation to commonly used electrical detection schemes. The standard way to electrically detect Si:P spin states involves utilizing spin dependent recombination with nearby probe spins, usually of defects at the Si-SiO\(_2\) interface. This process has a fast, fixed timescale, thereby limiting coherence times. We find that these times are of order 1\(\mu\)s, in agreement with other studies. By moving to high magnetic fields (\(B > 8 \text{T}\)) we enter a new regime - complete electron polarization. This allows us to utilize a different readout mechanism, namely, capture into the donor D\(^-\) state which causes a decrease in the photocurrent in the sample. We have developed a system which allows us to investigate the donor spin phase coherence times at these high magnetic fields; we find them to be over 100\(\mu\)s [1]. Additionally, the signal observed at these high fields is significantly larger (\(\Delta I/I \sim 5\%\)) than at low fields, providing a pathway towards single spin detection. [1] PRL 101, 207602 (2008)

3:18PM D22.00003 SU(4) Kondo in a single donor transport in a Si FinFET. G.P. LANSBERGEN, G.C. TETTAMANZI, A. VERDUIJN, M. BLAUBOER, S. ROGGE — Recently, single dopants became experimentally accessible and there is a large effort to exploit their atomic characteristics in nano devices. Orbital Kondo effects in Si and SiGe are of fundamental interest since they explore the role of the valley degree of freedom in this material system. It has been theoretically predicted that the valley degeneracy leads to SU(4)-correlations which entangles the spin and momentum of exchanged electrons. Here, we experimentally study Kondo effects in a novel system, a single shallow donor in a three-terminal geometry. We use Si wrap-around gate (FinFET) devices with a single Arsenic donor atom in the channel dominating the sub-threshold transport characteristics. The ground state of this system originates from the hybridization of the donor hydrogen-like state which has no valley degeneracy (due to the strong valley-orbit interaction) and a quantum dot-like state which is two-fold valley degenerate. In the Coulomb-blockade regime with a single electron on the system we observe a set of transport resonances. We show these resonances to originate from Valley Kondo effects by means of their dependence on temperature, magnetic field, orbital splitting and their substructure. The entanglement between spin and momentum provides new opportunities for spin control in silicon. For example, we show that this device operates as a gated spin filter in Si with a potentially high transitivity.

3:30PM D22.00004 Electric field control of spins in a silicon two-dimensional electron gas. R. JANSEN, B.C. MIN, S. P. DASH, R. S. PATEL, M. P. DE JONG, University of Twente, MESA+ Institute for Nanotechnology, The Netherlands — A key objective in the development of semiconductor spintronics is the active control of spins in semiconductors. The manipulation by electric rather than magnetic fields is preferred as this is more efficient for nanoscale high frequency devices. Proposals for electric spin control, for example in use in a spin transistor, have so far focused on mechanisms that require spin-orbit interaction. Unfortunately, in silicon, the mainstream semiconductor, the weak spin-orbit interaction renders these mechanisms unsuited. Hence, alternative approaches are paramount to the success of semiconductor spintronics. Here we demonstrate spin control by electric fields in a silicon two-dimensional electron gas (2DEG), exploiting the discrete electronic structure of the 2DEG. This, in combination with an electric field, allows spin manipulation without the need for spin-orbit interaction. The spin control is manifested as resonances in the tunnel magnetoresistance between the Si 2DEG and a ferromagnetic tunnel contact, with amplitude of up to 8%.
3:42PM D22.00005 Injection and extraction of spins in a Silicon lateral transport structure . OLAF VAN 'T ERVE, CHAFFRA AWO-AFFOUDA, AUBREY HANBICKI, MICHAEL HOLUB, CONNIE LI, PHILLIP THOMPSON, BÉRENDE JONKER, Naval Research Laboratory, NAVAL RESEARCH LABORATORY TEAM — Significant progress has recently been made on spin injection into the technologically important semiconductor, Si. A nonlocal measurement technique, which excludes spurious contributions from AMR and local Hall effects, was used to show lateral diffusive spin transport through silicon using Fe/Al2O3 surface contacts. The tunnel contacts are used to create and analyze the flow of pure spin current in a silicon transport channel. The nonlocal signal shows that a spin current can be electrically detected after diffusive transport through the silicon transport channel and the signal depends on the relative orientation of the magnetization of the injecting and detecting contacts. Hanle effect measurements up to 125 K demonstrate that the spin current can be modulated by a perpendicular magnetic field, which causes the electron spin to precess and dephase in the channel during transport. By changing the bias on the injector contact we can either inject or extract spin from the Silicon channel. Here we will show using Hanle and lateral spin-valve measurements that we can change the polarization of the spin accumulation by going from the injection regime to the extraction regime and we will compare the efficiency of spin-injection versus spin extraction.

3:54PM D22.00006 Spin Precession in Oblique Magnetic Fields . JING LI, BIQIN HUANG, Department of Electrical and Computer Engineering, University of Delaware, IAN APPELBAUM, Department of Physics, University of Maryland, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, UNIVERSITY OF DELAWARE TEAM — Spin precession and dephasing (“Hanle effect”) provide an unambiguous means to establish the presence of spin transport in semiconductors. We compare theoretical modeling with experimental data from drift-dominated silicon spin transport devices, illustrating the non-trivial consequences of employing oblique magnetic fields (due to misalignment or intentional, fixed-in-plane field components) to measure the effects of spin precession. Model results are also calculated for Hanle measurements under conditions of diffusion-dominated transport, revealing an expected Hanle peak-widthing effect induced by the presence of fixed-in-plane magnetic bias fields.

4:06PM D22.00007 Geometric dephasing-limited Hanle effect in long-distance lateral silicon spin transport devices . BIQIN HUANG, HYUK-JAE JANG, University of Delaware, IAN APPELBAUM, University of Maryland — Using ballistic injection and hot-electron spin filter detection, lateral spin transport over 2 millimeters is demonstrated in undoped single-crystal Silicon. In these devices, geometrically-induced dephasing (Hanle effect) is so strong that the effects of spin precession could not be measured with only a single-axis magnetic field. However, a two-axis magnetic field can be used to obtain unequivocal evidence of spin precession and transport despite full dephasing. We therefore conclude that there is never a reason to avoid measurement of spin precession as unequivocal evidence of spin transport in semiconductor devices.

4:30PM D22.00009 Indirect Optical Injection of Carriers and Spin in Silicon . JINLUO CHENG, Hefei National Laboratory for Physical Sciences at Microscale, University of Science and Technology of China, JULIEN RIOUX, JOHN SIPE, Department of Physics and Institute for Optical Sciences, University of Toronto — Degenerate two-photon indirect absorption in silicon is an important limiting effect on the use of silicon structures for all-optical information processing at telecommunication wavelengths. Optical injection of spins in silicon is potentially important for spintronics applications. We theoretically investigate one- and two-photon indirect absorption in silicon, using a pseudopotential description of energy band and the adiabatic bond charge model to describe phonon dispersion and polarization. Spin injection is calculated as well. We compare our results with experiments.

4:42PM D22.00010 Transient Current Spectroscopy of a Si Quantum Dot . MING XIAO, HONGWEN JIANG, UCLA — We present a transient current spectroscopy study of a Si-MOS based quantum dot. The study was conducted in the few electron region. A voltage pulse pumps the electrons into an excited orbital state and the non-equilibrium transient current through the dot was recorded. The evolution of the excited state as a function of magnetic field shows signatures of a transition from a spin singlet state to a triplet state of an electron pair. A pump-and-probe technique was employed to set a lower limit of the triplet-singlet relaxation time. The work was sponsored by United States Department of Defense.

4:54PM D22.00011 Magneto-transport properties of Bi-based Nanowires . SUNGMU KANG, JUGDERSUREN BATTGGOTOKH, ANDREW C. BUCHELE, DAVID A. MCKWEO, IAN L. PEGG, JOHN PHILIP1, Catholic University of America, VITREOUS STATE LABORATORY COLLABORATION — We report the growth and magneto-transport properties of Bi-based, Mn$_3$SiC nanowires grown using chemical vapor deposition. High resolution transmission electron microscopy and x-ray diffraction studies show that the nanowires crystallize in Mn$_3$SiC orthorhombic structure. Ferromagnetic Mn$_3$SiC nanowires were grown using a coordination complex-based precursor. In the presence of an external magnetic field, Mn$_3$SiC nanowire-based devices exhibit spin dependent transport at room temperature. A large change in current with almost two orders of magnitude increase is observed when a small field is applied parallel to the axial direction of the nanowire. We will discuss in details the magneto-transport properties of Mn$_3$SiC nanowire based devices.

5:06PM D22.00012 Prospects of Spin Injection in Germanium Nanowires . EN-SHAO LIU, KAMRAN VARAHRAMYAN, JUNGYO NAH, SANJAY BANERJEE, EMANUEL TUTUC, Microelectronics Research Center, University of Texas at Austin — Efficient spin injection from ferromagnetic (FM) contacts into semiconductors (SC), the prerequisite for spin-based semiconductor devices, is typically suppressed by the conductivity mismatch between the FM contact and the SC. A significant spin injection can be achieved however if the contact resistivity at the FM/SC interface is appropriately engineered [1]. We report here contact resistivity measurements of n-type germanium (Ge) nanowires (NWs) with two FM metals, namely permalloy (Ni$_{80}$Fe$_{20}$) and nickel (Ni), for NW doping densities between $10^{16}$ and $10^{20}$cm$^{-3}$, and for temperatures between 77K to 300K. Using back-gated two- and four-terminal measurements, we show that the contact resistivity varies from $10^{-2}$($\Omega \cdot \text{cm}$) for highly-doped NWs, to $10^{-4}$($\Omega \cdot \text{cm}$) for moderately-doped NWs. Within the framework of the spin injection theory [1], these values indicate that by optimizing the device parameters, namely the choice of FM metal, contact width, NW diameter and doping density, spin injection into Ge NWs is possible. [1] A. Fert and H. Jaffres, Phys. Rev. B. 64, 184620 (2001)

Session D23 DCMP: Diffusion and Transport Properties 325

2:30PM D23.00001 A multiscale study of hydrogen embrittlement of metals: Revisiting the hydrogen enhanced local plasticity (HELP) mechanism. JOHANN VON PEZOLD, JÖRG NEUGEBAUER, Max Planck Institut fuer Eisenforschung GmbH, Duesseldorf, Germany — The embrittlement of metals by H is a long-standing problem, whose underlying mechanisms are still largely unclear. Here we consider the atomistic basis of the HELP mechanism, which asserts that H mobilises dislocations by shielding elastic dislocation-dislocation interactions. Using a combination of density-functional theory calculations, semiempirical EAM potentials and an effective lattice gas Hamiltonian we determine the interaction of H with the strain field around edge dislocations in Ni. Our results reveal an attractive, but short ranged interaction between H interstitials, which leads above a critical concentration to the formation of a precursor hydride phase. The increased lattice parameter of this hydride phase induces significant misfit stress, but localises the dislocation stress field due to a localisation of the dislocation strain field. For H concentrations of up to 0.25 at. %, the stress localisation is found and thus effectively shields the stress field of the dislocation, pointing towards a novel atomistic basis for the HELP mechanism.

2:42PM D23.00002 DFT energetics of hydrogen binding to point defects in iron and steels. WILLIAM COUNTS, CHRIS WOLVERTON, RON GIBALA, Northwestern University — It is well known that hydrogen degrades the properties of iron and steel. One proposed mechanism of hydrogen attack is the concept of "hydrogen traps", which are generally microstructural material defects that bind hydrogen atoms. The stability and energetics of a number of potential traps (like vacancies, interstitials, and substitutional alloying elements) in bcc and fcc iron are investigated using density functional theory (DFT). We find that hydrogen is very sensitive to its local environment. For example, in a perfect bcc iron lattice, hydrogen prefers to sit in the tetrahedral site rather than the octahedral site or a substitutional site, and there is a repulsive interaction between carbon and hydrogen. In the presence of a vacancy, the energy barrier between the octahedral and tetrahedral sites disappears and hydrogen only resides in the octahedral sites. The hydrogen-vacancy binding energy changes as more hydrogen atoms bind to the vacancy, but the binding energy does not significantly change in the presence of carbon. We also find that H2 molecules are not stable inside a vacancy: they dissociate spontaneously (without a barrier) into octahedral positions. Details about vacancy and other potential traps are presented and their roles in hydrogen embrittlement are discussed.

2:54PM D23.00003 First-principles studies of helium in palladium tritides: PdT3 = (0 ≤ x ≤ 1). PEI LIN, YAN WANG, M.Y. CHOU, School of Physics, Georgia Institute of Technology — Helium bubbles have significant impact on the stability and mechanical properties of materials used in nuclear-energy systems. Theoretical studies on the behavior of H in various metals have been reported in the past. However, few studies have taken into account the effect of the coexistence of He and tritium (3H) in the metal lattice. We have performed first-principles calculations of He inside palladium tritides with various H concentrations. Instead of interacting with He impurities directly, the interstitial H mainly modifies the electronic structure of the metal lattice. The Pd d-orbital near the Fermi-level shifts downward as H atoms occupy the interstitial sites, which in turn promotes the interaction between He 2-s and Pd 4-d states. We have examined the changes in the formation energy of an He impurity with various H concentrations. The effect will further modify the energetics of trapping multiple He atoms to form a cluster inside the hydrogenated Pd system.

3:18PM D23.00005 Prediction and Modeling of Atomic Mobility in Alloys, ZI-KUI LIU, Department of Materials Science and Engineering, The Pennsylvania State University — Atomic diffusion is a common and important non-equilibrium process in solids that takes place at finite temperatures. To computationally simulate atomic diffusion processes, the thermodynamic and atomic mobility databases of the materials of interest are needed. The modeling technique of atomic mobility databases and related software has been becoming more and more matured in the last decades. However, the input data for the modeling is exclusively taken from experimentally measured tracer and chemical diffusion coefficients. In this presentation, our recent progress in predicting self and dilute diffusion coefficients by quantum mechanics calculations will be discussed [1]. Our approach to the unstable vibrational mode of transition states during diffusion will be presented. The contribution to phenomenological modeling of atomic mobility will be briefly.

3:30PM D23.00006 Analysis of Cd jump rates among the two Ga sublattices in Ga2-Pd3 using a stochastic model of hyperfine interactions. , M. O. ZACATE, Northern Kentucky University, Highland Heights, KY, W. E. EVENSON, Utah Valley University, Orem, UT, G. S. COLLINS, Washington State University, Pullman, WA — Atomic jump rates of Cd among the two inequivalent Ga sublattices in Ga2-Pd3 were measured using perturbed angular correlation spectroscopy (PAC). Atomic jumps result in a reorientation and/or change in strength of electric field gradients experienced by the Cd PAC probes. Spectra were fitted to model functions generated using a stochastic model for fluctuating EFGs under the assumption that Cd probes can jump to nearest neighbor sites of each Ga sublattice. Jump activation energies were determined by fitting spectra collected at different temperatures simultaneously under the constraint that jump rates obey Arrhenius behavior. The following activation energies were determined for intra-sublattice jumps: 0.52(1) eV for Ga(3)→Ga(3) and 0.25(4) eV for Ga(4)→Ga(4) and for inter-sublattice jumps: 0.6(3) eV for Ga(3)→Ga(4) and 0.47(9) eV for Ga(4)→Ga(3), in which Ga(4) denotes the site with .3m point symmetry.

3:42PM D23.00007 Vanadium diffusion in ferrite, SUNGHO KIM, JEFFREY HOUZE, SEONG-GON KIM, MARK HORSTE-MEYER, Mississippi State University — Vanadium is a very important additive in high strength steel alloys. Small amount of vanadium addition strengthens the steel alloys. As a first step to study the effect of vanadium addition in steel alloys we calculated the diffusion path and the migration energy of vanadium atom in ferrite crystal using first principles calculations.
3:54PM D23.00008 Anisotropic physical properties of RSn2 (R = Gd - Lu) single crystals, EMILIA MOROSAN, MICHAEL MEHLMAN, LIANG ZHAO, THOMAS SANDERS, Physics and Astronomy, Rice University — A wealth of magnetic and electronic properties (including metamagnetism, spin glass, non Fermi liquid behavior etc) has been observed in rare earth intermetallic compounds. The availability of these systems in single crystal form is imperative for characterizing their complex behavior. We are reporting the anisotropic physical properties of single crystals of the orthorhombic RSn2 compounds (R = Gd - Lu). Complex anisotropic H-T phase diagrams are observed in GdSn2, which has an antiferromagnetic ground state below 27.5 K, with two more transitions at lower temperatures. The magnetic field induces magnetostatic phase transitions in several of the R members of the series.

4:06PM D23.00009 Mesostructural properties of RCO2 (R = rare earth) compounds1, DURGA PAUDYAL, YA. MUDRYK, Ames Laboratory of the USDOE, Iowa State University, Ames, IA-50011, V. K. PECHARSKY, K. A. SCHNEIDER, JR., Ames Laboratory of the USDOE and Department of Materials Science and Engineering, Iowa State University, Ames, IA-50011 — First principles electronic structure calculations show that the cubic Laves phase (C15) is stable for GdCO2 and TbCO2, while the ground state structures of DyCO2, HoCO2, and ErCO2 are tetragonal distortions of the cubic C15, orthorhombic, and rhombohedral structures, respectively. The R and Co moments exhibit antiparallel coupling, forming a ferrimagnetic state in every monomorphic ground state structure of RCO2. The predicted mesostructural properties of RCO2 are in good agreement with x-ray powder diffraction and magnetic measurements. The spin splitting of the conduction electrons due to the indirect R-R exchange plays a crucial role in the mesostructural transformations in the R = Dy, Ho, and Er RCO2 phases, and accounts for its absence in the monomorphic GdCO2 and TbCo2 compounds.

4:18PM D23.00010 Transition in NiMnSn and NiMnIn, C.P. OPEIL, Boston College, J.C. LASHLEY, J.L. SMITH, Los Alamos National Laboratory, T. PLANES, L. MANOSA, University of Barcelona — Magneto-transport, specific heat, magneto-striction and temperature dependent UV photoemission are used to explore the martensite transition of the ferromagnetic shape memory alloys Ni2MnIn2, Ni2MnIn2Sn2. Comparisons will be made to a previous work on the stoichiometric single crystal Ni2MnGa which reveals a temperature (T ≥ 190 K) and field dependent (0 – 1 T) positive/negative magneto-resistance slope. Our experimental results will be discussed in light of a possible pseudo-gap formation coincident with the martensite transition in the two off-stoichiometric alloys.

4:30PM D23.00011 Measurements of persistent currents in normal metal rings with cantilever torsional magnetometry, WILLIAM SHANKS, ANIA BLESZYNSKI JAYICH, BRUNO PEAUDECERF, JACK HARRIS, Department of Physics, Yale University — We have measured the magnetization of arrays of micron-scale aluminum rings at low temperatures and in high magnetic fields using cantilever torsional magnetometry. We see clear evidence of normal state persistent currents in these rings. The current’s dependence on magnetic field, temperature and the rings’ circumference is consistent with theoretical predictions (due to Riedel and von Oppen) for non-interacting electrons in the diffusive regime. To fully characterize these samples, we also measured the magnetization of codeposited rings in the superconducting state and the magnetoresistance of codeposited wires. Together these measurements provide an especially clear picture of the normal-state persistent currents.

4:42PM D23.00012 ABSTRACT WITHDRAWN —

4:54PM D23.00013 AC-conductance of a quantum chaotic cavity (semiclassical approach)1, C. PETITJEAN, D. WALTNER, J. KUIPERS, I. ADAGIDELI, K.R. RICHTER — Due to the progress made in the control and the manipulation of mesoscopic structures driven by high frequency periodic voltages, the ac regime has been recently experimentally investigated [1] and consequently its theoretical interest has been renewed. We consider here, a quantum chaotic cavity that is coupled via tunnel barriers and gates to a macroscopic circuit which contains ac-sources [2]. By extending to the ac-transport, the recent trajectory-based semiclassical theory of quantum chaotic transport in presence of tunnel barrier [3], we derive for arbitrary tunneling rates and arbitrary positive Ehrenfest time, the averaged and the weak-localization correction to the screened conductance. Then we use these results to investigate the effect of dephasing on the relaxation resistance of a chaotic capacitor in the linear low frequency regime. This last investigation is of prime importance as it is very close to the recent measurement of the admittance at zero magnetic flux of a mesoscopic capacitor [1,4].

5:06PM D23.00014 ABSTRACT WITHDRAWN —

5:18PM D23.00015 Evidence for Conditioning as a Progenitor of Double-C Transformation Mechanisms in Pu-Ga Alloys1, J.R. JEFFRIES, K.J.M. BLOBAUM, M.A. WALL, A.J. SCHWARTZ, Lawrence Livermore National Laboratory — By alloying Pu with Ga, the fcc δ phase can be retained down to room temperature. This metastable δ phase is realized due to slow Ga diffusion, which prevents the δ phase from decomposing into the equilibrium mixed phase structures. The metastable δ phase in a Pu-1.9 at.% Ga alloy, however, does yield to chemical driving forces by undergoing the δ → α' isothermal martensitic transformation below Mα' ≈ -100 °C. This transformation exhibits poorly understood double-C behavior in the time-temperature-transformation diagram. Recently, a “conditioning” treatment—which entails isothermally holding a specimen at sub-annal temperatures but above Mα' —has been shown to dramatically affect the amount of α' phase formed at low temperature. We report evidence that the conditioning treatment induces the lower-C of the double-C curve, and we implicate the classical nucleation of equilibrium phases as the underlying mechanism behind conditioning in Pu-Ga alloys.

Session D24 DMP: Focus Session: Nanotube manipulation and processing 326
2:30PM D24.00001 Carbon nanotube devices: Sorting, Assembling, Characterizing  
RALPH KRUPKE, Forschungszentrum Karlsruhe — Carbon nanotubes have been studied extensively over the last decade. Various exceptional properties have been revealed which still drive the vision about using carbon nanotube in future electronics, for instance as molecular nanoscale transistors or electromigration resistant interconnects. For many years a major obstacle was the inability to grow nanotubes with defined dimensions (length, diameter) and electronic properties (metallic, semiconducting). Recently these problems have been solved to a large extent by advanced sorting techniques. Today the challenge is to assemble nanotubes devices with defined properties to form a complex circuit. As progress is made in making highly-integrated nanotube device arrays new characterization techniques have to be developed which allow testing large number of devices within an acceptable time. Along this line I will report on the state-of-the-art of sorting of carbon nanotube, as a base for nanotube device fabrication [1]. I will then explain our strategy to assemble high-density arrays of nanotube devices [2] and discuss a new characterization technique for nanotube devices [3]. Finally I will introduce a novel device engineering tool [4].

3:06PM D24.00002 Self-healing and adsorbate-induced removal of defects on graphene and carbon nanotubes  
LEONIDAS TSETSERIS, Vanderbilt University and University of Thessaloniki (Greece), SOKRATES PANTELIDES, Vanderbilt University and Oak Ridge National Laboratory — The presence of point defects is known to induce significant changes in the electronic, chemical, transport, and mechanical properties of graphitic systems. Here, we use first-principles calculations based on density-functional theory to describe several adatom-related processes that alter key physical traits of graphene and carbon nanotubes. We find that, while pairs of C adatoms and clusters of four or more self-interstitials stay idle unless the system is heated to very high temperatures, clustering of three C adatoms leads to removal of hillock-like features and creates mobile species, resulting in self-healing of defective structures. We also demonstrate the reactivity of defect pairs using hydrogen and oxygen as prototype adsorbates, and we show that interaction with extrinsic species is an alternative healing mechanism for adatom structures in the above systems. The results relate to the evolution of defects either during growth of carbon nanotubes or during post-growth treatment and operation of related devices. This work was supported in part by DOE Grant DEFG0203ER46096.

3:18PM D24.00003 Self-similar mechanics of vertically aligned carbon nanotube organization  
MICHAEL DE VOLDER, SAMEH TAWFICK, DANIEL VIDAUD, A. JOHN HART, University of Michigan — It is well-known that carbon nanotube (CNT) growth from a dense arrangement of catalyst nanoparticles creates a self-organized vertically aligned CNT “forest” that offers attractive anisotropic mechanical, thermal, and electrical properties. Self-organization is governed by the CNT diameter and spacing, and the surface interactions between contacting CNTs. We demonstrate that arrays of CNT microstructures having micron-scale diameter organize in a similar manner as individual CNTs within a forest. For example, as postulated for forest CNTs, entanglement of CNT microstructures during the initial stage of growth creates a self-supporting network, and this enables coordinated subsequent growth of the structures in the vertical direction. The alignment of these self-similar CNT forests is inversely related to the spacing of the individual CNTs, and like individual CNTs, widely-spaced microstructures that are not self-supporting fail to organize into an oriented superstructure. The growth rate and final forest height also depend on these geometric conditions, suggesting that mechanical interactions affect the collective progression and termination of a CNT film. This study and method offers new insights into the self-organization of one-dimensional nanostructures, and coordinated assembly of CNT microstructures offers opportunity for engineering energy-absorbing foams and photonic crystals.

3:30PM D24.00004 Debundle of Single-Walled Carbon Nanotubes with Exfoliated Nanoplatelets1, DAZHI SUN, WILLIAM EVERETT, CHIEN-CHIA CHU, HUNG-JUE SUE, Texas A&M University, PROF. SUE'S TEAM — We report a simple and effective colloid method to disperse single-walled carbon nanotubes (SWNTs) down to individual-tube level by utilizing exfoliated nanoplatelets in various solutions and polymer matrices. This approach yields a substantial amount of individual tubes without compromising their physical properties. The de- bundling and dispersion of SWNTs are confirmed by high-resolution transmission electron microscopy, UV-vis-NIR and Raman spectroscopy. After incorporated into polymers, SWNTs maintain individual dispersion. The dispersion mechanisms and implications of this approach are also discussed.

1We thank Kaneka and Defense Logistic Agency (SP0103-02-D-0003) for their partial financial support of this research.

3:42PM D24.00005 Motion and Manipulation of Suspended Single-Walled Carbon Nanotubes in Solution  
YA-QIONG XU, Laboratory of Atomic and Solid State Physics, Cornell University, ARTHUR BARNARD, School of Applied and Engineering Physics, Cornell University — In this study, we fabricated and manipulated single-walled carbon nanotubes (SWNTs) in a liquid medium using microfluidics. The microfluidic system combines manipulative techniques with optical trapping techniques and the scanning photomicroscopy to investigate the motion of suspended single-walled carbon nanotubes in solution. This setup enables us to study the movement of nanotubes by monitoring their photocurrent images and to measure their thermal fluctuations through observing the movement of microbeads that are tightly attached to nanotubes by single-stranded DNA. By analyzing their thermal fluctuations, we are able to obtain the thermal and translational stiffness of nanotubes and then calculate their diameters. We can also manipulate their motions by using an optical trap to pull on microbeads attached to nanotubes.

3:54PM D24.00006 Processing of SWNT Dispersions – Microfluidic Processing vs. Ultrasonication  
TAO LIU, SIDA LUO, CHUCK ZHANG, BEN WANG, High Performance Materials Institute, Florida State University — Ultrasonication is the most commonly used processing technique for dispersing SWNTs in various media. High-power sonication enables the desired dispersibility enhancement and the exfoliation of large SWNT bundles to smaller and even individual tubes. However, one disadvantage for this process is that the SWNT particles can be cut to shorter length. Using a newly developed characterization technique by us for quantifying the structures of SWNTs in a dispersion, we investigated the structural changes of SWNTs due to two different dispersion processing techniques, namely, microfluidic processing and ultrasonication. As a result, the microfluidic processing method shows significantly improved exfoliation efficiency as compared to ultrasonication. Moreover, the length of the exfoliated SWNT particles is maintained upon microfluidic processing, in contrast to the cutting effect caused by the high power sonication. In this presentation, we will discuss in-depth on the processes of SWNT dispersions processed by these two different processing methods.

4:06PM D24.00007 Steric Mode Separation of Nanotubes Using Electric Field, Field-Flow Fractionation  
FREDERICK PHELAN, BARRY BAUER, NIST — A Brownian dynamics simulation is used to study the separation of rodlike particles in Electric Field, Field-Flow Fractionation (EF-FFF), in which in addition to the FFF cross-flow, a uniform AC field acts in the gradient direction. Under these conditions, the electric field acts to align the tubes in the gradient direction in competition with both the shear field and Brownian motion. The simulation results show that as the rods become increasingly aligned, they undergo a transition from normal mode to steric mode separation. By exploiting field conditions in which either metallic or semi-conducting types are preferentially oriented relative to the other, this can be used in the context of nanotube separation as a means for separating tubes by type.
Stokes and antiStokes Raman scattering, from which we infer the mode population of the G-mode phonons. We observe a large nonequilibrium phonon population of the zone-center (G-mode) optical phonons is created by an initial fs laser pulse. A subsequent fs probe pulse generates both 650K. The measurements are performed using a pump-probe Raman scattering scheme with femtosecond (fs) laser pulses [Song et al. PRL 100, 225503 (2008)].

We report on the temperature implications of these models for experiment.

The present work brings a unifying picture to the process of radial compression/deformation of SWNTs, where experimental data are analyzed through a rescaling model yielding a universal-type behavior. Specifically, our AFM measurements show that the quantity

\[ F \propto \frac{1}{r^2} \]

is the SWNT diameter, is a universal function of the compressive strain. Such universality is reproduced analytically in a model where the graphene bending modulus is the only fitting parameter. The application of the same model to the radial Young modulus \( E_r \) leads to a further universal-type behavior that explains the large variations of the SWNTs \( E_r \), reported in the literature. [1] M. S. C. Mazzoni and H. Chacham, Appl. Phys. Lett. 76, 1561 (2000). [2] A. P. M. Barboza et al., Phys. Rev. Lett. 100, 256804 (2008).

Optimal matching of thermal vibrations into carbon nanotubes[1]. K.G.S.H GUNAWARDANA, KIERAN MULLEN, Homer L. Dodge Department of Physics and Astronomy, The University of Oklahoma — Carbon nanotubes (CNTs) are promising candidates to improve the thermal conductivity of nano-composites. The main obstacle to these applications is the extremely high thermal boundary (Kapitza) resistance between the CNTs and their matrix. In this work our goal is to maximize the heat flux through the CNT by functionalizing their ends. We develop theoretical continuum models in which we vary the elasticity and density from surrounding medium to the CNT so as to maximize the transmission of thermal vibrations. We calculate the transmission coefficients using a scalar wave equation. Since the transport in CNT is strictly one dimensional, a Landauer formula is used to estimate the heat flux into the CNT. We determine the optimal continuous variation of elasticity and density with position for different geometries. We also investigate how to optimally match the nano-tubes to their matrix using a small number of discrete interfaces. Finally, we discuss the implications of these models for experiment.

This work is supported by the DuPont Co. through a Science & Engineering Grant and NSF grant DMR-0520550.

Temperature dependence of the anharmonic decay of optical phonons in carbon nanotubes and graphite. IOANNIS CHATZAKIS, Columbia University, New York, NY 10027 — The present work was supported in part through the Global COE Program, “Global Center of Excellence for Mechanical Systems Innovation,” by the Ministry of Education, Culture, Sports, and Technology.

Universal response of single-wall carbon nanotubes to radial compression: theory and experiment, HELIO CHACHAM, ANA PAULA M. BARBOZA, BERNARDO R. A. NEVES, Departamento de Física, Universidade Federal de Minas Gerais, Brazil — Since the early 90’s, the electronic and structural properties of single-wall carbon nanotubes (SWNTs) have been thoroughly investigated. Regarding SWNT mechanical properties, most of the attention has been given to their large resistance to axial tension, even though several electromechanical effects have been observed on radially compressed SWNTs, such as the predicted [1], and recently observed [2], metal-insulator transition. The present work brings a unifying picture to the process of radial compression/deformation of SWNTs, where experimental data are analyzed through a rescaling model yielding a universal-type behavior. Specifically, our AFM measurements show that the quantity

\[ F \propto \frac{1}{r^2} \]

is the SWNT diameter, is a universal function of the compressive strain. Such universality is reproduced analytically in a model where the graphene bending modulus is the only fitting parameter. The application of the same model to the radial Young modulus \( E_r \) leads to a further universal-type behavior that explains the large variations of the SWNTs \( E_r \), reported in the literature. [1] M. S. C. Mazzoni and H. Chacham, Appl. Phys. Lett. 76, 1561 (2000). [2] A. P. M. Barboza et al., Phys. Rev. Lett. 100, 256804 (2008).

Carbon Nanomaterials Under Highly Energetic Heavy Ion Irradiation. J.M. CALLAHAN, Michigan State University, B.W. JACOBS, Sandia National Laboratories, C.A., K. MCELROY, M.A. CRIMP, Michigan State University, R.M. RONNINGEN, A.F. ZELLER, National Superconducting Cyclotron Laboratory, H.C. SHAW, NASA Goddard Space Flight Center — The radiation performance of carbon nanomaterials: carbon onions and single-walled carbon nanotubes under highly energetic heavy ion irradiation was investigated, with highly oriented pyrolytic graphite (HOPG) used as the control. Samples were irradiated with a krypton-86 beam at 142 MeV/nucleon, a krypton-78 beam at 140 MeV/nucleon, and a calcium-48 beam at 140 MeV/nucleon and 70 MeV/nucleon at the National Superconducting Cyclotron Laboratory at Michigan State University. Fundamental structural and chemical modifications were investigated using Micro Raman spectroscopy and high-resolution transmission electron microscopy (HRTEM). Results indicated that the radiation resiliency of the single-walled carbon nanotubes exceeded that of highly oriented pyrolytic graphite, while the carbon onions showed structural modifications of the outer onion layers in the form of facetting and onion fusion.

Synthesis, characterization and thermal stability of CVD-grown graphene nanoribbons. JESSICA CAMPOS-DELGADO, Advanced Materials Department, IPICYT, Mexico, Y.A. KIM, ENDO MORINOBO, Shinhu University, Japan, KATSUHI KANeko, Chiba University, Japan, HUMBERTO TERRONES, IPICYT, Mexico, MILRED S. DRESSELHAUS, ECCS, MIT, USA, MAURICIO CIRO TERRONES, IPICYT, Mexico — A route to produce large amounts of nanometer scale graphene ribbons is presented. The process involves the thermal decomposition of ethanol-ferrocene and minute concentrations of thiophene solutions. The material consists of stacked graphene sheets with dimensions of several microns in length, 100-500 nm in width and 10-20 nm in thickness. The morphology and structure of such material have been studied by SEM, HRTEM, Raman spectroscopy, XRD, XPS, TGA. In order to investigate the thermal stability of the pristine material, the as-prepared ribbons were annealed at various temperatures in the range 1000 °C to 2800 °C. The annealing treatments induced interesting structure changes in the samples, such as defect annihilation and loop formation at the edges, confirmed by HRTEM. A Raman spectroscopy study with many laser energies, enabled us to observe the overall behavior of the main Raman features (D, G, D', G', D+G bands). These phenomena will be discussed in detail.
2:42PM D25.00002 Nitrogen-induced structures in epitaxial graphene on 6H-SiC(0001)

GUOFENG SUN, SUNG-HYON RHM, University of Wisconsin-Milwaukee, YUN QI, MICHAEL WEINERT, LIAN LI, University of Wisconsin-Milwaukee — Nitrogen-induced structures on epitaxial graphene grown on 6H-SiC(0001) are studied by scanning tunneling microscopy (STM) and first-principles calculations. Several defect structures produced by nitrogen incorporation are observed by STM. Calculations of the energetics of nitrogen substitution at various sites neighboring a carbon vacancy indicate that nitrogen prefers to be at the site nearest to the vacancy, consistent with the STM observations.

3:30PM D25.00004 Kelvin Probe Microscopy of Single- and Multi-layer Graphene on SiO$_2$

ALEXANDRA CURTIN, University of Maryland, THERESA SWANSON, Westminster College, MICHAEL S. FUHRER, Materials Research Science and Engineering Center and Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland — Kelvin probe microscopy (KPM) was carried out on mechanically exfoliated graphene samples on SiO$_2$ in conjunction with standard atomic force microscopy. Potential differences between the SiO$_2$ substrate and graphene flakes were large relative to the average fluctuations over the surface of the graphene. KPM shows a consistent surface potential variation between monolayer, bilayer, and multi-layer graphene, and over folded pleats occasionally found in graphene. The source of these surface potential differences will be discussed.

4:06PM D25.00007 Planar tunneling spectroscopy of graphite

RICHARD JONES, WAN KYU PARK, SAM JOHNSON, XIN LU, NADYA MASON, LAURA GREENE, University of Illinois at Urbana-Champaign — The electronic properties of graphite/graphene have become an intriguing area of research in recent years. Probing their electronic density of states (DOS) is of fundamental importance. For this purpose, we choose to do tunneling spectroscopy based on planar junctions. We prepare planar tunnel junctions on graphite using superconducting and normal metal counter-electrodes. An AlO$_3$ tunnel barrier is deposited onto a cleaved surface of HOPG using atomic layer deposition, reactive sputtering, thermal oxidation, or plasma oxidation. Differential conductance spectra are taken as a function of temperature down to 4.2K. In general, conductance increases with bias-voltage, which is qualitatively consistent with the predicted DOS in graphite. However, variances in the detailed structures are observed, including a zero-bias conductance dip and multiple peak and hump structures. We will also discuss different growth techniques we propose to yield reproducible junction characteristics.

4:42PM D25.00003 Large area, Few Layer Graphene Films on Insulating Substrates

JING KONG, Massachusetts Institute of Technology — Graphene has exceptional electronic, thermal and mechanical properties. For the realization of graphene-related applications, it is necessary to develop reliable and low cost fabrication methods of graphene-based structures, ideally on any substrates. In this talk I will present our method of fabricating large area (~cm$^2$) films of single- to few-layer graphene and transferring the films to arbitrary substrates. The graphene films are synthesized by ambient pressure Chemical Vapor Deposition, consist of regions of 1 to ~10 graphene layers and have an average thickness of 2-3 nm. Despite their ultra-thin nature, the films thus produced are continuous over the entire area. Regions of single- or bi-layer graphene with lateral sizes of up to 25 $\mu$m were observed. High Resolution Transmission Electron Microscopy (HRTEM) and electron diffraction revealed that they are crystalline over the entire area and their Raman features were compared to those of graphene derived from mechanical exfoliation of Highly Oriented Pyrolytic Graphite (HOPG). Transistor devices made from these graphene show similar characteristics to ones made from graphitized SiC. Scanning tunneling microscopy imaging reveals interesting Moré patterns and helpful insights for the growth of the graphene films on the Ni substrate. The method presented in this work can potentially be scaled to industrial production of graphene films, for applications such as ultra-thin conductive and transparent electrodes, or devices and interconnect for integrated circuits.
4:42PM D25.00010 Electrical Transport in Graphene Hybrid Structures, FENG MIAO, WENZHONG BAO, HANG ZHANG, CHUN NING LAU, Department of Physics and Astronomy, University of California, Riverside, CA 92521 — Graphene, monolayer carbon atoms with honeycomb lattice, has intrigued condensed matter physics field for its unique electrical properties since its first discovery in 2004. The graphene hybrid structures that consist of both single and bi-layers were also experimentally studied recently for its novel properties. We will present our experimental study on the electron transport in graphene hybrid structures and the latest experimental data will be discussed in terms of various theoretic models.

4:54PM D25.00011 Dependence of the Low Energy Electronic Structure of Multi-layer Graphene on Stacking Order Probed by Infrared Absorption, MATTHEW SFIEIR, KIN FAI MAK, JAMES MISEWICH, TONY HEINZ, COLUMBIA UNIVERSITY, NEW YORK, NY 10027 COLLABORATION, BROOKHAVEN NATIONAL LABORATORY, UPTON, NY 11973 COLLABORATION — Optical conductivity spectra of multi-layer graphene samples were determined for photon energies in the range of 0.2 – 1.0 eV. The measurements were performed using synchrotron radiation on well-characterized exfoliated graphene samples on a transparent substrate. We observed distinct optical conductivity spectra for different samples having precisely the same number of layers. In particular, two well-defined types of spectra were obtained in measurements of more than a dozen of four-layer samples. This result can be understood by considering the existence of two stable configurations of four-layer graphene, namely, the ABAB Bernal stacking and the ABCA rhombohedral stacking. The observed absorption features were reproduced by explicit calculations, within a tight-binding model of the optical conductivity for the two stacking sequences. We have thus shown the possibility of identifying these different crystallographic structures optically. Further, the significant difference found in the low-energy electronic structure suggests that the charge transport behavior of multilayer graphene may also depend on stacking order.

5:06PM D25.00012 AFM study of the ridge-like network on epitaxial few-layer graphene grown on 4H-SiC [0001], GYAN PRAKASH, Dept. of Physics and Birck Nanotechnology center, Purdue U., W. Lafayette 47907, MICHAEL CAPANO, MICHAEL BOLEN, School of Electrical Eng. and Birck Nanotechnology center, Purdue U., W. Lafayette 47907, DMITRY ZEMLYANOV, Birck Nanotechnology center, Purdue U., W. Lafayette 47907, RONALD REIFENBERGER, Dept. of Physics and Birck Nanotechnology center, Purdue U., W. Lafayette 47907 — Few-layer graphene (FLG) is produced when SiC is heated to temperatures T>1475°C under vacuum conditions. The FLG grown on SiC exhibits a 2D mesh of interconnected ridges that extends over many square microns. Smooth regions of FLG are surrounded by the 2D ridges, forming a tile-like surface morphology. The origin of the network is attributed to the compressive stress generated by cooling. For FLG growth at moderately higher temperatures, the thickness of the FLG increases. Under these conditions, AFM studies reveal the emergence of a few well-defined folds that relax the surface stress. In contrast to the previous ridge-like network, the folds appear at only a few locations and have a greater height than the ridges. This AFM study provides insights on how to improve the quality of FLG material grown at elevated temperatures on SiC substrates.

5:18PM D25.00013 Moiré Patterns: Fingerprints of Few-Layer Epitaxial Graphene Growth on 4H-SiC(0001), LAURA BIEDERMANN, Dept. of Physics and Birck Nanotechnology Center, Purdue University, MICHAEL BOLEN, MICHAEL CAPANO, School of Electrical Engineering and Birck Nanotechnology Center, Purdue University, DMITRY ZEMLYANOV, Birck Nanotechnology Center, Purdue University, RONALD REIFENBERGER, Dept. of Physics and Birck Nanotechnology Center, Purdue University — Few-layer epitaxial graphene (FLG) was grown on heating [0001] silicon carbide to high temperatures (1350–1600°C) in vacuum. A continuous graphene surface layer was formed at temperatures of 1475°C and greater. X-ray photoelectron spectroscopy (XPS) and scanning tunneling microscopy (STM) were used to characterize the quality, thickness, and topography of the FLG. STM studies revealed a wide variety of different nanometer-scale features that include rough graphene, 1D superlattices, grain boundaries, and Moiré 2D superlattices. Detailed studies of the Moiré superlattices showed enhanced conductivity due to density of states effects. These Moiré superlattices also provided insights into the growth mechanisms of FLG on the carbon-face of SiC. L. Biedermann et al., “Insights into Few-Layer Epitaxial Graphene Growth on 4H-SiC(0001) Substrates from STM Studies,” Phys. Rev. B (submitted).

Monday, March 16, 2009 2:30PM - 5:30PM — Session D26 DMP DCOMP: Focus Session: Computational Nanoscience III: Defects, Doping, and Structure 328

2:30PM D26.00001 Intrinsic magnetism in nonmagnetic nanostructures: Role of localized states and quantum confinement1, PEIHONG ZHANG, University at Buffalo, SUNY — Manipulation of carrier spins in semiconductors for spintronics applications has received much attention recently driven by the promise of new or improved functionalities. This has stimulated extensive research in the area of magnetic semiconductors. Magnetism is traditionally recognized as arising from unpaired electrons in 3d and 4f materials. However, there has been increasing evidence that localized defect states (and/or surface/edge states) in sp materials, especially in some nanostructures, may form local moments and exhibit collective magnetism. In a recent paper [PRL100, 117204 (2008)], we proposed that the duality (i.e., localized vs extended nature) of defect states in wide-gap nitrides and oxides may promote collective magnetism in these materials without magnetic ions. We have recently extended this study to include unexpected magnetism observed in GaN and ZnO nanowires and other artificial quantum structures. Particular attention will be paid to the role of localized states and quantum confinement in promoting unconventional magnetism in these systems.

3:06PM D26.00002 Defect induced magnetism in semiconductor nanostructures1, HYUNWOOK KWAK, University of Minnesota, TZU-LIANG CHAN, JAMES CHELIKOWSKY, University of Texas — It has been proposed that magnetic semiconductors can be designed by using non-magnetic defects, e.g., through the introduction of an extrinsic impurity atom that does not exhibit magnetism by itself (Phys. Rev. Lett. 99, 127201). In order to address such proposals, we have employed a real-space pseudopotential method based on the generalized gradient approximation to determine the magnetic properties of boron and aluminum doped silicon nanocrystals and nanowires. We will discuss theoretical evidence for defect induced magnetism as a function of the nanostructure size. We suggest that defect induced magnetism can be strongly enhanced by quantum confinement.

3:18PM D26.00003 Ferromagnetism driven by extended defects in nanostructured ZnO

ALINE L. SCHOENHALZ, JEVERTON T. ARANTES, ADALBERTO FAZZIO, GUSTÃO M. DALPIAN, Universidade Federal do ABC — Spintronics has a particular interest in diluted magnetic semiconductors because these materials present both semiconducting and magnetic properties at the same time. ZnO-based materials and nanostructures have potential applications in this area because they can present room-temperature ferromagnetism when doped with transition metals and, in some cases, spin polarization can be observed even without magnetic impurities. Following recent experimental results reporting this (Nano Lett. 6, 1489 (2007) )), we have analyzed several ZnO nanocrystals, with diameters varying from 0.9 to 1.78 nm. Using DFT, we observed that a large amount of surface reconstructions appear in the non-passivated nanocrystals. Depending on the reconstruction, spin polarization without magnetic impurities can be observed at the surface region, what can lead to long-range spin interactions. Thus, we propose that the referred experimental results for nanostructured ZnO can be originated by extended defects such as surfaces. This can also explain the same magnetic behavior presented by non-doped thin films and other ZnO nanostructures.

3:20PM D26.00004 Self-doping in Boron Nanostructures

HUI TANG, SOHRAB ISMAIL-BEI, Department of Applied Physics, Yale University — Boron nanotubes with large radii (R > 10 Å) are predicted to be metallic with large densities of states at their Fermi energies, which may provide excellent conducting systems for one-dimensional electronics. In previous work [1], we have shown a class of stable boron sheets, composed of mixtures of triangular and hexagonal motifs, that are likely to be the precursors of boron nanotubes. These sheets are stabilized by a balance of 2-center and 3-center bonding. Here, using density functional theory and Maximally Localized Wannier Functions, we show that adding a boron atom to a boron sheet is equivalent to doping the boron sheet with all three valence electrons of the added atom. Based on this self-doping picture, we propose a simple counting scheme to construct stable boron nanostructures, e.g. from corresponding carbon wanniersons. We also apply this knowledge to study Mg-doped boron sheets and discuss the possible stable structures of MgB2 nanotubes.

3:22PM D26.00005 Computational Studies of Nanostructures of Boron

P. TANDY, M. YU, C. LEAHY, University of Louisville, W.Q. TIAN, Jilin University, S.Y. WU, C.S. JAYANTHI, University of Louisville, U. OF LOUISVILLE/JILIN U. — The goal of this work is to develop a reliable semi-empirical Hamiltonian for boron that may be used to predict nanostructures of boron. It is well known that bonding in boron is complicated as it may form three-center, two-electron bonds. The semi-empirical Hamiltonian used here was recently developed by Leahy et al. in the framework of linear combination of atomic orbitals [1]. The salient feature of this Hamiltonian is that it treats environment dependency and charge redistributions on equal footing. It will be shown that such a parameterized Hamiltonian can predict the B80 cage structure with C2V symmetry as found in a recent first-principles study [2]. Having validated our semi-empirical Hamiltonian for boron with small boron clusters and the B80 cage, we have performed a systematic study of other boron nanostructures: (i) larger cage structures (e.g., B215), (ii) boron clusters cut from the bulk alpha boron, and (iii) boron sheets (triangular sheets with and without holes). We will discuss the ground state structures of these boron nanostructures as well as the energetics and HOMO-LUMO gaps of different families of boron clusters as a function their diameters.

3:42PM D26.00005 Computational Studies of Nanostructures of Boron

P. TANDY, M. YU, C. LEAHY, University of Louisville, W.Q. TIAN, Jilin University, S.Y. WU, C.S. JAYANTHI, University of Louisville, U. OF LOUISVILLE/JILIN U. — The goal of this work is to develop a reliable semi-empirical Hamiltonian for boron that may be used to predict nanostructures of boron. It is well known that bonding in boron is complicated as it may form three-center, two-electron bonds. The semi-empirical Hamiltonian used here was recently developed by Leahy et al. in the framework of linear combination of atomic orbitals [1]. The salient feature of this Hamiltonian is that it treats environment dependency and charge redistributions on equal footing. It will be shown that such a parameterized Hamiltonian can predict the B80 cage structure with C2V symmetry as found in a recent first-principles study [2]. Having validated our semi-empirical Hamiltonian for boron with small boron clusters and the B80 cage, we have performed a systematic study of other boron nanostructures: (i) larger cage structures (e.g., B215), (ii) boron clusters cut from the bulk alpha boron, and (iii) boron sheets (triangular sheets with and without holes). We will discuss the ground state structures of these boron nanostructures as well as the energetics and HOMO-LUMO gaps of different families of boron clusters as a function their diameters.

4:06PM D26.00007 Graph-based global optimization of fully-coordinated cluster geometries

EDWIN FLITKEEMA, Aberystwyth University, UK, STEFÁN BROMLEY, Universitat de Barcelona, Spain — To study systems with substitutional disorder researchers commonly use effective Hamiltonians known as cluster expansions. In a cluster expansion the phase space of a system is coarse-grained over a fixed set of crystal sites and the energy is expressed as a linear combination of interactions between these sites. The coefficients of the linear expansion are typically fit to training data generated using ab-initio methods. Low-symmetry systems such as nanoparticles require the determination of a large number of distinct coefficients. A large amount of training data must be generated for such problems, and the cost of calculating the energy of each training structure is high due to the low symmetry of the system. For these reasons it has been impractical to use the cluster expansion to study low-symmetry materials with the same level of accuracy as bulk materials. We address this problem by demonstrating new methods that significantly reduce the prediction error of a cluster expansion for a given training set size. Our approach makes it possible to study atomic ordering in nanoparticles at a fraction of the current computational cost.

4:18PM D26.00008 Nanostructure determination from the atomic pair distribution function

LUKE GRANLUND, Michigan State University, PAVOL JUHAS, Columbia University, SAURAB GUJARATHI, PHIL DUXBURY, Michigan State University, SIMON BILLINGLE, Columbia University — Many materials at the nanoscale cannot benefit from crystallographic analysis and are unsuitable for refinement techniques that require an initial guess at the structure. One approach to overcoming these difficulties is the Liga algorithm, which generates structures relying solely on distances extracted from the atomic pair distribution function [1,2]. This method is shown to successfully reconstruct the buckyball from experimental data. Recent extensions to multi-component and periodic systems have also allowed reconstruction of common crystals from experimental data. The ability to handle both periodic and nonperiodic cases may make the algorithm a useful tool in the study of local structure deviations in nanocrystals in addition to noncrystalline nanomaterials. [1] P. Juhas, D. M. Cherba, P. M. Duxbury, W. F. Punch, S. J. L. Billinge. Ab initio determination of solid-state nanostructure. Nature, 440, 655-658 (2006). [2] P. Juhas, L. Granlund, P. M. Duxbury, W. F. Punch, S. J. L. Billinge. The Liga algorithm for ab initio determination of nanostructure. Acta Cryst., A64, 631-640 (2008).
4:30PM D26.00009 The role of confinement on the diffusion barriers in semiconductor nanocrystals¹, Tzu-Liang Chan, Alexey Zayak, University of Texas at Austin, Gustavo Dalpian, Universidade Federal do ABC, James Chelikowsky, University of Texas at Austin — We find that quantum size effects not only play an important role in the electronic properties of defects in semiconductor nanocrystals, but also strongly affect the incorporation of defect atoms into the nanocrystals. In particular, using ab initio methods based on density functional theory, we predict that Mn defects will be energetically expelled to the surface of CdSe and ZnSe nanocrystals, and that the diffusion barriers of a Mn interstitial defect in a CdSe nanocrystal will be significantly lower than that in the bulk. This can be ascribed to the large surface to volume ratio of nanocrystals, which can effectively release the strain during diffusion. By calculating the vibrational spectrum of the CdSe nanocrystal, we estimated the diffusion rate within the nanocrystal. Our results suggest that energetics can play a role in the self purification of small CdSe and ZnSe nanocrystals, as diffusion of the defect atom can readily occur inside such small nanocrystals.¹

¹This work was supported in part by National Science Foundation under DMR-0551195 and the U. S. Department of Energy under DE-FG02-06ER46286 and DE-FG02-06ER15760. GMD thanks financial support from FAPESP and CNPq.

4:42PM D26.00010 Accelerated Kinetic Monte Carlo Simulations of Vacancy-Mediated Arsenic Diffusion and Clustering in Silicon, Brian Puchala, University of Michigan, Michael Falk, Johns Hopkins University, Krishna Garikipati, University of Michigan — During semiconductor device fabrication, ion implantation of dopants creates large populations of defects, vacancies and interstitials, which mediate dopant diffusion. Experiments have shown large changes in dopant diffusivity in silicon as a function of annealing time and dopant concentration in the proximity of their critical concentrations. Kinetic Monte Carlo (KMC) simulations of vacancy-mediated arsenic diffusion in silicon to investigate the effect of dopant concentration, distribution and clustering on diffusivity. In order to follow the diffusion and breakup of clusters, on the order of minutes, our KMC simulations are accelerated using absorbing Markov chain analysis on states intelligently chosen on-the-fly to fill trapping basins in the local energy landscape. At lower dopant concentrations, we calculate the diffusivity and breakup rates of different cluster types and a mean field approach can be used to describe the overall cluster population evolution and dopant diffusivity. Above a critical concentration this mean field description fails as dopants become close enough to form a percolating structure throughout the material. At all concentrations, diffusivity decreases significantly over time as larger, less mobile clusters form.

4:54PM D26.00011 First Principles Study of the Effect of Lattice Strain on Diffusion Barriers¹, Handan Yildirim, Talat S. Rahman, University of Central Florida — To understand the three times larger values of the Erlich Schoewebel barriers for Ag on Cu(100) as compared to that for Cu on Ag(100), as obtained from our density functional theory calculations, we performed the diffusion of Ag adatom on Ag(100) and Cu adatom on Cu(100) under uniform lattice strain of 0-5%. We find the origin of the differences in the energetics to be the combination of Cu-Ag electronic coupling, relative atomic sizes and adsorbate-substrate lattice mismatch. The diffusion barriers on the ideal surfaces are found to decrease with increasing compressive strain and to increase with increasing tensile strain and almost a linear function of strain up to 5%. We show that this trend is universal and transferable to other materials. We will discuss the consequences of the modifications in the height of the ES barriers on growth modes.

¹This work was supported by the National Science Foundation under DMR-0551195 and the U.S. DOE under DE-FG02-06ER46286 and DE-FG02-06ER15760.

5:06PM D26.00012 Quantum confinement in P-doped Si[110] nanowires¹, Jiaxin Han, Tzu-Liang Chan, James Chelikowsky, University of Texas at Austin — Recently, doped Si nanowires have been synthesized and demonstrated experimentally that they can be used as interconnects in electronic circuits or building blocks for semiconductor nanodevices. In order to understand how doping operates at the nanoscale, we used a real-space first-principles pseudopotential method to study P-doped Si[110] nanowires. We examined the size dependence of the electronic binding energy for the P donor level. We found the donor electron to be more strongly bound to the P atom with decreasing nanowire diameter owing to quantum confinement. We also examined the energetically favorable position of the P atom in Si nanowires. For nanowires with diameter less than 1 nm, the P atom is expelled to the surface owing to the stress induced by the defect, which suggests that doping will be difficult for small-diameter Si nanowires. In addition, we calculated the core-level binding energy shift as the P atom moves from the surface towards the center of the nanowire. We will compare our results with experimental measurements.

5:18PM D26.00013 Effect of structure, surface passivation, and doping on the electronic and optical properties of GaAs nanowires: A first principles study,¹ S. V. Khare, Dept. of Physics, V. Gade, Dept. of EECS, University of Toledo, N. Shi, R. Ramprasad, Dept. of Chemical, Materials, and Biomolecular Engineering, Univ. of Michigan — We investigate the structural, energetic, electronic, and optical properties of hydrogen-passivated doped and undoped gallium arsenide nanowires along [001], [110], and [111] directions with diameter d ≤ 3 nm, using ab initio methods. A critical diameter d̃ ≈ 2 nm is found above which all wires have faceted cross sections determined by the symmetry of their axis. The wires possess several electronic properties relevant for sensing and other nanoelectronic applications: (i) Quantum confinement has a substantial effect on the electronic band structure and hence the band gap (Eg), which increases with decreasing diameter. (ii) Unlike Si or Ge wires, GaAs wires oriented along all axes are found to have a direct Eg. (iii) The electronic band structure shows a significant response to changes in surface passivation with hydrogen. (iv) Doping of wires with n and p type atoms produces a response in the band structure similar to that in a doped bulk crystal. (v) However, the dielectric function shows differences in absorption peaks with p type versus n type doping.

Monday, March 16, 2009 2:30PM - 5:30PM –
Session D27 GIMS: Advances in Instrumentation and Measurement I 329

2:30PM D27.00001 Mechanical properties of silicon nanowires studied by polarization-enhanced fiber-optic interferometry¹, John Nichol, University of Illinois at Urbana-Champaign, Eric Hemesath, Lincoln Lauhon, Northwestern University, Raffi Budakian, University of Illinois at Urbana-Champaign — Silicon nanowires have recently attracted attention as promising force sensors due to their inherent low dissipation and high frequency. One of the principal challenges to the use of nanowires as scanning probe force sensors is displacement detection. By exploiting the polarization anisotropy in light scattering from single nanowires, we have used fiber-optic interferometry to detect the displacement of individual silicon nanowires. We achieve a displacement sensitivity of 0.5 pm/vHz for 15 µW of light incident on the nanowire. The nanowires studied have ultralow mechanical dissipation in the range of 2×10⁻¹⁵-2×10⁻¹⁴ kg/s. We also discuss the effects of hydrogen surface passivation on mechanical dissipation. Further progress toward the use of nanowires as scanning probe force sensors is discussed.

¹This work was supported by the ARO (MURI grant W911NF-05-0414) at the University of Illinois and by the NSF (NIRT program) at Northwestern University.
I. Electromagnetic fluctuations cause the power law suppression at low voltages, transport through a quantum dot in the Coulomb blockade regime. We obtain the analytic expression for the elastic cotunneling current which shows that the magnetic fluctuations.

By attaching these single spins to the tip of a scanning probe, we were able to perform sensitive scanning probe magnetometry at nanoscale.

II. Precise measurements of individual colloidal spheres’ dimensions and optical properties, while simultaneously tracking their three dimensional motions with highly resolved in-line holographic video microscopy, can be interpreted with Lorenz-Mie theory to obtain exceptionally high spatial resolution. We assert that additional analysis of the secondary electrons will also exhibit a comparable resolution.

III. Synchrotron-based angle-resolved photoemission spectroscopy has proven to be a powerful tool in the elucidation of electronic structure of solids. The technique is now being applied to a wide variety of materials, and the macroscopic sampling area has become a limitation. For example, cleaving may expose different crystal planes, and the area covered by the incident photon beam may then consist of a collection of small domains with different photoemission spectra. The result is an average which obscures the true nature of the material. For this reason a beamline with a small focus has been proposed to be used with an angle-resolved photoemission endstation at the Synchrotron Radiation Center in Stoughton, WI. Reflective optics would be used to produce a microfocus at the sample of the light from an undulator beamline, providing submicron spatial resolution, while electron emission angles and energies are measured using an imaging electron energy analyser. The microfocusing optics and possible applications will be discussed.

IV. Second harmonic technique to be used eventually to probe the thermal conductivity of LSCO with superconductivity suppressed by high magnetic fields. The technique is suitable for the high-noise environment of pulsed magnets. Unlike the $3\omega$ technique, a heater and a thermometer are mounted separately. Therefore, the $2\omega$ signal is the dominant signal in the thermometer output. The frequencies are chosen so that the thermal penetration depth is smaller than the sample thickness. The thermometer response time and thermal impedance associated with material interfaces are carefully tested and compared to calculation. The calculations are based on exact solutions of the full bulk heat transport equations and produce results different from the lumped-constant approximations often used in ac calorimetry. Work performed under the auspices of the National High Magnetic Field Laboratory.

3:42PM D27.00007 Development of a Microfocus Beamline for Angle-Resolved Photoelectron Spectroscopy, T. MILLER, Univ. of Illinois at Urbana-Champaign, M. BISSEN, Univ. of Wisconsin Synchrotron Radiation Center, T.-C. CHIANG, Univ. of Illinois at Urbana-Champaign — Synchrotron-based angle-resolved photoemission spectroscopy has proven to be a powerful tool in the elucidation of electronic structure of solids. The technique is now being applied to a wide variety of materials, and the macroscopic sampling area has become a limitation. For example, cleaving may expose different crystal planes, and the area covered by the incident photon beam may then consist of a collection of small domains with different photoemission spectra. The result is an average which obscures the true nature of the material. For this reason a beamline with a small focus has been proposed to be used with an angle-resolved photoemission endstation at the Synchrotron Radiation Center in Stoughton, WI. Reflective optics would be used to produce a microfocus at the sample of the light from an undulator beamline, providing submicron spatial resolution, while electron emission angles and energies are measured using an imaging electron energy analyser. The microfocusing optics and possible applications will be discussed.

3:54PM D27.00008 Near field emission scanning electron microscopy, TARYL KIRK, LORENZO DE PIETRO, OLIVIER SCHOLDER, THOMAS BAehler, URS RAMSPERGER, Danilo Pescia, Swiss Federal Institute of Technology Zurich (ETHZ) — We present a simple “near field emission scanning electron microscope” (NFESEM) capable of imaging conducting surfaces with high spatial resolution. In this instrument electrons are excited from the sample surface after undergoing interactions with a low-voltage (< 60V) primary beam of electrons emitted from a Tungsten tip positioned tens of nanometers above the sample. Topographic images, determined from the intensity variations of secondary and backscattered electrons, yield a vertical resolution on an atomic scale and a lateral resolution of less than two nanometers. We report on the first topographic electron intensity images of terraces and mono-atomic steps on a single crystal substrate, not yet attained with a remote electron gun in conventional scanning electron microscopy. The topographic contrast of the extracted electrons and the field emission (FE) current are indistinguishable, in agreement with theoretical models of optimal spatial resolution. We assert that additional analysis of the secondary electrons will also exhibit a comparable resolution.

4:06PM D27.00009 Particle Characterization using Holographic video Microscopy, FOO CHIONG CHEONG, DAVID GRIER, New York University — In-line holographic video microscopy can be interpreted with Lorenz-Mie theory to obtain exceptionally precise measurements of individual colloidal spheres’ dimensions and optical properties, while simultaneously tracking their three dimensional motions with nanometer-scale spatial resolution at video rates. This method works over the entire range of particle sizes and compositions for which Mie scattering theory applies. Unlike other light scattering techniques for measuring particle size or refractive index, holographic particle analysis can be applied directly to individual particles.
4:18PM D27.00010 Three-dimensional position determination of nanoparticles using a two-photon microscope. JAMES GERMANN, LLOYD DAVIS, BRIAN CANFIELD, ALEXANDER TEREKHOV, University of Tennessee Space Institute - Center for Laser Applications — We are developing a means to extend the two-photon microscope to enable three-dimensional sub-diffraction measurement of the position and trajectory of a single nanoparticle as it traverses the probe volume. By use of a Ti-Sapphire laser and a double-Mach-Zehnder interferometer configuration, four laser beams with temporally interleaved pulses are created. These are tightly focused by a 1.2-NA water-immersion microscope objective to four overlapping volumes centered at slightly offset points arranged in a tetrahedron. Fluorescence from the four-focus probe volume is then collected onto a single-photon avalanche diode and the photon time stamps are recorded. Time-resolved photon detection with maximum-likelihood analysis is thereby used to determine the position of the nanoparticle from the relative intensities of fluorescence from each of the four foci. We present measurements of the profile of the four-focus configuration and results from calibration experiments obtained by translating a single gold nanodot or a fluorescent nanobead through the probe volume. Application of the position determination to single-particle trapping is also briefly discussed.

4:30PM D27.00011 Capabilities of high-sensitivity spectral fluorescence-lifetime imaging for resolving spectroscopically overlapping species. JUSTIN CRAWFORD, University of Tennessee Space Institute - Center for Laser Applications, LLOYD DAVIS, BRIAN CANFIELD, University of Tennessee Space Institute — The ability to separate the contributions from spectroscopically overlapping fluorophores has enabled significant breakthroughs in cellular imaging. However, commercial microscopes for this purpose generally use analog light detection with least-squares curve-fitting analysis. Improvements in sensitivity are possible and will lead to new applications. To this end, we have constructed a microscope with a high-throughput Brewster-prism spectrometer and four high-quantum efficiency single-photon detectors, coupled with time-correlated single photon counting electronics to provide added temporal resolution. We have demonstrated the use of maximum-likelihood (ML) methods for analyzing small numbers of photons to find the contributions from fluorescent species with differences in excitation and emission spectra. However, it is difficult to resolve fluorophores with different temporal decay profiles because the single-photon counting modules exhibit a count-rate-dependent time-walk. We discuss extension of the ML-analysis to account for a varying time-walk and results from Monte Carlo simulations to ascertain the minimum number of photons needed to reliably resolve specific fluorophores.

4:42PM D27.00012 Development of a low-cost small-sized scanning transmission ion microscope of moderate resolution with educational and other potential applications. ARTHUR PALLONE, Murray State University — Scanning transmission ion microscopy (STIM) has applications in many fields of study such as materials and device engineering, biological and geological sciences, and the arts. Since STIM is practiced at ion beam facilities, many persons outside of the ion beam community who could benefit from STIM are unaware of its potential. In an effort to better educate the public about STIM, an inexpensive portable demonstration unit suitable for interactive classroom use and public outreach events is under development. The required parts are readily available, mostly at local electronics and office supply stores. Progress toward completion of the demonstration unit and future efforts to modify the unit to support thin film research will be discussed. Activities that demonstrate the three modes of STIM will also be presented.

4:54PM D27.00013 A two dimensional piezoelectric micro-positioner1. K.-W. NG, JOHN NICHOLS, J. W. BRILL, University of Kentucky — A scanning probe microscope can provide very high resolution imaging, but only within a small scanning area. There is a high demand for compact long range positioners, so that distant locations on the same sample can be imaged and studied. We will present information on the design and operation of a piezoelectric driven two-dimensional micropositioner that can provide long range motion in the x- and z-directions. The z-direction motion can be used for coarse approach, while the x-direction motion can be used to scan along the sample surface. The device is build as one single unit, so it is extremely compact and rigid, and can provide a high resonance frequency platform for high performance scanning probe microscopy.

5:06PM D27.00014 High Speed Scanning Property Mapping (>1 frame per second)1. BRYAN HUEY, NICHOLAS POLOMOFF, ATIF RAKIN, VINCENT PALUMBO, University of Connecticut, Institute of Materials Science — Atomic Force Microscopy is coupled with concepts of acoustics to achieve nanoscale property contrast at line scanning rates approaching several kHz. This allows novel measurements of surface dynamics, efficient large area imaging, and high throughput experiments with SPM. Examples for mechanical contrast on block copolymers, semiconductors, and eutectic alloys are included, as well as high speed electric and magnetic field imaging. Coupled electromechanical contrast (piezoelectric) is also employed with PZT thin films to uniquely monitor ferroelectric domain dynamics.

5:18PM D27.00015 Method for Detecting Position and Orientation of Convex Objects in 3D Scans, ALEXANDER JAOSHVILI, PAUL CHAIKN, NYU — We have developed an algorithm for detecting the center positions and orientations of monodisperse objects which pack a container from the data collected in a 3 dimensional scan such as obtained by MRI. The algorithm is applied to a variety of geometrical convex shapes including, ellipsoids, cubes and tetrahedrons. From the positions and orientations we are able to reconstruct the number and type of interparticle contacts and constraints and thus to test Maxwell’s isostatic conjecture in the case of “random close packing.” We also obtain translational and orientational correlation functions.

Session D28 DMP FLAP: Focus Session: Thermolectric Materials: Oxides and Complex Crystals 330

2:30PM D28.00001 Thermoelectricity in oxides and weakly coupled single molecules. SUBROTO MUKERJEE, University of California, Berkeley — Complex oxides have emerged as promising candidate materials for thermolectric and energy applications. The study of charge and heat transport in these systems is also very interesting and important from the point of view of fundamental physics. We show that oxides in the narrow-bandwidth limit have high values of the thermopower and power factor and also violate the Wiedemann-Franz law yielding high values of the electronic part of the figure of merit. These theoretical results agree with the data on Na$_x$CoO$_2$. We argue that in another oxide Sr$_{1-x}$La$_x$TiO$_{3−δ}$, a large effective mass (small bandwidth) band appears due to oxygen vacancies, which can be exploited for thermolectric applications and comment on recent experiments. Finally, we show that there are commonalities in the thermoelectric behavior of narrow bandwidth oxides and weakly coupled single molecules. The latter systems also offer promise as thermolectric materials due to the possibility of large values of thermopower and we comment on the limiting effect of phonons on their figures of merit.
3:06PM D28.00002 Magneto-Spectroscopic Measurements of Ca$_3$Co$_2$O$_9$ Thin Films and Single Crystals\textsuperscript{1} JIUFENG TU, DIMITAR DIMITROV. The City College of New York, WEIDONG SI, QIANG LI, Brookhaven National Lab., CCNY/BNL TEAM — In recent years, the 2D-layered cobaltates have emerged as promising p-type thermoelectric materials due to their unique combinations of high thermo-coefficient and good metallic transport properties at ambient temperatures. These systems show high thermoelectric figure of merit and are ideal candidates as the materials of choice at elevated temperatures. We have carried out far-infrared magneto-spectroscopic studies of Ca$_3$Co$_2$O$_9$ thin films as a function of frequency, magnetic field and temperature with the emphasis on the coupling between the lattice, the charge and the spin degrees of freedom. The spectral response of this material is determined by the charge carriers and the polaronic field perpendicular or parallel to the CoO$_2$ layers. Below 20K, hysteresis occurs for perpendicular field but not for parallel field. This indicates that the negative magneto-resistance is due to reduced magnetic scattering when Co spins become aligned. Our results are consistent with co-existence of two types of carriers.

\textsuperscript{1}Supported by CUNY-RF-80209-11-13, DOE-AC02-98CH10886 and NSF-DMR-0451605.

3:18PM D28.00003 Direct measurement of charge transfer and spin state transitions in thermoelectric Ca$_3$Co$_2$O$_9$. GUANG YANG, University of Illinois at Chicago, QUENTIN RAMASSE, National Center for Electron Microscopy, Lawrence Berkeley National Laboratory, ROBERT KLINK, University of Illinois at Chicago — The misfit-layered thermoelectric material Ca$_3$Co$_2$O$_9$ has been the focus of many recent studies due to its high thermal power and good high temperature stability. In particular, it has been suggested that the presence of a mixed valence state in the strongly correlated CoO$_2$ layer is essential for the high p-type thermoelectric properties in Ca$_3$Co$_2$O$_9$. In this study, we combine aberration-corrected scanning transmission electron microscopy (STEM) with electron energy loss spectroscopy (EELS) to study the atomic and electronic structures of Ca$_3$Co$_2$O$_9$. We will show that the position of the O atomic columns in the CoO$_2$ layers are highly ordered and can therefore be directly imaged, while the CoO columns in the Ca$_2$Co$_2$O$_9$ rocksalt layer exhibit a strong modulation in the (010) direction. Further, we measure the local Co valence and find significant hole transfer from the rocksalt CoO to the strongly correlated CoO$_2$ layers. In addition, we will present the results of our in-situ heating experiments for power generation. The results of both substitutions will be discussed in light of recent first-principles electronic structure calculations. In the Sb-doped alloys, ZT was found to reach 0.5 at 1000 K and is projected to increase to 0.6 K at 1100 K, surpassing the industry standard for p-type materials as set by SiGe alloys.

3:30PM D28.00004 Thermoelectric properties of doubly doped Strontium Titanate thin films. JAYAKANTH RAVICHANDRAN, Applied Science and Technology Graduate Group, University of California, Berkeley, CA 94720, MATTHEW L. SCULLIN, Dept. of Materials Science and Engineering, University of California, Berkeley, CA 94720, SUBROTOM KUNERJEE, JOEL MOORE, Dept. of Physics, University of California, Berkeley, CA 94720, R. RAMESH, Dept. of Materials Science and Engineering, University of California, Berkeley, CA 94720, ARUN MAJUMDAR, Dept. of Mechanical Engineering, University of California, Berkeley, CA 94720 — Lanthanum doped Strontium Titanate (SrTiO$_3$) is amongst the most promising n-type thermoelectric materials for power generation. We report a double doping method for thin films of SrTiO$_3$, grown on (001) oriented LSAT substrates by Pulsed Laser Deposition (PLD), where doping of SrTiO$_3$ in the A-site by Lanthanum is accompanied by doping with oxygen vacancies. Based on careful transport measurements, we show that it is possible to obtain enhanced thermoelectric power factor in the limit of high effective mass and large carrier concentration in these thin films. The presence of oxygen vacancies also seems to decrease the thermal conductivity due to effective phonon scattering. The optimized doping concentration leads to a thermoelectric figure of merit, ZT > 0.2 at room temperature.

3:42PM D28.00005 Thermoelectric Properties and Band Structure Calculations of Novel Boron Network Compounds. TAKAO MORI, TOSHIYUKI NISHIMURA, National Institute for Materials Science (NIMS), YURI GRIN, Max Planck Institute for Chemical Physics of Solids, TOETSU SHISHIDO, KAZUO NAKAJIMA, Institute for Materials Research, Tohoku University — Boron is an interesting element, tending to form atomic networks such as 2D atomic nets and clusters, with some analogy to carbon systems which have been more extensively studied. Boron has less than an electron and thus is electron deficient when forming atomic networks, but this causes it to have a special affinity with the rare earth elements and as a result, many new compounds have recently been discovered \cite{1}. Their potential as viable thermoelectric materials is attracting interest since they have high thermoelectric materials and possess intrinsic low thermal conductivity, with some compounds exhibiting Seebeck coefficients in excess of 200 $\mu$V/K above 1000 K. The thermoelectric properties and band structure calculations of novel borides such as RB$_4$Si$_2$, RB$_7$CN, RB$_{22}$CoNi, RB$_{28}$Sc will be presented. Features in the band structure near the Fermi level indicate large doping effects in these compounds. Various doping experiments were carried out resulting in large increases to the figure of merit. [1] T. Mori, “Higher Borides,” in: Handbook on the Physics and Chemistry of Rare Earths, Vol. 38, (North-Holland, Amsterdam, 2008) p. 105-173.

3:54PM D28.00006 Electronic structure and high-temperature properties of doped Hf$_{0.5}$Zr$_{0.5}$CoSb phases. JACK SIMONSON, SLADE CULP, S. JOSEPH POON, University of Virginia, VIJAYABHARATHI PONNAMBAL, JUSTINE EDWARDS, TERRY TRITT, Clemson University — Half-Heusler alloys with compositions of the form Hf$_{0.5}$Zr$_{0.5}$CoSb were synthesized with Mn substituted to one or both of the Hf/Zr or Co sites or with the Sn site doped with Sn. The thermoelectric properties were evaluated from 300 K to 1000 K. The introduction of Mn was performed to investigate modifications to the band structure near the Fermi energy caused by transition metal substitution. Mn substitutions were discovered to increase the electrical resistivity dramatically while having no beneficial impact upon the thermopower. The Sb-doped alloys, on the other hand, exhibited lowered resistivity and thus increased efficiency of high temperature power generation. The results of both substitutions will be discussed in light of recent first-principles electronic structure calculations. In the Sb-doped alloys, ZT was found to reach 0.5 at 1000 K and is projected to increase to 0.6 K at 1100 K, surpassing the industry standard for p-type materials as set by SiGe alloys.

4:06PM D28.00007 Thermoelectric power generation in ternary skutterudites: a first-principles Wannier-functions\textsuperscript{1} study. DMITRI VOLJA, Massachusetts Institute of Technology, MARCO FORNARI, Central Michigan University, BORIS KOZINSKY, Bosch GmbH, NICOLA MARZARI, Massachusetts Institute of Technology — We study from first-principles ternary skutterudites derived from Co$_3$B$_8$, where the pnictogen is substituted with elements from the IVB and VIB groups. We focus on Co$_{2}$Ge$_{2}$As$_{2}$, Co$_{2}$Ge$_{2}$Te$_{2}$ and Co$_{3}$Sn$_{2}$Te$_{2}$, and compute the structure, electronic structure and vibrational properties from density-functional and density-functional perturbation theory. Since the direct evaluation of transport quantities in the relaxation-time approximation is computationally demanding, we use maximally-localized Wannier functions (MLWFs) for accurate integrations of operators across the Brillouin zone. This MLWFs basis leads to a very efficient and well-conditioned scheme to calculate the thermoelectric transport coefficients and to disentangle and identify the contribution of single bands. In addition, it provides a detailed, transferable picture of bonding in these complex materials.

4:18PM D28.00008 Thermoelectric Properties in Nanostructured p-type Skutterudites. XIAO YAN, Boston College, QING HAO, Massachusetts Institute of Technology, JIAN YANG, HUI WANG, YUCHENG LAN, DEZHI WANG, Boston College, GANG CHEN, Massachusetts Institute of Technology, ZHIFENG REN, Boston College, BOSTON COLLEGE COLLABORATION, MASSACHUSETTS INSTITUTE OF TECHNOLOGY COLLABORATION — Skutterudites are good examples of phonon glass electron crystal (PGEC), which is proposed to be one of the most desirable materials to maximize the thermoelectric figure of merit. The skutterudite structure has two voids in each unit cell that are large enough to accommodate a variety of atoms, such as La, Ce, Nd, Sm, Yb, etc. These atomic void-fillers rattle about in their oversized cages, thereby drastically reducing thermal conductivity and maximizing ZT. Our work on p-type skutterudites is based on compounds of a general formula FeRh$_{3}$Co$_{5}$Sb$_{2}$, which stands for a void filler. Besides the influence of rattling of the void fillers, thermal conductivity can be further depressed by the increased phonon scattering at the increased grain boundaries due to nano size grains.
4:30PM D28.00009 Calculation of electric field gradients and site preference in Ba-Al-Ge clathrates, SERGIO RODRIGUEZ, WEIPING GOU, JOSEPH ROSS, Texas A&M University — Sn, Ge or Si can form cage-like clathrate structures, many of which exhibit enhanced thermoelectric performance. To understand Al substitutional occupation in $\text{Ba_xGa_{16-x}Si_xGe_{30-x}}$ Clathrates we performed NMR lineshape simulations for $3 \leq x \leq 24$, and $0 \leq y \leq 3$, where $\square$ represents a vacancy. The electric field gradient (EFG) was calculated for Al sites assuming an ordered structure. To obtain the EFG we used ab initio methods in the Generalized Gradient Approximation as implemented by the WIEN2k code with structural relaxation. Results where used to simulate NMR lineshapes numerically. These were compared to our previously reported NMR lineshapes. For fully occupied $\text{Ba_xGa_{16-x}Al_y}$ we compare different site occupations, obtaining good agreement and thus information about Al site preferences. For reduced-Al samples, WDS measurements indicate the presence of spontaneous vacancies. In the case of the Zintl phase $\text{Ba_xGa_{16-x}Al_{y+x}}$, we found that Al sites adjacent to the vacancy exhibit a large EFG, while those with the vacancy further away have smaller EFG's. Assuming a larger Knight shift for sites next to vacancies, we obtain good agreement with NMR experimental results for reduced-Al $\text{Ba_xGa_{16-x}Al_{y+z}}$. We infer that Al prefers locations close to vacancies rather than random occupation. Supported by Robert A. Welch Foundation (Grant A-1526).

4:42PM D28.00010 The effects on the electronic properties of the clathrates $\text{A_xGa_{16}Si_xGe_{30-x}}$ ($A=\text{Ba, Sr}$), EMMANUEL NENGHABI, CHARLES MYLES, Texas Tech University — We have studied the structural and electronic properties of the Ba and Sr guest-containing type-I semiconductor clathrates $\text{Ba_xGa_{16}Si_xGe_{30-x}}$ and $\text{Sr_xGa_{16}Si_xGe_{30-x}}$ for Si compositions $x = 0, 5$ and $15$. Our calculations are based on the general gradient approximation (GGA). Starting with stable structures of the Ge-based type I clathrate semiconductors $\text{Ba_xGa_{16}Ge_{30-x}}$ and $\text{Sr_xGa_{16}Ge_{30-x}}$ containing no Ga-Ga bonds, we have constructed unit cells of $\text{Ba_xGa_{16}Si_xGe_{30-x}}$ and $\text{Sr_xGa_{16}Si_xGe_{30-x}}$ by replacing appropriate number of the framework Ga atoms with Si. For the values of $x$ that we have considered, we find that the fundamental band gap of $\text{Ba_xGa_{16}Si_xGe_{30-x}}$ increases with increasing $x$ but that the band gap of $\text{Sr_xGa_{16}Si_xGe_{30-x}}$ increases with increasing $x$. We also find that several electronic states near the top of the valence band and near the bottom of the conduction band in both materials are modified by the Si p states. The trends in the structural and electronic properties of Si are varied and discussed, and our results are compared to experiment where possible.

5:06PM D28.00012 Large Thermolectric power factor in CrN, CAMILO QUINTELA, Applied Physics Department, University of Santiago de Compostela, 15782-Santiago de Compostela, Spain, FRANCISCO RIVADULLA, Physical Chemistry Department, University of Santiago de Compostela, 15782-Santiago de Compostela, Spain, JOSE RIVAS, Applied Physics Department, University of Santiago de Compostela, 15782-Santiago de Compostela, Spain. — We report the electrical resistivity and thermoelectric power of stoichiometric and hole-doped chromium nitride (CrN). The results indicate a considerably large power factor, of the order of 1(microW/cmK2) at 400 K, increasing with temperature. Hall effect measurements were used to elucidate the mechanism of electronic transport in this system, in order to optimize its properties. The easy of grow in the form of nanoparticles and thin films, along with a good thermal stability up to 700 K, could make this material interesting for applications at moderate temperatures.

Monday, March 16, 2009 2:30PM - 5:30PM Session D29 Fed: Focus Session: The Physics and Astronomy New Faculty Workshops I

2:30PM D29.00001 A Dozen Years and a Thousand Participants: The Workshops for Preparing New Faculty in Physics and Astronomy¹, KENNETH KRANE, Department of Physics, Oregon State University, Corvallis OR 97331 — Beginning in 1996, an annual workshop for newly hired faculty in physics and astronomy has been held under the organizational leadership of AAPT, APS, and AAS. To date more than 1000 faculty have participated in this workshop, representing approximately 25% of the new hires at all U. S. institutions that award a baccalaureate in physics or astronomy, from 4-year colleges through research universities. The original motivation for the workshops was to improve physics teaching by introducing new faculty to instructional strategies and innovations that had been shown to be effective in a variety of contexts. The need for such a program was suggested in part by the belief that a national mentoring workshop could effectively address a commonality of physics and astronomy teaching challenges that transcended institutional characters and types, and also in part by the reaction to a significant decrease in the number of baccalaureate physics degrees awarded in the U. S. in the 1990s, which many believed was due to ineffective and uninspiring teaching at the undergraduate level and especially in introductory courses. Based on surveys of the participants (and their department chairs), we have found that a large fraction of the participants have become adopters of innovative teaching techniques and that they rate the workshops as the most significant cause of the improvements in their teaching. This talk will summarize the development of the workshop program since its inception, the measures of its success in improving teaching, and the plans for its future.

¹Supported in part by NSF DUE grants 9554738 and 0121384.

3:06PM D29.00002 Teaching New Dogs New Tricks: The Next Generation of Physics Faculty, GERALD FELDMAN, George Washington University — I was privileged to attend the first New Faculty Workshop (NFW) in 1996, and that was the spark that kindled my keen interest in teaching methodology, learning assessment, and Physics Education Research (PER). Following Eric Mazur’s introduction to Peer Instruction, I became a strong advocate of ConcepTests in class, implemented an electronic student response system before they were widely in vogue, and emphasized conceptual understanding on the same footing as numerical computations. This led to a research project on the efficacy of in-class ConcepTests, and further, to the linking of conceptual and numerical aspects in a “thinking skills” curriculum for introductory physics at George Washington University (Gwu). After “dabbling” in PER for some years, several of us at GWU now have a credible research program and our first Ph.D. student in PER. The methods espoused by PER have extended to other members of the Physics Department, and even beyond, to other science departments on campus. Following this trend, we have most recently (Spring 2008) implemented a SCALEUP collaborative classroom modeled after the work of Bob Beichner at NC State. Overall, the teaching climate in the GWU Physics Department has changed considerably over the past decade, and it is clear that these changes ultimately trace their origins back to the impact of the NFW on the faculty members who have attended over the years.

3:18PM D29.00003 Effects of the New Faculty Workshop at WFU, FREDDIE SALSIBURY, Wake Forest University — Two members of the Wake Forest University Physics department have attended the Physics and Astronomy New Faculty Workshop and have implemented many of the lessons learned in their classes and in the department. In particular, the impacts on teaching introductory and upper-level physics, and developing a biophysics track will be discussed.
3:30PM D29.00004 Twenty semesters later: how NFW helped us to multiply majors. A. ALAN MIDDLETON, Syracuse University — In the Fall of 1997, I missed my daughter’s first Halloween to attend the NFW. Though that was disappointing, I was pleasantly surprised to learn that there were a number of people who thought about teaching and had very constructive ideas to share. I immediately applied what I had learned in the large lecture class that I taught for a few years, with success for my students and my career. I then spent 7.5 years as the Director of Undergraduate Studies: the contacts and insights provided by the NFW and subsequent occasional attendance at AAPT meetings were most helpful in improving our program (the number of graduating majors increased from about 3 to over 15 per year), along with the help of a few dedicated faculty at Syracuse. The specific pedagogical viewpoints and tools introduced at the NFW were helpful in my teaching and administrative work, but the most useful part of the experience was the license granted to seek improvements in both teaching and the undergraduate program and provide contact with others who took such issues seriously.

3:42PM D29.00005 The Best of Both Worlds, ELIZABETH H. SIMMONS, Michigan State University — Thanks to the New Faculty Workshop, I now have dual identities: as a professor in a research-focused university physics department and as Dean of a teaching-focused undergraduate residential science college within that university (Lyman Briggs College). I’ll talk first about how the NFW changed my perspective on education and outreach — and how that affected the climate in the department I was in at the time. Next, I’ll comment on how this shift of perspective eventually led to new professional opportunities, including my current dual position. The lessons from the NFW have contributed directly to my acquiring the skills required of a leader in an interdisciplinary college that encourages its faculty both to be active disciplinary researchers and to take a scholarly approach to teaching. Finally, I’ll mention how being part of the college’s community of teacher-scholars has helped my teaching to continue evolving in directions compatible with the aims of the New Faculty Workshop.

3:54PM D29.00006 ReDUCE: Rethinking Directions in Undergraduate Curriculum Experiences, CARLOS WEXLER, DEBORAH HANUSCIN, MATTHEW MOWER, HASKELL TAUB, University of Missouri — There is a major emphasis in higher education on rethinking undergraduate science instruction, particularly in introductory courses. In Fall/2007 a collaborative team at the University of Missouri formed and was given a “green light” to start an overhaul of the curriculum and instruction of (algebra-based) Physics I and the associated laboratory/recitation, a course taken by > 500 students/yr. Earlier, we had identified problems with the current status of the course: the number of topics “crammed into the syllabus,” disconnection of laboratories to each other, and lack of conceptual coherence between laboratory, recitations and lectures. In Spring/2008, the group was awarded an interdepartmental grant from the College of Education to begin work on realigning the lecture, lab, and recitation components of the course around a coherent curriculum that builds towards “big ideas” in the discipline (a “narrow but deep” approach). In Fall/2008 we implemented the first pilot test by combining exploratory labs, “take-home-mini-labs,” and the use of Tutorials (in one section of the lab of this course, ca. 20 students). In this talk I will discuss early results and conclusions of this experiment, the next steps in the academic transformation, funding issues, and hurdles faced towards implementation on larger scale.

4:06PM D29.00007 JiTT and Peer Instruction in the General Physics Sequence at Dominican College: A One-Year Retrospective, KATHLEEN HINGE, Dominican College — Energized by the New Faculty Workshop of November, 2007, the author returned to Dominican College of Blauvelt with dreams of colossal gains on Force Concept Inventory (FCI) scores. Replicating the reported successes at Harvard and the US Air Force Academy would be difficult at Dominican: More than one-third of Dominican’s physics students are minority, and an even greater portion of students come from secondary education without the ability to synthetically apply concepts. Undeterred, the author was committed to overthrowing the General Physics sequence around NFW tenets. Beginning in January, 2008, material presentation went from traditional lecture format to a combination of Just in Time Teaching (JiTT) and Peer Instruction. This paper presents a one-year retrospective on this process, with emphasis on lessons learned, the impact on student learning and satisfaction, and next steps. Student response to the change has been uniformly enthusiastic. The actual FCI gain achieved in this first year was G=0.31, a modest advance over the 0.25 reported for traditionally taught courses. Spurred by this early success, implementation of JiTT has spread to courses in Biology and Mathematics.

4:18PM D29.00008 A Tale of Two Curricula: The performance of two thousand students in introductory electromagnetism, MICHAEL SCHATZ, MATTHEW KOHLMYER, MARCOS CABALLERO, School of Physics, Georgia Institute of Technology, RUTH CHABAY, BRUCE SHERWOOD, Department of Physics, North Carolina State University, RICHARD CATRAMBONE, MARCUS MARR, School of Psychology, Georgia Institute of Technology, MARK HAUGEN, Department of Physics, Purdue University, LIN DING, Department of Physics, The Ohio State University — Student performance in introductory calculus-based electromagnetism (E&M) courses at four large research universities was measured using the Brief Electricity and Magnetism Assessment (BEMA). Two different curricula were used at these universities: a traditional E&M curriculum and the Matter & Interactions (M&I) curriculum. At each university, post-instruction BEMA test averages were significantly higher for the M&I curriculum than for the traditional curriculum. The differences in post-test averages cannot be explained by differences in variables such as pre-instruction BEMA scores, grade point average, or SAT scores.

4:47PM D29.00009 Improving clicker questions for enhanced learning in the interactive physics classroom, ERTAN SALIK, Cal Poly Pomona — Classroom response systems, or clickers, have become widely used in physics classes in the last decade. Physics education research has demonstrated clearly that it is not the clicker as an electronic tool, but the interactive learning that occurs through clickers is what improves student learning. For clickers to work as expected, however, many subtle details need to be addressed. An instructor can start using many questions developed for the purpose of peer instruction. For a particular student population, and for a particular learning environment and constraints of the educational institution, questions used and the instructor’s teaching style may need to be altered over time. We will present a systematic way of improving clicker questions and one’s own teaching style utilizing data collected during clicker sessions. In addition, by adding a small writing component to some clicker questions, one can simply peek into student reasoning in order to determine preconceptions and misconceptions. Such direct knowledge of student reasoning in one’s own class may be very revealing, and help improve learning ultimately.

1Supported by NSF DUE.

3:30PM D29.00009 Improving clicker questions for enhanced learning in the interactive physics classroom, ERTAN SALIK, Cal Poly Pomona — Classroom response systems, or clickers, have become widely used in physics classes in the last decade. Physics education research has demonstrated clearly that it is not the clicker as an electronic tool, but the interactive learning that occurs through clickers is what improves student learning. For clickers to work as expected, however, many subtle details need to be addressed. An instructor can start using many questions developed for the purpose of peer instruction. 4:42PM D29.00010 Propagations of the AAPT New Faculty Workshop: A case study of the infusion of student-centered technological and pedagogical innovations in the introductory physics program at West Point, BRYNDOL SONES, US Military Academy — Since 2002, the Department of Physics at West Point has been the fortunate recipient of yearly attendance at the AAPT New Faculty Workshop. This sustained involvement has contributed directly to enhancements in our two-semester introductory physics program. Two aspects of West Point’s environment make our involvement with the workshop especially fruitful: our diverse students and our frequent faculty turn-over. We teach to over 1100 students with majors across the entire spectrum. The majority of our faculty is an active duty Army officer here for just three years. At West Point, we rely on the workshop as a wellspring for faculty development, technological innovation, and pedagogical refinement. In the past few years, we have incorporated aspects of peer instruction, activity-based learning, and tutorials for student discovery. On the technological side, we now have TabletPCs for faculty, rf response cards (TurningPoint), high speed video analysis (LoggerPro) projects, and video tutoring capabilities (Camtashia). Student achievement is measured through our traditional course evaluation tools as well as nationally recognized standardize tests. Results will be discussed in the presentation.

4:54PM D29.00011 Instilling best educational practices into future physics professionals and faculty, PHILIP G. COLLINS, Department of Physics and Astronomy, Univ. of California Irvine, Irvine CA 92697-4576 — A primary aim of the New Faculty Workshop (NFW) has been to communicate best educational practices in faculty beginning their teaching careers. However, further amplification of NFW goals is achieved by providing similar content and training to Ph.D. candidates working as Teaching Assistants (TAs). NFW experience led to the successful creation at UCI of a relatively extensive, 30-hour training course now required of every graduate student in the Dept. of Physics and Astronomy. Half of the training occurs before the first week of classes, and focuses on peer instruction, active learning, and results from Physics Education Research. This orientation segues into peer evaluation as first-time TAs and soon-to-be TAs practice teaching styles for each other and evaluate videos of each other teaching their actual courses. This course directly trains 25-30 graduate students each year, indirectly affecting dozens of discussion sections and the experience of nearly 2000 students per quarter.

5:06PM D29.00012 Applying New Faculty Workshop Lessons to Intermediate-Level Physics Courses, MELISSA EBLEN-ZAYAS, Carleton College — Although much innovative work on physics teaching techniques and curriculum has been carried out at the level introductory physics resources, there has been less focus on the intermediate-level physics courses. Since my participation in the new faculty workshop, I have been particularly interested in finding ways to implement peer instruction and other active learning strategies in sophomore and junior level physics classes. Many curricular resources are available for introductory physics, but finding appropriate materials for courses beyond the introductory level is more challenging. I will discuss the use of comPADRE resources as well efforts to develop original activities to promote active learning and conceptual understanding, and I will highlight the successes and challenges of integrating these types of activities in intermediate-level physics courses.

5:18PM D29.00013 From Syllabus To Diagnostic Exam: Learnings from the New Faculty Workshop Applied into the Intro Physics Classroom, MICHAEL TANOFF, Kalamazoo College — Kalamazoo College offers a “one-size-fits-all” concept-based introductory physics sequence. The widely varying demographic composition of the class — including majors in biology, chemistry, pre-med, physics, and math, along with occasional humanities majors — adds obvious challenges to the successful learning experience. As such, educational techniques that apply across the demographic are required. Several ideas presented at the Fall 2005 New Faculty Workshop apply to the needs of this broad range of students at Kalamazoo College, including an “organic” course syllabus that has been allowed to grow to whatever extent necessary to address student concerns and misunderstandings about course expectations, policies, and guidelines, and to provide advice on recurring themes; peer instruction for maximizing classroom value; and hiring teaching assistants with first hand experience in the course and the labs. Details on implementing these techniques, including developing a syllabus with unusual section headings such as “Attendance and Homework Dramas” and “Introductory Physics Survival Requirements,” will be presented. Success of the techniques, as evidenced by performance on diagnostic exams, class attendance, and comments from course evaluations, will be discussed.

Monday, March 16, 2009 2:30PM - 5:30PM —
Session D30 DMP GMAG: Focus Session: Cobaltite and Manganite films 334

2:30PM D30.00001 Emergent Phenomena in Spatially Confined Manganites, THOMAS WARD, University of Tennessee & Oak Ridge National Laboratory — There is evidence that chemically disordered single crystal manganites exhibit electronic inhomogeneity in which areas with vastly different electronic and magnetic properties form and coexist in phase separated domains ranging in size from a few nanometers to micrometers. This phase separation is of particular interest, as it has been suggested that it is the central feature that leads to colossal magnetoresistance in manganites, the Mott transition in VO2 and may play a part in high-TC superconductivity in cuprates. We will discuss our ongoing efforts to answer fundamental questions about the specific role of PS in complex oxides using a novel spatial confinement technique. Unlike transport measurements on bulk or thin films where the electrons follow only the metallic path of least resistance, spatially confining a phase separated material to the scale of its inherent domains forces electrons to travel through both the metallic and insulating regions that lie along the conduction path. This has led to observations of several new phenomena such as a reemergent metal-insulator transition, ultra-sharp jumps in resistivity at the metal-insulator transition, and the first high resolution observation of stable single domain electronic phase transitions in time. La(5/8-x)Pr(x)Ca(3/8)MnO(3) (LPCMO) is used as a model system due to its large scale electronic phase separation into ferromagnetic metal (FM) and charge ordered insulator (COI) electronic phase domains and well documented spin-charge-lattice interactions. These properties allow us to isolate domains through conventional wet etch techniques and offer a wide range of tunability through doping and substrate strain. This ability to control key elements of the underlying complexity and observe the resulting changes in the emergent behavior help answer questions about the fundamental physics that rule complex materials.

3:06PM D30.00002 Electric field induced anisotropic transport properties of phase separated (La(1-x)Pr(x))0.67Ca0.33MnO3 thin films1, HYOUNG JEEN JEEN, ALESSANDRA GALLASTEGUI, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, Florida 32611 — The perovskite manganese oxide (La1−xPrx)0.67Ca0.33MnO3 thin films exhibit electronic phase separation i.e., a ferromagnetic metallic phase and a charge ordered insulated phase coexist in a certain temperature range. It was shown that in such a phase separated state thin films of manganites show a colossal magnetoresistance (CER) although the mechanism driving this phenomenon is still unknown. We present transport measurements which show that the CER is due to an electric field driven anisotropy in phase separated manganites. LPCMO thin films were grown on NdGaO3 (110) substrates using Pulsed Laser Deposition. A cross shaped micro-structure, with 60 by 10 µm legs, was fabricated using UV photolithography and chemical etching. We observe CER close to the insulator to metal transition temperature (Tc) in the longitudinal direction i.e. parallel to the applied electric field. We simultaneously measure the transverse resistance in the other (orthogonal) leg of the microstructure. We observe a clear anisotropy in the conduction of the cross shaped microstructure which could be the origin of CER in manganites.

3:18PM D30.00003 Colossal electroresistance in phase separated manganite nanobridges1, G. SINGH-BHALLA, A. BISWAS, A. F. HEBARD — We have examined the electric field effect on the nanometer scale in the manganite (La$_{1-y_3}$/Pr$_y$)MnO$_3$ thin films. The interfacial strain between the ferromagnetic (FM) and antiferromagnetic (AFM) phase is obtained by first principles and consistent with each fully-optimized atomic structure at different pressures. With structurally invariant dielectric response, we show that atomic-resolution Z-contrast imaging and electron energy-loss spectroscopy in combination with ab-initio first-principles DFT calculations can be utilized to measure the spin-state transition in the current-voltage characteristics implying either a change in resistance arising from spin canting or a change in the ferromagnetic phase fraction. Next, within the micrometer scale PS temperature regime, current-voltage measurements reveal colossal, step-like drops in resistance with increasing current. We will discuss our results both in the context of previously considered models for manganite electroresistance and new interpretations with a focus on the microscopic details of the metallic and insulating regions.

3:30PM D30.00004 Phase modification of La$_{1/4}$Pr$_{3/4}$Ca$_3$MnO$_3$ thin films by light, magnetic field and applied stress1, JUSTIN OLAMIT, MIKHAIL ZHERNENKOV, MIKE FITZSIMMONS, Los Alamos National Laboratory, HAILE AMBAYE, VALERIA LAUTER, Oak Ridge National Laboratory, HYOUNG JEEN JEEN, AMLAN BISWAS, University of Florida — Complex oxide materials exhibit a wide variety of fascinating electromagnetic properties related to the coexistence of multiple electric and magnetic phases. The temperature-magnetic field phase diagram of La$_{27}$Pr$_{40}$Ca$_{33}$MnO$_3$ (LPCMO) is intriguing; a ferromagnetic metallic (FM) phase, charge ordered insulating (COI) phase, and conditions where both phases coexist are accessible with changes in temperature and magnetic field. We have performed neutron reflectometry to understand the emergence of the FMF phase in a COI matrix of a LPCMO thin film as functions of temperature, irradiation with light, magnetic field and stress. Specular reflectivity reveals the emergence of ferromagnetism below the phase transition temperature. Diffuse scattering shows that the length scale of FM domains is 1-2 microns. [1] Ch. Renner et al., Nature 416, 518 (2002). [2] L. Zhang et al., Science 298, 805 (2002). [3] T. Dhakal et al., Phys. Rev. B 75, 092404 (2007).

3:42PM D30.00005 Real-Space Imaging of Electronic Phase Separation in a Mn-Doped Bilayered Ruthenate1, TAE-HWAN KIM, M. ANGST, R. JIN, X.G. ZHANG, J.F. WENDELKEN, A.P. LI, Oak Ridge National Laboratory, B. HU, E.W. PLUMMER, The University of Tennessee — Transition-metal oxides with multiple nearly degenerate states show very complicated phase diagrams. Small perturbations can often dramatically change their functionalities. It is believed that electronic phase separations (PS) play an important role in the exotic functionality. Direct experimental observation of PS has thus become crucial to understanding underlying mechanisms of the striking functionalities. We have studied the PS and the evolutions of phase domains with temperature near the Mott transition in a Mn-doped bilayered ruthenate Sr$_5$(Ru$_{1−x}$Mn$_x$)$_2$O$_7$. Our experimental approach combines electron microscopy, scanning tunneling microscopy, and electron transport spectroscopy, which provide unprecedented capabilities of imaging PS and interrogating individual microscopic domains in situ. A quantitative correlation has been determined between the macroscopic metal-insulator transition and the microscopic phase domain percolation in Sr$_5$(Ru$_{1−x}$Mn$_x$)$_2$O$_7$.

1The research at Oak Ridge National Laboratory was sponsored by the Scientific User Facilities Division and the Division of Materials Science and Engineering, Office of Basic Energy Sciences, U.S. DOE.

3:54PM D30.00006 Mapping the phase boundaries in thin-film manganites using scale-invariant dielectric response1, P. MICKEL, G. SINGH-BHALLA, S. TONGAY, A. BISWAS, A. F. HEBARD, University of Florida — Magneto-capacitance techniques have been used in a study of (La$_{1−x}$Pr$_x$)$_3$Ca$_3$MnO$_3$ (LPCMO) thin films to determine the range of phase space, described by frequency ($\omega$), temperature (T) and field (H), over which a dielectric response of the form, C($\omega$,T,H) = [C($\omega$,T,H) - C$_0$]$^{1/\gamma}$, is found to hold. This power-law scaling collapse (PLSC) of the complex capacitance (C), expressed in a Cole-Cole formulation, differs from the well-known "universal" dielectric response (UDR), where the exponent $\gamma = 1$. The influence of film thickness and stoichiometry on the extent of the PLSC region is investigated with the implementation of a new phase-space mapping technique. The mappings clearly illustrate the onset of phase competition in LPCMO, delineating boundaries which correspond to capacitive minima at low temperatures, where the first-order insulator-metal transition occurs, and to the second-order paramagnetic-insulator/charge-ordered-insulator transition at higher temperatures, where a resistive transition signature exists in bulk but not in thin films. Modeling with distributions of UDR elements corresponding to the different manganese phases gives a good qualitative account of the observed behavior, and can lead to the determination of individual phase fractions.

4:06PM D30.00007 Direct measurement of the low-temperature spin-state transition in epitaxially strained LaCoO$_3$ thin films, ROBERT KLIE, GUANG YANG, YUAN ZHAO, Department of Physics, University of Illinois at Chicago — The perovskite oxide LaCoO$_3$ exhibits an anomaly in its magnetic susceptibility at 80 K associated with a thermally excited transition of the Co$^{3+}$-ion spin. We will show that atomic-resolution Z-contrast imaging and electron energy-loss spectroscopy in combination with ab-initio first-principles DFT calculations can be utilized to measure the spin-state transition in LaCoO$_3$. In particular, we utilize in-situ cooling experiments in a transmission electron microscope to demonstrate that the O K edge pre-peak is sensitive to the Co$^{3+}$-ion spin-state. Our experimental results will be compared to first-principles calculations, and we will conclude that the thermally excited spin-state transition occurs from a low to an intermediate spin state, which can be distinguished from the high-spin state. Next, we will examine the effects of biaxial strain and point defects in LaCoO$_3$ thin-films on the Co$^{3+}$-ion spin-state. We will show that a single-crystal pseudo-cubic LaCoO$_3$ (001) film can be successfully grown on LaAlO$_3$ (001). Moreover, we will show that the epitaxially strained LaCoO$_3$ film exhibits a ferro-magnetic transition at the current level that was not observed in bulk LaCoO$_3$. We will discuss the origin of this transition and the possibility of stabilizing different Co$^{3+}$-ion spin-states in LaCoO$_3$ using interfacial strain.

4:18PM D30.00008 First-principles study for low-spin LaCoO$_3$ with structurally consistent Hubbard $U$, HAN HSU, KOICHIRO UMEMOTO, MATTEO COCOCCIONI, RENATA WENTZCOVITCH, Chemical Engineering and Materials Science, University of Minnesota — We use the local density approximation + Hubbard $U$ (LDA+U) method to calculate the structural and electronic properties of low-spin LaCoO$_3$. The Hubbard $U$ is obtained by first principles and consistent with each fully-optimized atomic structure at different pressures. With structurally consistent $U$, the fully-optimized atomic structure agrees with experimental data better than the calculations with fixed or vanishing $U$. A discussion on how the Hubbard $U$ affects the electronic and atomic structure of LaCoO$_3$ is also given.

1This work was supported primarily by the MRSEC Program of the National Science Foundation under Award Number DMR-0212302 and DMR-0819885, and supported partially by the NSF/ITR program through the University of Texas (ITAMIT).
4:30PM D30.00009 Direct observation of local magnetic properties in strain engineered lanthanum cobaltate thin films. S. PARK, WEIDA WU, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA; J. W. FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA; J. X. MA, J. SHI, Department of Physics, University of California, Riverside, California 92521, USA — Strain engineered thin film devices with emergent properties have significant impacts on both technical application and material science. We studied strain-induced modification of magnetic properties (Co spin state) in epitaxially grown lanthanum cobaltate (LaCoO$_3$) thin films with a variable temperature magnetic force microscopy (VT-MFM). The real space observation confirms long range magnetic ordering on a tensile-strained film and non-magnetic low-spin configuration on a low-strained film at low temperature. Detailed study of local magnetic properties of these films under various external magnetic fields will be discussed. Our results also demonstrate that VT-MFM is a very sensitive tool to detect the nanoscale strain induced magnetic defects.

4:42PM D30.00010 Understanding the Origin of Ferromagnetism in Strained LaCoO$_3$ Thin Films. J.X. MA, J. SHI, Department of Physics, University of California at Riverside, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory — Using strain to control the behavior of strongly correlated materials offers new opportunities to control fundamental properties. For the case of magnetism, LaCoO$_3$ offers the ability to use strain through thin film growth to manipulate directly the spin-state of Co in this system. Here we present the results of a detailed polarized x-ray spectroscopy study of LaCoO$_3$ thin films grown on SrTiO$_3$(001) and LaAlO$_3$(001) substrates. X-ray diffraction from 25 nm thin films confirms the films are fully strained in both cases and, for films under tensile strain, total moment magnetometry shows a clear transition to ferromagnetic state at ≈0.6 Tesla. X-ray absorption shows that the films grown from a LaCoO$_3$ target are slightly hole doped due to non-stoichiometry generated during growth (effective doping ≈0.1 holes per unit cell), which in the bulk is sufficient to destroy the low-spin state. However, even though the films are slightly hole doped, the films under tensile strain show long range ferromagnetic order unlike the bulk system. Since the films are insulating, these results are consistent with a ferromagnetic insulating state arising due to superexchange. Work at UCR is supported by ONR/DMEA under award H94003-08-2-0803.

4:54PM D30.00011 Structure, Magnetism, and Transport in SrTiO$_3$(001) / La$_{1-x}$Sr$_x$CoO$_3$: Evidence for Interfacial Magnetic Phase Separation. M.A. TORJIA, M. SHARMA, C. HE, Univ. of Minnesota, J. GAZQUEZ, M. VARELA, ORNL, M. LAVER, B.B. MARANVILLE, J.A. BORCHERS, NIST, C. LEIGHTON, Univ. of Minnesota — Doped cobaltites have proven to be excellent choices for the study of the magneto-electronic phase separation phenomenon. Strong motivation exists for the study of these materials in films and heterostructures, the effect of dimensional confinement on this phase separation being a prime example. We investigated the structure, magnetism, and magnetotransport, in epitaxial La$_{1-x}$Sr$_x$CoO$_3$ on SrTiO$_3$(001). We have observed deterioration in ferromagnetism and conductivity in the thin film limit (e.g. < 8 nm at x = 0.5). We demonstrate that this can be definitively ascribed to interfacial magnetoelectronic phase separation. Key observations are the existence of an intercluster "GMR", anomalous multiterminal transport, strongly non-gaussian resistance fluctuations, and direct measurement of short-range ferromagnetic order by SANS. The thickness of the phase-separated region diverges as the doping is reduced from x = 0.50 to x = 0.18, and it can also be induced by deposition of SrTiO$_3$ overlayers. STEM/EELS data rule out the possibility of chemical phase separation proving that the deterioration in magnetic and electronic properties near the interface with SrTiO$_3$ is due to an intrinsic magnetic phase separation effect. [Supported by NSF and DOE].

5:06PM D30.00012 Electronic structure of La$_{1-x}$Sr$_x$CoO$_{3-\delta}$ in the presence of ordered oxygen vacancies$^1$. JAUME GAZQUEZ, M. VARELA, Oak Ridge National Laboratory, M.P. OXLEY, W. LUO, S.T. PANTLEIDES, Vanderbilt Univ., M.A. TORJIA, M. SHARMA, C. LEIGHTON, Univ. of Minnesota, S.J. PENNYCOOK, Oak Ridge National Laboratory — Here we present a study of oxygen vacancy ordering in La$_{1-x}$Sr$_x$CoO$_{3-\delta}$ (LSCO) thin films using a combination of atomic resolution Z-contrast imaging and electron energy-loss spectroscopy (EELS). Substituting Sr for La in LSCO results in either the formation of oxygen vacancies or an increase in the mean cobalt valence in order to preserve charge neutrality. At large concentrations, oxygen vacancies in LSCO form ordered structures with orientations determined by epitaxial strain. This talk will show how different O K-edge fine structures can be observed in EEL spectra obtained from different sites of the superstructure, while the Co L-edges are unchanged. These results, together with density functional theory and dynamical scattering calculations, suggest that there is no charge ordering but a modulation of the effective density of states in these systems.

5:18PM D30.00013 Magnetic phase separation-induced coercivity enhancement in epitaxial Nd$_{0.5}$Sr$_{0.5}$CoO$_3$ films$^1$. M. SHARMA, M. VARELA, ORNL, J. GAZQUEZ, M. VARELA, ORNL, C. LEIGHTON, ORNL — Interfacial magneto-electronic phase separation has recently been observed in epitaxial thin films of the doped perovskite cobaltite La$_{1-x}$Sr$_x$CoO$_3$ at doping values where no such phase separation exists in bulk. Such systems also display anomalously large coercivity, which is not understood. To achieve a better understanding of this phenomenon we have extended this study to Nd$_{0.5}$Sr$_{0.5}$CoO$_3$ (x = 0.5), the perovskite cobaltite with the largest coercivity in bulk. Thin films of Nd$_{0.5}$Sr$_{0.5}$CoO$_3$ are grown via high pressure reactive sputtering on SrTiO$_3$(001) substrates. We have observed a rapid deterioration in magnetization and onset of large intercluster-type magnetoresistance below a critical thickness of 80 Å. Signatures of interfacial magneto-electronic phase separation also seen in our earlier work on La$_{1-x}$Sr$_x$CoO$_3$. The temperature, angular, and thickness dependence of the coercivity ($H_c$) was studied using magnetoresistance. Low temperature $H_c$ values become very large (up to 3.6 Tesla) at low thickness, and a strong, superlinear $T$ dependence emerges. We propose that the coercivity enhancement arises due to efficient domain wall pinning by the inhomogeneously magnetically phase separated region near the SrTiO$_3$ substrate.

Session D31 GMAG: Focus Session: Quantum Magnets 335

2:30PM D31.00001 Spin Relaxation in Pure and Doped GGG. MICHAEL SCHMIDT, THOMAS ROSENBAUM, DANIEL SILEVITCH, University of Chicago, GABRIEL AEPPLI, University College London, SAYANTANI GHOSH, Y.K. VERMA, University of California, Merced — Geometric frustration in Gadolinium Gallium Garnet (GGG) leads to local regions of correlated spins that can be manipulated without affecting the background spin susceptibility. These “quantum protectorates” can be accessed via the non-linear response at milliKelvin temperatures using a hole burning technique. We study the effect of impurities on both the structure of the spin clusters and the dissipation spectrum in Neodymium-doped GGG crystals via pump-probe ac magnetic susceptibility and direct optical measurements.
2:42PM D31.00002 Bose-Einstein Condensation of Triplons in Ba$_3$Cr$_2$O$_6$\textsuperscript{1}, A.A. ACZEL, McMaster University, Y. KOHAMA, M. JAIME, Los Alamos National Laboratory, L. BALICAS, National High Magnetic Field Laboratory, K. NINIOS, H.B. CHAN, University of Florida, H.A. DABKOWSKA, G.M. LUKE, McMaster University — By performing heat capacity, magnetocaloric effect, torque magnetometry and force magnetometry measurements up to 33 T, we have mapped out the T-H phase diagram of the S = 1/2 spin dimer compound Ba$_3$Cr$_2$O$_6$. We found evidence for field-induced magnetic order between Hc1 = 12.52(2) T and Hc2 \sim 23.6 T, with the maximum transition temperature Tc \sim 2.7 K at H \sim 18 T. There are many qualitative features of the data suggesting that the transition at Hc1 corresponds to a Bose-Einstein condensation of triplons universality class. These include the apparent preservation of U(1) symmetry for applied fields below Hc1, a highly symmetric phase diagram, and an absence of any magnetization plateaus in the magnetic torque and force measurements.

\textsuperscript{1}We acknowledge support from NSERC and CIFAR at McMaster.

2:54PM D31.00003 Specific heat measurements in the novel frustrated quantum magnets SrHoO$_4$ and SrDy$_2$O$_4$, A. D. BIANCHI, B. PREVOST, U. de Montreal, QC, Montreal, Canada, N. KURITA, F. RONNING, R. MOVSHOVICH, T. W. KLIEMCZUK, LANL, Los Alamos, NM, USA, M. KENZELMANN, LDM, PSI, Villigen, Switzerland, R. J. CAVA, Princeton University, Princeton, NJ, USA — We investigated the specific heat of the novel geometrically frustrated quantum magnets SrHoO$_4$ and SrDy$_2$O$_4$ to determine the nature of their ground states. We present a study of the magnetic field dependence of specific heat $C_p(T, H)$ measured in a dilution refrigerator between 0.1 K and 4 K and a PPMS between 2 and 50 K for magnetic fields H between 0 and 9 T. We subtracted the phonon background $C_{\text{ph}}$ by using a temperature dependent Debye temperature determined from measurements on the non-magnetic structural analogue SrLu$_2$O$_4$. After this subtraction, in SrHoO$_4$ we observed a broad anomaly in the magnetic specific heat $C_{\text{mag}} = C_p - C_{\text{ph}}$ centered at 0.5 K in zero field. At high fields, we found a broad peak centered at 0.35 K which decreases with rising magnetic field. SrDy$_2$O$_4$ in zero field has a broad anomaly at 1.2 K. The peak broadens with increasing H and its amplitude decreases, and by 5 T it is completely suppressed. By 50 K, each ion in the Dy compound has recovered 21.5 J/mol K of its spin entropy, which is comparable to the entire spin entropy of a free Dy ion of $R \cdot \ln(2J + 1)$, whereas we observe only 11.1 J/mol K for SrHoO$_4$.

3:06PM D31.00004 The Interplay of Quantum Criticality and Frustration in Columbite\textsuperscript{1}, RIBHU KAUL, Station Q, UCSB, SUNGBIN LEE, Department of Physics, UCSB, LEON BALENTS, KITP, UCSB — CoNb$_2$O$_6$ is a remarkable material. It can be modeled as a lattice of Ising chains coupled to each other in a frustrated anisotropic triangular lattice in the basal plane perpendicular to the chain direction. Applying a strong transverse field tunes the chains through a quantum phase transition into a paramagnetic phase. The interplay between two of the most interesting features of correlated quantum physics, quantum criticality and geometric frustration, produces a rich phase diagram which reflects the fundamental underlying quantum many-body physics. Using a variety of analytic and numerical techniques, we map out the phase diagram of this material in both transverse and longitudinal fields and provide a comparison with experiment.

3:18PM D31.00005 Quantum phase transitions of the asymmetric three-leg spin tube, TORU SAKAI, JAEA/SPring-8, University of Hyogo, JST TRIP, MASAHIRO SATO, RIKEN, KOUCHI OKUNISHI, Niigata University, YUICHI OTSUKA, University of Hyogo, KIYOMI OKAMOTO, Tokyo Institute of Technology, CHIGAK ITOI, Nihon University — We investigate quantum phase transitions of the S=1/2 three-leg antiferromagnetic spin tube with asymmetric inter-chain (rung) exchange interactions. On the basis of the electron tube system, we propose a useful effective theory to give the global phase diagram of the asymmetric spin tube. In addition, using other effective theories we raise the reliability of the phase diagram. The density-matrix renormalization-group and the numerical diagonalization analyzes show that the finite spin gap appears in a narrow region around the rung-symmetric line. In contrast to a recent paper by Nishimoto and Arikawa \cite{1}. The numerical calculations indicate that this global phase diagram obtained by use of the effective theories is qualitatively correct. In the gapless phase on the phase diagram, the numerical data are fitted by a finite-size scaling in the $c=1$ conformal field theory. We argue that all the phase transitions between the gapful and gapless phases belong to the Berezinskii-Kosterlitz-Thouless universality class \cite{2}.

3:30PM D31.00006 Critical behavior study of antiferromagnetism in isostructural La$_2$CuO$_{4+\delta}$ and La$_2$NiO$_{4+\delta}$, BENJAMIN WHITE, JOHN NEUMEIER, Montana State University, A. ERB, Walther Meissner Institute — Neutron diffraction \cite{1} and nuclear quadruple resonance \cite{2} experiments coupled with theory calculations provide substantial evidence to support the widely-accepted belief that the two-dimensional Heisenberg model describes the antiferromagnetic interactions in La$_2$CuO$_4$ ($S = 1/2$) and La$_2$NiO$_4$ ($S = 1$). The heat capacity critical exponent $\alpha$, which could provide further evidence in these two compounds because of the weak nature of the anomalies at $T_N$. We present heat capacity and high-resolution thermal expansion measurements of La$_2$CuO$_4$ and La$_2$NiO$_4$ single crystals, grown by the floating-zone method, and an analysis of $\alpha$ within the context of predicted values for a variety of universality classes. This material is based upon work supported by the NSF (DMR-0504769) and US DOE Office of Basic Energy Sciences (DE-FG-06ER46260) \cite{1}.\cite{2} Y. Endoh et al., PRB 37, 7443 (1988); G. Aeppli and D.J. Buttrey, PRL 61, 203 (1988).

3:42PM D31.00007 Physics of the spin gap in the $S = 1/2$ Heisenberg antiferromagnet on kagome$^1$, OLEG TCHERNYSHYOV$^2$, Johns Hopkins University — A combination of low spin and strong frustration makes the $S = 1/2$ Heisenberg antiferromagnet on kagome a likely candidate for an unusual ground state and elementary excitations. Exact-diagonalization studies$^1$ on finite clusters point to a lack of magnetic order in the ground state and to an energy gap of order $1/20$ for $S = 1$ excitations. The exact nature of the ground state and elementary excitations remains a subject of vigorous debate. Among the proposed ground states are chiral$^2$ and non-chiral$^3$ spin liquids and a valence-bond crystal (VBC)$^4-5$; spin excitations range from deconfined spinons with a Bose$^6$ or Fermi statistics$^2-3$ to magnons$^7$. We show that the system behaves as a collection of spinons, quasiparticles with $S = 1/2$ and Fermi statistics, whose motion disturbs valence-bond order. Attraction between spinons, mediated by exchange, binds them into small, massive pairs of $S = 0$ with a binding energy of $0.06 J$.$^8$ The pair formation strongly suppresses the motion of individual spinons and makes the survival of the Singh-Huse VBC plausible. A spin excitation amounts to breaking up a pair into two (nearly) free spinons with $S = 1$. The survival of the VBC is expected to lead to spinon confinement; however, small energy differences between various valence-bond configurations would make the confinement length large.

4:30PM D31.00009 ABSTRACT WITHDRAWN —

4:42PM D31.00010 Order and Disorder in AKLT Antiferromagnets in Three Dimensions$^1$, SIDDHARTH PARAMESWARAN, S.L. SONDHI, Princeton University, DANIEL AROVAS, UC San Diego — The models constructed by Affleck, Kennedy, Lieb, and Tasaki (PRL 58, 799 (1987)) describe a family of quantum antiferromagnets on arbitrary lattices, where the local spin $S$ is an integer multiple $M$ of half the lattice coordination number. The equal time quantum correlations in their ground states may be computed as finite temperature correlations of a classical O($3$) model on the same lattice, where the temperature is given by $T = 1/M$. In dimensions $d = 1$ and $d = 2$ this mapping implies that all AKLT states are quantum disordered. We consider the $d = 3$ case where the nature of the AKLT states is now a question of detail depending upon the choice of lattice and spin; for sufficiently large $S$ some form of Néel order is almost inevitable. On the unfrustrated cubic lattice, we find that all AKLT states are ordered while for the unfrustrated diamond lattice the minimal $S = 2$ state is disordered while all other states are ordered. On the frustrated pyrochlore lattice, we find (conservatively) that several states starting with the minimal $S = 3$ state are disordered. These are a significant addition to the catalog of magnetic Hamiltonians in $d = 3$ with ground states known to lack order on account of strong quantum fluctuations.

4:54PM D31.00011 Global phase diagrams of frustrated quantum antiferromagnets in two dimensions: doubled Chern-Simons theory, CENKE XU, SUBIR SACHDEV, Harvard University — We present a general approach to understanding the quantum phases and phase transitions of quantum antiferromagnets in two spatial dimensions. We begin with the simplest spin liquid state, the $Z_2$ spin liquid, whose elementary excitations are spinons and visons, carrying $Z_2$ electric and magnetic charges respectively. Their dynamics are expressed in terms of a doubled U(1) Chern-Simons theory, which correctly captures the “topological” order of the $Z_2$ spin liquid state. We show that the same theory also yields a description of the variety of ordered phases obtained when one or more of the elementary excitations condense. Field theories for the transitions and multicritical points between these phases are obtained. We also survey experimental results on antiferromagnets on the anisotropic triangular lattice, and make connections between their phase diagrams and our results.

5:06PM D31.00012 Stability of the U(1) spin liquid with spinon Fermi surface in 2+1 dimensions$^1$, SUNG-SIK LEE, McMaster University — We study non-perturbative stability of a 2+1 dimensional critical spin liquid state, the U(1) spin liquid with a spinon Fermi surface. By mapping the spinon Fermi surface into an infinite set of 1+1 dimensional chiral fermions, we show that an instanton has an infinite scaling dimension for any nonzero N, where N is the number of spinon flavors. Therefore, the spin liquid state can be stable against confinement in physical systems, such as spin 1/2 magnets on the triangular lattice.

5:18PM D31.00013 Finite-size scaling of string order parameters characterizing the Haldane phase. HIROSHI UEDA, Graduate School of Engineering Science, Osaka University, HIROKI NAKANO, Graduate School of Material Science, University of Hyogo, KOICHI KUSAKABE, Graduate School of Engineering Science, Osaka University. We have developed a numerical procedure to clarify the critical behavior near a quantum phase transition by analyzing a multi-point correlation function characterizing the ground state. The procedure focuses on the gradient of the inverse-system-size dependence of the correlation function on a logarithmic plot. It requires only the correlation functions of several finite sizes under the same condition as a candidate for the long-range order. We apply the analysis to the string order parameter of the $S = 1/2$ XXZ chain with uniaxial single-ion anisotropy obtained by the density matrix renormalization group method. The present analysis gives precise estimates of transition points and critical exponents, $\nu$ and $\eta$, in Ising transitions, Gaussian transitions, and Berezinskii-Kosterlitz-Thouless transitions. Consistent results with those obtained from the analysis of the energy-level structure. This method will contribute much for a direct observation of quantum phase transitions.

Session D32 GMAG DMP: Focus Session: Spin Dependent Physics in Organic Materials and Graphene 336

2:30PM D32.00001 Magnetism by nonmagnetic defects in a 2D BN sheet: ab initio studies. CHRISTOPHER MALEC, DRAGOMIR DAVIDOVIC, Georgia Institute of Technology. Few layer graphene as well as thin graphite samples are measured by magnetic resonance (EPR) experiments (Eastern Washington University, JOHN SCHLUETER, Argonne National Laboratory). Latest results will be discussed.

2:42PM D32.00002 Magnetoresistance in hydrogen-doped graphene nanoribbons. F. MUNOZ-ROJAS, Universidad de Alicante, D. SORIANO, J. FERNANDEZ-ROSSIER, J. J. PALACIOS. Recent works have focused on hydrogen-doped graphene, both in the diluted and highly doped concentrations. It is known that a single hydrogen atom on top of a carbon atom in graphene has a magnetic moment. In the case of a low concentration of hydrogen dopants, it is believed that the ground state features local moments with zero total spin. Application of a strong enough magnetic field can spin polarize the system, in analogy with diluted magnetic semiconductors. In this work we study whether this spin order changes the resistance of the system. We study the relation between conductance and spin order for hydrogen-doped graphene armchair nanoribbons. We use both mean field Hubbard model and density functional theory calculations and compare results from both approaches. For the latter one, B3LYP hybrid functional is used. The conductance is calculated for the diluted limit. We use the Landauer formalism with the Green’s Function Approach for the conductance calculation. We find that the conductance in these systems is significantly affected by spin order. Thus, we predict magnetoresistance in graphene ribbons doped with Hydrogen.

2:54PM D32.00003 Spin dependent Transport in Thin Graphite and Few Layer Graphene. CHRISTOPHER MALEC, DRAGOMIR DAVIDOVIC, Georgia Institute of Technology. Few layer graphene as well as thin graphite samples are measured by local and non-local spin injection techniques at 4.2 K. Both spin valve, and spin precession measurements are performed. Spins remain coherent over micron length scales. Latest results will be discussed.

3:06PM D32.00004 Magnetism and magnetic interactions in graphene and graphite. OLEG YAZYEV, Ecole Polytechnique Federale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland. Magnetic materials and nanostructures based on carbon and other light elements provide a number of attractive opportunities for future information technologies such as spintronics and quantum information processing. In this talk, I review the first-principles studies of the magnetism induced by defects and edges in graphene and graphite. We show that in graphene the single-atom defects (e.g. vacancies and hydrogen chemisorption) induce the spin-polarized defect states in different defect configurations. We explain the recent experimental observations of high-temperature ferromagnetism in proton-irradiated graphite. Similarly, the zigzag edges of graphene are predicted to induce local magnetic moments which can serve as a base for novel spintronic devices. We address the question of the spin orientation stability length in this one-dimensional magnetic system and establish the limitations of the proposed spintronic devices [3]. Finally, I consider the hyperfine interactions (i.e. the magnetic interactions between the spins of electrons and nuclei) in carbon nanostructures and materials [4]. Possible approaches for achieving long electron spin decoherence times in graphene-based nanostructures are discussed.

3:42PM D32.00005 Determining the spatial and spin anisotropy of reduced-dimensionality Cu-based magnets using EPR, ultra-high-field magnetization and simulations. SUSAN COX, ROSS MCDONALD, JOHN SINGLETON, National High Magnetic Field Laboratory, PINAKI SENGUPTA, Los Alamos National Laboratory, PAUL GODDARD, STEPHEN BLUNDELL, Physics, University of Oxford, JANEZ BONCA, Physics, Ljubljana University, SAMIR EL SAWISH, Jozef Stefan Institute, JAMIE MANSON, Chemistry, Eastern Washington University, JOHN SCHLUETER, Argonne National Laboratory. Pulsed-field magnetization experiments (up to 85 T) and electron paramagnetic resonance (EPR) experiments (10 – 110 GHz) are reported on a family of organic Cu-based two-dimensional (2D) Heisenberg magnets. The low-$T$ $M(H)$ relationship is concave, with a sharp transition to a saturation value at a critical field $H_c$. Monte-Carlo simulations including a finite interlayer exchange energy quantitatively reproduce the data. Thus, one can obtain accurate values for both intra- and interlayer exchange energies. The EPR spectra show pronounced changes in effective $g$ factor, linewidth and zero-field intercept at temperatures, fields and frequencies of the same energy scale as the dominant exchange parameter. The EPR results are modeled using finite-cluster-size methods, and the data are well matched by an easy-plane spin anisotropy in the range 0.01 – 0.05. Thus, EPR measurements allow the spin orientation dependence of the exchange interaction to be determined.
3:54PM D32.00006 Fermomagnetic transition coupled to magnetoelastic interactions1. J.L. MUSELDT, L.I. VERSGARA, T.V. BRINZARIL, University of Tennessee, L.C. TUNG, Y.J. WANG, NHMFL, J.A. SCHLUETER, Argonne, J.L. MANSON, Eastern Washington, UNIVERSITY OF TENNESSEE TEAM, NHMFL TEAM, ARGONNE TEAM, EASTERN WASHINGTON TEAM — We investigate the magneto-infrared response of CuHF$_2$(pz)$_2$BF$_4$, a quasi-two-dimensional Heisenberg antiferromagnet, in order to probe the microscopic aspects of magnetoelastic coupling through the field-driven antiferromagnetic to ferromagnetic transition. The ferromagnetic transition is accompanied by substantial changes in the out-of-plane pyrazine ring distortion, suggesting a mechanism for explaining the soft magnetism of this system. The size of these field-induced distortions tracks the bulk magnetization, demonstrating that the ferromagnetic transition is coupled to magnetoelastic interactions in this material. We discuss these results in terms of local structural distortions and the effect on in-plane superexchange interactions.

We thank the Division of Materials Research at NSF for support of this work.

4:06PM D32.00007 Magnetic phase diagram of a 2D quantum Heisenberg antiferromagnetic compound Cu(pz)$_2$(ClO$_4$)$_2$, FAN XIAO, Clark University, NAT FORTUNE, Smith College, CHRISTOPHER LANDEE, MARK TURNBULL, Clark University — Cu(pz)$_2$(ClO$_4$)$_2$ is a 2D quantum Heisenberg antiferromagnet with an exchange strength of 17.5(5) K and a zero-field ordering temperature of 4.25 K. The ordering temperature has been found to be affected by an applied field. The phase diagram of Cu(pz)$_2$(ClO$_4$)$_2$ is determined by measuring the magnetization and the in-field specific heat. The behavior of the ordering temperature can be interpreted as a field induced 2D Heisenberg to 2D XY crossover.

4:18PM D32.00008 Gapped quantum spin-liquid state in a frustrated triangular magnet K-(BEDT-TTF)$_2$Cu$_3$(CN)$_3$, MINORU YAMASHITA, NORIHI TO NAKATA, Department of Physics, Graduate School of Science, Kyoto University, Kyoto 606-8502, Japan, YUI CHI KASAHARA, TAKAKIHO SASAKI, NAOKI YONEYAMA, NORIO KOYAYASHI, Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, SATOSHI FUJIMOTO, TAKASADA SHIBAUCHI, YUJI MATSUDA, Department of Physics, Graduate School of Science, Kyoto University, Kyoto 606-8502, Japan — Unveiling the nature of quantum-spin-liquid (QSL) states, quantum fluctuation-driven disordered ground states, has been a central challenge in condensed matter physics. Especially the nature of the low-lying spin excitations and the presence/absence of the “spin gap” have been of great interest. Recently, NMR measurements have shown that a QSL state is realized in n = (BEDT-TTF)$_2$Cu$_2$(CN)$_3$ with a nearly isotropic 2D triangular lattice structure. Here we report on our thermal-transport measurements in this compound down to 80 mK. We find that the QSL state has a full gap of ∼ 0.5 K (∼ 1/100) and the gap is hardly affected by magnetic fields up to 10 T [1], which sharply contradicts recent reports of heat capacity measurements reporting a finite γ-term. We will discuss some possibilities to explain this tiny spin gap in this present system. [1] M. Yamashita et al., Nature Physics (in press).

4:30PM D32.00009 Neutron scattering measurements of spin excitations in the spin ladder compound (pip)$_2$CuBr$_2$. A.T. SAVICI, C.L. BROHOLM, Dept. of Physics and Astronomy, Johns Hopkins Univ., Baltimore, MD, G.E. GRANROTH, S.E. NAGLER, NSDD, ORNL, Oak Ridge, TN, K.P. SCHMIDT, G.S. UHRIG, Technische Univ. Dortmund, Dortmund, Germany, D.M. PAJEROWSKI, M.W. MEISEL, Dept. of Physics, Univ. of Florida, Gainesville, FL, D.R. TALHAM, Dept. of Chemistry, Univ. of Florida, Gainesville, FL, C.M. BROWN, NIST Center for Neutron Research, Gaithersburg, MD — Recent theoretical and experimental work on S = 1/2 ladders has been inspired, in part, by the realization of a novel quantum spin liquid state. Bulk magnetization measurements indicate that (Cu$_2$H$_2$N)$_2$CuBr$_4$ (BPCB) is a two-leg spin ladder with stronger coupling along the rung (J$_H$) than along the leg direction (J$_L$) [1]. Here we report neutron spectroscopy measurements performed on a deuterated BPCB. We show that J$_H$ and J$_L$ are consistent with the previous measurements. No dispersion in the inter-ladder direction means that the ladders are magnetically isolated, likely due to frustrated inter-ladder exchange. We show that any diagonal exchange is < J$_H$/10, confirming that BPCB is an excellent realization of a S = 1/2 ladder in the strong coupling limit. [1] B.C. Watson et al., Phys.Rev.Lett. 86, 5168 (2001). *Work supported by NSF DMR-0603136, DMR-0701400, DMR-0543362, DMR-0454672, DOE DE-AC05-00OR22725, ESF and EuroHorcs.

4:42PM D32.00010 Neutron scattering measurements of the molecule-based magnets M[TCE]$_{n}$$(NCMe)$_{2}X$, ALEXANDER E. MIDGLEY, University of Missouri-Kansas City, KONSTANTIN POKHODNYA, C. OLSON, North Dakota State University, A.N. CARUSO, MICHAEL B. KRUGER, University of Missouri-Kansas City — M[TCE]$_{n}$$(M=V, Fe, Mn, Co, Ni; X=tetracyanoethylene) molecule-based magnets demonstrate high magnetic ordering due to a strong antiferromagnetic interaction between the unpaired d- and p-electrons of the metal ions and the ligands; however, the type of bonding involved in the superexchange mechanism remains unclear. The Raman active C-C vibration depends solely upon the degree of charge transfer from the metal ion to the π-active C=C vibration. Raman spectra of the M[TCE]$_{n}$$(M=Fe, Mn, Ni; X=FeCl$_3$, SbF$_6$) molecule-based magnets were collected in a diamond anvil cell at pressures up to 36 kbar. The observed pressure-induced strengthening of the ν(CC) and ν(CN) Raman modes provides a clearer picture of the type and degree of backbending, which will ultimately help build a model of how superexchange is occurring in these systems.

5:04PM D32.00011 Bonding, Backbonding and Spin-Polarized Molecular Orbitals: Basis for Magnetism and Semiconducting Transport in V[TCE]$_{2}X$, JEFFREY KORTRIGHT, Lawrence Berkeley National Laboratory, DEREK LINCOLN, RUTH SHIMA EDELSTEIN, ARTHUR EPESTEIN, The Ohio State University — V[TCE]$_{2}$ films exhibit magnetic order up to 400 K, magneto-resistance, and photo-induced magnetism. Yet the spin-polarized interactions between the TM and molecular species underlying these properties have remained elusive, in part because of its structural disorder. Using element-specific x-ray absorption spectroscopy (XAS) and magnetic circular dichroism (MCD) at the V L edges, and the C and N K edges we have gained new insight into these mechanisms [1]. We find evidence for covalent bonding between the V $\epsilon$L and TCE σ MO states, and a bridging interaction between V $\chi$MO and TCE π MO states, consistent with a generalized bonding/backbending model with V octahedrally coordinated by N in σ-bridging positions between TCE radical anions. C and N XAS and MCD reveal spin-polarized splitting of the former LUMO of neutral TCE, indicating that a direct exchange interaction underlies these properties. This indicates an active role of TCE* in the magnetic properties of extended V[TCE]$_{2}$ and related systems, which is distinctly different from superexchange models generally used to describe magnetic Prussian blue analogs. [1] Phys. Rev. Lett. 100, 257204 (2008).

Supported by DOE/BES and AFOSR.

5:06PM D32.00012 XPS and UV/Vis MCD studies of M[TCE] organic-based magnets, SAAD JANJUA, University of Missouri Kansas City, KONSTANTIN POKHODNYA, Center for Nanoscale Science and Engineering, Fargo,ND, MARCUS DRIVER, ANTHONY CARUSO, University of Missouri Kansas City, CARUSO'S RESEARCH GROUP TEAM — M[TCE]$_{n}$$(M=V, Fe, Mn, Ni; TCE = tetracyanoethylene) organic-based magnets provide a systematic means of studying magnetic superexchange by varying the 3d $\epsilon$L and $\epsilon$H filling. X-ray photoemission binding energy spectra of core electrons C (1s), N (1s) and M (3p) were used to study valency and bond type, giving a correlation between binding energy and transition temperature. UV/Vis Magnetic Circular Dischroism studies were conducted to investigate lowest unoccupied state and onsite Coulomb repulsion for both M 3d and TCE π* orbital. This talk will focus on providing empirical evidence of the near Fermi edge spin polarized electron structure in the context of magnetic exchange.
2:30PM D33.00001 Giant nonlinear electron-lattice interaction in cuprate superconductors, and origin of the pseudogap1, DEENNIS NEVINS, IBM T.J. Watson Research Center — The pseudogap is a key property of the cuprate superconductors, whose understanding should illuminate the pairing mechanism. Recent data support a close connection between the pseudogap and an oxygen-driven C4 symmetry breaking within the CuO2 plane unit cell. Using ab initio Molecular Dynamics, we show the existence of a strong nonlinear electron-oxygen vibrator coupling in two cuprates. In a mean field approach applied to this coupling, we derive a C4 splitting/pseudogap phase diagram in agreement with experiment — providing an explanation for the pseudogap phenomenon from first principles. The implications for superconductivity, Fermi surface arcing, and other properties are discussed.

2:42PM D33.00002 An explanation of the dichotomy between Fermi arcs and Fermi pockets in underdoped high-\(T_c\) superconductors1, XUN JIA, SUDIP CHAKRAVARTY, University of California at Los Angeles — We have numerically computed the spectral function \(A(\vec{k},\omega)\) of an underdoped cuprate superconductor for the \(d\)-density wave state subject to a long range correlated disorder. The intensity of the spectral function is significantly reduced for the electron pockets for an intermediate range of correlation length, but the Fermi arcs remain quite intact. This result provides one possible explanation as to why the electron pockets are not observed in angle resolved photoemission experiments. A calculation of Shubnikov-de Haas (SdH) oscillations using a real space transfer matrix method shows that two main frequencies are still present in the presence of a moderate amount of white noise disorder. The SdH oscillations in other relevant broken symmetry states are also computed.

2:54PM D33.00003 Quantum oscillations in a highly renormalized Fermi liquid model of Fermi pockets in underdoped cuprates1, TUDOR STANESCU, VICTOR GALITSKI, University of Maryland, DENNIS DREW, CNAM, University of Maryland — Motivated by the recent experimental observation of quantum oscillations in the underdoped cuprates, which suggest the existence of small electron pockets characterized by a relatively large cyclotron mass, we address two basic questions: 1) How can one explain the relatively large cyclotron effective mass observed experimentally and its relation with the effective Hall mass? 2) Why the electron pockets are not seen in ARPES experiments? We propose an explanation based on a model of a highly renormalized Fermi liquid characterized by a reconstructed Fermi surface and strongly momentum-dependent quasiparticle properties. We find that the cyclotron mass is enhanced by a factor \(<1/Z>\), while the effective Hall mass is proportional to \(<Z>/<Z^2>\), where \(<...>\) implies an averaging over the Fermi surface. If the \(Z\)-factor becomes small in some part of the Fermi surface, the cyclotron mass is enhanced sharply while the infrared Hall mass may remain small.

3:06PM D33.00004 Superconductivity near structural phase transition: the case of NbN1, SIMON BLACKBURN, MICHEL CÔTÉ, Département de physique, Regroupement québécois des matériaux de pointe (RQMP), Université de Montréal, CANADA, STEVEN G. LOUIE, MARVIN L. COHEN, Department of Physics, University of California at Berkeley and Materials Sciences Division of Lawrence Berkeley National Laboratory — Using density functional theory within the local density approximation we report the study of the electron-phonon coupling in NbC1-xN x crystals in the rocksalt structure. The Fermi surface of the system allows important nesting. The associated Kohn’s anomaly greatly increases the electron-phonon coupling and induces a structural instability when the electronic density of states reaches a critical value. Our results reproduce the observed rise in \(T_c\) from 11.2 K to 17.3 K as the nitrogen doping is increased. To further understand the important effect of the structural instability to the superconducting temperature, we model the Eliashberg spectral function with two contributions, one for the unstable phonons and the other for the unaffected phonons. Using the McMillan formula, we can predict the evolution of \(T_c\) within this simple model that reproduces well our \(ab\) initio results and the experimental data.

3:18PM D33.00005 Competition between antiferromagnetism and superconductivity, electron-hole doping asymmetry and “Fermi Surface” topology in cuprates1, SANDEEP PATHAK, Indian Institute of Science, VIJAY SHENOY, IISC Bangalore and Ohio State, NANDINI TRIVEDI, MOHIT RANDERIA, The Ohio State University — We study the asymmetry between electron and hole doping in a 2D Mott insulator, and the resulting competition between antiferromagnetism (AF) and \(d\)-wave superconductivity (SC), using variational Monte Carlo for projected wave functions. We find that key features of the \(T_c\) vs \(d\) phase diagram, such as critical doping for SC-AF coexistence and the maximum value of the \(SC\) order parameter, are determined by a single parameter \(\eta\) which characterizes the topology of the “Fermi surface” at half filling defined by the bare tight-binding parameters. Our results give insight into why AF wins for electron doping, while SC is dominant on the hole doped side. We also suggest using band structure engineering to control the \(\eta\) parameter for enhancing SC.

3:30PM D33.00006 Density Matrix Renormalization Group Study of a Dynamic Hubbard Model, a Comparative Study1, FATIH DOGAN, University of Alberta, Edmonton, AB, Canada, FRANK MARISGLIO, University of Alberta — A one-dimensional model of holes locally coupled to pseudo spin degrees of freedom is studied using density matrix renormalization group. The model used in this talk is one in the family of dynamic Hubbard models. We look at density-density correlations, and frequency dependent functions to see existence and nature of the attraction of the holes in an electron-hole asymmetric system.

3:42PM D33.00007 ABSTRACT WITHDRAWN —
3:54PM D33.00008 Valence bond glassy order and the pseudogap phase in underdoped high Tc cuprates. LIANG, REN, ZIQIANG WANG, Boston college — Different origins of the pseudogap phenomena in underdoped high Tc cuprate have been proposed over the years, but a consistent theory has been challenging. We argue that the low-energy fluctuations of the valence bond, originating from the superexchange interaction, are pinned by the doping induced electronic disorder to give rise to a valence bond glass (VBG) pseudogap phase. Using an extended t-J model within the Gutzwiller approximation, we show that the normal state VBG phase exhibits a genuine Fermi arc and a V-shaped average density of state at low energies. In the superconducting phase below Tc, the VBG can coexist and compete with an inhomogeneous d-wave superconductor, leading to the two-gap phenomena. We discuss the evolution of the local and momentum-space spectroscopy with doping and temperature, which capture the salient properties of the pseudogap phenomena and electronic disorder observed by recent ARPES and STM experiments.

4:06PM D33.00009 On stability of odd-frequency superconducting state. DMITRY SOLENOV, IVAR MARTIN, DAMITRY MOZRYSKY, Theoretical Division, Los Alamos National Laboratory — Odd-frequency pairing mechanism has been investigated for several decades. Nevertheless the properties of such superconducting phase as well as its thermodynamic stability have remained unclear. In particular it has been argued by numerous authors that the odd-frequency state is thermodynamically unstable, has an unphysical Meissner effect (at least within the mean-field approximation), and therefore can not exist as a homogeneous phase in equilibrium physical systems. We argue that such a conclusion is incorrect because it relies on an inappropriate assumption that the odd-frequency superconductor can be described by an effective Hamiltonian that breaks the U(1) symmetry. We show that the odd-frequency state can be appropriately formulated within the functional integral representation by using the effective action to describe such a superconducting state within the mean field approximation. We find that the odd-frequency superconductor is thermodynamically stable and exhibits ordinary Meissner effect, and therefore, in principle, it can be realized in equilibrium solid state systems.

4:18PM D33.00010 Wave function for composite odd-frequency superconductors. HARI DADA, Los Alamos National Laboratory, ELIHU ABRAHAMS, Department of Physics and Astronomy, Rutgers University, DMITRY MOZRYSKY, Los Alamos National Laboratory, YUKIO TANAKA, Department of Applied Physics, Nagoya University, JAPAN, ALEXANDER BALATSKY, Los Alamos National Laboratory — Berezinskii proposed a new class of superconducting state that has an anomalous gap function that is odd function of frequency. Following initial work of Berezinskii there has been growing interest in properties of such superconductors. We propose a BCS-like wave function for an s-wave triplet odd-frequency superconductor. The wave function describes a condensate of spin-0 Cooper pair and spin-1 magnon, a composite order parameter. By minimizing a Hamiltonian, suggested earlier in Ref. [3] to study the odd-frequency superconductor, we derive the quasiparticle dispersions, the self-consistent gap equation, and the density of states. We show that the odd-frequency state is thermodynamically stable and exhibits ordinary Meissner effect, and therefore, in principle, it can be realized in equilibrium solid state systems.

4:30PM D33.00011 Ginzburg Landau Theory for Cuprate Superconductivity. TIRUPPATTUR RAMAKRISHNAH, Dept. of Physics, Indian Institute of Science, Bangalore 560012, Also Banaras Hindu University, Varanasi 221005, INDIA, SUMILAN BANERJEE, CHANDAN DASGUPTA, Dept. of Physics, Indian Institute of Science, Bangalore 560012, INDIA — We propose and develop the consequences of a theory of a cuprate is expressed as a functional of the complex nearest neighbour spin singlet bond pair order parameter $\Delta_{ij} \exp(i\phi_{ij})$, $F$ is a sum of two terms $\sum_{m,n}(a\Delta^2_m+b\Delta^2+n)$, and $F_1 = -\sum_{m,n} x m c \cos(\phi_{mn} - \phi_{ij});$ here $m$ is the site corresponding to $ij$ on the dual lattice (also square) and $m, n$ are nearest neighbours. The doping $x$ and temperature $T^*$ dependences of $a, b$ and $c$ are rationalized (eg, $a \propto x$ for small $x$). The pseudogap (due to incoherent bond pairs) and the parabolic $x$ dependence of $T_c$ (AF ordering of the 2d-XY spin $\Delta_{mn} \exp(i\phi_{mn})$ leading to d wave superconductivity) are described. The observed $C_1(T)$ behaviour is shown to be due to disorder parameter fluctuations. Detailed calculations of the vortex structure show a crossover from a Josephson like to a BCS like form with increasing doping, mirroring a similar change in superconductivity.

4:42PM D33.00012 Levitation and lateral forces between a small magnet and superconducting sphere and the stability of the magnet. H. AL-KHATEEB, M. ALQADI, F. ALZOUBI, B. ALBISS, M. HASAN, N. AYOUB, Department of Physics, Jordan University of Science & Technology — Using the dipole-dipole interaction model, we obtained analytical expressions for the levitation and lateral forces act on a small magnet for anti-symmetric magnet/spherical superconductor system. Breaking the symmetry of the system, allow us to study the lateral force which is important in the stability of the magnet above superconducting sphere in the Meissner state. Our formulas are written in terms of the radius of the superconductor as well as the height, the lateral displacement and the orientation of the magnetic moment of the magnet. We found that the levitation force is linearly dependent on a lateral displacement whereas the lateral force is independent of the lateral displacement. Moreover, the levitation and lateral forces are varying solinoidally with the polar and azimuthal angle of the orientation of the moment of the magnet. The stability of the magnet has been discussed for special orientations of the moment of the magnet.

4:54PM D33.00013 HTSC Measurements Explained by Defended Superconductivity Theory. JOHN JAMES, St. Louis University — Resonance between the superconducting gap and the low energy optical phonon mode creates a burst of coherent phonons which prevents the unstable superconducting state from collapsing. Surrounding lattice defects with charge states prevents interactions which would stop the coherent phonons from forming. This simple model of why $T_c$ is high can explain many other phenomena, such as; insufficient density of states and phonons which prevents the unstable superconducting state from collapsing. Surrounding lattice defects with charge states prevents interactions which would stop the coherent phonons from forming.

5:06PM D33.00014 A Dynamical Mean Field Study of the Three-Band Copper-Oxide Model. XIN WANG, Columbia University, LUCA DE' MEDICI, Rutgers University, CAPONE MASSIMO, Università di Roma La Sapienza, ANDREW J. MILLIS, Columbia University — We apply the dynamical mean field theory to study the three-band Copper-Oxide Model related to the High-Tc Cuprates. Both continuous-time quantum Monte Carlo and Exact Diagonalization impurity solvers are used. The spectral function, mass enhancement and optical conductivity in both paramagnetic and antiferromagnetic case are computed. We determine the contribution of antiferromagnetic order to the gap observed in the undoped material. We show that in the paramagnetic Mott insulating regime the quasiparticle mass enhancement is larger for hole than for electron-doped compounds, but an opposite trend in matrix elements means that a the optical conductivity in these two cases is comparable.

5:18PM D33.00015 Retarded vs instantaneous interactions in high-temperature superconductors. What is the glue?1.21 BUMSOO KYUNG, DAVID SENECHAL, A.-M.S. TREMBLAY, Université de Sherbrooke — In BCS theory, the phononic origin of the attraction that leads to Cooper pairs was confirmed by theoretical and experimental developments that clearly showed that the interaction was retarded and that the corresponding energy scales were associated with phonons. Using Cellular Dynamical Mean-Field Theory with exact diagonalization at $T = 0$, we identify retardation effects in pairing and associate the corresponding energy scales with the spectral function of short-range spin fluctuations. These fluctuations are clearly seen in neutron and optical spectroscopy probes. Since the pairs have vanishing wave function at zero distance, the energy scale $U$ is absent from the pair dynamics. That dynamics can be monitored by the anomalous spectral weight. The Heisenberg exchange $J$ is a characteristic energy scale of that spectral weight and it appears in a manner analogous to what is found in mean-field theories. However, the anomalous spectral weight has additional structure caused by retardation.

Monday, March 16, 2009 2:30PM - 5:30PM – Session D34 DCMP: Superconductivity: Josephson Effects 404

2:30PM D34.00001 Temperature and Field Dependence of the Emission of Terahertz Waves from Intrinsic Josephson Junctions1.2 YOSHIHIKO NONOMURA, Computational Materials Science Center, National Institute for Materials Science, Tsukuba, Ibaraki 305-0047, Japan — We have recently succeeded in extracting coherent cw THz-radiation from intrinsic Josephson junctions in BSCCO [Science 318, 1291, (2007)]. An electromagnetic cavity resonance inside the sample generates a coherent state in which a large number of junctions are synchronized to oscillate in phase resulting in emission powers of up to 5 µW at frequencies up to 0.85 THz. The emission displays a non-monotonic temperature dependence with a sample dependent sharp maximum in the range of 25 to 45 K which we attribute to the interplay of self-heating effects and re-trapping of intrinsic junctions. Application of magnetic fields of less than 100 Oe parallel to the CuO planes as well as perpendicular leads to the rapid suppression of the emission.

2:42PM D34.00002 Spin-Josephson effect in antiferromagnetic tunnel junctions1.2 DOMINIQUE CHASSE, A.-M.S. TREMBLAY, Université de Sherbrooke — In the Josephson effect, coherent Cooper pair tunneling is driven by the phase difference between the superconducting order parameters on opposite sides of the junction. By analogy, differences in order parameters across a junction should lead to coherent tunneling of the condensed objects that exist in the broken symmetry state. To exhibit the generality of this phenomenon and make predictions from a realistic model, we study the case of a tunnel junction between two itinerant antiferromagnets. At the mean-field level, we find an equilibrium current of the staggered magnetization through the junction that is proportional the normal state conductance and to $S_{x}$ x $S_{y}$ where $S_{x}$ and $S_{y}$ are the staggered magnetizations on either sides. Microscopically, this effect comes from coherent tunneling of spin-one charge-zero particle-hole pairs that have a net wave vector equal to the antiphase difference between one and zero spin projection along the direction of the order parameter. We explain similarities and differences with the standard DC and AC Josephson effects.

1CRSNG, CRC, CIFAR

2:54PM D34.00003 Angular dependence of the radiation power of a Josephson STAR-emitter1.2, RICHARD KLEMM, University of Central Florida, KAZUO KADOWAKI, University of Tsukuba — We calculate the angular dependence of the power of stimulated terahertz amplified radiation (STAR) emitted from a dc voltage applied across a stack of intrinsic Josephson junctions. During coherent emission, we assume a spatially uniform ac Josephson current density in the stack acts as a surface electric current density antenna source, and the cavity features of the stack are contained in a magnetic surface current density source. A superconducting substrate acts as a perfect magnetic conductor with $H_{c1,ac}$ = 0 on its surface. The combined results agree very well with recent experimental observations. Existing Bi$_{2}$Sr$_{2}$CaCu$_{2}$O$_{8+δ}$ crystals atop perfect electric conductors could have Josephson STAR-emitter power in excess of 5 mW, acceptable for many device applications.

1supported by JST, CREST, MANA, CTC, and MEXT.

3:06PM D34.00004 Surface effects in THz wave emission from intrinsic Josephson junctions1.2 YOSHIIKO NONOMURA, Computational Materials Science Center, National Institute for Materials Science, Tsukuba, Ibaraki 305-0047, Japan — Recently THz wave emission from intrinsic Josephson junctions without external fields [1] was observed experimentally. As possible states to characterize this emission, the McCumber-like state with little spatial dependence of electric fields (for the surface impedance $Z_{c}$ = 1) [2] and novel phase-kink state (for large and complex $Z$) [3] have been proposed. In the present study [4] it is numerically shown that both states are stationary and that the dynamical phase transition between these two states occurs as $Z_{c}$ is varied. The McCumber-like state is stable for low current and small $Z_{c}$. For higher current, the phase-kink state accompanied with symmetry breaking along the $c$ axis is stable even for $Z_{c}$ = 1, though strong emission in the vicinity of cavity resonance points only takes place for larger $Z_{c}$. Value of $Z_{c}$ is optimized for the strongest emission, and effect of surface roughness will also be discussed. [1] L. Ozyuzer et al., Science 318, 1291 (2007); [2] Kadowaki et al., Physica C 468, 634 (2008); [3] Y. Nonomura, arXiv:0810.3756.

3:18PM D34.00005 All-MgB$_{2}$ sandwich-type Josephson junctions with MgO barrier1.2 KE CHEN, CHENGGANG ZHUANG, QI LI, Department of Physics, Penn State University, University Park, PA 16802, YE ZHU, PAUL VOYLES, Department of Materials Science and Engineering, University of Wisconsin, Madison, WI 53706, X. X. XI, Department of Physics and Department of Materials Science and Engineering, Penn State University, University Park, PA 16802 — Reproducible all-MgB$_{2}$ Josephson junctions have been made to meet the expectation for superconducting electronics that can work at above 20 K. The sandwich-type junctions were fabricated using MgB$_{2}$ electrodes grown by hybrid physical-chemical vapor deposition and MgO barrier deposited by RF magnetron sputtering. The $I-V$ characteristics show tunneling behavior with a small resistive shunt. The $I_{c}R_{n,prod}$ product is 2.1 and 0.7 mV at 4.2 and 20 K, respectively, with temperature dependence following the theory qualitatively. The junctions exhibit good Fraunhofer pattern and Shapiro steps under applied magnetic field and microwave radiation, respectively. The $J_{c}$ of the junction varies exponentially with the barrier thickness, from 100 to 0.01 A/cm$^{2}$. Transmission electron microscopy reveals both MgB$_{2}$ layers are epitaxially grown with $c$-axis parallel to the SiC (0001) substrate normal. With the same chip $J_{c}$ speed less than 10%, this junction technology has the potential for MgB$_{2}$ circuits.

1Supported by ONR and NSF.
3:30PM D34.00006 Direct observation of THz radiation from cylindrical structure of intrinsic Josephson junction system of Bi2212, M. TSUJIMOTO, T. YAMAMOTO, H. MINAMI, K. KADOWAKI, M. TACHIKI, University of Tsukuba, U. WELP, W. KWOK, Argonne National Laboratory — Intense terahertz (THz) radiation was observed from a single crystalline high-Tc superconductor Bi2Sr2CaCu2O8+δ (Bi2212) system1–2. We have performed various experiments on THz radiation with Bi2212 rectangular mesa structure fabricated by Argon-ion-milling and photolithography technique with changing the sample parameters. In this work, we report new experimental results obtained with samples which have a cylindrical structure fabricated by focused ion beam milling. The intense emission of electromagnetic radiation can be obtained in the return branch only. The frequency is directly measured by FT-IR spectrometer to be \( f = 0.474 \) THz in this particular sample of diameter with 90 \( \mu \)m. This frequency value is in good agreement with the fundamental cavity resonance mode frequency. 1) L. Ozyuzer et al., Science 318 (2007) 1291 2) K. Kadowaki et al., Physica C 468 (2008) 634-639

3:42PM D34.00007 Sin(2\( \phi \)) component in the current-phase relation of SFS Josephson junctions near the 0-\( \pi \) transition, M. A. STOUTIMORE, Department of Physics, University of Illinois at Urbana-Champaign, A. YU. RUSANOV, V.A. OBOZNOV, V.V. BOLGINOV, A.N. ROSSOLENKO, V.V. RYAZANOV, Laboratory of Superconductivity, Institute of Solid State Physics, Russian Academy of Sciences, D.J. VAN HARLINGEN, Department of Physics, University of Illinois at Urbana-Champaign — We directly determined the Josephson current-phase relation (CPR) of superconductor-ferromagnet-superconductor (SFS) junctions by rf-SQUID interferometry, and corroborated it with measurements of the critical current as a function of temperature and magnetic field and rf-induced Shapiro steps in the current-voltage characteristics. Our Nb-Cu41Ni53:Nb trilayer junctions, with 2\( \times \mu \)m\(^2\) area and 7nm CuNi thickness, show a transition with temperature from the usual Josephson 0-junction state to a \( \pi \)-junction state, defined by a phase difference of \( \pi \) in the ground state, at temperatures between 1.5K and 3.5K. Near the transition, we observe second harmonics in the CPR, deviations from the usual Fraunhofer diffraction pattern and half-integer Shapiro steps, all consistent with a sin(2\( \phi \)) component in the CPR.

3:54PM D34.00008 Josephson interferometry evidence for order parameter with anisotropic and possibly complex phase in UPt3, J. B. KYCIA, J. P. DAVIS, WILLIAM HALPERIN, Northwestern University — The unconventional superconductor UPt3 exhibits many interesting properties. Among the most exciting is that it has two superconducting transitions, believed to arise from different degenerate order parameters, at least one of which breaks time-reversal symmetry. The nature of the order parameter in each of these phases and the crossover between them is still not fully understood. We have fabricated Josephson junctions on various faces of high quality single crystals of UPt3. Measuring the magnetic field dependence of the critical current through these junctions produces patterns that reveal the intrinsic phase differences and underlying symmetry of the order parameter. Our results point to an order parameter with anisotropic and possibly complex phase that extends throughout the entire crystal. This is in contrast with our work on Sr2RuO4, which also breaks time-reversal symmetry but exhibits a distribution of dynamic chiral order parameter domains.

4:06PM D34.00009 Interactions between Josephson Junction Metamaterials and Evanescent Waves, LAURA ADAMS, Center for Nanophysics and Advanced Materials, Physics Department, University of Maryland, College Park, MD 20742, STEVEN ANLAGE, Center for Nanophysics and Advanced Materials, Physics Department, University of Maryland, College Park, MD 20742 — Amplification of evanescent waves is an exciting, yet controversial application of negative index of refraction metamaterials in pursuit of creating a "perfect lens". We will describe evanescent wave amplification experiments using lossless metamaterials, i.e. arrays of Josephson junctions (JJ). The effects of input power, temperature, and dc magnetic field on JJ arrays below the cutoff frequency of a waveguide have been investigated. At low temperatures a pronounced, tunable microwave resonance emerges in transmission. This resonance has been systematically studied in terms of its transmission and reflection coefficients. In the regime between -45 and -25 dBm, we observe a non-hysteretic emission of microwave photons that reverberate at the same frequency. Amplification of these photons (parametric amplification) will also be described. This work was supported by the Intelligence Community Postdoctoral Fellowship program.

4:18PM D34.00010 Direct test of pairing fluctuations in the pseudogap phase of an underdoped cuprate, JEROME LESUEUR, NICOLAS BERGAL, LPEM, MARCO APRILI, LPS, BRIGITTE LERIDON, LPEM, GIANCARLO FAINI, LPN, JEAN-PIERRE CONTOUR, Thales-CNRS — In underdoped cuprates, many experiments have provided evidence for the presence of a gap-like structure in the electronic excitations spectrum, in a region above the critical temperature and below a characteristic temperature \( T^* \). The origin of this so-called pseudogap is still hardly debated and the answer to this question turns out to be essential for the understanding of high-Tc superconductivity. One doesn’t know if the pseudogap is related to superconductivity or to an order in competition. In the former case, it has been suggested that superconducting pairing fluctuations may be responsible for the partial suppression of electronic excitations. This remains to be tested experimentally, but most of the probes used to investigate the pseudogap are not sensitive to pairs and therefore cannot provide such a test. Here, we report for the first time on a direct test of pairing fluctuations in the pseudogap regime using a Josephson-like experiment. Our results shows that fluctuations survive only in a restricted range of temperature close to \( T_c \) (\( T-T_c<15K \)), and therefore cannot be responsible for the opening of the pseudogap at high temperature. Nature Physics 4, 608 - 611 (2008)

4:30PM D34.00011 ABSTRACT WITHDRAWN

4:42PM D34.00012 Underdamped fluxon diffusion in a Josephson junction parallel array, KENNETH SEGALL, Colgate University, JUAN MAZO, University of Zaragoza, ADAM DIOGUARDI, UC Davis, NIKHIL FERNANDES, Colgate University — We present experimental measurements and numerical simulations on the dynamics of fluxons in a parallel array of Josephson junctions. Fluxons trapped in a parallel array of Josephson junctions upon cooldown experience a periodic potential determined by the junction critical currents and the cell inductances. As shown in two recent papers [1,2], under certain conditions fluxons can move through the array in a series of noise-induced phase slips. This leads to a low-voltage diffusion branch in the current-voltage characteristics, similar to that in underdamped phase diffusion for a single junction. Unlike underdamped phase diffusion, however, this fluxon diffusion does not need frequency-dependent damping to occur. We demonstrate the existence of this state by direct measurements of the current-voltage characteristics and measurements of the switching current distribution of the array. 1. J.J. Mazo et al. Phys. Rev. B78, 174510 (2008) 2. K. Segall et al. http://arXiv.org/abs/0807.2978, to appear in J. Low Temp. Phys.
4:54PM D34.00013 A tunable Josephson current in a Rashba Ring by Aharonov-Casher Phase
XIN LIU, MARIO F. BORUNDA, XIONG-JUN LIU, JAIRO SINOVÁ1, Department of Physics, Texas A&M University, College Station, TX 77843-4242, USA. JAIRO SINOVÁ’S GROUP AT TAMU TEAM — We study the interference effect induced by the Aharonov-Casher (A-C) phase on the transport between an asymmetrically confined two-dimensional electron ring system and the superconducting leads of a Josephson junction. The Josephson phase and the Andreev levels are studied both analytically and numerically. Our results also predict oscillations in the Josephson current due to the A-C phase in the ring that can be tuned electrically via the spin-orbit (SO) interaction. Based on these oscillations, we propose a novel mechanism to observe the A-C phase in mesoscopic rings with gate tunable SO interaction attached to superconducting leads using the Josephson current oscillations. An applicable method to control the Josephson current by a tunable gate voltage can be realized due to these phenomena.

1Principal Investigator

5:06PM D34.00014 Enhanced thermal activation of a superconductor-normal metal quantum interference device1, JIAN WEI, PAUL CADDEN-ZIMANSKY2, Northwestern University, VENKAT CHANDRASEKHAR — We measure the magnetoresistance and current-voltage characteristics (CVC) of a superconductor-normal metal quantum interference device in the form of a mesoscopic normal-metal loop in contact with two superconducting electrodes. Below the transition temperature of the superconducting leads, sharp switching from the zero-resistance state to a finite-resistance state is observed at half-flux quantum. The CVC in the finite-resistance state can be described by the Ambegaokar-Halperin (AH) theory of the effect of thermal fluctuations in Josephson junctions, but here this effect of thermal fluctuations is greatly enhanced. The CVC in the zero-resistance state can be described by the Langer-Ambegaokar-McCumber-Halperin theory of thermally activated phase slips in one dimensional superconductors, but also with enhanced phase slipping rates, or equivalently, lowered energy barriers.

1This was funded by the NSF through grant DMR-0604601.

5:18PM D34.00015 Static and dynamic effects in Superconducting/Normal metal/Superconducting long junctions, FRANCESCA CHIODI, BERTRAND REULET, HÉLENE BOUCHIAT, Laboratoire de Physique des Solides UMR 8502 — Université Paris-Sud, Bât 510 — 91405 Orsay cedex, LES NANOSTRUCTURES À LA NANOCONSEDE TEAM, PHYSIQUE MÉSOCOPICIE TEAM, J.C. CUEVAS-DEPARTEMENTO DE FISICA TEORICA DE LA MATERIA CONDENSADA-UNIVERSIDAD AUTONOMA DE MADRID COLLABORATION — We have studied four different Nb/Al long junctions at temperatures between 1.4 K and 4K (where the Al wire is still in the normal state). We have measured their low frequency current-voltage characteristics in the presence of an RF excitation (whose frequency varies from 100 kHz to 40 GHz). All the junctions show an important increase in critical current for frequencies above a threshold, which depends on the length of the normal wire. Is Thouless frequency playing a role? We have also studied the influence of geometry (narrow / square normal wire) on W/Au junctions. We have seen that the critical current/magnetic field curve changes from the well known Fraunhofer pattern (square wire) to a Gaussian dependence (narrow wire). We are interested in dynamic properties of SN junctions: inductively coupling a multilode LC resonator to an AC SQUID we hope to define the behaviour of Andreev bound states when excitation time becomes lower than the typical diffusion time.

Monday, March 16, 2009 2:30PM - 5:30PM —
Session D35 DMP: Focus Session: Iron Pnictides and Other Novel Superconductors IV: General Experiment 408

2:30PM D35.00001 Iron Pnictide Superconductors: discovery and advances, HIDEO HOSONO, Tokyo Institute of Technology — Superconducting transition in a layered ZrCuSiAsS-type crystal was first reported for LaFePO in 2006 [1] and subsequently, a similar Tc was found for LaNiPO with the same crystal structure in 2007. However, Tc of these compounds reminded low (∼4K). On February 23, 2008, our paper reporting a layered compound in LaFeAsO1−xFex (x=0.1) exhibiting a superconducting critical temperature Tc (mid-point) = 26K was published [3]. In this presentation I talk the background of this discovery and the subsequent advance in materials. The following points have been clarified to date; (1) Iron-based superconductors reported are 4-types crystal structures, the 1111 [3], 122 [4], 111 [5], and 11 [6] type. All the high Tc iron-based superconductors contain a FeAs plane and the Fe3d orbitals dominate the Fermi-level. (2) The occurrence of a crystallographic transition accompanying anti-ferromagnetic to paramagnetic state in the parent compound is a requisite for a high Tc. (3) There exist a vast number of materials containing the Fe square lattice. (4) A partial substitution of Fe with other transition metal is possible without serious reduction of Tc. (4) A new insulating layer AEF (AE=Ca, Sr)was found to be effective in the 1111 phase [7]. (5) High pressure synthesis was effective to obtain the 1111 phases with higher Tc. (6) Epitaxial thin films exhibiting a Tc almost the same as that in the bulk were fabricated for CaFeAsO-Co[8]. Epitaxial thin films of LaFeAsO was recently reported as well [9].

3:06PM D35.00002 Materials and Physics in Pnictide Superconductors, HAI-HU WEN, IOP, CAS — Superconductivity in the pnictides has shown itself to be very interesting and attractive. Some experimental results have revealed that the superconducting mechanism could be unconventional. In this talk I will survey our recent progress of both material synthesizing and physical properties of this rich family. We have made several major contributions to the synthesizing of new pnictide superconductors. (1) Fabrication of the hole doped RE1−xSrxFexAsO samples (RE=La and Pr); (2) Fabrication of a series of new parent compounds DvFeAsF (Dv=divalent metals: Sr, Ca, Eu etc.) and many new superconductors with Tc beyond 50 K by doping electrons into the system; (3) Invention of the new material (Sr3Sc2)Fe2As2 with rather large spacing distance between the FeAs planes. We have successfully grown the NdFeAsO1−xFex and Ba1−xKxFe2As2 single crystals. It is found that the anomalous electron scattering in the normal state cannot be simply attributed to the multiband effect. The influence given by the magnetic correlation may play an important role. Specific heat, lower critical field and point contact tunneling all indicate the unconventional superconductivity and multigap features, while the paring symmetry of the superconducting gap may be a non-trivial issue. In the 1111 phase, the superfluid density is rather low and contains probably a nodal feature. While in the 122 phase, both the superfluid density and the quasiparticle density of states is about 5-10 times higher than that in the 1111 phase. An s-wave component was found in the 122 phase. I will also report the measurements on anisotropy, critical current density, critical fields and vortex phase diagram. Small anisotropy, high upper critical field and fish-tail effect (in 122) were observed. All these suggest very good potential applications. In collaboration with Gang Mu, Zhaosheng Wang, Huiqian Luo, Huan Yang, Xiuyu Zhu, Ying Jia, Yonglei Wang, Fei Han, Bing Zeng, Bing Shen, Cong Ren, Lei Shan.
3:42PM D35.00003 Determination of the phase diagram of the electron doped superconductor Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$\textsuperscript{1}, JIJUN-HAW CHU, JAMES ANALYTIS, CHRIS KUCHARCZYK, IAN FISHER, Geballe Laboratory for Advanced Materials and Department of Applied Physics, Stanford University — Systematic measurements of the resistivity, heat capacity, susceptibility and Hall coefficient are presented for single crystal samples of the electron-doped superconductor Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$. These data delineate an $x-2\theta$ phase diagram in which the single magnetic/structural phase transition that is observed for undoped BaFe$_2$As$_2$ at 134 K appears to split into two distinct phase transitions, both of which are rapidly suppressed with increasing Co concentration. Superconductivity emerges for Co concentrations above $x > 0.025$, and appears to coexist with the broken symmetry state up to $x \sim 0.06$. The optimal $T_c$ appears to coincide with the Co concentration at which the magnetic/structural phase transitions are totally suppressed. Superconductivity is observed for a further range of Co concentrations, before being completely suppressed for $x \sim 0.18$ and above. The form of this $x-2\theta$ phase diagram is suggestive of an association between superconductivity and a quantum critical point arising from suppression of the magnetic and/or structural phase transitions.

3:54PM D35.00004 The magnetic and superconducting phase diagram of PrFeAs$_2$O$_{1-x}$\textsubscript{F$_x$}\textsuperscript{1}, COSTEL R. ROTUNDU, STEPHEN D. WILSON, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, BYRON K. FREELON, Department of Physics, University of California, Berkeley, CA 94720, USA, EDITH BOURRET-COURCHESNE, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, ROBERT J. BIRGENEAU, Department of Physics, University of California / Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA. — The single crystal phase diagram of the newly discovered iron pnictide superconductors RFeAsO$_{1-x}$F$_x$ (R=rare-earth) is of great interest and with implications in the understanding of the nature of superconductivity (SC) itself. Predicted by ab initio calculations \cite{1} and pointed by resistivity measurements \cite{2}, the relevance of a quantum critical point remains controversial in the light of the structural phase transition between the magnetic SDW and SC \cite{3}. We present a detailed magnetic and superconducting phase diagram of PrFeAsO$_{1-x}$F$_x$, as inferred from magnetic susceptibility and resistivity measurements. References: [1] G. Giovannetti et al., Physica B 403, 3653 (2008) [2] R. H. Liu et al., Phys Rev Lett 101, 087001 (2008) [3] H. Luetkens et al., cond.mat:0806.3533

4:06PM D35.00005 Doping-Driven Collapse of the SDW Correlation Gap in SmFeAsO$_{1-x}$F$_x$\textsuperscript{1}, J.B. KEMPER, SCOTT C. RIGGS, Z. STEGEN, G.S. BOEBINGER, National High Magnetic Field Laboratory - Florida State University, R.D. MACDONALD, F.F. BALAKIREV, Y. KOHAMA, A. MIGLIORI, National High Magnetic Field Laboratory - Los Alamos National Laboratory, H. CHEN, R.H. LIU, X.H. CHEN, Hefei National Laboratory and University of Science and Technology of China — We have investigated the Hall resistivity, $\rho_{xy}$, of polycrystalline SmFeAsO$_{1-x}$F$_x$ for four different fluorine concentrations from the onset of superconductivity through the collapse of the structural phase transition. For the two more highly-doped samples, $\rho_{xy}$ is linear in magnetic field up to 50 T with only weak temperature dependence, reminiscent of a simple Fermi liquid. For the lightly-doped samples with $x < 0.15$, we find a low temperature regime characterized $\rho_{xy}(H)$ being both non-linear in magnetic field and strongly temperature dependent even though the Hall angle is small. The onset temperature for this non-linear regime is in the vicinity of the structural phase (SPT)/spin density wave (SDW) transitions. The temperature dependence of the Hall resistivity is consistent with a thermal activation of carriers across an energy gap. The evolution of the energy gap with doping is reported.

4:18PM D35.00006 STM Investigation of the (001) surfaces of the Parent and Co-doped BaFe$_2$As$_2$\textsuperscript{1}, S. H. PAN, A. LI, D. R. JAYASUNDARA, Y. XUAN, J. P. O’NEAL, University of Houston, Houston, Texas 77204-5002, R. JIN, E. W. PLUMMER, Louisiana State University, Baton Rouge, LA 70803-4001, R. JIN, A. S. SEFAT, M. A. MCGUIRE, B. C. SALES, D. MANDRUS, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — We have used a UHV Low Temperature STM to study the surface structure of the parent and the Co-doped BaFe$_2$As$_2$ single crystals. Various STM images with different structural symmetry were observed. The dominant apparent surface structure is ($\sqrt{2}$x$\sqrt{2}$)R45° for the parent compound and 1 x 2 stripe-like for the Co-doped ones. We will compare the different surface structures and discuss the identification of the atomic plane exposure and the possible origins for such variety in surface structure.

4:30PM D35.00007 Electronic Structure on (001) Surface of BaFe$_2$As$_2$ Parent Compound Studied with Scanning Tunneling Spectroscopy\textsuperscript{1}, D. R. JAYASUNDARA, A. LI, Y. XUAN, J. P. O’NEAL, S. H. PAN, University of Houston, Houston, Texas 77204-5002, R. JIN, E. W. PLUMMER, Louisiana State University, Baton Rouge, LA 70803-4001, R. JIN, A. S. SEFAT, M. A. MCGUIRE, B. C. SALES, D. MANDRUS, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Doping can drive some metallic pnictide compounds to a magnetic/structural phase transition that is observed for undoped BaFe$_2$As$_2$ at 134 K appears to split into two distinct phase transitions, both of which are rapidly suppressed with increasing Co concentration. Superconductivity emerges for Co concentrations above $x > 0.025$, and appears to coexist with the broken symmetry state up to $x \sim 0.06$. The optimal $T_c$ appears to coincide with the Co concentration at which the magnetic/structural phase transitions are totally suppressed. Superconductivity is observed for a further range of Co concentrations, before being completely suppressed for $x \sim 0.18$ and above. The form of this $x-2\theta$ phase diagram is suggestive of an association between superconductivity and a quantum critical point arising from suppression of the magnetic and/or structural phase transitions.

4:42PM D35.00008 Structural Investigation of the BaFe$_{2-x}$As$_2$(001) Surface Using LEED and STM\textsuperscript{1}, VON BRAUN NASCIMENTO, X.B. HE, R. JIN, E.W. PLUMMER, Louisiana State University, Baton Rouge, LA, T.Y. CHIEN, BIAO HU, GUORONG LI, University of Illinois, Knoxville, TN, M.H. PAN, J.F. WENDELKEN, A.S. SEFAT, M.A. MCGUIRE, B.C. SÀLES, D. MANDRUS, Oak Ridge National Laboratory, Oak Ridge, TN, ANG LI, DILUSHAN R. JAYASUNDARA, YI XUAN, JARED O’NEAL, SHUHENG PAN, University of Houston, Houston, TX BaFe$_2$As$_2$, a parent compound to one of the newly discovered high-$T_c$ superconductors, presents very interesting physical properties such as a structural transition occurring prior to the formation of a spin density wave. It is surely of interest to investigate the effect of breaking the symmetry by creating a surface. Single crystals of BaFe$_2$As$_2$ were cleaved in vacuum exposing a (001) surface. Quantitative LEED I-V measurements and low-temperature STM topography revealed an ordered As surface with disordered Ba atoms present. LEED shows a clear (1 x 1) periodicity with a surface structure slightly different than the bulk. STM reveals a weak C(2 x 2) periodicity. We will explore the possibility that the C(2x2) STM image is electronic in origin.

\textsuperscript{1}Supported in part by Division of Materials Sciences and Engineering, DOE, EWP, GL, & TYC have also received support from NSF and DOE (DMS&E) (NSF-DMR-0451163).
4:54PM D35.00009 Temperature and Spatial Dependence of the Superconducting and Pseudogap of NdFeAsO$_{0.8}$F$_{0.14}$, X.B. HE, Louisiana State University, Baton Rouge, LA, M.H. PAN, Oak Ridge National Laboratory, Oak Ridge, TN 37831, G.R. LI, University Of Tennessee, Knoxville, TN 37996, J.F. WENDELKEN, Oak Ridge National Laboratory, Oak Ridge, TN 37831, R.Y. JIN, Louisiana State University, Baton Rouge, LA 70803, A.S. SEFAT, M.A. MCGUIRE, B.C. SALES, D. MANDRUS, Oak Ridge National Laboratory, Oak Ridge, TN 37831, E.W. PLUMMER, Louisiana State University, Baton Rouge, LA 70803 — Scanning tunneling microscopy/spectroscopy are used to investigate the superconducting gap and pseudogap of Fe based high-Tc superconducting material NdFeAsO$_{0.8}$F$_{0.14}$ at various temperatures from 17 K to 150 K. The superconducting gap (SG) in the tunneling spectra follows the BCS prediction and closes at Tc of the bulk material. Surprisingly, a pseudogap (PG) opens abruptly just above Tc and closes at 120 K, strongly suggesting that the SG and PG states have competing order parameters in contrast to the cuprates. The PG state may be related to spin fluctuations in the doped materials. Research was supported in part at ORNL by Laboratory Directed Research and Development funds and by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, US DOE.

5:06PM D35.00010 Scanning Tunneling Spectroscopy and Vortex Imaging in the Iron-Pnictide Superconductor BaFe$_{1.8}$Co$_{0.2}$As$_2$, YI YIN, M. ZECH, T.L. WILLIAMS, Harvard University, X.F. WANG, G. WU, X.H. CHEN, University of Science and Technology of China, J.E. HOFFMAN, Harvard University — We present an atomic resolution scanning tunneling spectroscopy study of superconducting BaFe$_{1.8}$Co$_{0.2}$As$_2$ single crystals in magnetic fields up to 9 Tesla. At zero field, a single gap with coherence peaks at 2Δ = 6.25 meV is observed in the density of states. At 9 T and 6 T, we image a disordered vortex lattice, consistent with isotropic, single flux quantum vortices. Vortex locations are uncorrelated with strong scattering surface impurities, demonstrating bulk pinning. The vortex-induced sub-gap density of states fits an exponential decay from the vortex center, from which we extract a coherence length ξ = 27.6 ± 2.9 Å, corresponding to an upper critical field Hc2 = 43 T.

5:18PM D35.00011 STM measurements on iron pnictides, ZHANYBEK ALPICHSHEV, Stanford — Some results of scanning tunneling microscopy/spectroscopy of cobalt doped pnictides at different doping levels are presented.

Monday, March 16, 2009 2:30PM - 5:30PM –
Session D36 DCMP: Carbon Nanotubes: Low Temperature Electronic Properties

2:30PM D36.00001 Non-equilibrium tunneling spectroscopy in carbon nanotubes, NADYA MASON, YUNG-FU CHEN, TRAVIS DIRKS, University of Illinois at Urbana-Champaign, GASSEME AL-ZOUBI, NORMAN BIRGE, Michigan State University — We report measurements of the non-equilibrium electron energy distributions in carbon nanotubes. Carbon nanotubes can be considered model one-dimensional systems whose transport is strongly affected by electron interactions. Using tunneling spectroscopy via a superconducting probe, we have studied electron energy distribution functions, and hence inelastic electron scattering, in nanotubes that have bias voltages applied between their ends. We find that at low temperatures, electrons interact weakly in nanotubes of a few microns channel length, independent of end-to-end conductance values. Surprisingly, the energy relaxation rate can increase substantially when the temperature is raised to only 1.5 K. In general, tunneling spectroscopy with a superconducting probe may be a powerful new tool for characterizing electron behavior in carbon nanotubes.

2:42PM D36.00002 Method for determining the conductance tensor of quantum junctions from the ground state alone, ARMIN RAHMANI, CHANG-YU HOU, CLAUDIO CHAMON, Boston University, IAN AFFLECK, University of British Columbia — Conductance is related to dynamical correlation functions and is considered a non-equilibrium quantity. Here we propose a method to obtain the small-bias low-temperature conductance tensors of quantum junctions through equilibrium calculations such as time-independent DMRG. Using the dependence of a finite system ground state energy on the boundary conditions, we determine the junction conductance by finding the S-matrix. The method is applicable to interacting junctions connected to an arbitrary number of non-interacting leads.

2DOE Grant DE-FG02-06ER46316

2:54PM D36.00003 Transition from the Sequential to the Resonant Tunneling in a Dissipative Environment, YURIY BOMZE, HENOK MEBRAHTU, IVAN BORZENETS, ALEX MAKAROVSKI, GLEB FINKELSTEIN, Duke University — We study the shape of the single-electron conductance peaks in a quantum dot coupled to a dissipative environment. In the regime of sequential tunneling through a single quantum level, the peak height increases as the temperature is lowered, although due to the dissipative environment it scales slower than the conventional 1/T. As the temperature is lowered further into the resonant tunneling regime, the peak width approaches saturation, while the peak height starts to decrease. To our knowledge, the non-monotonic peak height dependence on temperature is experimentally observed for the first time. We associate this behavior with coherent tunneling through a single quantum level in the presence of dissipative environment.

3:06PM D36.00004 Possible electric-field induced one dimensional excitonic insulators in carbon nanotubes pairs, JAY SAU, University of California Berkeley and MSD Lawrence Berkeley National Laboratory, MARVIN COHEN, University of California, Berkeley and MSD, Lawrence Berkeley National Laboratory — Recently there has been significant interest in the possibility of realizing excitonic insulator states in semiconducting systems in electric fields. Using a tight-binding formulation of the GW and Bethe-Salpeter methods parametrized from first-principles density functional theory calculations, we show that an electric field strength of 0.06 eV/A fails to close the quasiparticle gap of the system but closes the excitonic gap. This can cause a phase transition of the system into an excitonic phase where the ground state is populated with a quasi-one dimensional repulsive gas of excitons. Such a state provides a realization of a one-dimensional excitonic insulator phase with a spin degree of freedom which can lead to novel phases. We discuss some of the properties of the resulting excitonic phase and the transition and also discuss how similar properties may be observed in experiments on nanotube bundles.

3This work was supported by NSF Grant No. DMR07-05941 and by the Director, Office of Science, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources have been
3:18PM D36.00005 A recursion formula for the local density of states in finite Luttinger liquids1, SEBASTIAN EGGERT, IMKE SCHNEIDER, Univ. of Kaiserslautern, Germany — The local density of states (LDOS) in quantum wires is one of the most central quantities for the experimental verification of the predictions from Luttinger Liquid theory. By now, it has been well understood how boundaries lead to a crossover of powerlaws in the LDOS as a function of position and energy. It is also possible to calculate the LDOS for individual levels in finite wires analytically and numerically. However, the connection from finite wavefunctions to a semi-infinite powerlaw description remains unclear. We now present a simple recursion formula that ties together both limits and even allows to express the crossover of powerlaws in a closed analytic form in terms of hypergeometric functions. With the help of the formula it is now also possible to calculate the LDOS of long range interacting systems explicitly.

3:30PM D36.00006 Superconducting Tunneling Spectroscopy of a Carbon Nanotube Quantum Dot1, TRAVIS DIRKS, YUNG-FU CHEN, NADYA MASON, Department of Physics and Materials Research Laboratory, University of Illinois, NORMAN DIRGE, Department of Physics and Astronomy, Michigan State University. We report results on tunneling spectroscopy of a carbon nanotube quantum dot. Using a three-probe technique that includes a superconducting tunnel probe, we map out changes in conductance due to band structure, excited states, and applied bias. We also see features due to the unique nature of the superconducting probe, including enhancement of weak tunneling processes. In addition, we see conduction inside the superconducting gap when an end to end bias is applied, which suggests some inelastic, possibly assisted, tunneling process inside the quantum dot.

3:42PM D36.00007 ABSTRACT WITHDRAWN —

3:54PM D36.00008 A DMRG approach to impurities and interactions in carbon nanotubes, ALEXANDER STRUCK, University of Kaiserslautern, SEBASTIAN REYES, University of Kaiserslautern and Pontificia Universidad Catolica de Chile, SEBASTIAN EGGERT, University of Kaiserslautern — Carbon nanotubes (CNTs) are well suited to study strong electronic correlations in quasi-one-dimensional systems experimentally and theoretically. Of particular interest is the interplay of interactions between the conducting electrons and impurities in the nanotube. Impurities include the boundaries of short tubes as well as structural imperfections such as the Stone-Wales lattice distortion. Interactions can lead to different phases of the electron liquid, depending on their range and strength, and can produce quasi-localized ground states of e.g. the Mott insulator type or a charge density wave. Here we discuss a systematic approach using the density-matrix renormalization group (DMRG) method to treat a recently derived lattice model for a single-wall armchair CNT with short-range interactions and a Stone-Wales impurity. We show interaction driven modifications to the expected density patterns that can lead to anomalous Friedel oscillations around the impurity.

4:06PM D36.00009 Zero-bias anomalies in multi-section carbon nanotube FETs1, YANFEI YANG, GEORGY FEDOROV, Department of Physics, Georgetown University, SERHII SHAFRANIUK, Department of Physics and Astronomy, Northwestern University, RUPERT LEWIS, BENJAMIN COOPER, CHRISTOPHER LOBB, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, PAOLA BARBARA, Department of Physics, Georgetown University — Carbon nanotube field effect transistors (CNFETs) with high transparency contacts show maxima of differential conductance at zero bias voltage [1]. These zero-bias anomalies (ZBAs) occur at large negative gate voltages and in narrow gate voltage ranges (about 1 V wide). Our proposed explanation is superconductivity in the nanotubes, occurring when the gate voltage shifts the Fermi energy into van Hove singularities of the electronic density of states. Here we probe this scenario using 3 FETs fabricated from different sections of one semiconducting carbon nanotube. Source and drain electrodes were patterned by e-beam lithography to achieve FET lengths of 500 nm, 1500 nm and 7000 nm, respectively. All devices showed high transparency contacts to their Pd electrodes. We report the observation of pronounced ZBAs in the multi-section CNFETs, their magnetic field (up to 7 T) and temperature evolution, and the modulation on the ZBAs by Fabry-Perot oscillation. [1] J. Zhang et al., Zero-bias anomaly and possible superconductivity in single-walled carbon nanotubes, Phys. Rev. B, 74, 155414 (2006).

4:18PM D36.00010 Interacting resonant level side-coupled to a Luttinger liquid: Duality to resonant tunneling, MOSHE GOLDSTEIN, RICHARD BERKOVITS, The Minerva Center, Department of Physics, Bar-Ilan University, Ramat-Gan 52900, Israel. — We study a model of a single level quantum dot side-coupled to a Luttinger liquid wire by both hopping and interactions. By canonical transformations and a Coulomb gas mapping, we prove a duality between this problem and that of resonant tunneling through a level connecting the edges of two wires with the inverse Luttinger liquid parameter $g$. The two systems thus have complementary transport properties: when one is conducting the other is insulating, and vice-versa. Using this result, as well as an exact solution at $g = 2$ and Monte-Carlo simulations on the Coulomb gas, we fully characterize the system's conductance. It exhibits an anti-resonance as a function of the level energy, whose width vanishes (enhancing transport) as a power law at low temperatures and bias voltages for $g > 1$, while diverging (suppressing transport) for $g < 1$. Level population is shown to be either a linear, a power law, or a discontinuous function of a small level energy, depending on the parameters.

4:30PM D36.00011 Wigner crystal vs. Friedel oscillations in the 1D Hubbard model1, STEFAN SOEFFING, Univ. of Kaiserslautern, Germany, MICHAEL BORTZ, Univ of Kaiserslautern, Germany, SEBASTIAN EGGERT, Univ. of Kaiserslautern, Germany — We investigate the ground state density distribution of the Hubbard model in a finite one-dimensional wire. For weak interactions we find the expected Friedel oscillations, but for low filling a distinct Wigner crystal state can be observed. Although there cannot be a phase transition in a 1D system we observe a well-defined crossover into a Wigner crystal region with different physical behavior even for relatively weak short range interactions. The combination of Luttinger liquid theory and numerical Density Matrix Renormalization Group (DMRG) calculations allows a quantitative analysis of the crossover as a function of system length, lattice filling, and interaction strength.

4:42PM D36.00012 Mott Insulating State in Ultra-clean Carbon Nanotubes, VIKRAM DESHPANDE, Caltech, BHUPESH CHANDRA, ROBERT CALDWELL, Columbia University, DMITRY NOVIKOV, Yale University, JAMES HONE, Columbia University, MARC BOCKRATH, Caltech — The Mott insulating state is a manifestation of strong electron interactions in nominally metallic systems. Using transport spectroscopy, we show that an energy gap exists in nominally metallic carbon nanotubes, and occurs in addition to the band-gap in small-band-gap nanotubes, indicating that carbon nanotubes are never metallic. This gap has a magnitude ~10-100 meV and nanotube radius dependence ~1/r, in good agreement with predictions for a nanotube Mott insulating state. We also observe neutral excitations within the gap, as predicted for this state. Our results underscore nanotubes’ exceptional capabilities for studying correlated electron phenomena in 1D.

4:54PM D36.00013 Superconductivity in thin films of boron-doped carbon nanotubes, J. HARUYAMA, N. MURATA, Aoyama Gakuin Univ., J. REPPERT, A. RAO, Clemson Univ., T. KORETSUNE, S. SAITO, Tokyo Institute of Technology — It is well known that the small mass of carbon can promote high transition temperature (T_c) in BCS-type superconductivity (SC). Recently, new carbon-based superconductors with order of T_c of ~10K [1, 2] were discovered and higher T_c has been expected. In particular, the SC in a carbon nanotube (CNT) is attracting considerable attention [3]. We reported that entirely end-bonded multi-walled CNTs could show SC with T_c = 12K, previously [4]. In contrast, it had problem in reproducibility, because correlation with carrier doping was not clarified. Moreover, none has succeeded substitutional carrier doping into CNTs and also revealed the correlation with SC. Here, we report on the Meissner effect found in thin films consisting of assembled boron-doped single-walled CNTs [5]. We reveal that only highly homogeneous CNT films consisting of low boron concentration leads to evident Meissner effect with T_c = 12 K. The first-principles electronic-structure study of the B-SWNT strongly supports these results. [1] T. E. Weller et al., Nature Physics 1, 39 (2005), [2] E. A. Ekimov et al., Nature 428, 542 (2004), [3] M. Kociak et al., Phys. Rev. Lett. 86, 2416 (2001), [4] I. Takesue, J.Haruyama, et al., Phys. Rev. Lett. 96, 057001(2006), [5] N.Murata, J.Haruyama, et al., Phys.Rev.Lett. 101, 027002 (2008)

5:06PM D36.00014 Fabrication and transport properties of size tunable single-walled carbon nanotube quantum dots, PAUL STOKES, YODCHAY JOMPOL, SAIFUL I. KHONDAKER, University of Central Florida, Nanoscience Technology Center and Dept of Physics — Single electron transistors (SETs) have attracted considerable attention because of their potential as a building block for quantum based nanoelectronic devices. However fabrication of reproducible and controllable quantum dot sizes that can operate at high temperature is challenging. We developed a novel technique for the fabrication of size tunable and controllable quantum dot using single-walled carbon nanotube (SWNT) [1]. Our technique is based on the formation of two tunnel barriers of controllable separation by naturally bending SWNT at the edges of a raised local gate. A SWNT is placed on a local Al/Al2O3 bottom gate of width L, and then contacted with Pd source and drain electrodes of 1 μm separation on Si/SiO2 substrates. The Al gate serves three purposes: (i) it acts as a “mechanical template” to define two tunnel barriers at the edges by naturally bending the nanotube due to van der Walls interactions with the substrate, (ii) the width of the gate defines the size (L) of the quantum dot, and (iii) it acts as a local bottom gate to control the operation of the SET device. Using this approach we fabricated SETs of different sizes down to 50 nm. We present detailed fabrication procedures and low temperature transport studies of these SET devices. [1] P. Stokes and S. I. Khondaker, APL 92, 262107 (2008)

5:18PM D36.00015 Conductance of a Conjugated Molecule with Carbon Nanotube Contacts, NOLAS BRUQUE, University of California, Riverside, KHALID ASHRAF, THOMAS HELANDER, ROGER LAKE — Quantitative predictions of the energy levels is a well-known weakness of density functional theory (DFT). To understand the HOMO level alignment of a π-cruciform molecule [1] with the Fermi level of a carbon nanotube (CNT) contact, we have performed quantum chemical calculations of the adiabatic ionization potential (IP) of the central molecule. The adiabatic IP of the molecule is -5.86 eV. The image charge potential, calculated using our fully self-consistent DFT - Recursive Green Function (RGF) approach, is 0.7 eV. Treating the image potential as a self-energy correction to the IP, the HOMO energy level is at -5.16 eV which is comparable to the intrinsic CNT Fermi level at -5 eV. The above considerations of the energy level alignments, combined with the DFT-RGF analysis of the molecular orbitals and transmission spectrum, indicate that the HOMO resonance lies within the 50 meV energy window created by the experimental source-drain bias. This appears to be the most likely scenario that would give rise to the relatively small resistance of 6 MΩ. 1. X. Guo, et. al. Science, 311, 356 (2006).

Session D37 DCP: Focus Session: Fundamental Developments in Density Functional Theory

2:30PM D37.00001 Bounds on the correlation energy of Coulomb interacting systems: How negative does E_c get, and what does this imply for approximate density functionals, KLAUS CAPELLE, University of Sao Paulo, Brazil — The indirect part of the Coulomb interaction energy of a three-dimensional many-fermion system has a lower bound in terms of a power of the particle density, known as the Lieb-Oxford bound. This bound can be reformulated as a bound on the correlation energy, and in this reformulated version is an ingredient in the construction of many modern density functionals. In this talk, I describe several recent investigations and refinements of this bound: (i) an empirical analysis strongly suggesting that the bound can be tightened without losing its universality [collaboration: Mariana Odashima], (ii) the construction of a particle-number dependent version of the bound and an exploration of its consequences for PBE GGA [collaboration: Mariana Odashima and Sam Trickey], (iii) a simplified scaling derivation of the power law in the bound, and its application to construct similar bounds also for one- and two-dimensional systems [collaborators: César Proetto, Esa Räsänen and Stefano Pittalis], and (iv) a connection between the Lieb-Oxford bound and common hybrid functionals, providing an alternative rationale for why these functionals work, as well as a possible route for the construction of improved beyond-GGA functionals [collaborator: Mariana Odashima].

1Supported in part by grants from FAPESP and CNPq.
3:06PM D37.00002 Van der Waals Interactions in Density-Functional Theory. AXEL BECKE, Dalhousie University — The application of conventional GGA, and meta-GGA, density functionals to van der Waals complexes is fraught with difficulties. Conventional functionals do not contain the physics of the dispersion interaction. To make matters worse, the exchange part alone can yield anything from severe over-binding to severe over-repulsion depending on the choice of functional. We rectify these problems by - adding a dispersion term with nonempirical C6, C8, and C10 dispersion coefficients (the Becke-Johnson dispersion model), and - selecting a GGA exchange functional (PW86, also nonempirical) that gives excellent agreement with exact Hartree-Fock repulsion curves. The result is a simple GGA+dispersion theory giving excellent noble-gas pair interaction energies for He through Kr with only two adjustable parameters in the dispersion cutoff.

3:42PM D37.00003 Van der Waals interactions in density functional theory1, DAVID C. LANGRETH, Rutgers University — The van der Waals density functional which we introduced half a decade ago1, and its self-consistent generalization2 will be briefly reviewed. There are many collaborators in the application review that will follow, not only those who worked in the physics department at Rutgers1, but also at Denmark Technical University3, the chemistry department at Rutgers3, and most recently at the University of Texas at Dallas4. I will expand on our recent review article5 which hopefully will be published before the present talk, and include applications by other groups not listed below. If possible, I will also review results from a more recent collaboration to study nucleosomal DNA and beyond.

4:18PM D37.00004 Accurate van-der-Waals interactions from (semi)-local density functional theory , ALEXANDRE TKATCHENKO, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, Germany — Non-covalent forces, such as hydrogen bonding and van der Waals (vdW) interactions, are crucial for the formation, stability and function of molecules and materials. At present, vdW interactions can only be satisfactorily accounted for by high-level quantum-chemical wave function or by the Quantum Monte Carlo (QMC) method. In contrast, (semi)-local DFT and Hartree-Fock approximation fail for the description of vdW forces. We present a parameter-free method for describing the long-range vdW interaction in (semi)-local DFT. The leading C6 coefficients are derived from the electron density of a molecule/solid and accurate reference values for the free atoms. The mean absolute error in the C6 coefficients is 5.5% when compared to accurate experimental values for 1225 intermolecular pairs. We show that the C6 coefficients depend strongly on the bonding type and geometry of molecules/solids. Finally, we analyze the vdW radii and the damping function in the C6R−6 correction method for DFT calculations.

4:30PM D37.00005 Efficient van der Waals density functional interactions1, JOSE M. SOLER, GUILLERMO ROMAN-PEREZ, Univ. Autonoma de Madrid — The LDA and GGA functionals are the non empirical methods of choice for large system calculations, but they cannot describe nonlocal dispersion forces. This limits severely their application to many systems of large interest like molecular solids and liquids, physisorbed molecules, and interactions between biological molecules. Several schemes have been proposed to add ad-hoc atom-atom or atom-electron potentials. But dispersion is an electron-electron correlation effect, that must be described by an appropriate density functional, such as that proposed by Dion et al (PRL 92, 246401 (2004)). It is a true universal and general-purpose DFT functional that describes semiquantitatively the week dispersion interactions, without compromising the accuracy of the best GGA functionals for stronger bonds. Its direct evaluation for large molecular systems is very expensive, however, because it requires a double integral in real space. We present a new implementation that avoids this N2 scaling by applying a density-2D convolution technique to an accurately interpolated kernel. The resulting method scales as N log N and it allows to perform vdW-DFT simulations of essentially any system that can be simulated with GGA.

4:42PM D37.00006 The discontinuous nature of the exchange-correlation functional — critical for strongly correlated systems, PAULA MORI-SANCHEZ, ARON COHEN, WEITAO YANG, Duke University — Standard approximations for the exchange-correlation functional have been found to give big errors for the linearity condition of fractional charges, leading to delocalization error, and the constancy condition of fractional spin, leading to static correlation error. These two conditions are now unified for states with both fractional charge and fractional spin: the exact energy functional is a plane, linear along the fractional charge coordinate and constant along the fractional spin coordinate with a line of discontinuity at the integer. This sheds light on the nature of the derivative discontinuity and calls for explicitly discontinuous functionals of the density or orbitals that go beyond currently used smooth approximations. This is key to understand the physics of strongly correlated systems within DFT, for example the band-gap of Mott insulators. [arXiv:0809.5108]

4:54PM D37.00007 Advances in Local Hybrid Functionals, ALEKSEY ARBUZNIKOV, MARTIN KAUPP, HILKE BAHMANN. University of Wuerzburg — Local hybrids provide a promising new generation of exchange-correlation functionals for the simultaneous accurate description of various properties (atomization energies, reaction barrier heights, INMR chemical shifts, energetics of transition-metal systems, etc.) Compared to traditional (global) hybrids (e.g., B3LYP), instead of a constant exact-exchange admixture, local hybrids employ a position-dependent one. The latter is governed by a so-called local mixing function (LMF), and this is the crucial quantity controlling the performance of local hybrids. Here we present and compare new results obtained with LMFs derived both in a semiempirical way and using ab initio considerations, e.g., the adiabatic local correlation formalism. The former approach yields better results, while the latter brings valuable insights into the performance and limits of local hybrids.

5:06PM D37.00008 Calculation of functional derivatives with respect to the external potential, NICK SABLON, TIM FIEVEZ, FRANK DE PROFT, PAUL W. AYERS, PAUL GEERLINGS, Vrije Universiteit Brussel — Apart from its many computational advantages, density functional theory (DFT) presents a conceptual framework for the reactivity and stability interpretation of chemical systems. The central idea is to identify chemical concepts with first and higher order (functional) derivatives of the electronic energy with respect to the number of electrons N and the external potential \( v(r) \). The local interpretation of chemical reactivity is generally given in an exact theory. Practical DFT calculations make however use of approximate exchange-correlation functionals for which the DFT concepts can only correctly be obtained by an effective evaluation of the electronic derivatives. A recent methodology for the calculation of functional derivatives with respect to \( v(r) \) is presented. Results are shown for a wide range of molecules among which substituted benzenes. A reactivity description of the alkaline earth oxides’ (100) surface is expounded on as well.

5:18PM D37.00009 Simple Illustration of Partition Theory, ADAM WASSERMAN, Department of Chemistry - Purdue University, MORREL COHEN, Department of Physics - Rutgers University, and Department of Chemistry - Princeton University, KIERON BURKE, Department of Chemistry - UC-Irvine, ROBERTO CAR, Department of Chemistry - Princeton University — In Partition Theory (PT) \cite{Wasser2007} the density of a system is decomposed exactly into a superposition of the densities of its parts through the introduction of a common partition potential acting on each of the parts as if they were isolated. In this talk we illustrate PT on a simple one-dimensional model of a heteronuclear diatomic molecule. We show that a sharp definition for the charge of the fragments emerges from PT, and that the ensuing population analysis can be used to study how charge redistributes during dissociation. By studying the preservation of the shapes of the parts as different parameters of the model are varied, we address the issue of transferability of the parts. We find good transferability within the chemically meaningful parameter regime, raising hopes that PT will prove useful in chemical applications.

2:30PM D38.00001 Exciton migration and fluorescence quenching in photosystem II, LEONAS VALKUNAS, Institute of Physics, Savanoriu 231, 02300 Vilnius and Theoretical Physics Chair, Vilnius University, Sauletekio 9, build. 3, 10222 Vilnius, Lithuania — When exposed to excess light illumination photosynthetic organisms switch into a photoprotective quenched state where the excess energy is safely dissipated as heat. It was recently discovered that the main light-harvesting complex of plants, LHCII, plays a key role in the dissipation of excess energy. Here we demonstrate that the excitation kinetics in the quenched state can be described by a simple model, which assumes specific trapping centers to be present in the system \cite{Holt2007}. In order to explain the experimental results exciton-exciton annihilation is taken into account. To verify the effectiveness of the non-photochemical quenching center, possessing a short lifetime, in preventing the excess excitations from reaching the reaction center, the studies of the excitation quenching depending on positioning and origin of the quencher in the antenna complexes are also considered.

3:06PM D38.00002 Environment-assisted quantum transport in photosynthetic complexes, ALAN ASPURU-GUZIK, Harvard University — Transport phenomena at the nanoscale are of interest due to the presence of both quantum and classical behavior. In this work, we demonstrate that quantum transport efficiency can be enhanced by a dynamical interplay of the system Hamiltonian with the pure dephasing dynamics induced by a fluctuating environment. This is in contrast to fully coherent hopping that leads to localization in disordered systems, and to highly incoherent transfer that is eventually suppressed by the quantum Zeno effect. We study these phenomena in the Fenna-Matthews-Olson protein complex as a prototype for larger photosynthetic energy transfer systems. We also show that disordered binary tree structures exhibit enhanced transport in the presence of dephasing. We address the question of the role of quantum coherence in the energy transfer in the FMO complex and discuss details about the theoretical modeling of photosynthetic complexes and organic photovoltaic materials.

3:42PM D38.00003 Engineering Efficient Exciton Energy Transfer in Artificial Arrays, LESLIE VOGT, ALEJANDRO PERDOMO, SEMION SAIKIN, ALAN ASPURU-GUZIK, Harvard University — A critical component of light harvesting devices is efficient transfer of excitonic energy. Biological systems have optimized this process over time for the particular molecular components involved. Understanding this energy transfer in model arrays will allow us to engineer new materials for solar cell technology. In particular, we explore a perturbative approach to optimize both coherent and incoherent transport in small arrays. By following the evolving coherences and populations over time using a density matrix formalism, we gain an intuition about the importance of coherent processes in exciton transfer in natural and designed light harvesting systems.

3:54PM D38.00004 Coherent Excitonic Transfer in the Fenna Matthews Olson Complex, GREGORY ENGEL, The University of Chicago — Evidence for a purely quantum mechanical mechanism of energy transfer in photosynthetic complexes was discovered in the Fenna-Matthews-Olson complex of Chlorobium tepidum in 2007. The quantum beating phenomenon observed in this complex is now much better understood. Specifically, detailed, testable microscopic models for the mechanism of this energy transfer have emerged, and precise quantum dynamical models now predict that this mechanism accounts for approximately one quarter of the energy transferred at room temperature. Further, new data indicate that this mechanism is not specific to FMO, but manifests in reaction centers of purple bacteria and antenna complexes of higher plants. A new experimental effort to observe quantum coherence at room temperature will be discussed. Specifically, by comparing population transfer rates and coherence transfer quantum beating signals, we calculate the fraction of the energy moving through the wave-like mechanism. Further, by studying the temperature dependence of the energy transfer, we elucidate the microscopic mechanism for wavelike energy transfer and be able to comment on the robustness of the mechanism. Are light harvesting proteins delicately “tuned” by evolution to support coherence transfer or should any proteinaceous environment support this mechanism? Details of the experimental apparatus, results and future experiments will be presented.

4:06PM D38.00005 Excitation transport in open quantum systems: the role of environmental correlations, MOHAN SAROVAR, YUAN-CHUNG CHENG, BIRGITTA WHALEY, University of California, Berkeley — The recent discovery of quantum coherent phenomena in photosynthetic complexes \cite{Engel2007a} has prompted several studies into the efficiency of transport processes in open quantum systems. Several of these studies have revealed a subtle interplay between coherent and decohered dynamics in the overall efficiency of transport in these open systems. Some have shown that decoherence can improve efficiency. However all studies have used simple uncorrelated models of decoherence that are not accurate for photosynthetic complex environments, which are known to be spatially and temporally correlated. In this work we investigate the role of environmental correlations in quantum transport in open systems and show that the exact nature of the correlations can have a large impact on the efficiency of energy harvesting. We illustrate our results using the Fenna-Matthews-Olson photosynthetic complex.
fluctuations in oscillatory activities significantly. Then study the extended repressilator system to investigate the effect of extra component and identify the combinatoric regulation pattern that reduces the fluctuations.

We will show how the details of the stochastic process can be characterized by a few effective parameters, which facilitates modeling but complicates interpretation of current experiments. I will show how the resulting noise can provide advantageous or deleterious phenotypic fluctuation and how noise control in the copy number control system of plasmin can change the selective pressures. This system illustrates the direct connection between molecular dynamics and evolutionary dynamics.

APAM, C2B2 — Modeling the dynamics of biological networks while respecting the intrinsic stochasticity requires accounting for intrinsic fluctuations arising from the low copy count of the constituent particles. Traditional simulation-based approaches to computing the probability distribution, rather than by directly solving for the distribution using a fast and accurate method that exploits the natural basis of the uncoupled problem from the same class. We illustrate our method on a ubiquitous biological example: linear signaling cascades. The huge efficiency gains permit optimization of information transmission over input and regulatory parameters, revealing design properties of the most informative cascades. We find, for threshold regulation, that a cascade of strong regulations converts a unimodal input to a bimodal output, that multimodal inputs are no more informative than bimodal inputs, and that a chain of DC up-regulations outperforms a chain of AC down-regulations.

Session D39 DBP GSNP: Focus Session: Noise and Fluctuations in Biochemical Networks

Monday, March 16, 2009 2:30PM - 5:18PM

2:30PM D39.00001 Stochasticity in cell biology: Modeling across levels. JUAN MANUEL PEDRAZA, Harvard University. Effective modeling of biological processes requires focusing on a particular level of description, and this requires summarizing de details of lower levels into effective variables and properly accounting for the constraints that other levels impose. In the context of stochasticity in gene expression, I will show how the details of the stochastic process can be characterized by a few effective parameters, which facilitates modeling but complicates interpretation of current experiments. I will show how the resulting noise can provide advantageous or deleterious phenotypic fluctuation and how noise control in the copy number control system of plasmin can change the selective pressures. This system illustrates the direct connection between molecular dynamics and evolutionary dynamics.

2:33PM D39.00002 Mean-field vs. Stochastic Models for Transcriptional Regulation. RALF BLOSSEY, CLAUDIU GIURANIUC, CNRS, BIOLOGICAL NANOSYSTEMS TEAM. We introduce a minimal model description for the dynamics of transcriptional regulatory networks. It is studied within a mean-field approximation, i.e., by deterministic ode's representing the reaction kinetics, and by stochastic simulations employing the Gillespie algorithm. We elucidate the different results both approaches can deliver, depending on the network under study, and in particular depending on the level of detail retained in the respective description. Two examples are addressed in detail: the repressor, a transcriptional clock based on a three-gene network realized experimentally in E. coli, and a bistable two-gene circuit under external driving, a transcriptional network motif recently proposed to play a role in cellular development.

2:36PM D39.00003 The stochastic spectral analysis of transcriptional regulatory cascades. ANDREW MUGLER, Columbia University, Physics, ALEKSANDRA M. WALCZAK, Princeton University, PCTS, CHRIS H. WIGGINS, Columbia University, APAM, C2B2. Modeling the dynamics of biological networks while respecting the intrinsic stochasticity requires accounting for intrinsic fluctuations arising from the low copy count of the constituent particles. Traditional simulation-based approaches to computing the probability distribution, rather than by directly solving for the distribution using a fast and accurate method that exploits the natural basis of the uncoupled problem from the same class. We illustrate our method on a ubiquitous biological example: linear signaling cascades. The huge efficiency gains permit optimization of information transmission over input and regulatory parameters, revealing design properties of the most informative cascades. We find, for threshold regulation, that a cascade of strong regulations converts a unimodal input to a bimodal output, that multimodal inputs are no more informative than bimodal inputs, and that a chain of DC up-regulations outperforms a chain of AC down-regulations.

2:39PM D39.00004 Tuning stochastic transition rates in a bistable genetic network. VIJAY CHICKKARNE, California Institute of Technology, CARSTEN PETERSON, Lund University, Sweden. We investigate the stochastic dynamics of a simple genetic network, a toggle switch, in which the system makes transitions between the two alternative states. Our interest is in exploring whether such stochastic transitions, which occur due to the intrinsic noise such as transcriptional and degradation events, can be slowed down/speeded up, without changing the mean expression levels of the two genes, which comprise the toggle network. Such tuning is achieved by linking a signaling network to the toggle switch. The signaling network comprises of a protein, which can exist in either an active (phosphorylated) or inactive (dephosphorylated) form, and where its state is determined by one of the genetic network components: the active form of the protein in turn feeds back on the dynamics of the genetic network. We find that the rate of stochastic transitions from one state to the other, is determined essentially by the speed of phosphorylation, and hence the rate can be modulated by varying the phosphatase levels. We hypothesize that such a network architecture can be implemented as a general mechanism for controlling transition rates and discuss applications in population studies of two differentiated cell lineages, ex: the myeloid/erythroid lineage in hematopoiesis.

2:42PM D39.00005 Optimizing information flow in small genetic networks. ALEKSANDRA M. WALCZAK, Princeton University, GASPER TKACIK, University of Pennsylvania, CURTIS G. CALLAN, WILLIAM BIALEK, Princeton University. Many of the biological networks inside cells can be thought of as transmitting information from the inputs (e.g., the concentrations of transcription factors or other signaling molecules) to their outputs (e.g., the expression levels of various genes). On the molecular level, the relatively small concentrations of the relevant molecules and the intrinsic randomness of chemical reactions provide sources of noise that set physical limits on this information transmission. Given these limits, not all networks perform equally well, and maximizing information transmission provides a candidate design principle from which we might hope to derive the properties of real regulatory networks. As a starting point, I will consider the simple case of one input transcription factor that controls many genes. I will discuss the properties of these specific small networks that can transmit the maximum information. Concretely, I will show how the form of molecular noise drives predictions not just of the qualitative network topology but also the quantitative parameters for the input/output relations at the nodes of the network. In an attempt to link these general theoretical considerations to real biological systems, I will illustrate the predictions on the example of transmission of positional information in the early development of the fly embryo.

2:45PM D39.00006 Characterizing noise in genetic oscillatory systems. BYUNGJOON MIN, KWANG-IL GOH, IN-MOOK KIM, Korea University. Quantitative understanding of fluctuations in genetic circuits is crucial for understanding living systems. Despite the recent advances in the subject, however, fluctuations in non-stationary activities such as molecular oscillations have not been much investigated yet. Here we quantify the fluctuations in periods and amplitudes of oscillation and the noise propagation in the genetic oscillatory system, the repressilator, using exact stochastic simulation. At the single protein level, we found that the fluctuation in oscillation amplitudes is larger than that in oscillation periods. Noise propagation is studied in terms of the correlations in the successive periods and amplitudes, respectively, which decay exponentially down the regulatory cascades. We then study the extended repressilator system to investigate the effect of extra component and identify the combinatoric regulation pattern that reduces the fluctuations in oscillatory activities significantly.

LOCAL CORRELATION CALCULATIONS USING STANDARD AND RENORMALIZED COUPLED-CLUSTER METHODS. PIOTR PIEUCH, WEI LIU, JEFFREY GOUR, Department of Chemistry, Michigan State University. Local correlation variants of the coupled-cluster (CC) theory with singles and doubles (CCSD) and CC methods with singles, doubles, and non-iterative triples, including CCSD(T) and the completely renormalized CR-CC(2,3) approach, are developed. The main idea of the resulting CIM-CCSD, CIM-CCSD(T), and CIM-CR-CC(2,3) methods is the realization of the fact that the total correlation energy of a large system can be obtained as a sum of contributions from the occupied orthonormal localized molecular orbitals and their respective occupied and unoccupied orbital domains. The CIM-CCSD, CIM-CCSD(T), and CIM-CR-CC(2,3) algorithms are characterized by the linear scaling of the total CPU time with the system size and embracing parallelism. By comparing the results of the canonical and CIM-CC calculations for normal alkanes and water clusters, it is demonstrated that the CIM-CCSD, CIM-CCSD(T), and CIM-CR-CC(2,3) approaches recover the corresponding canonical CC correlation energies to within 0.1 % or so, while offering savings in the computer effort by orders of magnitude. By examining the dissociation of dodecane into C_{12}H_{26} and CH_{4} and several lowest-energy structures of the (H_{2}O)_{n}, clusters, it is shown that the CIM-CC methods accurately reproduce the relative energetics of the corresponding canonical CC calculations.
4:06PM D39.00007 Purely stochastic binary decisions in cell signaling models without underlying deterministic bistabilities. Maxim N. Artymov, Massachusetts Institute of Technology, Jayajit Das, Ohio State University, Mehran Karidar, Arup Chakraborty, Massachusetts Institute of Technology — Detection of different extra-cellular stimuli leading to functionally distinct outcomes is common in cell biology, and is often mediated by differential regulation of positive and negative feedback loops that are a part of the signaling network. For cellular responses stimulated by small numbers of molecules, the stochastic effects are important. Therefore, we studied the influence of stochastic fluctuations on a simple signaling model with dualing positive and negative feedback loops. The class of models we have studied is characterized by single deterministic steady states for all parameter values, but the stochastic response is bimodal; a behavior that is distinctly different from models studied in the context of gene regulation. For small numbers of signaling molecules, stochastic effects result in a bimodal distribution for this quantity, with neither mode corresponding to the deterministic solution; i.e., cells are in “on” or “off” states, not in some intermediate state. For a large number of molecules, the stochastic solution converges to the mean-field result. When fluctuations are important, we find that signal output scales with control parameters “anomalously” compared to mean-field predictions.

4:18PM D39.00008 Fitness effects of fluctuations in biochemical networks. Sorin Tanase-Nicolae, University of Michigan — The concentration of many cellular components fluctuates not only as a response to external and internal inputs but also due to random birth and death events of individual molecules. This biochemical noise affects the capacity of every individual cell to respond and adapt to the environment. While the sources and effects of biochemical fluctuations on individual cells have been intensively studied, the effects of noise on the growth rate of a population of cells are much less understood. We present a model of the cell cycle in which the growth and division of individual cells are coupled with the noisy dynamics of their internal components. The model allows us to compute the contribution of the biochemical noise to the average growth rate of a population of cells as a function of the noise strength and the correlation time of the fluctuations. We show that, due to fluctuations, the growth rate of a population of cells is always larger than the average growth rate of a individual cell and can be larger even than a corresponding deterministic model. In many cases it is assumed that the average concentration of a cellular component is close to a value that maximizes the population growth as given by the external, environmental, conditions and the internal cellular regulation. In such cases we show that contribution of fluctuations to the growth rate is negative and increases with the sensitivity of the biochemical network to the noise sources and the noise correlation time. We also discuss how the selection pressure due to fluctuations affects the structure and parameters of genetic regulatory networks.

4:54PM D39.00009 Effects of delay and noise in a negative feedback regulatory motif. Matteo Palassini, University of Barcelona, Marta Dies, Laboratori de Bioquimica i Biofisica Computacional, Institut Municipal d’Investigació Medica, Barcelona — The small copy number of the molecules involved in gene regulation can induce nontrivial stochastic phenomena such as noise-induced oscillations. An often overlooked aspect of regulation dynamics are the delays involved in transcription and translation. Delays introduce analytical and computational complications because the dynamics is non-Markovian. We study the interplay of noise and delays in a negative feedback model of the p53 core regulatory network. Recent experiments have found pronounced oscillations in the concentrations of proteins p53 and Mdm2 in individual cells subjected to DNA damage. Similar oscillations occur in the Hes-1 and NK-kB systems, and in circadian rhythms. Several mechanisms have been proposed to explain this oscillatory behaviour, such as deterministic limit cycles, with and without delay, or noise-induced excursions in excitable models. We consider a generic delayed Master Equation incorporating the activation of Mdm2 by p53 and the Mdm2-promoted degradation of p53. In the deterministic limit and for large delays, the model shows a Hopf bifurcation. Via exact stochastic simulations, we find strong noise-induced oscillations well outside the limit-cycle region. We propose that this may be a generic mechanism for oscillations in gene regulatory systems.

5:06PM D39.00010 Individuals in the crowd: studying bacterial quorum-sensing at the single-cell level. Pablo DelFino Perez, Jonathan Young, Elaine L. Johnson, Stephen J. Hagen, University of Florida, Physics Department, Gainesville FL 32611-8440 USA — Like many bacterial species, the marine bacterium Vibrio fischeri can detect its own population density through a quorum sensing (QS) mechanism. The bacterium releases a small molecular signal – the autoinducer (AI) – into its environment: high AI concentration indicates high population density and triggers a genetic switch that, in V.fischeri, leads to bioluminescence. Although the QS behavior of bulk cultures of V.fischeri has been extensively studied, little is known about either the response of individual cells to AI signal levels or the role of noise and local diffusion in QS signaling. We have used a photon-counting camera to record the luminescence of individual V.fischeri cells immobilized in a flow cell and subject to varying concentrations of AI. We observe that light output by individual cells varies not only with bulk AI concentration, but also over time, between cells, with local (micron-scale) population density, and even with the flow rate of the medium. Most of these variations would not be evident in a bulk culture. We will present an analysis of this heterogeneity at the cell level and its implications for the role of noise in QS signaling.

Monday, March 16, 2009 2:30PM - 5:30PM — Session D40 DBP: Nucleic Acids: Packaging, Ejection and Translocation 412

2:30PM D40.00001 Anomalous scaling of nano-pore translocation times of structured biomolecules. Malcolm Mccauley, Robert Forties, Department of Physics, Ohio State University, Ulrich Gerland, Arnold Sommerfeld Center for Theoretical Physics, University of Munich (LMU), Ralf Bundschuh, Department of Physics, Ohio State University — Translocation through a nano-pore is a new experimental technique to probe physical properties of biomolecules. A bulk of theoretical and computational work exists on how the main observable, the time to translocate a single molecule, depends on the length of the molecule for unstructured molecules. Here, we study the same problem but for RNA molecules for which the breaking of the secondary structure is the main barrier for translocation. To this end, we calculate the mean translocation time of single-stranded RNA through a nanopore of zero thickness and at zero voltage for many randomly chosen RNA sequences. We find the translocation time to depend on the length of the RNA molecule with a power law. The exponent changes as a function of temperature and exceeds the naively expected exponent of two for purely diffusive transport at all temperatures.

2:42PM D40.00002 DNA Physical Mapping via the Controlled Translocation of Single Molecules through a 5-10nm Silicon Nitride Nanopore. Derek Stein, Walter Reisner, Zhijun Jiang, Nick Hagerty, Charles Wood, Jason Chan, Brown University — The ability to map the binding position of sequence-specific markers, including transcription-factors, protein-nucleic acids (PNAs) or deactivated restriction enzymes, along a single DNA molecule in a nanofluidic device would be of key importance for the life-sciences. Such markers could provide an indication of the active genes at particular stage in a cell’s transcriptional cycle, pinpoint the location of mutations or even provide a DNA barcode that could aid in genomics applications. We have developed a setup consisting of a 5-10 nm nanopore in a 20nm thick silicon nitride film coupled to an optical tweezer setup. The translocation of DNA across the nanopore can be detected via blockades in the electrical current through the pore. By anchoring one end of the translocating DNA to an optically trapped microsphere, we hope to stretch out the molecule in the nanopore and control the translocation speed, enabling us to slowly scan across the genome and detect changes in the baseline current due to the presence of bound markers.
2:54PM D40.00003 The Effects of Bio-functionalization on Solid-state Nanopore Transport — Theory and Experiments on DNA.\textsuperscript{1} YALING LIU, ABHIJIT RAMACHANDRAN, Department of Mechanical and Aerospace Engineering, SAMIR M. IQBAL, Department of Electrical Engineering, NanoFAB Center, University of Texas at Arlington — Solid-state nanopore channels have been reported recently to show selectivity for various target bio-molecules. The surfaces of nanopore channels are functionalized to achieve such selectively. The organic molecule coatings alter the behavior of molecular transport as well as change surface energies, chemical and physical properties, and make these more bio-compatible. We present theoretical considerations of DNA-modified nanopore channels which treat the functional molecules on the surface as a combination of series of potential sites. The potential function depends on the physical interactions of two ssDNA molecules. The simulated DNA trajectories and translocation speed under various test conditions are consistent with the reported experimental data.

\textsuperscript{1}This work is supported by University of Texas at Arlington Research Enhancement Program.

3:06PM D40.00004 Nanopores as a Single-Molecule Probe for Protein-DNA Complexes, A.R. HALL, S.W. KOWALCZYK, R.M.M. SMEETS, N.H. DEKKER, C. DEKKER, Kavli Institute of Nanoscience, Delft Institute of Technology — In recent years, solid state nanopores have emerged as a productive novel technique for molecular biophysics. The electrophoretic motion of single molecules through these small-scale structures can offer insights into both conformation and charge structure. Here, we apply the method to the ReCA nucleoprotein filament — a conformation where proteins polymerize along the entire length of a double-stranded DNA. This offers a unique geometry and charge structure which we probe through a combination of translocation experiments and optical tweezer measurements. We discuss conductance blockade events that are notably larger (12 nS) than those measured for bare dsDNA (1 nS), and present force spectroscopy data showing a high level of charge screening in solution (>90%).

3:18PM D40.00005 Computational model of controlled translocation of DNA molecule through a nanopore membrane with tunable electrostatic potential, ALEXEY NIKOLAEV, MARIA GRACHEVA, Clarkson University — We present results of computational modeling of controllable DNA translocation through a nanopore in a thin electrically tunable membrane composed of two layers of n-type and p-type semiconductor materials. Membrane potential biases are used to obtain distinct electrostatic potential landscapes. The membrane-DNA system is immersed in a biased electrolyte solution under bias to induce DNA translocation. A simple charges-and-springs model is used to model polynucleotide molecule. We compare electrostatic potential landscapes of the membrane with one and more potential extrema and show how electrostatic potential landscape in the nanopore alters the control over the molecule translocation. In particular, we specify different conditions under which DNA nucleotides can be translocated through the nanopore one by one in both directions as well as paused in the nanopore.

3:30PM D40.00006 Heterogeneity in Retroviral Nucleocapsid Protein Function, CHRISTY LANDES, University of Houston — Time-resolved single-molecule fluorescence spectroscopy was used to study the human T-cell lymphotropic virus type 1 (HTLV-1) nucleocapsid protein (NC) chaperone activity as compared to that of the HIV-1 NC protein. HTLV-1 NC contains two zinc fingers with each having a CCHC binding motif similar to HIV-1 NC. HIV-1 NC is required for recognition and packaging of the viral RNA and is also a nucleic acid chaperone protein that facilitates nucleic acid restructuring during reverse transcription. Because of similarities in structures between the two retroviruses, we have used single-molecule fluorescence energy transfer to investigate the chaperoning activity of HTLV-1 NC protein. The results indicate that HTLV-1 NC protein induces structural changes by opening the transactivation response (TAR)-DNA hairpin to an even greater extent than HIV-1 NC. However, unlike HIV-1 NC, HTLV-1 NC does not chaperone the strand-transfer reaction involving TAR-DNA. These results suggest that despite its effective destabilization capability, HTLV-1 NC is not as effective at overall chaperone function as is its HIV-1 counterpart.

3:42PM D40.00007 Energetics of genome ejection from phage revealed by isothermal titration calorimetry, MEERIM JEEMBAEVA, BENGT JONSSON, MARTIN CASTELNOVO, ALEX EVILEVITCH — It has been experimentally shown that ejection of double-stranded DNA from phage is driven by internal pressure reaching tens of atmospheres. This internal pressure is partially responsible for delivery of DNA into the host cell. While several theoretical models and simulations nicely describe the experimental data of internal forces either resisting active packaging or equivalently favoring spontaneous ejection, there are no direct energy measurements available that would help to verify how quantitative these theories are. We performed direct measurements of the enthalpy responsible for DNA ejection from phage \( \lambda \), using Isothermal Titration Calorimetry. The phage capsids were “opened” in vitro by titrating \( \lambda \) into a solution with LamB receptor and the enthalpy of DNA ejection process was measured. In his way, enthalpy stored in \( \lambda \) was determined as a function of packaged DNA length comparing wild-type phage \( \lambda \) (48.5 kb) with a shorter \( \lambda \)-DNA length mutant (37.7 kb). The temperature dependence of the ejection enthalpy was also investigated. The values obtained were in good agreement with existing models and provide a better understanding of ds-DNA packaging and release mechanisms in motor-packaged viruses (e.g., tailed bacteriophages, Herpes Simplex, and adenoviruses).

3:54PM D40.00008 Inhibition of DNA ejection from bacteriophage by Mg\(^{\pm2}\) counterions, SEIL LEE, School of Physics, Georgia Institute of Technology, CATHY V. TRAN, School of Chemistry and Biochemistry, Georgia Institute of Technology, TOAN T. NGUYEN, School of Physics, Georgia Institute of Technology — The problem of inhibiting viral DNA ejection from bacteriophages by multivalent counterions, especially Mg\(^{\pm2}\) counterions, is studied. Experimentally, it is known that MgSO\(_4\) salt has a strong and non-monotonic effect on the amount of DNA ejected. There exists an optimal concentration at which the least DNA is ejected from the virus. At lower or higher concentrations, more DNA is ejected from the capsid. We propose that this phenomenon is the result of DNA overcharging by Mg\(^{\pm2}\) multivalent counterions. As Mg\(^{\pm2}\) concentration increases from zero, DNA net charge changes from negative to positive. The optimal inhibition corresponds to the Mg\(^{\pm2}\) concentration where DNA is neutral. At lower/higher concentrations, DNA genome is charged. It prefers to be in solution to lower its electrostatic self-energy, which consequently leads to an increase in DNA ejection. Our theory fits experimental data well. The strength of DNA-DNA short range attraction, mediated by Mg\(^{\pm2}\), is found to be \(-0.003 k_B T \) per nucleotide base.

4:06PM D40.00009 Osmotic pressure: resisting or promoting DNA ejection from phage? Internal capsid-pressure dependence of viral infection, ALEX EVILEVITCH, MEERIM JEEMBAEVA, Department of Biochemistry, Lund University, Sweden, SARAH KOESTER, Department of Physics, Harvard University, Cambridge, MA, MARTIN CASTELNOVO, Laboratoire de Physique, Ecole Normale Superieure de Lyon, France, DAVID WEITZ, Department of Physics, Harvard University, Cambridge, MA — Recent in vitro experiments have shown that DNA ejection from phage can be partially stopped by surrounding osmotic pressure when ejected DNA is digested by DNase I on the course of infection. We argue in this work by combination of experimental techniques (UV absorbance, pulse-field electrophoresis, and cryo-EM) that intact genome (i.e. undigested) ejection in a crowded environment is, on the contrary, enhanced or eventually complete with the help of a pulling force resulting from DNA condensation induced by the osmotic stress itself. This demonstrates that in vivo, the osmotically stressed cell cytoplasm will promote phage DNA ejection rather than resisting it. While, in vitro, the ejection depends sensitively on internal pressure within the virus capsid, the effect of internal pressure on infection of bacteria is unknown. We use microfluidics to monitor individual cells and determine the distribution of lysis due to infection as the capsid pressure is varied. The lysis probability decreases markedly with decreased capsid pressure.
and heavy fermion superconductors. The energy of the BT of the spin susceptibility is strikingly similar to the phenomenology of resonance peaks in high-Tc superconductors. We assume that the HO gap is due to a particle-hole condensate that connects nested parts of the Fermi surface with nesting vector $Q^*$. The predicted behavior in URu2Si2 and argue that a gap in the fermion spectrum will produce an incommensurate spin resonance at $Q^* = (1 - 2\pi/3)$ in the case of a B phase without pentamers does not change, while the modified A and C phases show a large drop in their breaking force to approximately the value of the B capsids. This result indicates that upon DNA packaging a structural change at or near the pentamers occurs which mechanically reinforces the capsid structure. The reported binding of proteins UL17/UL25 to the pentamers of the A and C capsids seems the most likely candidate for such capsids strengthening. Finally, the data supports the view that initiation of DNA packaging triggers the maturation of HSV-1 capsids.

3 Medizinische Hochschule Hannover, Germany

4:42PM D40.00012 Effect of ions on polymer ejection dynamics from viral capsids1. ISSAM ALI, Department of Physics, College of Science, PO Box 36, Sultan Qaboos University, Al Khod 123, Oman, DAVIDE MARENDUZZO, SÚPA, School of Physics, University of Edinburgh, Mayfield Road, Edinburgh, EH9 3JZ, UK, JULIA YEOMANS, Rudolf Peierls Centre for Theoretical Physics, 1 Keble Road, Oxford, OX1 3NP, UK — We present simulations investigating the impact of adding ions on the dynamics of semiflexible (DNA-like) polymers ejecting from spherical viral capsids. We find that when the DNA charge is less screened, due to, for example, the addition of monovalent ions like Na+, the resulting electric interactions give rise to larger ejection forces, speeding up the ejection process. The results suggest that DNA ejection can be controlled by tuning the salt concentration in the environment, in agreement with recent experiments. We also observe that the DNA structure inside the capsid changes when electrical forces are present, tending to become more spool-like.

5:06PM D40.00014 Electrically Gated Solid State Nanopores, ZHIJUN JIANG, WALTER REISNER, DEREK STEIN, Brown University — We are exploring the use of electrically functionalized solid-state nanopores for controlling the transport of ions and single DNA molecules in solution. We have integrated annular gate electrodes inside solid-state nanopores that can electrostatically adjust both the polarity and the density of the inner surface charge. An applied gate potential can thereby influence the density of mobile counter-ions inside a pore at low salt concentrations. Our theoretical calculations show that a 0.1 V change in the gate potential can change the pore conductance by more than a factor of 5, making the nanopore behavior similar to that of a transistor. Furthermore, the electrostatic interaction between the nanopore surface and negatively charged DNA molecules can be probed in the regime of double-layer overlap. A negatively charged inner nanopore surface should repel DNA, and limit its possibility to insert into the nanopore. Positive surface charges, on the other hand, will attract DNA, and translocation should be favored. We seek to electrostatically control the translocation of DNA through the nanopore, and thereby mimic single-molecule regulatory capabilities of biological nanopores.

5:18PM D40.00015 Structural transitions in packing of a semi-flexible chain confined in a sphere, ARTEM LEVANDOVSKY, LEONID PRYADKO, ROYA ZANDI, University of California, Riverside — We study phases and phase transitions (crossovers) between phases of a semi-flexible polymer chain confined in a spherical cavity. Such a problem is relevant to DNA or RNA packaging in viruses whose organization is characterized by both simplicity and economy. The confinement involves both energetic and entropic effects controlled by the stiffness of the chain, its length and diameter, and the sphere radius. Formation of different packing configurations and structural changes in these configurations is studied with a non-local “cluster” Monte Carlo method. We introduce several order parameters characterizing different packing symmetries and compute the corresponding probability distributions. This allows us to reconstruct the Landau free energies for these order parameters, and thus develop a simple theory of packing transitions.

Monday, March 16, 2009 2:30PM - 5:06PM — Session D41 DMP DCMP: Hidden Order and Quantum Criticality in Heavy Fermions 413

2:30PM D41.00001 Incommensurate spin resonance in URu2Si2. JIAN XIN ZHU, ALEXANDER BALATSKY, ATHANASIOS CHANTIS, HARI DAHAL, LANL, DAVID PARKER, NRL — The nature of the hidden order (HO) in URu2Si2 below $T_{HO} = 17.5$K has been a puzzle for a long time. Here we propose to search for the spin resonance as a tool to elucidate the nature of the HO. We considerinelastic neutron scattering in URu2Si2 and argue that a gap in the fermion spectrum will produce an incommensurate spin resonance at $Q^{*} = (1 pm 0.4, 0.0)$ at $\omega_{res} = 4.6$ meV. We assume that the HO gap is due to a particle-hole condensate that connects nested parts of the Fermi surface with nesting vector $Q^{*}$. The predicted behavior of the spin susceptibility is strikingly similar to the phenomenology of resonance peaks in high-Tc and heavy fermion superconductors. The energy of the resonance peak scales with $T_{HO} \omega_{res} \sim 4 k_{BT_{HO}}$

2:42PM D41.00002 Thermodynamical Properties across Quantum Critical Points...JIANDA WU, LIJUN ZHU, QIMIAO SI Quantum critical points (QCPs) are of extensive current interest, in part because they strongly influence the physical properties at finite temperatures. Thermodynamical properties have recently been used as a means to probe the energy scales in the quantum critical heavy fermion metals [1]. In addition, the divergence of the Gruneisen ratio (thermal expansion to specific heat) or its magnetic analog at any QCP, theoretically predicted a few years ago [2], has been observed in a growing list of quantum critical materials. In this work, we study the entropy as a function of control parameter in several theoretical models for quantum criticality. We explicitly demonstrate that the entropy is maximized near the QCP, which is compatible with the divergence of the Gruneisen ratio exactly at the QCP. When the control parameter is a magnetic field, we also study the field dependence of the isothermal magnetization and other magneto-thermal properties. [1] P. Gegenwart et al, Science 315, 969 (2007); [2] L. Zhu et al, PRL 91, 066404 (2003).

2:54PM D41.00003 Cyclotron Resonance in the Hidden-Order Phase of Ultraclean URu$_2$Si$_2$ Single Crystals... T. SHIBAUCHI, K. HASHIMOTO, K. IKADA, S. TONEGAWA, H. SHISHIDO, Department of Physics, Kyoto University, Y. HAGA, T. D. MATSUDA, Advanced Science Research Center, Japan Atomic Energy Agency, Y. ONUKI, Graduate School of Science, Osaka University, H. YAMAGAMI, Department of Physics, Kyoto Sangyo University, Y. MATSUDA, Department of Physics, Kyoto University — In the heavy fermion compound URu$_2$Si$_2$, the hidden-order transition occurs at 17.5 K, whose origin is still an enigma. Of primary importance is elucidating the electronic structure of the hidden-order phase. Here we report the first observation of cyclotron resonance in the ultraclean crystals of URu$_2$Si$_2$ with residual resistivity ratio $RRR > 670$. The magnetic-field dependence of the microwave surface impedance in the Azbel-Kern geometry shows clear cyclotron resonance lines whose width has characteristic temperature dependence consistent with the transport measurements. In addition to the bands which have been previously identified in the quantum oscillation measurements, we newly find the missing band with the heaviest mass, which can account for the large specific heat coefficient in the hidden-order phase of URu$_2$Si$_2$.

3:06PM D41.00004 Reconstruction of the Fermi Surface Deep inside the Hidden-Order Phase of Very Clean URu$_2$Si$_2$... Y. MATSUDA, H. SHISHIDO, T. SHIBAUCHI, K. HASHIMOTO, Department of Physics, Kyoto University, Y. HAGA, T.D. MATSUDA, Advanced Science Reserach Center, Japan Atomic Energy Agency, Y. ONUKI, Graduate School of Science, Osaka University, T. Sasaki, T. OIZUMI, N. KOBAYASHI, Institute for Materials Research, Tohoku University, Y. IMANAKA, National Institute for material Science — The nature of the hidden order (HO) phase in URu$_2$Si$_2$ is a long standing mystery in heavy-fermion physics. It has been shown that the HO phase is destroyed at $H_{\mathrm{c}} = 36$ T ($T = 0$) and several new phases appear above $H_{\mathrm{c}}$. Here we studied the low temperature/high field phase of very clean URu$_2$Si$_2$, single crystals ($RRR > 670$) by the transport properties. We find that the Hall resistivity jumps at $H_{\mathrm{c}} = 22$ T well inside the HO phase and new quantum oscillations appear at high fields starting slightly below $H_{\mathrm{c}}$. These results indicate a reconstruction of the Fermi surface and a possible phase transition well inside the HO phase. The present results provide strong evidence that the HO transition is described by an itinerant rather than a localized electron picture.

3:18PM D41.00005 Probing the Hidden Order in URu$_2$Si$_2$ by Impurity Doping... SEUNG-HO BAEK, Los Alamos National Laboratory, NICHOLAS CURRO, U. of California, Davis, M. GRAF, A. BALATSKY, ERIC BAUER, JASON COOLEY, JIM SMITH — URu$_2$Si$_2$ exhibits a clear broken symmetry ground state at 17.5 K, but the nature of the order parameter has not been determined for more than two decades. Motivated by the fact that Rh doping in this compound induces antiferromagnetism, indicating that the hidden order is closely related with the antiferromagnetism, we studied $^{29}$Si NMR with varying Rh concentration. This $^{29}$Si NMR study reveals that the antiferromagnetism arises from the local suppression of the hidden order by Rh doping. We propose that the antiferromagnetism emerges as a result of the local suppression of the hidden order yet only within the long range hidden order phase.

3:30PM D41.00006 Electronic structure model of the hidden order and Fermi surface gapping in URu$_2$Si$_2$... PETER OPPENEER, SAAD ELGAZZAR, JAN RUSZ, MICHIO-SUZUKI, Uppsala University, JOHN MYDOSH, University of Cologne — The hidden order (HO) in the heavy-fermion superconductor URu$_2$Si$_2$ has been studied for more than 20 years, without that the nature of this unusual phase could be uncovered. We present a microscopic explanation for the mechanism of the hidden order, on the basis of state-of-the-art electronic structure calculations. In particular, we show that our calculations explain very well all the known properties of the paramagnetic and large moment antiferromagnetic (LMAF) phases. Exploiting the known experimental equivalence between the Fermi surface properties of the LMAF and HO phases, we identify the Fermi surface “hot spots” where a Fermi surface instability is lifted through spontaneous symmetry breaking, causing a surprisingly large Fermi surface gapping. We quantify that symmetry breaking through collective modes of antiferromagnetic moment excitations can induce a substantial Fermi surface gapping that consistently explains the transport properties and entropy loss of the HO phase.

3:42PM D41.00007 Heavy Fermion and non-Fermi Liquid Properties vs Size: From the Micro to the Nano...G.R. STEWART, J.S. KIM, Physics/University of Florida, K. SAMWER, Physikalisches Institut, Universitäts-Göttingen — Y. Y. Chen et al. have studied nanoparticles of several systems, including CePt$_2$I$_3$. We report here the specific heat, C, down to 0.05 K and $\chi$ to 2 K as a function of size for several Ce- and U-heavy Fermion and non-Fermi liquid (nFl) systems, including UBe$_{13}$ and Rh-doped CeRu$_2$Si$_2$. Using dry sieves (for larger particles) and aqueous suspension/filtration techniques using Isopore filters (for smaller particles), size gradations from 45-53 $\mu$m (essentially bulk) down to 0.6-1.2 $\mu$m were studied. One goal was to study the evolution of nFl behavior versus decreasing size at a Quantum Critical Point, where the spatial extent of the fluctuations should become infinite, or at least larger than the particle at some size. Ce-systems showed the beginning of Kondo peak behavior in C below 3 $\mu$m, however it was still possible to determine the evolution of the intrinsic low temperature nFl C/T vs $\log$ T in Rh-doped CeRu$_2$Si$_2$ as a function of decreasing size to address this goal. The effect of size on superconductivity and $m^*$ in UBe$_{13}$ will also be discussed. [1] Y. Y. Chen et al., Phys. Rev. Lett. 98, 157206 (2007).

3:54PM D41.00008 Quantum criticality in the Bose-Fermi Kondo model and the quantum-to-classical mapping... STEFAN KIRCHNER, QIMIAO SI, Rice University — The Bose-Fermi Kondo model (BFKM) occurs as the effective quantum impurity model within the Extended Dynamical Mean Field Theory (EDMFT) for quantum critical heavy fermion metals. The quantum critical point (QCP) of the BFK is therefore related to the one in the Kondo lattice model, relevant low-energy model for heavy fermion compounds. There have been indications that the QCP of the BFKM cannot be described in terms of a local O(3)-symmetric $\phi^4$-theory as predicted by the quantum-to-classical mapping, but the issue remains to be settled. In this work we demonstrate that the quantum-to-classical mapping for the spin-isotropic SU(N) BFKM breaks down in a large N limit[1]. We also show that this feature is associated with the Berry phase term of the spin path integral and therefore persists for finite N[2]. We analyze the influence of this breakdown on the dynamic scaling properties of the Kondo lattice obtained through the EDMFT, and also discuss the connection of our results with those of the Ising-anisotropic BFKM. [1] L. Zhu, S. Kirchner, Q. Si and A. Georges, PRL 93, 267201 (2004). [2] S. Kirchner and Q. Si, arXiv:0808.2647 (2008).
4:06PM D41.00009 Thermal expansion and magnetostriction of the heavy fermion antiferromagnet YbAgGe. G.M. SCHMIEDESHOFF, A.W. LOUBSURY, S.J. TRACY, Occidental College, S.L. BUD’KO, P.C. CANFIELD, Ames Laboratory/Iowa State University — YbAgGe is a stoichiometric heavy fermion compound that exhibits antiferromagnetic order and field induced quantum criticality. We will discuss this behavior, and present a unified phase diagram of this compound in the T-H plane, in light of our recent thermal expansion and magnetostriction measurements. We find a remarkable agreement between thermodynamic, transport and microscopic measurements on this model system. Work at Occidental College was supported by the National Science Foundation under DMR-0704406. Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

4:18PM D41.00010 Magnetic-field-dependence of the YbRh$_2$Si$_2$ Fermi surface. PATRICK ROURKE, ALIX MCCOLLAM, University of Toronto, GERARD LAPIERT, GEORG KNEBEL, JACQUES FLOQUET, DFMPC, SPSMS, CEA Grenoble, STEPHEN JULIAN, University of Tokyo — Magnetic-field-induced changes of the Fermi surface play a central role in theories of the exotic quantum criticality of YbRh$_2$Si$_2$. We have carried out de Haas–van Alphen measurements in the magnetic field range 8 T $\leq H \leq 16$ T, and directly observe field-dependence of the extremal Fermi surface areas. Our data support the theory that a low-field “large” Fermi surface, including the Yb $4f$ quasi-hole, is increasingly spin-split until a majority-spin branch undergoes a Lifshitz transition and disappears at $H_d \approx 10$ T, without requiring $4f$-localization at $H_d$.

4:30PM D41.00011 Electron Spin Resonance in a Kondo lattice. PEDRO SCHLOTTMANN, Florida State University — Until recently it was commonly believed that due to the broad linewidth electron spin resonance (ESR) could not be observed in heavy-fermion compounds. This proven to be wrong, since an ESR signal was found in single crystals of YbRh$_2$Si$_2$ as well as in other systems. Recently, Abrahams and Wölfle$^1$ studied the ESR signal of a heavy fermion band within the framework of the Anderson lattice. They obtained that the heavy mass in conjunction with ferromagnetic fluctuations can lead to narrow resonances, and concluded that the observed ESR in YbRh$_2$Si$_2$ is due to the heavy fermion conduction states and not the Kondo localized moments. Here I study the ESR linewidth for localized moments within the framework of the Kondo lattice model. An ESR signal can only be observed if the Kondo temperature is sufficiently small. In addition, to obtain an observable signal short-range ferromagnetic correlations between the localized spins are necessary, which may lead to a bottleneck situation, that narrows the linewidth. It is concluded that from ESR data alone it is not possible to distinguish if the resonance is due to localized spins or conducting heavy electron spins. Work supported by the Department of Energy under grant No. DE-FG02-98ER45797.

4:42PM D41.00012 Crystalline Synthesis of Novel Yb-Pt-Pb Phases. CARLOS MARQUES, Brookhaven National Laboratory and Stony Brook University, YURI JANSSEN, Brookhaven National Laboratory, MARCUS BENNET, University of Michigan, MOO SUNG KIM, KEESOEONG PARK, Brookhaven National Laboratory, PETER KHALIFAH, MEIGAN ARONSON, Brookhaven National Laboratory and Stony Brook University — We have used flux techniques to explore the Yb-Pt-Pb ternary phase diagram, and have grown a number of intermetallic compounds including YbPt$_4$, Yb$_3$Pt$_5$, and the new Yb$_2$Pt$_9$, Yb$_3$Pt$_{10}$, Yb$_4$Pt$_{12}$, and Yb$_5$Pt$_{12}$Pb, as well as Yb$_2$Pt$_8$Si and Yb$_4$Pt$_8$Si. The crystal structure of these different compounds will be compared. A particular focus has been the synthesis of single crystals of quantum critical antiferromagnet (AF) Yb$_3$Pt$_4$, and we show that it is possible to synthesize crystals which are large enough for neutron diffraction measurements. Laue patterns and neutron rocking curves along with other methods show that these crystals are of very high quality. Initial results of neutron diffraction and inelastic scattering experiments on single Yb$_2$Pt$_9$ crystals and arrays of multiple Yb$_2$Pt$_9$ crystals will be presented.

$^1$Work at Stony Brook was supported by the National Science Foundation under grant NSF-DMR-0405961.

4:54PM D41.00013 Neutron scattering studies on Yb$_3$Pt$_4$. Y. JANSSEN, Brookhaven National Laboratory, M.C. BENNETT, Brookhaven National Laboratory and University of Michigan, C. MARQUES, L. WU, Brookhaven National Laboratory and Stony Brook University, M.S. KIM, K.S. PARK, Brookhaven National Laboratory, Q. HUANG, J.Y. LI, Y. CHEN, J.W. LYNN, NCNR NIST, M.C. ARONSON, Brookhaven National Laboratory and Stony Brook University — The antiferromagnetic (AF) intermetallic compound Yb$_3$Pt$_4$ shows a magnetic phase diagram which includes a quantum critical point, but is different from other Yb-containing quantum critical compounds. We elucidated the zero-field behavior by neutron scattering on both polycrystal and single-crystal samples. The magnetic structure due to the single-site-low-symmetry Yb moments was determined by diffraction. The AF unit cell coincides with the crystallographic unit cell, and shows pairs of Yb nearest-neighbor moments pointing directly towards each other. The order parameter is consistent with a continuous transition at the Néel temperature (2.4 K) and can be described by a simple mean-field model. The ordered moment amounts to $\sim 1.2 \mu_B$/Yb at 0 K. Inelastic neutron scattering reveals that the crystal electric field lifts the degeneracy of the Yb 4f ground state into 4 doublets, consistent with specific heat results.

Monday, March 16, 2009 8:00PM - 9:12PM — Session G1 Energy and the Environment Spirit of Pittsburgh Ballroom A

8:00PM G1.00001 The flow of energy through the climate system and changes with global warming. KEVIN E. TRENBERTH, National Center for Atmospheric Research — A review is first given of the mean and annual cycle of energy flowing through the climate system, and its storage, release, and transport in the atmosphere, ocean, and land surface as estimated with recent observations. Of the roughly 175 Petawatts coming into the planet, about 120 are absorbed and drive the weather and climate system through the unequal distribution with latitude and between land and ocean. We are able to close the energy budget reasonably well, although largest errors are determined to be in changes in ocean heat content, especially south of about 35°S. The winter hemisphere atmospheric circulation is identified as the dominant contributor to poleward energy transports outside of the Tropics (6 to 7 PetaWatts), with summer transports being relatively weak ($\sim 3$ PW) slightly more in the Southern Hemisphere and slightly less in the Northern Hemisphere. Ocean transports outside of the Tropics are found to be small ($< 2$ PW) for all months. The current imbalance in radiation at the top-of-atmosphere (about 0.5 PW) owing to human-induced increases in greenhouse gases means that the atmosphere, land and ocean are warming up, and ice is melting, leading to a rise in sea level. This comes about from increasing greenhouse gases in the atmosphere, notably carbon dioxide, from human activities. The interference with the natural flows of energy is a factor of 60 or so larger than the direct energy released by human activities. A brief outline will be given of the resulting climate change underway and projections for the future.
8:36PM G1.00002 Materials for Sustainable Energy, GEORGE CRABTREE, Argonne National Laboratory — The global dependence on fossil fuels for energy is among the greatest challenges facing our economic, social and political future. The uncertainty in the cost and supply of oil threatens the global economy and energy security, the pollution of fossil combustion threatens human health, and the emission of greenhouse gases threatens global climate. Meeting the demand for double the current global energy use in the next 50 years without damaging our economy, security, environment or climate requires finding alternative sources of energy that are clean, abundant, accessible and sustainable. The transition to greater sustainability involves tapping unused energy flows such as sunlight and wind, producing electricity without carbon emissions from clean coal and high efficiency nuclear power plants, and using energy more efficiently in solid-state lighting, fuel cells and transportation based on plug-in hybrid and electric cars. Achieving these goals requires creating materials of increasing complexity and functionality to control the transformation of energy between light, electrons and chemical bonds. Challenges and opportunities for developing the complex materials and controlling the chemical changes that enable greater sustainability will be presented.

Tuesday, March 17, 2009 8:00AM - 11:00AM
Session H1 DCMP: Electronic Structure of Disordered Graphene Spirit of Pittsburgh Ballroom A

8:00AM H1.00001 Scanning Single Electron Transistor Microscopy on Graphene1, JENS MARTIN, Harvard University — We use a scanning single electron transistor to map the local density of states of graphene and the carrier density landscape in the vicinity of the neutrality point. At zero magnetic field our results confirm the existence of electron-hole puddles. These puddles could explain graphene’s anomalous non-zero minimal conductivity at zero average carrier density. Moreover, we find that, unlike non-relativistic particles the density of states can be quantitatively accounted for by considering non-interacting electrons and holes. At high magnetic field we investigate the appearance of localized states. Particle localization is an essential ingredient in quantum Hall physics. In conventional high mobility two-dimensional electron systems Coulomb interactions were shown to compete with disorder and to play a central role in particle localization. Surprisingly, despite the stronger disorder in graphene compared to the standard two-dimensional systems, our findings indicate that localization in graphene is also dominated by Coulomb interactions and not single particle physics.

8:36AM H1.00002 Magnetic Oscillations and Landau Quantization in Decoupled Epitaxial Graphene Multilayers*, JOSEPH A. STROSCIO, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD 20899 — A fundamental challenge to the development of a new electronics based on single atomic sheets of carbon, known as graphene, is to realize a large-area production platform that can produce a carbon system with the same intrinsic properties as a single sheet of graphene. Multi-layer epitaxial graphene (MEG) grown on SiC substrates has been proposed as a possible platform to this end [1]. The central question is, Can MEG behave as single layer graphene with the same intrinsic electrical characteristics? In this talk we show that MEG graphene on SiC exhibits single layer graphene properties through new tunneling magnetic measurements. The circular motion of electrons in a magnetic field has historically been a powerful probe of the Fermi surface properties of materials. Oscillations in many measurable properties, such as magnetization, thermal conductivity, and resistance, all reflect the Landau quantization of the electron energy levels. In this talk we show the ability to observe tunneling magneto-conductance oscillations (TMCOs) in the tunneling differential conductance as a function of both magnetic field and electron energy. The TMCO arise from intense Dirac quantization of the 2-dimensional Dirac electron and hole quasiparticles in MEG grown on SiC substrates. Spatial profiles of the Landau quantization demonstrate the high quality of MEG on SiC with carrier concentrations that vary less than 10% over hundreds of nm. The single layer quantization observed in these multi-layer samples is attributed to observed rotational stacking domains that effectively decouple the carbon layers in MEG on SiC, thereby yielding single layer graphene properties in a large area carbon production method. *In collaboration with Lee Miller, Kevin Kubista, Gregory M. Rutter, Ming Ruan, Mike Sprinkle, Claire Berger, Walt A. de Heer, and Phillip N. First, Georgia Institute of Technology

9:12AM H1.00003 Effect of potential barriers on transport in graphene1, B. HUARD, Physics Department, Stanford University, Stanford, CA 94025, USA — The energy of graphene charge carriers grows linearly with their momentum. This zero-mass behavior, associated with an absence of a forbidden region between electrons and holes, deeply modifies transport properties of electrons across potential steps and barriers. We perform transport measurements in graphene monolayers where the potential profile is tuned by a set of local gates [1,2]. By varying the height and width of potential barriers and the energy of charge carriers, we can test the predictions on the transmissions of the conduction channels across a potential step in graphene. Besides, we observe the effect of disorder and of screening of an external field in graphene. These experiments have a direct consequence in any transport measurement in graphene. We indeed showed that such potential steps naturally develop at the interface between graphene and a metallic electrode [3]. We discuss the effects of these steps in various geometries [4]. In collaboration with N. Stander, J.A. Sulpizio, Physics Department, Stanford University, Stanford, CA 94025, USA; and J. Cayssol, D. Goldhaber-Gordon, CPMOH, UMR5798, Université de Bordeaux, 33405 Talence, France.

1Present address : Laboratoire Pierre Aigrain, 24 rue Lhomond, 75005 Paris.
9:48AM H1.00004 Ground-state Properties of Inhomogeneous Graphene Sheets \textsuperscript{1}, MARCO POLINI, NEST-CNRS-IFM and Scuola Normale Superiore di Pisa — When inter-valley scattering is weak and gauge fields due to \textit{e.g.} ripples are neglected, doped and gated graphene sheets can be described using an envelope-function Hamiltonian with a new sublattice pseudospin degree-of-freedom, an ultrarelativistic massless-Dirac free-fermion term, a pseudospin \textit{scalar} disorder potential, and a non-relativistic instantaneous Coulombic interaction term. There is considerable evidence from experiment that this simplified description of a honeycomb lattice of Carbon atoms is usually a valid starting point for theories of those observables that depend solely on the electronic properties of \textit{n}-electrons near the graphene Dirac point [1]. Although the use of this model simplifies the physics considerably it still leaves us with a many-body problem without translational invariance, which we do not know how to solve. In this talk we present a Kohn-Sham-Dirac density-functional theory (DFT) scheme for graphene sheets that treats slowly-varying inhomogeneous scalar external potentials and electron-electron interactions on an equal footing [2]. The theory is able to account for the unusual property that the exchange-correlation contribution to chemical potential increases with carrier density in graphene [3,4]. Consequences of this property, and advantages and disadvantages of using the DFT approach to describe it, are discussed. The approach is illustrated by solving the Kohn-Sham-Dirac equations self-consistently for a model random potential describing charged-point-like impurities located close to the graphene plane. The influence of electron-electron interactions on these non-linear screening calculations is discussed at length, in the light of recent experiments [5,6] reporting evidence for the presence of electron-hole puddles in nearly-neutral graphene sheets.

10:24AM H1.00005 Ground-state of Two-dimensional Graphene in the Presence of Random Charged Impurities \textsuperscript{1}, ENRICO ROSSI, Condensed Matter Theory Center, University of Maryland — The low energy electronic excitations of graphene are described by a massless Dirac fermion model. In clean isolated graphene the Fermi energy lies exactly at the Dirac point where the linear chiral electron and hole bands cross each other. Close to the Dirac point the average carrier density vanishes and the density fluctuations are expected to dominate the physics of graphene. In current experiment the fluctuations are mostly due to quenched disorder. In this talk I present the Thomas-Fermi-Dirac (TFD) theory [1] to calculate the \textit{carrier density} of graphene in presence of disorder. The TFD theory includes the effects of non-linear screening, exchange and correlation. The approach is independent of the disorder source and very efficient allowing the calculation of disorder-averaged quantities that can be directly compared with experiments. Recent transport results strongly suggest that in current graphene samples charge impurities are the main source of disorder. I then present the results of the TFD theory for this case. I show that close to the Dirac point the carrier density breaks up in electron-hole puddles and is characterized by two types of inhomogeneities: wide regions of low density and sparse narrow regions of high density and a typical correlation length of \textit{10 nm}. I present detailed results that show how the disordered averaged quantities characterizing the carrier density profile depend on the experimental parameters. I show that at finite voltages the density probability distribution has a bimodal character providing direct evidence for the existence of puddles over a finite range of gate voltages. In graphene the exchange-correlation term increases with density contrary to parabolic-band electron liquids and because of this it tends to suppress density inhomogeneities. I show that this effect becomes very important close to the Dirac point, especially at low impurity densities.

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H2 DPOLY: Polymer Physics Prize Symposium Honoring Steve Granick Spirit of Pittsburgh Ballroom BC

8:00AM H2.00001 Polymer Physics Prize Talk: Polymer Mobility at Surfaces and in Confined Environments, STEVE GRANICK, University of Illinois at Urbana-Champaign — Rich new chemistry and physics emerge when one considers confined fluids, where the environment is distinctly different than in bulk. The intuition of what to expect based on bulk properties is found to break down. This talk will emphasize recent findings using a combination of single-particle imaging and fluorescence correlation spectroscopy of polymers at hard surfaces (mica), soft surfaces (phospholipid bilayers) and random network environments. A surprising dependence is found on the polymer molecular weight and concentration, as well as on the substrate makeup.

8:36AM H2.00002 Engineered Colloids Having Particles of Controlled Size, Shape, and Chemistry \textsuperscript{1}, JOSEPH DESIMONE, UNC Chapel Hill — This lecture will focus on opportunities for complex particles made using a novel “top-down” fabrication method called PRINT (Particle Replication In Non-wetting Templates). PRINT enables the production of monodisperse, shape-specific nano and micro-particles from an extensive range of organic and inorganic liquid precursors. The assembly of colloidal particles has long been a rich and continuously growing area of materials science, with great potential for a broad range of applications including electronics, control systems, optics and biotechnology. Within this field, the bulk of research has been devoted to studying the assembly of isotropic spherical particles. In spite of this, there has been a growing interest in studying the assembly of anisotropic particles due to the more complex and useful structures that these particles can potentially assemble into. There are few reports on the assembly of anisotropic particles, in part because of the lack of effective fabrication processes for the preparation of these particles with the monodispersity, control and range of compositions required for in-depth study. Herein we will discuss the use of PRINT to fabricate monodisperse, nanometer- and micron-sized particles of varying size, shape and composition. PRINT stands out because of the high degree of molding resolution, the broad range of chemistries that can be molded, and the ease with which reel-to-reel technology can be incorporated for scalability. Thus, it is ideally suited to the synthesis of unique, highly anisotropic particles in a wide range of compositions. Herein we discuss the use of dielectrophoresis to study the assembly of highly anisotropic polymer particles: rods, discs, hexnuts and boomerangs, fabricated with the PRINT process. In addition, the discussion will focus on the details and opportunities for loading shape controlled particles with magnetite and their manipulation when dispersed in various liquid media.

\textsuperscript{1}Departments of Chemistry & Pharmacology, University of North Carolina at Chapel Hill; Dept. of Chemical & Biomolecular Engineering, North Carolina State University
9:12AM H2.00003 Polymers under Cylindrical Confinement, THOMAS RUSSELL, University of Massachusetts — Anodized alumina oxide (AAO) membranes offer a unique platform to investigate polymers under confinement. AAO membranes have been prepared where the diameters of the nanopores in the membrane have been varied from 8 to 50 nm by varying the anodization conditions. Capillary force is sufficiently large to draw high molecular weight polymers into the membrane, producing either nanotubes or nanorods. Polymer solutions can also be used place a thin film on the walls of the nanopores, forming nanotubes. With pore diameters less than the radius of gyration, a quantitative understanding of perturbations to chain dynamics due to geometric constraints was examined. We found a weak molecular weight-dependent mobility of polymers confined within AAO nanopores having diameters smaller than the dimension of the chains in the bulk. The measured mobility of polymers in the confined geometry was much higher than the mobility of the unconfined chain. Rayleigh instabilities in thin polymer films confined within nanoporous alumina membranes were also found where periodic undulations on the film surface were found to increase with time, eventually bridging across the cylindrical nanopore, resulting in the formation of polymer nanorods with a periodic array of encapsulated holes. We use microphase separated block copolymers, where the characteristic period of the BCP morphology is comparable to the pore diameter, significant deviations from the bulk morphology as revealed by electron tomography. Small angle neutron scattering was also used to investigate the influence of cylindrical confinement on the order-disordered transition. This work was done in collaboration with T. J. McCarthy (UMass), K. Shin (Seoul National University), H. Jinmai (Kyoto University), D. Chen, J. Chen, H. Xiang, T. Kim, and P. Dobryalov, and was supported by the DOE, NSF MRSEC, NSF CHM.

9:48AM H2.00004 The Challenge of Understanding the “Complexity” of Polymeric Fluids and Solutions, JACK DOUGLAS, Polymers Division, National Institute of Standards and Technology — It is well known that the complexity of polymer conformational shapes makes this class of molecules prone to glass formation and that high molecular mass polymers exhibit rubbery viscoelastic flow properties associated with their topological and packing interactions. Many natural and synthetic polymers also exhibit complex associative interactions arising from the variation of chemical species and the presence of charged and polar groups within the molecule that can give rise to polymer supermolecular organization into a wide range of fragile structures at the nanoscale and larger. There are changes in both the thermodynamics and dynamics of these fluids associated with these general patterns of “complex fluid” behavior that provide a fundamental challenge for theoretical understanding so that this field remains at the frontier of materials science. The high level of regularity observed in the relatively high frequency glassy dynamics of polymer fluids, and other glass forming liquids more broadly, and in the viscoelastic properties that define chain “entanglement” in high molecular mass polymers, provides some hope for a general theoretical framework describing the complex fluid dynamics of polymeric fluids. Specifically, it is argued, and supported by evidence, that the complex fluid behavior underlying glass formation, entanglement and self-assembly in polymeric fluids all involve emergent collective behavior taking the form of supermolecular polymer structures that form and disintegrate in dynamic equilibrium. This “dynamic heterogeneity” paradigm, which is not addressed by conventional mean field theories such as the mode-coupling model of glass formation and the reptation model, provides a framework for understanding many aspects of the linear and non-linear dynamics of polymer complex fluid behavior such as stretched exponential stress relaxation, and shear thinning and “aging” following cessation of flow. It also provides a framework for understanding the influence of nanoparticles, and other additives to polymeric fluids, that modify the fluid mesoscale structure, often with significant changes in material properties.

10:24AM H2.00005 Anisotropic Self-Assembly of Nanoparticle Amphiphiles, SANAT KUMAR, Columbia University — It is easy to understand the self-assembly of particles having anisotropic shapes or interactions, such as Co nanoparticles or proteins, into highly extended structures. However, there is no experimentally established strategy for creating anisotropic structures from common spherical nanoparticles. We demonstrate that spherical nanoparticles, uniformly grafted with macromolecules, robustly self-assemble into a range of anisotropic superstructures when they are dispersed in the corresponding homopolymer matrix. This phenomenon is driven by the microphase separation between the inorganic nanoparticles and the (organic) polymeric chains grafted to their surfaces in a fashion similar to block copolymers. This microphase separation driven particle self-assembly provides a unique means of controlling the global nanoparticle dispersion state in polymer nanocomposites. The relationship between the state of particle dispersion and nanocomposite properties can thus be critically examined, and in particular we focus on the mechanical reinforcement afforded when particles are added to polymers. Grafted nanoparticles are thus versatile building blocks for creating tunable and functional particle superstructures with significant practical applications. With Pinar Akcora, Hongjun Liu, Yu Li, Brian Benicewicz, Linda Schadler, Thanos Panagiotopoulos, Jack Douglas, P. Thiyagarajan and Ralph Colby.

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H3 DBP: New Frontiers in Biomolecular Physics 301/302

8:00AM H3.00001 Are DNA transcription factor proteins Maxwellian Demons?, ALEXANDER YU. GROSBERG, New York University — This abstract is not available.

8:36AM H3.00002 The mechanism of load detection in the molecular motor myosin VI, ALEXANDER R. DUNN, Department of Biochemistry, Stanford University — Myosin VI is thought to act as both a molecular transporter and as an anchor in vivo. Recent results demonstrate that a rigid isolated alpha helix extends the myosin VI lever arm, generating an unexpectedly large stroke size of approximately 30 nm. Here we use single-molecule fluorescence, optical trapping, and gold nanoparticle tracking to examine the role of the lever arm extension in both myosin VI translocation and anchoring. Our results suggest that the rigidity of this unusual structural element plays an essential role in load-induced anchoring.

9:12AM H3.00003 Full Counting Statistics for Brownian Sieves and Brownian Molecular Machines, R. DEAN ASTUMIAN, University of Maine — A Brownian sieve is a spatially periodic microstructured device that combines the effects of thermal noise, local spatial asymmetry, and external forces to separate particles based on their transport properties. By treating the motion of an individual particle as a cyclical process in which the particle fluctuates away from and returns to the origin of some unit cell I derive generalized fluctuation-dissipation and reciprocal relations for the averages (for all moments) of the number of periodic displacements that are exact and valid for arbitrary values of the external forces. These relations hold not only for Brownian sieves, but for all molecular machines in which a nanoscale system couples two chemical, mechanical, or transport processes by a cycle in which the molecular machine itself fluctuates away from, and then returns to some arbitrary reference state, in the process doing or receiving work in an environment.

9:48AM H3.00004 Theory of protein misfolding and applications to misfolding diseases, STEVEN S. PLOTKIN, Department of Physics and Astronomy, University of British Columbia — Physics-based algorithms can predict the misfolding mechanisms of proteins involved in aggregation-related diseases, including ALS and the Prion diseases. Predictions based on such an algorithm that we have developed, which employs both atomistic interactions and surface-area based coarse-graining, have been recently verified by immunological assays and point to diagnostic and therapeutic applications. I will describe the results of our misfolding theory, and discuss future directions towards drug research.
10:24AM H3.00005 Theoretical methods for engineering protein structure and function. JEFFERY G. SAVEN, Department of Chemistry, University of Pennsylvania — Designing and engineering proteins provides ways to probe the determinants of folding, to facilitate their study, and to arrive at novel molecules, materials and nanostructures. Recent computational methods for identifying the properties of proteins consistent with a desired structure and function will be discussed. Computationally designed protein-based molecular systems will be presented, including proteins tailored to accommodate nonbiological cofactors and their novel functional properties.

Tuesday, March 17, 2009 8:00AM - 10:24AM –
Session H4 DCMP: New Developments in Heavy Electron Superconductivity 306/307

8:00AM H4.00001 New developments in our understanding of superconductivity in the 115 materials1, TUSON PARK, Los Alamos National Laboratory / Sungkyunkwan University — Is a quantum critical point (QCP) pertinent to unconventional superconductivity? There are several heavy-fermion compounds in which unconventional superconductivity emerges in proximity to a spin-density-type quantum-critical point (1). The absence of superconductivity in prime candidates for a local or Kondo-breakdown quantum criticality, however, raises the question of whether this type of criticality could benefit superconductivity (2). Using the heavy-fermion antiferromagnet CeRhIn5 as an example (3), we present the first evidence that critical modes associated with the Kondo-breakdown criticality can provide a new route to unconventional superconductivity. At a local QCP, accessed by applied pressure, magnetic and charge fluctuations coexist and produce electronic scattering that is maximal at the optimal pressure for unconventional superconductivity. References: (1) Mathur et al., Nature 394, 39 (1998); Monthoux et al., Nature 450, 1177 (2007). (2) Gegenwart et al., Nat. Phys. 4, 186 (2008). (3) T. Park et al., Nature 440, 65 (2006); T. Park et al. Proc. Nat. Acad. Sci. 105, 6825 (2008).

1Work at Los Alamos National Laboratory was performed under the auspices of the US Department of Energy, Office of Science.

8:36AM H4.00002 Unconventional superconductivity of NpPd5Al2, DAI AOKI, CEA-Grenoble — The 5f electrons in actinide compounds has an intermediate character between the 4f-localized state and the 3d-itinerant state. This leads to a variety of exotic phenomena, such as non-Fermi liquid behavior, multipole ordering, broken state order and unconventional superconductivity. The discovery of superconductivity in PuCoGa5 and PuRhGa5 with high critical temperatures provides a new perspective on the physics of actinides compounds. It is generally believed that Np compounds have more 5f-related character features like d-electron metals compared with U compounds. In fact, the results of dhYAs experiments in Np-115 compounds are in good agreement with the 5f-itinerant band model. However, the complicated magnetic properties in Np-115 are well explained by the mean field theory including the orbital ordering based on the 5f-localized model. This indicates the dual nature of 5f electrons. NpPd5Al2 is the first Np-based heavy fermion superconductor with the ZrNiAl-type tetragonal structure. The superconductivity was found below Tc = 5 K. The non-Fermi liquid behavior and the large specific heat coefficient (γ ≈ 200 mJ/K2mol) were detected. The upper critical field Hc2 at 0 K is large and highly anisotropic: 37 kOe for H || [100] and 143 kOe for H || [001]. Hc2 is strongly suppressed by the magnetic field in the Hc2–T phase diagram for both field direction, indicating the strong Pauli paramagnetic effect. The d-wave spin-singlet superconductivity is most likely realized. The large specific heat jump ΔC/γTc ≈ 2.33 suggests the superconductivity with strong coupling. The results are compared with the well known heavy fermion superconductor CeCoIn5.

9:12AM H4.00003 Heavy electrons and symplectic symmetry of a spin1, MAXIM DZEROTO, Rutgers University — Motivated by the recent discovery of the heavy fermion materials NpPd5Al2 [1] and PuCoGa5 [2] which transform directly from Curie paramagnets into superconductors, we have developed a novel theory of these materials based on the idea of composite pairing between local moments and electron pairs. This talk will discuss a simple model of this kind of pairing that can be solved exactly in a large-N limit [3]. The talk will discuss how this concept enables us to understand the giant entropy of condensation, the symmetry of the order parameter as well as an enhancement of the Andreev reflection in tunneling measurements and an upturn in the NMR relaxation rate above Tc. Park et al. Proc. Nat. Acad. Sci. 105, 6825 (2008).

1This work was funded by NSF grant DMR 0605935.

9:48AM H4.00004 Quantum Criticality and Superconductivity in β-YbAlB4, SATORU NAKATSUJI, University of Tokyo — Heavy fermion systems have provided a number of prototypical compounds to study unconventional superconductivity and non-Fermi-liquid (NFL) states. A long standing issue in the research of heavy fermion superconductivity in 4f intermetallics is the dramatically different behavior between the electron like Ce (4f1μ) and hole like Yb (4f11+) compounds. While superconductivity has been found in a number of Ce based heavy fermion compounds, no superconductivity has been reported for the corresponding Yb systems. In this talk, I present our recent finding of the superconductivity in the new heavy fermion system β-YbAlB4 [1–3]. The superconducting transition temperature is 80 mK, and above it, the system exhibits pronounced NFL behavior in the transport and thermodynamic properties [2,3]. Furthermore, the magnetic field dependence of the NFL behavior indicates that the system is a rare example of a pure metal that displays quantum criticality at ambient pressure and under zero magnetic field. Using our latest results, we discuss the detailed properties of superconductivity and quantum criticality. This is the work performed in collaboration with K. Kuga, Y. Matsumoto, T. Tomita, Y. Machida, T. Tayama, T. Sakakibara, Y. Karaki, H. Ishimoto, S. Yonezawa, Y. Maeno, E. Pearson, G. G. Lonzarich, L.Balicas, H. Lee, and Z. Fisk.

Tuesday, March 17, 2009 8:00AM - 11:00AM –
Session H5 FIAP FGSA: Physicists as Entrepreneurs 401/402

8:00AM H5.00001 From a PhD in Physics to Manufacturing Carbon Nanotubes, XINDI WU, C Nanotechnology — No abstract available.
8:36AM H5.00002 Building an R&D Based Company, R.D. VISPUTE, Blue Wave Semiconductors, Inc. — Entrepreneurship is the wellspring of innovation and the ability to seek out opportunities and turn them to profitable businesses. It is also closely associated with desire to succeed with taking risk. According to the U.S. Small Business Administration, entrepreneurs are major contributors to our economy. Entrepreneurs are also major employers, as small businesses generate 60-80 percent of all new jobs annually. It is agreed that small businesses are one of the key engines of economy and growth by contributing to employment creation. In this regard, having your own business is regarded as one of the most respectable pathways to prosperity and fulfillment. While some strike success the first time around, most successful entrepreneurs overcome several hurdles before succeeding. In my talk I will present my experience in starting my technology based company. “Blue Wave Semiconductors, Inc.” I will focus on opportunities as well as numerous factors faced as the small technology start-up including finance, access to Small Business Innovation Research (SBIR), identifying market, managerial skills, team and infrastructure development. Also, I will highlight some of the important factors such as perseverance, independence, ingenuity, confidence and the determination to overcome barriers for eventual success. If you are sitting on a great idea that can possibly create a good technology business and you don’t know where to start, then this talk will be helpful for getting your dream closer and resolving your risk factors for great rewards.

9:12AM H5.00003 Lessons Learned as a Serial Technology Entrepreneur, NICHOLAS ECONOMOU, Carl Zeiss SMT — Starting a new technology company can be an exciting experience, and can, on occasion, be financially lucrative as well. Aside from the obvious requirement to have some new technology to offer, the main impediment to making the leap is usually fear of unknown. This arises from several real issues: a) you don’t know how to do it; b) you assume the new situation will be less secure; c) you have to give up progress along your current career path; d) you fear failure itself, and how it will reflect on you as a person. There is no easy way to resolve these concerns, and although talking with others who have done it is helpful, the final decision is always difficult and very personal. Assuming you decide to go forward, there are some simple rules that will help along the way: 1. Have a PRODUCT idea, not just an innovative technology: it’s a business, not a way to continue interesting research. 2. Team up with experienced people in certain (not all) key jobs. The specifics depend on what your own skills are. 3. Make sure you have adequate funding at the outset to achieve some significant milestones. 4. Be selective about who funds you: they will be your business partners and will have a lot to say about what happens. 5. Start thinking about the liquidity/exit strategy from day one. The stories of how other companies were started and developed are good background information. Several of these from my own experiences will be discussed. They include a company that struggled for many years but ultimately went public and was successful, one that was quickly a success and was acquired, one that was an outright failure and two that continue on but with dubious prospects of success. Some thoughts on what went right or wrong, and what could have been done better will be presented.

9:48AM H5.00004 My experience with Bandwidth9, CONNIE CHANG-HASNAIN, University of California, Berkeley — No abstract available.

10:24AM H5.00005 The Roller Coaster Ride of an Entrepreneur, ZHIYUN CHEN, Pixelligent Technologies LLC — No abstract available.

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H6 DCMP DAMOP: Quench Dynamics and Thermalization in Quantum Systems 406

8:00AM H6.00001 Eigenstate Thermalization Hypothesis and Quantum Thermodynamics1, MAXIM OLSHANII2, University of Massachusetts Boston — One of the open questions in quantum thermodynamics reads: how can linear quantum dynamics provide chaos necessary for thermalization of an isolated quantum system? To this end, we perform an ab initio numerical analysis of a system of hard-core bosons on a lattice and show [Marcos Rigol, Vanja Dunjko & Maxim Olsnianii, Nature 452, 854 (2008)] that the above controversy can be resolved via the Eigenstate Thermalization Hypothesis suggested independently by Deutsch [J. M. Deutsch, Phys. Rev. A 43, 2046 (1991)] and Srednicki [M. Srednicki, Phys. Rev. E 50, 888 (1994)]. According to this hypothesis, in quantum systems thermalization happens in each individual eigenstate of the system separately, but it is hidden initially by coherences between them. In course of the time evolution the thermal properties become revealed through (linear) decoherence that needs not to be chaotic.

1Supported by NSF and ONR.
2in collaboration with Marcos Rigol and Vanja Dunjko

8:36AM H6.00002 Microscopic diagonal entropy and many-body dynamics1, ROMAN BARANKOV, Boston University — We define microscopic diagonal entropy to characterize many-body dynamics of systems far from equilibrium. For the systems prepared initially in thermal equilibrium, it increases with time and is related to the heat generated in the dynamics. We illustrate our results with numerical simulations of a toy-BCS model.

1AFOSR YIP

9:12AM H6.00003 Statistics of the Work done in a Quantum Quench, ALESSANDRO SILVA, Abdus Salam ICTP — The quantum quench, i.e. a rapid change in time of a control parameter of a quantum system, is the simplest paradigm of non-equilibrium process, completely analogous to a standard thermodynamic transformation. The dynamics following a quantum quench is particularly interesting in strongly correlated quantum systems, most prominently when the quench in performed across a quantum critical point. In this talk I will present a way to characterize the physics of quantum quenches by looking at the statistics of a basic thermodynamic variable: the work done on the system by changing its parameters [1]. I will first elucidate the relation between the probability distribution of the work, quantum Jarzynski equalities, and the Loschmidt echo, a quantity that emerges usually in the context of dephasing. Using this connection, I will then characterize the statistics of the work done on a Quantum Ising chain by quenching locally or globally the transverse field. I will then show that for global quenches the presence of a quantum critical point results in singularities of the moments of the distribution, while, for local quenches starting at criticality, the probability distribution itself displays an interesting edge singularity. The results of a similar analysis for other systems will be discussed.

9:48AM H6.00004 ABSTRACT WITHDRAWN —

10:24AM H6.00005 ABSTRACT WITHDRAWN —

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H7 DBP: Cellular Imaging at the Nanometer Scale 407
Depletion (STED) microscopy where the spot diameter follows states and transitions of the fluorescent marker to neutralize the limiting role of diffraction. The first viable concept of this kind was Stimulated Emission barrier in far-field fluorescence microscopy. To set the scene for future directions, I will show that all these concepts share a common strategy: exploiting selected microscopy, the 3D-imaging of the interior of (live) cells requires the use of focused visible light. I will discuss new developments of optical microscopy that numerical aperture of the lens and λ. Dep. of NanoBiophotonics — The resolution of a far-field optical microscopy is usually limited to d ≈ 414/415, W. E. MOERNER, Stanford University — In the two decades since the first optical detection and spectroscopy of a single molecule in a solid (Phys. Rev. Lett. 62, 2535 (1989)), much has been learned about the ability of single molecules to probe local nanoenvironments and individual behavior in biological and nonbiological materials in the absence of ensemble averaging that can obscure heterogeneity. The early years concentrated on high-resolution spectroscopy in solids, which provided observations of lifetime-limited spectra, optical saturation, spectral diffusion, optical switching, vibrational spectra, and magnetic resonance of a single molecular spin. In the mid-1990’s, much of the field moved to room temperature, where a wide variety of biophysical effects were subsequently explored, but it is worth noting that several features from the low-temperature studies have analogs at high temperature. For example, in our first studies of yellow-emitting variants of green fluorescent protein (EYFP) in the water-filled pores of a gel (Nature 388, 355 (1997)), optically induced switching of the emission was observed, a room-temperature analog of the earlier low-temperature behavior. Because each single fluorophore acts a light source roughly 1 nm in size, microscopic imaging of individual fluorophores leads naturally to superresolution, or determination of the position of the molecule with precision beyond the optical diffraction limit (i.e., by discrimination of the point-spread function from the single emitter). Recent work has allowed measurement of the shape of single filaments in a living cell simply by allowing a single molecule to move through the filament (PNAS 103, 10929 (2006)). The additional use of photoswitched control of single-molecule emission allows imaging beyond the diffraction limit (superresolution) by several novel approaches proposed by different researchers. For example, using photoswitchable EYFP, a novel protein superstructure can now be directly imaged in a living bacterial cell at sub-40nm resolution (Nat. Meth. 5, 947 (2008)). These important advances provide the impetus for the further development of both new imaging schemes with 3-D capability as well as invention of new photoswitchable single-molecule emitters for use in polymers and in biological systems (JACS 130, 9204 (2008); J. Phys. Chem. B 112, 11878 (2008)).

Depletion (STED) microscopy where the spot diameter follows d ≈ 414/415, STEFAN HELL, Max Planck Institute for Biophysical Chemistry/Dep. of NanoBiophotonics — The resolution of a far-field optical microscopy is usually limited to d = λ/(2n sin α) ≈ 200 nm, with n sin α denoting the numerical aperture of the lens and λ the wavelength of light. While the diffraction barrier has prompted the invention of electron, scanning probe, and x-ray microscopy, the 3D-imaging of the interior of (live) cells requires the use of focused visible light. I will discuss new developments of optical microscopy that I anticipate to have a lasting impact on our understanding of living matter. Emphasis will be placed on physical concepts that have overcome the diffraction barrier in far-field fluorescence microscopy. To set the scene for future directions, I will show that all these concepts share a common strategy: exploiting selected states and transitions of the fluorescent marker to neutralize the limiting role of diffraction. The first viable concept of this kind was Stimulated Emission Depletion (STED) microscopy where the spot diameter follows d ≈ λ/(2n sin α(1 + I/I0)), I/I0 is a measure of the strength with which the molecule is send from the fluorescent state to the dark ground state. For I/I0 → ∞ it follows that d → 0, meaning that the resolution that can, in principle, be molecular. The concept underlying STED microscopy can be expanded by employing other transitions that shuffle the molecule between a dark and a bright state, such as (i) shelving the fluorophore in a dark triplet state, and (ii) photoswitching between a ‘fluorescence activated’ and a ‘fluorescence deactivated’ conformational state. Examples for the latter include photochromic organic compounds, and fluorescent proteins which undergo a cis-trans photoisomerizations. Photoswitching provides ultrahigh resolution at ultralow light levels. Switching can be performed in an ensemble or individually in which case the image is assembled molecule by molecule at high resolution. By providing molecular markers with the appropriate transitions, synthetic organic chemistry and protein biotechnology plays a key role in this endeavor. Besides being a fascinating development in physics, far-field optical “nanoscopy” is highly relevant to the life sciences. In fact, it has already been a key to answering important questions in biology [1, 2]. Due to its simplicity and improving performance, I expect far-field optical nanoscopy to enter virtually every cell biology laboratory in the near future.

References:
Formation, GEOFFREY POORE, Department of Physics, University of Illinois at Urbana-Champaign, SUSAN KIEFFER, Department of Geology, sensitive to these initial conditions, while the Hack exponent and hypsometry show little or no sensitivity. The results suggest that initial conditions deserve systematically studied. We used simulations of a stream power law, with initial conditions consisting of a flat or sloping surface combined with random dynamics. Previous research suggests that river network scaling and geomorphic properties may be sensitive to initial conditions, but this has not been.

2 normal diffusion to superdiffusion. That reaction fronts in this system typically pin to moving vortices. We explore any changes in front propagation behavior when the transport changes from forcing protocol. We find that the network with the oscillatory reaction synchronizes if the mixing is superdiffusive with long-range connections. We also find networks of branching angle and branching ratio for up to 10 branching generations. Both optimal angle and optimal ratios are found to be decreasing functions of or minimize expenditure of energy for different fixed numbers of absorbers. For constant salinity absorbers, we give the total water production rate as functions of having the same pressure difference across the absorbers, ii) all nodes producing permeate at identical rates, and iii) each node having the same salinity. Optimal criteria. Using the analogy to electrostatics, the diffusion equation is solved for the desalination systems under three different boundary conditions, i) all nodes introduced as Iterated Function Systems (IFS) to optimally design networks for efficient reverse osmosis desalination in deep seawater. Ramified flow networks and synchronization in an advection-reaction-diffusion system. The reaction is either the excitable or oscillatory Belousov-Zhabotinsky chemical reaction, and the flows is an array of annular chain of vortices forced using magnetohydrodynamic techniques. The reaction in each vortex acts as a node in a complex fluid network, and communication between these nodes is via chaotic mixing. Mixing in this system is either diffusive (enhanced) or superdiffusive, depending on the forcing protocol. We find that the network with the oscillatory reaction synchronizes if the mixing is superdiffusive with long-range connections. We also find that reaction fronts in this system typically pin to moving vortices. We explore any changes in front propagation behavior when the transport changes from normal diffusion to superdiffusion.

8:00AM H8.00001 Devastation and Renewal: Water, Air and Land in Pittsburgh Environmental History, JOEL TARR, Carnegie Mellon University — This talk will focus on the metabolism of cities as a concept through which to view the environmental history of Pittsburgh. In many ways, the history of Pittsburgh, perhaps more than that of any other city in the nation, reflects the impact of industrialism and of urban infrastructure on environmental quality. The talk will explore these effects and attempts at remediation through a slide lecture that will examine three domains: water supply and wastewater disposal; smoke and air pollution; and land contamination.

8:36AM H8.00002 Air Quality from Early Pittsburgh to the Present: The Science of Change, CLIFF DAVIDSON, Carnegie Mellon University — Throughout Pittsburgh's history over the past 250 years, coal reserves in the city and nearby have influenced its economy, demographics, and environmental quality. They have also played a major role in determining air quality in the region. For example, Pittsburgh became famous for its high particle loadings as early as the beginning of the nineteenth century, when the first complaints about air quality in the city were recorded. Nevertheless, residents tolerated the high coal smoke levels since jobs depended on the iron works, steel mills, and other industries. When natural gas was discovered just east of the city in the 1870's and replaced coal for some applications, particle concentrations decreased. But the local supplies of natural gas ran short several years later, and as industry continued to expand in the 1890’s the city went back to the use of coal as its primary fuel. The return to smoky air was met with resistance that marked the beginning of sustained public outcry and initiation of several air pollution studies. The next half century was marked by periods of occasional high and low concentration, the latter due to events such as the financial panic of 1907 and the depression of the 1930’s. It was not until the 1940’s that effective regulations were passed to reduce smoky conditions. Particle levels fell throughout the 1950’s and 1960’s, and eventually the decline of heavy industry in Pittsburgh led to relatively clean air in many parts of the city. Over the past few decades, airborne particle concentrations averaged across the Pittsburgh region have remained below their earlier levels. However, there are still "hot spots" of high concentration resulting from regional background coming from upwind areas and emissions of some large sources that have continued to operate in the Pittsburgh region. Furthermore, the composition of airborne particles in the city has changed from earlier times. Such particles are now the result of emissions from sources in upwind states, greater numbers of mobile sources, and the influence of control technologies that remove certain classes of pollutants but not others.

9:12AM H8.00003 Material Science and Construction, ALAN TRAUGOTT, CLJ Engineering — We will review the new materials and technologies that are being applied in the construction of high performance (green) buildings to improve energy efficiency, Indoor Air and Environmental Quality, water conservation and reclamation, and resource conservation. We present an introduction to state-of-the-art building concepts, including “Net-Zero” buildings, which generate as much energy as they use, reclaim water, and minimize waste; and “Waste as Resource,” including waste to energy plants, biofuels, materials reclamation and recycling. The role of advanced materials and technologies, such as spectrally selective glazing, photocatalytic concrete, solar heating and cooling, and organic solar collectors will be discussed. We also give an overview of advanced analytic tools used in building design, including Computational Fluid Dynamics, energy, and lighting/daylighting computer-based simulation programs.

9:48AM H8.00004 The Greening of the David L. Lawrence Pittsburgh Convention Center, MARK LEAHY, The Lawrence Convention Center — The David L. Lawrence Convention Center is the largest Gold LEED NC (new construction) certified convention center in the USA and the first of its kind in the world. The designation has been awarded by the United States Green Building Council through its Leadership in Energy and Environmental Design (LEED) Green Building Rating System. In this talk we discuss the unique green properties of this 1.5 million square foot Convention Center including the design and use of daylight, natural ventilation and other sustainable design and practices. No other building the size of the Convention Center (1.5 million square feet), uses natural ventilation or can illuminate an exhibition hall entirely through its windows and skylights. Approximately 75% of the convention center’s exhibition space is lit by natural daylight. The use of natural ventilation and extensive day lighting is designed to reduce energy consumption by nearly 35% compared to traditional ventilated and lit buildings of a similar size.

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H9 GSNP: Complex Networks and Their Applications 303

8:00AM H9.00001 Dependence on Initial Conditions in a Numerical Model of River Network Formation, GEOFFREY POORE, Department of Physics, University of Illinois at Urbana-Champaign, SUSAN KIEFFER, Department of Geology, University of Illinois at Urbana-Champaign — We investigated the effect of initial conditions on river network formation, using a simple model of erosional dynamics. Previous research suggests that river network scaling and geomorphic properties may be sensitive to initial conditions, but this has not been systematically studied. We used simulations of a stream power law, with initial conditions consisting of a flat or sloping surface combined with random fluctuations in elevation, and considered dependence of steady-state solutions on initial slope and randomness. The sinuosity exponent and the sinuosity are sensitive to these initial conditions, while the Hack exponent and hypsometry show little or no sensitivity. The results suggest that initial conditions deserve greater consideration in attempts to understand the emergence of scaling in river networks.

8:12AM H9.00002 Optimization of Ramified Flow Networks, MARTIN SINGLETON, ALFRED HUBLER, Department of Physics, UIUC, GREGOR HEISS, Institut fuer physikalische Chemie, Ludwig Maximilians Universitaet Muenchen — A class of Ramified graphs (RG) is introduced as Iterated Function Systems (IFS) to optimally design networks for efficient reverse osmosis desalination in deep seawater. Ramified flow networks of absorbers, ranging from simple structures with constant weights, branch angles, and branch ratios, to fully optimized binary networks are considered. A contracting IFS with fixed overall length is presented for the generation of RG’s which serve as candidates for optimality in terms of desalination performance criteria. Using the analogy to electrostatics, the diffusion equation is solved for the desalination systems under three different boundary conditions, i) all nodes having the same pressure difference across the absorbers, ii) all nodes producing permeate at identical rates, and iii) each node having the same salinity. Optimal branching angles and branch length ratios will be found by phase-space methods for each boundary condition, which either maximize production of permeate or minimize expenditure of energy for different fixed numbers of absorbers. For constant salinity absorbers, we give the total water production rate as functions of branching angle and branching ratio for up to 10 branching generations. Both optimal angle and optimal ratios are found to be decreasing functions of generation for constant salinity absorbers.

8:24AM H9.00003 Reaction fronts and synchronization in ordered and disordered vortex networks, TOM SOLOMON, GARRETT O’MALLEY, JUSTIN WINOKUR, Bucknell University — We present experimental studies of front propagation and synchronization in an advection-reaction-diffusion system. The reaction is either the excitable or oscillatory Belousov-Zhabotinsky chemical reaction, and the flows is an array of annular chain of vortices forced using magnetohydrodynamic techniques. The reaction in each vortex acts as a node in a complex fluid network, and communication between these nodes is via chaotic mixing. Mixing in this system is either diffusive (enhanced) or superdiffusive, depending on the forcing protocol. We find that the network with the oscillatory reaction synchronizes if the mixing is superdiffusive with long-range connections. We also find that reaction fronts in this system typically pin to moving vortices. We explore any changes in front propagation behavior when the transport changes from normal diffusion to superdiffusion.

for evaluating the link partitions is also introduced. As a set of (related) links. We show how this alternative viewpoint incorporates significant aspects including overlapping communities. A quantitative framework for the problem of community detection in complex networks. Rather than defining a community as a set of densely interconnected nodes, we define a community as a family of novel fat-tail random matrix ensembles characterized by a parameter \( \lambda \). We show that the eigenvalue spectrum can be used as a tool to detect SD in real-life networks. We illustrate this ability for the eigenvalue spectrum of a spatially dependent polymeric gel.

A family of fat-tail random matrix ensemble, JIMMY CHO, K.A. MUTTALIB — We present a family of novel fat-tail random matrix ensembles characterized by a parameter \( \lambda \). We show that the eigenvalue densities of the ensembles exhibit a power law distribution. In particular, for \( \lambda > 1 \), the tail of the distribution is bounded, whereas for \( \lambda < 1 \), the distribution has a fat tail. In the limit \( \lambda = 1 \), the ensembles reduce to the GOE and critical ensemble. We evaluate the eigenvalue correlations in terms of a novel family of orthogonal polynomials that are generalizations of the q-Hermite polynomials. We show that the two-level correlation of the novel fat-tail ensemble is qualitatively different from that of either the Gaussian or the critical ensemble.

Poisson vaccination for epidemic control in adaptive social networks, LEAH SHAW, College of William and Mary, IRA SCHWARTZ, Naval Research Laboratory — We study an epidemic model for disease spread on an adaptive network modeling avoidance behavior. Individuals are assumed to adapt their social behavior to minimize their risk of disease. Non-infected nodes rewire their connections away from infected nodes to connect instead to other non-infected nodes, and the disease follows an SIS (susceptible-infected-susceptible) dynamics. We add Poisson distributed vaccination of susceptibles. Effects of the vaccination frequency and amplitude are studied in the full system and compared to a mean field theory. Disease extinction rates using vaccination are found for both adaptive and static networks. We show that vaccine control is much more effective in adaptive networks than in static networks due to an interaction between the rates of adaptive network rewiring and vaccine application.

Epidemics in Complex Networks: The Diversity of Hubs, MAKSIM KITSK, Boston University, LAZAROS K. GALLOS, The City College of New York, SHLOMO HAVLIN, Bar-Ilan University, H. EUGENE STANLEY, Boston University, HERNAN A. MAKSE, The City College of New York — Many complex systems are believed to be vulnerable to spread of viruses and information owing to their high level of interconnectivity. Even viruses of low contagiousness easily proliferate the Internet. Rumors, fads, and innovation ideas are prone to efficient spreading in various social systems. Another commonly accepted standpoint is the importance of the most connected elements (hubs) in the spreading processes. We address following questions. Do hubs conduct epidemics in the same manner? How does the epidemics spread depend on the structure of the network? What is the most efficient way to spread information over the system? We analyze several large-scale systems in the framework of of the susceptible-infected-susceptible (SIR) disease spread model which can also be mapped to the problem of rumor or fad spreading. We show that hubs are often ineffective in the transmission of virus or information owing to the highly heterogeneous topology of most networks. We also propose a new tool to evaluate the efficiency of nodes in spreading virus or information.

Prevalence of and Epidemic Spreading on Hierarchical Networks, JIANKUI HE, Department of Physics & Astronomy, Rice University, Houston, TX, 77005, USA, MICHAEL DEEM, Department of Physics & Astronomy, Department of Bioengineering, Rice University, Houston, TX, 77005, USA, MICHAEL W. DEEM TEAM — Recent studies show that real networks are organized in a modular or even hierarchical fashion. However, there is no clear mathematical definition of hierarchy and current studies do not tell us the degree to which a network is hierarchical. In this talk, we will discuss a quantitative measurement of hierarchy. We find that networks of protein interactions, metabolic pathways, electronic circuits, power grids, and email display strong hierarchy compared with networks generated at random or scale free networks of the Barabasi-Albert model. Further, we investigated the spread of virus in hierarchical networks. Viral spread on hierarchical networks displays quite different pattern from scale free and random networks.

Understanding the spreading patterns of mobile phone viruses, PU WANG, MARTA GONZALEZ, CESAR HIDALGO, ALBERT-LASZLO BARABASI — Mobile viruses are little more than a nuisance today, but given our increased reliance on wireless communication, in the near future they could pose more risk than their PC based counterparts. Despite of the more than three hundred mobile viruses known so far, little is known about their spreading pattern, partly due to a lack of data on the communication and travel patterns of mobile phone users. Starting from the traffic and the communication pattern of six million mobile phone users, we model the vulnerability of mobile communications against potential virus outbreaks. We show that viruses exploiting Bluetooth and multimedia messaging services (MMS) follow markedly different spreading patterns. The Bluetooth virus can reach all susceptible handsets, but spreads relatively slowly, as its spread is driven by human mobility. In contrast, an MMS virus can spread rapidly, but because the underlying social network is fragmented, it can reach only a small fraction of all susceptible users. This difference affects both their spreading rate, the number of infected users, as well as the defense measures one needs to take to protect the system against potential viral outbreaks.

Partitioning Links: A New Approach to Communities in Complex Networks, JAMES BAGROW, YONG-YEOL AHN, SUNE LEHMANN, ALBERT-LASZLO BARABASI, Northeastern University — We propose a new viewpoint for the problem of community detection in complex networks. Rather than defining a community as a set of densely interconnected nodes, we define a community as a set of (related) links. We show how this alternative viewpoint incorporates significant aspects including overlapping communities. A quantitative framework for evaluating the link partitions is also introduced.
analysis of their localization both in the $z$ and $(\text{In},\text{Ga})\text{As}$ quantum dots, using a multi-band atomistic pseudopotential approach. We offer a classification of both hole and electron states based on an approximation.

exhibit a large oscillator strength in optical absorption. We calculate oscillator strengths for various optical transitions in the framework of the effective mass paradox according to which some of the optical transitions in PbSe and PbS semiconductor nanocrystals seemingly forbidden by the parity selection rule.

tals: Drastic effect of structure inversion asymmetry, SERGUEI GOUPALOV

The observation of biexciton Stokes shift underpins the physics of optical gain in quantum dots. We report on the first observation of a biexciton Stokes shift, which we will discuss in terms of non-Aufbau filling and biexciton fine structure. The spectrum of the biexciton has remained elusive due to the ultrafast timescale of relaxation processes in quantum dots which mask observation of the excited states. Here, we show the first, direct observation of spectrum of states of the biexciton, completing the analogy of excitons in quantum dots to atomic and molecular systems. We report on the first observation of a biexciton Stokes shift, which we will discuss in terms of non-Aufbau filling and biexciton fine structure. The observation of biexciton Stokes shift underpins the physics of optical gain in quantum dots.

The speed at which information travels from one site to another in a complex system is largely determined by the number of short-cuts within the network topology. It remains an important open question how to optimize the connectivity of the links in the network structure to minimize the travel time. Here we show that ideas taken from renormalization group theory applied to complex self-similar networks are essential to define distinct regimes of information flow within the network. We find that networks that are human decision based such as the WWW are sufficiently randomized to give a topology that is close to optimal. On the other hand, biological evolution-based networks show evidence of clear sign of a modular deterministic structure shaped by evolution showing suboptimal large-world character which may be even so as a mean of protection, preservation and conservation.

ditmate to understanding the physics of quantum dots. Patanjali Kambham-Pati, Samuel Sewall, Ryan Cooney, McGill University — Confinement of carriers in quantum dots results in hydrogenic like states for the exciton. Thus a single excitation in a quantum dot bears resemblance to a hydrogen atom; these materials are often referred to as “artificial atoms.” A pair of excitons will form a four body bexciton, akin to a helium atom. The excitonic $^2$He atom should have an eigenstate spectrum in the $\text{He}$ atomic orbitals. The eigenstate spectrum of the bexciton has remained elusive due to the ultrafast timescale of relaxation processes in quantum dots which mask observation of the excited states. Here, we show the first, direct observation of spectrum of states of the bexciton, completing the analogy of excitons in quantum dots to atomic and molecular systems. We report on the first observation of a bexciton Stokes shift, which we will discuss in terms of non-Aufbau filling and bexciton fine structure. The observation of bexciton Stokes shift underpins the physics of optical gain in quantum dots.

Coherent Optical Phenomena in Quantum Dots, DUNCAN G. STEEL, University of Michigan — The quantum confinement provided by a semiconductor quantum dot suppresses much of the many body physics associated with the coherent nonlinear optical response observed in higher dimensional systems. This makes them attractive for potential device applications where atomic like properties, such as high $Q$ resonances, strong optical interactions, or long quantum coherence times, could be important. In this talk, we present recent results demonstrating high field effects beyond Rabi oscillations including the Mollow absorption spectrum showing gain without inversion, dark state formation in single electron doped dots, and suppression of nuclear fluctuations by the hyperfine interaction leading to longer electron spin coherence times.

Creating an artificial periodic table using quantum dots, PATANJALI KAMHBAM-PATI, SAMUEL SEWALL, RYAN COONEY, McGill University — Confinement of carriers in quantum dots results in hydrogenic like states for the exciton. Thus a single excitation in a quantum dot bears resemblance to a hydrogen atom; these materials are often referred to as “artificial atoms.” A pair of excitons will form a four body bexciton, akin to a helium atom. Patterns of behavior in an online community, LAZAROS GALLOS, Levich Institute, City College of New York, DIEGO RYBSTKI, FREDRIK LILJEROS, SHLOMO HAVLIN, HERNAN MAKSE — Human behavior can be seen as the expression of inherent motives. Despite the diverse range of these motives, social theorists have long identified a small number of distinct underlying mechanisms, where, consciously or unconsciously, every individual tries to exploit a different aspect of social interactions and/or optimize the efficiency of certain procedures for the benefit of the society or for personal gain. Here we show that users in an online community follow certain behavioral patterns and the choice of their favorite members is far from a random process. More importantly, these patterns are systematically modified with time as a member becomes more involved in such a community. We are able to identify a crossover in the average behavior of the members when their favorites list exceeds roughly 10 favorites. Additionally, this process allows us to identify individuals with a markedly different behavior than the average person. This study can help us understand the process of establishing friendships and the motives behind this process.

The appearance of localized resonances above the continuum in quantum dots, VOICU POPESCU, National Renewable Energy Lab, Golden CO, GABRIEL BESTER, Max Planck Institute for Solid State Research, Stuttgart, Germany, ALEX ZUNGER, National Renewable Energy Lab, Golden CO — We investigate the nature of hole and electron states in self-assembled InAs/GaAs and (In,Ga)As quantum dots, using a multi-band atomistic pseudopotential approach. We offer a classification of both hole and electron states based on an analysis of their localization both in the $z$ and $xy$-directions. We show that the coherent dot-matrix strain present in self-assembled quantum dots distorts the electron confining potential, creating "wings" in the vicinity of the dot. This results in the appearance of dot-confined electronic states that lie above the continuum of the matrix material. The spectroscopic manifestation of these resonant states is investigated, by calculating the inter-band as well as the intra-band absorption spectra. We find, in both cases, that clear finger-prints of the resonances appear, in the form of sharp, well-defined peaks. In contrast, the previously suggested "cross-transitions" between wetting-layer states and dot states are shown to disappear once realistic strain is included.

9:12AM H10.00005 Effect of Atomic-Scale Alloy Randomness on the Optical Polarization of Semiconductor Quantum Dots\textsuperscript{1}. VLAGAN MLINAR, ALEX ZUNGER, National Renewable Energy Lab., Golden, CO 80401 — Alloyed Ga\textsubscript{x} In\textsubscript{1-x} As system consists of different random assignments \( \sigma \) of the Ga and In atoms to the cation sublattice sites; each configuration having, in principle, distinct physical properties. For self-assembled dots made of finite number of cations \((\lesssim 10^3)\), self-averaging of configurations may not be complete, so single-dot spectroscopy can observe the atomic-scale alloy randomness effects. We examine the effect of such atomic-scale randomness on the fine structure-splitting (FSS) of the exciton observed via the polarization anisotropy of its components. We find: (i) The FSS of the monoelecton X\textsuperscript{1}\textsuperscript{+} changes by more than a factor of 7 with \( \sigma \). Thus, finite nanostructure systems provide clear evidence for the effects of atomic-scale randomness on physical properties. (ii) The polarization anisotropy of two X\textsuperscript{1}\textsuperscript{+} transitions is affected both by \( \sigma \) variations and from possible QD base elongation. Thus, the polarization anisotropy cannot be used as a measure of geometrical anisotropy alone, (iii) Polarization directions of different multiexciton emission lines are determined by \( \sigma \).

9:24AM H10.00006 Blinking suppression on millisecond-to-minutes time scales in giant nanocrystal quantum dots\textsuperscript{,} ANTON MALKO, University of Texas at Dallas, DAVID BUSSIAN, HAN HTOON, Los Alamos National Laboratory, SID SAMPAT, University of Texas at Dallas, JAVIER VELA, YONGFEN CHEN, JENNIFER HOLLINGSWORTH, VICTOR KLIMOV, Los Alamos National Laboratory — Fluorescence intermittency (blinking) is an intrinsic feature of molecular-like fluorophores, including nanocrystal quantum dots (NQDs). The effect complicates applications of NQDs in areas such as quantum informatics, bio-imaging, and real-time tracking. Previously we developed “giant” NQDs in which a small emitting core is overcoated with a thick shell of a wider-gap material and observed strong blinking suppression on a time scale of 100s ms and longer. In this work, we employ time-tagged correlated single photon counting to detect photoluminescence (PL) traces from individual “giant” CdSe/CdS NQDs with resolution better than 1 ms. We observe a strong dependence of the fluorescence on/off times on shell thickness and almost complete blinking suppression on all measured time scales for NQDs coated with more than \( \sim 10 \) monolayers of CdS. Further systematic analysis of our PL traces reveal a photon statistics that differs significantly from a power-law distribution of on/off times typically observed for “regular” NQDs.

9:36AM H10.00007 Photoluminescence and multiexciton dynamics in semiconductor nanoparticle, MOUNGI BAWENDI, MIT — No abstract available.

10:12AM H10.00008 Scaling of Multiexciton Nonradiative and Radiative Decay Rates with Exciton Number in Semiconductor Nanocrystals\textsuperscript{1}. JOHN A. MCGUIRE, VICTOR I. KLIMOV, Chemistry Division, Los Alamos National Laboratory — Rapid multiexciton decay by nonradiative Auger recombination places strong constraints on potential applications of semiconductor nanocrystals (NCs) in lasing and solar energy conversion exploiting carrier multiplication. Hence, it is important to understand the scaling of the Auger recombination rate with exciton number in NCs. Likewise, understanding the scaling of multiexciton radiative rates with exciton number is important both for potential applications of, e.g., ordered multiphoton emission and for interpreting experimental measurements of time-resolved photoluminescence. We report measurements of the scaling of Auger and recombination rates in CdSe and PbSe NCs and of multiexciton radiative rates in PbSe NCs. The more rapid scaling of Auger rates with exciton number \( N \) in PbSe compared to CdSe can be understood in terms of the different symmetries of \( N \)-excitons with \( N \geq 2 \) due to the different degeneracies of the lowest-energy excitonic states. The scaling of the multiexciton radiative rates in PbSe can be interpreted in terms of a “free-carrier” model.

10:24AM H10.00009 Carrier Multiplication in PbSe Nanocrystals and Extraneous Processes\textsuperscript{1}, JOHN A. MCGUIRE, JIN JOO, JEFFREY M. PIETRYGA, ISTVAN ROBEL, VICTOR I. KLIMOV, Chemistry Division, Los Alamos National Laboratory — Spatial confinement of electronic wave functions in semiconductor nanocrystals (NCs) can enhance the efficiency of carrier multiplication (CM), a process whereby multiexcitons are generated from single absorbed photons. In the last year, a controversy has emerged due to large discrepancies between values of CM efficiencies reported by different groups using different techniques – transient absorption (TA) and photoluminescence upconversion (uPL). We report studies of CM in solutions of PbSe NCs using measurements of exciton dynamics by both TA and uPL and find excellent agreement between the CM efficiencies extracted by both techniques. Moderate variations in efficiencies are observed for nominally similar samples. More dramatically, measurements of static and stirred solutions can display large differences in dynamics. This indicates that extraneous effects such as NC photoionization can distort the results of CM studies and are a likely contribution to the discrepancies between previously reported CM efficiencies.

10:36AM H10.00010 Universal size dependence of Auger constants in direct- and indirect-gap semiconductor nanocrystals, ISTVAN ROBEL, Chemistry Division, Los Alamos National Laboratory, RYAN GRESBACK, UWE KORTSHAGEN, Department of Mechanical Engineering, University of Minnesota, RICHARD D. SCHALLER, VICTOR I. KLIMOV, Chemistry Division, Los Alamos National Laboratory — We compare Auger recombination rates in several direct- and indirect-gap semiconductor nanocrystals including Ge, PbSe, InAs, and CdSe. Our size-dependent biexciton lifetime measurements indicate that the most important factor determining recombination rates is nanocrystal size, while details of the materials’ electronic structure such as the width of the energy gap or its direct/indirect nature play only a minor role. We observe that the effective Auger constants for all semiconductor nanocrystals in this study exhibit a universal cubic dependence on particle radius \( R \), \( C_A \sim R^3 \). Moreover, absolute values of nanocrystal Auger constants are comparable across different materials despite a dramatic difference (up to 4-5 orders of magnitude) in \( C_A \) values in the respective bulk solids. Our results can be explained by confinement-induced relaxation of momentum conservation, diminishing the difference between direct- and indirect-gap semiconductors at the nanoscale.
10:48AM H10.00011 Steady-state fluorescence spectroscopy of multiexcitons in single ‘giant’ nanocrystal quantum dots, HAN HTOON, DAVID BUSSIAN, JAVIER VELA-BECERRA, YONGFEN CHEN, JENNIFER HOLLINGSWORTH, VICTOR KLIMOV, Los Alamos National Lab — Due to ultrafast nonradiative Auger recombination, emission of multiexciton states is not pronounced in steady-state spectra of nanocrystal quantum dots (NQDs). Here, we report the first observation of multiexcitonic signatures in steady-state photoluminescence (PL) from single ‘giant’ core/shell NQDs*, in which a CdSe core is overcoated with a thick (>10 monolayers) CdS shell. At low temperature, we observe the emergence of multiple high-energy PL peaks with increasing pump power. Analysis of intensity scaling of these PL peaks with pump power allows us to assign them to bi-, tri- and higher order multiexcitons. Lifetimes of these multiexciton states obtained by single-dot time- and wavelength-resolved PL further corroborate this assignment. These results suggest that in ‘giant’ NQDs Auger recombination is greatly suppressed compared to regular NQDs, which likely stems from their large effective volume and decreased spatial overlap between electrons (occupy entire NQD volume) and holes (localized in CdSe core).* Y.F. Chen et al. J. Am. Chem. Soc. 130, 5026 (2008)

Tuesday, March 17, 2009 8:00AM - 11:00AM
Session H11 DMP: Focus Session: Transport Properties of Nanostructures II: Molecular Junctions

8:00AM H11.00001 Conductance of Conjugated Organic Compounds in Controlled Environments1, CHRISTIAN SCHONENBERGER, Department of Physics, Univ. of Basel — We use the mechanical and the electromigration break junction technique, as well as nanoparticle arrays, to measure the electrical conductance of a range of conjugated organic molecules with different end functionalities at room temperature in a liquid cell. We first report on a comparison between oligo(phenylene vinylene) (OPV) oligo(phenylene ethynylene) (OPE). We find that OPV conducts slightly better than OPE. Solubilizing side groups do not prevent the molecules from being anchored within a break junction. With the aim to realize a functional switch, we show preliminary electrical conductance studies of a newly synthesized cruciform molecule. Using the nanoparticle platform we further demonstrate light and electrochemical-induced conductance switching of photochromic and redox molecules. We further discuss OPV and OPE molecules with different end groups, including asymmetric ones. To our surprise, molecules having an anchor group only on one side also gave rise to a pronounced mo-lecular signal. We attribute this effect to the interaction between neighboring molecules in the junction likely induced by π-π stacking. This remarkable property highlights the importance of intermolecular interaction in molecular junctions, an often overlooked aspect. If time permits, a recent study on low-frequency fluctuations in molecular junctions will be mentioned as well. Collaborators are (alphabetical order): J. Agustsson, J. Brunner, M. Calame, T. 8:36AM H11.00002 Externally controlled spin state switching in metal-organic complexes, ALEXEI BAGRETS, VELIMIR MEDED, MARIO RUBEN, FERDINAND EVERS, Institute of Nano Technology, Research Center Karlsruhe, Germany — Recent transport experiments have demonstrated that a manipulation of the charge of individual molecules is feasible using electromigrated metal junctions [1] or electrochemical gates in conjunction with the STM [2]. Using elaborated density functional theory calculations, we will discuss a possibility to induce – by means of charging or applied stress – a switching between low and high spin states in certain metal-organic systems, Fe(bpp)$_2$[2]+ (bpp: bispyrazolyl pyridine) and Mn(tpy)$_2$[2]+ (tpy: terpyridine). Based upon a recent success of the single molecular conduction experiment through Ru(II) complex [3], we anticipate the transport properties of Fe(II) and Mn(II) complexes to be gate controlled via exploiting their spin degree of freedom.

8:48AM H11.00003 ABSTRACT WITHDRAWN —

9:00AM H11.00004 Quantum-Interference-Controlled Molecular Electronics, SAN-HUANG KE, WEITAO YANG, H. U. BARANGER, Duke University — Quantum interference in coherent transport through single molecular rings may provide a mechanism to control the current in molecular electronics. We investigate its applicability, using a single-particle Green function method combined with ab initio electronic structure calculations. We find that the quantum interference effect (QIE) is strongly dependent on the interaction between molecular π-states and contact σ-states. It is masked by σ tunneling in small molecular rings with Au leads, such as benzene, due to strong π – σ hybridization, while it is preserved in large rings, such as [18]annulene, which then could be used to realize quantum interference effect transistors. [Nano Letters 8, 3257 (2008)]

9:12AM H11.00005 Simultaneous electronic transport and Raman spectroscopy in single-molecule devices, DOUGLAS NATIELSON, Rice University, Dept. of Physics and Astronomy — Over the last decade several techniques have been developed to examine electronic transport through individual small molecules. These include scanned probe methods, mechanical break junctions, and electromigrated junctions. One recurring challenge is the need to confirm that current flow is, indeed, through the molecule of interest rather than a contaminant. We recently discovered (D. R. Ward et al., Nano Lett. 7, 1396 (2007)) that the same electromigrated Au source and drain electrodes used for transport are tremendously effective optical antennas in the near infrared. Surface plasmon modes localized to the nm-scale interelectrode gap lead to large enhancements of the local electric field relative to that from incident radiation. The result is that these nanoscale gaps are tremendous “hot spots” for surface-enhanced Raman scattering (SERS). We perform simultaneous measurements of electronic transport and SERS in junctions incorporating molecules of interest, and find in 10-15% of devices that the conductance and SERS emission are strongly correlated in time (D. R. Ward et al., Nano Lett. 8, 919 (2008)). Since the conductance mechanism is tunneling and therefore dominated by a volume comparable to that of a single molecule, this strongly implies that the SERS emission comes from that same molecule. The distinctive SERS spectra allow us to confirm that conduction in these devices is through the molecule of interest. Furthermore, these devices open up many opportunities, including studies of electron-vibrational couplings and dissipation at the single-molecule level.

2This work was done in collaboration with D. R. Ward, N. J. Halas, P. Nordlander, and J. M. Tour. Financial support includes Robert A. Welch Foundation grant C-1636, NSF DMR-0347253, and the David and Lucille Packard Foundation.
Films 308 appears whenever a conductance channel is opened.

with the peak index in the conductance histogram. The present study shows that the [110] nanowire behave as ballistic conductors, and a conductance peak either an atomic sheet or a hexagonal prism. The number of conductance channels calculated for each atomic structure by first principles theory, coincided well =2e microscrope images. The conductance histogram exhibits a series of peaks whose conductance values increased nearly in steps of the conductance quantum, G0 elongated along the [110] direction (gold [110] nanowire) was measured during many breaking procedures, while simultaneously acquiring transmission electron microscope images. The conductance histogram lineshapes show strong correlation between measured conductance step length and molecular backbone length, with phosphine link groups showing longer steps than amine link groups. We model adiabatic junction evolution by discrete steps, with structure determined by energy minimization in a DFT approach and the low bias junction conductance at each step computed using a Green’s function approach. We identify different mechanisms whereby the attachment point to the electrode can shift while maintaining similar conductance, explaining why conductance steps can extend over distances of several angstroms. Phosphine and amine link groups sustain different maximum forces, accounting for key differences in junction evolution.

Kondo effect in the electronic transport of magnetic atomic-size contacts

M. REYES CALVO, JOAQUIN FERNANDEZ-ROSIER, JUAN JOSE PALACIOS, Dept. Fisica Aplicada. Universidad de Alicante, DAVID JACOB, Dept. Physics and Astronomy. Rutgers University, DOUGLAS NATELSON, Dept. Physics and Astronomy. Rice University., CARLOS UNTIEDT, Dept. Fisica Aplicada. Universidad de Alicante — Low coordination alters dramatically the magnetic properties of materials at the nanoscale. Our results indicate that, in the case of atomic contacts of certain materials, a localized magnetic moment appears at the contact and is screened at low temperatures by means of the Kondo effect. We observe characteristic Fano-Kondo lineshapes in the spectroscopy of atomic contacts of typical ferromagnetic materials (Fe, Co and Ni). The parameters obtained from the fitting of these curves to the Fano equation show statistical distributions that agree with the Kondo theory. The Kondo origin of the measured resonances is confirmed by their temperature dependence and supported by our theoretical calculations. These results are surprising since ferromagnetism and Kondo effect are expected to compete. We have also observed a similar spectroscopy in atomic contacts of palladium and platinum monoatomic chains. In this case, the Kondo resonances would be the signature of an emergent magnetism that is ultimately screened. Partially founded by Spanish MEC (grant nr. MAT2007-65487 and CONSOLIDER CSD2007-0010) and EU (project nr. 211284).

Magnetic phenomena, ferro and antiferro Kondo, and transport in transition metal break junction nanocontacts

Spectra of discrete electrons-in-a-box energy levels in chemically-formed Au and Pt nanoparticles.

SU-FEI SHI, F. KUEMMETH, K.I. BOLOTIN, W. LI, D.C. RALPH, Cornell University — We report tunneling spectroscopy measurements of the discrete electron spectra of individual metal nanoparticles formed by chemical synthesis, that they are well-defined in their composition, size, and shape. The spectra of 5-15 nm diameter gold particles exhibit as many as 40 resolvable electronic excited states for a fixed value of gate voltage. We find excellent agreement between the measured level statistics and random matrix predictions for the regime of strong spin-orbit coupling and ballistic transport. As a function of changing gate voltage, the energy-level spectra in the Au particles are not scrambled by the addition of electrons, indicating that in these particles the variation in the strength of electron-electron interactions between states is negligible. We have also succeeded in fabricating single-electron transistors from individual Pt nanoparticles and hope to present measurements of their discrete spectra. Unlike Au, has a sufficiently strong exchange interaction that it is expected to exhibit non-zero values of the ground state spin in the form of “mesoscopic magnetism”.

Ballistic transport in gold [110] nanowire

YOSHIHIKO KURUI, YOSHIFUMI OISHIMA, Tokyo Institute of Technology, MASAKUNI OKAMOTO, Hitachi Ltd, KUNIO TAKAYANAGI, Tokyo Institute of Technology — Conductance of gold nanowire elongated along the [110] direction (gold [110] nanowire) was measured during many breaking procedures, while simultaneously acquiring transmission electron microscope images. The conductance histogram exhibits a series of peaks whose conductance values increased nearly in steps of the conductance quantum, G0 =2e2/h. However thick nanowires above 10G0 showed dequantization, where the increment was only 0.9G0. The structure for each peak was determined to be either an atomic sheet or a hexagonal prism. The number of conductance channels calculated for each atomic structure by first principles theory, coincided well with the peak index in the conductance histogram. The present study shows that the [110] nanowire behave as ballistic conductors, and a conductance peak appears whenever a conductance channel is opened.

Tuesday, March 17, 2009 8:00AM - 11:00AM –
Session H12 DMP DCMP: Focus Session: Directed Organization of Molecular Semiconductor Films 308
8:00AM H12.00001 Structural evolution of the self-assembled layers of functionalized fullerenes on metal surfaces , BOGDAN DIACONESCU, Department of Physics, University of New Hampshire, MIKAEL JAZDZYK, GLEN MILLER, Department of Chemistry, University of New Hampshire, KARSTEN POHL, Department of Physics, University of New Hampshire — Self-assembled organic thin films have a great number of practical applications, ranging from sensors and biological interfaces to medical implants to organic electronics and photovoltaics. Self-assembled monolayers (SAMs) form as a result of a delicate balance between competing molecule-substrate and intermolecular interactions. To control such self-assembly processes, it is mandatory to understand how this balance reflects onto the SAM’s final structure. Here, we present a STM study of the self-assembly of C60 functionalized with alkane chains of various lengths (F-C60) on Ag(111). We find that F-C60 molecules lay down on the Ag surface and form a zigzag like pattern with an oblique unit cell of size dependent on the alkyl chain length and two molecules per basis. The C60s are placed at a larger than van der Waals distance. The symmetry of the F-C60 SAM is dictated by the alkane-surface interaction while the size of the unit cell is a consequence of the intermolecular interactions. These results show that C60s can be assembled in 2D and non-compact molecular arrays with a surface density controllable via appropriate chemical functionalization. Funded by the NSF Center for High-rate Nanomanufacturing (NSF NSEC-425826).

8:12AM H12.00002 Controlled Chemical Morphology in TiO Pc - C60 Films , YINYING WEI, Department of Chemistry and Biochemistry, University of Maryland , STEVE ROBEY, National Institute of Standards and Technology, JANICE REUTT-ROBEY, Department of Chemistry and Biochemistry, University of Maryland — A key strategy for the improvement of organic electronic devices involves the optimization of chemical morphology for efficient charge separation. Fundamental studies of chemical morphology - electronic property relations, particularly along crucial domain boundaries, are needed to realize these goals. We present STM/STS studies of TiO Pc: C60 films, prepared by vapor deposition on Ag (111). We show how growth conditions can be adjusted to harness anisotropic TiO Pc - TiO Pc interactions, leading to three dramatically distinct film structures: nanophase segregated TiO Pc and C60 domains, a co-crystalline TiO Pc(C4H9)2-C60(111) honeycomb network, and a quasi-periodic array of triangular TiO Pc domains and C60 nanoclusters. Electronic transport gaps measured by STS (Z(V)) prove to be sensitive to the phase, varying by up to about 0.5 eV along domain boundaries. We propose structural models for each hetero interface and discuss the physical origin of the observed transport characteristics.

8:24AM H12.00003 Monte Carlo Study of the Honeycomb Structure of Anthraquinone Molecules on Cu(111) , KWANGMOO KIM, T. L. EINSTEIN, University of Maryland, College Park, LUDWIG BARTELS, University of California, Riverside — Using Monte Carlo calculations of the two-dimensional (2D) lattice gas model, we demonstrate a mechanism for the spontaneous formation of honeycomb structure of anthraquinone (AQ) molecules on a Cu(111) plane. Unlike the suggestion of long-range substrate-mediated repulsion, long-range attractions play important roles in our calculations. However, the interplay between attractions and repulsions is still integral to the spontaneous formation of AQ’s honeycomb structure. We also compare the critical local coverage rate of AQ’s where the honeycomb structure starts to form. Furthermore, we study the diffusion of CO molecules inside AQ honeycombs on the Cu(111) plane. The surface phase transitions of CO molecules between solid, liquid, and gas 2D phases are studied via the specific heat singularity in short-range correlation functions. Supported primarily by NSF Grants CHE07-50334 with a secondary support from MRSEC Grant DMR05-20471.

8:36AM H12.00004 Patterned molecular nanostructures , KLAUS KERN, Max Planck Institute for Solid State Research and EPFL (Switzerland) — Surfaces and interfaces not only determine to a large extent the properties of small-scale materials due to their high surface-to-volume ratio, they are also an ideal platform for the design, fabrication and device integration of nanostructures. Both, top-down and bottom-up methods have been developed for the handling of matter at the molecular and atomic scale. In the present talk I will demonstrate how the remarkable progress in controlling atomic and molecular interactions at surfaces has provided the unique ability to engineer supramolecular architectures of well-defined shape, size, composition and functionality. Using noncovalent interactions as hydrogen bonding, ionic bonding and metal-ligand interactions, molecular building blocks can be rationally combined into desired functional architectures. The potential functionalities comprise molecular magnetism, novel heterogeneous catalysis, selective host-guest interactions and new concepts of nanoscale mechanics.

9:12AM H12.00005 Reactions on surfaces for the creation of stable templates , M. MATENA, M. WAHL, M. STOEHR, Universität Basel, Switzerland, T. A. JUNG, Paul-Scherrer-Institute, Switzerland, T. L. LEE, J. ZEGENHAGEN, ESRF Grenoble, France, T. RIEHM, L. H. GADE, University of Heidelberg, Germany — Molecular assemblies on surfaces can be used as templates that allow the study of host-guest interactions and thus provide a starting point for the generation of complex hierarchic structures. An important prerequisite besides the regularity of such structures is their stability. We reported the formation of a molecular network generated by thermal dehydrogenation of a perylene derivative (DPDI) on a substrate surface before and after the thermal activation. The formation of the network involves a lowering of the height difference utilizing this network for the incorporation of guest molecules. NIXSW (normal incidence x-ray standing wave) experiments were carried out to determine the appropriate chemical functionalization. Funded by the NSF Center for High-rate Nanomanufacturing (NSF NSEC-425826).

9:24AM H12.00006 Meandering C60 Chains on Organic Film Substrates , WEI JIN, University of Maryland, DANIEL DOUGHERTY, National Institute of Standards and Technology (currently at North Carolina State University), QIANG LIU, WILLIAM CULLEN, JOHN WEEKS, University of Maryland, STEVEN ROBEY, National Institute of Standards and Technology, JANICE REUTT-ROBEY, University of Maryland — Meandering chains of C60 molecules are observed following vapor deposition of C60 on a variety of organic molecular films including pentacene and zinc phthalocyanine, as well as previously reported a-selenophene. Such filamentous structures are in complete contrast to C60’s typical close-packed growth habit, but are reminiscent of dipole fluids. We present STM images and a statistical analysis of chain structures observed for 0.2 - 0.9 mL C60 overlayers (a = 13.6 Å, b = 14.5 Å, α = 89°) on Ag (111). Large islands of meandering C60 islands indicate >50 nm C60 diffusion lengths on this ZnPc film. The C60 island length, ~20 nm, depends weakly on coverage, reflecting the ~constant C60 density within these islands, and exhibits multiple branches. Chain structures are compared to the molecular dynamics predictions of a 2-d dipole fluid with the C60 - C60 interaction described by the Girifalco Potential (1 eV attraction) with additional dipole terms. A vertical moment of ~0.8 D simulates filament formation. The structure of the ZnPc support, not included in this simulation, appears to be a secondary consideration in these chain structures. Supported by the Dept. of Commerce through the NIST Center of Nanomanufacturing and Metrology and the NSF-funded MRSEC via DMR-05-20471.
9:36AM H12.00007 Molecular dynamics study of polarized C60 on an organic surface1. QIAN LIU, WEI JIN, JOHN D. WEEKS, JANICE REUTT-ROBEY — The experimental results of vapor deposition of C60 on a variety of organic molecular films has showed unusual meandering chain structures. Here we use the Langevin molecular dynamics method to mimic the system. In the simulation, we considered interactions including the intermolecular Girifalco potential, dipole-dipole interactions, octupole interactions suggested by W. Losert2 and substrate potentials. Choosing different parameters can give us different C60 patterns: the close-packed C60 islands, isolated C60 molecules and meandering chain islands.

9:48AM H12.00008 Harnessing Surface Dislocation Networks for Molecular Self-Assembly1. KARSTEN POHL. University of New Hampshire — The controlled fabrication of functional wafer-based nano-arrays is one of the ultimate quests in current nanotechnologies. Well-ordered misfit dislocation networks of ultrathin metal films are viable candidates for the growth of two-dimensional ordered cluster arrays in the nanometer regime. Such bottom-up processes can be very complex, involving collective effects from a large number of atoms. Unraveling the fundamental forces that drive these self-assembly processes requires detailed experimental information at the atomic level of large ensembles of hundreds to thousands of atoms. The combination of variable temperature measurements from our home-built STM correlated with 2D Frenkel-Kontorova models based on first-principle interaction parameters is used to explain how uniform arrays can form with the strain in the thin film as the driving force responsible for the surface self-assembly process. This process is generally applicable to assemble many molecular species thus opening avenues towards complex self-assembled structures based on a lock-and-key type approach. Moreover, when increasing the molecular coverage and/or decreasing the strain in the thin film the intermolecular interactions will eventually dominate the elastic effects and dictate the self-assembly process via molecular structure and functionality. We will show that controlling this delicate balance leads to a richness of structures, ranging from disordered arrays of molecular clusters to patterned self-assembled monolayers (SAMs) of functionalized fullerenes and methanethiol.

1This work is supported in parts by the NSF-DMR and the Center for High-rate Nanomanufacturing (NSF-NSEC-425826).
8:12AM H13.00002 Iterative Diagonalization of Inhomogeneous Heisenberg Models1, VALTER LIBERO, FABIANO SOUZA, Universidade de Sao Paulo — The antiferromagnetic Heisenberg model is one of the most important in describing quantum spins coupled by exchange interactions. Difficulties arise especially in presence of broken symmetry, due for instance to impurities or defects. In these cases, even well-established numerical methods like Lanczos or Monte Carlo, encounter limitations. We propose a numerical method which works even in the absence of translational invariance. We diagonalize the Heisenberg model exploiting the conservation of both the z-component of the total spin and the square of the total spin, a much more complicated procedure but that renders an additional block diagonalization. In essence, the N-site Hamiltonian is built using basis-vectors generated from the direct product of the eigenvectors of the (N-1)-site Hamiltonian and the states of the added N-th spin. The procedure is also applied for the two-leg ladder, an experimental relevant system. Results are shown for ground-state energy and temperature dependent specific heat for chains with local spin impurities or with random distributions of spins 1/2, 1 or 3/2.

8:24AM H13.00003 Entanglement perturbation theory for the excitation spectrum in one dimension, SUNG CHUNG, Western Michigan University — A novel many-body method, entanglement perturbation theory, is developed for the excitation spectra in one dimension. Applied to the antiferromagnetic Heisenberg chains with spin one-half and 1, converging and hence exact results are obtained, including known Bethe Ansatz result for spin one-half and DMRG results for spin 1. We have found that the magnons are spread over about 4 lattice sites. An essential ingredient in this theory is the exact, un-renormalized ground state of arbitrary system sizes, which are also calculated by EPT in a simple, general and exact manner.

8:36AM H13.00004 A Brief Introduction to the Truncated Eigenfermion Decomposition1, JONATHAN E. MOUSSA, JAMES R. CHELIKOWSKY, UT Austin — We present a computational formalism for the approximate unitary transformation of a many-body fermion Hamiltonian with two-body interactions. This work is a further development of the numerical canonical transformation approach of S. R. White [J. Chem. Phys. 117, 7472 (2002)]. The Hamiltonian can be diagonalized in a basis of eigenfermion operators, in which case the eigenstates are all single Slater determinants of eigenfermions. The transformation of two-body interactions generates higher-order interactions that can be approximated by effective two-body interactions using a novel generalization of normal ordering. The error in representing a target eigenstate is minimized by performing the generalized normal ordering with respect to that eigenstate. Numerical results are presented for several test cases, including Hubbard model clusters.

8:48AM H13.00005 The Density Matrix Renormalization Group Algorithm for Strongly Correlated Systems: A Generic Implementation1, GONZALO ALVAREZ, Oak Ridge National Laboratory — I will present DMRG++, a fully functional generic Density-Matrix Renormalization Group (DMRG) code with sample cases for the Hubbard and Heisenberg model, and for one-dimensional chains and n-leg ladders. My talk will include an overview of the core C++ classes, effective symmetry blocking and parallelization found in DMRG++. I will also explain how to add new strongly correlated electron (SCE) models and geometries with minimal code changes. Even if you are not very familiar with the DMRG or C++, you will be able to understand the main motivations and advantages of generic programming applied to SCE systems.

3Supported by the Center for Nanophase Materials Sciences, sponsored by the Scientific User Facilities Division, Basic Energy Sciences, U.S. Department of Energy, under contract with UT-Battelle.

9:00AM H13.00006 A Renormalization Group for Treating 2D Coupled Arrays of Continuum 1D Systems, ROBERT KONIK, YURY ADAMOV, Brookhaven National Laboratory — We study the spectrum of two dimensional coupled arrays of continuum one-dimensional systems by wedging a density matrix renormalization group (DMRG) procedure to a renormalization group improved truncated spectrum approach. To illustrate the methodology we study the spectrum of large arrays of coupled quantum Ising chains. We demonstrate explicitly that the method can treat the various regimes of chains, in particular the three dimensional Ising ordering transition the chains undergo as a function of interchain coupling. We argue that the methodology’s success is based on finite size corrections being exponentially small which in turn allows the block DMRG entanglement entropy to be kept to a minimum.

9:12AM H13.00007 Low-temperature density matrix renormalization group using regulated polynomial expansion, SHIGETOSHI SOTA, TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University — We propose a new scheme of density matrix renormalization group (DMRG) for low dimensional strongly correlated electron systems at finite temperatures, which is a straightforward extension of the target-state procedure at zero temperature. In order to investigate thermodynamical properties, we employ the target state that is weighted by a Boltzmann factor [1]. Making use of a regulated polynomial expansion [2] and random sampling, we can calculate static and dynamical quantities at finite temperatures. In order to obtain good convergence in high temperature region, we need a large truncation number of the density matrix, while a necessary truncation number is small at low temperatures. The proposed method is, therefore, suitable for lower temperature region. As a demonstration of the method, we show the specific heat and dynamical current-current correlation function of the 1D Hubbard model at half filling. The DMRG results reproduce the exact digitalization results at low temperatures. [1] S. Sota and T. Tohyama, Phys. Rev. B 78, 113101 (2008). [2] S. Sota and M. Itoh, J. Phys. Soc. Jpn. 76, 054004 (2007).

9:24AM H13.00008 Screened Coulomb Interactions of Localized Electrons from First-Principles, BI-CHING SHIH, PEIHONG ZHANG, Department of Physics, University at Buffalo, State University of New York — We present a recently developed, maximally localized Wannier function approach for calculating the screened Coulomb(U) and exchange (J) interactions of localized electrons in solids. The localized orbitals are constructed using the maximally localized Wannier function approach. The dielectric screening is calculated from first-principles within the random phase approximation. Results for several systems containing strongly localized d electrons will be presented.

9:36AM H13.00009 Refinement of a Lanczos-based variational procedure to solve the Holstein model, ZHOU LI, University of Alberta, DEVIN BAILLIE, University of Alberta, CINDY BLOIS, University of Toronto, FRANK MARSIGLIO, University of Alberta — We propose a slight refinement to the Trugman variational procedure to more efficiently solve the Holstein model with Lanczos methods. The modified Lanczos method converges much more quickly compared with the usual one in the intermediate- and strong- coupling regimes. To get a 6-digit accuracy of ground state energy at intermediate-strong coupling in the adiabatic region (small phonon frequency), only about 5000 basis states are need to be included. We also construct a variational ground state based on the numerical results.
of like-charge attraction: the charge-dependent term in the interaction is purely repulsive, while the attraction is independent of particle charge. We report a decomposition of like-charge interactions into charge-dependent and -independent terms, leading to a striking insight into the long-standing paradox of lipid composition allowing the first self-assembled microparticle superstructures remains slow, however, and fundamental mysteries such as the attractions observed between like-charged particles and scientific importance of colloidal materials has spurred a large body of research into the functionalization of micron-scale particles. Progress towards self-assembled microparticle superstructures remains slow, however, and fundamental mysteries such as the attractions observed between like-charged particles and the large cluster is calculated using the Schwinger-Dyson equation. The method is applied to the 2D Hubbard model with cluster sizes $N_c^{(2)} \geq N_c^{(1)}$ and the results are compared with those calculated using QMC by increasing the size of the small cluster $N_c^{(1)}$ up to $N_c^{(2)}$. 1Supported by DOE SciDAC Grant #DE-FC02-06ER25792.

10:12AM H13.00012 Nonlinear conductance oscillation in strong correlation limit of molecular quantum dots near zero bias anomaly1, JONG E. HAN, SUNY at Buffalo — Recent experiments on strong correlation effects in molecular junctions have demonstrated that the interplay of electronic coupling to molecular vibrations and the Coulomb interaction produces intriguing oscillatory structures in the nonlinear conductance near zero bias anomaly at voltages in the energy scale of, presumably, the Kondo temperature. Using the imaginary-time quantum Monte Carlo technique recently developed for strongly correlated nonequilibrium, the nonlinear conductance of the Anderson-Holstein model at finite bias has been calculated. We discuss the mapping between the charge- and spin-Kondo limits and their distinctly different transport physics under finite chemical potential bias. We show that the conductance oscillation emerges at finite bias in the vicinity of the Kondo temperature due to strong electron-vibration coupling. The origin of the oscillation is from the bias-induced strong electron density modes as opposed to direct phonon excitations.

1Supported by NSF DMR-0426826.

10:24AM H13.00013 Role of phonons and of finite temperature on the spectral function of a single hole in a 2D quantum antiferromagnet, SATYAKI KAR, Department of Physics, FSU & MARTECH, EFSTRATIOS MANOUSAKIS, Department of Physics, FSU & MARTECH, Department of Physics, University of Athens, Greece — We study thermal broadening of the hole spectral function of the two-dimensional $t-J$ and $t-t'$ - $J$ model within the non-crossing approximation (NCA) with and without the contribution of optical phonons. We have also studied the range of validity of the NCA by including the role of vertex corrections. The broadening of the quasiparticle peak as well as the transfer of spectral weight as a function of momentum to higher energy string excitations is found to be in reasonably good agreement with experimental angle resolved photo-emission spectroscopy (ARPES) results using a rather large electron-phonon coupling.

10:36AM H13.00014 Inelastic Scattering from Local Vibrational Modes, BALAZS DORA, MIKLOS GULACSI, Max Planck Institute for the Physics of Complex Systems — We study a nonuniversal contribution to the dephasing rate of conduction electrons due to local vibrational modes. Bosonization allows us to evaluate the full T-matrix. The inelastic scattering rate is strongly influenced by multi phonon excitations, exhibiting oscillatory behaviour. For higher frequencies, it saturates to a finite, coupling dependent value. In the strong coupling limit, the phonon is almost completely softened, and the inelastic cross section reaches its maximal value. This represents a magnetic field insensitive contribution to the dephasing time in mesoscopic systems, in addition to magnetic impurities.

Tuesday, March 17, 2009 8:00AM - 10:36AM – Session H14 DFD: Colloids III: Formation and Control 315

8:00AM H14.00001 Connecting structure and rheology in sheared colloidal suspensions, JONATHAN MCCOY, ITAI COHEN, Cornell University — We investigate the shear properties of colloidal suspensions confined between parallel plates. When the distance between the plates is very small, i.e. approaching the size of the colloidal particles, a number of dramatic phase behaviors are observed under shear, including buckling, banding, jamming, and crystallization. This strongly confined regime is difficult to access using standard rheological techniques. Our experiment explores connections between microstructural behaviors and macroscopic flow by combining confocal microscopy and force measurement techniques in a custom-built thin-film shear cell. Here, we will focus on the interplay between confinement, slip, and order.

8:12AM H14.00002 Modulation of attractive colloidal interactions by lipid and protein membrane functionalization, YUPENG KONG, RAGHUVEER PARTHASARATHY, Univ. of Oregon, Dept. of Physics — The broad technological and scientific importance of colloidal materials has spurred a large body of research into the functionalization of micron-scale particles. Progress towards self-assembled microparticle superstructures remains slow, however, and fundamental mysteries such as the attractions observed between like-charged particles near a confining wall remain unresolved. These difficulties arise in large part due to the lack of experimental systems with tunable, attractive interparticle interactions. Biomembranes are appealing candidates for colloidal functionalization, enabling access to electrostatic and chemical properties that influence inter-particle relations. We describe here the first measurements of the pair interaction energy for membrane-functionalized colloids, using a newly developed optical line trapping technique. Two classes of particles, derivatized with lipid-only and lipid-plus-protein membranes, each show attractive interactions. The two particle types exhibit different relations between the depth and spatial range of the interactions, however. Control of lipid composition allows the first reported decomposition of like-charge interactions into charge-dependent and -independent terms, leading to a striking insight into the long-standing paradox of like-charge attraction: the charge-dependent term in the interaction is purely repulsive, while the attraction is independent of particle charge.
8:24AM H14.00003 Self-protected interactions in DNA-functionalized colloids: Nano Contact Glue. MIRIAM LEUNISSEN, Center for Soft Matter Research, New York University, REMI DREYFUS, ROUJIE SHAH, New York University, ALEXEI TKACHENKO, University of Michigan, NADRIAN SEE-MAN, DAVID PINE, PAUL CHAIKIN — The ability of single-stranded DNA to form a variety of sequence-dependent secondary structures, such as hairpins, is frequently used in DNA nanotechnology, but has so far not been explored for the directed assembly of (nano)colloidal structures. We will show how mono- and bimolecular hybridization events in the DNA coatings of individual micrometer-sized beads can give rise to unusual, quench-rate dependent aggregation behavior, and how it can give additional control over the colloidal self-assembly process. For example, it provides us with ‘self-protected’ interactions that are activated by temperature or prolonged proximity and that facilitate the formation of finite-sized structures. A simple quantitative model describes the underlying competition between intra- and interparticle hybridization events, based on the known thermodynamic parameters of the DNA sticky ends.

8:36AM H14.00004 A simple quantitative model for the reversible association of DNA coated colloids. REMI DREYFUS, MIRIAM LEUNISSEN, ROUJIE SHAH, New York University, ALEXEI TKACHENKO, University of Michigan, NADRIAN SEE-MAN, DAVID PINE, PAUL CHAIKIN — New York University — We investigate the reversible association of micrometer-sized colloids coated with complementary single-stranded DNA ‘sticky ends’ as a function of the temperature and the sticky end coverage. We find that even a qualitative description of the dissociation transition curves requires the inclusion of an entropic cost. We develop a simple general model for this cost in terms of the configurational entropy loss due to binding and confinement of the tethered DNA between neighboring particles. With this easy-to-use model, we demonstrate for different kinds of DNA constructs quantitative control over the dissociation temperature and the sharpness of the dissociation curve, both essential properties for complex self-assembly processes.

8:48AM H14.00005 Observation of condensed phases of quasi-planar core-softened colloids. PRIMOZ ZIHERL, University of Ljubljana & Jozef Stefan Institute, NATAN OSTERMANN, DUSAN BABIC, IGOR POBERAJ, University of Ljubljana; JURE DOBNIKAR, Jozef Stefan Institute — We experimentally study the condensed phases of repelling core-softened spheres in two dimensions. The dipolar pair repulsion between superparamagnetic spheres trapped in a thin cell is induced by a transverse magnetic field and softened by suitably adjusting the cell thickness. We scan a broad density range and we materialize a large part of the theoretically predicted phases in systems of core-softened particles, including expanded and close-packed hexagonal, square, chain-like, stripe/labyrinthine, and honeycomb phase. Further insight into their structure is provided by Monte Carlo simulations.

9:00AM H14.00006 In situ real time measurement of temperature responsive nanoparticles. DENIS PRISTINSKI, THOMAS Q. CHASTEK, VIVEK PRABHU, KALMAN MIGLER, Polymers Division, NIST — In this work, we combine dynamic light scattering (DLS) and diffusing wave spectroscopy (DWS) to evaluate the size of temperature responsive nanoparticles over a broad range of concentrations. A fiber optic probe DLS instrument was previously demonstrated to measure nanoparticle solutions at a relatively high concentration. The incorporation of back-scattering DWS further extends the technique application to highly turbid conditions. The combined setup was designed to have a simplified and compact optical arrangement employing single-mode fiber based components. Data analysis for both methods was carried out using integrated open source cross-platform software. Measurements were conducted to monitor the progress of poly(N-isopropyl acrylamide) nanoparticle syntheses, including a multi-step seeded polymerization, commonly used to prepare core-shell particles. These particles have received a lot of attention due to their potential for use as targeted drug delivery systems. It was found that DLS and DWS were in good quantitative agreement, and able to accurately characterize the samples.

9:12AM H14.00007 Enhanced particle transport in an oscillating sinusoidal optical potential. WEIQIANG MU, Northwestern University, LAN LUAN, Northwestern University, GANG WANG, Indiana University, Purdue University, Fort Wayne, GABRIEL SPALDING, Illinois Wesleyan University, JOHN KETTENOR, Northwestern University, NORTHWESTERN UNIVERSITY COLLABORATION, INDIANA UNIVERSITY, PURDUE UNIVERSITY, FORT WAYNE COLLABORATION, ILLINOIS WESLEYAN UNIVERSITY COLLABORATION — We have studied the delivery of a colloidal particle in the presence of an oscillating, spatially periodic, optical potential. The average particle velocity relative to the fluid velocity in this potential depends greatly on the oscillation amplitude and frequency. The results of both our simulations and experiments show that for some combinations of these parameters, the average particle velocity can be enhanced due to the synchronization of the particle movement with the oscillating potential.

9:24AM H14.00008 Charge inversion in monovalent ionic solutions1, ALEX TRAVESSET2, Iowa State University and Ames Lab, ALBERTO MARTIN-MOLINA, Universidad de Granada, CARLES CALERO, JORDI FARAUDO, Institut de Ciencia de Materials de Barcelona, MANUEL QUESADA-PEREZ, Universidad de Jaen, ROQUE HIDALGO-ALVAREZ, Universidad de Granada — We present measurements of the mobility of core-softened spheres in the presence of monovalent salt added to the mobility of nearly-spherical (TACl) core-softened colloids with increasing salt concentration that flips sign (charge inversion) at mM salt concentrations. A modified version of the O’Brien and White theory taking into account the hydrophobic nature of the phenyl groups describes the experimental data without fitting parameters. Saturation effects in the mobility as well as possible generalizations are also discussed.

9:36AM H14.00009 Position Control of Particles embedded in Microbeads and Fibers Produced by Electrohydrodynamics.1, UNYONG JEONG, EUN MIN JO, SUNGWON LEE, KYU TAE KIM, Department of Material Science and Engineering, Yonsei University, Seoul, Korea — Electrohydrodynamics is a good approach to produce uniform-sized colloids and fibers in a continuous process. The dimension can be controlled from tens of nanometers to a few micrometers. The structure of the colloids and nanofibers from electrohydrodynamics has been diversified according to the uses. Especially, core-shell structure and hybridization with functional nanomaterials are fascinating due to their possible uses in drug-delivery systems, multifunctional scaffolds, organic/inorganic hybrids with new functions, and highly sensitive gas- or bio-sensors. This talk will present the structural variations by tuning the position of small particles in the colloids and fibers produced from electrohydrodynamics and demonstrate their possible applications.

9:48AM H14.00010 Using colloids to model atomic thin film growth. RAJESH GANAPATHY, MARK BUCKLEY, ITAI COHEN, Cornell University — We epitaxially grow colloidal thin films by sedimenting micron sized colloidal particles on a microfabricated substrate. The attractive interaction between the colloids, induced by a depletant polymer, leads to the nucleation of islands that grow and coalesce with one another. We use confocal microscopy and particle tracking to study the dynamics of the colloidal particles as they diffuse, aggregate and rearrange configurations during deposition. The saturation island density is estimated as a function of the deposition rate and depletant concentration. We find that our results are in excellent agreement with those obtained from atomic deposition experiments suggesting that our system can be used to model various phenomena that occur in atomic thin film growth. Furthermore, we quantify the Ehrlich-Schwoebel step edge barrier by using holographic optical tweezers to create artificial islands and study the dynamics of colloidal monomers placed on the edge of these islands. Owing to the short-range of the attractive interaction in our system, the origin of the step edge barrier in colloids is strikingly different from atoms.
10:00AM H14.00011 Stochastic Rotational Dynamics Simulations of Nanocolloid Suspensions

JEREMY B. LECHMAN, MATT K. PETERSEN, STEVEN J. PLIMPTON, P. RANDALL SCHUNK, GARY S. GREST, Sandia National Laboratories, PIETER IN'T VELD, Polymer Research, BASF — The use of nanoparticle suspensions to potentially tailor the functionality of composite devices has broad applicability, but is limited in practice, in part, due to poor understanding of the phenomena at that scale. In order to address this we have implemented a mesoscale fluid technique called Stochastic Rotation Dynamics (SRD). Here, we discuss the use of this method to investigate the behavior of hard sphere like nanocolloids. In particular we will present a direct, “one-to-one” comparison of an SRD fluid with an explicit Lennard Jones solvent. For small colloids in this low viscosity fluid no “telescoping of timescales” is required for efficiency, which allows us to consider the accuracy of the base numerical scheme without complicating approximations. We present the diffusion and reduced viscosity as a function of volume fraction of colloids and compare to well known results. The efficiency of an SRD simulation relative to an explicit atom simulation is also discussed.

1Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under Contract No. DE-AC04-94AL85000.

10:12AM H14.00012 Light-induced structure transformation of colloidal nanocrystals by using generalized Ewald-Kornfeld formulation

M.J. ZHENg, K.L. CHAN, K.W. YU, The Chinese University of Hong Kong — When metallic nanoparticles are brought close together and they are illuminated by laser light, there will be strongly enhanced forces between these particles [1]. If these particles are suspended in a liquid, the force can promote aggregation. As a result, the cluster size can exceed the wavelength of light and retardation effect must be considered. For this sake, we derived a generalized Ewald-Kornfeld summation [2] which is valid for fully retarded electromagnetic interaction. More importantly, we have extended the formula for a many-point basis in a unit cell. We used the formula to study the colloidal nanocrystal formation and transition driven by surface plasmon resonance enhanced forces. Our results are of fundamental importance to the relevant topics in soft matter physics and can be widely applied in the research of light-induced manipulation.

10:24AM H14.00013 Universal Nanocolloid Deposition Patterns: Harmonics of a Taylor Cone and Separation of DNA-Hybridized Nanocolloids

XINGUANG CHENG, HSUEH-CHIA CHANG, University of Notre Dame — With judiciously placed far-field electrodes, harmonics of the Laplace equation are selected near a conducting Taylor cone with discrete polar angles for the field maxima. Charged nanocolloids ejected along the discrete electric field lines of these mode maxima are observed to deposit a universal spectrum of rings on an intersecting plane, with particles of different size occupying different spectral lines due to different residue charge. After an affine transformation, nanocolloids ejected into a microslit and deposited onto one substrate exhibit the same universal line spectra. The size-selective deposition pattern is used to quantify DNA hybridization yield onto oligo-functionalized nanocolloids.

8:00AM H15.00001 Reversible switching of charge states of single TCNE molecules on Cu(111)

TAEOYOUNG CHOI, JAY GUPTA, Ohio state university — The interplay of electronic structure and magnetic properties is of interest in various organic materials. TCNE (TCNE = tetracyanoethylene) is one component of well-known organic magnets with ferromagnetism up to room temperature. TCNE has a strong electron affinity that facilitates chemical bond formation and charge transfer with metals. We use scanning tunneling microscopy and spectroscopy to study single TCNE molecules on Cu(111) and Cu(100) surfaces. On Cu(111), we find that TCNE can be reversibly switched among three configurations via a controlled voltage pulse. We determine the adsorption sites for these configurations by co-adsorbing CO molecules, which are well known to adsorb atop Cu atoms. We believe these states represent different adsorption configurations and charge states. One of the configurations shows a strong Kondo resonance at low temperature; spectroscopic imaging indicates that this state is strongly localized at the corners of the TCNE molecule. Several features symmetric about V=0 suggest a convolution of the Kondo density of states with inelastic electron tunneling spectroscopy of vibrational modes.
