MIRCEA TRIF, Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland, FILIPPO TROIANI, DIMITRIJE STEPANENKO, DANIEL LOSS, BASEL/MODENA COLLABORATION — We study the triangular antiferromagnet Cu3 in external electric fields, using symmetry group arguments and a Hubbard model approach. We identify a spin-electric coupling caused by an interplay between spin exchange, spin-orbit interaction, and the chirality of the underlying spin texture of the molecular magnetic state. The dispersionless excitation with characteristic intensity modulation is observed at $\hbar \omega = 7.8 \text{ meV}$ at low temperature. The neutron cross section is

8:24AM H15.00003 Magnetic excitation in artificially designed oxygen molecule molecule

TAKATSUGU MASUDA, International Schools of arts and sciences, Yokohama city university, SATOSHI TAKAMIZAWA, KAZUMA HIROTA, MASAAKI OHBA, SUSUMU KITAGAWA — We performed inelastic neutron scattering experiment to study magnetic excitation of O2 molecules adsorbed in microporous compounds. The dispersionless excitation with characteristic intensity modulation is observed at $\hbar \omega = 7.8 \text{ meV}$ at low temperature. The neutron cross section is explained by spin dimer model with intradimer distance of 3.1 Å Anomalous behaviour in the temperature dependence is discussed in the context of enhanced magnetoelasticity in the soft framework of O2 molecule.
8:36AM H15.00004 Influence of the Dzyaloshinskii-Moriya exchange interaction on quantum phase interference of spins, WOLFGANG WERNSDORFER, CNRS, Institut Neel, T.C. STAMATATOS, G. CHRISTOU, Dept. of Chemistry, Univ. of Florida, Gainesville, CNRS, INSTITUT NEEL, GRENOBLE COLLABORATION, DEPT. OF CHEMISTRY, UNI. OF FLORIDA, GAINESVILLE COLLABORATION — Magnetization measurements of a Mn_{12}mda wheel single-molecule magnet (SMM) with a spin ground state of S = 7 show resonant tunneling and quantum phase interference, which are established by studying the tunnel rates as a function of a transverse field applied along the hard magnetization axis. We show how the Dzyaloshinskii-Moriya (DM) exchange interaction can affect the tunneling transitions and quantum phase interference of a SMM. Of particular novelty and importance is the phase-shift observed in the tunnel probabilities of some transitions as a function of the DM vector orientation. Such observations are of importance to potential applications of SMMs that hope to take advantage of the tunneling processes that such molecules can undergo.

8:48AM H15.00005 Coupling between molecular spin cluster qubits, MARCO AFFRONTE, CNR-INFM-S3 — Supramolecular chemistry enables nanoscale engineering of scalable structures, by introducing controlled interactions between well defined molecular building blocks. The ability to assemble weakly-interacting subsystems is a prerequisite for implementing quantum-information processing (QIP) and generating controlled entanglement. In recent years, molecular nanomagnets (MNNs) have been proposed as suitable candidates for the qubit encoding and manipulation. In particular, antiferromagnetic Cr7Ni rings at low temperature behave as effective spin-1/2 systems and exhibit long decoherence times. Here we show that these rings can be linked to each other through supramolecular functional groups, which allow an extensive tuning of the coupling between their spins. We demonstrate that maximally entangled states can be deterministically generated in tripartite supramolecular assemblies, formed by two Cr7Ni rings and a Cu ion, by simulating the system’s time evolution under the effect of realistic microwave pulse sequences (under consideration NanoTechnology).

9:00AM H15.00006 High Resolution Neutron Scattering Studies of Spin Excitations in the 2D Singlet Ground State Systems of SrCu2(BO3)2, SrCu(2-x)Mg(x)(BO3)2 and Sr(1-x)La(x)Cu2(BO3)2, SARA HARAVIFARD, SARAH DUNSIGER, BRUCE GAULIN, HANNA DABKOWSKA, Department of Physics and Astronomy, McMaster University, Hamilton, ON, Canada., MARK TELLING, TOBY PERRING, Rutherford Appleton Laboratory, ISIS Pulsed Neutron Facility, Didcot, Oxford, United Kingdom., SAMIR EL SHAWISH, J. Stefan Institute, Ljubljana, Slovenia., JANEZ BONCA, Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia. — SrCu2(BO3)2 is a quasi-2D quantum spin system known to possess a collective singlet ground state and a realization of the Shastry-Sutherland model. One aspect of the study of SrCu2(BO3)2 for which there is a little information is the influence of impurities on the nature of the singlet ground state. There is much interest in such studies due to the remarkable phenomena associated with doping other quasi-2D copper-oxide quantum magnets with high-T superconductivity. Here we report high resolution time-of-flight neutron scattering studies of single crystals of doped SrCu(2-x)Mg(x)(BO3)2 and Sr(1-x)La(x)Cu2(BO3)2 and compare these results to the pure SrCu2(BO3)2 neutron scattering measurements. Particular emphasis is placed on the lifetimes of one-triplet excitations as well as the existence of in-gap spin excitations in the presence of Mg and La impurities.

9:12AM H15.00007 Entanglement Perturbation Theory for Antiferromagnetic Heisenberg Chains, LIHUA WANG, SUNG CHUNG, Western Michigan University — We use a novel method, Entanglement Perturbation Theory (EPT) to solve the Heisenberg chain comprehensively for both spin 1/2 and spin 1. A variety of quantities for xxx model and xxz model are calculated, including the ground state energies, the spin-spin correlation functions, and the first excited state energies relevant to a phase transition. EPT allows us to calculate systems with nearly one thousand sites and obtain spin-spin correlation functions over hundreds of sites with unprecedented accuracy. The successful application of EPT to the Heisenberg model shows that it is simple, general and exact for macroscopic quantum systems with translational symmetry.

9:24AM H15.00008 MagnetoElectric Coupling in a Quantum Spin Ladder1, JESSICA WHITE, JANICE MUSFELDT, University of Tennessee, SCOTT CROOKER, JOHN SINGLETON, ROSS MACDONALD, Los Alamos National Laboratory, CHRIS LANDEE, MARK TURNBULL, Clark University, HANS CHRISTEN, Oak Ridge National Laboratory — We investigated the optical properties and magnetization of (2,3-dmpyH)2CuBr3, an antiferromagnetic quantum spin ladder with strong rail interactions. It is similar to the copper oxides, yet its modest exchange interactions allows it to be saturated at 29 T, whereas copper oxides require a much higher field. In the end, we were able to see that the field dependent integrated absorption difference tracks the magnetization, demonstrating that the structure is sensitive to the ferromagnetic transition.

9:36AM H15.00009 Valence-Bond Monte Carlo Study of Random-Singlet Phase Formation, HUAN TRAN, NICHOLAS BONESTEEL, Department of Physics and NHMFL, Florida State University — In valence-bond Monte Carlo (VBMC) the ground state of a quantum spin system is sampled directly from the valence-bond (VB) basis — a useful basis for visualizing the properties of singlet ground states. For example, the ground state of the uniform AFM spin-1/2 Heisenberg chain is characterized by strongly fluctuating bonds with power-law length distribution, while in the random-singlet phase (RSP) of a random Heisenberg chain these bonds, while still having a power-law length distribution, lock into a particular VB state on long length scales. We use VBMC to directly probe the formation of a RSP by calculating both the average number of bonds n_L leaving a block of L spins (the VB entanglement entropy) and its fluctuations, σ^2_n_L = ⟨(n_L^2)⟩−⟨n_L⟩^2. For the uniform chain they have been calculated exactly to and shown to grow logarithmically with L — signaling the strong bond fluctuations. For random chains while n_L grows logarithmically with L, we find σ^2_n_L saturate for large L, signaling the “freezing” of the bonds into a particular random singlet state.

1A. Sandvik, PRL 95, 207203 (2005).

9:48AM H15.00010 Quantum Monte Carlo simulations of dynamical behavior for gapped spin chains1, ZHAOXIN XU, JUANA MORENO, Louisiana State University, MARK JARRELL, Louisiana State University and University of Cincinnati — We study the dynamical properties of spin-1 antiferromagnetic chains and spin-1/2 ferromagnetic-antiferromagnetic bond alternating chains. We calculate their dynamical structure factors using quantum Monte Carlo simulations combined with the Maximum Entropy Method. We focus on the finite temperature dynamical behavior and impurity effects on these gapped spin chains. We also discuss the connection between our results and recent neutron scattering experiments.

The wavelength-independence and the weak constraints on angular alignment and position of the circular obstacle make Poisson's spot a promising candidate for experiments to be realized with neutral matter waves. In this paper we report the observation of Poisson's Spot using a beam of neutral deuterium molecules.

Bergen, Norway — In the Poisson-Spot experiment, waves emanating from a source are blocked by a circular obstacle. Due to their positive on-axis interference, a single spot is observed on a screen placed at a sufficient distance from the source. The spot’s visibility reveals important information on the properties of the examined particles, such as their mass and polarizability.

8:24AM H16.00003 The Two-Mode Approximation in a Realistic Bose-Josephson Junction in a 85Rb/87Rb BEC Mixture. JEFFREY HEWARD, MARK EDWARDS, Georgia Southern University, CHARLES CLARK, NIST — We have studied the behavior of an experimentally realistic Bose-Einstein condensate (BEC) mixture subjected to a double-well potential. The mixture studied consists of 85Rb and 87Rb held in an optical trap with an external magnetic field that enables tuning of the 85Rb–87Rb scattering length. This system, without the external double-well potential, has been implemented at JILA [S.B. Papp, et al, Phys. Rev. Lett. 101, 040402 (2008)]. A double-well potential can be added to this system by applying a pair of lasers as was done in a previous experiment for single condensates [M. Albiez, et al, Phys. Rev. Lett. 95, 010402 (2005)]. We have used the Variable Tunneling Model (VTM) within the two-mode approximation to search for novel condensate mixture behavior in this experimentally accessible system. Possible behaviors include Bose-Josephson oscillations with both swapping and non-swapping modes and macroscopic quantum self-trapping with zero and pi modes as described in a recent paper [I. Satija, et al, arXiv:0811.1921v1 [quant-ph]]. We compare the behavior as predicted by the two-mode VTM with the solution obtained by integrating the coupled Gross-Pitaevskii equations. We propose some new experiments designed to observe these novel phenomena.

8:36AM H16.00004 Spin-orbit coupled Bose-Einstein condensates. BRANDON ANDERSON, TUDOR STANESCU, VICTOR GALITSKII, University of Maryland — We consider a Bose-Einstein condensate (BEC) of cold atoms with an internal pseudo-spin-1/2 degree of freedom that is coupled to momentum. The pseudo-spin degree of freedom emerges from the trapped multi-level atoms moving in the presence of spatially modulated laser fields. Within a so-called tripod scheme, the atom-laser interaction generates a pair of degenerate dark states. Upon adiabatically projecting onto the dark states subspace, an effective Hamiltonian emerges with a spin-orbit coupled pseudo-spin-1/2 degree of freedom. For a symmetric, Rashba-type spin orbit interaction the ground state of the pseudo-spin space is continuously degenerate along a circle in momentum space and may lead to many-body states with nontrivial topological properties. We investigate the Rashba-type spin-orbit BEC in the presence of weak density-density interactions.

8:48AM H16.00005 Spin Squeezing in Spinor Condensates. SABRINA LESLIE, JAY SAU, MARVIN COHEN, DAN STAMPER-KURN, Physics Dept, UC Berkeley — Spin squeezing in spinor condensates enables the control of quantum spin fluctuations in a fascinating multi-mode system. Further, it provides a coherent spin system characterized by sub-shot-noise spin fluctuations, with applications towards sensitive spatially-resolved magnetometry. With the application of appropriate unitary transformations, we show that one may manipulate the spin fluctuations atop an arbitrary F=1 coherent state, and in so doing prepare an arbitrary F=1 spin squeezed state. Taking into account experimental limitations to spin squeezing such as atom loss and nonlinear interactions in the condensate, we find that one may achieve roughly 17 dB of spin squeezing in the single mode regime and 10 dB of spin squeezing in the multi mode regime, for reasonable experimental parameters.

9:00AM H16.00006 Squeezing and entanglement in a Bose-Einstein condensate. CHRISTIAN GROSS, JEROME ESTEVE, STEFANO GIOVANAZZI, ANDREAS WELLER, MARKUS OBERTHALER — We report on the observation of spin squeezing and entanglement in a Bose-Einstein condensate trapped in double well and periodic potential [1]. The measurement of two conjugate variables - atom number difference and relative phase between adjacent sites - allows a direct connection to the presence of entanglement. The observations indeed confirm that entanglement is present even at finite temperature. The observed coherent spin squeezing of 3.8 dB implies that a usable quantum resource has been generated which is directly applicable to overcome the standard quantum limit of atom interferometry. The limitations due to experimental imperfections, finite temperature and three body loss will be discussed in detail. Latest results on spin squeezing using hamiltonian dynamics of internal states are presented. [1] J. Esteve, C. Gross, A. Weller, S. Giovanazzi and M. K. Oberthaler: Nature 455, 1216-1219.

9:12AM H16.00007 Creation of resilient entangled states and a resource for measurement-based quantum computation with optical superlattices. ANDREAS NUNNENKAMP, Departments of Physics and Applied Physics, Yale University, PO Box 208120, New Haven, CT 06520, USA, BENOIT VAUCHER, DIETER JAKSCH, Clarendon Laboratory, University of Oxford, Parks Road, Oxford OX1 3PU, UK — We investigate how to create entangled states with ultracold bosonic atoms trapped in optical lattices by dynamical manipulation of the shape of the lattice potential. We consider a period-two superlattice that allows both the splitting of each site into a double-well potential and also the variation of the height of the potential barrier between the sites. We show how to use this array of double-well potentials to entangle neighboring qubits encoded on the Zeeman levels of the atoms, without using the different vibrational states of the atoms. Finally, we present a method of realizing a Bell-pair encoded cluster state, a resource for measurement-based quantum computing which remains resilient to collective dephasing noise throughout the computation [NJP 10, 023005 (2008)].

9:24AM H16.00008 ABSTRACT WITHDRAWN

9:36AM H16.00009 Numerical Model of Polariton Dynamics in GaAs Quantum Well-Microcavity Structures. VINCENT HARTWELL, DAVID SNOKE, RYAN BALILI, University of Pittsburgh — Recent experimental results from GaAs quantum well-microcavity structures show evidence for Bose-Einstein condensation of polaritons. A main indicator of this is a large accumulation of polaritons near k=0 above a critical density threshold. The polariton gas is never in complete equilibrium, however. To model the system, we therefore cannot use an equilibrium model for the momentum distribution; instead, we have developed numerical methods for solving the quantum Boltzmann equation for the polariton momentum distribution, including the effects of polariton-polariton scattering, polariton-phonon scattering, and polariton scattering with free electrons. The model allows direct comparison to experimental results. An unexpected experimental result which we address in our modeling is that at very low densities, the polariton momentum distribution is invariant and independent of density. At high densities, our numerical model predicts the accumulation of polaritons near k=0 is indeed the result of the boson statistics of the particles, and though it is not in complete equilibrium, it has the characteristics of a “quasicondensate.”

9:48AM H16.00010 Single vortex-antivortex pair in an exciton polariton condensate. GEORGIOS ROUMPOUS, E.L. Ginzton Lab., Stanford University, USA, SVEN HEOFLING, ALFRED FORCHEL, Technische Physik, Universitat Wurzburg, Germany, YOSHIHISA YAMAMOTO, E.L. Ginzton Lab., Stanford University, USA and National Institute of Informatics, Japan — We report the observation of a single vortex-antivortex pair in a two-dimensional exciton polariton condensate. The pairs are evidenced in the time-integrated phase maps acquired using Michelson interferometry. The striped pattern of the sample disorder potential prevents rotation of the pairs, but allows their translational movement.
10:00AM H16.00011 Rabi oscillations in semiconductor multiwave response , MIKHAIL EREMENCHOUK, MICHAEL LEUENBERGER, University of Central Florida — We study the semiconductor response with respect to high intensity resonant excitation on short time scale when the contribution of the Fermi statistics of the electrons and holes prevails. Both the single and double pulse excitations are considered in the framework of asymptotically exact description. For the double pulse excitation we consider the time evolution of the multiwave mixing (MWM) exciton polarization. The main difference between the excitation by a single pulse or by two non-colinear pulses is that the Rabi oscillations of the MWM response are characterized by two harmonics. The operator dynamics governed by the external excitation exhibits three invariant spin classes, which do not mix with the evolution of the system. Two classes correspond to the bright exciton states and one contains all dark states. The dynamics of the classes turn is described by six characteristic frequencies and the Rabi frequencies (RF) are only two of them (one for each bright class). We show that if initially the system is in the ground state then the semiconductor Bloch equation preserves the invariant spin classes thus proving absence of the dark excitons in the framework of this description. We found that due to the mass difference between holes of different kind two additional RF’s, presenting in the operator dynamics, should appear in the evolution of the exciton polarization.

10:12AM H16.00012 Single-atom trajectories of intermittent fluorescence with quantum jumps , PATRICK COLES, ROBERT GRIFFITHS, Department of Physics, Carnegie Mellon University — Understanding the trajectories of single quantum systems is a modern theoretical challenge, given that experiments are no longer restricted to ensemble-averaged dynamics. Here, we present a model for a single 3-level atom driven resonantly on two transitions, resulting in intermittent fluorescence from one transition. The consistent histories formalism provides insight into the intermittent “shelving” process and predicts the distribution of dark periods for a given trajectory. We further predict quantum interference that leads to oscillations in the quantum-jump probability and discuss the possibility of observing these oscillations experimentally.

10:24AM H16.00013 Dynamics and fidelity of entanglement of photons coupled to optical fibers and waveguides , BEREKET BERHANE, Embry-Riddle Aeronautical University — We investigate the time evolution of the quantum mechanical states of photon-modes in optical fibers and waveguides starting from a multipolar coupling of neutral atoms with a quantized electromagnetic field. We apply our results to the propagation of entangled photons in optical fibers and investigate the fidelity of entanglement for various optical fiber lengths. Furthermore, we obtain a quantum input-output formalism in three dimensions and investigate the dependence of coupling and transfer efficiency on the quantum state of the incident photons. We apply our results to the coupling and propagation of entangled photons for applications in quantum memory transfer over optical fibers and waveguides.

10:36AM H16.00014 Quantum fluctuations in small lasers , KAUSHIK ROY CHOUDHURY, STEPHAN HAAS, A.F.J LEVI, University of Southern California — Master equations are used to demonstrate the dominant role of quantum fluctuations in determining the steady-state and transient response of a laser when there is a small number of particles in the system. In this regime, quantum fluctuations are found to suppress the lasing threshold and create a non-Poisson probability distribution for n and transient response of a laser when there is a small number of particles. In this regime, quantum fluctuations are found to suppress the lasing threshold and create a non-Poisson probability distribution for n and transient response of a laser when there is a small number of particles.

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H17 GQ1: Focus Session: Semiconducting Qubit Approaches 318

8:00AM H17.00001 Solid state quantum memory using 31P spins in silicon: advantages of hybrid qubit systems , JOHN MORTON, Oxford University — No abstract available.

8:36AM H17.00002 Radio-frequency single-electron transistor coupled to a few-electron double quantum dot1, FENG PAN, JOEL STETTENHEIM, MUSTAFA BAL, MINGYUN YUAN, ALEX RIMBERG, Dartmouth College, VLADIMIR UMANSKY, Weizmann Institute of Science — The radio frequency single-electron transistor (rf-SET) has been shown to be a ultra fast and highly sensitive electrometer, and can be potentially operated close to the quantum noise limit as a qubit readout device [1]. The interplay between the rf-SET electrometer and a two-level system offer an interesting system for study. Here we report our progress on investigating rf-SET's capacitively coupled to few-electron double quantum dots (DQDs). We fabricate lateral-defined DQDs from an AlGaAs/GaAs heterostructure and the rf-SET from superconducting aluminum embedded in a tank circuit. The sensitivity and bandwidth of on-chip rf-SET electrometer can be used to probe DQD operated in the few-electron regime. We have observed coupling between SET and DQD and have optimized our device design to enhance coupling in the few-electron limit. Recent experimental results will be discussed. [1] M. H. Devoret and R. J. Schoelkopf, Nature, 406, 1039 (2000).

1Supported by the NSF and ARO.

8:48AM H17.00003 3D Acoustic Modes, Shot Noise and Strain Displacements in a Radio Frequency Quantum Point Contact1, J. STETTENHEIM, Dartmouth College, M. THALAKULAM, U. Wisconsin-Madison, F. PAN, M. BAL, Dartmouth College, L.N. PFIEFFER, K.W. WEST, Bell/Lucent, A.J. RIMBERG, Dartmouth College — As previously reported, our broadband frequency resolved measurements of shot noise in a radio frequency QPC (RF-QPC) reveal a remarkable frequency dependence absent from theoretical predictions. Based on piezoelectric coupling in GaAs, our data suggest a feedback loop in which shot noise drives resonant acoustic vibrations that in turn create correlations in electron tunneling. The feedback concentrates the initially white noise in a narrow band around the sample’s resonant frequency, allowing shot noise spectrum engineering. We solve for the 3D acoustic modes of our samples, finding close correspondence with measured frequencies. We have determined that the geometry and magnitude of the polarization field selects the acoustic mode excited. As polarization fields and strain displacements are linked in GaAs, we estimate the ultimate mechanical displacement sensitivity of our RF-QPC.

1Supported by the NSF and ARO.
9:00AM H17.00004 Radio-frequency quantum point contact in a silicon/silicon-germanium two-dimensional electron system, MADHU THALAKULAM, CHRISTIE SIMMONS, ERIC SACKMANN, BJORN VAN BAEL, D.E. SAVAGE, MAX LAGALLY, M.A. ERIKSSON, University of Wisconsin-Madison — Radio frequency quantum point contacts (RF-QPC) are sensitive and fast electrometers. The capability to integrate such devices with semiconductor-based quantum dot systems makes them an attractive candidate for fast charge readout, and the increasing interest in spins in group-IV quantum dots motivates the development of such devices in silicon/silicon-germanium two-dimensional electron systems. We report the operation of an RF-QPC fabricated on a silicon/silicon-germanium heterostructure with an on-chip matching network. An on-chip spiral inductor and the capacitance from the bonding pads define the tank circuit. The inductance and capacitance parameters are optimized to achieve a resonant frequency of approximately one GHz. The operation of RF-QPC at milli-Kelvin temperature and the charge readout of a quantum dot system using an RF-QPC will be discussed.

9:12AM H17.00005 Observation of tunnel rates of phosphorus dopants using silicon SETs, H. HUEBL, C.D. NUGROHO, A. MORELLO, C. ESCOTT, A.S. DZURAK, R.G. CLARK, Centre for Quantum Technology, University of New South Wales, Sydney, C. YANG, J.V. DONKELAAR, A. ALVES, D. JAMIESON, Centre for Quantum Computer Technology, University of Melbourne, Melbourne, M.A. ERIKSSON, Department of Physics, University of Wisconsin, Madison, Wisconsin — Charge centres, such as donors in semiconductors, have significant potential for quantum information processing. In silicon, which can be produced nuclear-spin free, phosphorus donors are a prime candidate for implementation of a qubit, due to their long spin coherence times. In this presentation we will discuss a hybrid structure, consisting of implanted phosphorus donors connected by a gate potential in close vicinity to a gate-induced, MOS-based silicon single electron transistor (Si-SET). We study the dual functionality of the nearby Si-SET as a sensitive charge detector as well as a gate-induced electron reservoir. Experimentally, we observe shifts in the position of the Coulomb peaks of the Si-SET corresponding to ~20% of an electron charge. We attribute these shifts to charge transfers between the Si-SET island reservoir and the nearby phosphorus donors. Pulsed voltage spectroscopy on one of these charge transitions allows us to investigate the capture and emission times of a donor resulting in a capture rate of 3000 s^-1 and an emission rate of 1000 s^-1 corroborating expectations from device modelling.

9:24AM H17.00006 Self-Correcting Dynamic Decoupling Pulse Sequences, ALEXEI M. TYRYSHKIN, STEPHEN A. LYON, Princeton University, WENXIAN ZHANG, VIATCHESLAV V. DOBROVITSKI, Ames Laboratory — Dynamic decoupling (DD) techniques employ a series of strong refocusing pulses to combat decoherence in quantum systems. However, each DD pulse is imperfect and thus introduces a small instrumental error; the error can accumulate rapidly upon applying many DD pulses, and this error can destroy the quantum state. We have examined several DD pulse sequences, including CPMG, ZZXX, ZXYX and their concatenated variants, using electron spin resonance (ESR) of donors electron spins in silicon. While all these DD sequences performed comparatively in cancelling the phase noise arising from magnetic field fluctuations, only one sequence (ZXYX) demonstrated the ability to protect an arbitrary coherent state, including X, Y, and Z states in the rotating frame. The other sequences (CPMG and ZZXX) were able to store only one state (Y) while destroying other states (X and Z). The superior performance of ZXYX arises from its internal ability to correct for pulse amplitude errors, the dominant error in these ESR experiments.

9:36AM H17.00007 ABSTRACT WITHDRAWN —

9:48AM H17.00008 Hyperfine tolerant triplet-singlet qubit in rotating double quantum dots, DAVID DRUMMOND, LEONID P. PRIYADKO, KIRILL SHTENGEL, Univ. California, Riverside — We examine the triplet-singlet state of pairs of GaAs single electron quantum dots, in which the singlet and m=0 triplet states represent the logical 0 and 1. Each electron’s spin feels a different magnetic field from the hyperfine coupling to the local nuclei of the GaAs, leading to a relative phase difference between the two electrons, and thus decoherence. Previous methods have delayed decoherence using complicated electrical pulse schemes or nuclear polarization with Overhauser fields, which can only be maintained for short times and require great energy. Instead we propose to eliminate hyperfine decoherence by repeatedly rotating the dots adiabatically, exposing the electrons to the same average magnetic field. In addition, we show that if these rotations are performed repeatedly in a symmetric fashion, the Dresselhaus and Rashba spin-orbit couplings are significantly suppressed. The construction of such a device might also be of interest to topological quantum computers, which depend on similar rotations.

10:00AM H17.00009 Multiple Nuclear Polarization States in a Double Quantum Dot, JEROEN DANON, Delft University of Technology — In a double quantum dot under conditions of electron paramagnetic resonance we have observed multiple stable states of nuclear polarization and also switching between those states. The system exhibited strong hysteretic behavior over a large range of magnetic fields, indicating the dynamical buildup of effective magnetic nuclear fields up to 150 mT. We have explained these findings in the framework of an elaborated theoretical model. The results reported enable applications of this nuclear polarization effect, including manipulation and control of the nuclear fields and possible use of this for improving the electron spin coherence time.

10:12AM H17.00010 Electron spin dephasing by hyperfine-mediated interactions in a nuclear spin bath, LUKASZ CYWINSKI, University of Maryland, College Park, WAYNE M. WITZEL, Naval Research Laboratory, Washington DC, SANKAR DAS SARMA, University of Maryland, College Park — We investigate pure dephasing decoherence (free induction decay and spin echo) of a quantum dot spin qubit interacting with a nuclear spin bath. While for infinite magnetic field the only decoherence mechanism is spectral diffusion due to dipolar flip-flops of nuclear spins, with decreasing B the hyperfine-mediated interactions between the nuclear spins become important. We give a theory [1] of decoherence due to these interactions which takes advantage of their long range nature. For a thermal uncorrelated bath we show that our theory is applicable down to B~10 mT, allowing for comparison with recent experiments on spin echo in GaAs quantum dots [2].

10:24AM H17.00011 Nuclear State Preparation via Landau-Zener-Stückelberg transitions in Double Quantum Dots, HUGO RIBEIRO, GUIDO BURKARD, University of Konstanz — We theoretically model a nuclear-state preparation scheme that increases the coherence time of a two-spin qubit in a double quantum dot. The two-electron system is tuned repeatedly across a singlet-triplet level-anticrossing with alternating slow and rapid sweeps of an external bias voltage. Using a Landau-Zener-Stückelberg model, we find that in addition to a small nuclear polarization that weakly affects the electron spin coherence, the slow sweeps are only partially adiabatic and lead to a weak nuclear spin measurement and a nuclear-state narrowing which prolongs the electron spin coherence. Based on our description of the weak measurement, we simulate a system with up to n=200 nuclear spins per dot and qualitatively explain recent experimental findings. Scaling in n indicates a stronger effect for larger n, also in qualitative agreement with experiments.
10:36AM H17.00012 Electromagnetic fluctuations as a source of decoherence for double quantum dot charge-based qubits, DIEGO VALENTE, Department of Physics, University of Central Florida, FRANK WILHELM, Institute for Quantum Computing, University of Waterloo, EDUARDO MUCCIOLLO, Department of Physics, University of Central Florida — Solid-state quantum dots are strong candidates for the physical realization of qubits. They present the ubiquitous advantage of easier scalability, but also couple rather effectively to external degrees of freedom which lead to decoherence phenomena. One such source of decoherence lays in the electromagnetic fluctuations occurring in the circuits utilized for preparation and measurement of these qubits. Here we investigate these sources of decoherence in double quantum dot charge-based qubit systems. We use effective circuit models and estimates of time correlations of such fluctuations to calculate the energy ($T_1$) and phase ($T_2$) relaxation times introduced into the qubit system. We also present ideas on how to suppress some of the destructive effects of these fluctuations and increase the quality factor for quantum oscillations.

10:48AM H17.00013 Probing the spin structure of $\nu = 2$ quantum Hall fluid around an antidot, LEE BASSETT, CHRIS FORD, NIGEL COOPER, JONATHAN GRIFFITHS, DAVID ANDERSON, IAN FARRER, GEB JONES, DAVE RITCHIE, University of Cambridge — We experimentally investigate spin and charge excitations in a small closed edge of integer quantum Hall fluid encircling a nano-scale potential island, or antidot (AD), in a two dimensional electron system. Using quantum point contacts to inject and detect spin-polarized currents via edge states, we have measured spin-resolved transport through single ADs at filling factor two. At relatively low magnetic fields (\approx 1T), tunneling between the AD states and higher Landau levels in the bulk produces pairs of Coulomb blockade peaks in conductance above the $2e^2/h$ plateau. These transmission resonances were thought to result from spin-polarized tunneling through individual single-particle AD states (of alternating spin), but our experiments show that, while spin is generally conserved during transport, the tunneling current is not spin-polarized. We interpret these results as signatures of interactions within the AD which result in a separation of the energy scales associated with spin and charge excitations.

Tuesday, March 17, 2009 8:00AM - 10:48AM –
Session H18 DPOLY: Block Copolymer Thin Films I 319

8:00AM H18.00001 Polymer Physics Prize Symposium Break –

8:36AM H18.00002 Analysis of block-copolymer thin film ordering through a moving thermal zone, KEVIN YAGER, NATHANIEL FRÉDIN, RONALD JONES, Polymers Division, National Institute of Standards and Technology — Block-copolymer thin films self-assemble into well-defined structures at the nanometer lengthscale. It has been shown that the morphology, orientation, and degree of order resulting from annealing is sensitive to a variety of preparation parameters, including annealing time and temperature, solvent exposure, substrate surface energy, application of electric fields, etc. A moving thermal zone can also strongly affect the ordering. We have shown that relatively “cold” zone annealing (CZA) conditions (above the glass-transition but well below the disordering temperature) can induce a preferential orientation of the microdomains in thin films. We further analyze this effect by measuring the ordering through the thermal front, using atomic force microscopy and scattering techniques (reflectivity and GI-SAXS), which are combined to quantify the order and 3D orientational distribution. Zone annealing leads to increased grain sizes and substantially faster coarsening kinetics, as compared to oven annealing. Moreover, the evolution of order through the thermal front constrains models which aim to explain the CZA’s ability to induce orientational bias.

8:48AM H18.00003 Neutral Parameter Window for Perpendicularly Oriented Block Copolymer Resists Deposited on Organosilicate Substrates with Tunable Surface Energy, HYOSEON SUH, KOOKHEON CHAR, Seoul National University, HUIMAN KANG, PAUL F. NEALEY, University of Wisconsin — Balancing the interfacial interactions of a block copolymer (BCP) with a substrate as well as the free surface can induce the perpendicular orientation of microdomains, allowing the BCP films to serve as templates for nanofabrication. However, it is known that such orientation of microdomains is quite sensitive to the film thickness. In this presentation, we investigated the effect of film thickness on the orientation of microdomains in lamellae-forming P(S-b-MMA) thin films placed on thermally cured organosilicate (OS) substrates. For the film thickness of a P(S-b-MMA) ranging from 1 L$_0$ up to 2.5 L$_0$, we varied the surface energy of the OS substrate around the value close to the enthalpically neutral condition by controlling the substrate cure temperature. We will demonstrate the origin of the observed thickness effect by taking into account the increase in surface area at the free surface when P(S-b-MMA) films make holes or islands depending on the incommensurable conditions of the BCP film. This analysis allows us to define a more accurate neutral window for the P(S-b-MMA) in terms of both substrate surface energy and BCP film thickness.

9:00AM H18.00004 Effect of Surface Energies on Block Copolymer Thin Film Phase Behavior, JULIE LAWSON, MICHAEL BANEY, THOMAS EPPS, University of Delaware — The development of block copolymer materials for future nanotechnologies requires an understanding of how surface energetics affect block copolymer thin film phase behavior. In this work, we use combinatorial methods to study these effects and to identify transitions in thin film phase behavior and microstructure orientation. Surface energy gradients were created using a vapor deposition technique developed by our group in which cross-diffusion of functionalized chlorosilanes under dynamic vacuum results in a linear gradient in surface energy on a silicon substrate. These gradients were characterized using X-ray photoelectron spectroscopy (XPS) and contact angle measurements. We then cast a thin film of block copolymer on the modified substrates using a flow coating technique. Finally, we used thermal and solvent annealing conditions to affect the surface energy at the free surface. The surface morphology of the films was examined with atomic force microscopy (AFM), and morphological changes across the gradient were found.

9:12AM H18.00005 Systematic tunability of self-assembled block copolymer patterns, YEON SIK JUNG, CAROLINE ROSS, Massachusetts Institute of Technology — The morphology and length scale of diblock copolymers (BCPs) are determined by the chain lengths, and therefore to obtain different geometries and feature sizes, polymers with different chain lengths or BCP/homopolymer blends have been employed. Here, we report on the solvent vapor induced tunability of pattern dimension and morphology of thin films of polystyrene-polydimethylsiloxane (PS-b-PDMS) BCPs, which provide robust patterns with exceptionally good ordering due to their large interaction parameter. Vapor pressure can control the interfacial interaction between the two blocks, and a mixed solvent can manipulate the effective volume fraction of each block. We show both coupled and independent control of the microdomain size and the periodicity by changing the vapor pressure and the mixing ratio of a selective (heptane) and a partially selective (toluene) solvent. We also demonstrate the transformations from spheres to cylinders and from cylinders to perforated lamellar structures by increasing the portion of selective solvent in the vapor. These results are supported by a theoretical model.

9:24AM H18.00006 Solvent annealing of Micropatterned PS-b-PEO copolymer films1. TAE HEE KIM, HIMADRI ACHARYA, HEE JUNE JOENG, CHEOLMIN PARK, Yonsei University — Solvent annealing of block copolymer thin films have been known as an effective way to control both orientation of microdomains with respect to the surface and their registration into a well ordered periodic lattice structure. We have recently demonstrated hierarchically ordered microdomains in a thin poly(styrene-b-ethylene oxide)(PS-b-PEO) film combined with microcontact printing. The solvent annealing gave rise to well ordered spherical PEO microdomains in large area by the confined dewetting of thin PS-b-PEO films which had been micropatterned on chemically modified surface during solvent annealing. In this presentation, we intentionally prepare a micropatterned dewet film of PS-b-PEO by spincoating a block copolymer solution on a topographic PDMS pre-pattern. Convex lens shaped spherical caps of PS-b-PEO individually located on each PDMS mesa were successfully transferred to a Si substrate by a conventional transfer printing technique. We investigate the effect of solvent on not only film wettability but also formation of hierarchical nanostructures.

9:36AM H18.00007 Transition Behavior of Block Copolymer Thin Films. DU YEOL RYU, CHANGHAK SHIN, HYUNJU AHN, JUNE HUH, Yonsei University, Korea, KWANG-WOO KIM, Pohang Accelerating Laboratory, Korea, THOMAS RUSSELL, University of Michigan — We examine the transition behavior of thin films of diblock copolymers at the substrate/polymer interface. We employ the modified theory for bilayer model with surface capillary waves on simple viscoelastic liquid films. The viscosity obtained in this study is compared with that from rheology measurements for bulk. We found that the PDMS-rich layer near the surface appears at the temperature higher than the glass transition temperature. We apply the modified theory for bilayer model to thin films and show that the order to disorder transition, when the enthalpic term of free energy of mixing is equal to the entropic term. In thin films, interactions at the substrate/polymer and polymer/air interfaces influence this free energy balance, resulting in a change in the transition behavior. Here, we report on the transition behavior of BCP thin films. The thickness dependence of the transition temperature shows that interfacial interactions enhance the orientation of the lamellar microdomain parallel to the film surface even in 40L0 in thickness, where L0 is the equilibrium period of the BCP in the bulk. In thin film geometry, this phenomenon can be attributed to the fact that a preferential interaction of one component with the substrate leads to an amplification of a periodic variation in the composition and a shift of transition temperature.

9:48AM H18.00008 Thin Film Morphology of Diblock and Triblock Copolymers with Bulk Order-Order Transition (OOT). K.E. SOHN, R.C. COFFIN, G.C. BAZAN, E.J. KRAMER, UCSB, K. KOJIO, Nagasaki, B.C. BERRY, A. KARIM, NIST, M. SPRUNG, J. WANG, ANL — The thin film morphology of SEB and SEBS block copolymers that have an OOT in the bulk from cylinders to spheres as the annealing temperature is increased was studied as a function of increasing film thickness using AFM and GISAXS. For both SEB and SEBS, the morphological transition is the same no matter if the film is annealed above or below the bulk OOT. The SEB morphology is governed by the free energy penalty due to chain stretching, showing spheres when the film thickness is less than that of a monolayer of cylinders. The cylindrical morphology dominates when the film thickness is larger than two monolayers of cylinders. The SEBS morphology is governed by the free energy penalty due to loops of the midblock at the surface. Spheres require a lower fraction of midbloks to loop at the surface than cylinders, therefore spheres pay a lower free energy penalty due to chainlooping and were found for all film thicknesses studied (up to ~100nm).

10:00AM H18.00009 UV-Induced Order-to-Order Transition (OOT) in Thin Films of Supramolecular Diblock Copolymer Assemblies Containing 2-(4'-Hydroxyphenylazo)benzoic Acid. WEI CHEN, JIA-YU WANG, XINYU WEI, ANNA BALAZS, THOMAS RUSSELL — Long-range lateral ordering and orientation in block copolymer thin films, which are highly desired for applications requiring addressability, as in magnetic storage, can be obtained in a controlled way via a one-dimensional order-to-order transition (OOT) in microphase separated structure. The photoinitiation and photolysis of benzene results in volume changes that, when integrated into copolymers, can bring about phase transitions that, in turn, by sweeping the light across a surface, will promote long-range lateral ordering, similar to zone-refinement process used to produce large single crystals. We investigated UV-induced OOT in the supramolecule-assembled thin films of 2-(4'-hydroxyphenylazo)benzoic acid and polystyrene-block-poly(2-vinylpyridine) diblock copolymer. Grazing incidence small angle X-ray scattering demonstrated that phase transition from lamellae to hexagonally packed cylinders occurred at 150 °C after UV radiation for 1 hour due to a significantly enhanced interfacial fluctuations induced by photoisomerization as evidenced by X-ray Reflectivity. This suggested that UV light can be utilized to control OOT in the supramolecule-assembled thin films and, hence, to fabricate long range ordered nanostructures, and even smart responsive surfaces.

10:12AM H18.00010 Dilute Micelle Arrays in Block Copolymer Thin Films. JOHN PAPALIA, RICHARD REGISTER, Princeton U., DOUGLAS ADAMSON, U. Connecticut, PAUL CHAIKIN, NYU — Thin films of sphere-forming block copolymers are attractive templates for surface patterning and nanofabrication. While the areal density of spheres (micelles) can be adjusted through the diblock’s molecular weight, sparse micelle arrays are quite difficult to achieve. Instead, we blend the diblock with matrix homopolymer in the “dry brush” regime, which eliminates the “terracing” (island/ hole formation) present in films of the neat diblock. Furthermore, by choosing a system where the sphere-forming block wets the substrate and/or free surface, we control the areal density of micelles by stepwise dilution with PS matrix homopolymer dilution, by using the film thickness as the control parameter rather than the blend ratio. Specifically, we employ a polystyrene-poliosoponoe diblock (PS/PI blocks of 68/12 kg/mol) blended with PS homopolymer; the PI block wets both the free surface and the SiOx substrate. For sufficiently thin films (<60 nm for 50 wt% homoPS), all the block copolymer goes to form brush-like layers at the two surfaces, yielding no micelles. For thicker films, sufficient block copolymer remains to form spherical microdomains between the brushes; the areal density of micelles can be continuously tuned via the film thickness. We evaluate this approach by preparing a film with a thickness gradient, and apply a simple model to the measured areal densities of micelles.

10:24AM H18.00011 Surface Dynamics of Segregation Layer in Blockcopolymer Films1. SANG- HOON SONG, WONSUK CHA, Sogang University, Korea, ZHANG, JIANG, SURESH NARAYANAN, Advanced Photon Source, ANL, ADRIAN RUEHM, Max Planck Institute for Metal Research, Germany, SUNIL K. SINHA, Univ. of California, San Diego, HYUNJUNG KIM, Sogang University — We have investigated the surface dynamics of supported block copolymer films of poly(styrene)-b-poly(dimethylsiloxane) (PS-b PDMS) in the spherical phase, i.e., PDMS cores surrounded by PS shells by x-ray photon correlation spectroscopy (XPCS) in grazing angle geometry. The experiment was performed at the beamline 8ID-I in Advanced Photon Source. We found that the PDMS-rich layer near the surface appears at the temperature higher than the glass transition temperature. We applied the modified theory for bilayer model to thin films and show that the order to disorder transition, when the enthalpic term of free energy of mixing is equal to the entropic term. In thin film geometry, this phenomenon can be attributed to the fact that a preferential interaction of one component with the substrate leads to an amplification of a periodic variation in the composition and a shift of transition temperature.

10:36AM H18.00012 Block Copolymer Brushes1. MARK MATSEN, University of Reading — Using self-consistent field theory (SCFT), we examine dry brushes of AB diblock copolymer, where the B ends are uniformly graftied to a planar substrate. Four different morphologies are predicted, which are conveniently described as the uniform, stripe, hexagonal, and inverted hexagonal phases on the basis of the patterned formed at the air surface by the A-rich domain. Phase diagrams are calculated for different grafting densities and for different A-segment surface affinities. In contrast to unanchored diblock-copolymer films, the brush system has a much greater tendency to form chemically-patterned surfaces.

1Sponsored by EPSRC (grant no. EP/F029616/1)
The obtained values are in good agreement with the dynamic heterogeneity length estimated by 4 dimensional NMR for the main structural relaxation. Thus the relative timescale of the relaxational process by altering the polymer network structure is shown to directly influence the Case II front propagation velocity and the nature of the observed transport behavior.

9:24AM H19.00006 On the Nature of Gas Transport of Ethylene Vinyl Alcohol Copolymers
SERGEI NAZARENKO, JUSTIN BRANDT, BRIAN OLSON, University of Southern Mississippi, ALEXANDER JAMIESON, Case Western Reserve University — Historically, all the approaches describing gas diffusion in polymers can be roughly divided in two categories, based on free volume models and the activation molecular models, which take into account the cooperative penetrant-polymer chain motions, chain rigidity and intermolecular forces. Although gas transport characteristics exhibit a general correlation with free volume, alone free volume can not adequately describe gas barrier. The chain rigidity and the strength of intermolecular interactions are two additional important factors which are manifested via activation energy. The main objective of this work was to develop fundamental understanding of oxygen transport in a broad range of EVOH copolymers as it is related to free volume characteristics probed by positron annihilation lifetime spectroscopy and hydrogen bonding interaction.
elastic modulus is the inverse of the decaying characteristic relaxation time. Parameter of the isothermal ripening process is the “ripening time”, scaling function with two pronounced powerlaw regions, a fast ripening process ($G_t$), scaling relations for the slow ripening of an out-of-equilibrium model colloidal solid that consists of clay particles that swell and exfoliate into randomly oriented hardening in bidisperse glasses and its relation to microscopic conformational changes. The mixtures contain chains of very different lengths but equivalent topological constraints. Unlike related algorithms, the chain shortening has little effect on the craze structure, allowing the entanglements to be followed in real space, as well as along chains. CRETA is applied to molecular simulations of crazing using a coarse-grained bead-spring polymer model. The number of beads in each chain $N$ and the entanglement length $N_e$ are varied. Our results show that entanglements do not act like fixed chemical crosslinks. There is a systematic loss in entanglements during craze formation that does not occur when chains are deformed affinely and is nearly independent of $N/N_e$. The role of chain length, $N$, interchain friction and other parameters in determining the degree of entanglement loss is discussed.

We gratefully acknowledge support of the NSF-IGERT fellowship program

10:00AM H19.00009 Dynamics of a polymer nanocomposite during active deformation, ROBERT RIGGLEMAN, GREGORY TOEPPEWEIN, JUAN DE PABLO, HAU-NAN LEE, M. D. EDGER, University of Wisconsin, Madison — Recent molecular simulation and experimental studies have explored the effects of stress on the dynamics of polymer glasses and both have demonstrated that relaxation times can decrease by more than two orders of magnitude. However, many questions on the origins of the changes in the dynamics remain unaddressed. In this study, we have performed extensive molecular dynamics and Monte Carlo simulations of a polymer glass and a polymer nanocomposite undergoing active deformation. We measure the dynamics during both constant stress and constant strain rate deformations and provide a detailed comparison of the two modes of deformation. The nanoparticles impart mechanical reinforcement onto the polymer, requiring larger stresses to achieve the same deformation. In both systems, the dynamics correlate very well with the instantaneous strain rate whether we deform at constant stress or constant strain rate. Additionally, we explore the effects of each mode of deformation on the potential energy landscape and find qualitatively different behaviors when we deform at constant stress versus constant strain rate. Finally, we provide a brief comparison of our simulation results to recent experiments and demonstrate that the simulations are capable of reproducing all of the behaviors observed in the experiments.

10:12AM H19.00010 Rheological Scaling Relation for an Out-of Equilibrium Colloidal Solid1, H. HENNING WINTER, University of Massachusetts Amherst, X. WANG, G. XUE, Nanjing University, China, P. SUN, Nankai University, China — We explore scaling relations for the slow ripening of an out-of-equilibrium model colloidal solid that consists of clay particles that swell and exfoliate into randomly oriented clay sheets through the action of end-functionalized (“sticky”) polymer molecules. A freshly mixed sample quickly forms a sample-spanning network structure that gradually approaches its equilibrium. The ripening process accelerates at elevated temperature. After rescaling (Rheol Acta 45:331-338, 2006), the complex modulus data $G'(\omega)$, $G''(\omega)$ from time-resolved mechanical spectroscopy (Rheol Acta 33:385-397, 1994) shows that, surprisingly, the growth function of the elastic modulus is the inverse of the decaying characteristic relaxation time. Parameter of the isothermal ripening process is the “ripening time”, $t_r$. A single scaling function with two pronounced powerlaw regions, a fast ripening process ($\sim t_r^{-2}$) followed by slow ripening ($\sim t_r^{-1/2}$), defines the state of ripening and projects the time necessary to reach equilibrium.

10:24AM H19.00011 Strain Hardening in Bidisperse Polymer Glasses, MARK O. ROBBINS, Johns Hopkins University, ROBERT S. HOY, Materials Research Laboratory, University of California, Santa Barbara — The connections between glassy and rubbery strain hardening have been a matter of great controversy in recent years. Recent experiments and our earlier simulations have suggested that the hardening modulus $G_r$ is proportional to the entanglement density in glasses, as it is to the crosslink density in rubbers. In this work we present more extensive studies of strain hardening in bistable glasses and its relation to microscopic conformational changes. The mixtures contain chains of very different lengths but equivalent chemistry. $G_r$ does not scale simply with the entanglement density. Instead it obeys a simple mixing rule, with $G_r$ equal to the volume fraction weighted average of the moduli of the two pure components. As in recent studies of monodisperse systems (R. S. Hoy and M. O. Robbins, Phys. Rev. Lett. 99, 117801 (2007)), the stress is directly correlated to the degree of chain orientation. Chains of a given length undergo almost the same degree of alignment in pure systems and mixtures, explaining why the mixing rule applies. The connection to recent analytic theories by K. Chen and K. S. Schweizer (PRL, in press) will be discussed.

10:36AM H19.00012 A Model of Glassy Polymers that Includes both Spatial and Temporal Fluctuations, GRIGORI MEDVEDEV, JAMES CARUTHERS, Purdue University — Glass forming polymers near and below $T_g$ are dynamically heterogeneous as has been found via a number of experimental techniques, where the dynamic heterogeneity is the probable cause of the non-exponential decay of the orientation correlation function of probe molecules embedded in polymer matrix as well as “breaking” of the Stokes-Einstein relations for rotational and translational diffusion. Although dynamic heterogeneity in glassy polymers is well established, constitutive models for describing the mechanical behavior employ quantities that ignore fluctuations. Consequently, the mechanical implications of dynamic heterogeneity are largely unexplored. In this talk we report on a finite element type model, where the local relaxation times in the material experience fluctuations, i.e. both the temporal and spatial nature of the fluctuations is explicitly acknowledged. The stochastic force between neighboring domains is assumed to be uncorrelated; however, since neighboring domains tile space, there is spatial and temporal correlation in the stochastic response of the system. The mechanical response of the sample under different deformation histories, including constant strain rate tensile and compressive loading as well as creep under constant load, will be presented.
polymers within the film greatly extends the pH range of stable electroactivity. Immobilization of polyaniline within a polymer acid matrix retards dopant diffusivity and reduces proton mobility. The preservation of local acidic conditions previously reported polyaniline systems. In comparison, polyaniline that is doped with small-molecule acids loses its electroactivity in solutions beyond pH 4. We studied the stability of polyaniline that is template synthesized on poly(2-acrylamido-2-methyl-1-propanesulfonic acid) as a function of pH. Transitions between biosensor and organic electrochemical transistor devices. For many conducting polymers, however, stable electrochemical activity often demands restrictively side of the chain to the other. This causes bending in alternating directions, leading to a sinuosoidal shape, while maintaining a straight chain axis on average.

Since PPY and PANI can change from a coil to a straight rod, these polymers can achieve strains about an order of magnitude higher than PA. This work was supported by Honda R&D Co., Ltd.

9:36AM H20.00007 Quadratic Electro-optic Effect in a Novel Nonconjugated Conductive Polymer, iodine-doped Polynorbornene. ANANTHAKRISHNAN NARAYANAN, MRINAL THKUR, Photonic Materials Research Laboratory, Auburn University, AL. — Quadratic electro-optic effect in a novel nonconjugated conductive polymer, iodine-doped polynorbornene has been measured using field-induced birefringence at 633 nm. The electrical conductivity of polynorbornene increases by twelve orders of magnitude to about 0.01 S/cm upon doping with iodine. The electro-optic measurement has been made in a film doped at the medium doping level. The electro-optic modulation signal was recorded using a lock-in amplifier for various applied ac voltages (4 kHz) and the quadratic dependence of the modulation on the applied voltage was observed. A modulation of about 0.01% was observed for an applied electric field of 3 V/micron for a 100 nm thick film. The Kerr coefficient as determined is about 1.7x10^{-11} m/V^2. This exceptionally large quadratic electro-optic effect has been attributed to the confinement of this charge-transfer system within a sub-nanometer dimension. A. Narayanan, A. Palthi and M. Thakur, J. Macromol. Sci. – PAC, accepted.

9:48AM H20.00008 Quadratic Electro-optic Measurements in Nonconjugated Conductive Polymers, iodine-doped Polyisopropene and Poly(β-pinenes) at 1.55µm, ANANTHAKRISHNAN NARAYANAN, JITTO TITUS, MRINAL THKUR, Photonic Materials Research Laboratory, Auburn University, AL. — Exceptionally large near-resonant (at 633nm) quadratic electro-optic effects in nonconjugated conductive polymers, iodine-doped poly(β-pinenes) and 1,4-cis-polyisopropene have been previously reported. In this report, we discuss the quadratic electro-optic effects in these polymers at 1.55µm. The measurements were made using the field-induced birefringence technique. A modulation depth of about 0.1% was observed for a 1 µm thick sample of doped poly(β-pinenes) at an applied field of 1V/µm. The Kerr coefficient as determined was about 1.6x10^{-10} m/V^2. For polyisopropene the modulation was slightly smaller. These exceptionally large Kerr coefficients at a technologically important wavelength make these polymers promising for guided-wave applications in electro-optics. Techniques for longer-term stability of the samples have been established. The large optical nonlinearities as observed have been attributed to the sub-nanometer confinement of these charge-transfer systems.

10:00AM H20.00009 ABSTRACT WITHDRAWN —

10:12AM H20.00010 Ultrasensitive Solution Processed Polymer Photodetectors. XIONG GONG, MING-HONG TONG, GANG YU, CHAN-LONG SHIEH, BOO NILSSON, ALAN HEEGER, CBRITE INC TEAM, UC SANTA BARBARA TEAM. — Semiconducting polymeric optoelectronic and electronic devices have evolved as a promising cost-effective alternative to silicon-based devices. Organic photodetectors have been the subject due to several inherent advantages. Some of the important advantages of these so-called “plastic” electronics include large-area detection, low cost of fabrication, ease of processing and mechanical flexibility. However, there are few reports on organic photodetectors whose performances are comparable with inorganic counterparts. We report ultrasensitive solution processed photodetectors fabricated by different semiconducting polymers as the electron donors and various fullerences derivatives and/or inorganic quantum dots as the electron acceptors. Polymer photodetectors with different photo-responsivity and detectivity were demonstrated. One example is that polymer photodetectors have photo-response from 300nm to 1450nm, the detectivity larger than 10^{12} cm Hz^{1/2}/W, and linear dynamic range larger than 120 dB. All these values are comparable to or even better than their inorganic counterparts.

10:24AM H20.00011 Twin instability of Peierls distortion and its mechanical consequence on conductive polymer actuation, MINGHAI LI, ANDRE BOTELOHO, XI LIN, Boston University. — We prove analytically that a one-dimensional metallic chain is subject to two coupled spontaneous conformational relaxations, resulting in the well-known Peierls bond length alternation and an overall chain contraction. Using the Su-Schrieffer-Heeger (SSH) Hamiltonian, a tight-binding version of the Peierls theory, we find in a neutral defect-free polyacetylene chain these two coupled distortions work cooperatively against the backbone elastic deformation. The cooperative bond alternation and chain contraction deformations have two effects, allowing bonds alternate and contract less than the case when deformations are independent and breaking the charge conjugation symmetry which would otherwise be conserved. Making such a deformed neutral chain as the reference, we find that creation of self-localized solitons upon dopings results in spontaneous chain contractions within the self-localized domains where the anti-Peierls distortions are enforced. Our numeric results based on the SSH model and first-principles calculations indicate that chain contractions are proportional to the soliton density at low dopings, and the overall chain length varies non-monotonically with respect to the doping level, reaching a maximum contraction of 0.15% at 5% doping.

10:36AM H20.00012 Soliton migration along trans-polyacetylene backbone, MINGHAI LI, YONGWOO SHIN, XI LIN, Boston University. — We compute the minimum energy paths and activation barriers for the soliton migration process along trans-polyacetylene backbone via the Su-Schrieffer-Heeger (SSH) model and ab initio calculations. Our results confirm the conventional consensus that soliton hops over two CH sites in one single step, maintaining wavefunction nodal structures at intermediate CH sites. Standard SSH parameters give rise to negligible migration barriers, which increases exponentially as the localization width decreases. Favoring the opposite elastic strain as the boundaries, soliton prefers staying at the center of an open chain; this ground state energy increases linearly when the chain length decreases. Starting at the center and moving towards the chain termination, soliton first sees a quadratic wash-board energy landscape when it is far away from the boundary and then smoothly switches to an exponentially increased wash-board energy landscape when it is in the vicinity of the boundary due to its localization width shrinkage. The local minima energy has a larger exponent compared to that of the activation barrier so they cross each other at a certain point, beyond which the barrier disappears and solitons cannot get closer to the boundary.

10:48AM H20.00013 ABSTRACT WITHDRAWN —

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H21 FIAP: Spectroscopic Studies of Semiconductors 323

8:00AM H21.00001 Two- and three-photon absorption of germanium in the mid-infrared, DONGMIN SEO, LEONARD FELDMAN, NORMAN TOLK, PHILIP COHEN. — We have studied the nonlinear optical response of crystalline germanium using high-power infrared picosecond laser pulses at wavelengths ranging from 2.8 µm to 5.2 µm. Transmittance as a function of fluence at 2.8 µm and 4.4 µm were fitted by using two- and three-photon absorption, respectively. Data at 3.2, 3.6, and 4.0 µm, however, required consideration of simultaneous two- and three-photon absorptions in order to fit the experimental data. Transmittance as a function of wavelength further supports the onset of the two- and three-photon absorption at appropriate wavelengths.

Owing to the bi-stable nature of the Si donor, samples cooled in the dark are insulating. In the present work, an infrared LED is used to photodope 0 OHNO, Tohoku University — Highly Si-doped Al persistent photoconductivity, JENNIFER MISURACA, STEPHAN VON MOLNAR, PENG XIONG, MARTECH, Florida State University, 0 be extracted for various illumination times as the Fermi energy is tuned systematically. Application to Si-doped Al Soc. Jpn. 56, 2259 (1987) [2] I. Terry, et al. Solid State Commun. 84, 235 (1992)

For Ns higher than 6 10 11, only this new interaction is clearly visible though its amplitude decreases when increasing Ns. The origin of this new interaction is very likely related to mechanisms involving phonons. The different possibilities are discussed.

We study ensembles of phosphorus donor bound excitons in Si via photocurrent measurements at low temperatures since Auger non-radiative decay process is primarily dominant in an indirect band-gap semiconductor such as Si. We report electric and magnetic field effects on photocurrent signals of phosphorus donor bound excitons.

4:00AM H21.00007 Determining the bandtail shape of highly Si-doped Al 0.3 Ga 0.7 As using persistent photoconductivity, JENNIFER MISURACA, STEPHAN VON MOLNAR, PENG XIONG, MARTECH, Florida State University, JELENA TRBOVIC, Institute of Physics, University of Basel, JUN LU, JIANHUA ZHAO, Institute of Semiconductors, Chinese Academy of Sciences, HIDEO OHNO, Tohoku University — Highly Si-doped Al 0.3 Ga 0.7 As can be driven through the metal-insulator phase transition using persistent photoconductivity [1]. Owing to the b-stable nature of the Si donor, samples cooled in the dark are insulating. In the present work, an infrared LED is used to photodope the sample at SK for a range of illumination times, which populates shallow states and provides a way to change the carrier concentration of the sample in situ. Measuring the carrier concentration as a function of temperature allows for the finite temperature carrier concentrations and Hall activation energies to be extracted for various illumination times as the Fermi energy is tuned systematically. Application to Si-doped Al 0.3 Ga 0.7 As prepared by MBE allows one to infer the bandtail shape in the energy range between the Fermi energy of the unilluminated sample and the mobility edge. [1] S. Katsumoto, et al. J. Phys. Soc. Jpn. 56, 2259 (1987) [2] I. Terry, et al. Solid State Commun. 84, 235 (1992)
9:24AM H21.00088 Effect of order/disorder near the Γ-L and L-X crossovers in the conduction band of lattice-mismatched Ga$_x$In$_{1-x}$P alloys\textsuperscript{1}, L. BHUSAL, M. STEIJNER, J. GEISS, A. MASCARENHAS, National Renewable Energy Laboratory, 1617 Cole Blvd, Golden CO-80401 — In this work we studied the effect of order/disorder on the Γ-L and L-X crossover points in the conduction band of Ga$_x$In$_{1-x}$P alloys, using polarized photoluminescence and electroreflectance techniques at various temperatures. Ga$_{x}$In$_{1-x}$P samples ($x$=0.25-0.78) were grown by atmospheric pressure organometallic vapor phase epitaxy (OMVPE). Some samples were grown directly on a miscut GaAs substrate while in other samples a thick GaAsP step grade was grown first, to reduce the dislocation density. The significance of the crossover point in the conduction band of the alloy for the efficiency of devices such as multijunction high-efficiency solar cells and light emitting diodes will be discussed.

9:36AM H21.00009 Intersubband absorption in InAlN/GaN heterostructures, O. MALIS, C. EDMUNDS, Binghamton University, Binghamton, NY, M. J. MANFRA, D. L. SIVCO, Bell Labs, Alcatel-Lucent, Murray Hill, NJ, R. MOLNAR, MIT Lincoln Laboratories, Lexington, MA — Nitride superlattices are promising for intersubband light emission and detection in the currently inaccessible near-infrared range (2-3 µm). Efforts to explore the intersubband properties of nitrides have been hampered so far by difficulties related to the quality of the materials. Most studies to date have employed AlGaN/GaN heterostructures. However, the large lattice mismatch between AlGaN and GaN limits the total thickness of the structures. We are focusing on lattice-matched InAlN/GaN superlattices. InAlN has been less investigated due to the challenges in growing high-quality In-containing nitrides. Nevertheless, the large conduction band offset (1 eV) and lack of piezoelectric effect make the lattice matched nitrides ideally suited for near-infrared applications. We have performed a detailed intersubband absorption study of InAlN/GaN superlattices grown by MBE on HVPE GaN templates. X-ray diffraction analysis suggests that our samples are among the highest quality ever reported. The band structure of the materials was examined with Fourier-transform infrared spectroscopy. Strong intersubband absorption in the 430-530 meV energy range is reported for the first time for 2-4.5 nm-wide quantum wells.

9:48AM H21.00010 Beryllium acceptor binding energy in AlN. ASHK SEDHAIN, T. M. AL TAHTAMOUNI, JING LI, Kansas State University, JINGYU LIN, HONGXING JIANG, Texas Tech University, DEPARTMENT OF PHYSICS, KANSAS STATE UNIVERSITY COLLABORATION, NANO-TECH CENTER AND DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, TEXAS TECH UNIVERSITY COLLABORATION — The acceptor binding energy of an alternate dopant, Be, in AlN epi-layers has been probed by time-resolved photoluminescence (PL) spectroscopy. The binding energy of excitons bound to Be acceptors in AlN is determined to be about 33 meV, which implies that the Be acceptor binding energy in AlN is about 0.33 eV in accordance with Haynes’ rule. The measured PL decay lifetimes of the acceptor-bound exciton transitions in Be- and Mg-doped AlN (95 and 119 ps, respectively) also indicate that the binding energy of Be is smaller than that of the most common acceptor dopant in AlN, namely, Mg. The smaller activation energy of Be in AlN has the potential to partly address the critical p-type doping, issue in AlN- and Al-rich AlGaN by increasing the room temperature free hole concentration by ~10$^3$ compared to the case of Mg doping.

10:00AM H21.00011 Estimation of third-order nonlinear optical susceptibility $\chi^{(3)}$ of synthetic Cu$_2$O crystal\textsuperscript{1}, SHAHIN MANI, JOON JANG, JOHN KETTERSON, Department of Physics & Astronomy, Northwestern University, KETTERSON’S TEAM — High-quality crystals of Cu$_2$O were prepared by an improved method for thermally oxidizing metallic copper. We report the nonlinear refractive index $n_2$ and the nonlinear absorptive index of the Cu$_2$O crystals. The following methods were utilized: (i) Z-scan, (ii) third-harmonic generation, and (iii) intensity-dependent interferometry. The third-order susceptibility $\chi^{(3)}$ of a material plays an important role in optical signal processing including switching, altering the frequency and the transmission characteristics. A comparison between the third-order nonlinear susceptibilities of a standard nonlinear reference material, carbon disulfide (CS$_2$) and Cu$_2$O will be made.

1 Supported by the National Science Foundation under grant CCF 03-29957.

10:12AM H21.00012 Anomalous Fresnel coefficients for quadrupole polaritons in Cu$_2$O\textsuperscript{1}, JOON JANG, YI SUN, SHAHIN MANI, JOHN KETTERSON, Department of Physics, Northwestern University, KETTERSON’S TEAM — In a direct-gap semiconductor, a polariton is a quantum superposition of an excitation and a photon, formed near the light cone. Unlike dipole polaritons, a quadrupole polariton in a bulk Cu$_2$O is a coherently propagating bosonic state with an unusually long decoherence time owing to its unusual underlying electronic structure. Therefore, this unique semiconductor provides a model system for studying the theory of so-called additional boundary conditions at the vacuum-crystal boundary. Using resonant two-photon excitation, we create a coherently propagating polariton wave packet at 2 K and measure its reflectance (R) and transmittance (T) at the boundary opposite to the incoming surface. Surprisingly, we find an enhanced reflection of polaritons from sample surfaces such that the ratio R/T deviates significantly from the present theory. This anomalous boundary effect most likely arises from the quadrupole excitonic (matter) component of polaritons. Our experimental results have implications for the design of polariton-based waveguides and resonators in which traveling polaritons are effectively confined in the medium.

1 Supported by the NSF under grant CCF 03-29957.

10:24AM H21.00013 Photoluminescence Characteristics of Pulsed Laser Deposited ZnO Thin Films Grown in Nitrogen/Oxygen Ambients, M.A. THOMAS, J.B. CUI, Y.C. SOO, H. KANDEL, T.P. CHEN, University of Arkansas-Little Rock, C.P. DAGHLIAN, Dartmouth College — ZnO thin films were grown by pulsed laser deposition using a Zn target in different atmospheres. The samples were characterized by X-ray diffraction, energy dispersive X-ray analysis and temperature dependent photoluminescence (PL) measurements. The growth conditions were varied sequentially from a pure oxygen to a pure nitrogen atmosphere. The band structure of the materials was examined with Fourier-transform infrared spectroscopy.

10:36AM H21.00014 Optical properties of epitaxial ZnGeAs$_2$ thin film, S.G. CHOI, NREL, D.E. ASPNES, NCSU, M. VAN SCHILFGAARDE, ASU, T.J. PESHEK, T.J. COUTTS, A.G. NORMAN, J.M. OLSON, D.H. LEVI, NREL — Chalcopyrite ZnGeAs$_2$ lattice-matched to GaAs(001) is a promising 1.1 eV band gap semiconductor for applications in non-linear photonic devices and multijunction solar cells. Knowledge of the optical properties of epitaxial ZnGeAs$_2$ is essential for device applications. We present room temperature optical properties of a ZnGeAs$_2$ thin film grown epitaxially on a GaAs(001) substrate by metalorganic vapor phase epitaxy. Spec troscopic ellipsometry was employed to measure the pseudoelectric function of the ZnGeAs$_2$ thin film, and was compared with a theoretical calculation within the quasiparticle self-consistent GW approximation. The interband-transition critical-point energies were obtained from a standard lineshape analysis of the measured spectrum. We will also present a comparison of the optical properties of ZnGeAs$_2$ with those of other II-IV-V$_2$ chalcopyrite compounds as well as their corresponding III-V zincblende compounds. This abstract is subject to government rights.
In particular, Mn ions doped into GaAs quantum wells have spin lifetimes close to several nanoseconds and can be optically manipulated in zero magnetic field. In contrast, in bulk GaAs and semiconductors, the spin relaxation rate is much faster due to phonon scattering. To study this system in the low density limit, we incorporate a distributed Bragg reflector optical cavity around the Mn containing wells, which enhances Mn luminescence and allows spatial isolation of a small number of Mn ions imaged using scanning microphotoluminescence. In such structures, we observe unusually long Mn spin lifetimes.

To study this system in the low density limit, we incorporate a distributed Bragg reflector optical cavity around the Mn containing wells, which enhances Mn luminescence and allows spatial isolation of a small number of Mn ions imaged using scanning microphotoluminescence. In such structures, we observe unusually long Mn spin lifetimes. We discuss the effect of cavity coupling on spin dynamics Mn ions in the single ion limit.

M. Yasar, A. Petroiu, S. Suny at Buffalo, Buffalo NY, C. Li, A. Hanbicki, G. Kioseoglou, B. Jonker, Naval Research Laboratory, Washington D.C. — We have carried out optical pumping, Hanle and longitudinal Hanle studies of InGaAs:Al/GaAs quantum wells. The circular polarization at zero magnetic field has a maximum around 50 K indicating that at low temperatures the recombination is associated with a bound electron. The measured spin lifetimes at low temperatures are an order of magnitude longer than those measured in reference GaAs/AlGaAs quantum wells. This is attributed to the suppression of the Dyakonov-Perel spin relaxation mechanism in this bound system. As the temperature is increased from 5 to 50 K the spin lifetimes decrease and become comparable to the lifetimes of the reference sample. In the longitudinal Hanle geometry the circular polarization increases with magnetic field and reaches a maximum at B = 1.5 tesla. Beyond 1.5 tesla the circular polarization decreases. A series of polarization oscillations superimposed on the decreasing background with a periodicity of approximately 1 tesla is observed. These oscillations are tentatively attributed to the variations in the magnetic flux through the bound electron orbit. Work at SUNY was supported by ONR and NSF.
9:36AM H22.00007 Spontaneous Loss of Spin Coherence in GaAs/Si Heterostructure

GUANGLEI CHENG, PATRICK IRVIN, Department of Physics and Astronomy, University of Pittsburgh, BQIN HUANG, IAN APPELBAUM, Department of Physics, University of Maryland, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — We present a possible way to optically inject spins into silicon. In this work, GaAs and Silicon-on-Insulator (SOI) wafers are bonded together by an ultrathin Ag layer using UHV wafer bonding. Standard optical pump-probe Kerr microscopy technique is applied to examine the spin coherence in the GaAs/Si heterostructure. In some areas of the bonded wafer, a relatively long spin coherence time of T2*=0.5 ns is observed in the GaAs. In other parts of the sample, the spin coherence is observed to decay much more rapidly (T2*=140ps). One possible explanation is that the quality of the bond varies across the wafer and that the strongly bonded areas exhibit spin transport from GaAs to silicon.

9:48AM H22.00008 Coherent optical control of correlation waves of spins in semiconductors

ERAN GINOSSAR, Yale University, YEHOUSA LEVINSON, SHIMON LEVIT, Weizmann Institute of Science — We calculate the dynamical fluctuation spectrum of electronic spins in a semiconductor under a steady-state illumination by light containing polarization squeezing correlations. Taking into account quasi-particle lifetime and spin relaxation for this non-equilibrium situation we consider up to fourth order optical effects which are sensitive to the squeezing phases. We demonstrate the possibility to control the spin fluctuations by optically modulating these phases as a function of frequency, leading to a non-Lorentzian spectrum which is very different from the thermal equilibrium fluctuations in n-doped semiconductors. Specifically, in the time-domain spin-correlation can exhibit time delays and sign flips originating from the phase modulations and correlations of polarizations, respectively. For higher light intensity we expect a regime where the squeezing correlations will dominate the spectrum.

10:00AM H22.00009 Time Resolved Spectroscopy of InSb Quantum Wells Using Differential Transmission Technique

K. NONTAPOT, M. BHOWMICK, G.A. KHODAPARAST, Virginia Tech., S.J. CHUNG, M.B. SANTOS, University of Oklahoma — The growing interest in spin-related phenomena and devices has prompted intense activity in the science and engineering of narrow gap semiconductors (NGS). NGS offer several scientifically unique features such as small effective masses, large g-factors, high intrinsic mobilities, and large spin-orbit coupling effects. In this work we report the dynamics of photo-excited carrier/spin in several InSb/AlxIn1−xSb based quantum wells (QWs) using differential transmission spectroscopy. The InSb QW layers were selectively pumped and probed by mid-infrared pulses to avoid possible contributions from the barrier materials. We compare our results with the earlier measurements using magneto-optical Kerr (MOKE) effect. Our results are important to understand different relaxation mechanisms in NGS with strong-spin orbit interactions.

1 Supported by: NSF-DMR-0507866, NSF-DMR-0520550.

10:12AM H22.00010 Spin polarized current in InSb based structures

M. FRAZIER, M. BHOWMICK, J.J. HEREMANS, G.A. KHODAPARAST, Virginia Tech., S.J. CHUNG, M.B. SANTOS, University of Oklahoma, X. LIU, J. FURDYNA, University of NotreDame — Recently, there has been much interest in developing and exploring spin based semiconductor devices and phenomena. One of the key challenges in developing spin based devices is to generate, control, and measure spin currents directly. In this talk, we report interband circular photogalvanic (CPG) effects using pulsed near-infrared radiation in InSb quantum wells and two InSb films grown on GaAs and InP substrates. We observe a CPG current whose direction and magnitude depend on the helicity of the incident light, the angle of incidence, and temperature. Our observation is important to understand zero-field spin splitting mechanisms in a system with strong spin-orbit interaction.

10:24AM H22.00011 Optically-Induced 13C Nuclear Spin Polarization through Nitrogen-Vacancy Centers in Diamond

JONATHAN KING, PATRICK COLES, JEFFREY REIMER, University of California-Berkeley — The spin-1 negatively charged nitrogen-vacancy (NV) center in diamond has received much attention for its long spin-coherence times and optical polarization into the m_s=0 sublevel. These properties make it attractive for applications such as quantum information processing and high-resolution magnetometry. Large nuclear polarizations in diamond may be useful to quench decoherence, as an initialization step for quantum computing, or as a platform for enhancement of nuclear magnetic resonance (NMR) signal in dilute spin systems. In this work, we demonstrate the polarization of the bulk 13C nuclear spin system by interaction with the optically polarized NV center system at 9.4 Tesla and 5K nominal temperature. Large nuclear polarizations are observed through Faradic detection of bulk 13C NMR signals. The signals are opposite in sign to thermally-generated signals, indicating nuclear polarization into the m_f = -1/2 sublevel. We model the phenomenon and propose microscopic mechanism for the polarization.

1 Supported by NSF under project ECS-0608763.

10:36AM H22.00012 Optical hyperpolarization of the nuclear and electronic spins of 31P in 28Si

A. YANG, M. STEGER, T. SEKIUCHI, M. M. W. THEWALT, Dept. of Physics, Simon Fraser University, Burnaby, BC, Canada, T. D. LADD, E. L. Ginnot Laboratory, Stanford University, Stanford, CA, USA, K. M. ITOH, Keio University and CREST-JST, Yokohama, Japan, H. Riemann, N. V. Abrosimov, Institute for Crystal Growth (IKZ), Berlin, Germany, P. Becker, PTB Braunschweig, Braunschweig, Germany, H.-J. Poehl, VITCON Projectconsult GmbH, Jena, Germany, J. W. Ager III, E. E. Haller, UC Berkeley and LBNL, Berkeley, CA, USA — We have recently shown that the donor hyperfine splitting can be resolved for the 31P donor bound exciton in highly enriched 28Si, enabling either optical or optical-electrical readout of the electronic and nuclear spin state of this promising qubit candidate.[1] Here we show that these same optical transitions can be used to quickly achieve large nuclear and electronic hyperpolarizations of the 31P donor in 28Si. This may provide a viable solution to the problem of initializing the nuclear spins, a roadblock for quantum computing schemes involving nuclear spins in Si. We also report on the remarkably narrow homogeneous linewidth of this bound exciton transition, measured by hole burning spectroscopy. This suggests that even higher spin selectivity and hyperpolarization may be achievable in more highly enriched 28Si, or when dealing with individual 31P donors. [1] A. Yang et al., Phys. Rev. Lett. 97, 227401 (2006).
10:48AM H22.00013 Time-resolved Infrared Magnetospectroscopy of GaAs at the NSLS
G.L. CARR, NSLS, Brookhaven National Lab, J.J. TU, Physics Department, City College of the City Univ. of NY — We describe a facility for performing photoinduced time-resolved infrared spectroscopy of materials in magnetic fields up to 10T at beamline U4IR of the National Synchrotron Light Source (NSLS). The facility combines an existing time-resolved capability (based on pulsed synchrotron radiation and a synchronized Ti:sapphire laser to achieve ~100 ps resolution) with a split-coil superconducting solenoid and optical cryostat. We also report a THz study of photocarrier and exciton dynamics in GaAs using this facility. It is found that, for B>0, a portion of the photo-induced carrier absorption appears as an electron cyclotron resonance, while the exciton unbinding absorption splits into spin and orbital transitions (Zeeman effect). At low temperatures, we observe that the relaxation of photocarriers toward the band edge involves the breaking of existing excitons, leading to a combination of absorption and bleaching features that evolve on a ~1 ns time scale.

1Supported by DOE under contract DE-AC02-98CH10886 at the NSLS of Brookhaven Natl Lab. Portions of the time-resolved program supported under DE-FG02-02ER45984 at Univ. of Florida.

8:00AM H23.00001 Photoemission core level shifts and phonon broadening for Cs film on Cu(100)
XUBING ZHOU, KEVIN KOCH, J.L. ERSKINE — Department of Physics, University of Texas at Austin, Austin, TX 78712. We have measured Cs 5p photoemission core level broadening data for Cs film on Cu(100) at different temperatures and have obtained bulk-atom and surface-atom values of the zero-temperature phonon width and the effective Debye temperature, which governs the temperature dependence of the broadening. The coupling constant C for alkali metals in the phonon-broadening theory of Hedin and Rosengren[1] is about 30% higher in the surface than in the bulk. This result is compared with experiment results on other alkali metals[2]. We also studied the temperature dependent binding energy shifts for the Cs 5p core level peaks and our data fit the lattice expansion theory very well except at temperature higher than 220 K. At high temperature deviations are proved to be caused by thermal evaporation of Cs film. [1] L. Hedin and A. Rosengren, J. Phys. F. 7, 1339 (1977). [2] D.M. Riffe and G.K. Wertheim, Phys. Rev. B 61, 2302 (2000).

8:12AM H23.00002 Auger-Photoelectron Coincidence Spectroscopy measurement of the secondary electron distribution from 0 eV to 81 eV, created by the MVV Auger transition in Cu (100) , K. SHASTRY, S. MUKHERJEE, A.H. WEISS, University of Texas at Arlington, S.L. HULBERT, Brookhaven National Laboratory, R.A. BARTYN-SKI, Rutgers University — In conventional spectroscopic measurements, low energy Auger lines are superimposed upon a large background due to secondary electrons that arise from loss processes that are unrelated to the Auger process. Here we present the results of measurements in which Auger-Photoelectron coincidence techniques were used to eliminate background unrelated to the Auger process and obtain the energy distribution of electrons emitted as a result of the M_{2,3}VV transition in Cu (100) over the full range of emitted energies (0 eV – 81 eV). The measurements revealed a well formed Auger peak at ~60eV accompanied by a low energy tail (LET) associated with the MVV transition. The LET extends to 0 eV and has a broad maximum at ~ 7eV. The integrated intensity of the LET was ~ 6 times larger than that of the Auger peak itself. The origin of the LET will be discussed in terms of extrinsic mechanisms in which electrons from the peak lose energy as they propagate to the sample surface, as well as intrinsic mechanisms in which multi-electron Auger processes distribute the energy gained by the filling of the core-hole to multiple electrons.

8:24AM H23.00003 Ultrafast Spectroscopy on Solids at FLASH
DAVID BERNSTEIN, Stanford University, YVES ACREMANN, ANDREAS SCHEHRZ, SLAC, MARTIN BEYE, ALEXANDER FÖHLISCH, WILLIAM SCHLOTTER, DESY, TORBIN BEECK, FLORIAN SORGENFREI, ANNETTE PIETZSCH, WILFRIED WURTH, DESY, JOACHIM STÖHR, SLAC — X-ray/VUV free electron laser (FEL) facilities such as FLASH, LCLS, and the European X-FEL open the door to a wide variety of exciting experiments in x-ray physics. Due to the rapidly stochastic processes governing FEL radiation and the difficulties in tuning an FEL, it has not been clear whether spectroscopy could be done using such sources. Here we demonstrate the feasibility of doing near edge x-ray absorption fine structure (NEXAFS) spectroscopy on solids. Samples consisting of LaMnO and Al films, respectively, were lithographically fabricated on thin silicon nitride membranes. Ultrafast femtosecond pulses of radiation from the FLASH FEL were dispersed by the monochromator grating at beamline PG2 and impinged upon the samples. Absorption was measured in transmission using a Ce:YAG crystal and imaged by an intensified CCD. The incident intensity was measured through a blank nitride membrane next to the sample. We discuss the possibility of both subsurface Ce and Te as giving rise to this signal; density functional theory calculations indicate that the subsurface Ce atom gives a more significant contribution to the overall tunneling current.

8:36AM H23.00004 STM study of CeTe2: contribution of the subsurface lattice
ALEKSANDRA TOMIC, JOSH VEAZEY, ZSOLT RAK, CHRISTOS MALLIKAKAS, MERCOURI KANATZIDIS, S. D. MAHANTI, STUART TESSMER — We have studied the nature of the surface charge distribution in CeTe2 with scanning tunneling microscopy (STM). At 77 K, the STM topography and Fourier transform show both the atomic lattice of surface Te atoms arranged in a square net and the CDW modulations oriented at 45 degrees with respect to the Te net. In addition, we observe peaks in the Fourier transform that we attribute to atoms lying below the surface Te net. We discuss the possibility of both subsurface Ce and Te as giving rise to this signal; density functional theory calculations indicate that the subsurface Ce atom gives a more significant contribution to the overall tunneling current.

8:48AM H23.00005 Effect of a Fe substitutional impurity on the geometric and electronic structure of Au13 cluster
GHAZAL SHAFAI, TALAT RAHMAN, University of Central Florida — We have carried out spin-polarized density functional theory calculations based on the potential method to determine the changes in the characteristics of the Au13 cluster when one Au atom is replaced by Fe. For a pure Au13 cluster, the 2D geometry is the lowest-energy isomer, followed closely by a flake structure, while the icosaedron is higher in energy by ~2.98 eV and is not stable since it is found to undergo Mackay transition to form a cuboctahedron. When a surface or central Au atom is replaced by Fe, we find dramatic changes in the energy ordering of these nanoparticles, since Fe tries to move inwards so as to be highly coordinated. In fact the distorted icosaedron and a biplanar structure obtain the lowest energy. The structure of the Fe-centered icosaedron is slightly distorted (Jahn-Teller distortion), so that the degeneracy on two bands near Fermi level is removed. The lowest energy isomer in this study has the highest magnetic moment (3.98 μB) in comparison with that of the other isomers. The magnetic moment of the icosaedron with an Fe atom at the center is 3.1 μB, which is in agreement with previous findings.

1Work supported in part by DOE, under grant number DE-FG02-02ER45634

9:00AM H23.00006 ABSTRACT WITHDRAWN —
9:12AM H23.00007 Size-dependent crystallinity of nano-Pt/$\gamma_2\text{Al}_2\text{O}_3$1. LONG LI, Eng and Materials Sci Dept, Univ of Pittsburgh, L.-L. WANG, S. I. SANCHEZ, J. H. KANG, Univ of Illinois, Q. WANG, Yeshiva Univ, Z. ZHANG, Univ of Pittsburgh, A. I. FRENKEL, Yeshiva Univ, R. G. NUZZO, D. D. JOHNSON, Univ of Illinois, J. C. YANG, Univ of Pittsburgh — Metallic platinum nanoparticles (NP) on $\gamma_2\text{Al}_2\text{O}_3$ powders were synthesized with a size range from sub- to several nanometers. High-resolution transmission electron microscopy (HRTEM) studies revealed a size-dependent crystallinity of the Pt NPs, where Pt NPs with size $<1$ nm had a disordered structure, Pt NPs with size $>2.5$ nm all showed a crystalline structure. For Pt NPs with sizes between 1.1 and 2.4 nm, a transition zone exists in which $\sim85$% of NPs appeared disordered and $\sim15$% ordered. X-ray absorption spectroscopy (XAS) measurements support this result where increasing-disorder distribution of Pt-Pt bond lengths was noted with decreasing Pt nanoparticle size. A search for ground state structure of Pt$_{\gamma_2}/\gamma_2\text{Al}_2\text{O}_3$ (100) with density functional theory (DFT) showed that the disordered structure is energetically more favorable than the ordered close-packed structures by 1.53 eV at the size of 1.1 nm.

1DOE-BES funding, DE-FG02-03ER15476

9:24AM H23.00008 Size Distribution of Nano-Crystallites in Non-Crystalline Binary Alloys, YONG W. KIM, Lehigh University, ANDREW ABRAHAM, Moravian College, JERRY KIM, UCLA — The factors that affect thermophysical property determination for non-crystalline metallic alloys include non-uniformities in compositional and morphological property within a specimen. A series of measurements have shown that a specimen’s thermal history leads to a spatial profile of elemental composition that differ from one specimen to another for the same alloy. (See Y.W. Kim, Int. J. Thermophysics 28, 732 (2007), and references therein.) In order to develop a theoretical model for temperature dependence of thermophysical properties, we consider thermal dissociation of nano-crystallites within a randomly close-packed (RCP) medium. Once the size distribution of the nano-crystallites has been established at a given temperature, a set of coupled dissociation equations can be solved at all other temperatures. Transport properties can then be computed over a range of temperature. In this paper we present the size distribution of crystallites in a bed of RCP spheres. Two different size spheres are mixed at several compositions to simulate non-crystalline binary alloys in 2-D. The distribution is found to be peaked at a crystallite size specific to a given alloy composition. This work is support in part by the NSF-DMR(Metals).

9:36AM H23.00009 Irreversibility in Cooling and Heating Processes in the Magnetocalic MnAs and Alloys1, A.L. LIMA SHARMA, Dept. Physics, Tuskegee University, Tuskegee, AL 36088, S. GAMMA, Dept. of Physics, Univ. Fed. do Est. de Sao Paulo, Rua Prof. Artur Riedel, 275 - Jd. Eldorado - Diadema- SP 00972-270 - Brazil, A.A. COELHO, Inst. de Física Gleb Wataghin, Univ. Est. de Campinas (UNICAMP), C. P. 6165, Campinas, SP 13083-970 - Brazil — Irreversibility of adiabatic processes in the magnetocaloric MnAs and alloys are presented here. We used a differential scanning calorimeter in order to record the heat flux as a function of the temperature and applied field for MnAs, Mn$_0$$_1$$_9$$\gamma$$_2$$F$_0$$0$$_0$$0$$_0$$_0$ As and Mn$_0$$_1$$_9$$\gamma$$_2$$A$_0$$0$$_0$$0$$_0$As. From the measured heat flux, we extracted the latent heat and entropy associated to cooling and heating processes. In the cooling curve, we observed that $S_{c}$$\gamma$$_2$$F$_0$$0$$_0$$0$$_0$$ > S$_{c}$$\gamma$$_2$$A$_0$$0$$_0$$0$$_0$$ > S$_{c}$$\gamma$$_2$Mn$_0$$_1$$_9$$_0$$_0$$_0$$_0$$_0$ As, the index $c$ refers to cooling process, similarly, for the heating process: $S_{h}$$\gamma$$_2$$F$_0$$0$$_0$$0$$_0$$ > S$_{h}$$\gamma$$_2$$A$_0$$0$$_0$$0$$_0$$ > S$_{h}$$\gamma$$_2$Mn$_0$$_1$$_9$$_0$$_0$$_0$$_0$$_0$$_0$$_0$ As. On the doped samples, the thermomagnetic behavior is compatible with a scenario where Zener’s $p$- $d$ exchange mechanism dominates, i.e. the interaction range is weaker but long ranged, because the extended valence hole states mediate the ferromagnetic interaction. The difference of the entropy obtained from cooling and heating process was found to be as high as 37%.

9:48AM H23.00010 Semiconductor behavior in bcc Cr$_{1-x}$Al$_x$ thin films1, Z. BOEKELHEIDE, F. HELLMAN, University of California, Berkeley — Cr$_{1-x}$Al$_x$, with $x=0.15$-$0.25$, has semiconducting electronic properties: extremely high resistivity and a negative temperature coefficient of resistance, along with a gap in the infrared reflectivity. This is unusual for an alloy of two metals, but similar behavior has been observed in Fe$_3$VAl and has been attributed to a hybridization-induced band gap. In bulk, Cr$_{1-x}$Al$_x$ is known to be inhomogeneous, with two crystal phases coexisting: one, a disordered bcc solid solution, and the other, called the “X-phase”, with a microstructure consisting of 1-3nm domains. Because of this inhomogeneity, it was previously not known which phase was responsible for the semiconductor behavior. We used epitaxial thin film growth techniques to preferentially nucleate the bcc phase and study the effect of crystal structure on the electronic properties. We found that films grown epitaxially on MgO (100) substrates, expected to grow preferentially in the bcc phase, have high resistivity like bulk Cr$_{1-x}$Al$_x$ while polycrystalline films grown on amorphous SiO$_2$ have lower resistivity. This suggests that the semiconductor behavior is intrinsic to the bcc structure.

10:00AM H23.00011 Exciton Recombination in Nanometer-Wide GaN/AlN Quantum Wells. ZHENWEN PAN, MADALINA FURIS, University of Vermont, Burlington, VT, ALEXANDER N. CARTWRIGHT, University at Buffalo - SUNY, Buffalo, NY, WILLIAM J. SCHAFF, Cornell University, Ithaca, NY — In nitride semiconductor heterostructures, the presence of very strong built-in electric fields, oriented perpendicular to the semiconductor layers, dramatically impacts the electronic states, excitonic recombination, and photoluminescence in these materials. The origins of these fields lie in the non-centro- symmetric character and the strong piezoelectricity of the heterostructures. We investigated electronic states in the presence of strong built-in fields ($\sim$5 MV/cm) in very narrow, nanometer-wide GaN/AlN quantum wells via time-resolved photoluminescence spectroscopy. We find that the strong confinement ($\sim$2eV in the conduction band) leads to significant overlap in the electron and hole wavefunctions, even in the presence of large built-in fields. The temperature dependence of radiative lifetimes and emission energies indicates the band-edge recombination contributions (i.e., excitonic and/or shallow -acceptor pair) dominate the PL spectrum. Wells narrower than 3 monolayers exhibit temperature- independent emission and 1 ns radiative lifetimes.

10:12AM H23.00012 Enhancement of Subband Effective Mass in Ag/Ge(111) Thin Film Quantum Wells. SHU-JUNG TANG, WEN-KAI CHANG, Department of Physics and Astronomy, National Tsing Hua University, YU-MEI CHIU, Department of Electrophysics, National Chiao-Tung University, HSIN-YI CHEN, Department of Physics and Astronomy, National Tsing Hua University, CHENG-MAW CHENG, National Synchrotron Radiation Research Center, KU-DING TSUEI1, TOM MILLER, TAI-CHANG CHIANG, Department of Physics, University of Illinois at Urbana-Champaign — Subband dispersions of quantum-well states in Ag films on Ge(111) have been determined by angle-resolved photoemission. The effective masses of the subbands at the zone center increase substantially for decreasing film thicknesses. This peculiar behavior is attributed to a kinetic constraint for standing wave formation governed by a momentum-dependent phase shift function. No evidence is found for in-plane electron localization within the confined geometry.

1National Synchrotron Radiation Research Center
of the nanotubes. We have also observed that the interaction between polyynes and nanotubes is stronger for nanotubes with small diameters.

10:36AM H23.00014 Direct writing of hafnium diboride metallic nanostructures on silicon (100) surfaces using a UHV-STM

WEI YE, University of Illinois at Urbana Champaign, PAMELA MARTIN, NAVNEET KUMAR, JOHN ABELSON, GREG GIROLOMI, ANGUS ROCKETT, JOSEPH LYDING, University of Illinois at Urbana Champaign — The patterning of metallic nanostructures on surfaces is of great interest in fabricating nanoelectronics and quantum devices. In this work, we deposited HfB

2

nanostructures on silicon surfaces from Hf(BH

4

)4 by electron beam induced deposition (EBID). At positive sample bias, the electron beam from a STM probe initiates the local CVD by the decomposition of Hf(BH

4

)4 under STM tip. By repeatedly scanning STM tip along a specific path, well-defined HfB

2

nanostructures can be directly written onto the surface. Scanning tunneling spectroscopy was used to characterize the electronic properties of the nanostructures. We have achieved 4 nm linewidths and complete selectivity relative to adjacent H-Si(100) regions. The thickness of the nanostructures is controlled by the exposing time to the electron beam from STM tip, while the width is controlled only by the geometry of the tip apex and the sample-tip separation. STS data confirm that the HfB

2

nanostructures deposited are pure metallic, indicating minimum contaminations in the nanostructures, which we attribute to the carbon-free nature of the CVD precursor. To our knowledge this is the first demonstration of sub-5 nm metallic nanostructures in a STM/CVD experiment.

Tuesday, March 17, 2009 8:00AM - 11:00AM – Session H24 DCMP: Focus Session: Chemical Modification of Nanotubes 326

8:00AM H24.00001 Single Molecule Detection in Living Biological Cells using Carbon Nanotube Optical Probes

MICHAEL STRANO, MIT — Nanoscale sensing elements offer promise for single molecule analyte detection in physically or biologically constrained environments. Molecular adsorption can be amplified via modulation of sharp singularities in the electronic density of states that arise from 1D quantum confinement [1]. Single-walled carbon nanotubes (SWNT), as single molecule optical sensors [2-3], offer unique advantages such as photostable near-infrared (n-IR) emission for prolonged detection through biological media, single-molecule sensitivity and, nearly orthogonal optical modes for signal transduction that can be used to identify distinct classes of analytes. Selective binding to the SWNT surface is difficult to engineer [4]. In this lecture, we will briefly review the immersing field of fluorescent diagnostics using band gap emission from SWNT. In recent work, we demonstrate that even a single pair of SWNT provides at least four optical modes that can be modulated to uniquely fingerprint chemical agents by the degree to which they alter either the emission band intensity or wavelength. We validate this identification method in vitro by demonstrating detection and identification of six genotoxic analytes, including chemotherapeutic drugs and reactive oxygen species (ROS), which are spectroscopically differentiated into four distinct classes. We also demonstrate single-molecule sensitivity in detecting hydrogen peroxide, one of the most common genotoxins and an important cellular signal. Finally, we employ our sensing and fingerprinting method of these analytes in real time within live ST3 cells, demonstrating the first multiplexed optical detection from a nanoscale biosensor and the first label-free tool to optically discriminate between genotoxins. We will also discuss our recent efforts to fabricate biomedical sensors for real time detection of glucose and other important physiologically relevant analytes in vivo. The response of embedded SWNT in a swellable hydrogel construct to osmotic pressure gradients will be discussed, as well as its potential as a unique transduction mechanism for a new class of implantable sensors.

ZHENHUI WANG, PETER MORSE, JIANG WEI, OSCAR VILCHES, DAVID COBDEN, University of Washington — We have fabricated mass balances each consisting of an individual single-walled carbon nanotube suspended across a micron-sized trench in an oxidized Si wafer. The vibrational resonance frequency of a nanotube, which is in the range 50-500 MHz, is determined by monitoring the current through it while applying an electrostatic driving signal. The sensitivity of the balances corresponds to just a few atoms. We have compared the monolayer mass shifts due to Ar and Kr, and measured a family of adsorption isotherms on Ar below 77 K. From the latter we calculated the isosteric heat of adsorption on the nanotube surface, which is found to be lower than that of Ar on basal plane graphite and only slightly larger than the latent heat of sublimation of bulk Ar at these temperatures. In one device we observed a phase transition in the adsorbed Ar near monolayer completion. In another device, which probably consists of two nanotubes joined in parallel, we observed enhanced adsorption at lower coverages which may be in the groove between the two nanotubes. This work is supported by the NSF, grant number 0606078.

8:48AM H24.00003 Resonance Raman study of Polynes encapsulated in single-wall Carbon Nanotubes with different diameters

L. G. MOURA, L.M. MALARD, Universidade Federal de Minas Gerais, D. NISHIDE, Nagoya University, Y. ACHIBA, Tokyo Metropolitan University, M. A. PIMENTA, Universidade Federal de Minas Gerais — Polynes are one of the simplest linear carbon chains and they have been recently encapsulated in single-wall carbon nanotubes. The stability of encapsulated polynes opens a way to investigate experimentally these sp-hydrized carbon structures and to study of electronic correlation effects in 1D systems with potential applications in nanoelectronics. In this work we present a resonance Raman study of C10H2 and C12H2 polynes inside single-wall carbon nanotubes with different diameters, using many different laser energies in visible range. We show that the observed optical resonance energies of the polynes depends on the diameter of nanotubes, the maximum of the resonances decreasing with increasing diameter of the nanotubes. Moreover, the resonance energy is generally lower for C12H2 than C10H2. We have also observed a red-shift and strong changes in the shape of Raman G band of the metallic nanotubes when they encapsulate the polynes, and these results were interpreted in terms charge transfer between these two systems and its effect on the electron-phonon coupling of the nanotubes. We have also observed that the interaction between polynes and nanotubes is stronger for nanotubes with small diameters.
The data showed for the doped films the metallic term (linear in $T$) would be as case in a dc conductivity measurement. Also the dc resistance of both B-doped and annealed SWNT films were measured over 10 approach to transparent electrodes. The optical transmission ($T=300K$) of SWNT and B-doped SWNT films measured in the range 50-700 cm$^{-1}$ show that most of these compounds, little charge transfer ($< 0.1$) occurs. Finally, these calculations are compared with results for the adsorption at oxidation defects.

This research was supported by NSF through grant # DMR-0705077.

9:12AM H24.00005 Study of propane films adsorbed on Purified HiPco Carbon Nanotubes1. TOYOHISA FURUSHASHI, DINESH RAWAT, ALDO MIGONE, Department of Physics Southern Illinois University — We investigated the adsorption characteristics of propane on purified HiPco single-walled carbon nanotubes for coverages limited to the first layer. We found two prominent substeps present in the monolayer; this suggests the presence of at least two distinct groups of binding energy sites in the substrate. The results are similar to those that we have found for ethane, but different from those we measured for butane, on the same substrate. We compare and contrast the characteristics of the isotherms for these three alkanes. A high-binding-energy (low-pressure) adsorption isotherm substep is present for all three alkanes. By contrast, the high-pressure substep (corresponding to adsorption on the outer surface area of the nanotubes bundles) shows a gradual smearing with increasing alkane length; this feature is barely resolvable for butane. We also found a gradual increase in the binding energy of alkane molecules with the increasing carbon chain length. This result confirms findings of simulation results for similar systems.

This research was supported by NSF through grant # DMR-0705077.

9:24AM H24.00006 Adsorption of Nitro Aromatics on Single-Walled Carbon Nanotubes, ERIK ALLREDGE, STEFAN BADESCU, THOMAS REINECKE, NAVDEEP BAJWIA, F. KEITH PERKINS, ERIC SNOW, US Naval Research Laboratory — Recent experiments with arrays of carbon nanotubes reveal a strong conductivity response after exposure to aromatic molecules containing nitro functional groups, such as nitrobenzene and trinitrotoluene. The detection of these compounds is of particular interest in the use of nanotube arrays as chemical sensors. To develop an understanding of the microscopic mechanisms involved, we perform detailed ab initio calculations of adsorption geometries, charge configurations, and vibration spectra for these compounds on pristine armchair and zigzag nanotubes. We use density functional theory with localized orbitals in a cluster approach and the M05-2X functional that is appropriate for the weak interactions of physisorption for these systems. We find a strong increase in adsorption energy with the addition of each nitro group to a molecule (around 100 meV) and a gradual increase with nanotube size, in agreement with preliminary experimental results. For most of these compounds, little charge transfer ($< 0.1$ e) occurs. Finally, these calculations are compared with results for the adsorption at oxidation defects.

9:36AM H24.00007 Transparent Boron-Doped Nanotube Films1. XIAOMING LIU, HUGO ROMERO, HUMBERTO GUTIERREZ, PETER EKLUND — We report results of FTIR transmission and temperature-dependent resistance measurements on transparent thin films of bundled single-walled carbon nanotubes exposed to B2O3 at 1000C. This reaction is proposed to B-dope the films. Doping is observed to lower the $T=300 K$ dc sheet resistance by a factor of five without changing the optical transmittance in the visible range and suggests that boron-doped SWNT provide a better approach to transparent electrodes. The optical transmission ($T=300 K$) of SWNT and B-doped SWNT films measured in the range 50-7000 cm$^{-1}$ show that the doped films have a greater optical density in the mid to far IR, consistent with the B-doping creating new free carriers. This optical result shows that the DC conductivity of the doped tubes is indeed higher, with the interpretation not being entangled with changes in the tube-tube contact resistance within the film, as would be the case in a dc conductivity measurement. Also the dc resistance of both B-doped and annealed SWNT films were measured over 10$^2$-300 K. The data showed for the doped films the metallic term (linear in $T$) is $\sim 10$ times greater than for the annealed and undoped films. Work supported by NSF NIRT ECS 06-09243.

1 NSF NIRT ECS 06-09243

9:48AM H24.00008 Kinetic selectivity effects of binary mixtures on nanotube bundles: Internal and external adsorption, SEYOUNG TSIGE, MERCEDES CALBII, JARED BURDE, Southern Illinois University Carbondale — We investigate kinetic selectivity effects that take place during the adsorption of a binary mixture inside a nanotube and on the external surface of a bundle. By using a kinetic Monte Carlo Scheme we allow adsorption on sites with different binding energy (external surface) and we restrict adsorption/desorption only to the end sites in the case of the internal adsorption. In both cases, we analyze the appearance of an overshoot in the fractional coverage of the weaker species (before equilibrium) observed previously for a single, homogeneous, one-dimensional chain.

10:00AM H24.00009 Temperature Programmed Desorption on Carbon Nanotube Bundles: a Computer Simulation study, NAYELI ZUNIGA, MERCEDES CALBI, JARED BURDE, Southern Illinois University Carbondale — We present a study of gas desorption on external surfaces of carbon nanotube bundles by means of a kinetic Monte Carlo scheme. Starting with an initial coverage, we follow the amount of gas desorbed as the temperature increases for different values of initially occupied sites and initial temperature of the sample. We analyze the spectrum obtained in terms of the different binding energies of the adsorption sites. We also compare our results with some available experimental measurements on nanostructure bundles and other nanostructures.

10:12AM H24.00010 Scattering Process of Gas Molecules on Vertically Aligned Single-Walled Carbon Nanotubes, IKUYA KINEFUCHI, YUSHI HARADA, JUNPEI KAWASAKI, KEI ISHIKAWA, SHU TAKAGI, SHIGEO MARUYAMA, YOIYMATOH MATSUMOTO, The University of Tokyo — Scattering process of gas molecules on quartz surfaces covered with vertically aligned single-walled carbon nanotubes (VA-SWNTs) was investigated using the molecular beam technique. We found that the surface modification with VA-SWNT films significantly enhances the energy transfer between gas molecules and surfaces at room temperature and makes the energy accommodation coefficient of helium, which tends to be small even for contaminate surfaces because of the large mass mismatch between helium and surface atom, close to unity. Our results demonstrate a potential application of VA-SWNTs as nanoscale fin structures to enhance heat transfer between gas phase and solid surfaces. As the surface temperature increases, however, the energy accommodation becomes less efficient since the small adsorption energy reduces the trapping probability of helium on carbon nanotube (CNT) bundles. The weak dependence of the accommodation coefficient on the film thickness suggests that gas molecules penetrate into the films because of their high porosity and suffer more than one collision with CNT bundles.
Carbon Nanotube CdSe Nanoparticle Hybrid Materials: Synthesis and Optical Properties. AUSTIN AKEY, CHENGUANG LU. Columbia University, Department of Applied Physics and Applied Math, WEI WANT, Columbia University, Department of Chemistry, IRVING HERMAN, Columbia University, Department of Applied Physics and Applied Math — Carbon nanotubes present remarkable opportunities for the construction of nanomaterials with unique properties, and for use in sensors and optoelectronic device applications. Chemical attachment of nanoparticles to nanotubes has thus far resulted in low loading; direct nucleation of particles on the tube sidewalls leads to a loss of control over particle size and monodispersity. We report the synthesis of novel heterostructures composed of single-walled carbon nanotubes and chemically attached, monodisperse cadmium selenide nanoparticles. Pyridine is used to strip the ligand shell from the nanoparticles, which are then bound to SWNTs in suspension. The resulting hybrid material is stable and resists aggregation; TEM and SEM characterization shows the nanotubes to be densely covered with nanoparticles. The nanoparticles used range in size from 3.5 to 6.0 nm in diameter, and exhibit strong quantum confinement. Also synthesized were hybrids of carbon nanotubes with core-shell CdSe/ZnS nanoparticles and with CdSe nanorods. The absorption and photoluminescence properties of the hybrid materials are also presented.

Electrochemical and Optical Characterization of Metal-Decorated Carbon Nanotubes. TATYANA SHEPS, VAISKUNTH R. KHAPAL, ALEXANDER A. KANE, PHILIP G. COLLINS, Department of Physics and Astronomy, University of California Irvine, Irvine, CA 92697-4576 — HYUNMIN KIM, ERIC O. POTMA, Department of Chemistry, University of California Irvine, Irvine, CA 92697-4576 — Hybrid electrodes combining carbon nanotubes with metal and metal oxide particles are promising for many catalytic applications including energy conversion and energy storage. Understanding the chemical interactions between the nanotube substrate and the catalytic nanoparticle is crucial for optimizing these types of electrodes. Here, we describe techniques for interrogating the metal-nanotube interface on the single-molecule level, using isolated single-walled nanotubes (SWNTs) decorated by single metal particles as the most basic, representative element of a bulk hybrid electrode. The resulting composite and its chemical interface is studied by two complementary techniques, electrochemical voltammetry and Raman spectroscopy. Results comparing the electrochemical behavior with the surface chemistry are presented.

Electrochemical and Optical Characterization of Metal-Decorated Carbon Nanotubes. 

Tuesday, March 17, 2009 8:00AM - 10:48AM
Session H25 DMP: Focus Session: Probing and Modifying Materials with Lasers

Advances in micro/nano scale materials processing by ultrafast lasers. COSTAS FOTAKIS, IESL-FORTH — Materials processing by ultrafast lasers offers several attractive possibilities for micro/nano scale applications based on surface and in bulk laser induced modifications. The origin of these applications lies in the reduction of undesirable thermal effects, the non-equilibrium surface and volume effects coupled with reactive chemical interface, the suppression of photochemical effects in molecular substrates, the possibility of optimizing of energy dissipation by temporal pulse shaping and the exploitation of filamentation effects. Diverse applications will be discussed, including the development and functionalization of laser engineered surfaces, the laser transfer of biomolecules and the functionalization of 3D structures constructed by multiphoton stereolithography. Two examples will be presented in this context: A new approach for the development of superhydrophobic, self-cleaning surfaces [1,2] and the fabrication of functional scaffolds for tissue engineering applications [3-5].

Positional Accuracy in Optical Trap-Assisted Nanolithography. CRAIG B. ARNOLD, EUAN MCLEOD, Princeton University — The ability to directly print patterns on size scales below 100 nm is important for many applications where the production or repair of high resolution and density features are important. Laser-based direct-write methods have the benefit of quickly and easily being able to modify and create structures on existing devices, but feature sizes are conventionally limited by diffraction. In this presentation, we show how to overcome this limit with a new method of probe-based near-field nanopatterning in which we employ a CW laser to optically trap and manipulate dispersed microspheres against a substrate using a 2-d Bessel beam optical trap. A secondary, pulsed nanosecond laser at 355 nm is directed through the bead and used to modify the surface below the microsphere, taking advantage of the near-field enhancement in order to produce materials modification with feature sizes under 100 nm.

3D photofabrication by femtosecond laser pulses and its applications in biomedicine. ALEKSANDR OVSJANIKOV, XIAO SHIZHOU, MANGIRDAS MALINAUSKAS, BORIS CHICHKOV, Laser Zentrum Hannover e.V. — Two-photon polymerization (2PP) is a novel laser-based microstructuring technique. In this approach, the multiphoton absorption of femtosecond laser pulses is used to induce a highly localised chemical reaction leading to a photopolymerization of the material. By moving the laser focus in 3D the trace of modified material is created. In the next step, the unmodified material is removed by an appropriate developer, and the fabricated structure is revealed. Therefore, fabrication of any computer generated 3D structure by “direct laser recording” into the volume of photosensitive material is possible. Nonlinear nature of the interaction allows true 3D microfabrication and realisation of structures with submicrometer resolution. Realistically, we studied possible applications of 2PP in tissue engineering provides possibility to fabricate series of exactly identical scaffolds. Therefore, it is possible to conduct systematic studies of cell interactions in 3D environment. In this contribution, our recent advances in two-photon activated laser processing, properties of applied materials, and applications of this technology are discussed.
9:00AM H25.00004 Single-pulse fabrication of deep vertical nano-holes with a microjoule femtosecond laser.  
LOYD M. DAVIS, YELENA V. WHITE, XIAOXUAN LI, ZBIGNIEW SIKORSKI, WILLIAM H. HOFMEISTER, University of Tennessee Space Institute — When a single energetic 200-femtosecond laser pulse is tightly focused onto the surface of a dielectric material, Zener (tunnelling) ionization and Zener-seeded saturation avalanche ionization cause a plasma to be formed at the surface. The tail of the pulse reflects from the plasma so that the resultant damage is typically shallow. However, we have found that when the laser pulse is focused with negative spherical aberration, holes exceeding 11 microns in depth and with diameters at the surface of only 200—500 nm may be created. A simple acetate sample replication technique is used to estimate the dimensions of the holes. The validity of the replication technique for characterizing such high-aspect-ratio features is confirmed by focused ion-beam sectioning of holes followed by visualization with a scanning electron microscope. We discuss physical processes that may be responsible for the creation of such deep nano-holes, including the role of self-focusing of the laser beam, and the possibility of acceleration of electrons along the direction of the laser beam into the hole. Applications, including direct laser writing of vertical channels for nanofluidic devices, are discussed. Related research on femtosecond laser machining of diamond is also presented.

9:12AM H25.00005 Optical Bulk Metamaterials  
XUANG ZHANG, NSF Nanoscale Science and Engineering Center (NSEC) University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Lab — Metamaterials are artificially designed subwavelength composites that possess extraordinary properties not existing in naturally occurring materials. In particular, they can alter the propagation of electromagnetic waves resulting in negative refraction, sub-wavelength focusing, and transmission of sub-wavelength information over a finite distance. Such unusual properties can be obtained by a careful design of the metal-dielectric composites on a deep sub-wavelength scale. The metamaterials may have profound impact in a wide range of applications such as nano-scale imaging, nanolithography, and integrated nano photonics. I will discuss a few recent experiments demonstrating intriguing phenomena associated with Metamaterials. These include sub-diffraction limit imaging and focusing, low loss negative refraction and imaging in bulk optical metamaterials, and Negative-index Metamaterials (NIM) exhibiting negative phase propagation that can be accessed from free-space. I’ll also discuss nano plasmonics for imaging and bio-sensing.

9:48AM H25.00006 Coloration of single crystal ZnO with ultraviolet laser irradiation1.  
ENAMUL KHAN, S.C. LANGFORD, J.T. DICKINSON, Washington State University — Many dielectric crystals color in the visible region of the spectrum when exposed to intense ultraviolet light such as excimer laser irradiation. In the alkali and alkaline earth halides, the decay of self-trapped excitons produces strongly absorbing defects. We were recently surprised to see single crystal ZnO darken dramatically during exposure to 193-nm ArF excimer laser radiation. ZnO is a wide bandgap (3.44 eV) semiconductor of significant technological interest. The increase in absorption is very broadband, extending from the bandgap into the infrared, and appears nearly black or grey. We present convincing evidence that this color is due to metallic zinc nanoparticles residing on the surface of the irradiated region. As expected, the laser fluence has considerable impact on the size, number, and spatial distribution of these nanoparticles. We propose a model for production of metallic nanoparticles on the surface.

10:00AM H25.00007 Generation of point defects in femtosecond laser interactions with Cr targets  
EAMAN TAHIR, University of Baghdad, Iraq, ZHIBIN LIN, Texas A&M University, USA, LEONID ZHIGILEI, University of Virginia, USA — The mechanisms and driving forces responsible for the generation of point defects (vacancies and interstitials) in femtosecond laser interactions with Cr target are investigated in atomic-scale simulations. Two series of simulations are performed. In the first set of simulations, the processes induced by 200 fs laser pulse irradiation of a bulk Cr target are studied with a computational model that combines the classical molecular dynamic method with a continuum description of the laser excitation of conduction band electrons, electron-phonon coupling, and electron heat conduction. The distribution of point defects in the surface regions of irradiated targets is analyzed by a broad range of laser fluences, covering the regimes of surface melting, photomechanical spallation, and ablation. To investigate the relative contributions of the thermally-activated generation of vacancy-interstitial pairs and the production of the vacancies during the solidification process, the second series of simulations of solidification at fixed temperatures below the melting point is performed. The densities of vacancies generated under different undercooling conditions are related to the distributions observed in laser-irradiated targets. The implications of the computational predictions for atomic mixing and damage accumulation in multi-pulse irradiation regime are discussed.

10:12AM H25.00008 Nanostructuring of thin gold films by femtosecond laser-induced melt dynamics  
ARSENIY KUZNETSOV, JURGEN KOCH, BORIS CHICHKOV, Laser Zentrum Hannover e.V. — Femtosecond laser irradiation of thin gold films with fluences close to the ablation threshold induces formation of various nanostructures on the film surface [1-3]. These structures are formed due to laser-induced melting of gold and redistribution of the melted material from the edges into the center of the irradiated region. Shape of the created structures can be controlled by varying the laser intensity distribution over the gold film surface. It is shown that the sizes of the produced structures can be below than 100 nm. In this paper, a study of laser-induced molten material dynamics is presented. Analysis of the structural shapes produced with different laser intensity distributions and dynamical reflection measurements allow clarifying mechanisms of the structure formation. Possible applications of this nanostructuring method are discussed.

E. HARO-PONIATOWSKI, Universidad A. Metropolitana Iztapalapa Mexico, J. C. ALONSO-HUITRON, IIM-UNAM-Mexico, C. ACOSTA-ZEPEDA, M. C. ACOSTA-GARCIA, N. BATINA, Universidad A. Metropolitana Iztapalapa — Nanostructured silver thin films in a quasipercolated state are used as the starting morphology for inducing changes in shape and ordering effects by pulsed laser irradiation with a Nd:YAG laser (355 nm) [1,2]. The complex nanostructures are transformed into nanospheres which in turn are ordered in regular patterns when irradiated through a diffractive element such as a slit or a pinhole. The samples are deposited onto TEM grids by the pulsed laser deposition technique. These transformations are subsequently characterized by transmission electron microscopy and by atomic force microscopy. The observed effects are explained using Fresnel diffraction theory. Excellent agreement with the experimental results are obtained. [1] E. Haro-Poniatowski et al. Appl. Phys. Lett. 87, 143103, 2005 [2] E. Haro-Poniatowski et al. Radiation Effects & Defects in Solids 162, 491-499 (2007)
10:36AM H25.00001 Examining Femtosecond Laser Induced Plasma Dynamics via Ultrafast Electron Shadow Imaging1, JUNJIE LI, RICHARD CLINITE, XUAN WANG, JIM CAO, Physics Department/National High Magnetic Field Lab, Florida State University, ZHAOYANG CHEN, SAMUEL MAO, Department of Mechanical Engineering, University of California at Berkeley, JIM CAO TEAM, SAMUEL MAO COLLABORATION — We report a study of the dynamics of plasma creation and evolution in real time using a pulsed electron beam to create two-dimensional shadow images of the plasma plume. Due to the electron beam’s sensitivity to charge, the dynamics of electric fields and charge motion during the earliest stage of laser ablation of Copper plate were directly measured by taking snapshots of the plasma shadow images. Based on a dipole field assumption, a multiplying magnitude of Q(average charge), d(average electrons’ distance from surface), and t(duration of field) is obtained, Q*dt ~ 12*10^-8 *e*m*s, under 6.8*10^14 W/cm^2 laser power on 0.3mm diameter area, moreover, most electrons which are initially emitted retract back in 1 to 2 ps after laser pulse. The results provide new information about multi-photon emission and charge motion during intense laser material interaction.

Session H26 DMP: Focus Session: Graphene IV: Electronic and Structural Properties 328

8:00AM H26.00001 Graphene-based nanomechanical cooling device1, VAN JU LI, DAOXIN YAO, ERICA CARLSON, Purdue University — We propose a novel structure for nanomechanical cooling, based upon graphene. Because thermal transport occurs perpendicular to the surface of the substrate, the proposed structure can be used to facilitate thermal transport between two objects in contact. Furthermore, the strength of the Seebeck coefficient may be tuned by applying pressure. We calculate the Seebeck coefficient in this geometry, as a function of applied voltage and strain.

8:12AM H26.00002 Doping Single-Layer Graphene from SiO2 Substrates or Jointed Few-Layer Graphene, LAIN-JONG LI, YUMENG SHI, Nanyang Technological University — Electrostatic force microscopy (EFM) measurements reveal that the surface potential of graphene either increases or decreases, depending on the initial surface potential of substrates, to a “bulk” value with their thickness. Graphene layers tend to screen the substrate potential, which drives the charge exchange between graphene and the substrate. The direct consequence is the effective doping of graphene, where the substrate-dependent p- or n-doping of graphene is corroborated by Raman spectroscopy and electrical measurements for the transistor devices. Our results promise a practical method for tailoring the electronic properties of graphene for nanoelectronics.

8:24AM H26.00003 Graphene-based Materials1, RODNEY RUOFF, The University of Texas at Austin — Our top-down approaches [Lu et al.] inspired physicists to obtain graphene by micromechanical exfoliation. Another approach to individual layers involves converting graphite to graphene oxide (GO) to generate aqueous colloidal suspensions of ‘graphene oxide’(GO) sheets. (i) Reduced GO’ (RGO’) sheets were embedded in polymers such as polystyrene and their dispersion/morphology studied by SEM/TEM, and the conductivity/percolation threshold of such composites was determined; (ii) individual GO’ and RGO’ sheets were studied to elucidate their chemical, optical, and electrical properties, (iii) GO’ and RGO’ sheets were embedded in thin glass films by a sol-gel route yielding conductive/transparent films, (iii) a ‘paper’ material of stacked GO’ sheets was made and characterized, (iv) powders composed of RGO’ showed exceptional promise for use in ultracapacitors, and (v) C13-labeled GO was made and the detailed chemical structure of GO was determined with NMR. –Lu,Yu,Huang,Ruoff, “Tailoring graphite with the goal of achieving single sheets”, Nanotechnology, 10, 269-272 (1999).

9:00AM H26.00004 Quantum transport and Klein tunneling in graphene heterojunctions, ANDREA YOUNG, PHILIP KIM, Physics Department, Columbia University — I will discuss the observation of quantum conductance oscillations in extremely narrow graphene heterostructures where a resonant cavity is formed between two electrostatically created bipolar junctions. From analysis of the observed interference pattern, it can be inferred that individual p-n junctions have a collimating effect on transmitted carriers, leading directly to the observation of resonant oscillations despite the largely diffusive carrier dynamics. The oscillatory part of the conductance is insensitive to scattering within individual p-n junctions, electrons which scatter in the junctions, making them a novel probe of the ballistic physics of graphene at the Dirac point and allowing an estimate of the electric field due to nonlinear screening. In a weak applied magnetic field, the oscillations undergo a phase shift characteristic of reflectionless normal transmission, or “Klein Tunneling,” at the individual p-n junctions. Finally, at high magnetic field, graphene heterostructures show modified Shubnikov de Haas oscillations due to the inhomogenous external potential.

9:12AM H26.00005 Electronic transport properties of graphene irradiated by charged particles1, JIAN-HAO CHEN, WILLIAM CULLEN, CHAUN JANG, MICHAEL FUHRER, ELLEN WILLIAMS, Materials Research Science and Engineering Center, Center for Nanophysics and Advanced Materials, Dept of Physics, Univ. of Maryland, College Park, MD — We have measured the effect of low energy charged particle irradiation (electrons, He ions, Ne ions or Ar ions) on the electronic transport properties of clean graphene devices on SiO2. Charged particle irradiation induces additional scattering which is consistent with adding both short-ranged (i.e. point defect) and long-ranged (i.e. charged) impurities to the device. We also performed temperature-dependent conductivity of the irradiated devices from 9K to 400K in ultra high vacuum. In sharp contrast to graphene with charged impurity disorder, which remains metallic at low temperature, even a small amount of irradiation-induced disorder (one order of magnitude increase in room-temperature resistivity compared to pristine devices) produces a divergence of the resistivity and insulating behavior at low temperature for carrier densities below 4*10^{12} cm^{-2}.

1This work was supported by the University of Maryland MRSEC and the Nanoelectronics Research Initiative of the Semiconductor Research Corporation.

9:24AM H26.00006 Fractionalization in graphene-like systems, CONAN WEEKS, UBC, MARCEL FRANZ, University of British Columbia — I will discuss the possible interaction-driven instabilities that can arise in a system of masles Dirac fermions modeled by the extended Hubbard model on the π flux square lattice and the honeycomb lattice, and their relevance to fractionalization in 2D graphene-like systems. Through numerical studies we have shown that these instabilities can result in a number of interesting phases. In addition to the charge density wave and various stripe phases these include the exotic “quantum anomalous Hall” (Haldane) phase and the dimerized “Kekulé” phase. A self consistent calculation inside the Kekulé phase on the π flux lattice indicates that a discretized U(1) vortex can be stabilized in this region leading to a zero-energy bound state with fractional charge e/2.
The conductance of the GNR at the charge neutrality point was suppressed at low temperature, which suggests the opening of an energy gap due to the lateral modulation on the number of graphene layers. An 800-nm-wide bar-shaped device fabricated in single-layer graphene exhibits the half-integer quantum Hall bilayer, and multilayer graphene using tapping-mode atomic force microscope (AFM). We found that the width of the insulating oxidized area depends systematically on the position of the sample for different crystal periodicities. Such observations provide information about the stacking and domain boundaries in epitaxially-grown graphene.

In particular, we studied the evolution of the electronic structure of graphene nanoflakes with very high aspect ratios. Possible mechanisms of graphite exfoliation and graphene nanoribbon formation will be discussed.

\[ \Delta \varphi = \Delta \varphi_0 + \Delta \varphi_1, \]
8:00AM H27.00001 Temperature Dependence of Single-Asperity Friction for Diamond on Diamond and DLC Interfaces1 , C. DUNCKLE, University of California, Irvine, I.B. ALTFEDER, Air Force Research Laboratory, P. TABOREK, University of California, Irvine — A variable temperature, ultrahigh vacuum atomic force microscope with a diamond-coated probe was used to characterize interfacial friction over a temperature range of 30 to 300 Kelvin. A vertical scan was used to measure tip to surface adhesion and contact normal forces. Friction (lateral) force measurements were taken by dragging the tip along the surface. Calibration was done in situ using substrates with known dimensions and angles. Measurements were made on diamond-like carbon surface and a single crystallite in a micro crystalline diamond film. Results were analyzed by fitting into the DMT continuum model. Comparison of friction versus load showed approximately a factor of two increase in the friction at cryogenic temperatures compared to room temperature. Results are qualitatively consistent with MD simulations but are not well described by models of thermally activated friction. Problems associated with temperature gradients at the tip- surface interface will be discussed.

8:12AM H27.00002 Small amplitude vibrations of curved atomic force microscope cantilevers: Theory , ARVIND NARAYANASWAMY, CARLO CANETTA, NING GU, Columbia University — The shifts in resonance frequencies of cantilevers are used to infer tip–sample interactions in tapping–mode atomic force microscopy as well as in a wide variety of cantilever based sensors. In this work, we investigate theoretically as well as experimentally the effect of curvature on the vibration dynamics of micro–cantilevers to which a micro–sphere is attached at the free end. We show that resonance frequency shifts of cantilevers to which a tip mass is attached can be altered by controlling the curvature of the cantilever. This control over the resonance frequency spectrum is independent of other causes of resonance frequency variation, such as adsorbed mass on cantilever or variation of material properties due to change in temperature. In the case when the cantilever is a bi–material cantilever, this shift in resonance frequency can be used as to detect changes in the thermal environment of the cantilever.

8:24AM H27.00003 Intermodulation Atomic Force Microscopy and Spectroscopy , CARSTEN HUTTER, Stockholm University, DANIEL PLATZ, ERIK THOLEN, DAVID HAVILAND, Royal Institute of Technology, HANS HANSSON, Stockholm University — We present a powerful new method of dynamic AFM, which allows to gain far more information about the tip-surface interaction than standard amplitude or phase imaging, while scanning at comparable speed. Our method, called intermodulation atomic force microscopy (ImAFM), employs the manifestly nonlinear phenomenon of intermodulation to extract information about tip-surface forces. ImAFM uses one eigenmode of a mechanical resonator, the latter driven at two frequencies to produce many spectral peaks near its resonace, where sensitivity is highest [1]. We furthermore present a protocol for decoding the combined information encoded in the spectrum of intermodulation peaks. Our theoretical framework suggests methods to enhance the gained information by using a different parameter regime as compared to Ref. [1]. We also discuss strategies for solving the inverse problem, i.e., for extracting the nonlinear tip-surface interaction from the response, also naming limitations of our theoretical analysis. We will further report on latest progress to experimentally employ our new protocol.

8:36AM H27.00004 Independent determination of depth and energy of electronic trap states in dielectric films by Dynamic Tunneling Force Microscopy , JON PAUL JOHNSON, CLAYTON C. WILLIAMS, University of Utah, Physics Department — Dynamic Tunneling Force Microscopy (DTFM) is a new scanning probe technique that images electronic states in completely non-conducting films with sub-nanometer spatial resolution1. In DTFM, electrons are shuttled via quantum tunneling between a metallic tip and localized electronic states in an insulating dielectric film, while a lock-in amplifier detects an electrostatic force signal that is proportional to the shuttled charge. The DTFM signal provides a map of the available electronic states within tunneling range of the surface. These states are not observable by STM. The depth of the states can be estimated from the dependence of tunneling rate on the tip/sample gap2 and also inferred from their apparent lateral size. Image shows states below the surface that drop out of the image when the tip/sample gap is increased. A methodology is introduced to independently determine state energy and depth, potentially on a sub-nanometer scale. This work was supported by AFOSR and SRC. 8:48AM H27.00005 Applications of AFM for atomic manipulation and spectroscopy , OSCAR CUSTANCE, National Institute for Materials Science — Since the first demonstration of atom-by-atom assembly [1], atomic manipulation with scanning tunneling microscopy has yielded stunning realizations in nanoscience. A new exciting panorama has been recently opened with the possibility of manipulating atoms at surfaces using atomic force microscopy (AFM) [2-5]. In this talk, we will present two different approaches that enable patterning structures at semiconductor surfaces by manipulating individual atoms with AFM and at room temperature [2, 3]. We will discuss the physics behind each protocol through the analysis of the measured forces associated with these manipulations [3-5]. Another challenging issue in scanning probe microscopy is the ability to disclose the local chemical composition of a multi-element system at atomic level. Here, we will introduce a single-atom chemical identification method, which is based on detecting the forces between the outermost atom of the AFM tip and the atoms at a surface [6]. We demonstrate this identification procedure on a particularly challenging system, where any discrimination attempt based solely on topographic measurements would be impossible to achieve.

9:24AM H27.00006 Design of a variable temperatures scanning force microscope , E. NAZARETSKI, K. S. GRAHAM, J. D. THOMPSON, J. K. BALDWIN, Los Alamos National Laboratory, J. A. WRIGHT, University of California Los Angeles, D. V. PELEKHOV, P. C. HAMMEL, Ohio State University, R. MOVSITCHOVICH, Los Alamos National Laboratory — We have developed the variable temperature scanning force microscope capable of performing both magnetic resonance force microscopy (MRFM) and magnetic force microscopy (MFM) measurements in the temperature range between 5 and 300 K. Modular design, large scanning area, and interferometric detection of the cantilever deflection make it a sensitive, easy to operate and reliable instrument suitable for studies of the dynamic and static magnetization in various systems. We have verified the performance of the microscope by imaging microfabricated permalloy dots and vortices in Nb thin film in the MFM mode of operation. MRFM spectra in a diphenyl-picryl-hydrazyl film were recorded to evaluate the MRFM mode of operation.
9:36AM H27.00007 Bimodal atomic force microscopy imaging of isolated antibodies in air and liquids. JOSE R. LOZANO, ELENA T. HERRUZO, NICOLAS F. MARTINEZ, RICARDO GARCIA, Inst. Microelectronics Madrid -CSIC, FORCETOOL TEAM — We develop a dynamic atomic force microscopy (AFM) method based on the simultaneous excitation of the first two flexural modes of the cantilever. The instrument, called bimodal AFM, opens up additional channels (amplitude and phase of the 2

9:48AM H27.00008 High-Resolution Magnetic Resonance Force Microscopy using Iron Filled Carbon Nanotubes. MICHAEL HERMAN, PALASH BANERJEE, KIN CHUNG FONG, DENIS PELEKHOV, The Ohio State University, FRANZISKA WOLNY, THOMAS MUHL, BERND BUCHNER, Leibniz Institute for Solid State and Materials Research, CHRIS HAMMEL, The Ohio State University — Magnetic Resonance Force Microscopy is able to probe below surfaces to map out spins in a non-destructive manner by measuring the force from the dipolar coupling of a magnetic probe to spins in the sample. We have used low force constant cantilevers with low intrinsic dissipation to obtain 2 spin sensitivity. To obtain better sensitivity one avenue of improvement is to increase the magnetic field gradient from the magnetic probe. Iron-filled carbon nanotubes provide a promising route for very high magnetic field gradient micromagnetic probes; we have successfully attached these iron nanowires to IBM style ultrasoft silicon cantilevers. The smaller size of the tip (15 to 25 nm) allows gradients an order of magnitude greater than micron-sized rare-earth magnets. In addition, iron filled carbon nanotubes also exhibit high anisotropy fields, a result of the shape anisotropy. This work was supported by the Army Research Office under W911NF-07-1-0305 and the National Science Foundation under DMR-0807093.

10:00AM H27.00009 Electron Spin Magnetic Resonance Force Microscopy of Nitroxide Spin Labels. ERIC W. MOORE, SANGGAP LEE, STEVEN A. HICKMAN, SARAH J. WRIGHT, JOHN A. MAROHN, Department of Chemistry and Chemical Biology, Cornell University — Nitroxide spin labels are widely used in electron spin resonance studies of biological and polymeric systems. Magnetic resonance force microscopy (MRFM) is a magnetic resonance technique that couples the high spatial resolution of a scanning probe microscope with the species specificity of magnetic resonance. We report on our investigations of 4-amino TEMPO, a nitroxide spin label, by force-gradient MRFM. Our microscope operates at high vacuum in liquid helium, using a custom fabricated ultra-soft silicon cantilever in the magnet-on-cantilever geometry. An 18 T gap coupled microstrip line resonator supplies the transverse field.

10:12AM H27.00010 A Compact, Wide Temperature Range (300mK-300K) Magnetic Force Microscope using High Resolution Fibre Interferometer and Alignment-Free Cantilevers. OZGUR KARCII, NanoMagnetic Instruments Ltd., MUNIR DEDE, Bilkent University, AHMET ORAL, Sabanci University, NANOMAGNETICS INSTRUMENTS TEAM, BILKENT UNIVERSITY COLLABORATION, SABANCI UNIVERSITY COLLABORATION — We describe a design of a Low Temperature Magnetic Force Microscope (LT-MFM) for variable temperatures between milli-Kelvin temperatures to 300 K. The design of LT-MFM is very compact, 23.6mm ODx200mm, flexible and is compatible with almost any cryostat (included PPMS of Quantum Design Inc), even He3 systems or DR, provided that there is enough space. The sensor is mounted on a scan piezo tube which has five quadrants: four quadrants are used for scanning, the fifth electrode is used for dithering the cantilever by means of a digital Phase Lock Loop (PLL) with 5mHz frequency resolution. We employed a fibre interferometer deflection measurement for our LT-MFM. A special alignment holder is designed for this purpose. A 225µm length MFM cantilever is placed on an Alignment-Free AFM Cantilever holder chip from NanoSensors. Our design can sustain cantilever-fiber alignment down to 300mK without any signal loss. An improved fiber interferometer with ~1x10^{-3} A/Hz noise level is designed and used to detect cantilever deflection. LT-MFM also enables us to work under high external magnetic fields.

10:36AM H27.00012 Development of Superconducting Quantum Interference Device DC Magnetometer for High Magnetic Field and Dilution Refrigerator Applications. J.-H. PARK, T.P. MURPHY, S.W. TOZER, E.C. PALM, National High Magnetic Field Laboratory, FSU, Tallahassee, FL — A commercially available SQUID (Superconducting Quantum Interference Device) DC magnetometer is often limited by its relatively high temperature (≥ 1.9 K) and low magnetic field (≤ 7 T) operating environment. The need for the lower temperature and higher field DC magnetization measurements keeps growing as more materials show interesting physical phenomena whose energy scales are relevant to low temperatures (~ mk). To meet these needs we have developed a probe for a top loading dilution refrigerator in which all the DC magnetometer components including SQUID electronics, detection coil, and sample motion shaft are placed together. The probe was tested in a top loading dilution refrigerator and the results show that the base temperature at 25 mK increased ~ 1.6 % when the sample displacement was 3.2 cm with a speed of 3 cm/min. The moment of the test sample was successfully detected down to 50 mK. Improvement in coil balancing and shielding of the detection coil are planned.

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H28 DMP FIAP: Focus Session: Thermolectric Materials: Transport Physics
shells leads to the low thermal conductivities experimentally measured \[1\]. We consequently successfully compare the results of our calculations \[3\] with the magnitude of the isotope effect on the thermal conductivities of carbon and boron nitride single-walled nanotubes \[2\]. We furthermore show that intershell carbon nanotubes \[1\]. Using an ab initio atomistic Green's function approach, we demonstrate that localization cannot be observed in the thermal conductivity of isotope-disordered boron nitride and carbon nanotubes \[1\].

The difficulty associated with thermoelectric materials is the need to couple and optimize a variety of physical properties which determine the thermoelectric efficiency. The parameters of a thermionic device featuring a doped diamond material as the emitter electrode to maximize the output power produced. For example, a TEC operating between $900 \, ^\circ\text{C}$ and $300 \, ^\circ\text{K}$ with an emitter negative electron affinity of $0.5 \, \text{eV}$, a collector barrier height of $0.6 \, \text{eV}$, Richardson's constant of both electrodes equal to $10 \, \text{Acm}^{-2} \text{K}^{-2}$, emissivity of both electrode of $0.5$, and interelectrode spacing of $10 \, \mu\text{m}$ will have a maximum output power of $1.5 \, \text{Wcm}^{-2}$ and efficiency of $20\%$ occurring at an emitter barrier height of $1.2 \, \text{eV}$. The efficiency calculation includes electronic and blackbody heat transport across the device. The analysis establishes approaches to increase the efficiency to values greater than $20\%$. This work was funded by the Office of Naval Research through the TEC MURI Program.

**8:36AM H28.00002 Nanostructured materials design for thermoelectric applications**, KEIVAN ESFARJANI, MONA ZEBARJADI, ALI SHAKOURI, University of California at Berkeley — Nanostructured materials have shown great promise for superior thermoelectric properties. Recently, our collaborators and us have been able to enhance thermoelectric properties of InGaAs by doping it with ErAs nanoparticles. Transport properties are dominated by scattering of electrons with nanoparticles, phonons and impurities. We can design the scattering potential of the former to maximize the power factor, P is in fact an inverse problem, attempting to solve for the best nanoparticle scattering potential which maximizes P. Using a least square method, we find the potential which minimizes the difference between the actual scattering cross section and its target value. The target value is chosen so as to display energy filtering property. More generally, we also simply maximize the power factor with respect to the nanoparticle potential profile. A simple and fixed model is chosen for other scattering rates, as well as the dispersion relation for the bulk electrons results between the two approaches will be compared in order to see the effect of electron filtering property on the power factor enhancement.

**8:48AM H28.00003 Influence of Dimensionality on Thermoelectric Device Performance**\[1\] . RASEONG KIM, Purdue University, SUPRIYO DATTA, MARK S. LUNDSTROM — Significant improvements in the thermoelectric figure of merit have recently been demonstrated in low dimensional structures. These improvements have been largely due to the reduced lattice thermal conductivity, so the question of how much additional improvement is possible by engineering the electronic structure has become important. Our goal is to present a clear answer to this question using the Landauer formalism, which applies from the ballistic to diffusive limits. We first relate thermoelectric coefficients to the transmission and the number of conducting channels, M(E). The optimum M(E) is known to be a delta-function. We then compare thermoelectric coefficients in one, two, and three dimensions and show that the channels are utilized more effectively in lower dimensions. The shape of M(E) improves as dimensionality decreases, but lower dimensionality itself does not guarantee better performance because it is controlled by both the shape and the magnitude of M(E). To realize the advantage of lower dimensionality, the packing density must be more effectively in lower dimensions. The shape of M(E) improves as dimensionality decreases, but lower dimensionality itself does not guarantee better performance because it is controlled by both the shape and the magnitude of M(E). To realize the advantage of lower dimensionality, the packing density must be more effectively in lower dimensions.

**9:00AM H28.00004 Optimized vacuum thermionic energy conversion using diamond materials**, JOSHUA SMITH, Carnegie Mellon University, GRIFF BILBRO, North Carolina State University, ROBERT NEMANICH, Arizona State University — The vacuum thermionic energy conversion device (TEC) has been an attractive alternative to other means of energy production for some time due to its potentially high efficiency operation, but practical devices have been difficult to develop as a result of the low net space charge effect. It is well known that a hydrogen termination layer on a diamond material induces a negative electron affinity (NEA). In this study we present a theoretical analysis showing it is possible to tune the parameters of a thermionic device featuring a doped diamond material as the emitter electrode to maximize the output power produced. For example, a TEC operating between $900 \, ^\circ\text{K}$ and $300 \, ^\circ\text{K}$ with an emitter negative electron affinity of $0.5 \, \text{eV}$, a collector barrier height of $0.6 \, \text{eV}$, Richardson's constant of both electrodes equal to $10 \, \text{Acm}^{-2} \text{K}^{-2}$, emissivity of both electrode of $0.5$, and interelectrode spacing of $10 \, \mu\text{m}$ will have a maximum output power of $1.5 \, \text{Wcm}^{-2}$ and efficiency of $20\%$ occurring at an emitter barrier height of $1.2 \, \text{eV}$. The efficiency calculation includes electronic and blackbody heat transport across the device. The analysis establishes approaches to increase the efficiency to values greater than $20\%$. This work was funded by the Office of Naval Research through the TEC MURI Program.

**9:12AM H28.00005 Nanostructured Silicon as a Thermoelectric Material**, ARUNAVA MAJUMDAR, University of California at Berkeley — No abstract available.

**9:48AM H28.00006 Design of thermoelectric composite materials for energy applications**, MARTIN MALDOVAN, EDWIN THOMAS, Massachusetts Institute of Technology — Energy supply is becoming a major world-wide problem as fossil energy supplies decrease while energy demands increase. Thermoelectric materials, which reversibly convert thermal and electrical energy, offer the prospect of power generation and cooling by means of the rational transport of electrons and phonons. In nanocomposite materials, both quantum and classical effects provide opportunities to control the transfer of electrons and phonons. The difficulty associated with thermoelectric materials is the need to couple and optimize a variety of physical properties in order to exhibit necessary efficiencies, which are determined by the figure of merit ZT. To exhibit large efficiencies, the best thermoelectric material should possess low thermal conductivity (similar to that of a glass) and high electrical conductivity (similar to that of a perfect crystal material). In this paper we study thermoelectric materials by preparing composite materials that can provide the desired coupled physical properties. Our research concentrates on predicting and designing thermoelectric material properties using theoretical and computational methodologies. We use currently available algorithms with numerical techniques to design thermoelectric materials with increased efficiencies. The ultimate goal of our research is to develop a basic understanding of the coupled physical properties in these materials and to create a framework that allows for the systematic design, optimization, and characterization of their thermal and electric properties.

**10:00AM H28.00007 Thermal conduction mechanisms in isotope-disordered boron nitride and carbon nanotubes**, IVANA SAVIC, NATALIO MINGO, LITEN, CEA-Grenoble, France, DEREK STEWART, Cornell Nanoscale Facility, Cornell University, USA — We present first principles studies which determine dominant effects limiting the heat conduction in isotope-disordered boron nitride and carbon nanotubes \[1\]. Using an ab initio atomistic Green's function approach, we demonstrate that localization cannot be observed in the thermal conductivity of isotope-disordered boron nitride and carbon nanotubes \[1\].

**8:00AM H28.00001 Thermoelectricity: A Bottom-up View**, SUPRIYO DATTA, Purdue University — It is well-known that the nature of electronic transport changes significantly as the length L of the active region of a device is reduced from millimeter down to nanometer dimensions. Historically our understanding of electrical resistance and conduction has progressed top-down: from large macroscopic conductors to small atomistic conductors. Indeed thirty years ago it was common to argue about what, if anything, the concept of resistance meant on an atomic scale. Since then there has been significant progress in our understanding, spurred by actual experimental measurements made possible by the technology of miniaturization. However, despite this progress in understanding the flow of current on an atomic scale, the standard approach to the problem of electronic transport continues to be top-down and we have argued elsewhere that an alternative bottom-up viewpoint can be extremely illuminating \[1\]. In this talk we will briefly summarize this viewpoint and discuss the unique insights it provides into the subject of thermoelectricity and thermoelectric device design in general and into the possibilities of molecular thermoelectrics in particular.

Title: Phonon relaxation times extracted from first principles thermal conductivity calculations

Authors: D. A. BROIDO, A. WARD, Department of Physics, Boston College, Chestnut Hill, MA 02467

Abstract: The lattice thermal conductivity of semiconductors, κ_L, is a key component in assessing a material's utility for thermoelectric applications. Calculations of κ_L commonly employ phonon relaxation times, τ_pkh. Over the past few decades, a variety of mathematical forms have been used for these τ_pkh to represent the phonon-phonon scattering [1], which dominates the behavior of κ_L around and above room temperature. However, these forms have typically been obtained in a low frequency/low temperature approximation where umklapp scattering is weak and outside the thermal regime of interest for thermoelectrics. Recently we have developed a first principles approach that accurately calculates κ_L using no adjustable parameters [2]. In this presentation, we use our ab initio results for Si, Ge and diamond to examine the accuracy of the different models for τ_pkh, and we identify alternative models. [1] See for example, M. Asen-Falmer et al., Phys. Rev. B 56, 9431 (1997), and references therein. [2] D. A. Broido, M. Malorny, G. Birner, N. Mingo and D. A. Stewart, Appl. Phys. Lett. 91, 231922 (2007).

Title: Thermal boundary resistance of closely-spaced Si/Ge interfaces from lattice dynamics calculations

Authors: ERIC LANDRY, ALAN MCGAUGHEY, Carnegie Mellon University

Abstract: An ability to accurately predict the thermal boundary resistance (TBR) of closely-spaced semiconductor interfaces will allow the design of superlattices with high values of the thermoelectric figure-of-merit. Here, the TBR and phonon transmission coefficients of closely-spaced Si/Ge interfaces are predicted using harmonic lattice dynamics calculations and the scattering boundary method. The atomic interactions are modeled using the Stillinger-Weber potential. The computational domain contains a thin germanium layer sandwiched between two semi-infinite extents of silicon, forming two closely-spaced interfaces. We also consider the opposite situation, where a silicon layer is placed between two large extents of germanium. Due to the harmonic approximation, the calculations are only valid when the phonon scattering is elastic. To examine the assumption of elastic scattering, we compare the lattice dynamics predictions to those obtained using molecular dynamics simulations and the direct method, which require no assumptions about the nature of the phonon transport. We conclude by discussing how the atomic force constants needed in the lattice dynamics calculations can be calculated from density functional theory. This novel approach will allow for the prediction of TBR for interfaces between semiconductors for which a suitable interatomic potential does not exist.

Title: Prediction of phonon transport properties and thermal conductivities in superlattices by anharmonic lattice dynamics calculations

Authors: JOSEPH TURNEY, ALAN MCGAUGHEY, Carnegie Mellon University, CRISTINA AMON, University of Toronto

Abstract: Phonon transport in superlattices is investigated using anharmonic and quasi-harmonic lattice dynamics calculations. Within the lattice dynamics framework, we develop a method for predicting the properties of both coherent and incoherent phonons. The method is implemented for test systems consisting of Stillinger-Weber silicon-germanium superlattices. In these systems the mode dependent frequencies, heat capacities, group velocities, transmission coefficients, and relaxation times of the phonons are computed and used to predict the thermal conductivity. We relate changes in the superlattice structure (e.g., period length and interface roughness) to the predicted phonon properties and, for each structure, identify the phonon modes that dominate thermal transport.

Tuesday, March 17, 2009 8:00AM - 9:48AM – Session H29 FEd: The Physics and Astronomy New Faculty Workshops II

Title: How the New Faculty Workshop in 2004 affected my teaching-learning strategies

Authors: NATALIA DUSHKINA, Department of Physics, Millersville University

Abstract: In this presentation, I will discuss how my experience with the New Faculty Workshop in fall 2004 affected my course offering and teaching-learning strategies in PHYS 103, PHYS 132 and PHYS 331: Fundamentals of Optics courses. PHYS 103, Elements of Physics, is a general education conceptual physics lab course with no prerequisites for non-science majors. PHYS 331, Fundamentals of Optics, is a lab-based course required for physics majors, which was offered for the first time at the MU Department of Physics in fall 2007. I will discuss curricular changes, as well as new teaching-learning and assessment methods implemented in these courses for the first time at our department. I will offer examples of peer group discussions, just in time teaching and the effect of chapter summaries on motivating the students and their participation in problem solving.

Title: Taking inquiry to the next level: Tablet PC’s to stimulate active learning and unify introductory physics curriculum

Authors: TIKHON BYKOV, Physics Department, McMurry University, Abilene, TX 79697, YELENA KOSHElevA, Psychology Department, McMurry University, Abilene, TX 79697

Abstract: Tablet PC’s have been adapted to student peer group discussions. Student feedback showed that modifications were beneficial. Student knowledge assessment, performed with the FCI test, indicated improvement in student learning.
success at UCF during the initial phase of the project. R. Thornton, and P. Laws which has met with success at other universities and colleges. It was recently been adopted at the University of Central Florida (UCF), a large metropolitan university that is rapidly becoming a major research university. A key question is then if successful physics education practices

8:36AM H29.00004 How Physics Test Scores Reflect the Students’ Time Spent, MARIA BABUC-HAMILTON, Marshall University, Huntington, WV, TIM HAMILTON, Shawnee State University, Portsmouth, OH — We found that exam scores in introductory physics courses show a wedge-shaped pattern when plotted against the order they are turned in. The article will explore some of the factors contributing to this pattern and will propose guidelines to help determine an ideal test time limit, aimed at students with good perseverance and average skill. The reason for this pattern appears to stem from a combination of students’ skills and perseverance. The first students to finish tend to have either the best or worst grades in the class, with few in between. Students with the highest skills (knowledge, memory, problem-solving skills) need little time to finish, and they have the confidence to turn in the test quickly, before other students. Good students with moderately high skills tend to take longer. The later submissions gradually converge to a grade close the class average. Results of over 200 grades from students in different introductory physics classes, from two universities, taught using a variety of methods, when collected and analyzed, show the same wedge-shaped pattern. This seems to indicate a universal component of the pattern, which does not depend on the teaching methods or the test structure. From our analysis, we aim at deriving what an ideal test time limit would be, at which students hit a point of diminishing returns.

8:48AM H29.00005 “Physical Concepts in Cell Biology,” an upper level interdisciplinary course in cell biophysics/mathematical biology, DIMITRIOS VAVYLONIS, Department of Physics. Lehigh University — I will describe my experience in developing an interdisciplinary biophysics course addressed to students at the upper undergraduate and graduate level, in collaboration with colleagues in physics and biology. The students had a background in physics, biology and engineering, and for many the course was their first exposure to interdisciplinary topics. The course did not depend on a formal knowledge of equilibrium statistical mechanics. Instead, the approach was based on dynamics. I used diffusion as a universal “long time” law to illustrate scaling concepts. The importance of statistics and proper counting of states/paths was introduced by calculating the maximum accuracy with which bacteria can measure the concentration of diffuse chemicals. The use of quantitative concepts and methods was introduced through specific biological examples, focusing on model organisms and extremes at the cell level. Examples included microtubule dynamic instability, the search and capture model, molecular motor cooperativity in muscle cells, mitotic spindle oscillations in C. elegans, polymerization forces and propulsion of pathogenic bacteria, Brownian ratchets, bacterial cell division and MinD oscillations.

9:00AM H29.00006 The Quality Enhancement Plan Matrix (12 years and still tweaking the process!), GARY MANKEY, University of Alabama — As an alumni of the 1997 New Faculty Workshop, I’ve had plenty of opportunities to experiment with the teaching methods introduced there. Most recently, faculty at UA have been asked to develop a Learner-Centered approach to teaching, where regular, timely and thorough assessment of student learning becomes a key component of the curriculum. This involves four phases: 1) Identifying and defining learning outcomes, 2) Matching assessments to outcomes, 3) Identifying baselines and progression toward benchmarks and 4) Documenting the process using a quality enhancement plan matrix. This has led to the development of learning tools designed to enhance critical thinking and problem solving skills. This will be discussed in the context of setting teaching goals for new faculty, including how to document the process for teaching portfolios.

9:12AM H29.00007 Pedagogical Reforms from Private Engineering to Public University, LOK LEW YAN VOON, WSU — This talk will document my and associated colleagues’ impact on physics pedagogy at the two universities I have been employed at from my initiation at the New Faculty Workshop as an assistant professor in 1998 to being currently a full professor and chair. The present reforms involving our introductory physics courses are connected to our science education program.

9:24AM H29.00008 Applying Hands-On Activity Concepts to Advanced Mathematical Instruction for Physics, WILLIAM DIETERLE, California University of Pennsylvania — While the use of hands-on instruction by constructivist principles has been extensively documented and is covered in great detail in the New Faculty Workshops run by APS, most examples discussed in this series apply to the introductory course level. Many of the same principles can be applied at the upper division level, but topics that are normally considered purely mathematical do not readily lend themselves to such an approach. A common complaint of students first studying vector analysis in an upper division course is the fact that they can’t relate the divergence, curl, and gradient to real life. This talk discusses a method of presentation emphasizing the physical significance of these mathematical entities, with laboratory exercises for a two-dimensional gradient and for the divergence theorem in three dimensions. The approach has been successfully utilized in the first weeks of an upper division electricity and magnetism class.

9:36AM H29.00009 Meeting the Challenges of New Faculty – My Own Lesson, MIRELA FETEA, University of Richmond — A few years ago, I thought that students with different scientific backgrounds posed the biggest challenge for me – a new assistant professor teaching physics courses at a small liberal-arts private college. I thought that my knowledge of physics, enthusiasm, and willingness to succeed are most of the ingredients needed to become a very good teacher – how little I knew... Now, after being awarded tenure, having received a Distinguished Educator Award, an Outstanding Mentor award, and serving as acting-chair in my department, I am grateful for having had the opportunity to attend The Physics and Astronomy New Faculty Workshop which is responsible for who I am today. This presentation will offer a reflection on how the teaching techniques presented by specialists in pedagogy or educational methodology at The Physics and Astronomy New Faculty Workshop shaped my own performance as a teacher.

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H30 DMP GMAG: Focus Session: Superconducting and Magnetic Oxide Superlattices and Films 334
8:00AM H30.00001 Magnetism in Complex Oxide Heterostructures Determined with Neutron Scattering 1, SUZANNE G.E. TE VELTHUIS, Argonne National Laboratory — With the creation of high quality superlattices consisting of complex oxide materials novel materials exhibiting a wide range of interesting phenomena are emerging. Due to the diverse physical properties of complex oxides, (e.g., ferromagnetism, antiferromagnetism, superconductivity), some of which can be varied by doping, the versatility in their applications is large. The physical properties in these new materials, often is tied to the behavior at the interfaces between the different components of the superlattice, and therefore requires detailed knowledge of the relationship between the chemical and electronic composition. Polarized neutron reflectometry (PNR) provides access to the depth-dependent magnitude and orientation of the magnetization and can therefore link the magnetic to the electronic and chemical properties, especially close to these transitions. Antiferromagnetism, ferromagnetism, and superconductivity, some of which can be varied by doping, the versatility in their applications is large. The physical properties in these new materials, often is tied to the behavior at the interfaces between the different components of the superlattice, and therefore requires detailed knowledge of the relationship between the chemical and electronic composition. Polarized neutron reflectometry (PNR) provides access to the depth-dependent magnitude and orientation of the magnetization and can therefore link the magnetic to the electronic and chemical properties, especially close to these transitions.

8:36AM H30.00002 Spatial Mapping of the Interface Orbital Reconstruction in LaCaMnO$_3$/YBa$_2$Cu$_3$O$_7$ Heterostructures, J.W. FREELAND, E. KRATSOV, Advanced Photon Source, Argonne National Laboratory, S. GRENIER, J.-M. TONNERRE, Institute Neel, C.N.R.S., Grenoble, France, M. KAREEV, J. LIU, J. CHAKHALIAN, Department of Physics, University of Arkansas, Fayetteville — Interfaces between strongly correlated electron materials is an exciting area for exploring new phenomena as these states are altered in the proximity of the interface. In recent work, we have shown that at the interface between the ferromagnetic metal LaCaMnO$_3$ and the superconductor YBa$_2$Cu$_3$O$_7$ the electronic state of Cu undergoes an orbital reconstruction[1,2]. Here we present results using polarization-dependent resonant scattering at the Cu L edge to probe depth dependence of the orbital occupancies in the YBCO layer. By modeling the scattering in the region of the YBCO (001) Bragg peak in LCMO/YBCO heterostructures, we can work to extract a picture of the orbital occupancies in the interface region. Work at Argonne is supported by the U.S. Department of Energy, Office of Science, under Contract No. DE-AC02-06CH11357. JC is funded by U.S. DOD-ARO under Contract No. 0402-17291.

8:48AM H30.00003 Electronic and Magnetic Properties of the Interface Between a High-Tc Cuprate and CMR Manganese, JIAN LIU, University of Arkansas, J. FREELAND, B. KIRBY, M. KAREEV, H.U. HABERMEIER, G. CRISTIANI, J. CHAKHALIAN — Atomically controlled interfaces between two materials can give rise to novel physical phenomena and functionalities. Modern synthesis methods have yielded high-quality hetero-junctions of oxide materials with competing order parameters. Orbital reconstructions and covariant bonding has been shown to be important factors in the rational design of oxide heterostructures[1]. To clarify the role of superconductivity we study the interface between a high-temperature superconductor (Pr$_2$B$_2$Cu$_3$O$_7$ and CMR manganite La$_2$/3Cu$_1$/3Mn$_3$O$_7$ by resonant x-ray spectroscopy, magneto-optics and neutron reflectivity. The resulting data provide a hint of orbital changes and strong modification of magnetic structure in the heterojunction. 1. J. Chakhalian et al, Science, v. 318, 1155 (2007).

9:00AM H30.00004 Dynamics of Proximate Order Parameters Measured by the Time-Resolved Magneto-Optical Kerr Effect in SrRuO$_3$/YBa$_2$Cu$_3$O$_7$ Heterostructures, C.L.S. KANTNER, M.C. LANGNER, Dept. of Physics, UC Berkeley and Lawrence Berkeley National Lab, S.P. CRANE, L.W. MARTIN, Y.-H. CHU, P. YU, Dept. of Materials Science, UC Berkeley, R. RAMESH, Dept. of Physics and Dept. of Materials Science, UC Berkeley, J.W. ORENSTEIN, Dept. of Physics, UC Berkeley and Lawrence Berkeley National Lab — The interaction between ferromagnetic and superconducting complex oxides in a heterostructure is a subject of great interest. This recent observation of ferromagnetic resonance in SrRuO$_3$ by the time-resolved magneto-optical Kerr effect (TRMOKE) presents a new method for insight into such a system. TRMOKE has been used to compare the temperature dependence of magnetization dynamics in SrRuO$_3$ grown on insulating substrates and ferromagnetic SrRuO$_3$/superconducting YBa$_2$Cu$_3$O$_7$ heterostructures. The substantial differences between SRO grown on an insulating substrate compared to YBCO as well as the effects seen upon passing through the YBCO transition temperature are reported.

9:12AM H30.00005 Competition between high Tc superconductivity and ferromagnetism in oxide multilayers, CHRISTIAN BERNHARD, University of Fribourg and Fribourg Center for Nanomaterials — Artificial multilayers offer unique opportunities for combining materials with antagonistic orders such as superconductivity and ferromagnetism. It was previously shown for multilayers of classical superconductors and ferromagnets that fascinating new quantum states can be realized by tuning the layer thicknesses or the interface properties. In my talk, I will show that multilayers of cuprate high Tc superconductors (HTSC) in oxide-based ferromagnets provide an equally fascinating playground for studying the competition between the superconducting and ferromagnetic orders under the condition that both opponents are of comparable strength. I will present experimental results from neutron reflectometry and low energy muon spin rotation (LR) measurements on thin film superlattices that were grown by pulsed laser deposition (PLD). These measurements establish that the interaction between superconductivity and ferromagnetism is surprisingly strong and gives rise to a number of unexpected and very unusual phenomena. In particular, our data provide evidence that a giant superconductivity-induced modulation of the vertical profile of the ferromagnetic magnetization takes place in some of these superlattices.

9:48AM H30.00006 Enhanced Superconductivity in Superlattices of High-Tc Cuprates, SATOSHI OKAMOTO, THOMAS MAIER, Oak Ridge National Laboratory — We investigate the electronic properties of multilayers of strongly correlated models for cuprate superconductors using cluster dynamical mean-field techniques. We focus on combinations of underdoped and overdoped layers and find that the superconducting order parameter in the overdoped layers is enhanced by the proximity effect of the strong pairing scale originating from the underdoped layers. The enhanced order parameter can even exceed the maximum value in uniform systems. This behavior is well reproduced in slave-boson mean-field calculations which also find higher transition temperatures than in the uniform system. This work was supported by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, U.S. Department of Energy. A portion of this research at Oak Ridge National Laboratory’s Center for Nanophase Materials Sciences was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.
10:00AM H30.00007 Anomalous Expansion of the Cu-Apical O Distance in Superconducting Cuprate Oxide Bilayers , HUA ZHOU, National Synchrotron Light Source, Brookhaven National Lab, YIZHAK YACOB, Racah Institute of Physics, Hebrew University, RONALD PINDAK, National Synchrotron Light Source, Brookhaven National Lab, VLADIMIR BUTLER, DAVID G. HUDDLESTON, IVAN BOZOVIC, CMPMS Department, Brookhaven National Lab — Interfaces between complex oxides have received considerable attention due to the observation of fascinating quasi two- dimensional phenomena such as a high-mobility electron gas, interfacial ferromagnetism, and, recently, the observation of interfacial high-temperature superconductivity in epitaxially grown bilayers of metallic La0.55Sr0.45CuO4 and insulating La2CuO4 on LaSrAlO4 substrates.

To help understand the mechanism underlying the observed interfacial superconductivity, we directly measured the 3D electron density of this epitaxial bilayer, C.S. TUREL, T.L. WU, J.Y.T. WEI, University of Toronto, I.J. GUILARAN, P. XIONG, Florida State University — Andreev reflection has been extensively used to determine the spin polarization of various ferromagnetic materials, with conventional two-terminal measurements in magnetic fields of up to 12 Tesla were performed on thin film vanadium dioxide (VO2), ALEXANDRA A. FURSINA, Department of Chemistry, Rice University, 6100 Main st. Houston, TX, 77005, R.G. SUMESH SOFIN, IGOR V. SHVETS, CRANN, School of Physics, Trinity College, Dublin 2, Ireland, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University, 6100 Main st. Houston, TX, 77005 — Magnetite, Fe3O4, is an example of strongly electronically correlated system. It undergoes so called Verwey transition at TV ≈ 122 K accompanied both by structural distortion and drastic decrease in electrical conductivity, i.e. metal-insulator transition. Recently, we discovered a new electrically driven phase transition in magnetite nanoparticles and thin films. We observed that a low-temperature (T < TV) insulating state is broken upon applying an electric field, resulting in a sharp transition to the state with much higher conductivity. We report on further electrical characterization of this newly discovered state. There is a question whether this state is the same as high-temperature phase above Tc, or this is a new state of magnetite. In standard two-terminal measurement dominant contribution of contact resistance impedes intrinsic electrical properties. Thus, four-terminal configuration is necessary. Electrical and magnetoresistance properties are measured in challenging four-terminal geometry at nanoscale.

1 Funding for this research was provided by the Center for Emergent Materials at the Ohio State University, a NSF MRSEC (Award Number DMR-0820414).

10:24AM H30.00009 Magnetic and structural properties of half-metallic Sr2FeMoO6 epitaxial films fabricated by ultra-high vacuum sputtering1, ADAM HAUSER, R.A. RICCIARDO, A. GENC, R.E. WILLIAMS, P.M. WOODWARD, H.L. FRASER, F.Y. YANG, The Ohio State University — Sr2FeMoO6, a double-perovskite half-metallic ferromagnet, has attracted much attention because of its high Tc of 420 K. However, the fabrication of Sr2FeMoO6 epitaxial films has been challenging due to impurity phases and disorder. Using ultrahigh vacuum off-axis RF sputtering with precisely controlled low-concentration H2 in Ar, we have fabricated phase-pure Sr2FeMoO6 epitaxial films on SrTiO3 (001) and (111) substrates. X-ray diffraction confirms pure phase with double perovskite ordering. The phase purity and magnetic moments are highly sensitive to the H2 partial pressure. The optimal range for the H2 concentration is 0.4% to 0.6% in Ar with 70 mTorr total pressure. The saturation magnetization of the Sr2FeMoO6 films grown in this range is 1.5 μB/Fe per formula unit at 5 K, which is a strong magnetization considering the epitaxial strain. Aberration-corrected HAADF TEM images reveal atomically sharp interface between Sr2FeMoO6 and SrTiO3.

10:36AM H30.00010 Atomic structure of the polar Fe2O3(0001)/MgO(111) interface1, K. PANDE, M. GAJARDZISKA-JOSIFOVSKA, M. WEINERT, U. Wisconsin—Milwaukee — We present a first-principles investigation of the stability and structural properties of layer-by-layer growth of thin films of Fe2O3(0001) (hematite) on polar MgO(111). The interface is "oxide-like," atomically abrupt, and stabilized by significant structural relaxations. The electronic and magnetic properties are found to vary as a function of hematite film thickness. In contrast to the insulating and antiferromagnetic nature of bulk hematite, the heterointerface is half-metallic and ferromagnetic. Drastic structural rearrangements of the Fe2O3 overlay are observed at a critical thickness of three Fe bilayers, resulting in an effective expulsion of oxygen from the hematite film. To clarify the effect of the MgO(111) substrate polarity on the nature and growth of the Fe2O3 films, comparisons will be made to unsupported hematite slabs and to Fe2O3/Ti(0001) interfaces.

8:12AM H31.00002 Mott metal-insulator transition-induced electrical oscillation in VO₂, HYUN-TAK KIM, ETRI, YONG WOOK LEE, Pukyong University; ETRI, BONG-JUN KIM, SUN JIN YUN, ETRI, SONGYOUL CHOI, BYUNG-GYU CHAE, ETRI — Since Mott predicted the abrupt first-order metal-insulator transition (MIT) in 1949, one of the most important issues in contemporary solid-state physics has been to experimentally prove Mott’s MIT in a strongly correlated system with electron-electron interaction. The MIT has many practical applications and is believed to facilitate the understanding of physical phenomena, such as high-Tc superconductivity, colossal magnetoresistance, etc. In particular, in order to reveal the mechanism of the Mott MIT, many physicists have paid attention to a representative paramagnetic insulator, VO₂(4d³), with an abrupt resistance change near 68°C. The key issue is whether VO₂ is a Mott insulator, in which the abrupt MIT is not caused by a structural phase transition (SPT), or a Peierls insulator undergoing the SPT near Tₜₚₓ ≈ 68°C; this question can be answered when a monoclinic and correlated metal (MCM) phase different from a normal metal is observed. Here we show an MCM phase, high frequency electrical oscillations in the MCM phase of VO₂. The oscillation possibly is generated from a temporal capacitor, which is comprised of both temporary dielectric components, arising from inhomogeneity in a VO₂ film, and MCM phases acting like electrodes. This work concluded that the electrical oscillation is a characteristic of the Mott MIT. (Ref: Applied Physics Letters 92 (2008) 162903).

8:24AM H31.00003 De-coupling Electrical and Thermal Effects in Triggering Metal-Insulator Transition in VO₂ Thin Film Devices, GOKUL GOPALAKRISHNAN, SHRIRAM RAMANATHAN, School of Engineering and Applied Science, Harvard University — Vanadium dioxide (VO₂) has been shown to undergo an abrupt electronic phase transition near 70°C from a semiconductor to a metal, with an increase in dc conductivity of over three orders of magnitude, making it an interesting candidate for advanced electronics as well as for fundamental research into understanding the Mott transition. Recent experiments strongly suggest that this transition can be manifested independent of a structural phase transition in the system at a similar temperature, and that it can be triggered by the application of a critical field across the VO₂ thin film. To address the important question of thermal effects due to the applied field, we report the results of electro-thermal simulations on a number of common and promising device geometries showing the extent of heating caused by the leakage current in the “off” state of the VO₂ device. The simulation results are compared with experimentally observed device characteristics. Valuable insights into the nature of the metal-insulator transition can be obtained from such simulations and will be discussed in the presentation.

8:36AM H31.00004 Properties of Complex Oxides at the Nanoscale: First Order Phase Transitions through Avalanches, 1, AMOS SHARONI, Department of Physics, UC San Diego — Properties of complex oxides have been studied for decades, including many systems which exhibit a phase transition, among which are high temperature superconductors, multiferroics, and metal insulator (M-I) transition materials. We have studied a member of the later group, vanadium oxide (VO₂), which in spite of its long history, keeps surprising researchers today. We find that the M-I transition of nano-scaled VO₂ devices is drastically different from the smooth transition curves generally reported. The temperature driven M-I transition occurs through a series of resistance jumps ranging over two decades in magnitude, indicating that the transition between the two phases of the system happens by resistive avalanches. The avalanche magnitude follows statistically a power law similar to that observed in many other physical systems, such as Barkhausen noise in ferromagnets or sand avalanches in sand piles, and nonphysical systems such as connectivity of the internet. We discuss the effects on the distribution of avalanches due to the: device dimensions, percolative nature of the measurement and interactions between the different phases within the phase transition. We present additional evidence for the importance of interactions in macroscopic FORC measurements, and their role in the opening of the hysteresis in VO₂ M-I transitions.

1Work done in collaboration with J. G. Ramirez, Y. Dubi, M. E. Gomez and I. K. Schuller and funded by the U.S. Department of Energy and the AFOSR.

9:12AM H31.00005 FORC Analysis of the thermal hysteresis at the Metal Insulator Transition in VO₂, JUAN RAMIREZ, Universidad del Valle, Cali-Colombia, AMOS SHARONI, JONATHAN DUBI, University of California, San Diego, MARIA E. GOMEZ, Universidad del Valle, Cali-Colombia, IVAN K. SCHULLER, University of California, San Diego — We use the first order reversal curve method (FORC) to characterize the metal-insulator phase transition in VO₂ thin films. By studying the hysteresis properties of resistance vs. temperature we were able to obtain information regarding inter-domain interactions. An unexpected tail like feature in the contour plot of the FORC distribution indicates the existence of irreversible regions outside of the hysteresis loop. This irreversibility may arise from metallic domains present at various temperatures below the closing of the hysteresis, which interact with the surrounding medium and change the reversal path relative to one coming from a fully insulating state. We develop a model where the driving force which opens hysteresis in VO₂ is inter-domain interactions. This model is intrinsically different from the Preisach model that is usually used to describe hysteresis, since it identifies a microscopic origin of the hysteresis, and provides physical parameters to characterize it. Work Supported by the US Department of Energy, AFOSR and the Colombian agencies COLCIENCIAS and the Excellence Center for Novel Materials, CENM.

9:24AM H31.00006 Electric field effects on phase transition and electronic transport mechanisms in vanadium oxide thin films, CHANGHYUN KO, SHRIRAM RAMANATHAN, Harvard University — Metal-insulator transitions (MIT) in complex oxide thin films are of great interest from both scientific and application perspectives. Vanadium oxide is a model system to exploit strongly correlated electronic phenomena such as Mott transition. Furthermore, wide attention for application has been attracted by its transition functionality that can be tuned in terms of various external parameters: temperature, electric field, photocexcitation, and stress. The tunable conduction states allow creating novel devices whose functions are controlled by multiple parameters. We report on recent observations of electric-field assisted phase transition in vanadium oxide thin films. The conduction mechanisms were analyzed using both in-plane and out-of-plane modes and matched well. In the insulator phase, Poole-Frenkel emission was suggested to govern non-ohmic behavior at high field regime, while under low field application, ohmic conduction with activation energy of ~0.24 eV was observed. Activation energy of ohmic conduction in the metallic phase was ~0.08 eV. These preliminary results are encouraging towards exploring correlated oxides for computing device technologies.

9:36AM H31.00007 Conductivity Dynamics in the Correlated Metallic State of V₂O₃, M. LIU, B. PARDO, Boston University, Dept. of Physics, M.M. QAZILBASH, UCSD, Dept. of Physics, S.J. YUN, B.G. CHAE, B.J. KIM, H.T. KIM, Electronics and Telecommunications Research Institute, Korea, D.N. BASOV, UCSD, Dept. of Physics, R.D. AVERITT, Boston University, Dept. of Physics — V₂O₃ is a strongly correlated electron material that undergoes a transition from antiferromagnetic insulator at low temperatures to a strongly correlated metal above ~140K. We report on time resolved spectroscopic studies of V₂O₃ thin films where we have observed coherent oscillations in the far-infrared conductivity following excitation with a 35-fs optical pulse. The resultant ~100 ps conductivity oscillations result from the optically induced generation of strain which modulates the orbital overlap and hence the conductivity thus revealing a strong coupling of carriers to the lattice in the metallic state. This contrasts with other vanadates such as VO₂ where this effect is not observed. We will discuss the potential of V₂O₃ as a candidate material for investigating photoinduced phase transitions.
Subdomain studies of the metal-insulator transition in VO$_2$ nanobeams
JIAW WEI, JAE HYUNG PARK, JACOB BEEdle, ZENGHUI WANG, WEI CHEN, GEETA YADAV, DAVID COBDEN, Department of Physics, University of Washington — In many correlated materials, domain structure causes the bulk properties to differ from those on the sub-domain level. In addition, near first-order phase transitions it leads to transition broadening, hysteresis, and sample degradation. Studies of nanoscale crystals enable investigations of the domain-free homogeneous material. We demonstrate this by working with nanobeams of vanadium dioxide, thereby discovering or clarifying multiple aspects of its famous metal-insulator transition at 67°C. Amongst them are that the transition to the metal occurs at a constant value of the resistivity of the insulating phase; large supercooling of the homogeneous metallic phase is possible; and the activation energy in the insulating phase is consistent with the optical gap, in contrast with earlier reports on bulk samples. The nanobeams also enable new classes of experiments, including investigating a single metal-insulator interface wall, employing nanomechanical effects to determine the equilibrium transition temperature, and investigating the dynamics of a phase transition in quasi-one-dimensional geometry.

Infrared nano-imaging of metallic and insulating domains in single crystalline vanadium dioxide nanowires
ANDREW JONES, JIAW WEI, DAVID COBDEN, MARKUS RASCHKE, University of Washington — Correlated electron systems are often associated with heterogeneous electronic and structural phase transitions with ordering and domain formation on nanometer length scales. Vanadium Dioxide (VO$_2$) has long been a material of research focus due to behavior associated with its temperature induced metal-insulator transition (MIT) occurring around 340K. The underlying mechanism of this transition is thought to be the result of a complex interplay between the lattice and electronic degrees of freedom as the material passes through the MIT, whose origin is as of yet poorly understood. We study the nanometer scale formation of insulating and metallic domains of single crystal VO$_2$ nanowires bonded to silica substrate using infrared scattering-scanning near field optical microscopy (s-SNOM). Imaging contrast is obtained due to the distinct optical dielectric properties of the respective metallic and insulating phases. A hierarchy of domain sizes is observed, suggesting two distinct insulating phases in addition to the metallic phase as the material moves through the MIT.

Mapping the spatial scale of domain switching in heteroepitaxial vanadium dioxide thin films and nanoparticles
JOYEE NAG, RICHARD HAGLUND, Vanderbilt University — Vanadium dioxide is a strongly correlated electron system exhibiting a hysteresis semiconductor-to-metal transition around 67°C, accompanied by a structural change from monoclinic to tetragonal and huge changes in its electrical conductivity and near-infrared transmission. As interest grows in very thin films and nanoparticles of vanadium dioxide, the spatial scale and domain structure of the metal-insulator transition are critical issues. To elucidate these questions, thin films and nanoparticles of vanadium dioxide were grown on R-, C- and A-cut sapphire substrates, and the substrate-dependent epitaxial growth habits and in-and-out-of-plane orientations were characterized by near-infrared transmission, X-ray diffraction, scanning and transmission electron microscopy. Temperature variable XRD scans at intervals of one degree were performed from the onset to the completion of the transition hysteresis to map out the percentage of coexisting domains of monoclinic and tetragonal phases in one such 100nm thick epitaxial film.

Self-Limiting Growth of Magnetic Nanoparticles in a Glassy Matrix
SERGIO PICOZZI, MARK LAURENZI III, IAN PEGG, Department of Physics and Vitreous State Laboratory, The Catholic University of America, Washington, DC — Nanoparticles of magnetite can be grown by heat treatment of suitable glass compositions slightly above the glass transition temperature. We have investigated the transformation kinetics and magnetic properties, including the size dependence of the Verwey transition, in such systems. The initially rapid growth is quickly arrested leading to tight size distributions that become essentially independent of time. The mean size (a few nm) is dependent on the glass composition and temperature. In this paper, we investigate a simple model in which the self-limiting nature of this process is ascribed to the experimentally observed strong dependence of the glass transition temperature of the matrix on the concentration of one of the diffusing species, which in turn gives rise to a concentration-dependent diffusivity. In addition, the relationship between the equilibrium concentration of the diffusing species and the curvature of the particle-matrix interface (the Gibbs-Thomson effect) is shown to play a prominent role. The model reproduces the essential features of the transformation kinetics, predicting an initial power law growth that becomes nearly logarithmic at long times, and identifies the key physical parameters that determine the self-limited particle size.

Unusual electronic states in TiO$_2$/VO$_2$ (001) multilayers
VICTOR PARDO, WARREN PICKETT, University of California Davis, PARD0-PICKETT COLLABORATION — Abrupt interfaces between oxides display a wealth of unexpected behavior, and the interface between a band insulator and a Mott insulator is expected to display extra richness. Several multilayered TiO$_2$/VO$_2$ structures have been studied by ab initio density functional theory techniques, including the thin VO$_2$ regime corresponding to the quantum confined Mott insulator. VO$_2$ undergoes a metal-insulator transition near room temperature, but when deposited in thin films of thickness smaller than 5 nm, the metal-insulator transition disappears. Our calculations (using the correlated LDA+U method with modest values of U and J) show that the electronic character (metallic versus insulating) changes with the number of VO$_2$ layers embedded within insulating TiO$_2$ layers: metallic for five VO$_2$ layers, semimetallic and half-metallic for three layers, and insulating for a single VO$_2$ layer. These trends, and the peculiar nature of the three VO$_2$ layer case, will be discussed in some detail.
8:00AM H32.00001 Longitudinal spin fluctuations in itinerant ferromagnets, ANDREI RUBAN, Department of Materials Science and Engineering, Royal Institute of Technology, Stockholm — Finite-temperature properties of magnetic materials strongly depend on their magnetic configuration given by relative orientation of local magnetic moments. In itinerant ferromagnets, an additional degree of freedom becomes important: the value of local magnetic moment, which is sensitive to the magnetic state and the local chemical environment of atoms as well as the thermal electronic excitations of different type, leading to the so-called longitudinal spin fluctuations (LSF). LSF play an important role in itinerant magnetic systems at high temperatures. In particular, they are responsible for the existence of finite local magnetic moments on atoms in the paramagnetic state, which affect different physical properties. At the same time, an ab initio based description of the LSF is problematic. The LSF are ignored in the local density and related approximations of density functional theory, which for instance leads to a substantial underestimation or complete disappearance of the local magnetic moments on atoms in the itinerant ferromagnets in the corresponding calculations at high temperature in the paramagnetic state. Although the LSF can be included in more elaborate schemes, such as the dynamical mean-field theory, the application of such techniques to real systems is too cumbersome in most cases. In this work a generalized form of classical magnetic Hamiltonian is suggested, which includes both transverse and longitudinal spin fluctuations on equal footing. Parameters of the Hamiltonian can be determined in the first-principles calculations, within the local spin density approximation. The method is applied to the calculations of high-temperature magnetic properties of Co, Fe and Ni, including the Curie temperature. The effect of the LSF in the high-temperature paramagnetic state on chemical interactions and other physical properties is demonstrated for several alloys, including fcc Fe-Cr-Ni alloys, which is the basis of austenitic stainless steels.

8:36AM H32.00002 Spin excitations in solids from first principles, ARNO SCHINDLMAYR, Department Physik, Universitaet Paderborn, Germany, ERSOY SASIOGLU, MANFRED NIESERT, CHRISTOPF FRIEDRICH, STEFAN BLÜGEL, Forschungszentrum Juelich, Germany — The long-range order of the electron spins in magnetic solids gives rise to additional excitation modes that preserve the charge density but change the total spin of the electron system. While Stoner excitations, which correspond to spin-flip transitions between the majority and minority channels, can be described within a single-particle picture, spin waves are collective modes that result from the spin-dependent exchange interaction between the electrons. Here we discuss different approaches that we have explored for material-specific spin-wave calculations from first principles. All of these methods focus on the non-local and dynamic transverse spin susceptibility, whose spectral function can be directly related to experimental spectroscopies, but employ either time-dependent density-functional theory or many-body perturbation theory to treat exchange and correlation. In the latter case, maximally localized Wannier orbitals are used to efficiently obtain the electron-hole vertex of the multiple-scattering $T$ matrix, which is constructed with full frequency and wave-vector dependence. The implementation uses the full-polarized linearized augmented-plane-wave (FLAPW) method. For ferromagnetic transition metals like Fe, Co or Ni our results are in good agreement with experimental data and reproduce all important spectral features.

8:48AM H32.00003 Transverse spin susceptibility in Ni, Fe and Co, LIQIN KE, TAKAO KOTANI, MARK VAN SCHILFGAARDE, School of Materials, Arizona State University, Tempe, AZ, 85287-8706, VLADIMIR ANTROPOV, Ames Laboratory, Ames, IA, 50011, USA — We calculate the full transverse spin susceptibility $\chi^{\pm}(q,\omega)$ in the time-dependent local density approximation (TDLDA) for elemental Ni, Fe and Co. We extract the Heisenberg exchange constant from both the energy-dependent $\chi^\pm$ and the static one. The results are compared with those given by a method assuming the rigid rotation of the magnetic moments at each site (ref.kotani2008). We observe some differences between these two methods, especially around the Brillouin zone boundaries. We also calculate $\chi^{\pm}$ starting from the non-interacting Hamiltonian generated from the quasiparticle self-consistent GW (QSGW) approximation (ref.kotani2007). We analyze how the QSGW potential alter the LDA results.

9:00AM H32.00004 Ab-initio electronic structure calculations of periodic systems in the presence of arbitrary magnetic fields1, ALFREDO A. CORREA, EUNSEOK LEE, WEI CAI, Department of Mechanical Engineering, Stanford University, GIULIA GALLI, UC Davis — Ab-initio electronic structure calculations in the presence of magnetic fields have been mainly performed for isolated systems, or, in the case of periodic systems, by adopting perturbative approaches. Building on a recent formulation of electronic structure calculations in the presence of magnetic fields [1,2], we will discuss calculations for periodic systems under arbitrary conditions, which include arbitrary (finite) magnetic field, arbitrary periodic cell shapes, and arbitrary magnetic field spatial variations. Preliminary results based on a plane-wave numerical approach and local approximations to Density Functional Theory will be presented.[1] W.Cai, G.Galli, Phys. Rev. Lett. 92, 186402 (2004).[2] E. Lee, W. Cai, G. Galli, J. Comput. Phys. 226, 1310 (2007).

1The work is supported by the DOE/SciDAC project on Quantum Simulations of Materials and Nanostructures.

9:12AM H32.00005 Real space first-principles derived semiempirical pseudopotentials applied to tunneling magnetoresistance1, KIRK BEVAN, Oak Ridge National Laboratory, Materials Science and Technology Division, TONY LOW, Purdue University, Department of Electrical and Computer Engineering, HONG GUO, McGill University, Centre for the Physics of Materials and Department of Physics — We present a real space density functional theory (DFT) localized basis set semi-empirical pseudopotential (SEP) approach. The method is applied to iron and magnesium oxide, where bulk SEP and local spin density approximation (LSDA) band structure calculations are shown to agree within approximately 0.1 eV. Subsequently we investigate the qualitative transferability of bulk derived SEPs to Fe/MgO/Fe tunnel junctions. We find that the SEP method is particularly well suited to address the tight binding transferability problem because the transferability error at the interface can be characterized not only in orbital space (via the interface local density of states) but also in real space (via the system potential). To achieve a quantitative parameterization, we introduce the notion of ghost semi-empirical pseudopotentials extracted from the first-principles calculated Fe/MgO bonding interface. In general the results underscore the need for separate tight binding interface and bulk parameter sets when modeling conduction through thin heterojunctions on the nanoscale.

9:24AM H32.00006 Rational Design of Half-Metallic Alloys1, WILLIAM BUTLER, CLAUDIA MEWES, CHUN-SHENG LIU, MINT Center, University of Alabama, MAIRBEK CHSHIEV, Spintec — A half-metal is a material that is a metal for one spin-channel and an insulator or semiconductor in the other. Half-metals are potentially important for spintronic applications such as magnetic sensors for hard drives and magnetic random access memory. We show using very simple ideas that it is possible to rationally design a class of magnetic alloys by placing a gap at the center of one of the d-bands and placing the Fermi energy in this gap. We will present design rules that can be used to make an infinite number of half-metallic heterostructures. We will also show how the half-metallic feature may be maintained at surfaces and interfaces.

1Work Supported by NSF-DMR-0213985 and by the Information Storage Industry Consortium
9:36AM H32.00007 Density-functional theory study of the Co$_2$MnSi/MgO interface. BJÖRN HÜLSEN, Fritz-Haber-Institut der MPG, PETER KRATZER, University Duisburg-Essen, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG — Magnetic memory devices that exploit the tunneling magnetoresistance (TMR) effect depend crucially on the spin polarization of the electrode materials. Using ferromagnetic half-metals, such as the full Heusler alloy Co$_2$MnSi, perfect electrodes with 100% spin polarization could possibly be realized, at least at zero temperature. Here, we use density functional theory (DFT) calculations to model an epitaxially grown Co$_2$MnSi/MgO(001) interface in a prospective TMR device. The stability, the electronic and magnetic properties of different terminations of Co$_2$MnSi (stoichiometric Co- and MnSi- and non-stoichiometric Mn- and Si-planes) and different registry with respect to the insulating barrier (Mg-top, O-top, bridge and hollow site) are investigated. We find that the electronic and magnetic properties (including the existence of the spin gap) depend strongly on the termination. The formation energy of the various interfaces is presented in form of a phase diagram. Both the interface Co/O (Co at O top site) with a high spin polarization of $P = 70\%$, and the interface MnSi/O with only small $P$ form part of the thermodynamically accessible region. The MnMn/O interface preserves the half-metallicity of the bulk, but is found to be only metastable. Interface band structures are presented, and magnetic moments are compared to experimental data.

9:48AM H32.00008 Magneto-electric polarizability and axion electrodynamics in crystalline insulators. ANDREW ESSIN, JOEL MOORE, University of California, Berkeley, DAVID VANDERBILT, Rutgers University — Spin-orbit coupling can lead in two- and three-dimensional solids to time-reversal-invariant insulating phases that are “topological” in the same sense as the integer quantum Hall effect and similarly have protected edge or surface states. The three-dimensional topological insulator is known to have unusual magnetoelectric properties referred to as “axion electrodynamics”: it supports an electromagnetic coupling $\Delta E_{el} = (\theta e^2/2\hbar)c - B \cdot \nu$ with $\theta$ as the integer quantum of axial charge. An approach to $\theta$ in any three-dimensional crystal is developed based on the Berry-phase theory of polarization: $\theta e^2/2\hbar c$ is the bulk orbital magnetic polarizability (the polarization induced by an applied magnetic field). We compute the orbital magnetoelectric polarizability for a simple model and show that it predicts the fractional part of surface $\tau_{xy}$, computed using a slab geometry. Although $\theta$ is not quantized once time-reversal and inversion symmetries are broken, it remains a bulk quantity for the same reasons as ordinary polarization.

10:00AM H32.00009 ABSTRACT WITHDRAWN

10:12AM H32.00010 Flexomagnetic effect in Mn-based antiperovskites. RENAT SABIRIANOV, PAVEL LUKASHEV, University of Nebraska at Omaha — We report our theoretical results on the induced magnetization appearance in antiferromagnetic antiperovskites, such as Mn$_3$GaN, due to the gradient of applied external strain (flexomagnetic effect). We model the external flexure by forming a 40-atom Mn$_2$GaN$_2$ supercell with 4 domains under external strain gradient. This structure shows a net magnetization which increases parabolically up to 0.03$\mu_B$ (per Mn atom) in the (0,1,1) direction reflecting non-linear contribution to local piezomagnetic effect in the considered range of up to 0.005% external strain gradient. The calculated flexomagnetic effect is found to be relatively small with induced magnetic moment order of magnitude smaller than that of piezomagnetic contribution. The flexomagnetic effect can be especially important in the nanostructures, where the stress gradients are usually large due to the surface tension. All calculations were performed using the projector augmented wave method.

10:24AM H32.00011 Layered antiferromagnetism with high Neel temperature in the intermetallic compound Mn$_2$Au. SERGIY KHMELEVSKYI, PETER MOHN, Center for Computational Materials Science, Vienna University of Technology, CEMS TEAM — On the basis of earlier experimental studies the intermetallic compound Mn$_2$Au has been characterized as a non-magnetically ordered material. Here we report the results of first-principles calculations based on Local Spin-Density Approximation which describe Mn$_2$Au to have a narrow band antiferromagnetic ground state with rigid local moments on the Mn sites. Calculations of the inter-atomic exchange constants based on the magnetic force theorem and a Monte-Carlo modeling of the resulting Heisenberg-like Hamiltonian predict a very high Neel-temperature of $\sim$1580K. This temperature is considerably higher than for the other known high temperature antiferromagnetic Li$_2$-type Mn based binary alloys, which are widely used in magnetic storage applications. In particular, the source of the difficulties in determining magnetic order from the earlier experiments is discussed. The observed meta-magnetic like behavior and a susceptibility anomaly at low temperatures are linked to the frustrated magnetism on Mn anti-site impurities. We believe that the high temperature antiferromagnetism of Mn$_2$Au may have quite an impact in technology. In particular, it can be considered as a candidate for the application as a “pinning” layer in GMR devices.

10:36AM H32.00012 3d impurities in wide gap oxides—magnetism and carrier doping. HANNAE RAEBIGER, NREL, Golden, CO and Yokohama National University, Yokohama, JAPAN., STEPHAN LANY, ALEX ZUNGER, NREL, Golden, CO — 3d transition metal impurities in wide-gap oxides exist in multiple charged configurations[1], and may function as (i) donor/acceptor defects to modify carrier concentrations, (ii) magnetic elements to induce collective magnetism, and (iii) shift the host band edges. While previous investigations have addressed some of these phenomenologies separately, we link them together, and present the chemical trends for electronic properties, carrier doping, and magnetism along the series of 3d...3d8 impurities in the paradigmatic wide-gap oxide hosts ZnO and In2O3. For these general trends we find that, in In2O3 most 3d impurities are amphoteric and exhibit deep transitions, whereas in ZnO the early 3d impurities (Sc-V) have shallow donor transitions, and only the late 3d’s (Co, Ni, Cu) have acceptor transitions inside the band gap. Ferromagnetic interactions emerge upon the partial filling of 3d levels resonant inside the conduction band, an in general require electron doping from additional sources. [1] H. Raebiger, S. Lany, and A. Zunger, Nature 455, 783 (2008).

10:48AM H32.00013 Multifarious magnetism in copper oxide nanostructures from first-principles. X.-Y. CUI, A. SOON, University of Sydney, B. DELLEY, Paul Scherrer Institute, S.-H. WEI, National Renewable Energy Laboratory, C. STAMPFL, University of Sydney — Driven by the ever-increasing demand for novel spin-dependent advanced materials, investigation of nanoscale magnetic properties is currently actively pursued. With the latest developments focusing more on magnetic semiconducting oxides, materials based on cuprous oxide, Cu$_2$O, are of high interest as potential p-type semiconducting candidates. Thus developing an understanding of how intrinsic defects influence both its electronic and magnetic properties is important. We perform density-functional theory calculations to analyze both the electronic and magnetic properties of native defects in both bulk Cu$_2$O and its surfaces, as well as their respective formation/surface energies under different growth conditions. We find that under oxygen-lean conditions, the experimentally observed ferromagnetic behaviour [2] could originate from copper vacancies on Cu$_2$O(111) while under oxygen-rich conditions, low energy bulk oxygen interstitials might explain the ferromagnetic moment found in the same material. This suggests that the origin of observed magnetism in sub-stoichiometric copper oxide nanoparticles could be multifarious, highlighting the complimentary role of bulk and surface native magnetic defects.

8:00AM H33.00001 Observation of the Josephson effect in Pb/Ba$_{1-x}$K$_x$Fe$_2$As$_2$ single crystal junctions, XIAOHANG ZHANG, RICHARD GREENE, ICHIRO TAKEUCHI, University of Maryland, College Park, YOON SEOK OH, YONG LIU, LIQIN YAN, KEE HOON KIM, Seoul National University — We have fabricated Josephson junctions using single crystals of Ba$_{1-x}$K$_x$Fe$_2$As$_2$ and Pb (or Pbln) as the counter electrode in two geometries. The c-plane single crystals of Ba$_{1-x}$K$_x$Fe$_2$As$_2$ were synthesized by the Sn-flux method with the nominal composition of $x = 0.4$. In one junction geometry, Ag (30 nm) and Pbln (200 nm) were evaporated on the surface of the crystals. In the other geometry, a Pb point contact was used. Both geometry junctions show resistively shunted junction $I-V$ curves below the $T_c$ of the counter electrode. Microwave induced steps were observed in the $I-V$ curves, and the critical currents are completely suppressible with applied magnetic field in a manner consistent with a small junction limit. $IcR_N$ products of up to 0.3 mV have been observed in these junctions at 4.2 K. The observation of Josephson coupling along the c-axis between an iron pnictide superconductor and a conventional superconductor suggests the existence of a non-d-wave superconducting order parameter in iron pnictide superconductors.

8:12AM H33.00002 ABSTRACT WITHDRAWN

8:24AM H33.00003 Multigap superconductivity in pnictides, PETER SAMUELY, PAVOL SZABO, ZUZANA PRIBULOVÁ, GABRIEL PRISTAS, Centre of Low Temperature Physics Kosice, PAUL CANFIELD, SERGEY BUD’KO, Ames laboratory, INSTITUTE OF EXPERIMENTAL PHYSICS, SLOVAK ACADEMY OF SCIENCES, 04001 KOSICE, SLOVAKIA TEAM, AMES LABORATORY AND IOWA STATE UNIVERSITY, AMES, IA 50011, USA TEAM — Point-contact Andreev reflection studies of the superconducting energy gap on the NdFeAsO$_x$(Ba,K)$_2$Fe$_2$As$_2$ and BaFe$_2$(Co$_{1-x}$V$_x$)$_2$As$_2$ crystals will be presented. The analysis of the data points to a two-gap superconductivity in these materials. Possible existence of the pseudogap in the non-superconducting density of states related to the static or dynamic magnetic order will be discussed as well.

8:36AM H33.00004 Coexistence of two order parameters and a pseudogap in the iron-based superconductors, RENATO GONNELLI, Dipartimento di Fisica and CNISM, Politecnico di Torino, Italy — The number, the symmetry and the amplitude of the order parameters (OPs) in the Fe-As superconductors are still open issues, as well as the origin of the electron pairing. To address these issues, we performed point-contact Andreev-reflection measurements in SmFeAsO$_x$F$_{2-x}$ ($T^{\text{crit}} = 53$ K) and LaFeAsO$_x$F$_{0.1}$ ($T^{\text{crit}} = 27$ K) polycrystals. In both cases, the low-temperature conductance curves clearly indicate the presence of two OPs in the superconducting state. No zero-bias peaks were observed, which — considering the non-directional current injection — clearly rules out the d-wave symmetry. If a superconducting character is supposed for both the OPs, their amplitudes can be extracted from a generalized two-band BTK fit (with two s-wave gaps, as in MgB$_2$) of the normalized conductance curves. The fit is indeed very good and gives OP amplitudes, $\Delta_1$ and $\Delta_2$, that lie slightly below and well above the BCS value, respectively. In Sm-1111, their low-temperature values are $\Delta_1(0) = 6.15 \pm 0.50$ meV and $\Delta_2(0) = 18 \pm 3$ meV, which give gap ratios (2$\Delta/K_BT_c$) of about 2.7 and 8.0. Both $\Delta_1$ and $\Delta_2$ show a BCS-like temperature dependence and close at the bulk $T_c$. In La-1111 we obtained point contacts with different local $T_c$s (from 27.3 to 31.0 K) in crystallites with slightly different doping. Here $\Delta_1$ shows a non-BCS temperature dependence with a high-temperature “tail,” while $\Delta_2$ seems to close at $T < T_c$. While the low-temperature gap $\Delta_1(0)$ increases on increasing $T_c$ (remaining always around the BCS value), $\Delta_2(0)$ decreases and finally disappears when $T_c = 31$ K, reminding the case of cuprates. At $T_c$, the normal-state conductance is asymmetric and shows features at zero bias (a depression or pseudogap in La-1111, a hump in Sm-1111) that however are also present in the superconducting state and are progressively washed out on increasing temperature, to finally disappear at $T_c \approx 140$ K, close to the Néel temperature of the parent compound.

9:12AM H33.00005 Point-contact Andreev reflection tunneling spectroscopic (PCARTS) study on Ba$_{1-x}$K$_x$Fe$_2$As$_2$ and Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$, XIN LU, W. K. PARK, L. H. GREENE, Physics and FSMLR, UIUC, H. Q. YUAN, Zhejiang University, China, G. F. CHEN, G. L. LUO, N. L. WANG, Institute of Physics, CAS, Beijing, A. SEFAT, M. A. MCGUIRE, R. JIN, B. C. SALES, D. MANDRUS, MSTD, Oak Ridge National Lab. — PCARTS is applied to investigate the gap structure in the newly-discovered iron pnictide superconductors Ba$_{1-x}$K$_x$Fe$_2$As$_2$ and Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$. Double peaks due to Andreev reflection with strongly-sloping background are frequently observed in the conductance curves G (V) on the Au-Ba$_{1-x}$K$_x$Fe$_2$As$_2$ point-contact junctions on the freshly-cleaved surface along the c-axis. If normalized by the background baseline and analyzed by Blonder-Tinkham-Klapwijk model, the data show a gap size $\sim 4$ meV with $2\Delta/K_BT_c \sim 2.6$. However, it is observed that, for the Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$, G (V) curves evolve from V-shape to zero-bias conductance peak with increasing tip pressure, where the tip is likely to penetrate through surface layer. The existence of surface oxide layer is confirmed by comparative XPS characterization on freshly-cleaned and uncleaned surfaces.

9:24AM H33.00006 ABSTRACT WITHDRAWN

9:36AM H33.00007 Probing the Spin-Density-Wave Transition in SmOFeAs using Point-Contact Spectroscopy, T. Y. CHEN, S.X. HUANG, JHU, R. H. LIU, X. H. CHEN, USTC, C. L. CHEN, JHU, JOHNS HOPKINS UNIVERSITY COLLABORATION, UNIVERSITY OF SCIENCE AND TECHNOLOGY OF CHINA COLLABORATION — In spring 2008, a new family of superconductors with the general composition of SmFeAs(O$_{1-x}$F$_x$) has been discovered. The metallic parent compound SmFeAsF has a spin-density-wave (SDW) transition near 150 K with hysteretic temperature dependence in magnetic structure, crystalline structure, and resistance. Doping the parent compound with fluorine results in the suppression of the SDW transition and the emergence of superconductivity with transition temperatures up to 55 K. Some theories suggest that the SDW transition may be intimately related to the superconductivity. In this work, we use point-contact spectroscopy to investigate the SDW transition in the parent SmOFeAs compound. Instead of varying temperature, under a high bias voltage a small region underneath a point contact can be heated up through the SDW transition, resulting in differential conductance peaks. Similar to the temperature dependence of the resistance and structure, the SDW transition is hysteretic with bias voltage at the transition. We further show that this feature in differential conductance, which may be easily mistaken as a pseudo gap of a superconductor, is actually a characteristic of the ballistic heating effect.
Recent discovery of superconductivity in the iron based LaFeAsO\textsubscript{1-x}F\textsubscript{x} stimulation great interests as a new class of non-cuprate compound. We calculate the surface density of state of LaFeAsO\textsubscript{1-x}F\textsubscript{x} superconductor. The gap function is obtained microscopically by solving the Eliashberg equation in a 5-band Hubbard model with the random phase approximation (RPA). Green’s function of the surface state is obtained by inserting infinite potential barriers using Matsumoto and Shiba method. Although the gap function has a sign change between Fermi surfaces, we cannot find mid gap Andreev bound state in [100] and [110]-oriented interface.

Novel properties in Josephson junctions involving \( s_{\pi/2} \)-pairing state in Iron-Pnictides. WEI-FENG TSAI, DAO-XIN YAO, JIANGPING HU, Purdue University, B. ANDREI BERNEVIG, Princeton University — We present theoretical results of Andreev bound states in superconductor-normal metal (or insulator)-iron-pnictide junctions. Within the two-orbital exchange coupling model [1], the presence of non-trivial in-gap states, which uniquely appear in the theoretical results of Andreev bound states in superconductor-normal metal (or insulator)-iron-pnictide junctions. Within the two-orbital exchange coupling model [1], the presence of non-trivial in-gap states, which uniquely appear in the s-wave \( \cos k_x \cos k_y \) (\( s_{\pi/2} \)) pairing state, can be taken as a sharply distinct feature in contrast to other singlet pairing states. In addition, a proposed novel trilayer \( \pi \)-junction involving \( s_{\pi/2} \) superconductivity is also discussed as a new possible signature of such unconventional pairing symmetry.

Possible phase-sensitive test of pairing symmetry in superconducting pnictides, DAVID PARKER, IGOR MAZIN, U.S. Naval Research Laboratory — The discovery of the new class of pnictide superconductors has engendered a controversy about their pairing symmetry, with proposals ranging from an extended \( s \)-wave or “\( s_{\pi} \)” symmetry to nodal or nodeless d-wave symmetry to still more exotic order parameters such as p-wave. Although there is evidence that a fully gapped state may exist in the pnictides, the symmetry of this state remains indeterminate. Building on the earlier, similar work performed for the cuprates, we propose here a phase-sensitive Josephson interferometry experiment that may allow resolution of the issue, taking into consideration novel features such as the local orbital character (from DFT calculations), and employing a particular potential barrier to restrict the tunneling orientations to favorable directions.

Andreev Bound states as a phase sensitive probe of the pairing symmetry of the FeAs superconductors, POUYAN GAHEMI, UC Berkeley, FA WANG, ASHVIN VISHWANATH, UC Berkeley & LBNL — A leading contender for the pairing symmetry in the Fe-As-pnictide high temperature superconductors is extended \( s \)-wave \( s_{\pi} \), a nodeless state in which the pairing changes sign between Fermi surfaces. Verifying such a pairing symmetry requires a special probe that is sensitive to both phase and magnitude of the order parameter. We show that the sign structure of \( s_{\pi} \) pairing leads to Andreev bound states at the edge. In the clean limit they only occur when the edge is along the Fe-Fe bond, but not for a diagonal edge. In contrast to d-wave Andreev bound states, they are not at zero energy and, in general, do not produce a zero bias tunneling peak. Consequences for tunneling measurements are derived, within a simplified two band model and also for a more realistic five band model.

Examining SrFe\textsubscript{2}As\textsubscript{2} with a Low Temperature Scanning Tunneling Microscope, FRANCIS NIESTEMSKI, Boston College Dept. of Physics, J. GILLET , SUCHITRA SÉBASTIAN, Cavendish Laboratory, University of Cambridge, VIDYA MADHAVAN, Boston College Dept. of Physics — The new pnictide superconductors have generated huge excitement. These materials are the first to add some chemical diversity to the limited high-Tc list previously exclusive to cuprates. We examine the pnictide material parent compound SrFe\textsubscript{2}As\textsubscript{2} with a low-temperature ultra-high vacuum scanning tunneling microscope (STM) at 4 K. We find multiple types of topography and spectroscopy with low energy features. We relate our data to results from ARPES and other experiments.

Electronic Structure on (001) Surface of Co-doped BaFe\textsubscript{2}As\textsubscript{2} Studied with Scanning Tunneling Spectroscopy\(^1\). A. LI, D. R. JAYASUNDARA, Y. XIUAN, J. P. O’NEAL, Y. CHEN, W. KIM, C. S. TING, S. H. PAN, University of Houston, Houston, Texas 77204-5002, R. JIN, E. W. PLUMMMER, Louisiana State University, Baton Rouge, LA 70803-4001, R. JIN, A. S. SEFAT, M. A. MCGUIRE, B. C. SALES, D. MANDRUS, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Co-doping makes the pnictide compound BaFe\textsubscript{2}As\textsubscript{2} superconducting. We cleave the single crystals of this compound in UHV and study their surfaces with a low temperature STM. In this talk, we present the scanning tunneling spectrum obtained on the (001) surface of the optimally doped BaFe\textsubscript{2}As\textsubscript{2} single crystals (Tc = 23K) and compare these spectra with the ones obtained on the surface of the parent compound. We have found that the major feature of the spectra on the superconducting compounds is the opening of a superconducting gap of about 6 meV for the optimally doped one. We have also observed other detailed spectrum features. We will discuss the relation between spectrum features and the local environment and also present some theoretical fit to the superconducting energy gap spectrum.

Tuesday, March 17, 2009 8:00AM - 11:00AM – Session H34 DCMP: Superconductivity: Transport Properties 404

8:00AM H34.00001 Resistivity and superfluid density measurements on under- and over-doped La\textsubscript{2-x}Sr\textsubscript{x}CuO\textsubscript{4} films. THOMAS LEMBERGER, IULIAN HETEL, The Ohio State University, A. TSUKADA, MICHIO NAITO, Tokyo University of Agriculture and Technology — We have measured the resistivities and superfluid densities (or, penetration depths, \( \lambda \)) of a series of LSCO films with a wide range of Sr concentrations. Films are grown by MBE on LaSrAlO\textsubscript{4} substrates under nominally identical conditions. Due to substrate mismatch, films are under compression, Resistivities decrease smoothly as Sr concentration increases, and resistive transitions are sharp. Tc has a maximum at \( x \approx 0.18 \). Interesting features in the T-dependence of \( 1/\lambda^2 \) will be discussed. Absolute values of resistivity and superfluid density in these films indicates quality comparable to bulk materials. Falloff of superfluid density with overdoping, together with a smooth decrease in resistivity, is consistent with an interpretation in terms of a mesoscopically inhomogeneous superconducting state.
8:12AM H34.00002 Strong Reduction of Tc, Suppression by Magnetic Field in YBa2Cu3O7−x Films with Dispersed Nanoparticles, E. Cimpoiasu, J. D. Feldmann, U. S. Naval Academy, C. V. Varanasi, T. J. Haugan, P. N. Barnes, G. A. Levin, Air Force Research Laboratory — Improvements in the critical current density Jc in applied magnetic fields are of great importance for applications of the YBa2Cu3O7−x coated conductors. Nanopulse inclusions have shown to be effective in increasing Jc, but the precise physical mechanisms of their action are elusive. A broader range of experiments is needed in order to elucidate the physics of this phenomenon. Here we discuss the magnetic field H- and temperature T-dependence of the resistivity of thin films in the normal state and near Tc. Pure YBCO films will be compared with those that contain either dispersed Y2O3/nanoparticles or Ba5Sn2O10 nanorods. The resistance of highly c-axis oriented YBCO films was measured by the Montgomery method in the range 20 K < T < 300 K and in fields up to 9 T. The films with inclusions show a much sharper and less broadened in-field transition (smaller Tc suppression by field) than pure YBCO. This correlates well with increased Jc measured by conventional methods and indicates increased pinning strength at all temperatures. In order to further identify the signatures of the nano-inclusions, the samples were annealed in air at 420 deg C. The changes induced by the annealing will be discussed. This work was partially supported by AFOSR and the AFRL Propulsion Directorate.

8:24AM H34.00003 Quantum Oscillations and Hall Resistivity in YBCO and Tl-2201: Exploring the Fermi Surface of the Cuprates, Brad Ramshaw, Univ British Columbia — The field of high temperature superconductivity has enjoyed something of a Renaissance in the past two years with the discovery of quantum oscillations in Shubnikov de Haas and de Haas-van Alphen measurements preformed on YBCO and Tl-2201. DC transport measurements around the one eighth hole doping region of high Tc phase diagram have shown a temperature and doping dependence to the Hall coefficient. In this doping region the Hall coefficient changes sign from positive to negative as temperature goes to zero, indicating a competition of mobilities between holes and electrons. In high magnetic fields these measurements also exhibit oscillations in one over the field strength, indicating the existence of small pockets of Fermi surface. This information, coupled with the Hall data, gives rise to the interpretation that the large hole like Fermi surface found in the overdoped region on Tl-2201 reconstructs into smaller electron like Fermi pockets on the underdoped side. Combined with other theoretical and experimental techniques, these experiments are allowing us to develop an understanding of the electronic structure of the cuprates across the entire phase diagram. This understanding is crucial to uncovering the underlying mechanism that gives rise to high temperature superconductivity.

8:36AM H34.00004 Longitudinal and Transverse Transport properties of disordered graphene, Vincent Ugarte, Vivek All, Department of Physics and Astronomy, University of California-Riverside, California 92521, USA — We present results of calculations of the properties of thermal and electrical transport coefficients of disordered graphene in a weak magnetic field. In particular, we are interested in the vanishing of density of states and units and scattering on transport coefficients near the Dirac point. The effect of impurity states is included within a self-consistent t-matrix approximation. We find a peak in both the Nernst coefficient and thermopower around the chemical potential which grows as one approaches the Dirac point. Our experiments are a rich source of data to test the theories and models that have been developed to describe transport through disordered graphene.

8:48AM H34.00005 Linear-T resistivity and change in Fermi surface at the pseudogap critical point of a high-Tc, superconductor, Ramzy Daou, Nicolas Doiron-LeRaud, David Leboeuf, Shiyang Li, Francis Laliberte, Olivier Lour-Choineire, Universite de Sherbrooke, J.Y. Jo, Luis Balicas, NHMFL Tallahassee, J.-Y. Qian, J.-S. Zhou, John Goodenough, Texas Materials Institute, Universite de Sherbrooke and Canadian Institute for Advanced Research — A fundamental question of high-temperature superconductors is the nature of the pseudogap phase which lies between the Mott insulator at zero doping and the Fermi liquid at high doping. Here we report on the behaviour of charge carriers near the zero-temperature onset of that phase, namely at the critical doping p* where the pseudogap temperature Tg goes to zero, accessed by investigating a material in which superconductivity can be fully suppressed by a steady magnetic field. Just below p*, the normal-state resistivity and Hall coefficient of La2−xNd2−xSrxCuO4 are found to rise simultaneously as the temperature drops below Tg, revealing a change in the Fermi surface with a large associated drop in conductivity. At p*, the resistivity shows a linear temperature dependence as T → 0, a typical signature of a quantum critical point. These findings impose new constraints on the mechanisms responsible for inelastic scattering and Fermi-surface transformation in theories of the pseudogap phase.

9:00AM H34.00006 Transport Properties in Electron-Doped La2−xCexCuO4 Thin Films, Kui Jia, Xiaohang Zhang, Paul Bach, Richard Greene, University of Maryland, College Park — The electron-doped high-Tc cuprate La2−xCexCuO4 (LCCO) is quite different from other members, such as Pr2−xCe3−xO7, CeO2, and BaSrCuO3. One distinct difference is that the optimal Ce doping in LCCO is ~0.10, compared to ~0.15 in PCCO and NCBO. Here, we will present a detailed and systematic study of the magnetic field and temperature dependence of the transport properties of LCCO, including the low-temperature Hall effect and in-plane angular magnetoresistance.

9:12AM H34.00007 Evidence for individual quantum phase-slip events in homogeneous superconducting nanowires, Mitrabanu Sahai, Myung-Ho Bae, University of Illinois at Urbana-Champaign, Andreuy Rogachev, University of Utah, David Pekker, Harvard University, Nayana Shah, University of Illinois at Urbana-Champaign, Tzu-Chieh Wei, University of Waterloo, Paul Goldbart, Aleksey Bezryadin, University of Illinois at Urbana-Champaign — We report strong evidence for individual quantum tunneling events undergone by the superconducting order-parameter field in homogeneous Mo2Te2Sb nanowires. We obtain this via measurements of the distribution of switching currents, whose width exhibits a rather counter-intuitive, monotonic increase with decreasing temperature. We outline a stochastic model of phase-slip kinetics, which relates the basic phase-slip rates to switching rates. Comparison with this model indicates that the phase predominantly slips via thermal activation at high temperatures, but at sufficiently low temperatures switching is caused by individual topological tunneling events of the order-parameter field, i.e., quantum phase slips (QPS). Importantly, measurements on several wires show that quantum fluctuations tend to dominate over thermal fluctuations at larger temperatures in wires having larger critical currents. This fact supports the view that the anomalously high switching-rates observed at low temperatures are indeed due to QPS, and are not consequences of extraneous noise or inhomogeneity of the wire.

9:24AM H34.00008 Collapse of peak effect by alternating current and its frequency dependence in MgCNi3 single crystal, Dong-Jin Jang, Department of Physics, Pohang University of Science and Technology, Pohang, 790-784, Republic of Korea, Hyun-Sook Lee, Department of Physics, Pohang University of Science and Technology, Pohang, 790-784, Republic of Korea, H-G Lee, National Creative Research Initiative Center for Superconductivity and Department of Physics, Sogang University, Seoul 121-742, Republic of Korea — The peak effect, which appears as sharp rise in critical current near superconductor-normal transition of a superconductor, is first order phase transition. However, if vortices happen to move across sample by direct current (DC), sharp transition nature becomes blunted by edge contamination as intensively studied in NbSe2. This edge contamination has been shown to be removed by alternating current (AC) or by using edgeless Corbino geometry. Among few superconducting materials showing peak effect, MgCNi3 exhibits fairly sharp peak effect even in DC strip geometry. And remarkably, critical current measured by using AC is greatly suppressed as frequency of AC increases.
9:36AM H34.00009 Analytical Procedure for Measuring Electrical Resistivity of Anisotropic Materials, C.A.M. DOS SANTOS, B.S. DE LIMA, C.Y. SHIGUE, Escola de Engenharia de Lorena - USP, Lorena-SP, Brazil, A. DE CAMPOS, M.S. DA LUZ, A.T. RICE, B.D. WHITE, J.J. NEUMEIER, Department of Physics - MSU, Bozeman-MT, USA — The Montgomery method is used to determine the resistivity tensor of anisotropic materials [1] such as high-T_c and FeAs superconductors, 2-layer Mn oxides, organic conductors, and quasi-1D conductors. It uses the Wasscher transformation [2], which calculates an isotropic equivalent sample of the anisotropic sample. This is a timing-consuming task because it is a numerical method based upon graphical analyses obtained from calculations by Logan, Rice, and Wick [3]. In this work we report a simplification of the Montgomery method. Analytical equations are derived and applied to several isotropic and anisotropic samples (Cu, Al, Bi_{2}Sr_{2}CaCu_{2}O_{8+d}, Graphite, SnN_{2}O_{5}, \gamma-Mo_{2}O_{3}). Comparisons with results obtained using the standard four-probe method demonstrate the quality and simplicity of the procedure, which can easily be extended to data acquisition systems. This material is based upon work supported by FAPESP (grant No. 07-04572-8), NSF (grants Nos. DMR-0504769 and 0552458), and CNPq (grant Nos. 301334/2007-2 and 201439/2007-7). [1] H. C. Montgomery, J. Appl. Phys. 42, 2971 (1971). [2] J. D. Wasscher, Philips Res. Repts. 16, 301 (1961). [3] B. F. Logan, S. O. Rice, and R. F. Wick, J. Appl. Phys. 42, 2975 (1971).

9:48AM H34.00010 Doping dependence of the dynamic and static critical exponents in Pr_{2-x}Ce_{x}CoO_{4}, M.C. SULLIVAN, R. ISAACS, J.B. OLSON, J. SOUSA, M. SALVAGGIO, Department of Physics, Ithaca College, Ithaca NY, R.L. GREENE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park — Scaling analysis of voltage vs. current isothersms is a favorite tool to study the normal-superconducting phase transition in cuprate superconductors. This measurement has never been performed on the electron-doped cuprate superconductor Pr_{2-x}Ce_{x}CoO_{4}, due in part to difficulties which result from finite-thickness effects, even in thick (d \approx 3000\AA) films [2]. If finite-thickness effects are taken into consideration, we can find the critical isotherm and the dynamic critical exponent, and we can use small magnetic fields to find the static critical exponent. Similar measurements have been made on the more familiar hole-doped cuprates such as YBa_{2}Cu_{3}O_{7} [3]. We present our results of the dynamic critical scaling exponent z and static critical exponent \nu in our Pr_{2-x}Ce_{x}CoO_{4} films as a function of doping.

10:00AM H34.00011 Experimental study of superconductivity in single crystal few-layer NbSe_{2} and the effect of high electric fields, NEAL STALEY, Pennsylvania State University, LIJUN LI, ZHUAN XU, Zhejiang University, China — We report many studies on superconducting properties in two dimensional films. However, a detailed study of superconducting properties in the two-dimensional limit when crystallinity is still retained, which will allow the probing of band dependent superconductivity in 2D, has not been performed. Due to concerns over defects in ultra thin films deposited in the usual methods, we use the methods developed in preparing micromechanically exfoliated graphene devices. In these samples the band structure is present while maintaining extremely low defect density. Inspired by this simple process that created single crystal single sheet graphene we fabricated ultra thin single crystalline NbSe_{2} flakes ranging from single to many sheets as estimated using an optical technique correlated to AFM and Raman spectroscopy measurements. Transport and planar tunnel junction devices were fabricated using standard ebeam lithography techniques. We will also study the behavior of of these devices in high electric fields.

10:12AM H34.00012 Size effects in the nonlinear resistance in a virtual Berezinskii-Kosterlitz-Thouless state of superconducting films, ALEX GUREVICH, National High Magnetic Field Laboratory, VALERII VINOKUR, Argonne National Laboratory — We show that the size effects strongly affect the nonlinear electric field-current (E, A) relation of superconducting films. We calculate E(J) due to thermally-activated hopping of single vortices driven by current J across the film in a magnetic field H, taking into account interaction of free vortices with their antivortex images and peaks in the Meissner currents at the film edges. Unbinding of virtual vortex-antivortex pairs not only mimics the transport uniform BKT behavior, it can dominate the observed E(J) and result in the field-dependent ohmic resistance at small J. We show that E(J) can be tuned by changing the film geometry and propose experimental tests of this theory.

10:24AM H34.00013 Geometric Effects on the Tunneling Apparent Barrier Height, ARAN GARCIA-LEKUE, THOMAS FREDERIKSEN, DIPC, Donostia International Physics Center, ANDRES ARNAU, Centro de Fisica de Material — An experimental quantity which may help understanding the mechanism of electron tunneling, in STM experiments or across broken nanojunctions for example, is the apparent barrier height. In order to extract information from this experimental observable one can consider a simple one-dimensional tunneling model, where the apparent barrier height is the rate of change of the logarithm of the conductance with the tip-apex separation or vacuum gap. Theoretically, a faithful analysis of the apparent barrier height requires a precise description of the tunneling conductance in the vacuum region. However, most of the conductance calculations are performed using atom centered localized basis sets, which cannot adequately describe the tunneling current crossing the vacuum gap and can therefore lead to erroneous results. In this work, we present tunneling conductance calculations obtained using the transport calculation method introduced in Ref. [1]. Since this method employs a plane-wave basis set, it provides accurate results for the electron tunneling across the vacuum gap and, consequently, for the apparent barrier height. Here, we report results for broken Au nanojunctions with different geometries, which allows us to thoroughly investigate geometric effects on the apparent barrier height. 1. A. Garcia-Lekue and L.W. Wang, Phys. Rev. B 74, 245404 (2006).

10:36AM H34.00014 Thermopower across the pseudogap critical point of La(1.6-x)Nd(0.4)Sr(x)CuO(4): Evidence for a quantum critical point in a hole-doped high-Tc superconductor, OLIVIER CYR-CHIOINERE, RMZI DAOU, FRANCIS LALIBERTÉ, DAVID LEBEUFF, NICOLAS DOIRON-LEYRAUD, Université de Sherbrooke, JIAQIANG YAN, JIANSHI ZHOU, JOHN B. GOODENOUGH, Texas Material Institute, U of Texas at Austin, LOUIS TAILLEFER, Universite de Sherbrooke — The thermopower S of the high-Tc superconductor La(1.6-x)Nd(0.4)Sr(x)CuO(4) was measured as a function of temperature T near its pseudogap critical point, the critical hole doping p^* where the pseudogap temperature T^* goes to zero. Just above p^*, S/T varies as ln(1/T) over a decade of temperature. Below p^*, S/T undergoes a large increase below T^*. As with the temperature dependence of the resistivity, which is linear just above p^* and undergoes a large upturn below T^*, these are typical signatures of a quantum phase transition. This suggests that p^* is a quantum critical point below which some order sets in, causing a reconstruction of the Fermi surface, whose fluctuations are presumably responsible for the linear-T resistivity and logarithmic thermopower. We discuss the possibility that this order is the "stripe" order known to exist in this material.

10:48AM H34.00015 Low-Temperature Thermal Conductivity in a d-Wave Superconductor with Coexisting Checkerboard Charge Order, PHILIP SCHIFF, ADAM DURST, Stony Brook University — Given the experimental evidence of charge order in the underdoped cuprate superconductors, we consider the effect of coexisting checkerboard charge order on low-temperature thermal transport in a d-wave superconductor. We compute the quasiparticle excitation spectrum in the presence of both order parameters and perform a diagrammatic Kubo formula calculation of the zero-temperature thermal conductivity tensor as a function of the magnitude and wave vector of the charge order. Results depend on disorder, indicating that, in the presence of charge order, zero-temperature thermal transport is no longer universal.
8:00AM H35.00001 Effects of Magnetic Order and Pairing on the Fermi Surface of the Pnictides¹ . A. MOREO, M. DAGHOFER, R. YU, Oak Ridge National Lab, University of Tennessee, J. A. RIERA, Universidad Nacional de Rosario, Argentina, E. R. DAGOTTO, Oak Ridge National Lab, University of Tennessee — Based on numerical and mean-field calculations performed on models for the FeAs planes of the newly discovered Fe-based superconductors, we present results for the expected shape of the Fermi surface both in the undoped and the doped regime. In the undoped case, numerical studies, Lanczos and VCA, are performed for a two-orbital model, while a mean-field formalism allows us to study a more realistic 4 orbital case. A pocket structure is obtained for the intermediate Hubbard coupling regime of parameters in which the system is magnetically ordered but still metallic.[1] We construct a mean-field model for light electronic doping based on the pairing operator that is found by the unbiased Lanczos calculations in the two orbital model, i.e. a spin singlet, orbital even, operator transforming according to the $B_{2g}$ representation of the group $D_{4h}$. [2] We present the resulting nodal structure [3] and discuss comparisons with ARPES results.

8:12AM H35.00002 Nematic spin order and spin-lattice coupling in Fe-based Superconductors , JIANGPING HU, CHEN FANG, WEI-FENG TSAI, Purdue University, HONG YAO, STEVE KIVELSON, Stanford University — We show that the structure transitions observed in Fe-based superconductors are magnetically driven. A quantum Heisenberg model ($J_{1} - J_{2} - J_{3}$) exhibits a sequence of two phase transitions: from a high temperature symmetric phase to a narrow region of intermediate “nematic” phase, and then to a low temperature spin ordered phase when $J_{2}$ is small. Identifying phases by their broken symmetries, these phases correspond precisely to the sequence of structural (tetragonal to monoclinic) and magnetic transitions that have been recently revealed in neutron scattering studies of 1111 series of Fe-based superconductors. The structural transition can thus be identified with the existence of incipient (“fluctuating”) magnetic order. We also discuss the effect of spin-lattice coupling on the phase diagram of the model.

8:24AM H35.00003 Modeling of Fe pnictides: the Magnetic Order and Pairing Channels¹ . M. DAGHOFER, A. MOREO, Oak Ridge National Lab, University of Tennessee, J. A. RIERA, Universidad Nacional de Rosario, Argentina, E. ARRIGONI, TU Graz, Austria, D. J. SCALAPINO, University of California, Santa Barbara, E. R. DAGOTTO, Oak Ridge National Lab, University of Tennessee — We use numerical methods - exact diagonalization and the variational cluster approach - to study a two-orbital model for Fe-pnictide superconductors, including onsite Coulomb interaction $U$ and Hund’s rule coupling $J$.[1] Robust next-nearest neighbor hoppings stabilize the spin “striped” AF order for undoped clusters, in agreement with neutron scattering data. The ordered magnetic moment depends on $U$ and $J$, and we find a bad metal with small ordered moment at intermediate $U$, as observed experimentally. By adding two electrons to the undoped cluster, we identify three different pairings channels: An inter-orbital triplet at small $U$, which transforms as the $A_{1g}$ representation of the $D_{4h}$ group, an inter-orbital singlet transforming as $B_{2g}$ at the most realistic intermediate $U$, and an intra-orbital $A_{1g}$ singlet at large $U$. We compare the results to a three-orbital model including the $xy$ orbital in addition to the $xz$ ans $yz$ orbitals. [1] M. Daghofer et al., arXiv:0805.0148, to appear in PRL.

8:36AM H35.00004 Existence of a metallic magnetically ordered state at intermediate Hubbard couplings in multi-orbital models for undoped iron pnictides¹ , RONG YU, University of Tennessee and ORNL, KIEN TRINH, University of Southern California, ADRIANA MOREO, MARIA DAGHOFER, University of Tennessee and ORNL, JOSE RIERA, Universidad Nacional de Rosario, Argentina, STEPHAN HAAS, University of Southern California, ELBIO DAGOTTO, University of Tennessee and ORNL — We present the results of a mean-field study for models that describe undoped iron pnictides. A realistic four-orbital model including iron orbitals in addition to the $d_{xz}$ and $d_{yz}$ orbitals is mainly discussed. Results for a two-orbital model with $d_{xz}$ and $d_{yz}$ orbitals are also shown. In both models, we report the existence of a novel intermediate coupling regime where the system is metallic and exhibits a striped spin order. Several properties of this state are discussed. By performing a mean-field study of other models for iron pnictides, we argue that such a metallic striped ordered phase is a general feature of the theoretical models describing iron pnictides.[1]

8:48AM H35.00005 Low Ordered Magnetic Moment in Fe-As High-Tc Superconductors by Violation of Hund’s Rule¹ , JOSE RODRIGUEZ, California State University at Los Angeles, EDWARD REZAYI, California State University at Los Angeles — We study by exact diagonalization the $J_{0}$-$J_{1}$-$J_{2}$ model over the square lattice that Si and Abrahams introduced recently to describe magnetism in the newly discovered iron-arsenic class of high-Tc superconductors. The case of maximum frustration between the nearest-neighbor and the next-nearest-neighbor Heisenberg exchange terms, $J_{2} = \frac{1}{2}J_{1}$, over a 4 by 4 square lattice with periodic boundary conditions is focused on. Each site hosts two Fe orbitals. Hidden long-range antiferromagnetic order can appear in the absence of Hund’s rule coupling, $J_{0} = 0$. It shows no net ordered magnetic moment. The ordered collinear/SDW moment steadily increases from zero as Hund’s rule coupling turns on: $J_{0} < 0$. This result compares well with recent determinations of a low ordered magnetic moment for the insulating parent compounds of Fe-As based high-Tc superconductors by elastic neutron scattering. Our numerical results are also consistent with a quantum phase transition at intermediate Hund’s rule coupling, $J_{0} = -2|J_{1}|$, that separates the latter hidden-order state from a more familiar frustrated magnetic state that obeys Hund’s rule.

9:00 AM H35.00006 Magnetic Excitations in the Iron-based Superconductors1. DAOXIN YAO, JIANPING HU, ERICA W. CARLSON, Department of Physics, Purdue University — We calculate the expected inelastic neutron scattering response based on the spin-orderings found in the iron-based superconductors, using spin-wave theory. For the two-sublattice collinear antiferromagnet, we consider two types of superexchange couplings between Fe atoms: nearest-neighbor coupling $J_1$ and next-nearest-neighbor coupling $J_2$. We show how to distinguish experimentally between ferromagnetic and antiferromagnetic $J_1$. We show the existence of saddlepoints near ($\pi$, $\pi/2$) and (0, $\pi/2$), which are expected to give rise to extra scattering intensity. We find that the sublattice magnetization can be reduced by the zero-point motion of spin waves, although not enough to account for the small moments observed in experiment. By comparison with experimental results on SrFeAs$_2$, we estimate that the effective magnetic interlayer coupling is rather large, about 1/8 the value of the in-plane couplings. References: 1) Phys. Rev. Lett. 101, 167203 (2008); 2) Phys. Rev. B 78, 052507 (2008)

9:12 AM H35.00007 Iron pnictides as a model system for heavy fermion behavior: influence of conduction-electron magnetic ordering on Kondo effect. JIANHUI DAI, Zhejiang University, QIMIAO SI, Rice University, JIAN-XIN ZHU, LANL. — The rare-earth iron pnictides exhibit a number of magnetic ground states besides the unconventional superconductivity. With CeOfEP [1] and CeOfEAs [2] in mind as prototypes, we develop an extended Anderson lattice model which incorporates the hybridizations of the 5p (4p or 3p)-orbitals with both the iron 3d-orbitals and rare earth 4f-orbitals[3]. We show a new type of Kondo lattice physics: Kondo screening of the f-moments are suppressed by the antiferromagnetic ordering of the d-electrons. Inside the d-electron AF state (as in CeOfEAs), the f-moments are dominantly coupled by superexchange with competing components. The resulting magnetic frustration in general favors a helical order. The regime where d-electrons are paramagnetic (including CeOfEP) features the usual RKKY vs. Kondo competition. The implications of our results for heavy fermion physics in general are discussed.

9:24 AM H35.00008 Tight-binding Hamiltonian for LaFeAsO. DIMITRIOS PAPACONSTANTOPoulos, LANE NIXON, George Mason University, MICHAEL MEHL, Naval Research Laboratory — There have been several first-principles calculations reported recently for the superconducting pnictide LaFeAsO and related compounds. In addition, tight-binding(TB) Hamiltonians for these systems have been constructed with varying degrees of success. In this work we have used the NRL-TB method to fit our LAPW results to a TB basis with the aim of reproducing the band structure very accurately. We have included the s and d orbitals of Fe, the s and p orbitals of As, and the p orbitals of O. We present a study of these TB results in terms of the effect of each of the above orbitals on how accurately the first-principles band structure can be reproduced. Finally, we assess the feasibility of carrying out many-body theory with a Hamiltonian that may contain more than just the d-Fe orbitals.

9:36 AM H35.00009 Competing magnetism and superconductivity in two-band metals. ANTON VORONTSOV, MAXIM VAVILOV, ANDREY CHUBUKOV, University of Wisconsin - Madison — Recently discovered FeAs-based superconductors have a distinct multiple band structure - the hallmark model for these metals, with one electronic and one hole band. Within this model, we treat on equal footing magnetic spin density wave (SDW) and superconducting (SC) orders. We find that at low doping, magnetism wins, but at higher dopings superconducting instability comes first. We discuss the type of a transition between the two states, incommensurate SDW order at finite dopings, and co-existence of SDW and SC orders at $T = 0$ and finite temperatures. Our results reasonably well explain the phase diagram of LaO$_{1-x}$Fe$_{1-x}$As compounds.

9:48 AM H35.00010 Superconductivity in the multiband matrix t-J1-J2 model and its implications for the iron pnictides. QIMIAO SI, PALLAB Goswami, PREDRAG NIKOLIC, Rice University, ELIHU ABRAMHS, Rutgers University — We describe the iron pnictides in terms of an incipient Mott picture. We use local moments with frustrating J1-J2 interactions to model the incoherent electronic excitations, and couple them to the coherent electronic carriers. The resulting multiband matrix t-J1-J2 model is analyzed in terms of a slave boson theory, leading to a superconducting phase diagram as a function of doping and J2/J1 ratio. The different pairing symmetries reflect a competition between the strong coupling effects of the J1-J2 interactions, and the kinematic effects associated with the multiple sheets of Fermi surfaces.

10:00 AM H35.00011 Electronic states and material dependences of Fe-based superconductors. MICHIYASU MORI, IMR, Tohoku Univ., TAKAMI TOHYAMA, Kyoto Univ., NAVID AFZAL SHOOSHARY, SADAMICHI MAEKAWA, Tohoku Univ. — In this study, we discuss the electronic states of Fe-based superconductors and its material dependences, in particular, by taking account of the bond angle dependences. First, we calculate the crystal field splitting (\Delta) of Fe 3d orbital coordinated by four As's. Next, the hopping integrals (t) are estimated by using the Slater and Koster fs method. Note that these parameters, t and $\Delta$, change with $\alpha$. Finally, we can obtain the dispersion relation as a function of $\alpha$. It is found that the spectral weights near the Fermi energy are dominated by yz, xz and x^2-y^2 orbitals. The yz and xz orbitals are higher in energy around the regular tetragonal geometry, in which $\alpha$ is almost 109°. On the other hand, those two orbitals become lower in energy for the larger value of $\alpha$. Such an orbital crossing is crucial for the electronic states. The ground state phase diagram is obtained by the Hartree-Fock calculation of multi-band Hubbard model.
Begtrup et al, Phys. Rev. Lett. 408
Yao et al, Phys. Rev. Lett., transmission electron micrographs of the same nanotube. Our current progress toward quantitative pyrometry will be described.

Electrical current. Diffraction-limited optical microscopy identifies the nanotube position and orientation, and allows direct comparison with high-resolution eye, using individual carbon nanotubes as filaments. A nanotube is suspended over a hole in a solid silicon substrate, and is heated to incandescence with the angle between the axes of the nanotubes on the thermal conductivity.

Extended two dimensional structures (papers) containing these junctions. The investigation includes the effects of chirality, the off set in atomic register and nanopapers. Equilibrium and non-equilibrium molecular dynamics simulations are performed on non-bonded and bonded (fused) nanotube junctions and have great potential as electronic thermal management materials. Here we present our theoretical investigations on thermal properties of nanotube junctions

The Wiedemann-Franz law is restricted to each branch with its specific temperature; (b) thermoelectric power vanishes due to electron-hole symmetry. The model depicts different regimes such as ballistic and diffusive and shows excellent agreement with diffusive carrier transport in 1D conductors.

(a) The Wiedemann-Franz law is restricted to each branch with its specific temperature; (b) thermoelectric power vanishes due to electron-hole symmetry. The modell depicts different regimes such as ballistic and diffusive and shows excellent agreement with diffusive carrier transport in 1D conductors.

Tuesday, March 17, 2009 8:00AM - 11:00AM –
Session H36 DCMP: Carbon Nanotubes: Electrothermal Transport and Raman Spectroscopy

8:00AM H36.00001 Restricted Wiedemann-Franz law in 1D conductors, MARCELO KURODA, Dept. of Physics and Beckman Institute, University of Illinois at Urbana-Champaign, JEAN-PIERRE LEBURTON, Dept. of Electrical and Computer Engineering and Beckman Institute, University of Illinois at Urbana-Champaign — We show that under external electric fields or thermal gradients, carrier distributions in one-dimensional (1D) conductors with linear E-k dispersion have different temperatures for forward and backward (branch) carrier populations, as a consequence of self-consistent carrier-heat transport. We derive the moment equations of the Boltzmann transport equation, in the presence of elastic scattering, for which: (a) The Wiedemann-Franz law is restricted to each branch with its specific temperature; (b) thermoelectric power vanishes due to electron-hole symmetry. The model depicts different regimes such as ballistic and diffusive and shows excellent agreement with diffusive carrier transport in 1D conductors.

8:12AM H36.00002 Observation of Joule heating in multi-walled carbon nanotubes by electron thermal Microscopy, KAMAL BALOCH, TODD BRINTLINGER, NORVIK VOSKIANIAN, JOHN CUMINGS, University of Maryland — We report Joule heating in multi-walled carbon nanotubes under voltage bias by using an electron thermal imaging technique [1]. Briefly, the temperature profile is obtained by observing the solid to liquid phase transitions of indium islands sub-100nm in diameter, thermally deposited on the back side of an electron transparent dielectric membrane. The high spatial-resolution maps thus obtained demonstrate that in the high-voltage-bias regime the thermal dissipation occurs not at the electrode contacts but along the entire length of the nanotube as predicted in [2]. The low temperatures involved (<200 C) extend previous results [3] into a new temperature regime. The implications of these results when combined with other observations in the literature will be discussed.

8:36AM H36.00004 Thermal Transport Through Carbon Nanotube Junctions and Carbon Nanotube Nanopapers, CHARLES A. BARR, ALPER BULDUM, Department of Physics, The University of Akron — Carbon nanotubes have demonstrated exceptional thermal transport properties that show promise in a wide range of applications. Nanotube nanocomposites and nanopapers have great potential as electronic thermal management materials. Here we present our theoretical investigations on thermal properties of nanotube junctions and nanopapers. Equilibrium and non-equilibrium molecular dynamics simulations are performed on non-bonded and bonded (fused) nanotube junctions and extended two dimensional structures (papers) containing these junctions. The investigation includes the effects of chirality, the off set in atomic register and the angle between the axes of the nanotubes on the thermal conductivity.

8:48AM H36.00005 Imaging single carbon nanotubes with thermal radiation, YUWEI FAN, SCOTT SINGER, RAYMOND BERGSTROM, B.C. REGAN, UCLA Department of Physics and Astronomy — We have constructed tiny light bulbs, visible to the naked eye, using individual carbon nanotubes as filaments. A nanotube is suspended over a hole in a solid silicon substrate, and is heated to incandescence with electrical current. Diffraction-limited optical microscopy identifies the nanotube position and orientation, and allows direct comparison with high-resolution transmission electron micrographs of the same nanotube. Our current progress toward quantitative pyrometry will be described.

1Currently with the UCLA Nanoelectronics Research Facility, Department of Electrical Engineering
9:00AM H36.00006 Thermal conductance and bolometric response of individual single-walled carbon nanotubes1, DANIEL SANTAVICCA, JOEL CHUDOW, ANTHONY ANNUNZIATA, LUIGI FRUNZIO, DANIEL PROBER, Dept. of Applied Physics, Yale University, MENINDER PUREWAL, PHILIP KIM, Deps. of Physics and Applied Physics, Columbia University — We describe low temperature electrothermal characterizations of individual single-walled carbon nanotubes on insulating substrates. The increase in differential resistance with increasing dc bias current is attributed to Joule heating. This is confirmed by Johnson noise thermometry, and thus the resistance can be used as a direct probe of the average electron temperature. These measurements enable us to determine the nanotube thermal conductance. We also measure the rf heterodyne response and find that the data agree well with a linear response bolometric model using our experimental value for the thermal conductance. This is the first demonstration of bolometric detection in an individual nanotube.

9:12AM H36.00007 Investigation of Optical Absorption and Thermal Transport in Suspended Carbon Nanotube Bundles . , I-KAI HSU, Department of Materials Science and Electrical Engineering, University of Southern California, ADAM BUSHMAKER, MEHMET AKYOL, STEPHEN CRONIN, Department of Materials Science and Electrical Engineering, University of Southern California, MICHAEL PETTES, LI SHI, Department of Mechanical Engineering and Center for Nano and Molecular Science and Technology, Texas Materials Institute,University of Texas of Austin — The optical absorption in suspended carbon nanotube (CNT) bundles is measured using Raman spectroscopy and two platinum resistance thermometers (PRTs), located at both ends of the suspended CNTs. The power absorbed from an incident focused laser is determined from the thermal power flowing through both ends of the CNT, detected by resistance changes in the PRTs. The results show 0.03 to 0.44% absorption of a focused 532nm laser with a 0.4µm diameter spot size incident on CNT bundles with diameters and lengths varying from 7.1-8.2nm and 11.7-14.3µm, respectively. The thermal conductance of the suspended CNT bundles can also be obtained by measuring the temperature difference between the incident laser spot and both ends of the suspended CNT. Here, temperatures in the center of the nanotube are extracted from the temperature-induced downshifts of the G band Raman mode.

9:24AM H36.00008 Terahertz Bolometric Detection in an Individual Single-Walled Carbon Nanotube1, JOEL CHUDOW, DANIEL SANTAVICCA, ANTHONY ANNUNZIATA, LUIGI FRUNZIO, DANIEL PROBER, Dept. of Applied Physics, Yale University, CHARLES SCHUMITTEMAER, Dept. of Chemistry, Yale University, PHILIP KIM, Deps. of Physics and Applied Physics, Columbia University — We describe measurements of terahertz detection in individual single-walled carbon nanotubes. The terahertz power dissipated in the antenna-coupled nanotube is determined from the induced temperature change via the nanotube’s temperature-dependent resistance. This is the first demonstration of terahertz bolometric detection in an individual nanotube. This experimental technique is being developed to study high-frequency charge excitations in the nanotube, which are predicted to display Luttinger-liquid behavior due to the lack of screening in one dimension.

9:36AM H36.00009 Quantum-dot thermometry applied to the study of electron-phonon interaction in nanowires . , JASON MATTHEWS, University of Oregon, Eugene, Oregon, HENRIK NILSSON, LARS SAMUELSON, Lund University, Sweden, HEINER LINKE, University of Oregon, Eugene, Oregon — The thermal properties of mesoscopic devices are greatly influenced by quantum and finite-size effects. For example, the influence of electron-phonon coupling on heat flow through nanowires is different than in bulk materials and has not been studied in detail. One challenging aspect of performing thermal experiments with a mesoscopic device is the application and quantification of a temperature difference across a sub-micron distance. The recently introduced quantum-dot thermometry1,2 uses a quantum dot to measure the electronic temperature difference across the dot’s dimension. We present here experimental results demonstrating quantum-dot thermometry using a quantum dot embedded in an InAs nanowire. In addition, we show result which suggest that quantum-dot thermometry can be used to measure the strength of electron-phonon interaction in a one-dimensional nanowire. 1. Hoffmann, E.A. et al., Quantum-dot thermometry, Appl. Phys. Lett. 91(25), 252114 (2007). 2. Hoffmann, E.A. et al., Measuring temperature gradients over nanometer length scales, Submitted to Nano Letters (2008).

9:48AM H36.00010 Numerical study of heat flow and electron-phonon coupling in nanowires . , JASON MATTHEWS, ERIC HOFFMANN, JASON MATTHEWS, University of Oregon, Eugene, OR, HENRIK NILSSON, LARS SAMUELSON, Lund University, Sweden, HEINER LINKE, University of Oregon, Eugene, OR — The strength of electron-phonon (e-ph) interaction in one-dimensional systems is an important mechanism that controls heat flow generated by Joule heating, e.g. in nanowires. Here we use finite element modeling to study the effects of e-ph interactions on the electron temperature profile within a heterostructure nanowire. In recent experiments, we have measured the electron temperatures in the vicinity of a double-barrier quantum dot embedded in a nanowire. We find a significant electron temperature rise in the non-heated (drain) end of the nanowire near the dot. Such a temperature rise is unexpected due to electrons seeing the dot as both electrically and thermally insulating. It is suspected that this temperature rise is due to heat bypassing the quantum dot via phonons, which in turn heat electrons in the nanowire drain by means of e-ph interaction. Our modeling results are in agreement with measured electronic temperatures, suggesting that these measurements could be used to determine the strength of e-ph interaction.

10:00AM H36.0011 Nonlinear Optical Properties of Carbon Nanotubes from First Principles . , JACK DESLIPPE, University of California at Berkeley and Lawrence Berkeley National Lab, DAVID PRENDERGAST, Lawrence Berkeley National Lab, STEVEN LOUIE, University of California at Berkeley and Lawrence Berkeley National Lab — The optical excitation spectra of both semiconducting and metallic single-walled carbon nanotubes (SWNTs) as well as other 1D materials are dominated by exciton states of large binding energy and well defined symmetries in the group of the k-vector along the periodic direction. The optical oscillator strength is transferred almost entirely from the continuum into the excitons and the corresponding exciton-phonon states. Recent experiments have probed the spectral structure of the excited states of various symmetry in SWNTs using nonlinear optics techniques such as ultrafast spectroscopy, multi-photon spectroscopy, and phonon-assisted spectroscopy. We have developed and applied a new method based on the first-principles GW-Bethe Salpeter approach to the study of the nonlinear optical properties of the SWNTs. Supported by NSF Grant No. DMR07-05941, US DOE Contract No. DE- AC02-05CH11231 and DOE CSGF grant DE-FG02-97ER25308 and computational resources from Teragrid and NERSC.

10:12AM H36.00112 The BO Approximation Breakdown - Raman Spectroscopy of Suspended Single-Walled Carbon Nanotubes under Gate Voltages . , ADAM W. BUSHMAKER, University of Southern California, VIKRAM V. DESHPANDE, SCOTT HSIEH, MARC W. BOCKRATH, Caltech, STEPHEN B. CRONIN, University of Southern California — Since the creation of quantum dots, the BO approximation has been a useful heuristic for understanding quantum and finite-size effects. For example, the influence of electron-phonon coupling on heat flow through nanowires is different than in bulk materials and has not been studied in detail. One challenging aspect of performing thermal experiments with a mesoscopic device is the application and quantification of a temperature difference across a sub-micron distance. The recently introduced quantum-dot thermometry1,2 uses a quantum dot to measure the electronic temperature difference across the dot’s dimension. We present here experimental results demonstrating quantum-dot thermometry using a quantum dot embedded in an InAs nanowire. In addition, we show result which suggest that quantum-dot thermometry can be used to measure the strength of electron-phonon interaction in a one-dimensional nanowire. 1. Hoffmann, E.A. et al., Quantum-dot thermometry, Appl. Phys. Lett. 91(25), 252114 (2007). 2. Hoffmann, E.A. et al., Measuring temperature gradients over nanometer length scales, Submitted to Nano Letters (2008).

10:24AM H36.00013 Raman Scattering Study of Carbon Nanotube Serpentines. BEI WANG, AWNISH GUPTA, Department of Physics, Penn State University, PETER EKlund, Department of Physics, Department of Materials Science & Engineering and Materials Research Institute, Penn State University, JUN HUANG, WONBONG CHOI, Department of Mechanical and Materials Engineering, Florida International University, PENN STATE UNIVERSITY COLLABORATION, FLORIDA INTERNATIONAL UNIVERSITY COLLABORATION — Single-walled carbon nanotubes (SWNTs) were grown on step-edge single crystal quartz using CVD. SEM images were taken using FESEM showing serpentines and loops. Raman spectra were taken on SWNTs using excitation lines 514nm and 647nm with laser spot diameter ∼0.8μm. By tracing the Raman spectrum along a SWNT, we were able to record the change of Raman features with respect to the bending radius R of tube in the plane of the substrate. We found that there is linear upshift of the G-band and R-band with the curvature (1/R) of the bend. We attribute the shift of these frequencies to strain related change of carbon-carbon bond length. In semiconducting SWNTs changes were also observed in the intensities of these bands which we identify with a curvature induced change in the band-gap. This interpretation is also consistent with the results of electronic measurements.

This work is supported by NSF NIRT ECS 06-09243.

10:36AM H36.00014 Raman Spectroscopy of isolated double wall carbon nanotubes with different metallic and semiconducting configurations. FEDERICO VILLALPANDO, Department of Materials Science and Engineering, MIT, DANIEL NEZICH, Department of Physics, MIT, YOONG AHM KIM, Faculty of Engineering, Shinshu University, DAISUKI SHIMAMOTO, Faculty of Engineering, Shinshu University, HIROYUKI MURAMATSU, Institute of Carbon Science and Technology, Shinshu University, TAKUYA HAYASHI, Faculty of Engineering, Shinshu University, JING KONG, Department of Electrical Engineering and Computer Science, MIT, ENDO MORIBU, Faculty of Engineering, Shinshu University, MAURICIO TERRONES, Advanced Materials Department, IPICYT, MILDRED DRESSELHAUS, Department of Physics and 2. Department of Electrical Engineering and Computer Science, MIT — We have developed an experimental technique to obtain the Raman spectra from individual double wall carbon nanotubes (DWNt). A chemical vapor deposition (CVD) derived sample of DWNts is dispersed into solution and placed on a Si substrate. The Si substrate contains lithographic markers that allow us to record the exact location of individual and isolated DWNts and obtain their Raman spectra with various laser energies. The laser energy can be in resonance with the inner and/or the outer layers of the same DWNT. We report on the differences between individual DWNTs with different metallic and semiconducting configurations and compare our results to previous experiments performed on DWNT bundles.

CONACYT Mexico and NSF DMR-0704197.

10:48AM H36.00015 Softening of the Radial Breathing Mode in Metallic Carbon Nanotubes. HOOTAN FARHAT, MIT, KEN-ICHI SASAKI, Hiroshima University, MARTIN KALBAC, Academy of Sciences of the Czech Republic, MARIO HOFMANN, MIT, RIICHIRO SAITO, Tohoku University, MILDRED S. DRESSELHAUS, JING KONG, MIT — In this work, the Fermi level (εF) dependence of the radial breathing mode (RBM) of metallic single walled carbon nanotubes (M-SWNTs) has been investigated. In situ Raman spectra were obtained from several individual M-SWNTs while varying εF electrochemically. The RBM frequency of an intrinsic M-SWNT is shown to be downshifted relative to highly doped tubes by ∼2 cm⁻¹. The downshift is greatest for small diameter and small chiral angle nanotubes. Most tubes do not show any change in RBM linewidth. A comparison is drawn between the RBM and the G-band (A₁LO phonon) with respect to the εF dependence of their frequencies and linewidths.

Tuesday, March 17, 2009 8:00AM - 11:00AM — Session H37 DCP: Focus Session: Spectroscopic Probes of Biomolecular Structure and Function I 409

8:00AM H37.00001 Structure and dynamics in B12 enzyme catalysis revealed by electron paramagnetic resonance spectroscopy. KURT WARNCKE, Emory University — Challenges to the understanding of how protein structure and dynamics contribute to catalysis, and the use of time-resolved electron paramagnetic resonance (EPR) spectroscopic techniques to address the challenges, are examined in the context of the cobzyme B12-dependent enzyme, ethanalamine ammonia-lyase (EAL), from Salmonella typhimurium. EAL conducts the homolytic cleavage of the coenzyme cobalt-carbon bond, intraprotein radical migration (5-6 Å), and hydrogen atom transfers, which enable the core radical-mediated rearrangement reaction. Thermodynamic and activation parameters are measured in two experimental systems, which were developed to isolate sub-sequences from the multi-step catalytic cycle, as follows: (1) A dimethylsulfoxide (DMSO)/water cryosolvent system is used to prepare the kinetically-arrested enzyme/coenzyme/substrate ternary complex in fluid solution at 230 K.[1] Temperature-step initiated cobalt-carbon bond cleavage and radical pair separation to form the Co(II)-substrate radical pair are monitored by using time-resolved, full-spectrum EPR spectroscopy (234°C<T≤250 K).[1] (2) The Co(II)-substrate radical pair is cryotrapped in frozen aqueous solution at T<150 K, and then promoted to react by a temperature step. The reaction of the substrate radical along the native pathway to form the diamagnetic bound products is monitored by using time-resolved, full-spectrum EPR spectroscopy (187°C<T≤217 K).[2] High temporal resolution is achieved, because the reactions are dramatically slowed at the low temperatures, relative to the initiation and spectrum acquisition times. The results are combined with high resolution structures of the reactant centers, obtained by pulsed-EPR spectroscopies.[3] and the protein, obtained by structural proteomics[4] and EPR and electron spin echo envelope modulation (ESEEM) in combination with site directed mutagenesis,[5] to approach a molecular level description of protein contributions to catalysis in EAL.

8:36AM H37.00002 Time-resolved X-ray scattering of proteins in solution: a new method for probing biomolecular structure and function
We thank Bill Royer, John Olson, and Jayashree Soman for providing protein samples used in these studies. This research was supported in part by the Intramural Research Program of the NIH, NIDDK.

9:12AM H37.00003 Ultrafast Photodynamics in Diverse DNA Structures from A-tracts to Z-DNA
BERNH KOHLER, Department of Chemistry, The Ohio State University — The vulnerability of the genome to UV photodamage has sustained interest in excited electronic states in DNA for over 50 years. Progress in understanding the nature and dynamics of electronic excitations in DNA has accelerated rapidly thanks in part to ultrafast spectroscopy. Most excitations in single DNA bases decay nonradiatively in hundreds of femtoseconds. Surprisingly, much longer-lived excited states are observed in femtosecond pump-probe experiments on single- and double-stranded DNAs. Localized charge transfer states are prominent in runs of adenine bases (A tracts). DNA is polymorphic and can adopt a range of structures beyond the iconic B-form double helix. The effect of helix conformation on excited-state dynamics has been studied in a double-stranded oligonucleotide that can be switched between B- and Z-forms. Experiments on G quadruplex structures and on i-motif DNA reveal that these forms have significantly slower relaxation than B-DNA. By altering π − π stacking and hydrogen bonding, structure profoundly affects the complex photoprocesses observed in DNA.

9:48AM H37.00004 Charge Transfer States of Aqueous B-DNA at Energies Above the Bright Exciton States
ADRIAN LANGE, Chemistry Dept. (Physical), JOHN HERBERT, Chemistry Dept. — Charge transfer states have been proposed to explain experimentally observed long-lived excited states in aqueous DNA oligomer[1]. Due to the large number of atoms, tractably describing such excited states in DNA systems with ab initio theory is limited to TD-DFT. However, standard TD-DFT exchange-correlation functionals significantly underestimate CT excitation energies owing to incorrect asymptotic behavior. To circumvent this error, we instead apply recently developed and optimized long-range corrected TD-DFT functionals to better assess the low lying CT and exciton states of DNA oligomers. We show that long-range corrected TD-DFT yields results comparable to correlated wave function models, placing CT states of aqueous B-DNA at energies above the optically bright 1ππ* exciton states, contrary to TD-DFT results which find CT states below the exciton states.

10:00AM H37.00005 Low frequency dynamics of Cytochrome c
KARUNAKARAN VENUGOPAL, PAUL CHAMPION, Department of Physics and Center for Interdisciplinary Research on Complex System, Northeastern University, Boston — Femtosecond coherence spectroscopy is used to investigate the low frequency dynamics of cytochrome c (cyt c). There is good agreement between the higher frequency oscillatory components of the coherence spectra and the low frequency Raman spectra. A mode near ~40 cm⁻¹ is a universal feature of heme systems and has been assigned to doming motions that are strongly enhanced upon ligand photolysis [1]. A dominant heme ruffling mode near ~60 cm⁻¹ [2] appears in ferric cyt c for excitation in the region 425-432 nm, to the red of the Soret maximum (408 nm). This, along with a phase jump of ~ π in this region, suggests the ruffling mode is coupled to a charge transfer (CT) band underlying the Soret band [3] and that it is a potentially important electron transfer reaction coordinate. [1] F. Gruia, M. Kubo, X. Ye, P. M. Champion, Biophys. J., 2008, 94, 2252. [2] M. Kubo, F. Gruia, A. Benabas, A. Barabanschkov, W. R. Montfort, E. M. Maes, P. M. Champion, J. Am. Chem. Soc., 2008, 130, 9800. [3] K. T. Schomacker, P. M. Champion, J. Chem. Phys., 1986, 84, 5314.

10:12AM H37.00006 Ultrafast Dynamics of Leu-Enkephalin in Water and Membranes
SOOHWAN SUL, YUAN FENG, UYEN LE, NIEN-HUI GE, Department of Chemistry, University of California, Irvine — Ultrafast two-dimensional infrared (2D IR) spectroscopy has been applied to investigate the peptide-membrane interaction and conformational distribution of Leu-enkephalin (Lenk) in bilayer membranes. We compare the results from linear and 2D IR experiments on p-cresol in water, Lenk in water, and Lenk in membranes, focusing on the ring stretching mode of the Tyr side chain. Frequency-frequency correlation functions obtained from a series of waiting-time-dependent 2D IR spectra reveal a fast decaying component with a ~1 ps time constant that is common for all three systems. This spectral diffusion component is attributed to hydrogen-bond making-breaking dynamics of the Tyr side chain. Unlike p-cresol in water, both Lenk systems exhibit substantial spectral inhomogeneity that does not decay within the 4 ps window. The observed hydrogen-bond dynamics suggests that the Tyr side chain of Lenk in membranes is located at the water-abundant region at the water-membrane interface. The experimental results are compared with those from MD simulations and DFT calculations.

10:24AM H37.00007 Flap Conformations in HIV-1 Protease are Altered by Mutations
GAIL FANUCCI, MANDY BLACKBURN, ANGELO VELORO, LUIS GALIANO, University of Florida, DING FANGU, CARLOS SIMMERLING, Stony Brook — HIV-1 protease (PR) is an enzyme that is a major drug target in the treatment of AIDS. Although the structure and function of HIV-1 PR have been studied for over 20 years, questions remain regarding the conformations and dynamics of the β-hairpin turns (flaps) that cover the active site cavity. Distance measurements with pulsed EPR spectroscopy of spin labeled constructs of HIV-1 PR have been used to characterize the flap conformations in the apo and inhibitor bound states. From the most probably distances and the breadth of the distance distribution profiles from analysis of the EPR data, insights regarding the flap conformations and flexibility are gained. The EPR results clearly show how drug pressure selected mutations alter the average conformation of the flaps and the degree of opening of the flaps. Molecular dynamics simulations successfully regenerate the experimentally determined distance distribution profiles, and more importantly, provide structural models for full interpretation of the EPR results. By combining experiment and theory to understand the role that altered flap flexibility/conformations play in the mechanism of drug resistance, key insights are gained toward the rational development of new inhibitors of this important enzyme.
10:36AM H37.00008 An Investigation of Ionic Binding to Fatty Acid Monolayers by Broad-bandwidth Sum Frequency Generation Vibrational Spectroscopy1, CHENG TANG, HEATHER ALLEN, Ohio State University — Model study of ionic binding of fatty acid monolayer is a good proxy towards understanding the fundamental chemistry in biological processes. In this study, we used broad-bandwidth sum frequency generation (BBSFG) vibrational spectroscopy to investigate the ionic binding event that leads to deprotonation of the fatty acid head groups. Palmitic acid (C15C00H) exists as monolayer on aqueous surfaces, and on aqueous alkali and alkaline solutions surfaces. Surface vibrational stretching modes of palmitic acid from 1400 cm$^{-1}$ to 3700 cm$^{-1}$ were observed (COO$^*$, C=O, C-H, and O-H). Palmitic acid is mostly protonated at the aqueous surface at neutral pH ($\sim$6). However, various degrees of deprotonation are initiated by introduction of different cations in the salt solutions albeit at neutral pH.

1 NSF Chemistry Grant (analytical and surface science div.)

10:48AM H37.00009 Using Rotationally Resolved Electronic Spectroscopy to Probe Chiral Molecules in the Gas Phase1, JUSTIN YOUNG, LEONARDO ALVAREZ-VALTIERRA, DAVID PRATT, University of Pittsburgh — It is well established that biological processes involving chiral molecules can show a preference of one enantiomer relative to the other. Reported here are high resolution spectroscopy experiments that allow one to distinguish one diastereomer from another, and thereby establish if the structural requirements for diastereoisomeric present.

1 Work supported by NSF (CHE-0615755)

Tuesday, March 17, 2009 8:00AM - 10:48AM –
Session H38 DCP: Focus Session: Theory of Electron Transport Through Molecules I

8:00AM H38.00001 The Role of Symmetry in Molecular Electronic Conduction, JEFFREY REIMERS, University of Sydney, Australia — The Greens Function Density-Functional Tight-Binding (gDFTB) method is applied to determine the role that molecular symmetry plays in single-molecule conductivity. Both coherent elastic electron transport and inelastic electron-tunnelling spectroscopy (IETS) are considered. Symmetry becomes manifest in various ways: through the molecular point-group symmetry of the conducting molecule (D2h, for chemisorbed benzenedithiol between two gold electrodes), through the conductance point-group symmetry displayed by the gDFTB equations (this embodies junction symmetry and may be very low and nominally non-existent), and through an approximate molecular-conductance point group (C2h, for chemisorbed benzenedithiol). Indeed, the conductivities for a range of relevant problems are well approximated using the restriction of molecular-conductance point-group. This allows the complex transmission curves calculated by many research groups to be dramatically simplified and partitioned into symmetry-depicted channels. Means are introduced that isolate a very small number of component channels describing different aspects of single-molecule conductivity: input junction channels, through-molecule channels, and output-junction channels. For elastic transport, all through-molecule channels are totally symmetric and hence a rigorous selection rule appears that transport is allowed involving only input-junction and output-junction channels of the same symmetry. However, for IETS, the through-molecule channels have the symmetry of the scattering molecular vibration and hence the input-junction and output-junction channel symmetries may vary. In general, just one channel is expected to dominate the junctions, leading to the IETS propensity rule that totally symmetric transitions are the most intense ones. Simple physical pictures are presented showing the input, vibrational scattering, and output channels for IETS, leading to predictions of how this effect can be controlled chemically.

8:36AM H38.00002 Molecular and Nano Scale Device-conductance: steady state and dynamical analysis, BARRY D. DUNIETZ, University of Michigan — A computational approach is used and developed to study electron transport through molecular and nano scale devices. New models and methods are employed to describe the dynamics of electron transport under the influence of time dependent (TD) perturbations. Quantum interferences affecting the TD conductance are analyzed for transient aspects, effects of present bound states and transport under the effect of coherent excitations. I will also discuss our modeling of several recent high-profile experimental studies achieving molecular scale (steady state) conductance which provides intriguing insight at the molecular structural level on the functionality of the conducting devices. The studies involve metal recognition properties of short peptides or fabricated molecular sockets based on surface confined terpyridine ligands. If time permits I will describe the required structural features for a gating field to tune the conductance of a molecular conjugated system.

9:12AM H38.00003 The spectroscopic dynamics of electron transport through molecular junctions, ALEXANDER PROCIUK, BARRY DUNIETZ, University of Michigan — A non-equilibrium Green’s-Function (NEGF) model based on time dependent perturbation theory is developed to compute the spectroscopic dynamics of electron transport through molecular junctions under the influence of weak time dependent classical fields. In this model, we use the two time variable nature of the Kadanoff-Baym equations of motion to formulate a mixed time-frequency representation for the electronic density. The resulting highly informative time dependent Wigner distributions are used to shed light on the features of dynamical observables, such as electron current, dipole moment and population. We analyze laser induced coherence and population transfer effects for both Markovian and non-Markovian electrode models. If time permits, the analysis of transient conductance with respect to the system’s fundamental parameters will be discussed.

9:24AM H38.00004 Model ab initio studies of solvation and excess charge localization on conjugated carbon chains1, MICHAEL MAYO, YURI GARTSTEIN, The University of Texas at Dallas — Using long C$_n$H$_{2n}$ conjugated carbon chains with the polymeric structure as prototypical examples of one-dimensional (1D) semiconductors, we discuss self-localization of excess charge carriers in the presence of the interaction with a surrounding polar solvent. The solvation mechanism of self-trapping is different from the self-localization due to coupling with bond-length modulations of the underlying atomic lattice well-known in conjugated polymers. Model ab initio computations are carried out and compared that employ various methods such as hybrid density functionals and Hartree-Fock within the framework of the polarizable continuum model. We demonstrate the possibility of the formation of large 1D electron- and hole-polarons entirely due to solvation, but even larger degrees of charge localization occur when accompanied by atomic displacements. Also discussed are doubly-charged bipolaron states and topological kink-solitons that may be formed in these systems. For a brief report, see M. L. Mayo and Yu. N. Gartstein, Phys. Rev. B 78, 073402 (2008).

9:36AM H38.00005 Measuring single electron charging energy in self-assembled single nanoparticle devices: Coulomb blockade threshold vs. Arrhenius energy, AL-AMIN DHIRANI, AMIR ZABET-KHOSOUSI — Single-nanoparticle (NP) devices formed by self-assembling NPs onto alkanedithiol-functionalized break junctions exhibit Coulomb blockade (CB) conductance suppressions at low temperatures. We have studied temperature dependence of conductance inside the CB region and find multiple activation energies ($E_a$): A small $E_a$ at low temperatures, and a larger $E_a$ at high temperatures. The small $E_a$ is independent of NP size and is attributed to an energy state located at the metal–molecule contact. The larger $E_a$ scales with NP size and is attributed to single electron charging energy of the NPs. Importantly, we observe a significant (~5–100 fold) discrepancy between values of charging energies obtained from CB voltage thresholds and $E_a$. To account for the discrepancy, we propose a model in which electrons are temporarily localized at the energy states near the metal–molecule interface and lose energy. The proposed model is supported by ultraviolet photoelectron spectroscopy of alkanedithiol monolayers on gold which indicates a presence of energy states close to the Fermi level of gold likely arising from gold–thiolate bonds. A suitably modified Orthodox theory successfully describes our measurements.

9:48AM H38.00006 Molecular transport in the language of many-body states, MICHAEL GALPERIN, UCSD — Recent advancements in experimental techniques at nanoscale caused a surge in research of transport through molecular junctions. Nonlinearity of current-voltage characteristic at resonance makes this regime particularly important for potential molecular based memory, switches and logic devices. One of important differences of molecular junctions (compared e.g. to semiconductor QDs) is sensitivity of electronic and vibrational structure of the molecule to oxidation/reduction of the molecule. This implies necessity of treating the transport at resonance in the language of molecular states rather than single particle orbitals. The latter are the choice of majority of available ab initio approaches. We consider two possible schemes capable of incorporating isolated molecule (many-body) states as a basis for transport calculations. The schemes utilize Hubbard operators for description of single electron transitions between many-body states and go beyond previously proposed scattering theory and standard quantum master equation approaches.

10:00AM H38.00007 WKB modeling of single molecular transport and Molecular Nanometrology, VLADIMIR BURTMAN, Physics and Geophysics Department, University of Utah, SLC, ANDREI V. PAKOULEV, Department of Chemistry, University of Wisconsin, Madison — Wentzel–Kramers–Brillouin (WKB) approach to model transport mechanism in molecular nanostructures is discussed in context of molecular nanometrology. Two WKB models, direct tunneling (Simmons model) and field emission tunneling (Fowler-Nordheim tunneling), could be used to model conductivity in single molecular structure at low and elevated biased. Potentially, Simmons model could extract two molecular barriers, one for electrons and one for holes from conductivity spectra. Following this assumption electrical and optical gap-probed molecular nanometrology (GMN) could be developed. The main GMN principle is the small difference between the values of the HOMO-LUMO energy gap detected by electrical and optical measurements. We will compare experimentally derived electrical and optical probed gap and energy offsets between $E_F$ and nearest molecular orbital to discuss applicability and feasibility of this approach. 

1. A. Pakoulev acknowledges support from NSF grant CHE0650431.

10:24AM H38.00009 Theoretical study of electron transport through $\pi$-stacked ethylbenzene lines bonded to a Si surface, MANUEL SMEU, Center for the Physics of Materials and Department of Physics, McGill University, Montreal, QC, Canada, ROBERT WOLKOW, National Institute for Nanotechnology and Department of Physics, University of Alberta, Edmonton, AB, Canada, HONG GUO, Center for the Physics of Materials and Department of Physics, McGill University, Montreal, QC, Canada — Recently, experimental techniques were developed for lines of $\pi$-stacked ethylbenzene molecules to self-assemble on an H-terminated Si (100) surface in the laboratory of one of the authors. In this work, we use density functional theory (DFT) combined with the nonequilibrium Green’s function formalism (NEGF) to model electron transport through these ethylbenzene lines to determine if they could be used as molecular wires. In our calculations, the molecules are bonded to an H-terminated Si (100) surface and are bridging two Al leads. The transmission spectrum and its associated scattering states are determined by the NEGF-DFT technique. The presence of the Si substrate is found to play an important role for conduction: there is a dominant transmission peak near the Fermi level which is contributed by the Si substrate and not the $\pi$-stacked molecular line. The low-bias resistance is found to increase exponentially with the length of the molecular line, indicating a tunneling behavior in conduction.

10:36AM H38.00010 Stark Spectroscopy of Conjugated Oligomers and Polymers Important for Organic Devices, ALBERTO MOSCATELLI, DAVID C. COPPOCK, LINDA A. PETEANU, Carnegie Mellon University — Fluorescent conjugated oligomers, have been tested using this approach. Comparison of the results from single chains and from aggregates reveal how intermolecular interactions impact charge transfer and electronic delocalization in these technologically-important systems.
8:00AM H39.00001 A New Mechanism for Domain Size Selection in Curved Lipid Membranes\(^1\),
FANGFU YE, JONATHAN SELINGER, Kent State University — Lipid membranes, composed of saturated lipids, unsaturated phospholipids and cholesterol, play important roles in maintaining cellular activities. It is now well established that lipid membranes under proper conditions separate into saturated-lipid-enriched (L\(_o\)) phase regions and unsaturated-lipid-enriched liquid-disordered (L\(_d\)) phase regions, with the L\(_o\) phase having a larger bending modulus than the L\(_d\) phase. In this project, we study how the bending modulus difference between L\(_o\) and L\(_d\) phases may affect the phase separation behavior of uniformly curved lipid membranes. We believe that, for a spherical lipid vesicle, when the line tension and phase transitions are in the gel state, (i.e.: their acyl chains have a ~32 degree azimuthal tilt with respect to the membranes normal), the membrane as a uniaxial crystal would be able to change the position of the acyl chains by measuring the birefringence and optical orientation. By controlling the temperature of our sample we hope to better study the curvature changes that occur during phase transitions from gel to liquid states. The investigation of other lipid mixtures and the transformations they undergo during different phases will also be discussed.

8:12AM H39.00002 Making Sense of the Polymorphous Shapes of Giant Liposomes, YAN YU, Dept of Materials Science and Engineering, Univ of Illinois-Urbana Champaign, STEPHEN ANTHONY, Dept of Chemistry, Univ of Illinois-Urbana Champaign, JULIE VROMAN, SUNG CHUL BAE, Dept of Materials Science and Engineering, Univ of Illinois-Urbana Champaign, STEVE GRANICK, Dept of Materials Science and Engineering, Physics, Chemistry and Chemical Engineering, Univ of Illinois-Urbana Champaign — Lipid vesicles, especially giant unilamellar vesicles (GUVs) are often used as simplified models for biological membranes, but their polymorphous panoply of shapes and shape changes is notorious to those who work with them. This affords opportunities to study why phospholipid membranes so often fail to minimize their surface area to adopt spherical shapes. Instabilities can be triggered by the tension caused by optical tweezers, osmotic perturbations, or polymer anchorage. This talk will describe the evolution of GUVs from spherical to pearl-like and to tube-like shapes, and back again reversibly.

8:24AM H39.00003 Near-Field structural studies of lipid bilayers, MERRELL JOHNSON, RICARDO DECCA, IUPUI Physics Dept. — We use a Near-field Scanning Optical Microscope (NSOM) in conjunction with a Photo Elastic Modulator (PEM) to conduct birefringence measurements with a spatial resolution of ~80nm. With our current setup we are able to distinguish changes in retardance \(\alpha = \frac{2\pi(n_0-n_e)}{\lambda}\) on the order of \(5 \times 10^{-3}\) radians. Simultaneously while gathering information about \(\alpha\) we extract information about the samples optical orientation \(\theta\), reference to the sample’s axis, with an accuracy of \(3.64 \times 10^{-3}\) radians. We use our system on 1,2-dipalmitoylphosphatidylcholine (DPPC) bilayers, which at room temperature are in the gel state. (i.e.: their acyl chains have a ~32 degree azimuthal tilt with respect to the membranes normal). Modeling the membrane as a uniaxial crystal we are able to determine the position of the acyl chains by measuring the birefringence and optical orientation. By controlling the temperature of our sample we hope to better study the curvature changes that occur during phase transitions from gel to liquid states. The investigation of other lipid mixtures and the transformations they undergo during different phases will also be discussed.

8:36AM H39.00004 X-ray insight into cholesterol-phospholipid interactions, DAVID GIDALEVITZ, Division of Physics, BCPS department, CMoS, Illinois Institute of Technology, Chicago, IL, USA — The mechanism of nonideal cholesterol-lipids mixing yet remains controversial. We report on a systematic study of cholesterol-phospholipid interactions in lipid monolayers using Langmuir isotherms, synchrotron X-ray reflectivity (XR), and grazing-incidence X-ray diffraction (GIXD) techniques. Lipid monolayers consisted of cholesterol-DPPC mixtures with cholesterol mole fractions \(\chi_{CHOL}\), varying from 0 to 1. GIXD reveals that at both \(\chi_{CHOL}\) and \(\chi_{DPPC}\) above 85 mixed films exhibit packing order of a prevalent lipid. In between, cholesterol seizes places in DPPC crystalline lattice at the stoichiometry. Similar to that of the mixture inducing short-range regular-hexagonal packing order with increasing spacing between molecules as a function of cholesterol content. XR shows that cholesterol tends to stay in DPPC acyl chains at low \(\chi_{CHOL}\) while gradually descending to a subphase at higher \(\chi_{CHOL}\) accompanied by rearrangement of DPPC headgroups. Thus, a desire of highly nonpolar cholesterol to avoid contacts with polar water molecules and/or DPPC headgroups defines a mode of cholesterol-lipid interactions.

8:48AM H39.00005 ABSTRACT WITHDRAWN

9:00AM H39.00006 Monte Carlo Simulation of Coexisting Phases in DOPC/DSPC/Cholesterol Ternary Mixtures, REJWAN ALI, Polytechnic Institute of New York University, JIAN DAI, JUYANG HUANG, Texas Tech University — Lipid raft domain will open up path for modeling many cellular phenomena. Extensive studies on model raft consists of DOPC/DSPC/cholesterol ternary system have been reported by many experimental groups. We report Monte Carlo simulation to reconstruct experimental phase diagram. Both pair-wise and multi-body interactions have been used to simulate the phase boundary of liquid-ordered phase and liquid-disordered phase coexistence region. A new algorithm, named the "Composition Evaluation Method," was implemented to determine the compositions of the coexisting phases in simulations. The new method is about 20~50 times faster in determining phase boundaries, comparing to the traditional free energy calculation. In addition, pair correlation functions were used to map the phase boundaries in the critical region. We found that pair-wise interactions can reproduce the experimental critical point as well as the slope of tie lines, but not the compositions of the coexisting phases. Simulations with multi-body interactions produced a much better fit to the experimental phase diagram.

9:12AM H39.00007 Structural studies of mixed lipid bilayers on solid substrates using x-ray reflectivity, GANG CHEN, MINMAY MUKHOPADHYAY, YICONG MA, SUNIL SINHA, Department of Physics, University of California, San Diego, ZHANG JIANG, Advanced Photon Source, Argonne National Laboratory, CURT DECARO, JUSTIN BERRY, LAURENCE LURIO, Department of Physics, Northern Illinois University, ADRIAN BROZELL, ATUL PARIKH, Departments of Applied Science and Biophysics Graduate Group, University of California, Davis — The lipid bilayers of natural membranes generally exist in a fluid state which occurs above the gel to liquid crystalline phase transition temperature. Knowledge of the structure of such bilayers is important for understanding fundamental biological processes mediated by or occurring within membranes. We have performed systematic measurements on bilayers of 1,2-Dipalmitoyl-sn-Glycero-3-Phosphoethanolamine (DPPE) and its mixture with 1,2-Dioleoyl-sn-Glycero-3-Phosphocholine (DOPC) and cholesterol (CH) on silicon substrates with x-ray reflectivity both below and above their phase transition temperatures. Structural variations as a function of temperature are demonstrated by fitting the reflectivity data with both a model dependent and a model independent routine. Studies of Au nanoparticle labeled DOPC and DOPC + DPPE + CH mixture are also performed and the location of Au nanoparticles in these bilayers is established by analyzing the x-ray reflectivity data.

9:24AM H39.00008 Cellular adhesion and dynamic membrane tether extraction, SARAH NOWAK, TOM CHOU, UCLA — We consider the energetics and dynamics of pulling a ligand bound to an integral membrane receptor. Deformation of the cell membrane and cytoskeleton is considered as the ligand is pulled. We assume that deformation of the cytoskeleton obeys Hook’s law up to a critical force at which the cell membrane locally detaches from the cytoskeleton and a membrane tether forms. Depending on the pulling velocity and force, a membrane tether of varying length may form before the receptor-ligand bond breaks. We study the probability of tether formation and the mean tether length at the moment of ligand detachment as a function of system parameters. This problem is applicable to AFM studies of cellular adhesion molecules, and to the biological problem of leukocyte rolling.
9:36 AM H39.00009 Lipid Micromechanics: Tethers and Fingers in membrane, LOBAT TAYEBI, UCdavis, Applied Science Department, GREGORY MILLER, ATUL PARIKH, UCdavis, Department of Applied Science — A significant body of evidence now links local mesoscopic structure (e.g., shape and composition) of the cell membrane with its function; the mechanisms by which cellular membranes adapt the specific shapes remain poorly understood. Among all the different structures adopted by cellular membranes, the tubular shape is one of the most surprising one. While their formation is typically attributed to the reorganization of membrane cytoskeleton, many exceptions exist. We report the instantaneous formation of tubular membrane mesophases allowing the hydration under specific thermal conditions. The shapes emerge in a bimodal way where we have two distinct diameter ranges for tubes, ~20µm and ~1µm, namely fat fingers and narrow tethers. We study the roughening of hydrated drops of 3 lipids in 3 different spontaneous curvatures at various temp. and ion strength to select the dominant effect in formation of tethers and fingers. Dynamics of the tubules are of particular interest where we observe four distinct steps of birth, coiling, uncoiling and retraction with different lifetime on different thermal condition. These dynamics appear to reflect interplay between membrane elasticity, surface adhesion, and thermal or hydrodynamic gradient.

9:48 AM H39.00010 Pseudo-phase Diagram of Cholesterol-Rich Filamentous, Helical Ribbon, and Crystal Microstructures, Y.A. MIROSHNIKOVA, M. ELSENBECK, GUANQING OU, Y.V. ZASTAVKER, Olin College, K. KASHURI, G.S. IANNACCHIONE, WPI — Optical and calorimetric techniques are employed to study temperature and concentration dependence of three self-assembled microstructure types formed in Chemically Defined Lipid Concentrate (CDLC): filaments, helical ribbons, and crystals. CDLC consists of cholesterol, bilayer-forming amphiphiles, and micelle-forming amphiphiles in water, and is considered to be a model system for cholesterol crystallization in gallbladder bile. Phase contrast and DIC microscopy indicate the presence of all three microstructure types in all samples studied. Optically observed structural evolution indicates that filaments first bend to form helical ribbons followed by clustering and “straightening” of these structures into short and increasingly thickening filaments that dissolve with increasing temperature. Complementary calorimetric studies (differential-scanning and modulation) reveal thermal signatures that correspond to this observed structural evolution, which occurs throughout a large region of metastable chemical coexistence. These results suggest that a pseudo-phase diagram for the microstructures formed in CDLC may be developed to explain the observed behavior of the system.

10:00 AM H39.00011 PTEN interaction with tethered bilayer lipid membranes containing PI(4,5)P2, R. MOLDOVAN, S. SHENOY, P. SHEKHAR, A. KALINOWSKI, Carnegie Mellon University, A. GERICKE, Kent State University, F. HEINRICH, M. LOESCHE, Carnegie Mellon University — Synthetic lipid membrane models are frequently used for the study of biophysical processes at cell membranes. The tethered bilayer lipid membrane (tBLM) model, based on a (C14)2(PEO)8-thiol anchor, WC14 [1]. Such membranes can be prepared to contain single phospholipids or complex lipid mixtures [2], including functional lipids involved in cell signaling, such as the highly charged phosphatidylinositol phosphates (PIPs). To study the interaction between the tumor suppressor PTEN (phosphatase and tensin homologue deleted on chromosome 10) and model membranes we have incorporated phosphatidylinositol-4,5-bisphosphate (PI(4,5)P2) in tBLMs and use fluorescence correlation spectroscopy (FCS), neutron reflectometry (NR) and surface plasmon resonance (SPR) for their characterization. NR shows that tBLMs formed with PI(4,5)P2 are complete. FCS of labeled PI(4,5)P2 shows that diffusion occurs at the time scale characteristic of membrane-incorporated lipid. Finally, SPR shows specific binding of PTEN to the model membrane thus confirming the incorporation of PI(4,5)P2 into the tBLM. [1] McGillivray et al, Biointerphases 2, 21-33 (2007) [2] Heinrich et al, Langmuir, submitted

10:12 AM H39.00012 Subdiffusion and diffusion of lipid atoms and molecules in phospholipid bilayers, ELIHU FLENNER, Colorado State University, JHUMA DAS, MAIKEL RHEINSTADTER, IOAN KOZSTIN, University of Missouri-Columbia — We examine the dynamics of lipid atoms and molecules using a 0.1 µs all-atom molecular dynamics simulation of a hydrated diyristoyl-phosphatidylcholine (DMPC) lipid bilayer. We identify three well separated time regimes in the mean square displacement, ⟨δr²(t)⟩, of the lipid atoms and molecules: (1) a ballistic regime for t < 10 femtoseconds; (2) a subdiffusive regime where ⟨δr²(t)⟩ ~ t^β and β < 1 for times between 10 picoseconds and 10 nanoseconds; and (3) a Fickian diffusion regime where ⟨δr²(t)⟩ ~ t for t > 30 nanoseconds. We propose a memory function approach for describing the mean square displacement over the whole time range, and find that the lateral self diffusion coefficient found from the memory function approach agrees well with the one determined from the mean square displacement. We use the cumulant expansion of the self-intermediate scattering function to connect the three time scales in the mean square displacement to the interpretation of neutron scattering signals.

10:24 AM H39.00013 Suppression of fluid membrane fluctuations by a periodic pinning potential: Applications to red blood cells, MARK L. HENLE, School of Engineering and Applied Sciences, Harvard University, ALEX J. LEVINE, Department of Chemistry and Biochemistry, University of California, Los Angeles — The membrane of the red blood cell (RBC) is tethered to a two-dimensional triangular network of semi-flexible elastic spectrin filaments. This network allows the cell to maintain its structural integrity during the large shape deformations that occur as it circulates through the microcirculation. The lipid membrane is anchored to the spectrin filaments at the nodes of the network. Consequently, these attachments impose a two-dimensional periodic pinning potential upon the membrane. In this talk, we investigate the effect of this pinning potential on the thermal bending fluctuations of the membrane. We show that there is an exact mapping of this system onto the classic problem of non-interacting electrons subject to a periodic potential; we exploit this mapping to obtain an exact analytic solution for a defect-free triangular array of harmonic pinning sites. The pinning potential affects both the local and global structure of the bending fluctuations. To investigate the local structure we consider the bending correlations between two nearby points in the membrane, while for the global structure we consider the total area stored in the fluctuations. We also investigate the effective area modulus of the membrane/spectrin composite structure.

10:36 AM H39.00014 Rough-Smooth-Rough Interface transition in a supported lipid bilayer system, PIYUSH VERMA, NICK MELOSH, Stanford University — Dynamic evolution of interfaces with quenched disorder is common in nature including fluid flow in porous media, granular particle flow and bacterial colony growth. These interfaces, which are either modeled using the Quenched-KPZ equation or the Quenched-Edward-Wilkinson (QEW) equation, expand due to a driving force while the edge profile roughens monotonically over time due to a distribution of disordered trapping defects. We studied interface evolution of a supported phospholipid bilayer, which is an ideal two dimensional viscoelastic material. Surprisingly, we observed a unique rough-smooth-rough bilayer interface transition on chromium oxide which has never been reported before. This transition was found to be a result of the viscoelasticity of the lipid bilayer and could be modeled using a modified QEW equation, which includes a spring-like term to account for the bilayer elasticity.

10:48 AM H39.00015 The effect of curvature on the undulation spectrum of Red Blood Cell membranes, TATIANA KURIABOVA, University of Colorado, Boulder, MARK L. HENLE, Harvard University, ALEX J. LEVINE, University of California, Los Angeles — The human red blood cell (RBC) membrane has a composite structure of a fluid lipid bilayer tethered to an elastic 2D spectrin network. The study of the mechanical properties of RBCs is crucial to our understanding of their ability withstand large amplitude deformations during their passage through the microcirculation. The linear mechanical response of this composite membrane can be measured by observing its undulatory dynamics in thermal equilibrium, i.e. micro rheology. Previous models of these dynamics postulated an effective surface tension. In this talk, we show that surface tension is not necessary. Rather, the coupling of membrane bending to spectrin network compression by curvature can account for the observed dynamics. We use a simplified theoretical model to describe the undulatory dynamics of RBCs, measured experimentally by the Popescu group. Analyzing their data using our model, we observe dramatic changes in RBC membrane elasticity associated with cells’ morphological transition from discocytes to echinocyte to spherocyte.

8:00AM H40.00001 Application of EPR studies on Biologically Important Copper Acetyl Acetonate and Copper Tetraphenyl Porphine via Bayesian Inference and Density Functional Theory, LAXMAN MAINALI, INDIRA SAHU, KEITH EARLE, SUNY Albany — Quantitative lineshape analysis can allow one to infer information about spin probe structure and dynamics. Experiments were performed at different frequencies (S, X, K, and W Band) for Copper acetyl acetonate (Cu(acac)$_2$) and 5,10,15,20- Tetrathenyl - 2H,23H-porphine copper(I) (CuTPP) in toluene at different temperatures. In order to obtain unbiased estimates of model parameters within the context of a given model, EPR spectra were analyzed via methods of Bayesian Inference. Four different sets of model parameters used to describe cw EPR spectra for two different probe symmetries (axial and rhombic) were explored using a model for rotational diffusion that was analyzed via Stochastic Liouville Equation. The optimized magnetic and dynamic tensor parameters were inferred from individual and simultaneous multifrequency fits and were compared with the values obtained from density functional theory (DFT). The isotropic g values estimated with PW1PW for Cu(acac)$_2$ and CuTPP with the respective basis sets 6-31G and 6-31G(d) agree well with the experimental values, whereas the isotropic A values for Cu(acac)$_2$ and CuTPP estimated with Local and gradient corrected functionals PWP and Ahlrichs basis set DZ agree well with the experimental values.

8:12AM H40.00002 Application of Bayesian Inference and Relativistic Density Functional Theory on EPR Study of Biologically important Transition Metal (Vanadium) Compounds, INDIRA SAHU, LAXMAN MAINALI, KEITH EARLE, SUNY Albany — Quantitative lineshape analysis based on the stochastic Liouville equation allows one to infer information about spin probe structure and dynamics. The EPR parameters extracted from Experimental spectra can be used to check theoretical calculation based on Relativistic Density Functional Theory. Experiments on Vanadyl acetylacetonate [VO(acac)$_2$] and Vanadyl mesotetraphenyl porphine [VO(TPP)] in toluene at different temperatures were performed at five different frequencies(S,X,K,Q & W-band). Spectral Analysis was performed using methods of Bayesian Inference at the various frequencies, both independently and in a simultaneous multifrequency fit. Rotational diffusion parameters were inferred for two symmetries (Axial and Rhombic). The isotropic A value (A$_{iso}$) calculated for VO(acac)$_2$ with unrestricted and hybrid-functional PW1PW and for VO (TPP) with unrestricted and hybrid functional BHLYP and Pople style basis set with polarization function 6-311G(3df,3pd), deviated by 0.95% and 0.23% respectively compared to experimental A$_{iso}$ values. The isotopic g values (g$_{iso}$) calculated for VO (acac)$_2$ and VO(TPP) with unrestricted and hybrid-functional PW1PW and Ahlrichs basis set TZV, deviated by 0.18% and 0.05% respectively compared to experimental g$_{iso}$ values.

8:24AM H40.00003 Electrically stimulated contractions of Vorticella convallaria, DEEPENDRA KANTHA, DAVID VAN WINKLE, Department of Physics and Center for Materials Research and Technology (MARTECH), Florida State University — The contraction of Vorticella convallaria was triggered by applying a voltage pulse in its host culturing medium. The 50V, 1ms wide pulse was applied across platinum wires separated by 0.7 cm on a microscope slide. The contractions were recorded as cines (image sequences) by a Phantom V5 camera (Vision Research) on a bright field microscope with 20X objective, with the image size of 256 pixels $\times$ 128 pixels at 7352 pictures per second. The starting time of the cines was synchronized with the starting of the electrical pulse. We recorded five contractions of each of 12 organisms. The cines were analyzed to obtain the initiation time, defined as the difference in time between the leading edge of the electrical pulse and the first frame showing zoid movement. From multiple contractions of the same organism, we found the initiation time is reproducible. In comparing different organisms, we found the average initiation time of 1.73 ms with a standard deviation of 0.63 ms. This research is supported by the state of Florida (MARTECH) and Research Corporation.

8:36AM H40.00004 Pressure Effects on the Morphology of Mammalian Cells, JOHN SCHROEDER, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy, NY 12180, CHARLES R. KEESE, Appliedbiophysics Inc., 185 Jordan Rd., Troy, NY 1218010var, IVAR GIAEVER, Applied Biophysics Inc, 185 Jordan RD Try, NY 12180 — Living mammalian cells can be perturbed by high pressure in a continuous and controlled manner. The effects can be easily measured and quantified using the well-established method of Electric Cell-substrate Impedance Sensing (ECIS). ECIS is an electrical biosensor that quantitatively monitors behaviours of living cells including spreading and adhesion, micromotion and migration. Here we describe the experimental set-up of the pressure equipment and how ECIS is adapted to data collection under these conditions. Preliminary results suggest that high pressure affects the cell attachment and spreading and causes well-attached cells to round up. Results will be presented on the behavior of monolayers of BSC-1 cells upon application of pressures up to 2 kbars of nitrogen gas.

8:48AM H40.00005 The electronic properties of microbial nanowires: An STM investigation, JOSH VEAZEY, BECKY STEIDL, GEMMA REGUERA, STUART TESSMER — Geobacter species of bacteria present the prospect of an interesting physical system through the expression of pili that act as electrically conductive nanowires. These nanowires serve the biological role of transporting metabolically generated electrons outside the cell body to electron acceptors in the organism’s native environment. We have performed scanning tunneling microscopy and spectroscopy on Geobacter sulfurreducens in an effort to elucidate the mechanism of conductivity. Understanding this system may lead to the enhancement in the effectiveness of Geobacter species’ roles in microbial fuel cells and the bioremediation of hazardous waste, such as uranium and petroleum.

9:00AM H40.00006 Probing Ion Channel Insertion into a Bilipid Membranes with a Radio Frequency Tank Circuit, HYUN CHEOL SHIN, Materials Science Program, University of Wisconsin-Madison, WI 53706, ERIC STAFA, MINRUI YU, Department of Electrical and Computer Engineering, University of Wisconsin-Madison, WI 53706, HUA QIN, Suzhou Institute of Nano-Tech and Nano-Bionics, Suzhou City, Jiangsu 215123, People’s Republic of China, HYUN-SEOK KIM, ROBERT BLICK, Department of Electrical and Computer Engineering, University of Wisconsin-Madison, WI 53706 — We fabricated a radio frequency resonant circuit which can be applied for probing ion channels formed in bilipid membranes. The insertion of ion channels can be probed by monitoring the resonant response of the tank circuit. The circuit itself is realized on a glass chip, which simultaneously uses DC channel recordings (i.e. conventional on-chip patch clamping) and RF detection. The direct current recordings of the ion channels responses allows for the calibration of the radio frequency signal. Such radio frequency recordings of ion channel activity have great potential for high-throughput drug screening.

9:12AM H40.00007 Highly oil-producing microalgae selected through directed-evolution on a microfluidic chip, TROY MESTLER, ANDRE ESTEVEZ-TORRES, GUILLAUME LAMBERT, ROBERT H. AUSTIN, Princeton University — Some species of photosynthetic microalgae produce significant amounts of oil which can be easily converted to diesel fuel. However, as it stands today, biodiesel is significantly more expensive than fossil fuels. We wish to improve the oil yield and production rate of a single species of microalgae through directed evolution. We propose to utilize our microfabrication technology to create microhabitats to control the nutrient environment of the species, monitor oil production through Raman Spectroscopy, and punish colonies of algae which have low oil yield. We believe this process will produce a mutant species with a high oil yield.
9:24AM H40.00008 Structural Color of Biological and Biomimetic Amorphous Nanostructures, JASON FORSTER, HEESO NOH, VINODKUMAR SARANATHAN, HUI CAO, SIMON MOCHRIE, CHINEDUM OSUJI, RICHARD PRUM, ERIC DUFRESNE, Yale University — The feathers of many bird species have amorphous nanostructures of beta-keratin and air that produce non-iridescent color. These structural colors are the result of wavelength-selective scattering from nanostructures which have well-defined length scales but no long-range translational order. We quantify the optical properties of feathers with angle-resolved reflectance spectra and compare them to the nanostructure observed with X-ray scattering. We are exploiting self-assembly of polymeric and colloidal systems to create biomimetic nanostructures that capture the essential optical properties of bird feathers. By varying the characteristic length scale and index of refraction contrast of these structures we aim to enhance and tune wavelength selectivity.

9:36AM H40.00009 Directed Fluid Transport and Mixing with Biomimetic Cilia Arrays, A.R. SHIELDS, University of North Carolina - Chapel Hill, B.K. EVANS, Eric University, B.L. CARSTENS, M.R. FALVO, S. WASHBURN, R. SUPERFINE, University of North Carolina - Chapel Hill — We present results on the long-range, directed fluid transport and fluidic mixing produced by the collective beating of arrays of biomimetic cilia. These artificial cilia are arrays of free-standing nanorods roughly the size of biological cilia, which we fabricate from a polymer-magnetic nanoparticle composite that can be moved on a nanometer scale and actuated with permanent magnets to mimic biological cilia. The artificial cilia are modeled to produce low Reynolds number fluid transport and are increasingly being recognized as critical components in a wide range of biological systems. However, despite much effort cilia generated fluid flows remain an area of active study. In the last decade, cilia-driven fluid flow in the embryonic node of vertebrates has been implicated as the initial left-right symmetry breaking event in these embryos. With silica we generate directional fluid transport by mimicking the tilted conical beating of these nodal cilia. By seeding fluorescent microparticles into the fluid we have noted the existence of two distinct flow regimes. The fluid flow is directional and coherent above the cilia tips, while between the cilia tips and the floor particle motion is complicated and suggestive of chaotic advection.

9:48AM H40.00010 Physics of phagocytosis of foreign versus self-tolerance, RICHARD TSAI, PIA RO-DRIGUEZ, DENNIS DISCHER, University of Pennsylvania — The first cells to ‘attack’ an implanted or injected foreign material or microbe are phagocytic cells of the innate immune system. These cells actively and rapidly phagocytose foreign cells, surfaces, or particles, but the process is inefficient when faced with “self” cells. We have examined the biochemistry and some of the physics of this decision to eat or not eat. One particular protein on all animal cell membranes, called CD47, seems to engage phagocytic cell counter-receptors, and deactivate the force-generating myosin machinery that otherwise makes phagocytosis efficient. We will map the phagocytic synapse between phagocytes and particles or cells and describe the physicochemical dynamics that mediate this key decision in compatibility.

10:00AM H40.00011 The Dynamics of Foraging Ants, G. WILLIAM BAXTER, Penn State Erie, The Behrend College — We experimentally study the foraging of small black ants, Formicinae lasius fulvus, in order to describe their foraging behavior mathematically. Individual ants are allowed to forage on a two-dimensional surface in the absence of any food sources. The position of the ant as a function of time is determined using a high-resolution digital camera. Analysis of the average square displacements of many ants suggests that the foraging strategy is a non-reversing random walk. Moreover, the ants do not retrace their steps to return home but instead continue the random walk until it brings them back near their starting point.

10:12AM H40.00012 Elasticity in Ionically Cross-Linked Neurofilament Networks, NORMAN YAO, YI-CHIA LIN, Harvard University Department of Physics, CHASE BROÖDERSZ, Vrije University, KAREN KASZA, Harvard University SEAS, FREDERICK MACKINTOSH, Vrije University, DAVID WEITZ, Harvard University Department of Physics and SEAS — Neurofilaments are found in abundance in the cytoskeleton of nerve cells and they experience mechanical forces from extracellular stresses. To elucidate the nature of the mechanical properties that provide this protection, we measure the linear and nonlinear viscoelastic properties of networks of neurofilaments. These networks are soft solids that exhibit dramatic strain stiffening above critical strain ranges of 30-70%. Surprisingly, divalent ions, such as Mg$^{2+}$, Ca$^{2+}$, and Zn$^{2+}$, act as effective cross-linkers for neurofilament networks, controlling their solid-like elastic response. This behavior is comparable to that of actin-binding proteins in reconstituted filamentous actin. We show that the elasticity of neurofilament networks is entropic in origin and is consistent with a model for cross-linked semiflexible networks, which we use to quantitatively model cross-linking networks. Ultimately, we are able to extract microstructural network parameters such as the persistence length and the average distance between cross-links directly from bulk rheology.

10:24AM H40.00013 Exploring Cell-Assisted Cell Growth, ELLIJA BOGART, SHARON LAU, AMRISH DESHMUKH, CARL FRANCK, Cornell University — The population dynamics of microbial life in sheared liquid suspension affords opportunities to explore the ways in which cells can use each other to proliferate. Such elegant systems continue to inspire us to develop and test simple theories for cooperative behavior (e.g. Phys. Rev. E v. 77, p. 041905 (2008)) in living matter. We report on new insight afforded by the observation of the amoebae Dictostelium discoideum of the effect of population growth of the introduction of adhesive contacts of cells with each other as well as solid substrates. Through a hydrodynamic scaling argument we find that mechanical triggers provided by intercellular collisions are more important than collisions with container walls in encouraging growth. Finally, we confirm the discovery of a strain that lacks growth regulation due to density sensing. This work was supported by the NIH (P01 GM07856).

10:36AM H40.00014 Small Molecules Target Carcinogenic Proteins, CLAUDIU GRADINARU, University of Toronto — An ingenious cellular mechanism of effecting protein localization is prenylation: the covalent attachment of a hydrophobic prenyl group to a protein that facilitates protein association with cell membranes. Fluorescence microscopy was used to investigate whether the oncogenic Stat3 protein can undergo artificial prenylation via high-affinity prenylated small-molecule binding agents and thus be rendered inactive by localization at the plasma membrane instead of nucleus. The same approach was performed on a biological framework protecting the neuron from extracellular stresses. To elucidate the nature of the mechanical properties that provide this protection, we measure the linear and nonlinear viscoelastic properties of networks of neurofilaments. These networks are soft solids that exhibit dramatic strain stiffening above critical strain ranges of 30-70%. Surprisingly, divalent ions, such as Mg$^{2+}$, Ca$^{2+}$, and Zn$^{2+}$, act as effective cross-linkers for neurofilament networks, controlling their solid-like elastic response. This behavior is comparable to that of actin-binding proteins in reconstituted filamentous actin. We show that the elasticity of neurofilament networks is entropic in origin and is consistent with a model for cross-linked semiflexible networks, which we use to quantitively model cross-linking networks. Ultimately, we are able to extract microstructural network parameters such as the persistence length and the average distance between cross-links directly from bulk rheology.

10:48AM H40.00015 Direct observation of DNA dynamics toward solid state nanopore studied by fluorescence microscopy, TOMOHARU TAKITA, NORIYUKI TOYAMA, KAYA KOBAYASHI, TOSHIYUKI MITSU, Aoyama-Gakuin University — Translocation of single DNA through a solid state nanopore provides information of the length and the folding configuration of the DNA by sensing the ionic current profile. This sensing method opens the possibility to characterize individual polynucleotide molecule such as DNA and RNA and their interaction with various proteins. The interesting phenomena related to the nanopore based DNA sensing with the translocating ionic current have been reported recently and we also have found unexpected clogging probability of DNA into pore as a function of the biased voltage across the pore membrane. To visualize these phenomena as the dynamics of individual DNA molecule near nanopore, we have used fluorescence microscopy. The acceleration of DNA caused by an attractive force toward nanopore was observed in sequential images of the microscope images. By applying the langevin equations to follow the dynamical motion of DNA, the electric fields near the nanopore under the various biased voltages and ionic concentrations were estimated in DNA solution. In this presentation, we will report the results of the estimated electric fields near nanopore and discuss the shape of the potential.
8:00AM H41.00001 X-ray Diffraction measurements of the CDW phase in doped TiSe₂ and NbSe₂ , J.P. CASTELLAN, Argonne Nat. Lab, C.D. MALLIAKAS, Northwestern University, M. LAVARONE, S. ROSENKRAZ, Argonne Nat. Lab., R. OSBORN, Argonne Nat. Lab., F. WEBER, Argonne Nat. Lab. — Layered transition metal chalcogenides display a phase diagram similar to that of high Tc superconducting materials. In high Tc materials the superconductivity coincides with the suppression of magnetic order. In the case of TiSe₂ and NbSe₂ the onset of superconductivity involves a charge density wave (CDW) rather than magnetic order. The phase diagram of doped TiSe₂ and NbSe₂ has so far been interpreted as a competition of the CDW order and superconductivity order parameters. Another interpretation is that the softening of the excitons responsible for the CDW order enables the superconductivity. We have measured diffuse scattering associated with the fluctuations in the order parameter of the CDW on either side of the quantum phase transition using X-ray scattering. We will present the behavior of the critical exponents as the quantum phase transition is approached and discuss whether there is a coupling of the CDW and superconducting order parameters. Work supported by US DOE BES-DMS DE-AC02-06CH11357

8:12AM H41.00002 Interplane and Intraplane Coupling in Charge-Density-Wave Phases of 1T-TaS₂ and 1T-TaSe₂ , YIZHI GE, AMY LIU, Georgetown University — At low temperatures, the layered transition metal dichalcogenides 1T-TaS₂ and 1T-TaSe₂ adopt similar charge-density wave structures corresponding to a √3 x √3 reconstruction in which the Ta atoms cluster within the triangular layers. Yet TaS₂ also undergoes a metal-insulator transition, while TaSe₂ does not. Here we present a density-functional-theory study of the electronic structure of 1T-TaS₂ and 1T-TaSe₂. The half filled Ta d band at the Fermi level is found to differ significantly in the two materials: in TaSe₂ the band is three dimensional, while in TaS₂ it is highly one dimensional. These results are analyzed using maximally localized Wannier functions. The effects of stacking sequence and the spin-orbit interaction will also be discussed.

8:24AM H41.00003 A time-resolved observation of collective phenomena in the CDW compound TbTe₃ , F. SCHMITT, Stanford University, P. S. KIRCHMANN, U. BOVENSIEPEN, F. U. Berlin, R. G. MOORE, SRL, L. RETTIG, M. KRENZ, F. U. Berlin, J.-H. CHU, N. RU, Stanford University, L. PERFETTI, F. U. Berlin, D.-H. LIU, SRL, M. WOLF, F. U. Berlin, I. FISHER, Z.-X. SHEN, Stanford University — Strong correlations and collective phenomena in solids are a fascinating and challenging area of physics. Understanding how the interactions between the constituents give rise to collective phenomena like phase transitions and collective modes will greatly enhance our understanding in solid state physics. One such system, the Rare Earth TlTetrilulrides RT₆₃, is an excellent model system for a systematic study of charge-density wave (CDW) physics. We have performed time-resolved angle-resolved photoelectron spectroscopy (trARPES), a novel form of pump-probe spectroscopy, on Tb₆₃ and we will present our newest results. We observe two collective modes and what we term the time-dependent melting of the CDW, which we discussed earlier. Here, we will focus primarily on the detailed properties of the two collective modes.

8:36AM H41.00004 Voltage Induced Torsional Strain in Tantalum Trisulfide in its CDW State , J. NICHOLS, JUN ZHOU, L. LADINO, J.W. BRILL, University of Kentucky — In 2007, Pokrovskii et al [Phys. Rev. Lett. 98, 206404 (2007)] reported that crystals of tantalum trisulfide spontaneously twist when a voltage near the CDW depinning threshold is applied. The direction of twist reverses when the voltage is reversed, so that the twist angle describes a characteristic hysteresis loop as a function of applied voltage or current. We have studied this effect by placing the sample inside a resonant RF cavity so that the twisting sample modulates the resonant frequency of the cavity. A magnetic wire is attached to the sample so that magnetic torque can also be applied to the sample. We have reproduced the "Pokrovskii effect" and also observed the complement: application of torque induces an additional strain when the sample is biased above threshold. We have also found that the onset of the torsional strain occurs at a voltage slightly below that at which the shear modulus of the sample softens.

8:48AM H41.00005 Evidence for coupling between charge-density-wave and phonons in two-dimensional rare-earth tri-tellurides , M. LAVAGNINI, ETH-Zurich, M. BALDINI, La Sapienza Rome, A. SACCHETTI, ETH-Zurich, D. DI CASTRO, La Sapienza Rome, B. DELLEY, PSI Villigen, R. MONNIER, ETH-Zurich, J.H. CHU, N. RU, I.R. FISHER, Stanford University, P. POSTORINO, La Sapienza Rome, L. DEGIOGRI, ETH-Zurich — We report on a Raman scattering investigation of the charge-density-wave (CDW), quasi two-dimensional rare-earth tri-tellurides RT₆₃ (R=Ta, Ce, Pr, Nd, Sm, Gd and Dy) at ambient pressure, and of LaTe₃ and CeTe₃ under externally applied pressure. The observed phonon peaks can be ascribed to the Raman active modes for both the undistorted as well as the distorted lattice in the CDW state by means of a first principles calculation. The latter also predicts the Kohn anomaly in the phonon dispersion, driving the CDW transition. The integrated intensity of the two prominent modes scales as a characteristic power of the CDW-gap amplitude upon compressing the lattice, which provides clear evidence for the tight coupling between the CDW condensate and the vibrational modes.

9:00AM H41.00006 Pressure dependence of the single particle excitation in the charge-density-wave CeTe₃ system , L. DEGIOGRI, M. LAVAGNINI, A. SACCHETTI, ETH-Zurich, C. MARINI, M. VALENTINI, R. SOPRACASE, A. PERUCCHI, P. POSTORINO, S. LUPI, La Sapienza Rome, J.H. CHU, I.R. FISHER, Stanford University — We present data on the pressure dependence at 300 K of the optical reflectivity of CeTe₃, which undergoes a charge-density-wave (CDW) phase transition well above room temperature. The collected data cover an unprecedented broad spectral range from the infrared up to the ultraviolet, which allows a robust determination of the gap as well as of the fraction of the Fermi surface affected by the formation of the CDW condensate. Upon compressing the lattice there is a progressive closing of the gap inducing a transfer of spectral weight from the gap feature into the Drude component. At frequencies above the CDW gap we also identify a power-law behavior, consistent with findings along the RT₆₃ series (i.e., chemical pressure) and suggestive of a Tomonaga-Luttinger liquid scenario at high energy scales.
9:12AM H41.00007 Far infrared magnetospectroscopy of quasi-1D and 2-D density wave compounds,1 A.F. ISAKOVIC, G.L. CARR, NSLS, Brookhaven National Lab — We report a far infrared reflectance study of quasi-1D blue bronze (K1.3MoO3)2 and magnetically doped quasi-2D Mn611–xBa11xBi2223 over the temperature range from 10K up to 180K and fields up to 10T. For blue bronze, several features in the magnetoreflectance spectra, including amplitude and phonon-like modes, change substantially (up to 50%) when a magnetic field is applied. For 100K< <180K (below the CDW Tc of 183K), the spectra change nearly monotonically with T. Changes at lower T involve primarily the amplitude mode (CDW order parameter), consistent with creep transport of the CDW. The B and T dependent spectra of Mn doped NbSe2 reveal the presence of an isosbestic point near 5 meV photon energy and having a shape suggesting a local transfer of oscillator strength. The magnetoreflectance changes abruptly around a temperature of 16K for fields below 6T. Though a Drude-Lorentz fit can be applied to the spectra, a full understanding of charge transport in these materials will require a more detailed model.

9:24AM H41.00008 Microwave dielectric study of spin-Peierls and charge ordering transitions in (TMTTF)2PF6 salts, MARIO PORIER, ALEXANDRE LANGLOIS, CLAUDE BOURBOUNNAIS, Universite de Sherbrooke, PASCALE FOURY-LEYLEKIAN, ALEC MORAPOUR, Universite Paris XI Orsay — Using a microwave cavity perturbation technique at 16.5 GHz, we report a temperature and magnetic field study of the complex dielectric function along the stacking a-axis for a (TMTTF)2PF6, single crystal and its deuterated analog (d12). For both salts, the charge ordering transition (CO) is characterized by a decrease of the dielectric constant εa centered at TC0 (65 K and 85 K); concomitantly, the dielectric losses go through a maximum near TC0 and decreases rapidly below. The spin-Peierls transition (SP) is rather signalled by a rapid increase of εa below TSP (16 K and K3 K) accompanied by a small peak in the losses. For the deuterated salt, we have observed important relaxation effects below 40 K that complicate the analysis of the dielectric function in the SP ground state. The temperature dependence of the SP anomalies was analysed in magnetic field values up to 18 Tesla.

9:36AM H41.00009 NMR spin echo measurements of sliding spin density wave repinning in (TMTSF)2SbF6, W.G. CLARK, UCLA Physics and Astronomy, M.E. HANSON, SAP Labs, LLC., ERNEST W.H. WONG, Varian Inc. — We report the repinning rate of sliding spin density waves (SDW’s) in (TMTSF)2PF6, obtained from proton spin echo measurements. This method provides a local measurement of the square of the magnitude of the SDW velocity averaged over the sample as a function of time after the electric field responsible for the SDW sliding is reduced to below its depinning value. It shows a slow decay of the SDW current which we attribute to the corresponding adjustment of the SDW phase to the pinning centers and relaxation of the strain of the sliding SDW. Above the temperature T ~4 K, a thermally activated behavior for the characteristic decay time is observed whose activation energy of 2±1 K is close to the single electron excitation gap. This indicates that above 4 K, the repinning rate is dominated by thermally excited electrons. Below 4 K, a much weaker T-dependence is observed suggesting that tunneling may become the dominant repinning mechanism at lower T.

9:48AM H41.00010 Low-temperature states in quasi-one-dimensional charge transfer salt (TMTSF)2SbF6 studied by 13C NMR under hydrostatic high pressures, FUMITATSU IWASE, Institute for Molecular Science, KOICHI SUGIURA, The Graduate University for Advanced Studies, KOU FURUKAWA, TOSHIKAZU NAKAMURA, Institute for Molecular Science — We report 13C NMR study of a quasi-one-dimensional charge transfer salt, (TMTSF)2SbF6, under the application of the hydrostatic pressure. The antiferromagnetic phase transition at ambient pressure was confirmed by the line splitting and the divergent increase of the spin-lattice relaxation rate 1/T1. Under ~5 kbar, 1/T1 decreases abruptly at low temperatures without the enhancement, indicating that the ground state is a spin-gapped phase. However, the decrease of the Knight shift expected for spin-Peierls phase transition has not been observed. We observed additional lines, which split symmetrically, at low T, possibly originating from other states.

10:00AM H41.00011 The Theory of the Field-Induced Charge-Density-Wave Phases,1 ANDREI LELED, Dept. of Physics, University of Arizona — We study a problem about the appearance of the Field-Induced Charge-Density-Wave (FICDW) phases in a quasi-one-dimensional conductor in high magnetic fields. The calculated ratios for critical magnetic fields of the different FICDW phase transitions are in very good agreement with the existing experimental data in alpha-(ET)2K(Hg(SCN)4).

10:12AM H41.00012 Realistic Parameters for the Description of Organic Metals, ANDREAS DOLFEN, German Research School for Simulation Sciences, Germany, ERIK KOCH, Institut für Festkörperforschung, Forschungszentrum Jülich, Germany, VOLKER BLUM, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany, LAURA CANO-CORTES, JAIME MERINO, Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Spain — In molecular crystals correlation effects are often significant. For a non-perturbative description of the full Coulomb interaction we have therefore to resort to a model description in terms of generalized Hubbard models. The derivation of parameters for such models is crucial for realistic simulations. While hopping parameters are easily derived from density-functional theory (DFT) the Coulomb parameters pose a significant problem due to screening processes. We decompose their contributions into intra- and inter-molecular parts. The intra-molecularly screened parameters are realistic and the distributed-dipole approach in combination with a Ewald summation. Even for simple lattices of polarizable point dipoles we find intriguing screening phenomena. As realistic applications we discuss the one- and two-dimensional organic metals TTF-TCNO and θ-(BEDT-TTF)2I3.

10:24AM H41.00013 Spinodal decomposition of the charge ordering in the θ-based organic salt, MAJED ABDDEL-JAWAD, ICHIRO TERASAKI, Waseda University, HATSUMI MORI, University of Tokyo, TAKEHIKO MORI, Tokyo Institute of Technology — We have measured with X-ray diffraction, resistivity and thermopower the spinodal decomposition of the long range charge ordering in the organic compounds θ-(BEDT-TTF)2RbZn(SCN)4 and θ-(BEDT-TTF)2RbCo(SCN)4. Details of this spinodal decomposition reveals that the charge ordering growth in these compounds follows at first a two dimensional diffusion controlled mode followed abruptly by a change to a three dimensional diffusion controlled growth. Thermopower reveals that the long ranged charge ordered state in these compounds is characteristic of a system with strong on-site repulsion with narrow bandwidths. In contrast to this, the thermopower of the short ranged charge ordering is anomalous not only in its value but also in its temperature dependence.
are either not exactly coplanar with graphene, or are correlated, or are not the only source of disorder. This work is supported by the NSF.

dielectric-constant environment where Coulomb interactions of electrons with impurities and electrons with each other become weak. We show that screening

solution of the model of graphene subject to the disorder in the form of in-plane charged impurities. Our approach is asymptotically exact for graphene in high

nature of disorder at the NP and the still unsettled question of which type of disorder is really dominant. Here, we report on our progress towards analytical

socalled $\rho_{xx}(\theta, \phi)$ of the layered organic conductor (DMET)$_2$I$_3$ is reported for all possible orientations in a 9T magnetic field at 100 mK, and compared with existing theoretical models. We have also calculated $\rho_{x}\perp$ for such Q1D conductors using semiclassical calculations employing, for the first time, the true triclinic crystal structure. These calculations are in qualitative agreement with our data, especially in the $\gamma - z$ plane, where all previous models fail to reproduce the experimentally observed Lebed magic angle effect. These results will be useful to understand the relationship between the different kinds of angular effects in this and other families of layered organic conductors. Session J1 DCMP: Ballistic-Diffusive Crossover in Graphene Electron Transport
Spirit of Pittsburgh Ballroom A

11:15AM J1.00001 Electrical transport in suspended graphene, KIRILL BOLOTIN, Columbia University — Many quantum limit transport phenomena in graphene remain yet to be observed due to the omnipresence of carrier scattering. We report a sample preparation method that yields high quality graphene specimens and demonstrates that much of the scattering in traditional graphene-on-silica devices is not intrinsic but rather results from the interaction with the substrate underlying the graphene. We fabricate devices where electrically contacted and electrostatically gated graphene flakes are suspended over a substrate and use current-induced heating to remove the remaining impurities. The measured mobilities are found to exceed 200,000 cm$^2$/Vs in such devices, an order of magnitude improvement over the best values reported in the literature. The very high mobility of our specimens allows us to probe previously inaccessible transport regimes in graphene. At low temperatures transport is near-ballistic in a device of $\sim$2µm dimension. At large carrier density, we observe linear increase of resistivity with temperature, consistent with scattering off acoustic phonons. At near-room temperature we observe the mobility is $\sim$120,000 cm$^2$/Vs, higher than in any known semiconductor.

11:51AM J1.00002 A self-consistent theory for graphene transport, SHAFFIQUE ADAM, University of Maryland — Arguably, one of the most intriguing properties of graphene transport is the non-vanishing “minimum conductivity” at the Dirac point. The carrier density in these single monatomic sheets of carbon can be continuously tuned from electron-like carriers for large positive gate bias to hole-like carriers for negative bias. The physics close to zero carrier density (also called the intrinsic or Dirac region), is now understood to be dominated by the inhomogeneous situation where the local potential fluctuates around zero, breaking the landscape into puddles of electrons and holes. Here, we propose and discuss a particular hierarchy of approximations to understand graphene transport properties that includes a tight binding approximation for the low energy effective Hamiltonian, Random-Phase-Approximation to treat electron-electron interactions, the semi-classical Boltzmann transport theory to treat scattering of electrons by short and long-ranged disorder, and a self-consistent Fermi-Thomas approximation to treat impurity induced density inhomogeneity [1-2]. We find that this self-consistent theory for graphene transport is in remarkable agreement with recent experiments [3-5]. To better understand the range of validity of this theory we relax some of the assumptions and include the effects of tunneling [6], calculate transport properties using an effective medium theory [7], and examine the effects of phase-coherent quantum transport [8]. We believe that while most of the dc transport experiments on bulk graphene samples at zero magnetic field are in the parameter regime correctly captured by the semi-classical diffusive self-consistent transport theory, we demonstrate theoretically that by tuning external parameters, it is possible to access several other transport regimes.

12:27PM J1.00003 Theory of an inhomogeneous electron structure of graphene at its neutrality point, MICHAEL FOLGER, University of California, San Diego — Graphene is a surprisingly good conductor. Despite its direct exposure to various sources of disorder (charged impurities, non-uniformity of the substrate, etc.), graphene remains conductive even when the nominal concentration of both electron and hole carriers drops to zero - the neutrality point (NP). Theory of the minimal conductivity of graphene is an outstanding challenge because of the non-perturbative nature of disorder at the NP and the still unsettled question of which type of disorder is really dominant. Here, we report on our progress towards analytical solution of the model of graphene subject to the disorder in the form of in-plane charged impurities. Our approach is asymptotically exact for graphene in high dielectric-constant environment where Coulomb interactions of electrons with impurities and electrons with each other become weak. We show that screening of the impurity potential is nonlinear, producing a fractal structure of electron and hole puddles. Statistical properties of this density distribution as well as the charge compressibility of the system are calculated in the leading-log approximation. The minimal conductivity is shown to depend logarithmically on the dielectric constant. We compare our results with other theoretical works and current experiments. Our findings suggest that in real samples charged impurities are either not exactly coplanar with graphene, or are correlated, or are not the only source of disorder. This work is supported by the NSF.
1:03PM J1.00004 Electronic Transport in Disordered Graphene Sheets and Nanoribbons
EDUARDO R. MUCCIOLO, University of Central Florida — In this talk I will present recent results of our numerical simulations of electronic transport in disordered graphene. Issues related to the scaling of the conductivity and the shot-noise Fano factor of large graphene sheets at zero and finite doping will be discussed. Our calculations are based on an efficient implementation of the recursive Green function method. I will also show how edge and bulk disorder may affect the mesoscopic conductance of graphene nanoribbons under a variety of realistic situations. We find that even for weak edge roughness, conductance steps are suppressed and a transport gap develops near the neutrality point due to strong localization. The gap inferred from our simulations is similar in magnitude to the energy gaps induced by other mechanisms, such as Coulomb blockade, multi-body correlations, and lattice distortions. The effects of dephasing will also be discussed.

1:39PM J1.00005 Electron fractionalization in two-dimensional graphenelike structures CLAUDIO CHAMON, Boston University — Electron fractionalization is intimately related to topology. In one-dimensional systems, such as polycatenane, fractionally charged states exist at domain walls between degenerate vacua. In two-dimensional systems, fractionalization exists in quantum Hall fluids, where time-reversal symmetry is broken by a large external magnetic field. Recently, there has been a tremendous effort in the search for examples of fractionalization in two-dimensional systems with time-reversal symmetry. Here we show that fractionally charged topological excitations exist in tight-binding systems where time-reversal symmetry is respected. These systems are described, in the continuum approximation, by the Dirac equation in two space dimensions. The topological zero-modes are mathematically similar to fractional vortices in p-wave superconductors. They correspond to a twist in the phase in the mass of the Dirac fermions, akin to cosmic strings in particle physics. The quasiparticle excitations can carry irrational charge and irrational exchange statistics. These excitations can be deconfined at zero temperature, but when they are, the charge re-rationalizes to the value 1/2. REFS.: Chang-Yu Hou, Claudio Chamon, Christopher Mudry, Phys. Rev. Lett. 98, 186809 (2007); Claudio Chamon, Chang-Yu Hou, Roman Jackiw, Christopher Mudry, So-Young Pi, Andreas P. Schnyder, Phys. Rev. Session J2 DCMP: Dynamical Layer Decoupling and Stripe Order High Tc Superconductors
Spirit of Pittsburgh Ballroom BC

11:15AM J2.00001 Towards two-dimensional superconductivity in La_{2-x}Sr_{x}CuO_{4} in a moderate magnetic field^1 ALEXANDER SCHAFFGANS, Department of Physics, University of California, San Diego — We report a novel aspect of the competition and coexistence between antiferromagnetism and superconductivity in the prototypical high-Tc cuprate La_{2-x}Sr_{x}CuO_{4} (La214). With a modest magnetic field applied H || c-axis, we monitored the infrared signature of pair tunneling between the CuO2 planes and discovered the complete suppression of interlayer coupling in a series of La214 single crystals. We find that the in-plane superconducting properties remain largely intact, in spite of increased antiferromagnetism in the planes. Thus, our experiments show that an isolated CuO2 plane is capable of maintaining high-Tc superconductivity. The theoretical framework for antiferromagnetic-driven interlayer decoupling is identified in the work of Berg, et. al. [E. Berg, et. al., Phys. Rev. Lett. 99, 127003 (2007) and Cond-mat arXiv:0810.1564].

^1Work at UCSD is supported by the National Science Foundation (NSF-DMR-0705171)

11:51AM J2.00002 Theory of a striped superconductor ERZE BERG, Stanford — In the spin and charge striped-ordered cuprate La_{1-x}Ba_{x}CuO_{4}, the bulk superconducting Tc is strongly suppressed to about 4K. Nevertheless, recent experiments revealed unusual superconducting fluctuations far above Tc. In particular, these experiments show evidence for 2D superconductivity in this 3D (albeit anisotropic) system, which is unprecedented. We propose an explanation of these results in terms of a new phase, the “striped superconductor”, in which the superconducting order parameter is modulated periodically in space and averages to zero. Such a state can naturally explain the apparent vanishing of the inter-layer Josephson coupling in La_{1-x}Ba_{x}CuO_{4}. We discuss several phenomenological features of this phase, including a unique sensitivity to disorder which can lead to an “xy gauge glass” phase that breaks time reversal symmetry spontaneously. Possible microscopic mechanisms leading to striped superconductivity will be briefly discussed.

12:27PM J2.00003 Electronic liquid-crystal phases, symmetry breaking and Fermi-surface reconstruction in YBa_{2}Cu_{3}O_{6+x}^1 VLADIMIR HINKOV, Max-Planck-Institute for Solid-State Research, Stuttgart, Germany — The physics of undoped cuprates is governed by strong correlations and phase competition, and its understanding remains one of the challenges of condensed-matter research. Here we will discuss our systematic doping- and temperature-dependent neutron-scattering investigation of the spin correlations in underdoped YBa_{2}Cu_{3}O_{6+x} (YBCO) in the context of various proposed symmetry-breaking phases. In YBCO6.45 (Tc = 35 K), we observe the spontaneous onset of a one-dimensional, incommensurate (IC) modulation of the low-energy (< 10 meV) spin excitations below T ≈ 150 K, Hinkov et al., Science 319, 597 (2008). We interpret our finding as the occurrence of an electronic liquid-crystal phase breaking C4 symmetry, as predicted by Kivelson et al., Nature 393, 550 (1998). Below T ≈ 30 K, we observe the onset of quasi-static spin-correlations with the same IC geometry as the low-energy spin excitations. Their intensity is doubled by the application of a magnetic field of 15 T. First of all, this resolves a long-standing discrepancy with the La_{2-x}(Sr,Ba)_{x}CuO_{4} family where field-dependent, IC quasi-static spin correlations were reported before (Lake et al., Nature 415, 299 (2002)). More importantly, our results show how the recently reported quantum oscillations in high magnetic fields in YBa_{2}Cu_{3}O_{6.5} (Doiron-Leyraud et al., Nature 447, 565 (2007)) can be understood in terms of a Fermi-surface reconstruction induced by IC spin modulations. In the lack of experimental evidence for such IC modulations, this mechanism has not been pursued in the past, although it was discussed as a straightforward explanation for Fermi-surface reconstruction. Finally, we will discuss YBCO with a Tc of 10 K. Compared to the previous example, there is an enhancement of the quasi-static spin-correlations. In addition, there is indication for incipient commensurate AF order in reminiscence of the AF parent compound.

1:03PM J2.00004 Stripe order, electron pockets, and Fermi arcs^1 MICHAEL NORMAN, Materials Science Division, Argonne National Laboratory — The recent observation of an electron pocket by quantum oscillation experiments is naturally explained by the presence of magnetic stripe order near 1/8 hole doping in cuprates [1]. A bigger question is how these observations are related to other phenomena in the phase diagram - the pseudogap phase, quantum critical points, and Fermi arcs [2], and the implications this might have for the origin of high temperature superconductivity.

^1Work at Argonne National Laboratory was supported by the U.S. DOE, Office of Science, under Contract No. DE-AC02-06CH11357.
1:39PM J2.00005 Magnetic Field and Temperature Dependence of Charge Stripe Order in La2-xBaxCuO4 (x~1/8),1, YOUNG-JUNE KIM, University of Toronto — We report a comprehensive x-ray scattering study of charge stripe ordering in La2-xBaxCuO4 (x~1/8), for which the bulk superconducting Tc is greatly suppressed. We found that the charge order in this sample is described with one-dimensional charge density waves, which have incommensurate wave-vectors (0.23, 0, 0.5) and (0, 0.23, 0.5) respectively on neighboring CuO2 planes. The structural modulation due to the charge stripe order is simply sinusoidal, and no higher harmonics were observed. Just below the structural transition temperature, short-range charge density wave correlation appears, which then develops into a large scale charge ordering around 40 K, close to the spin density wave ordering temperature. However, this charge ordering fails to grow into a true long range order, and its correlation length saturates at ~23 nm, and slightly decreases below about 15 K. In addition, we report our observation of the unusual magnetic field dependence of the charge order correlation length. Specifically, in the superconducting phase the charge order correlation length increases as the magnetic field greater than ~5 T is applied.

Tuesday, March 17, 2009 11:15AM - 2:15PM —

Session J3 DCMP: SQUID Amplifiers: at the Quantum Limit

11:15AM J3.00001 Quantum information processing with the Josephson ring modulator, MICHEL DEVORET, Yale University — No abstract available.

11:51AM J3.00002 Nearly noiseless amplification of microwave signals with a Josephson parametric amplifier, MANUEL CASTELLANOS-BELTRAN, JILLA, NIST and the University of Colorado, and the Department of Physics, University of Colorado, Boulder, Colorado 0309-0440, USA — A degenerate parametric amplifier transforms an incident coherent state by amplifying one of its quadrature components while deamplifying the other. This transformation, when performed by an ideal parametric amplifier, is completely deterministic and reversible; therefore the amplifier in principle can be noiseless. We attempt to realize a noiseless amplifier of this type at microwave frequencies with a Josephson parametric amplifier (JPA). To this end, we have built a superconducting microwave cavity containing many dc-SQUIDs. This arrangement creates a non-linear medium in a cavity and it is closely analogous to an optical parametric amplifier. In my talk, I will describe the current performance of this circuit, where I show I can amplify signals with less added noise than a quantum-limited amplifier that amplifies both quadratures. In addition, the JPA also squeezes the electromagnetic vacuum fluctuations by 10 dB. Finally, I will discuss our effort to put two such amplifiers in series in order to undo the first stage of squeezing with a second stage of amplification, demonstrating that the amplification process is truly reversible.

12:27PM J3.00003 Flux-driven Josephson parametric amplifier, TSUYOSHI YAMAMOTO, NEC Corporation — Degenerate parametric amplifiers are phase sensitive amplifiers, which can in principle amplify one of the two quadratures of a signal without introducing extra noise. Parametric amplifiers based on the nonlinearity of an inductance of a Josephson junction have been studied for a long time. Recently, there has been a renewed interest in parametric amplifiers due in part to the increasing need for quantum-limited amplification in the field of quantum information processing using superconducting circuits. In the present work, we design a novel Josephson parametric amplifier, comprising a superconducting transmission-line resonator terminated by a dc SQUID. Contrary to the previous works, the pump is not used to directly modulate a current through the Josephson junction, but is instead used to modulate a flux through the dc SQUID. Because the dc SQUID determines the boundary condition of the resonator, the flux modulation gives the temporal variation of the resonant frequency, which leads to the parametric amplification of the signal coming into the resonator. The practical advantage of the scheme is, first, that the band center of the signal is widely controllable by a dc flux also applied to the SQUID. Second, as the pump and the signal are applied to different ports and their frequencies are twice different, it is straightforward to separate the output signal from the pump. We have operated such a flux-driven Josephson parametric amplifier at around 10 GHz and characterized its basic properties.

1:03PM J3.00004 Optimizing the Gain and Noise Temperature of Microstrip SQUID Amplifiers, DARIN KINION, LLNL — Microstrip SQUID amplifiers (MSA) offer near quantum-limited sensitivity and gains greater than 20 db at frequencies around 1 GHz. These properties make them desirable for applications ranging from dark-matter axion detection to dispersive readout of superconducting qubits. The input of the MSA is a microstrip transmission line in the shape of a square spiral coil surrounding the hole in the SQUID washer that serves as the ground plane. Near the fundamental resonance, there is strong flux coupling between the input coil and SQUID. To obtain maximum performance it is necessary to know the complete set of complex scattering parameters. We present measurements of the scattering parameters of MSAs cooled to 4.2 K. The input impedance is found by measuring the reverse scattering parameter (S11) and is described well by a low-loss transmission line model. We map the low-loss transmission line model into an equivalent parallel RLC circuit that accurately predicts the observed gain given by the forward scattering parameter (S21). This information is used to optimize the input and output matching circuitry to achieve optimal noise temperature and gain. We will present results for the gain, dynamic range, linearity and noise temperature of these optimized MSAs at 30-500 mK as a function of frequency and SQUID bias. We will compare the results to the prediction of the circuit model and to the theoretical expectation that the lowest noise temperature occurs off-resonance. This work is in collaboration with John Clarke and a portion of this work was supported by DOE.

1:39PM J3.00005 Lumped-Element DC-SQUID Microwave Amplifier, LAFE SPIETZ, NIST — We report on the development at NIST of microwave amplifiers in the 6-8 GHz frequency range using DC SQUIDs. Our design approach is to use small SQUIDs which can be modeled as lumped element circuits, thus separating the design process for the SQUID from that of the microwave impedance transformers. We present our model and measurements of the impedance, gain and noise temperature of these optimized MSAs at 30-500 mK as a function of frequency and SQUID bias. We will compare the results to the prediction of the circuit model and to the theoretical expectation that the lowest noise temperature occurs off-resonance. This work is in collaboration with John Clarke and a portion of this work was supported by DOE.

Tuesday, March 17, 2009 11:15AM - 2:26PM —

Session J4 CSWP, FIP: Panel Discussion: Around the World in 180 Minutes: Differences and Similarities among Women Physicists
World. KARIMAT EL SAYED, Physics Department, Faculty of Science, Ain-shams University — Until the end of the 19th Century Science was not

available female talent pool. If human society is to benefit to its fullest from various contributions that the field of physics can offer in addressing global issues

Although considerable progress has been made since 2002, it was clear that the global scientific workforce is still under-utilizing a large percentage of the

ICWIP unanimously approved a five-part resolution to IUPAP

recommendations actions to promote the recruitment, retention, and advancement of women in physics and related fields.

1 The Conference was partially supported by NSF (PHY#0824634).

12:10PM J4.00004 Marshak Lectureship Talk: Women in Physics in Egypt and the Arab World. KARIMAT EL SAYED, Physics Department, Faculty of Science, Ain-shams University — Until the end of the 19th Century Science was not classified into different disciplines. The first woman named in the history of science was Merit Ptah (2700 BC) in Egypt's Valley of the Kings. In the new Egypt the first girl's school started in Cairo in 1873 and the first University in 1908. Only a few girls attended the University at that time, mainly studying the humanities. The first Egyptian woman physicist graduated in 1940 and received her PhD in nuclear physics in the USA. Nowadays the number of women in physics is increasing in all branches of physics, some of them are senior managers and others have been decorated with various prizes. In this talk some statistics will be given to show the percentage of women in physics in relation to other fields of science in Egypt. In Saudi Arabia the first girls' school started in 1964 and the first college for women, which was a section of King Abdul-Aziz University (where education is not mixed), started in 1975. I was the founder of the Physics Department of this women's section. Egyptians have played significant roles in teaching schoolchildren and university students of both sexes in all the Arab countries: Saudi Arabia, Sudan, Kuwait, Yemen, the Gulf States, Libya, Lebanon, Syria, and Jordan. But with respect to Algeria, Tunisia and Morocco, our role was limited, since classes are taught in French. Arab women living in the countries located east of Egypt still have many difficulties facing them, needing to overcome many technical, academic, and social problems, while women in the countries located west of Egypt have fewer problems. There were many problems in the early days of education in Egypt but the women of Egypt worked hard to gain the same rights as men and were able to pave the way for all Arab women. I myself met many difficulties in my early days. This talk will also describe the impact of the regional conference on Women in Physics in Africa and Middle East, which was held in Cairo in 2007.

12:35PM J4.00005 Women Physicists in Asia. YOUNG-KEE KIM, Fermi National Accelerator Laboratory and University of Chicago — I will present the history of women scientists in Asian countries and discuss the current status and experiences from women physicists, and ways to create a better future for women in physics.

1:11PM J4.00006 Women in Physics: A Caribbean Perspective. KANDICE TANNER, University of California, Berkeley — This paper is concerned with aspects of post-secondary education of women in physics in the Caribbean, focusing more specifically on the main university campuses in Trinidad and Tobago, Jamaica, and Barbados. Within this framework, there are three institutions of tertiary education that provide for undergraduate and post-graduate studies in physics. On average, the bachelor-level graduating class is roughly 40% female. A great majority of these students go on to seek master's degrees in engineering. Among those enrolled in graduate programs featuring research in astronomy, materials science, environmental physics, medical physics, and quantum physics. From October 2008, 31% of all the women in physics in the 25 selected countries and from the Caribbean region are engaged in bachelor and doctoral programs in physics abroad, but no formal survey is available to provide the relevant quantitative information. However, an attempt will be made to quantify this component. Based in part on personal experience, a comparison will be made between domestic and foreign educational pathways, in terms of access to resources, level of research training, and occupational opportunities following graduation.

1:36PM J4.00007 Panel Discussion. MODERATOR: CHERRILL SPENCER, SLAC National Accelerator Laboratory — Participants: Yevgeniya Zastavker, Franklin W. Tuesday, March 17, 2009 11:15AM - 2:15PM — Session J5 DPOLY: Polymer Nanoparticle Interactions 401/402
Simulations of Polymer Grafted Nanoparticles in a Polymer Matrix

11:15AM J5.00001

SMITH, University of Utah — We have performed molecular dynamics (MD) simulations of polymer-grafted nanoparticles in a polymer melt. The model is a coarse-grained representation of spherical nanoparticles with a grafted poly(methyl methacrylate)-like bead-spring polymer in a matrix of the same polymer. Simulations were performed on both a single polymer-grafted nanoparticle as well as for a pair of polymer-grafted nanoparticles. The nanoparticle has a diameter of 5 nm. We have investigated the role of the molecular weight of the grafted and matrix polymer on both brush structure and nanoparticle-nanoparticle interactions. We find that brush density profile is independent of matrix molecular weight. Furthermore, the matrix chains penetrate almost to the particle surface, and there is no extended region with zero or near-zero matrix chain density. Hence, the highly curved brush does not exhibit “dry brush” behavior that would be expected at this investigated grafting density. We observe a repulsive interaction between the nanoparticles that sets in at a separation consistent with the polymer brush height. The combined brush-brush plus matrix effect on the nanoparticle-nanoparticle interactions is repulsive at all separations. Our simulations profile reveals no matrix-induced attraction between nanoparticles that is anticipated when the brush are truly “dry”, i.e., largely non-penetrable by the matrix. Such behavior would be expected for larger particles where the surface curvature effects on brush structure and brush-melt interactions are less important. However, for small nanoparticles, our simulations reveal that surface curvature effects are very important in determining the structure of the grafted polymer as well as nanoparticle-nanoparticle interactions.

11:51AM J5.00002

KRISHNAMOORTI, University of Houston — Grafting polymers to nanoparticles has proven to be an effective means to disperse isotropic and anisotropic nanoparticles in polymer matrices. Depending on the grafting density, polydispersity and nature of polymer - nanoparticle interaction, such grafted nanoparticles can either be liquid-like, gel-like or crystalline solids. We examine here the nature of interactions between such grafted nanoparticles and correlate those to the structure, dynamics and transport in both solvent and polymer media.

Modification of Block Copolymers Using Surface-Functionalized Hard and Soft Nanoparticles

12:27PM J5.00003

RICHARD SPONTAK, North Carolina State University — Due to their wide range of available nanostructures, ordered block copolymers provide excellent templating media into which nanoparticles can be incorporated with precise spatial modulation for various nanotechnologies. Previous experimental and theoretical studies have demonstrated that the relative size and selectivity of surface-functionalized inorganic nanoparticles can be used to tune the position of the nanoparticles along interfacial regions or within microdomains. Using a combination of experimental and theoretical methods, we furthermore show that these parameters, in addition to nanoparticle concentration, can be used to controllably alter the phase stability of block copolymers. While nanoparticles typically reduce the order-disorder transition (ODT) temperature of ordered block copolymers, a limited window exists wherein the nanoparticles increase the ODT temperature and stabilize the copolymer nanostructure. This nanoparticle-mediated design is extended in this study to include "soft" nanoparticles composed of core-shell microgels (CSMG) particles, which can be envisaged as permanent micelles. Addition of CSMG particles to ultrathin films consisting of ordered block copolymers varying in morphology and molecular weight is investigated here by electron microscopy.

Polystyrene Single Crystal Meets Nanoparticle, Toward Ordered Hybrid Materials

1:03PM J5.00004

CHRISTOPHER LI, Department of Materials Science and Engineering, Drexel University, Philadelphia, PA 19104 — Judiciously selected polymer single crystal (PSC) systems can interplay with 1-D and 0-D nanoparticles, forming ordered hybrid structures. In this presentation, I will first focus on patterning PSCs on individual carbon nanotubes (CNT). Using both controlled solution crystallization, thin film crystallization and physical vapor deposition methods, CNTs were periodically decorated with PSCs, resulting in nano hybrid shish-kebab (NHSK) structures. Because the polymer kebabs can be easily removed, these unique NHSKs can serve as templates to fabricate a variety of CNTs-containing hybrid materials with controlled patterning on the CNT surface. Sub-20 nanometer alternating patterning was achieved by using crystalline block copolymers. The mechanism was attributed to the crystallization induced block copolymer phase separation. This pattern was successfully used to template nanoparticles (NP) patterning on CNTs. In the second part of the talk, I will discuss fabricating Janus NPs and patterning these NPs using PSCs. Single crystals of thiol-terminated polyethylene oxide (PEO) were incubated in a gold sol. Au-S bonds were formed between the AuNPs and the PEO single crystal surfaces. The inter-particle spacing was controlled by PEO molecular weights, the incubation time, and the annealing temperatures after incubation. The planar geometry of the PSCs led to Janus NP formation. A series of NP dimers, trimers and tetramers were synthesized. NP nanowires were also fabricated. We anticipate that this observation could lead to controlled synthesis of artificial molecules and NP chains for a variety of optical, electronic, and biomedical applications.

DNA Directed Nanoparticle Assemblies

1:39PM J5.00005

FRANCIS W. STARR, Wesleyan University — While DNA is mostly noted for carrying genetic information, a single strand of DNA is simply a polymer with chemically specific recognition. As a result, DNA is an interesting polymer to consider for the development of new materials. In particular, attaching single strands of DNA to nanoparticles offers the possibility to encode highly specific binding between nanoparticles to create engineered building blocks, or “functionalized atoms.” These core units are an ideal candidate for the development of network-based, nanostructured materials. In this talk, we present results from computer simulations of a coarse-grained model examining several choices and DNA functionalization, and show how these design choices can affect dynamics, phase behavior, and the formation of crystal structures. We first discuss nanoparticles functionalized by four single DNA strands. These units give rise to a material with a hierarchy of interpenetrating networked structure and four thermodynamically distinct amorphous phases, unlike any naturally occurring pure material. On the other hand, the mechanism for the formation of the amorphous phases offers insight into anomalous networked liquids like water and silica. We also consider how varying the number of functionalizing DNA strands alters both the number and shape of these phase transitions. The formation of very low density crystals of nanoparticles tethered by DNA has recently been achieved experimentally, but the factors controlling crystal formation are still not well understood. Therefore, we also discuss the results of nanoparticles uniformly coated with DNA, similar to experimental systems. We show how the DNA strand length and stiffness affects the competition between energy and entropy that controls crystal formation.

1 Support from NSF DMR-0427239.

Tuesday, March 17, 2009 11:15AM - 2:15PM — Session J6 DCOMP: Computational Modeling of Crystallization and Nucleation Phenomena
surface induced nucleation. This is related to both the local static and dynamical properties of liquid surface.

Furthermore, in contrast to the common assumption that regards surfaces as heterogeneous center, we identify the homogeneous preferential nucleation in close proximity of free surfaces is related to the density decrease occurring upon freezing, and surface tension facilitating the initial nucleation. We provide direct computational evidence of surface induced crystallization in supercooled systems with $dP/dT < 0$. We show that the possibility of observing preferential nucleation in close proximity of free surfaces is related to the density decrease occurring upon freezing, and surface tension facilitating the initial nucleation.

The implications of coupled nucleation processes on phase formation, stability and nanoscale crystallization are discussed.

**Liquid-to-crystal nucleation and gel formation.** EDUARDO SANZ

In collaboration with Chantal Valeriani, Soft Condensed Matter, Debye Institute for Nanomaterials Science, Utrecht University, SUPA, School of Physics, University of Edinburgh — We study the kinetics of the liquid-to-crystal transformation and of gel formation in colloidal suspensions of oppositely charged particles. We analyse, by means of both computer simulations and experiments, the evolution of a fluid droplet quenched to a state point of the phase diagram where the most stable state is either a homogeneous crystalline solid or a solid phase in contact with a dilute gas. On the one hand, at high temperatures and high packing fractions, close to an ordered-solid/disordered-solid coexistence line, we find that the fluid-to-crystal pathway does not follow the minimum free energy route. On the other hand, a quench to a state point far from the ordered-crystal/disordered-crystal coexistence border is followed by a fluid-to-solid transition through the minimum free energy pathway. At low temperatures and packing fractions we observe that the system undergoes a gas-liquid spinodal decomposition that, at some point, arrests giving rise to a gel-like structure. Both our simulations and experiments suggest that increasing the interaction range favors crystallization over vitrification in gel-like structures.

In collaboration with Chantal Valeriani, Soft Condensed Matter, Debye Institute for Nanomaterials Science, Utrecht University, Princetonplein 5, 3584 CC Utrecht, The Netherlands and SUPA, School of Physics, University of Edinburgh, JCMB King’s Buildings, Mayfield Road, Edinburgh EH9 3JZ, UK; Teun Vissers, Andrea Fortini, Mirjam E. Institute of Science and Technology — We investigated the robustness of cellular metabolism by simulating the system-level computational models, and also performed the corresponding experiments to validate our predictions. We address the cellular robustness from the “metabolite”-framework by using the novel concept of “flux-sum,” which is the sum of all incoming or outgoing fluxes (they are the same under the pseudo-steady state assumption). By estimating the state-of-the-art high-throughput experimental techniques generate just a binary (yes or no) information about individual interactions. As a result, most of the previous research concentrated just on topology of these networks. In a series of recent publications [1-4] my collaborators and I went beyond purely topological studies and calculated the mass-action equilibrium of a genome-wide binding network using experimentally determined protein concentrations, localizations, and reliable binding interactions in baker’s yeast. We then studied how this equilibrium responds to large perturbations [1-2] and noise [3] in concentrations of proteins. We demonstrated that the change in the equilibrium concentration of a protein exponentially decays (and sign-alternates) with its network distance away from the perturbed node. This explains why, despite a globally connected topology, individual functional modules in such networks are able to operate fairly independently. In a separate study [4] we quantified the interplay between specific and non-specific binding interactions under crowded conditions inside living cells. We show how the need to limit the waste of resources constrains the number of types and concentrations of proteins that are present at the same time and at the same place in yeast cells.

Tuesday, March 17, 2009 11:15AM - 2:15PM – Session J7 GSNP DBP: Complex Cellular Biological Networks 407

11:15AM J7.00001 Mass-action equilibrium and non-specific interactions in protein binding networks1, SERGEI MASLOV, Brookhaven National Laboratory — Large-scale protein binding networks serve as a paradigm of complex properties of living cells. These networks are naturally weighted with edges characterized by binding strength and protein-nodes – by their concentrations. However, the state-of-the-art high-throughput experimental techniques generate just a binary (yes or no) information about individual interactions. As a result, most of the previous research concentrated just on topology of these networks. In a series of recent publications [1-4] my collaborators and I went beyond purely topological studies and calculated the mass-action equilibrium of a genome-wide binding network using experimentally determined protein concentrations, localizations, and reliable binding interactions in baker’s yeast. We then studied how this equilibrium responds to large perturbations [1-2] and noise [3] in concentrations of proteins. We demonstrated that the change in the equilibrium concentration of a protein exponentially decays (and sign-alternates) with its network distance away from the perturbed node. This explains why, despite a globally connected topology, individual functional modules in such networks are able to operate fairly independently. In a separate study [4] we quantified the interplay between specific and non-specific binding interactions under crowded conditions inside living cells. We show how the need to limit the waste of resources constrains the number of types and concentrations of proteins that are present at the same time and at the same place in yeast cells.

12:27PM J7.00003 Synthetic rescues and spontaneous cascades in metabolic networks1, ADILSON E. MOTTER, Northwestern University — Using in silico experiments, I will show that organisms evolving to maximize growth rate, ATP production, or any other linear function of metabolic fluxes tend to significantly reduce the number of active metabolic reactions compared to typical non-optimal states. The reduced number appears to be constant across the microbial species studied and just slightly larger than the minimum number required for the organisms to grow at all. I will show that this massive reaction silencing is triggered by the irreversibility of a large fraction of the metabolic reactions and propagates through the network as a cascade of inactivity. Following these significant observations, I will introduce a network method to recover the loss of metabolic function due to mutations and other defects, which is based on bypassing rather than correcting the defective pathways. In particular, I will present predictions of synthetic recovery, in which the knock-out of one enzyme-coding gene results in a non-viable phenotype while the concurrent knock-out of a second enzyme-coding gene restores viability. In addition to their potential role in metabolic engineering and medical research, these results have puzzling implications for the recently observed temporary activation of latent pathways.

1:03PM J7.00004 Robustness of metabolic networks, HAWOONG JEONG, Department of Physics, Korea Advanced Institute of Science and Technology — We investigated the robustness of cellular metabolism by simulating the system-level computational models, and also performed the corresponding experiments to validate our predictions. We address the cellular robustness from the “metabolite”-framework by using the novel concept of “flux-sum,” which is the sum of all incoming or outgoing fluxes (they are the same under the pseudo-steady state assumption). By estimating the changes of the flux-sum under various genetic and environmental perturbations, we were able to clearly decipher the metabolic robustness; the flux-sum around a metabolite does not change much under various perturbations. We also identified the list of the metabolites essential to cell survival, and then “acclimator” metabolites that can control the cell growth were discovered. Furthermore, this concept of “metabolite essentiality” should be useful in developing new metabolic strategies to improve the production of various bioproducts and designing new drugs that can fight against multi-antibiotic resistant superbacteria by knocking-down the enzyme activities around an essential metabolite. Finally, we combined a regulatory network with the metabolic network to investigate its effect on dynamic properties of cellular metabolism.
1:39PM J7.00005 Discrete dynamic modeling of T cell survival signaling networks, RANRAN ZHANG, Pennsylvania State University — Biochemistry-based frameworks are often not applicable for the modeling of heterogeneous regulatory systems that are sparsely documented in terms of quantitative information. As an alternative, qualitative models assuming a small set of discrete states are gaining acceptance. This talk will present a discrete dynamic model of the signaling network responsible for the survival and long-term competence of cytotoxic T cells in the blood cancer T-LGL leukemia. We integrated the signaling pathways involved in normal T cell activation and the known deregulations of survival signaling in leukemic T-LGL, and formulated the regulation of each network element as a Boolean (logic) rule. Our model suggests that the persistence of two signals is sufficient to reproduce all known deregulations in leukemic T-LGL. It also indicates the nodes whose inactivity is necessary and sufficient for the reversal of the T-LGL state. We have experimentally validated several model predictions, including: (i) Inhibiting PDGF signaling induces apoptosis in leukemic T-LGL. (ii) Sphingosine kinase 1 and NFκB are essential for the long-term survival of T cells in T-LGL leukemia. (iii) T box expressed in T cells (T-bet) is constitutively activated in the T-LGL state. The model has identified potential therapeutic targets for T-LGL leukemia and can be used for generating long-term competent CTL necessary for tumor and cancer vaccine development. The success of this model, and of other discrete dynamic models, suggests that the organization of signaling networks has an determining role in their dynamics. Reference: R. Zhang, M. V. Shah, J. Yang, S. B. Nyland, X. Liu, J. K. Yun, R. Albert, T. P. Loughran, Jr., Network Model of Survival Signaling in LGL Leukemia, PNAS 105, 16308-16313 (2008).

Tuesday, March 17, 2009 11:15AM - 2:15PM –
Session J8 FEId FIAP: Preparing Physics Students for Careers in Industry 414/415

11:15AM J8.00001 The Physics Workforce: The Latest Data on Supply and Demand, ROMAN CZUJKO, American Institute of Physics — This paper will provide an overview of the trends both in physics education at all degree levels and in the employment of physicists throughout the economy. The paper also includes comparative data on the trends in related fields. There will be a discussion of the common career paths pursued by physicists at different degree levels with particular emphasis on non-academic employment. The paper includes a detailed description of professional master’s degree programs in physics departments as well as findings from AIP* studies that describe the skills that employers value. The paper concludes with suggestions for how physics departments might assist their students in finding employment during these difficult economic times.

11:51AM J8.00002 Industrial Physics Careers: A Large Company Perspective, STEFAN ZOLLNER, IBM — Statistical data from the American Institute of Physics and the National Science Foundation show that only about a third of physics graduates get permanent jobs in academia. A few work in government labs and hospitals. The majority of physics Ph.D.s, however, find employment in the private sector (industry). This trend has been increasing, i.e., recent Ph.D.s are even more likely to start careers in industry. Industrial physicists work in small, medium or large companies in a broad range of fields, including aerospace, semiconductors, automotive, energy, information technology, contract research, medical, chemical, optics, etc. They are also represented in fields outside of physics, such as finance. Even the “inventor” of the Powerball lottery game is a Ph.D. physicist. In my talk, I will describe pathways to success for an industrial physicist, from the perspective of employment in three different large corporations. Based on the NIST Baldridge criteria of Performance Excellence, I will discuss how to achieve and measure organizational success through focus on products and customers. Individual performance is linked to the goals of the organization. Performance has two components: Goals and behaviors. Both are key to success as an individual contributor or manager.

12:27PM J8.00003 The Rutgers Undergraduate Physics Program: Preparing Students for Varied Careers, MOHAN KALELKAR, Rutgers University — At Rutgers University we offer three main physics major tracks, each tailored towards different kinds of career aspirations. The Professional Option is for students who intend to go on to physics graduate study. The Applied Option is for students who desire technical jobs in industry, but without graduate study. The General Option is for students who have an interest in physics, but do not aspire to a technical career. I will discuss how these Options prepare students for their desired careers, and will give specific examples of jobs obtained. I will especially focus on the Applied Option, explaining how it has evolved based on lessons learned, and what further steps we need to take at Rutgers. I will close by briefly discussing a new, fourth physics major track we have just introduced, our Ocean Physics Option. I will describe this new Option and discuss prospects for its success.

1:03PM J8.00004 ABSTRACT WITHDRAWN –

1:39PM J8.00005 Training PhD Physicists for Industrial Careers: The Industrial Leadership in Physics Program at Georgetown University, EDWARD VAN KEUREN, Department of Physics, Georgetown University — The Physics department at Georgetown University has a unique PhD level graduate program designed to prepare PhD physicists for positions in high-tech business. Launched in 2001, the Industrial Leadership in Physics (ILP) graduate program combines training in technical subjects and business topics with a focus on group learning, communication skills, and practical work experience. Some highlights of the program include a modular curriculum in fundamental physics, centered on solid-state physics, instrumentation, problem solving and computer modeling; a year-long apprenticeship at the site of an industrial partner chosen to match the interests of the student and coursework in the McDonough School of Business at Georgetown. This presentation will give an overview of the program.

Tuesday, March 17, 2009 11:15AM - 2:03PM –
Session J9 GSNP: Focus Session: Elasticity and Geometry of Thin Objects II 303

11:15AM J9.00001 The self assembly of closed surfaces from flat sheet, MICHAEL BRENNER, Applied Mathematics and Applied Physics, School of Engineering and Applied Sciences, Harvard University — We will discuss theoretical and some experimental work to understand the conditions which a flat sheet with embedded permanent magnets can spontaneously fold into a closed surface. The critical question is understanding how to design the system — both the cut of the sheet and the position of the magnets — to maximize the yield of assembling into a closed surface without misfolding. This problem also raises novel and interesting questions in thin plate elasticity, which will be highlighted.
phenomena such as spontaneous buckling and the emergence of a boundary layer. When the prescribed reference curvatures and 2D metric do not comply with one another, the system is frustrated (non-Euclidean). Such systems exhibit various behaviors: sheets with imposed positive Gaussian curvature have weak thickness dependence, their bending content is bounded and their total bending energy scales like thickness cube. On the other hand, sheets with imposed negative Gaussian curvature undergo a set of bifurcations, as they obtain configurations uniformly when heated above 33°C. This process prescribes a non-Euclidean “target” metric on the sheets. In order to reduce their energy, the plates buckle with a wavelength proportional to the interaction range. This model can be simulated on a random mesh, which can be defined on any arbitrary curved geometry. Through these simulations, we determine how stripped phases respond to curvature on spheres, tori, and other geometries.

12:03PM J9.00003 Simulating Complex Modulated Phases Through Spin Models, JONATHAN V. SELINGER, LENA M. LOPATINA, JUN GENG, ROBİN L. B. SELINGER, Kent State University — We extend the computational approach for studying stripped phases on curved surfaces, presented in the previous talk, to two new problems involving complex modulated phases. First, we simulate a smeared liquid crystal on an arbitrary mesh by mapping the director field onto a vector spin and the density wave onto an Ising spin. We can thereby determine how the smectic phase responds to any geometrical constraints, including hybrid boundary conditions, patterned substrates, and disordered substrates. This method may provide a useful tool for designing ferroelectric liquid crystal cells. Second, we explore a model of vector spins on a flat two-dimensional (2D) lattice with long-range antiferromagnetic interactions. This model generates modulated phases with surprisingly complex structures, including 1D stripes and 2D periodic cells, which are independent of the underlying lattice. We speculate on the physical significance of these structures.
When the self-interaction of the SQD becomes significant. We explore these three regimes in detail and set bounds on each.

As the coupling is further increased by increasing the sizes of both the SQD and the MNP, we find a regime of bistability. This originates by increasing the size of the SQD, we find a double peaked Fano structure in the response. This second peak occurs when the induced field becomes stronger field limit that each exhibit novel properties. In the first regime, we find that the energy absorption spectrum displays an asymmetrical Fano shape (as previously

Bryant, NIST, Gaithersburg — We study the optical response of a semiconductor quantum dot (SQD) coupled with a metal nanoparticle (MNP). In particular,

we explore the relationship between the size of the constituents and the response of the system. We identify, three distinct regimes of behavior in the strong

1:27PM J9.00010 Wrinkles/Folds and the Role of Interfacial Thermodynamics 1, LUKA POČIVAVŠEK, BRIAN LEAHY, The University of Chicago, ENRIQUE CERDA, Universidad de Santiago de Chile, BINUHA LIN, KA YEE LEE, The University of Chicago — We recently developed a general model for studying instabilities like wrinkling and folding in interfacial membranes on fluid substrates. The dominant length scales describing the instability are set by the elastic response of the membrane (primarily bending) and the “stiffness” of the substrate. These length scales, like the wrinkle wavelength and fold amplitude, are independent of the particular interfacial molecular interactions for micron thick membranes where typical system energies like the membrane bending stiffness are thousands of times larger than intermolecular potentials. However, as the membranes become thinner and the chemical interactions between the membrane and the fluid substrate strongly influence the wrinkling and folding length scales. We present data for two such systems (a lipid monolayer and a gold nanoparticle layer) on different hydrogen bonding fluids and discuss possible mechanisms and modifications of our wrinkle-to-fold scaling laws to account for this new degree of freedom.

1:39PM J9.00011 Universal Shapes of Interacting Mode-I Cracks, MELISSA FENDER, FREDERIC LECHEAULT, Dept. of Physics, North Carolina State University, PEDRO REIS, Dept. of Mathematics, MIT, BENÖIT ROMAN, P.M.M.H, UMR 7636 CNRS/ESPCI/Paris6,Paris7, KAREN DANIELS, Dept. of Physics, North Carolina State University — We experimentally investigate the interaction between two parallel cracks propagating towards each other under uniaxial traction in quasi-2D slabs of gelatin. A single crack would propagate perpendicular to the direction of traction. However, after they pass each other, the two cracks rotate and ultimately meet, leaving behind a lens-shaped remnant. We find a universal length-to-width ratio for this remnant, independent of the pulling speed and initial crack separation; the same phenomenon is observed in a variety of elastic materials. Moreover, the overall dimensions of the lens-shaped remnant are set by the initial crack separation.

1:51PM J9.00012 The Life and Times of a Ruck in a Rug, DOMINIC VELLA2, MOHTKAR ADDA-BEDIA, AREZKI BOUDAOU, LPS ENS, Paris — We study the familiar problem of a ruck in a rug. Under lateral compression, a rug bends out of the plane forming a ruck — a localised region in which it is no longer in contact with the floor. We consider the equilibrium of such a ruck. Once the external force that caused the compression is removed, experience tells us that the ruck may either remain or flatten out under its own weight. We quantify the conditions under which each of these two scenarios occurs. We also consider how the propagation of a ruck along the carpet facilitates large-scale sliding.

11:15AM J10.00001 Optical Detection and Control of Single Magnetic Ions in Photonic Microcavities1, 2, DAVID D. AWSCHALOM2, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — As the density of magnetic information storage scales upwards, their spin lifetimes increase with decreasing concentration as the ions become isolated. Here we describe the spatially-resolved observation and manipulation of isolated Mn spins integrated within photonic microcavities. A single magnetically-doped GaAs quantum well is fabricated within both microdisk and vertical Fabry-Perot cavities in which their respective cavity modes are coupled to the neutral Mn acceptor emission. Scanning micro-photoluminescence measurements reveal cavity-coupled emission and a dramatic increase in the measured signal to noise ratio, thereby allowing direct imaging of narrow linewidth luminescence from the Mn moments. These Mn ion spins are optically polarized at zero-field, exhibit long spin lifetimes, and may be manipulated through a variety of techniques.

11:51AM J10.00002 ABSTRACT WITHDRAWN —

12:03PM J10.00003 Silicon nanocrystal photoluminescence in cylindrical whispering gallery resonators, P. BIANUCI, Department of Physics, University of Alberta, Edmonton AB, T6G 2G7, Canada, J.R. RODRIGUEZ, Department of Chemistry, University of Alberta, Edmonton AB, T6G 2G2, Canada, C.M. CLEMENTS, Department of Physics, University of Alberta, Edmonton AB, T6G 2G7, Canada, J.G.C. VEINOT, Department of Chemistry, University of Alberta, Edmonton AB, T6G 2G2, Canada, A. MELDRUM, Department of Physics, University of Alberta, Edmonton AB, T6G 2G7, Canada — We present photoluminescence studies of Silicon-nanocrystal (Si-NC) coated cylindrical microcavities. The coatings were prepared by dip-coating standard optical fibers with a solution-based precursor followed by a high-temperature annealing step. The photoluminescence spectra measured perpendicular to the fiber axis show high Q-factor (~2500) whispering gallery modes, and allows distinction between TE and TM modes. We also show a proof-of-principle implementation of a far-field refractometric sensor using a nanocrystal-coated fiber.

12:15PM J10.00004 Optical Response of Strongly Coupled Quantum Dot-Metal Nanoparticle Systems: Double Peaked Fano Structure and Bistability, RYAN ARTUSO, University of Maryland College Park, GARNETT BRYANT, NIST, Gaithersburg — We study the optical response of a semiconductor quantum dot (SQD) coupled with a metal nanoparticle (MNP). In particular, we explore the relationship between the size of the constituents and the response of the system. We identify, three distinct regimes of behavior in the strong field limit that each exhibit novel properties. In the first regime, we find that the energy absorption spectrum displays an asymmetrical Fano shape (as previously predicted). It occurs when there is interference between the applied field and the induced field produced by the SQD at the MNP. When the coupling is increased by increasing the size of the SQD, we find a double peaked Fano structure in the response. This second peak occurs when the induced field becomes stronger than the external field. The coupling is further increased by increasing the sizes of both the SQD and the MNP, we find a regime of bistability. This originates when the self-interaction of the SQD becomes significant. We explore these three regimes in detail and set bounds on each.
12:27PM J10.00005  Excitons and plasmons in coupled nanoparticles and nanowires. PEDRO L. HERNANDEZ-MARTINEZ, ALEXANDER O. GOVOROV, Ohio University — In this study, we develop theoretical models of coupled nanoparticles (NPs) and nanowires (NWs). In particular, we focus on exciton energy transfer between NPs and NWs and consider both metal and semiconductor nanocrystals. We obtain analytical equations for the long distance limit and a numerical solution for the general case. For long distances, the energy transfer rate is proportional to 1/d^5, where d is the distance between NP and NW [1]. In a coupled NP-NW structure, excitonic energy can be efficiently extracted and channelled to nanowires/nanotubes by utilizing the Förster energy transfer mechanism [1,2]. The calculated energy transfer rates are in good agreement to the experimental values [2]. The NP-NW system has potential for applications in optoelectronic devices and sensors [3]. [1] P. Hernandez-Martinez, A. O.Govorov, Phys. Rev. B 78, 035314 (2008). [2] J. Lee, A. O. Govorov, and N. A. Kotov, Nano Letters 5, 2063-2069 (2005). [3] J. Lee, P. Hernandez, J. Lee, A. O. Govorov, and N. A. Kotov, Nature Materials, 6, 291 – 295 (2007).

12:39PM J10.00006  High-transmission ridge nanoapertures for quantum dot devices1. AKIHIRO KIRIHARA, JUNICHI FUJIKATA, NEC Corporation, TOSHIHIRO NAKAOKA, NAOTO KUMAGAI, KATSUYUKI WATANABE, University of Tokyo, MASAYUKI SHIRANE, SHUNSUKI OHKOUCHI, SHINICHI YOROZU, NEC Corporation, YASUHIKO ARAKAWA, University of Tokyo — We report on double-ridge apertures to enhance the coupling between a single quantum dot (QD) and optical field. The double-ridge aperture has two metallic tips protruding inward and facing each other, which work as an effective antenna for a QD just below the tips. We performed FDTD simulation to optimize the apertures, and fabricated them on InAs/GaAs QDs emitting at 960nm. By single-dot PL spectroscopy through the double-ridge aperture, we demonstrated 5-6 times enhancement in PL extraction efficiency, compared to that through a conventional circular aperture. Because our double-ridge aperture works not only as an optical antenna but also as an electrode for a QD, it will be applicable to electrically-driven photon generators or photon detectors.

12:51PM J10.00007  Polarization and Angle Dependent Spontaneous Emission Rates in Hybrid Metal-Semiconductor Nanostructures, YIKUAN WANG, TIANYU YANG, MARK TUOMINEN, MARC ACHERMANN, University of Massachusetts Amherst — Recently, the coupling of a dipole emitter to surface plasmons (SPs) of metal nanostructures has attracted much attention for its potential applications in light emitting devices. Our time-resolved photoluminescence (PL) study on the emission of CdSe/ZnS core/shell nanocrystals (NCs) deposited on a two-dimensional array of gold nanodiscs demonstrates that the spontaneous emission of dipole emitters is strongly dependent on the detection angles and polarizations. The in-plane, s-polarized PL measurements are independent on detection angles, and can be described by the PL decay dynamics of two NC subsets: the emission from NCs on the dielectric substrate and from NCs on the gold nanodiscs that experience non-radiative quenching by the metal.

The out-of-plane, p-polarized PL measurements show an additional decay caused by SP-induced enhancement of the spontaneous emission rate. This angular-dependent enhancement is explained by interactions between NC dipole moments and the out-of-plane SP resonance of the gold nanodiscs.

1:03PM J10.00008  Decay-rate distribution of single quantum dots in nanometer-scale proximity to a metal film. MATTHEW PELTON, XIAOHUA WU, Argonne National Laboratory — Recently, the interaction between fluorescent colloidal semiconductor quantum dots and plasmonic metal nanostructures has attracted great interest, both for the development of a basic understanding of nanoscale photophysics and for potential applications in improved light-emitting devices and integrated plasmonic circuits. Time-resolved measurements on single dots are required in order to overcome the obscuring effects of ensemble averaging and of time averaging, and thus reveal the physical mechanisms of dot-metal interaction. In this work, we present measurements of photoluminescence decay dynamics from single colloidal CdSe/ZnS core-shell quantum dots in nanometer-scale proximity to a smooth gold film. We extract the decay rate, k_ν, for each dot when it is in its maximum-intensity state, thereby removing the effects of nonradiative decay-rate fluctuations. We find that, as the separation between the dot and the metal decreases, the k_ν distribution becomes broader and its maximum increases. The increase in maximum decay rate is caused by stronger energy transfer from the quantum dot to the metal film, as expected. The broader distribution of decay rate, on the other hand, reflects inherent variations in the interactions between individual dots and the metal film.

1:15PM J10.00009  Demonstration of Optical Resonances in a Cylinder-Shell Lattice of Quantum Dots, JARED MAXSON, SLAVA ROTKIN, Department of Physics, Lehigh University — We present a model for the calculation of the optical response of a cylinder-shell quantum dot or metallic nanostructures. Our model is a shell cluster as a lattice of non-permanent point dipoles with a known polarization and a single transition frequency. We then utilize the second quantization formalism to compute the cluster response. The eigenmodes and quantum mechanical response function of the lattice interacting with an external field, polarized respective to the cylinder axis, are calculated numerically. The cylinder radius is treated as a parameter to identify resonator metallic effects due to the cylindrical geometry. Varying the frequency of the external field, regions of response maxima are determined. In these regions resonant interaction between the coupled dipoles results in transferring significant oscillator strength into a few eigenmodes of the cluster, having high spatial and temporal coherence with the external field. Further analysis of the spatial distribution of eigenstates in each region of response maxima reveals significant contributions from groups of modes with equal angular momenta, permitting rigorous excitation classification.

1:27PM J10.00010  Two-Photon Transitions in Molecular Quantum Dot System, MICHAEL SCHEIBNER, ILYA PONOMAREV, DANNY KIM, ALLAN BRACKER, DANIEL GAMMON, Naval Research Laboratory — Two-photon excitations are at the heart of important nonlinear optical processes and provide a key to the rich physics and fresh opportunities of designer quantum materials. In this study we consider double dot quantum dot molecules (QDMs) that were designed by molecular beam epitaxial growth to exhibit either electron or hole tunnel coupling of the two dots. The electron or hole levels of the two dots can be tuned into resonance with applied electric field created by Schottky diode structure. We demonstrate that, by using two polarizations of two photon transitions, one can control the absorption spectrum of the molecular biexciton in such a QDM. We identify a new two-photon transition which is the first example of a simultaneous, coherent optical excitation of a pair of QDs in a weakly coupled regime. We further show that a photoluminescence excitation measurement with stereo-chromatic detection can be used to gain access to the spin physics in this regime.

1:39PM J10.00011  Qubit extraction and manipulation in optically-driven self-assembled quantum dot molecules.1, J.E. ROLON, S.E. ULOA, Ohio University — Semiconductor quantum dot molecules (QDMs) allow studies of different mechanisms of coherent optoelectronic control of excitative states in the pursuit of stable and well characterized qubits. In this work, we develop a realistic calculation of the dressed spectrum and exciton dynamics of InAs/GaAs QDMs. The dressed spectrum contains electron and hole tunneling as well as exciton Förster resonant energy transfer (FRET) level anticrossing signatures, from which we derive an effective Hamiltonian using a projection operator formalism. The state dynamics is analyzed using a multilevel Lindblad master equation, in which the projected density matrix is obtained by partial tracing of the irrelevant exciton degrees of freedom. We find that the interplay of FRET and carrier tunneling can produce a charge qubit subspace whose indirect exciton character makes it resilient to lifetime limited decoherence. Furthermore, it is shown that a set of universal quantum gates can be constructed and its unitarity assured by the application of an external electric field that prevents the mixture of qubit subspace dynamics with other excitonic degrees of freedom, present upon optical excitation.

and bias. Properties of open quantum dots, in which QPC conductances are quantized.

We have investigated the transport properties of a 1.5 µm lateral GaAs/AlGaAs quantum dot molecules under lateral electric field using empirical pseudopotentials and configuration interaction. Our model structure is directly taken from recent experiments where an In-poor basin develops below the dot. The coupling of the electron states is significantly enhanced by the presence of the basin, while the holes remain mainly uncoupled. At the proper electric field —between 0 V/cm and 200 V/cm, depending on the dot molecule—the electron states can be tuned to be evenly distributed between both dots, forming bonding and antibonding states. The optical absorption is shown to exhibit two bright transitions, mostly independent of the applied field. In emission, we argue that a fast electron-dynamics must be introduced, since the electrons are not subject to a true potential barrier between the dots and consequently only the lowest of the electron states is occupied. Following this approach, we obtain only one bright peak at high electric fields and two peaks (at higher temperature, four peaks) at the tuning point of the electron states. The results are shown to compare very well with recent experiments. A simple 4x4 Hamiltonian is derived to explain the results in the intuitive dot-localized basis.

11:27AM J11.00002 Imaging Double Quantum Dots in InAs/nP Nanowires. HALVAR J. TRODAHL, ERIN E. BOYD, R. M. WESTERVELT, Dept. of Physics and Sch of Eng and App Sci, Harvard Univ, LINUS E. FROBERG, KRISTIN NILSSON, LARS SAMUELSON, Dept of Solid State Physics, Lund Univ — Coupled quantum dots formed in InAs/nP heterostructure nanowires are attractive candidates for non-electronic, spintronic and quantum information processing. The ability to manipulate the charge state of a single quantum dot defined in these nanowire systems using a low temperature scanning probe microscope (SPM) tip has been shown previously [1] and provides a tool to investigate the properties of nanowire systems down to the tens of nanometer scale. In order to realize the above applications, multiple InAs quantum dots can be formed in an InAs/nP nanowire system by using InP barriers. Using a conducting SPM tip as a movable electrostatic gate, the charge can be tuned independently on each dot of a double quantum dot defined in a semiconductor nanowire. [1] A. C. Bleszynski-Jayich, et al. Synchrotron Radiation News 21, 153 (2008)

11:39AM J11.00003 Phase Coherence and Mesoscopic Coulomb Blockade in Open Quantum Dots. ILEANA RAU, MICHAEL GROBIS, SAMI AMASHA, RON POTOK, Stanford University, HADAS SHTRIKMAN, Weizmann Institute, DAVID GOLDBABER-GORDON, Stanford University — The phase coherence of electrons in open systems at low temperatures leads to mesoscopic effects such as universal conductance fluctuations and weak localization of electrons. These effects are encountered in open large quantum dots and are explained by a model of non-interacting electrons. We have investigated the transport properties of a 1.5 µm<sup>2</sup> and a 3 µm<sup>2</sup> lateral GaAs/AlGaAs quantum dot in the open regime. The weak localization effect is complicated at low temperatures by the presence of residual interactions (Mesoscopic Coulomb Blockade) that persists even when the dot is coupled by one or two fully transmitting modes to each of the two leads. We present measurements of the electron dephasing rate at low temperatures in the open quantum dots and discuss how they are affected by the suppression of conductance by these Coulomb blockade effects.

11:51AM J11.00004 Mesoscopic Coulomb Blockade in a Quantum Dot with Two Open QPCs. SAMI AMASHA, ILEANA RAU, MICHAEL GROBIS, RON POTOK, Stanford University, HADAS SHTRIKMAN, Weizmann Institute, DAVID GOLDBABER-GORDON, Stanford University — A quantum dot consists of a confined droplet of electrons connected to an electron reservoir by two quantum point contacts (QPCs). When the conductance of each of these QPCs is less than 2e<sup>2</sup>/h, the dot is in the closed regime and Coulomb Blockade effects dominate the transport properties. Open quantum dots, in which QPC conductances are 2e<sup>2</sup>/h or above, are generally thought to be well-described by non-interacting electron theory. While Mesoscopic Coulomb Blockade (MCB) effects can occur in a quantum dot with one open and one closed QPC, these effects are expected to be absent for quantum dots with two open QPCs. We have investigated the transport properties of a 1.5 µm<sup>2</sup> and a 3µm<sup>2</sup> lateral GaAs/AlGaAs quantum dot in the open regime and find a clear signature of MCB. We will discuss the dependence of MCB on various controllable parameters, including magnetic field, temperature, and bias.

12:03PM J11.00005 Quantum Phase Transition to a Zigzag Wigner Crystal 1 \textsuperscript{,} A. C. MEHTA, Duke University, C. J. UMRIGAR, Cornell University, A. D. GUCLU, National Research Council of Canada, K. A. MATVEEV, Argonne National Lab, H. U. BARANGER, Duke University — We use Quantum Monte Carlo techniques to map out the phase diagram of interacting electrons in a quantum wire. Interacting quasi-one-dimensional systems provide excellent examples of quantum phase transitions that are tractable. Previous work gave a qualitative description of the phase diagram of a quasi-one-dimensional system [Meyer, Matveev, and Larkin, PRL 2007]. At low density, electrons confined to one dimension by a transverse harmonic potential form a linear one dimensional Wigner crystal; as the density increases, symmetry about the axis of the wire is broken and there is a transition to a quasi-one-dimensional zigzag crystal. We use variational and diffusion Monte Carlo to study the phase diagram of this system quantitatively.

12:15PM J11.00006 Quantum Phase Transition in a single-molecule Quantum Dot, N. ROCH, S. FLORENS, V. BOUCHIAT, W. WERNSDORFER, F. BALESTRO, Nöel Institut, Grenoble, France, NANOSCIENCES DEPARTMENT COLLABORATION — Quantum criticality is the intriguing possibility offered by the laws of quantum mechanics when the wave function of a many-particle physical system is forced to evolve continuously between two distinct, competing ground states. This phenomenon, often related to a zero-temperature magnetic phase transition, can be observed in several strongly correlated materials such as heavy fermion compounds or possibly high-temperature superconductors, and is believed to govern many of their fascinating, yet still unexplained properties. In contrast to these bulk materials with very complex electronic structure, artificial nanoscale devices could offer a new and simpler vista to the comprehension of quantum phase transitions. This long-sought possibility is demonstrated by our work in a fullerene molecular junction, where gate voltage induces a crossing of singlet and triplet spin states at zero magnetic field. N. Roch, S. Florens, V. Bouchiat, W. Wernsdorfer & F. Balestro, Quantum phase transition in a single-molecule quantum dot, Nature, 2008, 453, 633-637.

12:27PM J11.00007 Aharonov-Bohm-type interference effects in narrow gap semiconductor heterostructures, R.B. LILLIANFELD, R.L. KALLAHER, J.J. HEREMANS, Virginia Tech, HONG CHEN, University of North Florida, N. GOEL, S.J. CHUNG, M.B. SANTOS, University of Oklahoma, W. VAN ROY, G. BORGHS, IMEC (Belgium) — We present experiments on quantum interference phenomena in semiconductors with strong spin-orbit interaction, using mesoscopic parallel ring arrays fabricated on InSb/InAsSb and InAs/AlGaSb heterostructures. Both external electric field effects and temperature dependence of the ring magnetoresistance are examined. Top-gate voltage-dependent oscillations in ring resistance in the absence of an external magnetic field are suggestive of Aharonov-Casher interference. At low magnetic fields the ring magnetoresistance is dominated by oscillations with $h/2e$ periodicity characteristic of Altschuler-Aronov-Spivak (AAS) oscillations, whereas the $h/e$ periodicity characteristic of Aharonov-Bohm (AB) oscillations persists to high magnetic fields. Fourier spectra (FS) reveal AB amplitudes on the same order as AAS amplitudes at low fields, and in some samples reveals a splitting of the AB peaks, which has been interpreted as a signature of Berry’s phase. The FS are also used to quantify the temperature dependence of the oscillation amplitudes (NSF DMR-0618235, DOE DE-FG02-08ER4652, NSF DMR-0920550).

12:39PM J11.00008 Time-resolved detection of single-electron interference, SIMON GUSTAVSSON, Massachusetts Institute of Technology, MATTHIAS STUDER, ETH Zurich, RENAUD LEURTQURC, IEMN-CNRS, France, THOMAS IHN, KLAUS ENSSLIN, ETH Zurich, D. C. DRISCOLL, A. C. GOSSARD, University of California, Santa Barbara — We demonstrate real-time detection of single electron interference in a double quantum dot embedded in an Aharonov-Bohmer interferometer, with visibility approaching unity [1]. We use a quantum point contact as a charge detector to perform time-resolved measurements of single-electron tunneling. With increased bias voltage across the quantum point contact a back-action is exerted on the interferometer leading to decoherence. We attribute this to emission of radiation from the quantum point contact, which drives electronic transitions in the quantum dot [2]. Surprisingly, the efficiency of this process depends strongly on external magnetic field, with variations occurring on a small fraction of the magnetic field scale associated with one flux quantum penetrating the ring. The unexpected features demonstrate the complex interplay between radiation, absorption and coherence in mesoscopic systems. [1] S. Gustavsson et al., Nano Lett. 8, 2547 (2008). [2] S. Gustavsson et al., PRL 99, 206804 (2007).

12:51PM J11.00009 Non-equilibrium Charge Fluctuations as a Source of Inelastic Back-action in Quantum Point Contact Qubit Detectors, CAROLYN YOUNG, AASHISH CLERK, McGill University — Many recent experiments make use of a quantum point contact (QPC) as a qubit readout (e.g., of a double quantum dot (DQD) qubit). It has long been realized that QPC current fluctuations can give rise to inelastic back-action effects on the DQD [1] [2]. In contrast, the role of QPC charge fluctuations in generating inelastic back-action has not been fully studied, despite the fact that this is a more fundamental mechanism. We provide a full theoretical study of charge-noise induced inelastic back-action effects in a QPC plus DQD system, showing that these effects should be appreciable in typical experimental setups. We also discuss a novel contribution to the charge noise associated with the physics of Friedel oscillations. Finally, we discuss how the effects of charge noise back-action can be distinguished from current noise back-action in experiment.

1:03PM J11.00010 Hole Spin Filtering by quantum point contacts, TAISUKE MINAGAWA, YULI LYANDER-GELLER, Department of Physics, Purdue University — We calculate the charge carrier spectra in two-dimensional hole systems (2DHS) and in quantum point contacts (QPC) formed in the 2DHS in an in-plane magnetic field $B$. The origin of the spin splitting for holes differs significantly from that for electrons. For bulk holes, the g-factor is defined not only by the constant of coupling of the angular momentum $3/2$ to magnetic field, but also by the Luttinger constants $\gamma_1, \gamma_2$ and $\gamma_3$ defining the heavy and light hole masses. In the high mobility 2DHS, the width of the quantum well (QW) $L$ becomes comparable to the magnetic length $\lambda_B$ for the in-plane $B \sim 3T$. We find that the spin splitting for 2D holes and for holes in QPC is strongly affected by the orbital motion in the presence of the in-plane $B$. We developed the new approach to spectra based on confluent hypergeometric functions. We take into account the anisotropy of the Hamiltonian and calculate the spin splitting for [113] orientation of the 2DHS. For QPC spectra, configurations of in-plane $B$ along and perpendicular to the direction of the current are studied. Our results explain many of the features of spin-resolved QPC conductance observed by Robinson group (PRL, 100, 126401) and by Hamilton group (PRL, 97, 026403). Our analysis also resolves the puzzling red shift of the Fermi energy discovered in optical spectra for QW in-plane magnetic field by Crooker group (Physica E, 22:624).

1:15PM J11.00011 Ferromagnetic vs. Antiferromagnetic Correlations in a Double Dot System, MANAS KULKARNI, Stony Brook University and Brookhaven National Laboratory, ROBERT KONIK, ALEXEI TSVELIK, Brookhaven National Laboratory — We study a double dot system in a parallel geometry using both a large-N diagrammatic and a SBMFT approach. We consider the role of interdot ferromagnetic correlations upon the conduction. We find that at the particle-hole symmetric point that the Friedel sum rule holds and the conduction vanishes. We find that the ground state of the double dot system is a singlet although the correlations between the two dots is primarily ferromagnetic. Hence we observe that the RKKY interaction does not bind the two electrons on the dots into a triplet. We compare our results to a Bethe ansatz analysis of the same system [1]. [1] R.Konik PRL 99, 076602 (2007).
1:27PM J11.00012 Magnetic Splitting of the Zero Bias Peak in a Quantum Point Contact with a Variable Aspect Ratio1. TAI-MIN LIU, BRYAN HEMINGWAY, ANDREI KOGAN, University of Cincinnati, STEVEN HERBERT, Xavier University, MICHAEL MELLOCH, Purdue University, UNIVERSITY OF CINCINNATI TEAM, XAVIER UNIVERSITY COLLABORATION — We have measured the nonlinear conductance of a four-gate Quantum Point Contact (QPC) device fabricated in a GaAs/AlGaAs heterostructure containing a 2-dimensional electron gas. By continuously varying the longitudinal potential profile of the QPC, we controllably create and destroy a local bound state. The nonlinear transport data show both a characteristic Coulomb blockade diamond and a zero-bias peak similar to the Kondo effect signature peak in quantum dots. We find that even when the bound state is suppressed the zero-bias peak persists. Applying an in-plane magnetic field perpendicular to the direction of the current produces a splitting of the peak which closely matches the g-factor data obtained via the cotunneling spectroscopy method in a separate quantum dot on the same chip.

1The research is supported by NSF DMR award No. 0804199 and by University of Cincinnati.

1:39PM J11.00013 Topological spin textures in strongly interacting quantum dots, JORDAN KRYIAKIDIS, CATHERINE J. STEVENSON, Dalhousie University, Halifax, CANADA — We present results of configuration-interaction calculations on two-dimensional quantum dots containing charges with long-range Coulomb repulsion. We focus on correlation-induced spin textures formed at zero magnetic field. By looking at chiral structures, at two- and three-point spin-correlation functions, and at explicit symmetry-breaking fields, a consistent picture emerges of incipient topological spin textures formed throughout the dot and particularly at annular regions of increased electron density. In addition to singular vortex-type structures, 2n-windings are observed in the spin field along these annular regions. These textures are solely due to statistics and repulsion.

1:51PM J11.00014 Spin interference in quantum rings manipulated with quantum point contacts1. FRANCISCO MIRELES, Centro de Nanociencias y Nanotecnología – UNAM, México, LEO DIAGO, Universidad de la Habana, Cuba — The Aharonov-Bohm (AB) and Aharonov-Casher (AC) effects are two well known interference phenomena that may appear in semiconductor quantum rings (QR’s). Although the AB effect has been long observed, its counterpart, the AC effect has been only recently detected in cleaver magnetoconductance oscillations experiments on HgTe/HgCdTe based QR’s exhibiting strong Rashba SO-interaction [1]. In this work, using the S-matrix formalism we study the role of the contacts between the leads and the QR on the AB and AC conductance oscillations of the device in the presence of Rashba and Dresselhaus type of SO interactions. We describe the backscattering and transparency of the conjunctions lead-to-ring through quantum point contacts (QPCs) modelled with gate-controllable saddle-point potentials. The variable transmissivity of the QPCs, adjusted in the experiment by gate voltages and/or applied magnetic fields, is readily incorporated in our approach. It is shown that manipulating electrostatically the confinement strength at the QPCs, may be of utility to implement a novel way to modulate spin interference effects in semiconductor quantum rings. 2:03PM J11.00015 NGEF Study of the Spontaneous Spin Polarization in a Quantum Point Contact1. JUNJUN WAN, MARC CAHAY, RICHARD NEWROCK, PHILIPPE DEBRAY, University of Cincinnati — A non-equilibrium Green function formalism (NEGF) is used to study the conductance of a side-gated quantum point contact (QPC) in the presence of lateral spin-orbit coupling (LSOC) induced by the electric field due to the gradient of the lateral confining potential. A small asymmetry in the confining potential induced by difference of potential between the two side-gates (SGs) leads to an inversion asymmetry in the LSOC which triggers a spontaneous spin polarization in the QPC. In the regime of single-mode transport, the spontaneous spin polarization can reach nearly 100% when a strong electron-electron (e-e) interaction is taken into account. This leads to the occurrence of a plateau at G = 0.5 (e²/h) in the ballistic conductance without the need of any externally applied magnetic field. Two ingredients are essential for the occurrence of the 0.5 plateau: an asymmetric LSOC and a strong e-e interaction.

11:15AM J12.00001 Valence band structure in crystalline pentacene thin films1, RICHARD HATCH, DAVID HUBER, HARTMUT HÖCHST, Synchrotron Radiation Center, UW-Madison — Organic semiconductors, such as pentacene (Pn), are beginning to show promise as a low-cost substitute for conventional semiconductors for a variety of electronic devices. The overlap of π-orbitals in the Pn crystal leads to molecular orbital-derived bands. We used angle-resolved photoemission spectroscopy (ARPES) to reveal the Pn in-plane band structure of the two highest occupied molecular orbital-derived bands in crystalline thin film Pn (grown on a Bi substrate) for various temperatures between 75 K and 300 K. We mapped these two bands in several crystallographic directions with special attention given to the region near the top of the valence band and show, within the limits of our experimental resolution, that temperature does not change the dispersions of these bands. We fit the band structure to a tight binding model and compared our results with recent theoretical predictions[1-2]. We also calculated the in-plane reciprocal effective mass for the M point and compared it with the measured mobility. [1] H. Yoshida et. al. Phys. Rev. B 77, 235205 (2008). [2] G. A. de Wijs et. al. Synth. Met. 139, 109 (2003).

1This work is based upon research conducted at the Synchrotron Radiation Center, University of Wisconsin-Madison, which is supported by the NSF under Award No. DMR-0537588

11:27AM J12.00002 The growth mechanism of anisotropic organic molecular films, A. AL-MAHBOOB, WPI-Advanced Institute for Materials Research, Tohoku University, Y. FUJIKAWA, Institute for Materials Research, Tohoku University, J.T. SADOWSKI, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY 11973, QIKUN XUE, T. SAKURAI, WPI-Advanced Institute for Materials Research, Tohoku University — The anisotropy in molecular structure and crystal packing may complicate nucleation and growth processes in organic molecular films. The growth mechanism of pentacene (Pn) films has been studied by real time low-energy electron microscopy. Pn is most promising for FET application as it shows the highest field-effect mobility among organic thin-films. We observed delayed nucleation and formation of large grains (as large as 0.5 mm in diameter) on semiconducting α/3-Bi-Si(111) and on semi-metallic Bi(0001)/Si(111), with a significant delay in film growth after stopping Pn deposition, indicating long diffusion time. This is in contrast to the growth of Pn on SAMs, oxides or wetting layer on clean silicon surfaces. The long diffusion time could be explained by large barrier for Pn nucleation with standing-up orientation from a lying-down diffusing state due to stronger interaction between lying molecules and Bi-treated substrates.
11:39AM J12.00003 Morphology and Crystalline Structure of the Epitaxial Growth of Tetracene Thin Films on H/Si(001)-2x1 Substrate \cite{1}, ANDREW TERSIGNI, DE-TONG JIANG, XIAORONG QIN, Dept. of Physics, University of Guelph — Epitaxial growth of tetracene films on H/Si(001)-2x1 surface has been studied systematically using AFM, STM and X-ray diffraction. The surface morphology and in-plane lattice structure observed from AFM and STM are compared with that extracted from the diffraction measurements to reach a consistent description on the in-plane and out-plane lattice parameters of different epitaxial domains, respectively. The influence of the substrate roughness and film coverage to the morphology and underlying lattice structures will be discussed in the light of various characteristics revealed by the multiple structural tools.

1 NSERC Canada

11:51AM J12.00004 Structural investigation of pentacene on Ag(111) by density functional theory \cite{2}, FATIH DANISMAN, Middle East Technical University, ERSEN METE, Balikesir University, SINASI ELLIAALTIĞGLU, Middle East Technical University — We have used density functional theory (DFT) calculations based on the projector augmented wave (PAW) method to investigate the initial growth patterns of pentacene (C_{22}H_{14}) on Ag(111) surface. Here we will report our initial findings and provide a discussion of the results from the point of view of our previous experimental findings. Pentacene prefers to stay planar on Ag(111) surface and aligns perfectly along lattice vector (1,-1,0) without any molecular deformation at a height of 3.74 Å. At 1 ML coverage the separation between the molecular layer and the surface plane extends to 4.14 Å due to intermolecular interactions weakening surface-pentacene attraction. While the first ML remains flat, the molecules on a second full pentacene layer rearrange in a herringbone fashion which is energetically slightly more preferable when compared with a second layer composed of flat lying molecules. With addition of third and fourth layers pentacene molecules continue to maintain the herringbone configuration, with the stability of the herringbone configuration relative to the flat one increasing to 0.13 eV for the 3 ML film, while the first ML always remains flat. Therefore, our calculations indicate bulk-like initial stages for the growth pattern.

12:03PM J12.00005 Magnetic and structural behaviors of transitional metallo-porphines monolayer and bilayer on Ag(111) \cite{3}, Q.X. TIAN, J.B. XU, DEPT OF ELEC ENGI AND MSRC, THE CHINESE UNIVERSITY OF HONG KONG TEAM, CHEMISTRY DEPT, PRINCETON UNIVERSITY COLLABORATION — Five monolayers and bilayers of transitional metallo-porphine(MP) (Mn, Fe, Co, Ni, Cu) on Ag(111) substrate are investigated by ab initio calculation. The strong coupling of FeP and CoP MP/Ag(111) interface leads to magnetic-nonmagnetic transition. The competition mechanism between intermolecular ferromagnetic exchange interaction and coupling of FeP/Ag(111) prevents the magnetic-nonmagnetic transition of interface. The top layer of all 5 bilayers keeps its intrinsic magnetic properties and planar structures, so the bottom layer of the bilayer serves the role of buffer layer. These theoretical results could be used to explain the recent STM and XPS experiments. A new interfacial magnetic competition mechanism has been proposed and hopefully it will influence the construction and design of future molecular spintronics.

12:15PM J12.00006 Quantitative Grain Size Distributions of Magnetic Organic Thin Films \cite{4}, THOMAS GREDIG, K. PAUL GENTRY, California State University Long Beach, IVAN K. SCHULLER, University of California San Diego — Many electronic, optical, and magnetic properties of organic thin films depend on the precise morphology of grains. Quantitative grain size distributions of an asymmetric organic molecule are presented and correlated with the magnetic characteristics. Iron phthalocyanine (FePc) thin films are grown on sapphire substrates at varied deposition temperatures to study the effect of grain growth and to experimentally quantify the grain size distributions in organic thin films based on atomic force microscopy images. The data of over 3000 grains for each sample show a pronounced asymmetric growth of grains from a spherical to an elongated needle-like shape. The size along the major axes increases from 35nm to 200nm and is distributed in a different way than the minor axes, which grow from 25nm to 90nm. The dissimilar distributions are attributed to an asymmetric growth rate. Low-temperature hysteresis loops and temperature-dependent magnetization curves for these FePc thin films illustrate the effect of the length of quasi one-dimensional Fe chains on the magnetic properties.

12:27PM J12.00007 The structure of the C_{60} monolayer on Pb(111) \cite{5}, HSIN-I LI, Physics Department, Penn State University, KATHARINA FRANKE, JOSE PASCUAL, Institut fuer Experimentalphysik. Freie Universitaet Berlin, RENEE DIEHL, Physics Department, Penn State University, LEED, PHYSICS DEPARTMENT, PENN STATE UNIVERSITY TEAM, STM, INSTITUT FUER EXPERIMENTALPHYSIK, FREIE UNIVERSITAT BERLIN TEAM — Low-energy electron diffraction and scanning tunneling microscopy studies indicate that a monolayer of C_{60} on Pb(111) forms a modulated structure having an average C_{22}H_{14} nearest-neighbor distance of about 10Å, but a period of about 46Å. The data were analyzed in the context of the Tkatchenko method \cite{6}, and the monolayer structure was identified as two coexisting higher-order commensurate structures, namely (√169 x √169)R16.90° and (√169 x √169)R21.31°, both with 21 C_{60} molecules and 169 Pb atoms in their unit cells. This modulated structure has implications for the electronic structure of the C_{60} film, as measured using scanning tunneling spectroscopy.

12:39PM J12.00008 The structures of a C_{60} monolayer on Al(111) \cite{7}, HEEKEUN SHIN, HSIN-I LI, The Pennsylvania State University, KATARIINA PUSSI, Lappeenranta university of technology, RENEE DIEHL, The Pennsylvania State University — The interfaces of C_{60} films with metal surfaces are of particular interest for molecular electronics applications. The electronic properties of these films are known to depend strongly on their structures and the relative molecular orientations of the C_{60} molecules, yet there are few detailed structure determinations for C_{60} films. When grown at room temperature, C_{60} on Al(111) forms a (2/3×2/3×1)R30° structure with one C_{60} molecule per unit cell, which upon heating converts to a 6x6 structure with 3 C_{60} molecules per unit cell. We present a LEED study of the transition between these structures, a LEED I(E) analysis of the 6x6 structure, and characterization of the adsorption of rare gases onto the surface of the 6x6 C_{60} film. This research is supported by NSF-DMR-0505160 and the Academy of Finland.
The adsorption of C_{60} fullerene molecules on Nanostructured Au (111)  

XIN ZHANG, QUANMIN GUO, RICHARD PALMER, University of Birmingham, NANOSCALE PHYSICS RESEARCH LABORATORY TEAM — The monolayer growth of C_{60} molecules on the Au (111) surface has been studied using STM in ultra high vacuum. The C_{60} molecules tend to form close-packed layers due to a strong inter-molecular interaction. However, within the close-packed layer, there are finer, secondary structures that are specific to each of the three C_{60}/Au interfacial structures (2√3×√3,R30°, in-phase (R0°) and R14°) observed [1]. This is a consequence of the molecule-substrate interaction and our findings demonstrate a much more complex structural variation at the molecule-substrate interface than previously assumed. Furthermore, within the R14° C_{60} layer, slightly darker molecules (30 pm lower) aligned along the 311-20 direction with a ~6 nm spacing are observed and these molecules are arranged in a reasonably well-ordered two-dimensional lattice. C_{60} molecules are also found to decorate the elbow sites of the herringbone reconstructed Au(111) even at room, and when fullerences are deposited to arrays of fabricated monolayer gold stripes (gold-fingers) [2], the molecules show step-specific attachment where the step edges with the (111) micro-facet are preferentially populated.

Quasi-Particle 309

11:15AM J13.00001 Evaluation of time-resolved photoemission spectra from nonequilibrium,
time-domain Green functions, B. MORITZ, T. P. DEVEREAUX, SLAC and Stanford University, H. R. KRISHNAMURTHY, Indian Institute of
Science, J. K. FREERICKS, Georgetown University — Recent experiments have shown the power of femtosecond time-resolved, pump-probe photoelectron
spectroscopy to probe, directly, the nonequilibrium, real-time dynamics of excitations in a correlated material. We use nonequilibrium dynamical mean-field
theory to study the spinless Falicov-Kimball model driven (pumped) out of equilibrium by a constant electric field turned on at \( t = 0 \). We demonstrate the
proper evaluation of the time-resolved photoemission intensity as a function of pump-probe delay for both metallic and Mott-insulating phases of the model
and the dependence of the intensity profile on the specific details of the probe pulse’s lineshape and duration.

11:27AM J13.00002 Mott-like behavior in the pseudogap region of the Hubbard model(1), DIM-
ITRIOS GALANAKIS, Louisiana State Univ., KARLIS MIKELSONS, EHSAN KHATAMI, MARK JARRELL, Louisiana State Univ. and Univ. of Cincinnati,
ALEXANDRU MACRIDIN, MICHAEL MA, Univ. of Cincinnati, JUANA MORENO, Louisiana State Univ. — We study the phase diagram of the two-dimensional
Hubbard model using the Dynamical Cluster Approximation (DCA) in conjunction with the weak-coupling continuous time quantum Monte Carlo (CTQMC) as
the cluster solver. We verify the existence of a quantum critical point at a finite electron doping which separates a fermi liquid region at low electron doping
from the pseudogap region at high electron doping(2). In the pseudogap region the double occupancy, the two particle correlation functions and spectra reveal
a synergism between the development of momenstate and the appearance of short ranged order. We discuss the connection between our results and experiments.

3Vidhyadhiraja et. al., arXiv:0809.1477v1

11:39AM J13.00003 Pairing instabilities and Bose condensation in Hubbard nanoclusters , GAYANATH FERNANDO, KALUM PALANDAGE, Department of Physics, University of Connecticut, Storrs, ARMEN KOCHARIAN, Department of Physics,
California State University, Los Angeles, JAMES DAVENPORT, Computational Science Center, Brookhaven National Laboratory, Upton — Pairing instabilities
found from exact studies of small Hubbard clusters with different topologies appear to provide answers to some long standing puzzles. Electronic charge and spin
pairing instabilities in a phase space defined by temperature, magnetic field and chemical potential, lead to properties that are remarkably similar to correlated,
inhomogeneous bulk systems such as the high temperature superconductors and colossal magnetoresistance materials. In particular, the role of square- planar
graphene is geometry born out as the vertex coupling in an octahedron is shown to have a detrimental effect on the negative charge and positive spin gaps, which are
favorable to forming a Bose condensate in the region of instability. In addition, it is shown that magnetic flux can get trapped in stable minima at half integral
units of the flux quantum.

11:51AM J13.00004 Functional renormalization group beyond the static approximation and
its application to two-dimensional Hubbard model, HIROKAZU TAKASHIMA, University of Tokyo, Dept. Phys., RYOTARO
ARITA, University of Tokyo, Dept. Applied Phys., KAZUHIKO KUROI KUROI, University of Electro-Communications, HIDEO AOKI, University of Tokyo, Dept. Phys.
— While the functional renormalization group(1RG) is a powerful theoretical method for strongly correlated electron systems which treats diagrams systematically
within a framework of quantum field theory, the static approximation is adopted where the Matsubara frequency dependence of the four-point coupling and renormalization
for the self-energy are ignored. Here we propose a method to go beyond the static approximation by devising an efficient parameterization for the
four-point coupling in the Matsubara frequency space, which is combined with a previous improved algorithm of ours(1) based on a Cartesian box discretization.

12:03PM J13.00005 Parquet approximation calculation for the 2D Hubbard model(1) , SHUXIANG
YANG, HERBERT FOTSO, JUN LIU, MARK JARRELL, University of Cincinnati, EDUARDO D’AZEVEDO, THOMAS MAIER, Oak Ridge National Laboratory,
KAREN TOMKO, Ohio Supercomputer Center, RICHARD SCALETTAR, University of California - Davis, THOMAS PRUSCHKE, University of Goettingen,
Germany — We present a numerical solution of the parquet approximation on a half-filled 4x4 Hubbard cluster. The parquet formalism is a two-particle self
consistent set of equations relating the reducible, irreducible, and fully irreducible vertexes. The simplest approximation from this formalism is the so-called
parquet approximation, in which the fully irreducible vertex is approximated by the bare interaction. Our results are compared with results from Self-Consistent
2nd-order approximation, Fluctuation Exchange (FLEX) approximation and the Determinental Quantum Monte Carlo (DQMC) calculation.

3We would like to acknowledge the support from SciDAC and NSF PIRE

12:15PM J13.00006 Spatially inhomogeneous phase in the two-dimensional repulsive Hubbard
model(1), CHIA-CHEN CHANG, SHIWEI ZHANG, Department of Physics, The College of William and Mary — Using recent advances in the constrained-
path auxiliary-field quantum Monte Carlo method, we study the ground state of the two-dimensional, single-band Hubbard model at intermediate interactions
\( (2 < U/J \leq 4) \). In the first part of this study, we have determined the equation of state and also calculated the spin-spin correlation functions in square
lattices up to size 16 x 16. Shell effects are eliminated and finite-size effects are greatly reduced by boundary condition integration. It was shown that, upon
doping, the system separates into a region with antiferromagnetic (AF) order and a hole-containing region without AF order. In the second part, we study
rectangular supercells up to 8 x 64 to examine the nature of this inhomogeneous phase, in particular to probe phase separation versus stripes and spin-density
12:27PM J13.00007 Inhomogeneous ground state in the Hubbard model: a mean-field study. JIE XU, CHIA-CHEN CHANG, ERIC J. WALTER, SHIWEI ZHANG, The College of William and Mary — We report unrestricted Hartree-Fock (UHF) results for the ground state of the single-band Hubbard model in two- and three-dimensions with repulsive onsite interaction and nearest-neighbor hopping. At half-filling, the Hartree-Fock (HF) approach is sufficient to capture the basic physics of long-range antiferromagnetic order. Away from half-filling, many earlier HF calculations have been performed in the 2-D Hubbard model, which indicated the formation of domain walls and stripes. We numerically solve the self-consistent UHF equations for a range of densities at weak and intermediate interaction strengths. An annealing scheme coupled with multiple initial configurations is adopted to reach the global minimum. Our goal is to contrast the UHF ground state in the Hubbard model and the HF spin-density wave states in the continuum (jellium) [1]. A second goal is to obtain quantitative information of the UHF ground state for examination by accurate many-body methods such as quantum Monte Carlo. [1] A. W. Overhauser, Phys. Rev. 128, 1437 (1962); Shiwei Zhang and D.M.Ceperley, Phys. Rev. Lett. 100, 236404 (2008).

12:39PM J13.00008 Discontinuous quenching of quasi-particle states in nonequilibrium dynamical mean-field theory. RYAN HEARY, JONG HAN, SUNY at Buffalo — In an effort to model strongly correlated heterojunctions in nonequilibrium we construct a nonequilibrium dynamical mean-field theory for the Hubbard model where each lattice site is a superposition of a left-moving and right-moving state. The left and right movers have the respective chemical potentials, \( \mu_L = \frac{\Phi}{2} \) and \( \mu_R = -\frac{\Phi}{2} \), where \( \Phi \) is the chemical potential bias. The quasi-particle properties are calculated as a function of the Coulomb interaction, \( U \), and \( \Phi \). As the chemical potential bias is turned on we find that the quasi-particles become strongly renormalized. When \( U_{ij} < U < U\mu \), where \( U\mu \) is the critical \( U \) for the metal-insulator transition in equilibrium and \( U_{ij} \sim 0.7U\mu \). the quasi-particles are destroyed discontinuously at a critical chemical potential bias, \( \Phi_{\text{crit}} \). For \( U < U_{ij} \) the quasi-particles disappear continuously as \( \Phi \) is enhanced. Therefore \( U_{ij} \) is the critical \( U \) which defines the boundary between the quasi-particles being continuously and discontinuously suppressed. By defining the quasi-particle energy, \( \epsilon_{QP} \), as the half-width at half-maximum of the quasi-particle peak, we find that for \( \Phi/\Phi_{\text{crit}} \leq 0.4 \), the quasi-particle energies scale to a single curve.

1Supported by NSF DMR-0426826

12:51PM J13.00009 Self-consistent solution for the Hubbard model at the two-particle and one-particle level using the parquet formalism. HERBERT FOTSO, SHUXIANG YANG, JUN LIU, MARK JARRELL, University of Cincinnati, EDUARDO D’AZEVEDO, THOMAS MAIER, Oak Ridge National Laboratory, KAREN TOMKO, Ohio Supercomputer Center, RICHARD SCALLETAR, University of California - Davis — The parquet formalism is used to solve self-consistently, both at the one-particle and at the two-particle levels, the Hubbard model on a 2-D square lattice. The parquet equation and the Bethe-Salpeter equation are combined into one Newton fixed point problem which is then solved by taking advantage of the existing linear solvers such as GMRES and BiCGStab. Some quantities of interest are calculated and the results are compared to those of Determinental Quantum Monte Carlo (DQMC). We also discuss the importance of this work in the multiscale treatment of the High Tc Cuprates.

1We would like to acknowledge support from SciDAC and NSF PIRE

1:03PM J13.00010 Quantum Monte Carlo study of few-electron concentric double quantum rings. LEONARDO COLLETTI, Istituto Nazionale di Fisica Nucleare, Italy, FRANCESC MALET, MARTI PI, Universitat de Barcelona, Spain, FRANCESCO PEDERIVA, Università di Trento, Italy — We consider few-electron concentric double quantum rings with parabolic confining potential and compare the ground-state energies calculated by exact diagonalization of the Hamiltonian, accurate quantum Monte Carlo and local spin-density functional approaches. Electronic localization in one of the rings and the formation of rotating Wigner molecules is shown respectively from the one-body and the two-body density operators. As the confinement strength is finely increased, the circularly-symmetric electron density exhibits a radial crossover from the outer ring to the inner one without altering the angular character of the system.

1:15PM J13.00011 Accurate Determination of Tensor Network State of Quantum Lattice Models in Two Dimensions. TAO XIANG, H.C. JIANG, Z.Y. XIE, Q.N. CHEN, Z.Y. WENG, Institute of Physics, Chinese Academy of Sciences — We have proposed a novel numerical method to calculate accurately physical quantities of the ground state using the tensor network wave function in two dimensions. The tensor network wave function is determined by an iterative projection approach which uses the Trotter-Suzuki decomposition formula of quantum operators and the singular value decomposition of matrix. The norm of the wave function and the expectation value of a physical observable are evaluated by a novel second renormalization group method of tensors. Our method allows a tensor network wave function with a high bond degree of freedom to be handled accurately and efficiently in the thermodynamic limit. For the Heisenberg model on a honeycomb or square lattice, our results for the ground state energy and the staggered magnetization agree well with those obtained by the quantum Monte Carlo and other approaches.

1:27PM J13.00012 ABSTRACT WITHDRAWN

1:39PM J13.00013 Electronic structure of LaM\(_{2}\)O\(_{3}\) (M=Ti~Cu) by GW approximation. YOSHIRO NOHARA, TAKEO FUJIWARA, University of Tokyo — We investigate the electronic structure of LaM\(_{2}\)O\(_{3}\) (M=Ti~Cu) by GW approximation. The calculated spectra show good agreement with the experimentally observed ones. The on-site Coulomb interaction is affected by strong screening mechanism in trivalent transition metal ions, which is qualitatively different from those in mono-oxides M\O\(_{3}\) of divalent transition metals. In trivalent transition metal ion systems LaM\(_{2}\)O\(_{3}\), 3d electrons are affected by deep atomic potential. Therefore, the 3d orbital locates energetically much nearer to O 2p levels than in M\O\(_{3}\). Moreover, in the cases of M\(^{++}\)=C\(_{2}\)\(^{2+}\), M\(^{++}\)=Mn\(_{2}\)\(^{4+}\) and Fe\(_{2}\)\(^{3+}\) systems, transition metal ions are well spin-polarized, and 3d levels locate very near to O 2p levels. As a result, these systems have large screening effects due to the extended d-electrons. In the cases of M\(^{++}\)=Ni\(_{2}\)\(^{2+}\) and Cu\(_{2}\)\(^{2+}\), the systems are metallic and are affected by strong screening effects. In the other cases of M\(^{++}\)=Ti\(_{2}\)\(^{4+}\), V\(_{2}\)\(^{4+}\), and Co\(_{2}\)\(^{3+}\), there are small screening effects causing large static screened Coulomb interaction.

1:51PM J13.00014 GW correlation effects on the quasiparticle energies of Np and Pu. ATHANASIOS CHANTIS, ROBERT ALBERS, Theoretical Division, Los Alamos National Laboratory, AXEL SVANE, NIELS CHRISTENSEN, Department of Physics and Astronomy, University of Aarhus, MARK VAN SCHILFGAARDE, TAKAO KOTANI, School of Materials, Arizona State University — We present results for the electronic structure of plutonium and neptunium by using a recently developed quasiparticle self-consistent GW method (QSGW). The self-consistent GW quasiparticle energies are compared to those obtained within the Local Density Approximation (LDA) for several volumes of the unit cell. The goal of the calculations is to understand systematic trends in the effects of electronic correlations on the quasiparticle energy bands as a function of the localization of the f orbitals. We show that correlation effects narrow the f bands in two significantly different ways. Besides the expected narrowing of individual f bands (flatter dispersion), we find that an even more significant effect on the f bands is a decrease in the crystal-field splitting of the different bands. We discuss how these changes affect the topology of the Fermi surface and we demonstrate the importance of the quasiparticle self-consistency in obtaining these results.
Porosity of mixed granular media of hard and soft grains. EMILIE VERNEUIL, DOUGLAS J. DURIAN, University of Pennsylvania — The addition of soft particles to granular media modifies the packing properties such as the volume fraction and the interconnection of pores as a consequence of the particles squishiness. A macroscopic property that depends on the local arrangement of the grains is the hydraulic conductivity. Hence, hydrogen particle disks are developed as additives to sandy soils to improve the irrigation efficiency by decreasing the rate of far depth infiltration. However, the parameters that control the mixed material porosity have not been explored. Our experimental study of the flow properties of mixtures of glass beads and swollen hydrogels aims at deriving simple arguments to connect the macro-scale measurement of the hydraulic conductivity to the arrangement of the grains around the soft particles, which determines the fraction of blocked pores. Our results show that the porosity decreases with the number of swollen gel per unit volume of the mixture. The conductivity also decreases as the size ratio of gel to glass bead decreases down to 1. A simple description accounting for the elastic contacts between glass beads and gel surface qualitatively accounts for the data.

Experimental characterization of microstate probabilities in mechanically stable packing of frictionless disks. M.D. SHATTUCK, Levich Institute and Physics Department, The City College of New York, New York, NY, G.-J. GAO, Department of Mechanical Engineering, Yale University, New Haven, CT, J. BLAWZDIEWICZ, C.S. O’HERN, Departments of Mechanical Engineering and Physics, Yale University, New Haven, CT — We report on a new experimental technique to produce mechanically stable packings of frictionless disks. The system consists of a quasi-2D vertical cell filled with bi-disperse disks. The disks are vigorously shaken and then allowed to settle under gravity in the presence of high-frequency low-amplitude vibrations to eliminate frictional effects. For a system of 7 particles we find approximately 1000 mechanically stable states. The most probable states occur at least 10^6 times more often than those that are least probable. This is in direct contradiction to the fundamental postulate in statistical mechanics, that all possible microstates are equally probable and calls into question granular theories based on this assumption. We have measured the frequency distribution of the states in the systems and in corresponding discrete element simulations, and find excellent agreement. We have also examined how the microstate distribution scales with system size and will connect the microstates to macroscopic quantities such as the density to predict the statistics of macroscopic properties.

Spectral responses in granular compaction. LING-NAN ZOU, The James Franck Institute and Department of Physics, the University of Chicago — I study the compaction of a granular pack under periodic tapping. The magnitude of acceleration \( \Gamma \) at each tap is modulated with frequency \( \omega \) and amplitude \( \delta \): \( \Gamma(t) = \Gamma_{DC} + \Gamma \sin(\omega t) \), where \( t \) is time measured by the number of taps. From the temporal modulation \( \delta v \) in packing volume \( v \), frequency-locked to the modulated tapping input, we can define the real and imaginary volume susceptibilities \( 
\chi'_\nu(t) = (\delta v / \delta \Gamma) \cos \theta \) and \( 
\chi''_\nu(t) = (\delta v / \delta \Gamma) \sin \theta \), where \( \theta \) is the phase lag between \( \Gamma(t) \) and \( \nu(t) \). As a function of \( \Gamma_{DC} \), \( \chi'_\nu \) and \( \chi''_\nu \) are peaked at low \( \Gamma_{DC} \), a behavior reminiscent of the temperature-dependent susceptibilities in dielectric and spin glasses. For the packing of small particles (\( d = 0.5 \text{ mm} \)) in ambient pressure, \( \chi'_\nu \) exhibits memory and rejuvenation effects under \( \Gamma_{DC} \) cycling, similar to that seen in the magnetic susceptibility of spin glasses when subjected to thermal cycling \( [1] \). However this memory effect is suppressed for the packing of larger particles and in vacuum. The measurement of volume susceptibilities shows promise as a new way to study the packing of granular materials, and as an avenue to explore analogies between jammed grains and molecular and spin glasses.

Deformed Droplets in Static Two-Dimensional Emulsions. PEARL J. YOUNG, DANDAN CHEN, ERIC R. WEEKES, Physics Dept., Emory University — We confine oil-in-water emulsions between two parallel plates, so that the droplets are essentially squeezed into quasi two-dimensional disks, somewhat analogous to granular photoelastic disks. By varying droplet area fraction, we seek to quantify the jamming transition of this static system. At a critical area fraction, the composition of the system should no longer be characterized primarily by circular disks but by disks deformed to varying degrees. We study a system of toluene droplets in water. As expected, we find that an increase in area fraction corresponds with an increase in average droplet deformation. Further, an increase in average droplet deformation corresponds with an increase in the heterogeneity of deformity within a given sample.

Jammed Rod-like Granular Materials in Hoppers. SUMMER SARAF, SCOTT FRANKLIN, Rochester Institute of Technology — Long thin rods form solid plugs that are far more rigid than piles of ordinary sand, greatly affecting their ability to flow through small openings. We have built a hopper whose aperture, angle, and width can be independently varied and are studying the frequency with which rods of different length, width, and aspect ratio jam. As the opening aperture becomes larger, the mean number of particles that exit the hopper before a jam occurs naturally increases, but the probability distribution of fluctuations about this mean is unchanged. Unexpectedly, whereas the event distribution function \( P(s) \) for spheres decays exponentially, we find the distribution for rods falls off as a power law with exponent \( \alpha = -1.41 \pm 0.08 \). We are also investigating the growth of the mean event size \( \langle s \rangle \), as the aperture increases for possible divergence, which would imply a critical aperture size above which particles would never jam.

Forces and displacements near the granular jamming threshold. MAHESH BANDI, Los Alamos National Laboratory, ANDRAS LIBAL, University of Antwerp, MICHAEL RIVERA, ROBERT ECKE, Los Alamos National Laboratory — We experimentally study the dynamics of jamming by dragging a probe disk in a two-dimensional bi-dispersed system of randomly packed photo-elastic disks. All measurements are made at packing fractions relative to the critical fraction at which jamming occurs. We measure the local force felt by the probe disk and compare it with the system’s global response with sensors placed along the system boundaries. We also visually monitor the disk displacements in the system, which are expected to become increasingly constrained as a function of increasing packing fraction.
12:27PM J14.00007 The angoricity describes the approach to the jamming , KUN WANG, CHAOMING SONG, PING WANG, HERNAN MAKSE, Levich Institute and Physics Department of CCNY — The application of concepts from equilibrium statistical mechanics to out of equilibrium systems has a long history offering the fascinating possibility to describe a diverse range of systems from glasses to grains. For jammed systems, the key idea was to replace the energy ensemble describing conservative systems by the volume ensemble for dissipative jammed systems. However, this approach is not able to describe the jamming critical point for deformable particles such as emulsions where the volume fraction, coordination number and elastic moduli behaves as power-law of the external stress as the system approaches jamming. The geometrical considerations to be augmented by the ensemble of stresses described by the angoricity which replaces the role played by the temperature in thermal systems. Here we perform a basic test of the stress ensemble of jammed matter by following two independent approaches: we exhaustively enumerate the available jammed states and numerically follow the dynamics of the system near the jamming point. A direct comparison between both methods supports the idea of thermalization at a given angoricity which is shown to determine the systems state as it approaches the jamming transition. This result opens the possibility to calculate important quantities near J-point.

12:39PM J14.00008 Equilibration in model granular subsystems: An experimental test for Edwards’ compactivity , FREDERIC LECHENAULT, JAMES PUCKETT, KAREN DANIELS, NCSU — We experimentally investigate the statistical features of the stationary states reached by two idealized granular liquids able to exchange volume. The system consists in two binary mixtures of the same number (and area) of soft disks, but with different surface properties. The disks sit on a horizontal air table and are separated by a mobile wall. Energy is injected in the system by means of an array of randomly activated coil bumpers standing as the edges of the cell. Due to the energy injection, the system acts like a slow liquid and eventually jams at high packing fraction. We characterize the macroscopic states by studying the motion of the piston. We find that its average position is different from one half, and is a non monotonic function of the overall packing fraction, which reveals the crucial role played by the surface properties in the corresponding density of states. We then study the bulk statistics of the packing fraction and find confirmation of the macroscopic behavior. However, the local fluctuations of the packing fraction are uniquely determined by its average, and hence independent of the interaction between disks. This result, together with the existence of a point at which the two sub-systems have the same volume, enables us to show that Edwards’ compactivity does not have the same value in the two equilibrated subsystems.

12:51PM J14.00009 Stability of Packings of Soft Elliptical Grains in 2D1 , MITCHELL MAILMAN, BULBUL CHAKRABORTY, Brandeis University, CARL SCHRECK, COREY O’HERN, Yale University — Simulations of hard ellipses packings show that these ellipse packings are generally hypostatic. By using a dynamical matrix approach to analyzing the stability of two-dimensional ellipse packings, we show that the degree of hypostaticity is related to the fraction of zero-frequency modes. The packings are generated using a compression protocol previously employed in disk packings and an energy function based on the overlap model developed by Perram and Wertheim. The density of states exhibits a low frequency peak that approaches zero as the compression is reduced. There is a gap separating this peak from the higher frequency modes. In this talk, we will demonstrate the existence of a scaling relation between the vibrational spectra at different aspect ratios. We will also discuss the origin of the low frequency modes and the origin of the scaling. Analysis of the relationship between contact numbers and vibrational modes will be used to compare and contrast the jamming transition in disks and ellipses.

1:03PM J14.00010 Shearing dynamics and jamming density , PETER OLSSON, DANIEL VÄGBERG, Department of Physics, Umeå University, Umeå, Sweden, STEPHEN TIETEL, Department of Physics and Astronomy, University of Rochester, Rochester, NY 14627 — We study the effect of a shearing dynamics on the properties of a granular system, by examining how the jamming density depends on the preparation of the starting configurations. Whereas the jamming density at point J was obtained by relaxing random configurations [O’Hern et al, Phys. Rev. E 68, 011306 (2003)], we apply this method to configurations obtained after shearing the system at a certain shear rate. We find that the jamming density increases somewhat and that this effect is more pronounced for configurations produced at smaller shear rates. Different measures of the order of the jammed configurations are also discussed.

1:15PM J14.00011 Theory of Elasticity and Glassy Dynamics of Suspensions of Soft Particles , JIAN YANG, KENNETH SCHWEIZER, University of Illinois, Urbana-Champaign — A microscopic theory for the shear modulus and slow dynamics of soft colloidal systems composed of many arm star-polymers and intra-molecularly crosslinked microgels is described. The role of particle volume fraction and softness (arm number for stars and contact modulus for micropel grains) on the ideal mode coupling kinetic arrest transition, elastic modulus, relaxation time in the activated hopping regime, diffusion constant, dynamic fragility, and absolute yield stress and strain have been systematically explored. The low-frequency shear modulus is characterized by two volume fraction regimes: power law scaling at intermediate volume fractions and a linear law beyond the nominal jamming point. Connections between single particle softenes, interparticle packing correlations, and viscoelastic properties have been established. For both microgels and many arm stars, the effective dynamical fragility varies over a wide range as a function of particle softness. Comparisons of the theoretical results with experiments on many arm star and microgel paste systems have been carried out.

Tuesday, March 17, 2009 11:15AM - 2:15PM –
Session J15 GQI: Quantum Entanglement 316

11:15AM J15.00001 Understanding Entanglement as a Resource for Quantum Information Processing2 , SCOTT M. COHEN, Department of Physics, Duquesne University — Ever since Erwin Schrodinger shocked the physics world by killing (and not killing) his cat, entanglement has played a critical role in attempts to understand quantum mechanics. More recently, entanglement has been shown to be a valuable resource, of central importance for quantum computation and the processing of quantum information. In this talk, I will describe a new diagrammatic approach to under-standing why entanglement is so valuable, the key idea being that the eglement between two systems “creates” multiple images of the state of a third. By way of example, I will show how to “visualize” teleportation of unknown quantum states, and how to use entanglement to determine the (unknown) state of a spatially distributed, multipartite quantum system. Illustirative examples of this entanglement-assisted local state discrimination are sets of orthogonal product states exhibiting what is known as “non-locality without entanglement”, including unextendible product bases. These ideas have also proven useful in using entanglement to implement a unitary interaction between spatially separated (and therefore non-interacting!) systems.

2Supported in part by NSF Grant PHY-0456951 and PHY-0757251 and through a grant from the Research Corporation.
the same central charge. Interpretations of the results are given in terms of branch-point twist fields. The present study provides a new way to show that the information is scale-invariant and depends on the compactification radius (or the Tomonaga-Luttinger parameter) of the bosonic field, as opposed to the general prediction of Calabrese and Cardy. Furthermore, we show that states known as the maximal slice states always violate the Svetlichny inequality and analogous to the 2-qubit case, the amount of violation increases with the 3-tangle. The generalized GHZ states and the maximal slice states have unique tripartite entanglement and nonlocality properties in the set of all pure states.

Quantum Noise as an Entanglement Entropy Meter.

We investigate the generic scaling of the mutual information in a class of one-dimensional quantum critical systems described by a bosonic field theory with a central charge $c=1$, and show that it is universal. A numerical analysis of a spin-chain model reveals that the mutual informations have unique tripartite entanglement and nonlocality properties in the set of all pure states. The present study provides a new way to determine the compactification radius, and furthermore demonstrates the ability of the mutual information to distinguish different conformal field theories with the same central charge.

Genuine tripartite entanglement and nonlocality in 3-qubit GHZ-class states.

SHOHINI GHOSE, NEIL SINCLAIR, SHANTANU DEBNATH, Wilfrid Laurier University. RENE STOCK, University of Toronto. PRANAW RUNGTA, IIS, India — Multiqubit entanglement is a crucial ingredient for large-scale quantum information processing, and has been the focus of several recent studies. Entanglement between qubits can lead to violations of Bell-type inequalities that are satisfied by local hidden variable models, indicating the nonlocal nature of the correlations between qubits. For 2-qubit pure states, bipartite entanglement is simply related to the Bell-CHSH nonlocality parameter. No such analytical relation between multipartite entanglement and nonlocality has yet been obtained for systems of three or more qubits. We have derived relationships between genuine tripartite entanglement and nonlocality for families of 3-qubit GHZ-class pure states. We quantify tripartite entanglement by the 3-tangle and derive its relationship to the Svetlichny inequality for testing tripartite nonlocality. For the class of generalized GHZ states, although the 3-tangle is always non-zero, we identify some states that do not violate the Svetlichny inequality. Furthermore, we show that states known as the maximal slice states always violate the Svetlichny inequality and analogous to the 2-qubit case, the amount of violation increases with the 3-tangle. The generalized GHZ states and the maximal slice states have unique tripartite entanglement and nonlocality properties in the set of all pure states.

Coherent Light Fields for Entanglement based Quantum Communication.

KIM FOOK LEE, Department of Physics, Michigan Technological University, Houghton, MI 49931 — Nonlocal polarization correlations of two distant observers based on Stapp's formulation are observed by using coherent light fields. Using a 50/50 beam splitter transformation, a vertically polarized coherent light field is entangled with a horizontally polarized coherent noise field. The superposed light fields at each output port of the beam splitter are sent to two distant observers, where the fields are interfered and manipulated at each observer by using a quarter wave plate and an analyzer. The interference signal contains information about the projection angle of the analyzer, which is hidden by the phase noises. The nonlocal correlations between the projection angles of two distant observers are established by analyzing their data through analog signal multiplication without any post-selection technique. This scheme can be used to implement Ekert's protocol for quantum key distribution. The implementation of two independent coherent states in this scheme is also discussed.

Quantum-entanglement aspects of polaron systems.

VLADIMIR STOJANOVIC, Carnegie Mellon University, MIHAJLO VANEVIC, University of Basel, Switzerland — We describe quantum entanglement inherent to the polaron ground states of coupled electron-phonon (or, more generally, particle–phonon) systems based on a model comprising both local (Holstein-type) and nonlocal (Peierls-type) coupling. We study this model using a variational method supplemented by the exact numerical diagonalization on a system of finite size. By way of subsequent numerical diagonalization of the reduced density matrix, we determine the particle-phonon entanglement as given by the von Neumann and linear entropies. Our results are strongly indicative of the intimate relationship between the particle localization/delocalization and the particle-phonon entanglement. In particular, we find a compelling evidence for the existence of a non-analyticity in the entanglement entropies with respect to the Peierls-coupling strength. The occurrence of such non-analyticity — not accompanied by an actual quantum phase transition — reinforces analogous conclusion drawn in several recent studies of entanglement in the realm of quantum-dissipative systems. In addition, we demonstrate that the entanglement entropies saturate inside the self-trapped region where the small-polaron states are nearly maximally mixed.

Entanglement generation under continuous parity measurement.

ANDREW JORDAN, Unv. of Rochester — We examine the stochastic dynamics of entanglement for an uncoupled two-qubit system, undergoing continuous parity measurement. Starting with a fully mixed state, the entanglement is zero for a finite amount of time, when it is suddenly created, which we refer to as entanglement genesis. There can be further entanglement sudden death/birth events culminating in the formation of a fully entangled state. We present numerical investigations of this effect together with statistics of the entanglement genesis time in the weak measurement limit as well as the quantum Zeno limit. An analytic treatment of the physics is presented, aided by the derivation of a simple concurrence equation for Bell basis X-states. The probability of entanglement border crossing and mean first passage times are calculated for the case of measurement dynamics alone. We find that states with almost the same probability of entanglement border crossing can have very different average crossing times. Our results provide insights on the optimization of entanglement generation by measurement.

Interferometric Determination of Concurrence of Unknown Two-Qubit Entanglement.

S.-S. B. LEE, H.-S. SIM, KAIST — We propose a scheme for both distilling and quantifying entanglement, applicable to individual copies of an arbitrary unknown two-qubit state. It is realized in a usual two-qubit interferometry with local filtering. Proper filtering operation for the maximal distillation of the state is achieved, by erasing single-qubit interference, and then the concurrence of the state is determined directly from the visibilities of two-qubit interference. For some representative quantum states, the efficiency is compared between our interferometric scheme and the full state tomography.

Scattering approach to the entanglement entropy area law for fermions.

GREGORY LEVINE, Hofstra University — The entanglement entropy (EE) of a critical fermion system coupled to another system by a “weak link” is studied. In this model, EE arises from two-qubit interference. For some representative quantum states, the efficiency is compared between our interferometric scheme and the full state tomography.

Mutual information and compactification radius in 3-qubit GHZ-class states.

SHOHINI GHOSE, NEIL SINCLAIR, SHANTANU DEBNATH, Wilfrid Laurier University. RENE STOCK, University of Toronto. PRANAW RUNGTA, IIS, India — Multiqubit entanglement is a crucial ingredient for large-scale quantum information processing, and has been the focus of several recent studies. Entanglement between qubits can lead to violations of Bell-type inequalities that are satisfied by local hidden variable models, indicating the nonlocal nature of the correlations between qubits. For 2-qubit pure states, bipartite entanglement is simply related to the Bell-CHSH nonlocality parameter. No such analytical relation between multipartite entanglement and nonlocality has yet been obtained for systems of three or more qubits. We have derived relationships between genuine tripartite entanglement and nonlocality for families of 3-qubit GHZ-class pure states. We quantify tripartite entanglement by the 3-tangle and derive its relationship to the Svetlichny inequality for testing tripartite nonlocality. For the class of generalized GHZ states, although the 3-tangle is always non-zero, we identify some states that do not violate the Svetlichny inequality. Furthermore, we show that states known as the maximal slice states always violate the Svetlichny inequality and analogous to the 2-qubit case, the amount of violation increases with the 3-tangle. The generalized GHZ states and the maximal slice states have unique tripartite entanglement and nonlocality properties in the set of all pure states.

Quantum Noise as an Entanglement Entropy Meter.

ISRAEL KLICH, University of Virginia, LEONID LEVITOV, MIT — Entanglement entropy, which is a measure of quantum correlations between separate parts of many-body systems, is defined solely in terms of the many-body density matrix, with no relation to any particular observables. Because of that, it has not been clear how to access this quantity experimentally. Here we unveil a universal relation between entanglement entropy of fermions and statistics of current flowing through a quantum point contact. This relation provides a way to experimentally measure entanglement entropy, and test seminal results of conformal field theory such as the prediction of Holzhey, Larsen and Wilczek for entanglement entropy, and test seminal results of conformal field theory such as the prediction of Holzhey, Larsen and Wilczek for entanglement entropy.
1:03PM J15.00010 Universal behavior of the entanglement entropy in 2D conformal quantum critical points and generalized quantum dimer models, BENJAMIN HSU, University of Illinois, Urbana-Champaign, MICHAEL MULLIGAN, Stanford University, EDUARDO FRADKIN, University of Illinois, Urbana-Champaign, EUN-AH KIM, Cornell University — We study the scaling behavior of the entanglement entropy of two dimensional conformal quantum critical systems, i.e., systems with scale invariant wave functions. They include two-dimensional generalized quantum dimer models on bipartite lattices and quantum loop models, as well as the quantum Lifshitz model and related gauge theories. We show that, under quite general conditions, the entanglement entropy of a large and simply connected sub-system of an infinite system has a universal contribution which is independent of the size of the region. This universal contribution is computable in terms of the properties of the underlying large-scale conformal structure of the wave function of these quantum critical systems.

1:15PM J15.00011 Theory of finite-entanglement scaling at one-dimensional quantum critical points, FRANK POLLMANN, SUBROTO MUKEERJEE, ARI TURNER, JOEL MOORE, UC Berkeley — We present a quantitative scaling theory of finite-entanglement approximations at one-dimensional quantum critical points. Finite-entanglement scaling is governed not by the scaling dimension of an operator but by the “central charge” of the critical point, which counts its universal degrees of freedom. An important ingredient is the universal distribution of density-matrix eigenvalues (the “entanglement spectrum”) at a critical point recently obtained by Calabrese and Lefevre. The theory is compared to the numerical error scaling of several quantum critical points, obtained by the infinite Time Evolved Block Decimation (iTEBD) method that extends the conventional Density-Matrix Renormalization Group (DMRG) algorithm.

1:27PM J15.00012 ABSTRACT WITHDRAWN

1:39PM J15.00013 Entanglement witnesses for n-qubit systems, RICHARD BONDE, ANDREW SCHAF, ELIZABETH BEHRMAN, Department of Physics, Wichita State University — We consider the entanglement of states under the renormalization-group (RG) transformations and apply it to the ground states of Hamiltonians that possess quantum phase transitions. We find that near critical points, the ground-state entanglement under RG transformation exhibits singular behavior. The singular behavior under finite steps of RG reveals the correlation length exponent. However, under the infinite steps of RG transformation, the singular behavior is rendered different, and it is not universal unless the critical point can be described by a conformal field theory.

1:51PM J15.00014 Comparisons of entanglement witnesses for n-qubit systems, RICHARD BONDE, ANDREW SCHAF, ELIZABETH BEHRMAN, Department of Physics, Wichita State University — An overlooked problem in witness design is the possibility of phase offset contamination. For example, the singlet EPS 2-qubit state $\frac{1}{\sqrt{2}} (|↑↓⟩ - |↓↑⟩)$ differs from $\frac{1}{\sqrt{2}} (|↑⟩|↓⟩ + |↓⟩|↑⟩)$ only by a relative phase factor of $e^{iπ}$, yet both states are fully entangled. We compare in detail several published witnesses on entangled pure and mixed systems with varying degrees of phase offset.

2:03PM J15.00015 ABSTRACT WITHDRAWN

Tuesday, March 17, 2009 11:15AM - 1:03PM — Session J16 DAMOP: Focus Session: Disorder in Ultra-Cold Gases 317

11:15AM J16.00001 The Role of Interactions in Disorder Induced Damping of Dipole Oscillations of a Bose-Einstein Condensate, SCOTT POLLACK, D. DRIES, T.A. CORCOVILOS, R.G. HULET, Rice Quantum Institute and Department of Physics and Astronomy, Rice University, Houston, TX 77005 — We investigate the damping of dipole oscillations of a $^7\text{Li}$ Bose-Einstein condensate (BEC) in a disordered optical potential. In our highly tunable system we vary the disorder strength $V_D$, the initial velocity of the BEC, and the chemical potential $\mu$ by adjusting the $s$-wave scattering length $a$ via a Feshbach resonance. We observe the breaking of superfluid flow, for values of $V_D$, as small as 0.1$\mu$, and cessation of motion for $V_D \sim \mu$. Counter-intuitively, at supersonic velocities the flow becomes asymptotically dissipationless regardless of the disorder strength. We test the validity of the scaling $V_D/\mu$ over several decades of $a$, including values of $a$ as small as 0.01$\mu$, where magnetic dipole effects dominate. We also report on observations of dissipative flow of nearly non-interacting ideal quantum gases and bright matter-wave solitons.

1Work supported by NSF, ONR, the Keck Foundation and the Welch Foundation.

11:27AM J16.00002 Disorder effects in the evolution from BCS to BEC superfluidity, LI HAN, CARLOS A. R. SA DE MELO, Georgia Institute of Technology — We discuss the effects of disorder on the critical temperature of superfluids during the evolution from BCS to BEC. For $s$-wave superfluids we find that the critical temperature is weakly affected by disorder in the BCS regime as described in Anderson's theorem, even less affected by disorder at zero chemical potential (near unitarity), but strongly affected by disorder in the BEC regime, where Anderson's theorem does not apply. This suggests that the superfluid is more robust to the effects of disorder at the interaction parameter where the chemical potential vanishes (close to unitarity). We construct a three dimensional phase diagram of critical temperature, disorder and interaction parameter $\lambda$, and show that there are regions of localized superfluidity, as well as insulating regions due to Anderson localization of fermions (BCS regime) and molecular bosons (BEC regime). The phase diagram for higher angular momentum (e.g. $p$-wave and $d$-wave) is also analyzed, where the effects of disorder are much more dramatic in the BCS regime in comparison to the $s$-wave case because pair breaking is strong, while the disorder effects in BEC regime are similar to what occurs in the $s$-wave case.

We thank NSF (DMR-0709584) for support.
11:39 AM J16.00003 Magnetism Localization and Hole Localization in Fermionic Atoms Loaded on Optical Lattice, MASAHIKO OKUMURA, SUSUMU YAMADA, CCSE, Japan Atomic Energy Agency, NOBUHIKO TANIGUCHI, Institute of Physics, University of Tsukuba, MASAHIKO MACHIDA, CCSE, Japan Atomic Energy Agency — In order to study an interplay of disorder, correlation, and spin imbalance on antiferromagnetism, we systematically explore the ground state of one-dimensional spin-imbalanced Fermionic atoms loaded on an optical lattice by using the density-matrix renormalization group method [1]. We find that disorders localize the antiferromagnetic spin density wave induced by imbalanced fermions and the increase of the disorder magnitude shrinks the areas of the localized antiferromagnetized regions. Moreover, the antiferromagnetism finally disappears above a large disorder. We also study hole doped cases [2]. Concentrating on the doped-hole density profile, we find in a large U/\tau regime that the clean system exhibits a simple fluid-like behavior whereas finite disorders create locally Mott regions which expand their area with increasing the disorder strength contrary to the conventional sense. References [1] M. Okumura, S. Yamada, N. Taniguchi, and M. Machida, arXiv:0810.3953. [2] M. Okumura, S. Yamada, N. Taniguchi, and M. Machida, Phys. Rev. Lett. 101 016407 (2008).

12:03PM J16.00005 Dynamical Effects of Disorder in Optical Lattices, M. BEELER, E.E. EDWARDS, TAO HONG, S.L. ROLSTON, Joint Quantum Institute and Department of Physics, University of Maryland, National Institute of Standards and Technology — The precise control available in systems of neutral atoms confined in optical lattices makes them an ideal place to investigate the effects of disorder on crystal structure. We experimentally investigate how disorder affects the dynamical properties of these systems. Using a 1D optical lattice with the addition of one or two weak incommensurate traps, we investigate the adiabaticity criteria for loading the ground state of the disordered lattice. We find that even a very small amount of disorder greatly increases the timescale needed for adiabatic loading. We attribute this change to the large change in the ground state of the wavefunction with the addition of an impurity, as the wavefunction becomes localized. In addition, we will report on experimental efforts to study the effects of disorder in two-dimensional systems and on the timescales of thermalization in one dimension.

12:15PM J16.00006 Impurity crystal in a Bose-Einstein condensate, DAVID ROBERTS, Los Alamos National Laboratory, SERGIO RICA, Ecole Normale Superieure — We investigate the behavior of impurity fields immersed in a larger condensate field. The conditions for stability and collapse of this system will be presented. We discuss the localization of a single impurity field within a condensate and note the effects of surface energy. We derive the functional form of the attractive interaction between two impurities due to mediation from the condensate in 1, 2, and 3 dimensions. Generalizing the analysis to N impurity fields, we show that within various parameter regimes a crystal of impurity fields can form spontaneously in the condensate. Finally, we show the system of condensate and crystallized impurity structure to have nonclassical rotational inertia, which is characteristic of superfluidity, i.e. the system can be seen to exhibit supersolid behavior.

12:27PM J16.00007 Experiments on Disordered Quantum Gases, BRIAN DEMARCO, Univ of Illinois - Urbana — No abstract available.

Tuesday, March 17, 2009 11:15AM - 2:15PM — Session J17 GQI: Focus Session: Superconducting Phase Qubits

11:15AM J17.00001 High-fidelity gates in Josephson phase qubits, ERIK LUCERO, University of California, Santa Barbara — Complex algorithms for a quantum computer require error correction and robust calibration protocols for extended pulse sequences. We present significant progress towards both of these goals with our detailed measurements of gate fidelity and coupled qubit experiments with multi-pulse sequences. We measure single qubit gate fidelities of 0.98, limited by energy relaxation; and by carefully separating out gate and measurement error we construct a complete error budget. Using the new metrological technique of “Ramsey filtering” we show how one important error process can be measured and reduced to a level of 10^-4, a magnitude believed to be near the fault tolerant threshold. This measurement demonstrates that our quantum system remains in the two-state qubit manifold during our single qubit operations. This precision and accuracy is made possible by custom control electronics that can create arbitrarily shaped microwave pulses.

11:51AM J17.00002 Universal Quantum Gates in Josephson Junction Phase Qubits, RADOSLAW BIALCZAK, M. ANISMAN, M. HOFHEINZ, E. LUCERO, M. NEELEY, A. O’CONNELL, D. SANK, U.C. Santa Barbara, M. STEFFEN, IBM T.J. Watson Research Center, H. WANG, J. WENNER, A. CLELAND, J. MARTINIS, U.C. Santa Barbara — Josephson junction phase qubits are at a point where they can be used to create more complex operations such as quantum gates. Here we present work where we have tuned capacitively coupled Josephson junction phase qubits on and off resonance to generate and characterize a SQiSW gate using quantum process tomography (QPT). The SQiSW is the most fundamental universal gate for our system because it arises directly from the Hamiltonian for the physical circuit of our coupled qubits. In order to create more complex gates such as the CNOT, the SQiSW gate must be used to generate the entanglement. We perform QPT and obtain the Chi matrix, from which quantitative measures such as the gate fidelities can be calculated. We also show how to correct for measurement crosstalk and reduced visibilities present in our system and we perform measurements that quantitatively characterize the on/off ratio of our coupling scheme.

12:03PM J17.00003 Engineering Tripartite Entangled States of Two Phase Qubits Coupled via a Cavity, JAE PARK, FABIO ALTOMARE, RAY SIMMONDS, NIST — We present an experimentally inexpensive scheme for preparing certain tripartite entangled states. We suggest ways to test the degree to which such target states have been successfully prepared. We present a convenient geometrical interpretation of the resonant unitary dynamics which gives a natural interpretation for the characteristic frequencies and provides intuition for the pulse sequence necessary to achieve a desired target state.
12:15PM J17.00004 Two Qubits and a Cavity: Three’s Company. FABIO ALTOMARE, MICHAEL ALLMAN, KATARINA CICAK, JAE A. PARK, MIKA A. SILLANPAÄ, ADAM SIROIS, JOSHUA STRONG, JED WHITTAKER, RAYMOND W. SIMMONDS, National Institute of Standards and Technology, Boulder, CO (USA) — Quantum information theory suggests that there are two inequivalent classes of tripartite entanglement under stochastic local operations and classical communications (PRA, 62, 062314). Representative of these classes are the GHZ state and the W states, respectively. In this talk I will describe our experimental results on two superconducting phase qubits coupled through a cavity: one of the few cases where three is company and not a crowd. This system, effectively three coupled qubits if we restrict the cavity excitation to the single photon manifold, has allowed us to observe the spectroscopic signature and dynamics of Tripartite Entanglement. The rich dynamics of this system has allowed us to also observe a) Bell state between two qubits (with the third one disentangled), and b) W state between the three qubits. Future possibilities include the observation of GHZ state, particularly interesting for its practical applications, and for testing the non-locality of quantum mechanics.

1 Helsinki University of Technology

12:27PM J17.00005 Relaxation Dynamics of Fock States in a High Q Microwave Resonator Coupled to a Superconducting Phase Qubit. HAOHUA WANG, MAX HOFHEIZN, MARKUS ANSMANN, RADOSLAW BIALCZAK, ERIK LUCERO, MATTHEW NEELEY, AARON O’CONNELL, DANIEL SANK, JIM WENNER, ANDREW CLELAND, JOHN MARTINIS, Department of Physics, University of California, Santa Barbara — We have improved the lifetime of our high Q microwave resonator that is coupled to a superconducting phase qubit. Using high speed electronics, we have successfully generated Fock states with up to 15 photons. We analyze the resonator number state using the qubit to verify the high purity of the Fock states. Finally we monitor the subsequent decay of the Fock states in time, and show that the decay matches that expected from theory, with the $n$-photon lifetime scaling as $T_1/n$, where $T_1$ is the one-photon lifetime. Measurements on the decay of the coherent states, generated in the resonator using classical pulses, are also in agreement with theory.

12:39PM J17.00006 Controllable Coherent Population Transfers in Superconducting Qubits for Quantum Computing. L.F. WEI, RIKEN and Southwest Jiaotong University, Chengdu 610031, China, J.R. JOHANSSON, L.X. CEN, S. ASHHAB, F. NORI — We propose an approach to coherently transfer populations between selected quantum states in one- and two-qubit systems by using controllable Stark-chirped rapid adiabatic passages. These evolution-time insensitive transfers, assisted by easily implementable single-qubit phase-shift operations, could serve as elementary logic gates for quantum computing. Specifically, this proposal could be conveniently demonstrated with existing Josephson phase qubits. Our proposal can find an immediate application in the readout of these qubits. Indeed, the broken parity symmetries of the bound states in these artificial atoms provide an efficient approach to design the required adiabatic pulses.

12:51PM J17.00007 Three and Four Coupled Josephson Junction Phase Quubits. ZECHARIAH THRAILKILL, JOSEPH LAMBERT, SAM KENNERLY, ROBERTO RAMOS, Drexel University — The Josephson junction phase qubit has been shown to be a viable candidate for quantum computing. The two coupled phase quibit system has been extensively studied theoretically and experimentally. We have analyzed the quantum behavior of systems with more, three and four capacitively-coupled phase quibits, with different possible configurations. We have used anharmonic oscillators to model the systems. We will discuss some of the properties of these simple networks. The focus is on natural state evolution using a time independent, or adiabatically changing Hamiltonian. Analyzing how to transfer quantum information from one qubit to another and performing operations to change the overall state of these systems will give a better understanding of how to utilize the different qubit configurations. We will report on the progress of spectroscopic measurements for the three phase quibit systems.

1:03PM J17.00008 Tunable Cavity QED with Josephson Phase Quibits. JOSHUA STRONG, NIST — We have designed a tunable Josephson resonator and have coupled it to two phase quibits. The resonator can act as a cavity for QED-type experiments. We discuss results.

1:15PM J17.00009 Emulation of spin dynamics using a superconducting phase qudit. MATTHEW NEELEY, M. ANSMANN, R. BIALCZAK, M. HOFHEIZN, E. LUCERO, A. O’CONNELL, D. SANK, H. WANG, J. WENNER, JOHN MARTINIS, ANDREW CLELAND, UC Santa Barbara — In superconducting quantum circuits, the nonlinearity of the Josephson junction allows energy-level transitions to be addressed individually by their unique frequencies. Typically this is used to operate the system as an effective two-level system, a qubit. In a recent experiment, we extended our coherent control of a phase qubit to the first five energy levels, allowing us to operate the device as a qudit with $d = 3$, $4$, or $5$. We use this system to emulate the dynamics of single spins with spin quantum number $s = 1/2$, $1$ and $3/2$. We show that the phase acquired by a spin under rotation around a closed path follows the theoretical prediction. In particular, we confirm the even (odd) parity of integer (half-integer) spins under $2\pi$ rotation.

1:27PM J17.00010 Multiplexed Phase qubit readout using SQUID-resonators. JED WHITTAKER, MICHAEL ALLMAN, University of Colorado at Boulder, FABIO ALTOMARE, KATARINA CICAK, DALE LI, JAE PAK, NIST, ADAM SIROIS, JOSHUA STRONG, University of Colorado at Boulder, RAYMOND SIMMONDS, NIST — Flux biased phase quibits have traditionally been read out using a critical current switching technique of a coupled DC SQUID. This method has three limitations: it is extremely slow (orders of magnitude longer than typical energy relaxation times), difficult to multiplex, and by exceeding the critical current, it is dissipative and feeds broadband radiation back into the qubit, decohering its state. We are developing a SQUID-resonator readout method that addresses all three of these limitations. By operating the SQUID as a resonator, we can measure the state of the quibit quickly (on the order of its coherence time), we can multiplex resonant readout lines, and we can operate on the SQUID’s supercurrent branch eliminating dissipation and decohering radiation. This faster, quieter readout should allow us to use measured results for real-time quantum feedback.

1:39PM J17.00011 Berry’s Phase of a Current-Biased Josephson Junction. ANTHONY TYLER, Drexel University, ROBERTO RAMOS, ZECHARIAH THRAILKILL, SAM KENNERLY, Drexel University — A quantum system, prepared in an eigenstate, can accumulate a geometric phase known as Berry’s phase in addition to the expected dynamic phase. This occurs when there are adiabatic changes to the Hamiltonian which trace a closed loop in parameter space. A common example of this phase is an electron in a slowly varying magnetic field which traces a closed path. From this adiabatic variation, the electron’s spin state has acquired a Berry’s phase in addition to the dynamic phase. Due to the similarities between spin-1/2 particles, such as the electron, and solid state quantum bits (qubits), there should be an analogous process by which these systems can gain a Berry’s phase. Such processes have been tested in the charge qubit and has been derived for the flux qubit. Here, we will derive the Berry’s phase for a phase qubit which can be found experimentally using quantum state tomography. We then utilize this to explore the possibility of creating topological gates with phase qubits.

Nürnberg, Erwin-Rommel-Strasse, 1, D-91058 Erlangen, Germany — An intrinsic SQUID is a superconducting ring made of Bi, X.Y. JIN, J. LISENFELD, Y. KOVAL, A. LUKASHENKO, A.V. USTINOV, P. MÜLLER, Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erwin-Rommel-Strasse, 1, D-91058 Erlangen, Germany — An intrinsic SQUID is a superconducting ring made of Bi-Sr2CaCu2O8, δ single crystal, intercepted by two intrinsic Josephson junction stacks. The inductance parameter βL can be tuned in a wide range by changing the height and the cross-section area of the stacks. When biased with dc current, the device showed typical properties of hysteretic dc-SQUIDs. When a device was coupled with a coil and a Nb readout dc-SQUID, typical rf-SQUID behavior was observed. By choosing a proper reset field, quantum escape from a single minimum has been measured on a sample of βL ≈ 10. The escape rate can be fine-tuned by applying short pulses down to 1 ns, which allows a fast readout technique. With these prerequisites achieved, our experiments have opened the path to directly using these intrinsic SQUIDs as high-Tc phase qubits. The first attempts to measure Rabi oscillations on these devices will be discussed.

2:03PM J17.00013 GHZ protocols for superconducting qubits1. ANDREI GALIAUTDINOV, University of Georgia, JOHN MARTINS, U. C. Santa Barbara — Superconducting circuits with Josephson junctions gained considerable attention as promising candidates for scalable solid state quantum computing architectures. While macroscopic quantum behavior of such circuits has already been demonstrated (e.g., Rabi oscillations, high fidelity state preparation and measurement, various logic gate operations, etc.), further progress in developing a workable quantum computer will depend crucially on architecture’s ability to implement various multibit entangled states. Here we show how Greenberger-Horne-Zeilinger states can be generated in tripartite systems with capacitive and inductive couplings. Generalization to architectures containing arbitrary numbers of qubits is also discussed.

Tuesday, March 17, 2009 11:15AM - 2:15PM — Session J18 DMP DPOLY: Charge Transport and Optical Properties of Organic Semiconductors

11:15AM J18.00001 Light Emitting Transistors of Organic Single Crystals, YOSHIHIRO IWASA, Tohoku University — Organic light emitting transistors (OLETs) are attracting considerable interest as a novel function of organic field effect transistors (OFETs). Besides a smallest integration of light source and current switching devices, OLETs offer a new opportunity in the fundamental research on organic light emitting devices. The OLET device structure allows us to use organic single crystals, in contrast to the organic light emitting diodes (OLEDs), the research of which have been conducted predominantly on polycrystalline or amorphous thin films. In the case of OFETs, use of single crystals have produced a significant amount of benefits in the studies of pursuit for the highest performance limit of FETs, intrinsic transport mechanism in organic semiconductors, and application of the single crystal transistors. The study on OLETs have been made predominantly on polycrystalline films or multicomponent heterojunctions, and single crystal study is still limited to tetracene [1] and rubrene [2], which are materials with relatively high mobility, but with low photoluminescence efficiency. In this paper, we report fabrication of single crystal OLETs of several kinds of highly luminescent molecules, emitting colorful light, ranging from blue to red. Our strategy is single crystallization of monomer or oligomeric molecules, which are known to have a very high photoluminescence efficiency. Here we report the result on single crystal LETs of rubrene (red), 4,4'-bis(diphenylyvinyleyl)-anthracene (green), 1,4-bis(5-phenylthiophene-2-yl)benzene (AC5) (green), and 1,3,6,8-tetraphenylpyrene (TPPy) (blue), all of which displayed ambipolar transport well as well as peculiar movement of voltage controlled movement of recombination zone, not only from the surface of the crystal but also from the edges of the crystals, indicating light confinement inside the crystal. Realization of ambipolar OLET with variety of single crystals indicates that the fabrication method is quite versatile to various light emitting molecular solids, providing novel opportunities to get further insight on the intrinsic optoelectronic processes in organic semiconductors.

11:51AM J18.00002 ABSTRACT WITHDRAWN —

12:27PM J18.00003 Modification of the electronic properties of rubrene crystals by extrinsic species, LEONIDAS TSETSERIS, Vanderbilt University and University of Thessaloniki (Greece), SOKRATES PANTELIDES, Vanderbilt University and Oak Ridge National Laboratory — The chemical stability of organic semiconductors is one of the most important factors for the performance of related electronic devices. Here, we report the results of first-principles calculations on the effect of some of the most typical defect culprits in the prototype system of rubrene, the current record-holder organic semiconductor in terms of carrier mobilities. We identify the most stable water and oxygen-related impurity structures, with opportunities for nanoscale surface functionalization of organic semiconductors and provides experimental access to the regime of high carrier density. Here, we report the results of first-principles calculations on the effect of some of the most typical defect culprits in the prototype system of rubrene, the current record-holder organic semiconductor in terms of carrier mobilities. We identify the most stable water and oxygen-related impurity structures, with opportunities for nanoscale surface functionalization of organic semiconductors and provides experimental access to the regime of high carrier density. Here, we report the results of first-principles calculations on the effect of some of the most typical defect culprits in the prototype system of rubrene, the current record-holder organic semiconductor in terms of carrier mobilities. We identify the most stable water and oxygen-related impurity structures, with opportunities for nanoscale surface functionalization of organic semiconductors and provides experimental access to the regime of high carrier density.

12:39PM J18.00004 Charge carrier transport and optical properties of SAM-induced conducting channel in organic semiconductors, VITALY PODZOROV, Rutgers University — Certain types of self-assembled monolayers (SAM) grown directly at the surface of organic molecular crystals can induce a high surface conductivity in these materials [1]. For example, the conductivity induced by perfluorinated alkyl silanes in organic molecular crystals approaches 10 to -5 Siemens per square. The observed large electronic effect opens new opportunities for nanoscale surface functionalization of organic semiconductors and provides experimental access to the regime of high carrier density. Here, we discuss the results of an extensive study of SAM-induced conductivity in several types of organic semiconductors. [1] M. F. Calhoun, J. Sanchez, D. Olaya, M. E. Gershenson and V. Podzorov, “Electronic functionalization of the surface of organic semiconductors with self-assembled monolayers”, Nature Mat. 7, 84 (2008).

12:51PM J18.00005 Infrared spectroscopy of organic semiconductor modified by self-assembled monolayers, O. KHATIB, University of California, San Diego, B. LEE, V. PODZOROV, Rutgers University, J. YUEN, A.J. HEEGER, University of California, Santa Barbara, Z.Q. LI, M. DI VENTRA, D.N. BASOV, University of California, San Diego — Recently, self-assembled monolayers (SAMs) were used to modify electronic surface properties of organic single crystals, leading to several orders of magnitude increase in the electrical conductivity. Motivated by this discovery, the same technique was applied to polymers. Here we present a thorough spectroscopic investigation of organic semiconductors based on poly(3-hexithiophene) (P3HT) that have been treated with a fluorinated trichlorosilane SAM. Infrared spectroscopy offers access to details of charge injection, electrostatic doping, and the electronic structure that are not always available from transport measurements, which can be dominated by defects and contact effects in organic films. The SAM molecules penetrate into the bulk, leading to a rich spectrum of electronic excitations in the mid-infrared energy range. [1] M. F. Calhoun, J. Sanchez, D. Olaya, M. E. Gershenson, V. Podzorov, “Electronic functionalization of the surface of organic semiconductors with self-assembled monolayers”, Nature Mater. 7, 84–89 (2008).
grain size is 29 of FTES-ADT; varying the FTES-ADT concentration by 2-fold induces a 3-order of magnitude change in the grain size. For channels in which the average can seed the crystallization of TES-ADT during solvent-vapor annealing. The grain size in these films follows an exponential dependence on the concentration phene (TES-ADT) films through the addition of fractional amounts of fluorinated 5,11-bis(triethylsilylethynyl) anthradithiophene (FTES-ADT). FTES-ADT YUEH-LIN (LYNN) LOO, Princeton University — We present a novel method for controlling the grain size in solution-processed triethylsilylethynyl anthradithiophene (TES-ADT) films through the addition of fractional amounts of fluorinated 5,11-bis(triethylsilylethynyl) anthradithiophene (FTES-ADT). FTES-ADT can seed the crystallization of TES-ADT during solvent-vapor annealing. The grain size in these films follows an exponential dependence on the concentration of FTES-ADT; varying the FTES-ADT concentration by 2-fold induces a 3-order of magnitude change in the grain size. For channels in which the average grain size is 29 μm, device mobility of the organic thin-film transistors (OTFTs) is 0.05 cm²/V·s. For channels in which the average grain size is 2700 μm, the device mobility is 0.35 cm²/V·s. The relationship between device mobility and grain size is well described by a composite mobility model, which assumes a high intrinsic grain mobility and a low grain boundary mobility. Grazing incidence x-ray diffraction indicates that the crystal lattice of TES-ADT is preserved despite the addition of FTES-ADT:

2:03PM J18.00011 Low temperature, field-dependent mobility in pentacene thin-film transistors. ADRIAN SOUTHERD, Center for Nanophysics and Advanced Materials (CNAM) and the Department of Physics (DOP), University of Maryland (UM), VINOD SANGWAN, Laboratory of Physical Sciences (LPS), CNAM, and DOP, UM, DAN LESKNI, MICHAEL FUHRER, CNAM and the DOP, UM, ELLEN WILLIAMS, LPS, CNAM, and the DOP, UM — We measure the field-effect and saturation mobility of Au bottom contact thin-film polycrystalline pentacene field-effect transistors while varying temperature, channel length, and gate voltage. We utilize Au bottom contacts without a wetting layer, and achieve contact resistance as low as 1 kΩ·cm despite disturbance of the pentacene morphology at the drain and source electrodes. By measuring multiple channel lengths, we extract a contact-resistance free mobility. We confirm this value using an alternative technique in which we short the source and drain electrodes and make two terminal measurements of the capacitance and loss between these electrodes and the gate as a function of frequency. We discuss the result of the mobility in the context of Poole-Frenkel theory to rationalize the non-linear dependence of drain current on drain voltage, and test the predictions of recently developed models for transport in such systems.

Tuesday, March 17, 2009 11:15AM - 2:15PM -
Session J19 DPOLY: Block Copolymer Thin Films II
11:15AM J19.00001 Self-assembled surface patterns from organometallic-containing triblock terpolymers , VIVIAN CHUANG, CAROLINE ROSS, Massachusetts Institute of Technology, JESSICA GWYThER, IAN MANNERS, University of Bristol — Block copolymers are useful in nanotechnology because they can self-assemble to form periodic nanostructures. Here, we demonstrate the formation of hollow ring arrays with a period of 54 nm from a core-shell cylindrical-morphology poly(styrene-b-ferrocenylmethylsilane-b-2-vinyl pyridine) (PS-b-PFS-b-P2VP) triblock terpolymer thin film. By spin-coating and solvent annealing, thin films of the polymer were self-assembled into arrays of core-shell structures oriented perpendicular to the top surface of the film. Various chemically modified substrates were employed to investigate the effects of interfacial interaction between the substrate and the film, as well as the effects of solvent annealing, on the film morphology. Results will be compared with those obtained from a poly(butadiene-b-styrene-b-methyl methacrylate) triblock terpolymer [1]. The PS core and P2VP matrix blocks were partly removed simultaneously using oxygen plasma, and the remaining PFS ring pattern was successfully transferred into a PS layer by imprinting.

11:27AM J19.00002 Improvement of Extraction Efficiency of LED with Surface Relief Nanostucture Fabricated by Self-Assembled Block Copolymer Pattern , RYOTA KITAGAWA, AKIRA FUJIMOTO, KOJI ASAKAWA, Corporate Research & Development Center, Toshiba Corporation — A surface relief nanostructure was fabricated on the emission surface of light-emitting diodes (LEDs) using a self-assembled diblock copolymer pattern. The pattern of the nanostructure possesses moderate short-range order with slightly deviation in size and spacing, which is different from conventional extraction surface structures, such as photonic crystal and randomly textured surface. The dot pattern of a self-assembled polystyrene -polymethylmethacrylate diblock copolymer (PS-b-PMMMA) was used as an etched mask. An average dot spacing was controlled by changing blend ratio of PS-b-PMMMA, homo (h-) PS, and h-PMMMA in a polymer solution. In the photoluminescence (PL) measurement, the light extraction efficiency of the nanostructure exceeded over twice, compared with a flat surface, by optimizing the average spacing of the nanostructure. It was also revealed that the nanostructure showed more than 10% higher extraction efficiency than the highly ordered nanostructure fabricated by a self-assembled nanosphere pattern. These results can be interpreted as a contribution of structural fluctuation in the nanostructure for enhancement of extraction efficiency.

11:39AM J19.00003 Self-Assembling Block Copolymer Resist Mixtures toward Lithographic Resists for Sub-10 nm Features , CURRAN CHANDLER, VIKRAM DAVA, JAMES WATKINS, University of Massachusetts Amherst — Significant improvements in 193 nm photolithography have enabled the extension of device feature sizes beyond the 45 nm and 32 nm nodes, yet uncertainty lies beyond 22 nm features as no single replacement has emerged. Here we show that low molecular weight, nonionic block copolymer surfactant blends are capable of self-assembling into highly ordered domains with feature sizes on the order of 5 nm. These surfactants, most of which lack the required $\chi N$ for microphase separation on their own, exhibit strong segregation and long-range order upon addition of a component capable of multi-point hydrogen bonding that is specific for one of the blocks in the copolymer. This has been demonstrated by our SAXS study for self-assembled (PS-b-PPO-b-PEO) and Brij (PEO-4-(CH$_2$)$_3$CH$_3$) surfactants of various molecular weights and PEO volume fractions. Furthermore, we employ these highly-ordered systems as thin film, nanolithographic etch masks for the transfer of 10 nm patterns into silicon-based substrates. Small molecule, hydrogen bonding additives containing aromatic or silsesquioxane structure are also used to tune etch contrast between the blocks which is important for reducing line edge roughness (LER) of such small features.

11:51AM J19.00004 Directed assembly of block copolymers on chemically nanopatterned substrates: enabling science for ultra high resolution lithography , PAUL NEALEY, University of Wisconsin — Self-assembling materials based on block copolymers spontaneously form structures with well-defined dimensions and shapes at length scales of interest in nanotechnology. Unfortunately the thermodynamic driving forces for self-assembly are small and low-energy defects can get easily trapped. At issue is the extent of direction or guidance required to meet criteria related to perfection and registration for use of such materials in nanofabrication. Through fundamental understanding of the physics, chemistry, and surface and interfacial phenomena associated with equilibrating block copolymer films in the presence of chemically nanopatterned substrates, we demonstrate how block copolymers may be integrated into and advance the performance of the lithographic process. The technological importance of this approach is discussed with respect to patterned media and the fabrication of integrated circuits.

12:03PM J19.00005 Conditions for the directed assembly of thick block copolymer films on chemically nano-patterned surfaces , ADAM M. WELANDER, PAUL F. NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin, Madison, WI 53706 — The extent to which a lamellae forming block copolymer (bulk period, $L_0 = 48$ nm) can be directed to assemble on chemically nano-patterned striped surfaces (period $L_S$) with domains registered to and extending vertically away from the underlying pattern with few defects was studied as a function of film thickness, commensurability between $L_S$ and $L_0$, and temperature. The thickness through which low defect assembly could be achieved increased as $L_S$ and $L_0$ became more commensurate and as the temperature increased from 190 °C to 230 °C. Under certain conditions ($L_S \approx L_0 \approx 230$ °C), block copolymer films approaching 750 nm (aspect ratio $\approx 30$) in thickness still exhibited low levels of defectivity. These results were interpreted in terms of a phenomenological model and minimization of free energy including surface and interfacial energies and chain configuration entropy.

12:15PM J19.00006 Directed self-assembly of diblock copolymer thin films on chemically-patterned substrates for defect-free nano-patterning , MIKIHIITO TAKENAKA, Department of Polymer Chemistry, Graduate School of Engineering, Kyoto University, YASUHIKO TADA, Materials Research Laboratory, Hitachi Ltd., SATOSHI AKASAKA, SYNUKE ABURAYA, Department of Polymer Chemistry, Graduate School of Engineering, Kyoto University, HIROSHI YOSHIDA, Materials Research Laboratory, Hitachi Ltd., HIROKAZU HASEGAWA, Department of Polymer Chemistry, Graduate School of Engineering, Kyoto University, ELIZABETH DOBISZ, DAN KERCHER, San Jose Research Center, Hitachi Global Storage Technologies — We demonstrate that Polystyrene-block-poly(methyl methacrylate) (PS-b-PMMMA) can self-assemble in a well-aligned, long-range ordered nano-pattern over an area large enough to form micropatterned with chemically pre-patterned, templates prepared by electron beam (EB) lithography. We also demonstrate that the self-assembly process can interpolate points in between the EB generated pattern, thus multiplying the pattern density. Moreover, we show the results of the investigation about the time-evolution of the self-assembled structure during annealing process.

12:27PM J19.00007 Lamellar and Non-bulk like Morphologies in Thin Films of Block Copolymer on Chemical Nanopatterned Surfaces , GUOLIANG LIU, FRANCOIS DETCHEVEREY, JUAN J. DE PABLO, PAUL F. NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin-Madison, 1415 Engineering Drive, Madison, WI, 53706 — Thin films of symmetric PS-b-PMMMA (bulk lamellae period $L_0$) were equilibrated on substrates patterned with periodic stripes such that the adjacent stripes are preferentially wet by the two blocks of the copolymer. The morphology of the films was quantified as a function of the following pattern characteristics: the period, $L_S$, where $L_S = \delta L_0$, $1 \leq \delta \leq 3$, the width of the PMMA wetting strips, $W$, and the interfacial energies between the blocks and the patterned stripes, $\chi_{i,j}$. Under different boundary conditions we can i) direct the assembly of lamellae perpendicular to the substrate and ordered in linear arrays so as to increase the density of features of the chemical pattern, or ii) obtain a number of stable non-bulk like structures including asymmetric lamellae, mixed orientated lamellae, dots, and check-board structures. The experimental results are compared to a phase-diagram predicted from molecular simulations.
Patterns Made from Electro-oxidation Nanolithography, JI XU, ANTONIO CHECCO, BENJAMIN OCKO, SOOJIN PARK, SHILIU WANG, THOMAS RUSSELL — The effect of confinement from chemical patterns on the self-assembly of block copolymer and related wetting physics has been studied. A variety of geometries designed in a mesh fashion were chemically patterned on OTS modified silicon wafers by electro-oxidation nanolithography. Thin films of a cylinder-forming PS-b-PEO were spin coated onto these patterned substrates. Thermal annealing of these films showed that the films were pinned on the patterned regions, due to the strong interaction between PEO block and carboxylic acid group on patterned surface while, over the non-patterned areas, dewetting was suppressed. The non-favorable interactions of both blocks with the substrate in the non-patterned areas caused the cylindrical microdomains to orient normal to the surface, being confined geometrically by the patterned regions. Defect-free, hexagonally packed cylindrical microdomains that conformed to hexagonal pattern written onto the surface were obtained. Point defects arose in the hexagonal packing of the microdomains when the dimensions or shape of the pattern were not commensurate with the natural packing of the copolymers.

12:51PM J19.00009 Time-Resolved SAXS Characterization of Block Copolymer Blends on Chemically Nanopatterned Surfaces, KARL STUEN, PAUL NEALEY, Univ. of Wisconsin-Madison Dept. of Chem. and Biol. Eng., DILLIP SATAPATHY, KIM NYGARD, HARUN SOLAK, Dept. of Synchrotron Rad. and Nanotech., Paul Scherrer Institut, Switzerland — The directed assembly of block copolymer/homopolymer ternary blend thin films on chemically nanopatterned substrates was investigated with in situ transmission SAXS. A ternary blend was used to match the block copolymer period with the period of a chemical pattern fabricated by x-ray interference lithography. The domain assembly in a 24-nm-thick block copolymer blend film on the chemical nanopattern was monitored with SAXS in real-time as a sample was heated from 100 to 240 °C at about 20 °C per minute. The strongest diffraction from the sample was detected after just 4.5 minutes of annealing (maximum temperature ~190 °C). Complementary results were obtained from top-down SEM images of films that were quenched to room temperature after various times during the temperature ramp. The SEM images revealed transient structures in the annealing process that may relate to the non-uniform distribution of homopolymer in the direction perpendicular to the substrate. The results were compared to previously reported Monte Carlo molecular simulations to better understand the three-dimensional structures that form during the annealing process.

1:03PM J19.00010 Imaging Layer Effect on Density Multiplication in the Directed Assembly of Block Copolymer Thin Films, HIUMAN KANG, Department of Chemical and Biological Engineering, University of Wisconsin-Madison, EUNGNACK HAN, PADMA GOPALAN, Department of Materials Science and Engineering, University of Wisconsin-Madison, PAUL NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin-Madison — We report a new parallel patterning technique, molecular transfer printing (MTP), for replicating geometrically complex patterns over macroscopic areas with sub-15 nm feature dimensions, and the ability to replicate the same pattern multiple times. In MTP, inks are mixed with block copolymers (BCPs) and deposited as films on a substrate. The inks are compatible with only one block of the BCP, and separated into domains of nanometer scale dimensions after microphase separation. A second substrate is then placed in contact with the surface of the film. By designing the inks to react, adsorb, or otherwise interact with the second substrate, inks are transferred to the second substrate in the exact pattern of domains present at the surface of the “master” BCP film. Here we demonstrate high degrees of perfection on both line and dot patterns. We also show that 1) the master template can be regenerated, 2) the resultant replica can be used to direct the assembly of BCPs as a daughter master for MTP, and 3) the master and daughter templates can be reused tens of times.

1:15PM J19.00011 Molecular Transfer Printing Using Block Copolymers, SHENGXIANG JI, CHI-CHUN LIU, GUOLIANG LIU, PAUL NEALEY, Department of Chemical & Biological Engineering, University of Wisconsin-Madison — A molecular model of block copolymer systems is used to conduct a systematic study of the morphologies that arise when thin films of symmetric, lamellar forming block copolymer materials are deposited on nanopatterned surfaces. Over 500 distinct cases are considered. It is found that, in general, three distinct morphologies can arise depending on the strength of the substrate-polymer interactions, the film thickness, and the period of the substrate pattern. The relative stability of those morphologies is determined by direct calculation of the free energy differences. The dynamic propensity of those morphologies to emerge is examined by careful analysis of simulated trajectories. The results of this systematic study are used to interpret recent experimental data for films of polystyrene-PMMA copolymers on chemically nanopatterned surfaces.

1:27PM J19.00012 Pattern interpolation in thin films of lamellar, symmetric copolymers on nano-patterned substrates, FRANCOIS DETCHEVERRY, UMGANG NAGPAL, GUOLIANG LIU, PAUL NEALEY, JUAN DE PABLO, University of Wisconsin — A molecular model of block copolymer systems is used to conduct a systematic study of the morphologies that arise when thin films of symmetric, lamellar forming block copolymer materials are deposited on nanopatterned surfaces. Over 500 distinct cases are considered. It is found that, in general, three distinct morphologies can arise depending on the strength of the substrate-polymer interactions, the film thickness, and the period of the substrate pattern. The relative stability of those morphologies is determined by direct calculation of the free energy differences. The dynamic propensity of those morphologies to emerge is examined by careful analysis of simulated trajectories. The results of this systematic study are used to interpret recent experimental data for films of polystyrene-PMMA copolymers on chemically nanopatterned surfaces.

1:39PM J19.00013 Thin Films of Polydimethylsiloxane-Containing Block Copolymers, MAURICE WADLEY, KEVIN CAVICCHI, The University of Akron — The self-assembly of block copolymers into ordered nanostructures such as spheres, cylinders, and lamellae in the range of 10-100 nm makes them interesting materials for patterning surfaces. Thin films of poly(dimethylsiloxane) (PDMS) containing block copolymers are attractive for patterning due to their high oxygen etch resistance compared to other polymers. The main disadvantage of these polymers for patterning is the low surface tension of PDMS. This causes the preferential migration of PDMS to the air/film interface driving the formation of domains parallel to the surface and wetting layers. In this work a series of AB block copolymers containing PDMS have been prepared via RAFT polymerization where the surface tension of the opposing block was varied. Using a macro chain transfer approach, it is possible to isolate the effect of changing the opposing block while keeping the PDMS the same in each different block copolymer. The effect of changing the surface tension mismatch between the blocks on the thin film morphology will be discussed.

1:51PM J19.00014 Interfacial Bending of Lamellar Microdomains of Block Copolymers, SANG-MIN PARK, IBM Almaden Research Center, MENG DONG, Department of Chemical and Biological Engineering, Colorado State, CHARLES RETTNER, IBM Almaden Research Center, QIANG WANG, Department of Chemical and Biological Engineering, Colorado State, HO-CHEOL KIM, IBM Almaden Research Center — We report our investigation on the interfacial bending property of the lamellar microdomains using a symmetric block copolymer of poly(styrene-b-methyl methacrylate) (PS-b-PMMA) deposited on a neutral surface. The degree of interfacial bending of lamellae on surface was controlled by varying the angle of elbow-like topographic guiding patterns prepared by E-beam lithography. The characteristic parameters of lamellae bending including the critical angles of elbow-like patterns which give maximum interfacial bending of lamellae, the lamellae tilting angle at sidewall were determined for both single and paired guiding patterns. The behavior of a block copolymer containing hybrid systems a minimum of poly(styrene-b-ethylene oxide) and organosilicate, was investigated as well. A computational calculation on the lamellae bending which provides more insights on the free energy and interfacial characteristics will be discussed as well.
2:03PM J19.00015 Observation of Surface Corrugation-Induced Alignment of Lamellar Microdomains in PS-b-PMMA Thin Films. HO-CHEOL KIM, SANG-MIN PARK, CHARLES RETTNER, IBM Almaden Research Center, BRIAN BERRY, Department of Chemistry, University of Arkansas at Little Rock, ELIZABETH DOBisz, Hitachi Global Storage Technologies

Previously we reported the alignment of lamellar microdomains of a block copolymer containing hybrid on a corrugated surface, which provides self-assembled crossbar nanostructures. The alignment of lamellae of the hybrid system is believed due to the anisotropic bending periphery of lamellae. Attempts to similarly align the lamellae of PS-b-PMMA using the same length scales of surface corrugation were not successful. In this study, we investigated the alignment of lamellar microdomains of PS-b-PMMA using even broader range of length scales of the surface corrugation. Within specific ranges of roughness scales, we observed that the lamellar microdomains of PS-b-PMMA align perpendicular to the direction of surface corrugation. The effect of relative scales of periodicity and film thickness of PS-b-PMMA to those of surface corrugation on the alignment of lamellae is discussed in this paper.

Tuesday, March 17, 2009 11:15AM - 1:27PM
Session J20 DPOLY: Frank J. Padden Jr. Award Symposium 321

11:15AM J20.00001 Pressure Effects on Polymer Coil-Globule Transitions near an LCST. DAVID SIMMONS, ISSAC SANCHEZ, University of Texas at Austin — A model for the pressure - temperature behavior of the coil-globule transition (CGT) of a polymer in dilute solution is developed without adjustable parameters. The predicted pressure-temperature conformational behavior semi-quantitatively correlates with extant experimental data. The model yields a heating induced coil-to-globule transition (HCGT) temperature that increases with pressure until it merges with a cooling induced coil-to-globule transition (CCGT). The point at which the CCGT and HCGT meet is a hypercritical point that also corresponds to a merging of lower critical solution temperature (LCST) and upper critical solution temperatures (UCST). Theoretical results are discussed in terms of a generalized polymer/solvent phase diagram that possesses two hypercritical points.

11:27AM J20.00002 Structure-property relationships in ABA copolymer gels with A homopolymer additions. MICHELLE SEITZ, Northwestern University, REBECCA ROTTSSLK, William Fremd High School, KIRT PAGE, NIST, KENNETH SHULL, Northwestern University — ABA acrylic triblock copolymers with poly(methyl methacrylate) endblocks and poly(butyl acrylate) midblocks transition from free flowing liquids to elastic solids with decreasing temperature in alcohol solvents. Homopolymer PMMA chains can be solubilized in the micelle cores if they are shorter than the endblocks. Indentation and compression tests were used to determine gel’s modulus and large strain behavior. Gels with volume fractions of PMMA less than ~0.2 are highly elastic and have modulus dictated by stretching of bridging midblocks. At higher PMMA contents, gels exhibit greater permanent deformation and moduli over an order of magnitude larger than would be expected from rubber elasticity alone. Small angle X-ray and neutron scattering and mean field simulations were used to correlate changes in gel structure and micelle morphology with the addition of homopolymer.

11:39AM J20.00003 A Versatile Method by Layer Assembly of Thin Organic Films. HERNAN R. RENGIFO, Columbia University, CRISTIAN GRIGORAS, University of Pennsylvania, JEFFREY KOBERSTEIN, Columbia University — Layer by layer (Lbl) assembly techniques construct multilayer thin films by sequential deposition of monomolecular layers of organic molecules. One of the drawbacks associated with their use is that monomolecular layers are usually held together by relatively weak forces such as Van der Waals, electrostatic and hydrogen bonding interactions, and can therefore be lacking in mechanical integrity. We demonstrate herein that heterofunctional polymers, functionalized with one azide chain terminus and a protected alkyne group as the other chain terminus, constitute a powerful and versatile means for the covalent layer-by-layer (Lbl) assembly of thin polymer films. Each monomolecular polymer layer is covalently bound to both the preceding and following layers to produce a robust multilayer structure. Because the coupling chemistry used, “click” chemistry, is highly chemoselective, the layering process is virtually independent of the chemical nature of the polymer so that the constitution of each layer can be selected at will.

11:51AM J20.00004 How do entangled polymeric liquids flow? SHAM SUNDAR RAVINDRANATH, SHI-QING WANG, University of Akron — This work focused on investigating fundamental questions in polymer dynamics such as how entangled polymeric liquids respond to fast external deformation. By developing an effective particle tracking velocimetric (PTV) method, along with conventional rheometric measurements, new insights can be gained into the phenomenology of entangled polymers in presence of startup shear, step strain and large amplitude oscillatory shear (LAOS). During startup shear of well entangled systems, the shear field becomes inhomogeneous after the stress overshoot for a range of applied shear rates beyond the Newtonian region [1]. The emergence of shear banding after stress overshoot helped us to identify the stress overshoot as indicating yielding, whose characteristics obey some scaling laws. In step shear, contrary to the conventional perception that entangled polymers would undergo quiescent relaxation, the PTV observations reveal macroscopic motions after shear cessation [2]. The recoil-like macroscopic motions appears to reflect an elastic breakdown of the entanglement network due to sufficient build-up of retractive forces. LAOS experiments also demonstrate that entangled polymers cannot sustain a high magnitude of fast deformation without undergoing cohesive failure [3].

12:03PM J20.00005 Polymer Diffusion in Carbon Nanofiller / Polymer Nanocomposites. MINFANG MU, Department of Materials Science and Engineering, University of Pennsylvania, NIGEL CLARKE, Department of Chemistry, Durham University, RUSSSELL COMPOSTO, KAREN WINEY, Department of Materials Science and Engineering, University of Pennsylvania — Polymer tracer diffusion through carbon nanofiller / polymer nanocomposites is measured using elastic recoil detection methods. Tracer diffusion through a single wall carbon nanotube nanocomposite is strongly suppressed at low concentrations (≤ 0.4-0.8 vol%) and then increases at higher concentrations. In contrast, the typical Maxwell model predicts only a weak monotonic decrease. We propose a model for the carbon nanotube composite system wherein the SWCNTs function as cylindrical traps. Simulations of this model found that at low concentrations, the isolated traps retard polymer diffusion and at higher concentrations the percolated traps allow polymer diffusion to recover by providing continuous pathways. A comparison of our experimental and simulation results finds that (1) the strength of the trap increases with the molecular weight of the diffusing polymers and (2) the trap diameter increases with the molecular weight of the matrix polymer. Similarly, tracer diffusion through C60/polymer nanocomposites exhibits a significant decrease at low concentrations and then slowly increases at concentrations larger than 0.7 vol%.

12:15PM J20.00006 Tunable Wetting of Polymer Nanocomposite Films. MARLA MCCONNELL, SHU YANG, RUSSSELL COMPOSTO, University of Pennsylvania — Surfaces with controlled wettability are of growing technological importance. In this study, nanoparticles (NPs) with tunable spacing were assembled on poly(styrene-random-acrylic acid), S-r-AA, films to manipulate the composite films' wetting properties. Amine-modified silica NPs (15-200 nm) were covalently grafted to the AA moieties on the surface of the S-r-AA films, in which the S phase imparts mechanical stability and the AA domains swell, increasing the roughness and surface area. By controlling surface roughness and reaction time, NP coverage ranged from 1%-70%. These films displayed NP-coverage-dependent water contact angles between 60° and 120°. The enhanced hydrophobicity is attributed to capillary climbing of S-r-AA chains to cover the previously hydrophilic NP surface. Upon increasing NP diameter, the contact angle was found to increase at a fixed total coverage. This increase is attributed to the increase in effective surface area with increasing particle size. This system is utilized as a platform to create Janus particles with unique optical properties and templates for investigating molecular motors.
12:27PM J20.00007 Direct Measurement of Molecular Mobility in Actively Deformed PMMA Glasses

Hau-Nan Lee, Keewook Paeng, Stephen Swallen, Mark Ediger, Department of Chemistry, University of Wisconsin-Madison

To quantitatively understand the response of segmental motions to external stress, we performed optical measurements of dye reorientation in PMMA glasses during tensile creep deformation. Up to 1000-fold increases in mobility are observed during deformation, which supports the view that stress-induced mobility allows plastic flow in polymer glasses. Although the Eyring model describes this mobility enhancement well at low stress, it fails to capture the dramatic mobility enhancement after flow onset. In this regime, in addition to lowering the barriers for molecular motion, external stress apparently forces the shape of distribution of relaxation times to narrow significantly. The effect of stress on physical aging was also investigated. At low stress, physical aging and deformation-induced mobility act as two independent processes. However, after flow onset, the data are consistent with the view that aging has been erased by deformation.

12:39PM J20.00008 Probing Surface Glass Temperature of Polymer Films via Pentacene Growth Mode, Microstructure, and Thin-Film Transistor Performance

Choongik Kim, Antonio Facchetti, Tobin Marks, Northwestern University

Pentacene-based organic thin-film transistors (OTFTs) have been extensively studied in organic electronics. In this study, we report the fundamental importance of the polymeric gate dielectric glass transition temperature on pentacene film growth mode, and microstructure and corresponding OTFT performance. From the knowledge that nanoscopically-confined thin polymeric films exhibit glass-transition temperature deviations dictated from the corresponding bulk materials, we show here that pentacene films grown on polymeric gate dielectrics at temperatures well-below their bulk glass transition temperature ($T_g$) exhibit morphological/microstructural transitions and dramatic OTFT performance variations at a well-defined temperature [herein defined as the polymer surface glass transition temperature, or $T_g$($s$)] characteristic of the polymer structure and independent of the film thickness. Our results demonstrate that TFT measurements represent a new methodology to probe polymer surface viscoelastic properties.

12:51PM J20.00009 Responsive Polymer Surfaces: Crumpling, Folding, and Snapping Films

Douglas Holmes, Alfred Crosby

This work focuses on understanding deformation mechanisms and responsiveness associated with folding, crumpling, and snapping of thin polymer films attached to patterned and nonpatterned substrates. By studying folding and crumpling in confined regimes, we gain insight into material properties, while developing new strategies for adhesive, optical, and patterning applications. Using a novel processing technique, microarrays of freestanding polydimethylsiloxane plates are placed in equibiaxial compression and transition through crumpled morphologies that are difficult to attain through traditional patterning techniques. The microstructures also change their curvature through a snap-through instability via environmental stimuli. When triggered via osmotic pressure, the snap transition time scales as the square of the plate thickness and the inverse of the plate modulus. Recently, we have transferred this knowledge into the crumpling of ultrathin polymer films. We have fabricated sharply folded films directly on elastomeric and silicon substrates. The fold width scales directly with the film thickness and applied strain. We find that normally brittle, polystyrene films can accommodate excessive compressive strains without fracture by undergoing strain-localizing fold events.

1:03PM J20.00010 Structure and mobility of PEO/LiClO4 solid polymer electrolytes

Susan Fullerton, Janna Maranas, Penn State

Solid polymer electrolytes (SPEs) for use in rechargeable lithium-ion batteries offer many advantages over traditional liquid electrolytes, including mechanical flexibility and environmental friendliness. The practical limitation is that room temperature conductivity remains insufficient to power a portable device. While it is well-established that ion mobility is driven by polymer dynamics, high conductivity values have also been reported through fully crystalline SPEs. PEO-based SPEs have a rich phase behavior, and form several crystalline complexes depending on the lithium concentration, temperature, and recrystallization time. We investigate the structure, mobility, conductivity, and thermal properties of both semi-crystalline and amorphous PEO/LiClO4 SPEs. Structure is measured with small-angle neutron scattering, and PEO mobility with quasi-elastic neutron scattering. We observe a decoupling of ionic conductivity and PEO mobility in a semi-crystalline sample. We also determine that PEO atomic motion ahs undergone restricted rotation on a circle. The radius of the circle is consistent with a cylindrical, crystalline structure that persists to some extent in the amorphous phase. The results suggest that directed ion transport via ordered structures is perhaps equally important as polymer mobility for increasing conductivity, provided that the structures percolate over large spatial scales.

1:15PM J20.00011 Architectural effects in strongly hydrogen bonded thermoplastic elastomers

Kathleen Feldman, Craig Hawker, Edward Kramer, University of California, Santa Barbara

In this work we demonstrate the synthesis of random copolymers of n-butyl acrylate with a quadruple hydrogen bonding acrylate monomer based on 2-ureido-4-[1H]-pyrimidinone (UPy). Despite low $T_g$s and a lack of crystallinity, these materials show thermoplastic elastomer properties through the strong but thermoreversible UPy groups. Through the use of controlled radical polymerization and post-polymerization functionalization we are able to reach high UPy monomer content while maintaining low polydispersity and excellent control over the total molecular weight. It was found that the average distance between UPys along the chain was the major determiner of the overall properties including the plateau modulus, tensile modulus, and relaxation timescale. By using a difunctional initiator it is also possible to synthesize materials containing a homopolymer midblock and random copolymer end blocks, allowing us to address the question of how the MHB group distribution along the chain affects the bulk properties. In concentrating the UPy groups near the chain ends, the plateau modulus remained constant but the crossover frequency decreased. This knowledge was used to synthesize materials containing a homopolymer midblock and random copolymer end blocks, allowing us to address the question of how the MHB group distribution along the chain affects the bulk properties. In concentrating the UPy groups near the chain ends, the plateau modulus remained constant but the crossover frequency decreased. This knowledge was used to synthesize materials containing a homopolymer midblock and random copolymer end blocks, allowing us to address the question of how the MHB group distribution along the chain affects the bulk properties. In concentrating the UPy groups near the chain ends, the plateau modulus remained constant but the crossover frequency decreased, indicating that the effective lifetime of the hydrogen bonds within the supramolecular network increased, in keeping with prior theoretical predictions.
Measurements reveal a thermally activated increase in free carrier concentration for temperatures above 150 K, suggesting the presence of a defect level below the conduction band edge. In the present work, we used annealing to probe the influence of N interstitials on the electronic properties of GaAsN. In as-grown GaAsN films, temperature-dependent Hall fraction, presumably due to N diffusion to As vacancies. However, the influence of interstitial N on the electronic properties of GaAsN alloys remains unknown. In this contribution, we report newly performed first-principles calculations that clarify spin polarization and lattice relaxation of carrier concentrations with various charge states in a few group-III nitrides. Spin-polarized electronic configurations obtained in the present study are indicative of intrinsic ferromagnetism due to cation vacancies in nitride semiconductors.

1:03PM J21.00008 Quaternary Ga$_{1-x}$In$_x$P$_{1-y}$N$_y$ alloys described by clustering of In and N in GaP
Koushik Biswas, Alberto Franceschetti, Stephan Lany, National Renewable Energy Laboratory, Golden, CO — The interactions between the different atomic constituents in an alloy affect the microstructure, and ultimately, the electronic properties of the alloy. Specifically, in group III-V alloys the energy of formation of single defects and the binding energy of defect complexes play an important role in determining the microstructure. We present a model that starts from the dilute defect picture and extends to alloys of low to moderate concentrations. Using a valence-force-field (VFF) method we calculate the energy of formation of isolated N and In defects and that of small defect clusters formed by N and In in a GaP host. Considering a 1:2.12 N to In ratio that conserves lattice matching to GaP, we show that in a N concentration range up to ~15%, the formation energy of the random alloy can be described by the random probability to form such defect clusters. This approach allows the thermodynamic modeling of the microstructure of quaternary alloys, such as GaInNP, without intricate lattice-energy expansions and Monte-Carlo simulation techniques. In GaInNP, we find that short range ordering due to large atom to small atom preferential binding (i.e. In-N+GaP) strongly reduces the energy compared to the random distribution.

1:15PM J21.00009 Mechanism of Interaction between Hydrogen and the Two-dimensional Electron Gas in AlGaN/GaN High Electron Mobility Transistors
Jason Gu, Mahak Khandelwal, Jacob Melby, Carnegie Mellon University, Michael Steeves, University of Maine, Yuh-Renn Wu, Robert Lad, University of Maine, Robert F. Davis, Carnegie Mellon University — The large polarization difference between AlGaN and GaN causes a two-dimensional electron gas (2DEG) to form at the interface between the two semiconductors. Capacitance-voltage (CV) measurements revealed a charge density of 4.71x10$^{12}$ electrons/cm$^2$ in our 60 nm Al0.2Ga0.8N on 1.5 microns of GaN heterostructure. Exposure to hydrogen in the presence of a catalyst (Pt) resulted in a marked increase in the conductivity through the 2DEG. An interface state passivation mechanism is proposed as the most probable cause of this phenomenon. This mechanism was modeled using a self-consistent Schrödinger-Poisson solver, which showed that the passivation of interface states causes the shift of the Fermi level towards the conduction band, thereby increasing the carrier density of the 2DEG by 9%. In-situ CV measurements showed a 16% increase in the carrier density and a non-parallel shift in the CV curve when hydrogen was introduced, indicating a change in the number of available states. This supports interface state passivation as a cause of the increase in the conductivity through the 2DEG.

1:27PM J21.00010 Magnetodielectric coupling in Au/GaAs:Si Schottky barriers
S. Tongay, A.F. HEBARD, University of Florida, Y. HIKITA, H. HWANG, The University of Tokyo — A surprisingly large (>20%) negative magnetocapacitance in non-magnetic Au/GaAs:Si Schottky barriers is attributed to a magnetic field (H) induced increase in the binding energy of the shallow donor Si impurity atoms. Capacitance (C) dispersion is used to identify the impurity ionization and capture processes that give rise to an H-dependent density of ionized impurities N$_H$(H) in the depletion region. Internal photoemission experiments confirm that the large H-induced shifts in the built-in potential $V_{bi}$, inferred from Mott-Schottky (1/C$^2$ versus voltage) measurements, are not due to an H-dependent Schottky barrier height (SBH), thus requiring a modification of the abrupt junction approximation which identifies the dependence of $V_{bi}$ on N$_H$(H) rather than the SBH. The linearity of the Mott-Schottky plots is preserved, as experimentally observed. The underlying magnetodielectric coupling not only allows a new opportunity for the tuning of the dopant carrier density by an external means (magnetic field) but should be important for understanding the behavior of related interfacial structures incorporating dilute magnetic semiconductors and/or complex oxides.

1:39PM J21.00011 Point Defects and Dielectric Loss at MM Wavelengths in Wide-Gap Semiconductors
Jyotsna Dutta, Charles Jones, North Carolina Central University, V.V. Parshin, Applied Physics Institute, RAS, B. Garin, V.I. Polyakov, A. Rukovishnikov, Inst. of Radio Engineering and Electronics, RAS — Data are presented on wide-gap semiconductors of various grades for their dielectric loss values at millimeter wavelengths to explore their potential for various RF technology related applications. In order to identify the impurities or electrically active defects that give rise to the excess loss, temperature-dependent conductivity and DLTS measurements have been undertaken. Dielectric loss measurements over a wide range of temperatures are in progress to verify the results obtained from electrical methods and help to determine the primary loss mechanisms for these materials in the millimeter wave length range. Experimental results and their implications to loss properties will be discussed.

1:51PM J21.00012 Dual-Surfactant effect on enhancing different p-type doping in GaP
Junyi ZHU, Gerald Stringfellow, FENG LIU, University of Utah — We report first principles calculations demonstrating a dual-surfactant effect of Sb and H on enhancing Zn, Mg, Be and Cd in vapor phase epitaxially grown GaP thin films. The combined effects of Sb and H lower significantly the doping energy all the p-type dopants in GaP, while neither Sb nor H can work alone as effectively. The role of H is to satisfy the electron counting rule. The role of Sb is to serve as an electron reservoir to help electron redistribution. The enhancement is the lowest for Mg which is probably due to the lowest electronegativity of Mg among these four elements.

2:03PM J21.00013 InSb epilayers and quantum wells grown on Ge(001) substrates by MBE
Mukul Debnath, Tetsuya Mishima, Mike Santos, University of Oklahoma, Khalid Hossain, Wayne Holland, Amethyst Research Inc., University of Oklahoma Team, Amethyst Research Inc. Collaboration — For digital logic applications, transistors with both electron and hole channels are required. InSb:Ge heterostructures is an ideal material since the highest carrier mobilities for n and p-type quantum wells (QWs) are observed in InSb and Ge channels, respectively. We report on the MBE growth of InSb-based materials on Ge(001) substrates. A temperature variation two-step growth procedure (TSGP) is more effective than direct growth of InSb on Ge(001). In the TSGP, an initial 100-nm InSb layer was grown at a temperature of 340°C before increasing the substrate temperature to 420°C for the rest of the growth. The initial growth forms a wetting layer that minimizes defects at the InSb/Ge interface. The X-ray rocking curve width of a 5.0-µm-thick InSb epilayer is 173 arc sec. Electron mobilities of a 5.0-µm-thick InSb epilayer and an InSb/Al$_{0.2}$In$_{0.8}$/In$_x$P$_{1-x}$/GaAs QW at room temperature are 34,500 and 8,600 cm$^2$/V·s, respectively. These are the highest mobilities for an InSb epilayer and QW on Ge(001) substrates reported so far. This work was supported by NSF Grant DMR-0520550 and OCAST contract AR071-025.

11:51AM J22.00002 Dynamical Nuclear Polarization via Triplet States in Self-Assembled Quantum Dot Molecules. S. C. BADESCU, D. KIM, A. S. BRACKER, D. GAMMON, T. L. REINECKE, Naval Research Laboratory, Washington DC — Recent experiments on self-assembled quantum dot molecules used molecular trion states to initialize and measure optically the electron spin in one of the dots [1]. The key to this experiment is the anticoating of two electron-triplet states in a magnetic field in Faraday configuration, which is due to spin-orbit coupling and electron-hole exchange. The experimental spin initialization and readout plots exhibit bifurcation and hysteresis features attributable to nuclear polarization. Here we present results for these effects from a model accounting for the feedback between the dynamical nuclear polarization and the electron spin states in the two dots, determined by the optical pumping and the asymmetric exchange. We explain the correlations between the nuclear polarizations in each of the dots and the asymmetry between the nuclear effects for the two measured electron states. [1] D. Kim et al, Phys. Rev. Lett. 101 (2008)

12:03PM J22.00003 Single frequency precession of inhomogeneous ensemble of electron spins. ALEX GREILICH, STEFAN SPATZEK, IRINA YUGOVA, ILJA AKIMOV, DMITRI YAKOVLEV, Experimental Physics 2, TU Dortmund University, Germany, ALEXANDER EFROS, Center for Computational Science, Naval Research Laboratory, Washington DC, USA, DIRK REUTER, ANDREAS WIECK, Angewandte Festkörperphysik, Ruhr-Universität Bochum, Germany, MANFRED BAYER, Experimental Physics 2, TU Dortmund University, Germany — We show that the spins of all electrons, each confined in a quantum dot of an (In,Ga)As/GaAs dot ensemble, can be driven into a single mode of precession about a magnetic field. This regime is achieved by allowing only a single mode within the electron spin precession spectrum of the ensemble to be synchronized with a train of periodic optical excitation pulses. Under this condition a nuclei induced frequency focusing leads to a shift of all spin precession frequencies into the synchronized mode. The macroscopic magnetic moment of the electron spins that is created in this regime precesses without dephasing. This ensemble can be used then as a macroscopic quantum bit.

12:15PM J22.00004 Control of the direction and rate of nuclear spin flips in InAs quantum dots using detuned optical pulse trains. SAM CARTER, SOPHIA ECONOMOU, Naval Research Laboratory, ANDREW SHABAEB, George Mason University, THOMAS KENNEDY, ALLAN BRACKER, THOMAS REINECKE, Naval Research Laboratory — Using two-color, time-resolved Faraday rotation and ellipticity measurements, we show that control of the direction and rate of nuclear spin flips in InAs quantum dots can be achieved through optical manipulation of the electron spin. A circularly polarized pump pulse train excites an ensemble of dots with varying electron spin precession frequencies and pump detunings. Resonant excitation has been described in Ref. [1], in which the electron spin polarization is greatly enhanced when the precession is synchronized to a multiple of the pulse repetition rate. Nuclear spin flips occur rapidly when the electron spin is not synchronized, with equal probability to flip up or down, leading to random walks that eventually lead the system to stable synchronized modes. In detuned dots, rotations of the spin away from the plane of precession lead to asymmetry in the nuclear spin flip rates, giving a clear pathway for nuclear reconfiguration. For dot energies below (above) the pump, the nuclear reconfiguration pushes electron spins towards (away from) synchronization. This effect is observed through a spectral shift in the Faraday rotation ellipticity amplitudes as a function of probe detuning. [1] A. Greilich, A. Shabaev et al., Science 317, 1896 (2007).

12:27PM J22.00005 Theory of the effect of detuned optical pulse trains on the electron-nuclear hyperfine interaction in quantum dots. SOPHIA ECONOMOU, SAM CARTER, Naval Research Lab, ANDREW SHABAEV, George Mason University, THOMAS KENNEDY, ALLAN BRACKER, TOM REINECKE, Naval Research Lab — A train of optical pulses detuned from resonance of the electron spin-trion transition in a quantum dot has the combined effect of generating and of rotating the spin polarization. The rotation is a direct consequence of the detuning and induces an electronic spin component parallel or antiparallel to the magnetic field, depending on the sign of the detuning. This electron spin component directs the nuclear spin to preferably flip in one direction. This pulse-assisted electron-nuclear flip-flop both affects the electron, because it changes the precession frequency and changes whether it is synchronized with the pulses, and it also opens up the opportunity for manipulating the nuclear polarization by using the detuning along with the pulse repetition rate as handles.

12:39PM J22.00006 Many-body theory of spin bath dynamics for qubit decoherence. REN-BAO LIU, WEN YANG, The Chinese University of Hong Kong — We have developed a cluster correlation expansion (CCE) theory for the many-body dynamics of a finite-size spin bath in a time scale relevant to decoherence of a center spin or a qubit embedded in the bath [1]. In terms of the linked cluster expansion, a cluster correlation term is the infinite summation of all the linked diagrams with all the spins in the cluster flip-flopped. The lowest order of the cluster correlation corresponds to the pair-correlation approximation developed previously [2]. In the thermodynamics limit, the CCE reduces to the standard cluster expansion. The CCE is especially useful for studying multi-spin interference in small spin systems such as NV centers in diamonds and molecular magnets, where the cluster expansion fails to converge to the exact solution.

This work was supported by Hong Kong RGC Project 401906.
12:51PM J22.00007 The Hyperfine-mediated and Nuclear-Dipolar-Induced Nuclear Spin. **EDDY YUSUF**, XUEDONG HU, Physics Department, University at Buffalo — We study nuclear spin diffusion in semiconductor quantum dots based on the density matrix approach. The nuclear spin interactions that we consider include both hyperfine-mediated and magnetic dipolar interactions. Furthermore, we take into account both the secular and the non-secular terms of the magnetic dipolar nuclear interactions. We discuss how the one- and two-electronic states in the quantum dots lead to quantitatively different nuclear spin polarization relaxation and nuclear spin diffusion time. We explore the behavior of the relaxation time and diffusion constant for various experimentally relevant parameters, and compare our results to the recently measured nuclear spin relaxation in GaAs double quantum dots [1].

1:03PM J22.00008 Theoretical study of the strain-induced nuclear spin depolarization in self-assembled quantum dots[1] . CHIA-WEI HUANG, XUEDONG HU, Department of Physics, University of Buffalo, SUNY Buffalo, NY 14260-1500 — We investigate how strain-induced quadrupole interaction is related to nuclear spin polarization in self-assembled quantum dots. Our calculation shows that the achievable nuclear spin polarization in In_{x}Ga_{1−x}As quantum dots is sensitively dependent on the strain distribution in the dots. There are two interesting regions of rapid changes in nuclear spin polarization when the Overhauser field is in the opposite direction to the external field. The first one occurs in the low field region (B < 1T) where nuclear spin polarization of individual nuclear species is suppressed due to a degeneracy between different nuclear spin states. The second one is a peak in nuclear spin polarization showing up in the intermediate field region. This peak corresponds to a local maximum of the Overhauser field, which happens when electronic Zeeman energy vanishes. Our results are in qualitatively agreement with the measured nuclear spin polarization in the experimental work of various groups.[2][3]

[1] We thank financial supports by NASA/LPS through ARO and NSF.

1:15PM J22.00009 Preparation of Nuclear Spin States in Double Quantum Dots[1]. JACOB J. KRICH, MICHAEL GULLANS, Harvard University, JACOB M. TAYLOR, MIT, MICHAEL STOPA, BERTRAND J. HALPERIN, MIKHAIL D. LUKIN, AMIR YACOBY, Harvard University — Recent experiments on double quantum dot systems with two electrons have shown rich dynamics associated with the hyperfine coupling to nuclear spins. We examine how the cycles used to produce dynamic nuclear polarization in such double quantum dots can lead to interesting non-equilibrium configurations of the nuclear spins. We develop a master equation for the nuclear spins, which we solve using time-dependent mean field theory. We find a rich set of phenomena in the system, including tendencies of the system to approach two very different configurations, one with equal effective magnetic fields produced by the nuclei in the two dots and the other with a large difference between the magnetic fields produced by the nuclei in the two dots, both of which are seen in experiments.

[1] This work has been supported in part by NSF grant DMR-0541988 and the Fannie and John Hertz Foundation.

1:27PM J22.00010 Zamboni force in pumping of angular momentum from electron to nuclear spins via the Overhauser effect. MICHAEL STOPA, AMIR YACOBY, JACOB KRICH, Harvard University — We identify a feedback mechanism between the electron states in a two-electron double quantum dot and the difference between the nuclear spin polarization in the two dots, which we term the “Zamboni force.” The Overhauser interaction is known to cause angular momentum transfer, spin flip-flops, between electrons and nuclei in GaAs-AlGaAs heterostructures. In double quantum dots, transport and pumping experiments have been performed to study the evolution of nuclear spin polarization in response to certain electronic transitions. We show that, in flipping from singlet (S) to triplet (T+), “flopping” of the nuclear spin can occur in the left dot, the right dot or in the barrier depending on the composition of the singlet state. Assuming a composite nuclear spin for each of the left dot, the right dot and the barrier, we numerically integrate the Schrödinger equation to study the gate voltage sweep through the S-T+ anti-crossing point. We show that the (nuclear) effective magnetic field gradient tends to produce spin flips in the dot with the weaker field and thereby constitutes a force toward nuclear spin equilibration.

1:39PM J22.00011 Spin Fluctuations in Magnetic Quantum Dots[1]. A.G. PETUKHOV, South Dakota School of Mines, R.M. ABOFATH, University of Texas, IGOR ZUTIC, SUNY Buffalo — We present a theoretical description of magnetism in quantum dots (QDs) doped with magnetic ions. It has been recognized that the mean-field theory (MFT) is inadequate for small magnetic systems, such as bound magnetic polarons (BMPs), at finite temperatures [1]. Magnetic QDs are in many respects similar to BMPs, however the latter are one-electron systems while the former may contain many electrons. Our approach requires the minimization of the generalized “free energy” functional [2] for QDs, which leads to a set of self-consistent Kohn-Sham-type equations that coincide with MFT-equations [3] in the thermodynamic limit. We reveal that the well-known spurious MFT second order phase transition in magnetization is completely removed by thermodynamic spin fluctuations.

1:51PM J22.00012 Carrier-mediated magnetism and bound magnetopolarons in quantum dots. RAFAL OSZWALDOWSKI, SUNY Buffalo and N. Copernicus University, Torun, Poland, ANDRE PETUKHOV, South Dakota School of Mines and Technology, Rapid City, IGOR ZUTIC, SUNY Buffalo — While Mn-doped quantum dots (QDs) offer versatile control of magnetic order [1], important challenges remain in understanding of these systems beyond the mean-field approximation. Furthermore, to describe the carrier-mediated magnetism in arrays of magnetic QDs and their non-equilibrium properties, it is important to consider the presence of both electrons and holes in these systems. We develop a formalism that accounts for both equilibrium and light-controlled magnetopolaron effects [2]. We study QDs of different sizes and find that their magnetic and photo-induced properties are extremely size-sensitive. We compare our theory with recent experiments on circularly-polarized photoluminescence in magnetic QDs [3] where both the magnetopolaron energies and power dependence of the circular polarization were measured. We thank I. R. Sellers for valuable discussions. Supported by ONR and NSF-ECCS CAREER. [1] L. Besombes et al., Phys. Rev. Lett. 93, 207403 (2004); R. M. Abolfath, A. G. Petukhov, and I. Zutic, Phys. 2:03PM J22.00013 ABSTRACT WITHDRAWN —
11:15AM J23.00001 Coexistence of quantum phases in the quantum Hall regime of the 2$^{nd}$ Landau Level$^1$. TREVOR RHONE, JUN YAN, Columbia University, YANN GALLAIS, Université de Paris 7, ARON PINCZUK, Columbia University, LOREN PFEIFFER, KEN WEST, Alcatel-Lucent — We report the experimental study of spin excitation modes in the regime of quantum hall phases of the 2$^{nd}$ Landau Level. In the ferromagnetic state at $\nu=3$ the long wavelength spin wave mode is seen at the bare Zeeman energy. At low temperatures and at filling factors slightly lower ($\nu \sim 2.97$), the spin wave attenuates and a broad ‘overdamped’ continuum of low-lying excitations emerges. Under these conditions, sharp and broad modes coexist, suggesting the presence of mixed quantum phases. At slightly elevated temperatures the continuum disappears. Further away from filling factor three, near the odd-denominator state at $\nu \geq 8/3$, the continuum dominates at low temperature. However, the sharp spin wave is recovered at $T \geq 1K$. For even lower filling factors, such as $\nu \geq 5/2$, low temperature spectra display only the broad continuum of low-lying excitations. At high temperatures ($T \sim 2K$) a sharp spin wave is recovered while the broad continuum persists, indicating the emergence of phase coexistence. The interplay between sharp and ‘overdamped’ modes may manifest tendencies towards loss of full spin polarization in the $N=1$ Landau level and may indicate that spin degrees of freedom have significant impact on the physics of quantum Hall states with $3 \leq \nu \leq 2$.

11:27AM J23.00002 The Virtual Scanning Tunneling Microscope: Induced Tunneling in Bilayer Two-Dimensional Electron Systems. ADAM SCIAMBI, MATTHEW PELLICCIONE, DAVID GOLDBABER-GORDON, Stanford University, SETH BANK$^1$, ARTHUR GOSSARD, University of California, Santa Barbara, MICHAEL LILLY, JOHN RENO, Sandia National Laboratory — We propose a novel probe technique, the virtual scanning tunneling microscope (VSTM), which will spatially and spectroscopically map two-dimensional electron systems (2DESs) in semiconductor heterostructures. The probe overcomes the typical inaccessibility of a buried 2DES by having a second parallel “probe” 2DES grown nearby. A biased tip overhead can then induce local tunneling from the probe 2DES into the original by adjusting the interlayer potential barrier. Prior bilayer studies have shown that a tunneling signal is dominated by the overlap of the layers’ Fermi surfaces, hindering VSTM-induced tunneling and obscuring any spectroscopy. We show, however, in widely-space bilayers systems where interlayer inelastic scattering is more prominent that the previous energy-momentum constraints are relaxed. In GaAs/AlGaAs samples grown by different sources, we show we can increase interlayer tunneling by an order of magnitude with gating, setting the stage for spectroscopy.

$^1$Now with University of Texas at Austin.

11:39AM J23.00003 Tunneling spectroscopy of a 2D-2D tunnel junction: Towards a local spectroscopic probe of 2D electron systems. MATTHEW PELLICCIONE, ADAM SCIAMBI, DAVID GOLDBABER-GORDON, Stanford University, SETH BANK$^1$, ARTHUR GOSSARD, University of California, Santa Barbara, JOHN RENO, MICHAEL LILLY, Sandia National Laboratory — We present measurements on GaAs/AlGaAs bilayer two-dimensional electron systems (2DES) that exhibit inelastic tunneling between the 2D electron layers. Due to a relatively large interlayer separation, scattering allows for tunneling events between states of different energy and momentum, which are not observed in similar systems with a small interlayer separation. This behavior can be used to measure spectroscopic information about the 2DES that is obscured when tunneling events conserve energy and momentum exclusively. We study the bulk behavior of this system in the integer quantum Hall regime on samples from different sources, and provide a model to explain the observed tunneling dynamics. We also discuss the prospect of using this system as a virtual scanning tunneling microscope (VSTM), where a scanning probe is used to locally induce tunneling between the 2D electron layers.

$^1$Now with the University of Texas at Austin

11:51AM J23.00004 Unusual Cyclotron Resonance Line Broadening in Ultra-High Mobility Two-Dimensional Electron Gas System. LI-CHUN TUNG, NHMFL, CHANGLI YANG, Institute of Physics, Chinese Academy of Sciences, L.N. PFEIFFER, K.W. WEST, Bell Laboratories, Lucent Technologies, R.R. DU, Department of Physics and Astronomy, Rice University, YONG-JIE WANG, NHMFL — Microwave induced resistance oscillation in the ultra high mobility two-dimensional electron gas system has attracted an intense interest in recent years. Under the illumination of an intense microwave radiation in the millimeter regime, the system exhibits an unique resistance oscillation with a microwave-frequency-dependent period. We have carried out a FIR magneto-optical study up to 33T on a set of GaAs/AlAs ultra-high mobility heterostructure samples at 4K. At low magnetic field, ultra-sharp electron CR has been observed as expected. At high magnetic field, the halfwidth of CR grows rapidly with increasing magnetic field and this phenomenon is uniquely found in the 2DEG in the heterojunction. At the same time, there is no indication of a reduced mobility at high field in the transport measurement. The sudden broadening of the CR line shape cannot be simply interpreted by either the short- or long-range random potential. The halfwidth changes by at least an order, thus it can hardly be explained by either magnetophonon effect, inhomogeneity or magnetic oscillation.

12:03PM J23.00005 Evidence of Auger Satellite Lines in Landau-Level Photoluminescence Spectroscopy in a Two Dimensional Electron Gas$^1$. S.K. LYO, W. PAN, J.L. RENO, Sandia National Laboratories — Landau-level spectroscopy has provided a powerful tool for investigating the electronic structure and the scattering dynamics in a two-dimensional electron gas (2DEG) in the past. In this paper, we present theoretical and experimental evidence for Auger satellite lines in the magnetoluminescence of the Landau-level spectroscopy from a 2DEG under a perpendicular magnetic field $B$ at low temperatures. These new anomalous lines with a weak intensity appear below the energy gap in the form of radial “spokes” with negative slopes in the so-called fan (energy vs. $B$) diagram, in contrast to the well-known standard spokes of the fan diagrams of the spectral lines which appear above the band gap energy with positive slopes. [S. K. Lyo, E. D. Jones, and J. F. Klem, Phys. Rev. Lett. 61, 2265 (1988)]. Our theoretical predictions yield reasonable agreement with observed low-temperature data from GaAs quantum wells. The satellite lines can be used to determine the conduction (valence) band mass in n-doped (p-doped) systems.

12:39PM J23.00008 Phase Separation of Bright and Dark Excitons in Coupled Quantum Wells

NICHOLAS SINCLAIR, ZOLTAN VOROS, JEFF WUENSCHELL, DAVID SNOKE, University of Pittsburgh, KENNETH WEST, LOREN PFIEFFER, Bell Labs — The diversity and complexity of solid-state environments suggests that Bose-Einstein Condensation (BEC) of excitations in a solid might manifest in a variety of interesting ways, in correspondence with the diversity of features around state of these systems. The pursuit of excitonic BEC is both enriched and obfuscated by this flexibility of condensate character. Previous research pursuing BEC of interwell excitons in GaAs coupled quantum wells (CQWs) has focused attention on observing unusual luminescence from ‘bright’, dipole-coupled (J=1) excitons to detect a BEC. However, theorists have recently predicted a ‘dark’ (J=2) ground state for interwell excitons in GaAs. Our recent work with interwell excitons confined in stress-induced, in-plane traps shows the critical onset of a dark spot in the exciton-recombination luminescence at trap center, suggestive of a dense population of dark excitons and a phase separation between the dark/bright species. The critical temperature vs. density in the low temperature regime matches well with ideal 2D harmonic trap BEC criteria, and preliminary theoretical work suggests that this degree of species separation cannot be explained by a model based on classical statistical level occupation using the bright/dark state energy separation.

12:51PM J23.00009 Ultrafast Relaxation Dynamics of a High Density Electron-Hole Plasma in High Magnetic Fields

JINHO LEE, DAVE H. REITZE, Physics Dept. University of Florida, JUNICHIRO KONO, Dept. of Electrical and Computer Engineering, Rice University, ALEXEY BELYANIN, Physics Dept., Texas A&M University, GLENN SOLOMON, NIST, STEVE MCGILL, NHMFL — We study the inter-Landau level relaxation dynamics of a dense electron-hole plasma in high magnetic fields (up to 31 T). Intense 150 fs pump pulses create carrier densities approaching 10^{13}/cm^2 in n_{GaAs}/GaAs multiple quantum wells. Relaxation dynamics are probed as a function of Landau level (LL) and magnetic field using time-resolved transient absorption (TRTA) and time-resolved photoluminescence (TRPL), which provide complementary information about the relaxation processes. Manifestly non-exponential decays of the TRTA signals are observed at high fields (above 15 T). TRPL emissions measured in the plane of the wells reveal the presence of multiple emission bursts from the LLs at high magnetic fields, suggesting a complicated relaxation process mediated by the field whereby carriers get trapped in a specific LL, emit PL through recombination, and then ‘reload’ as the carriers relax down to the previously occupied LLs.

1:03PM J23.00010 Spin splitting of the valence band Landau levels in GaAs quantum wells

I. KHAN, T. ALI, M. YASAR, A. PETROU, SUNY at Buffalo, Buffalo NY, A. HANBICKI, G. KIOSEOGLOU, C. LI, B. JONKER, Naval Research Laboratory, Washington D.C. — We have studied as function of magnetic field the electroluminescence spectra from a n-i-p LED that incorporates three GaAs quantum wells in the intrinsic region. This device has excess n-type doping and as a result, the quantum wells are populated by a two-dimensional electron gas. The broad zero field emission band evolves into a series of discrete features in the presence of a magnetic field. These are identified as interband transitions between the f = 0, 1, and 2 Landau levels associated with the e_v and h_v subbands, with the selection rule \Delta f = 0. The EL spectra were analyzed in their \sigma+(LCP) and \sigma-(RCP) components. An energy splitting between the two polarized components is observed for each Landau level transition, which is equal to the sum of the conduction and valence band spin splittings. Since the electron g-factor value is known (g = -0.44) we were able to determine the valence band spin splittings. Our experimental values are compared to calculated values (1) and were found to be in reasonable agreement. Work at SUNY was supported by ONR and NSF 1. H.A. Nickel et al., Phys. Rev. B, 62, 2773, (2000)

1:15PM J23.00011 Bose Einstein Condensation in Trapped Polaritons Versus Lasing Effects

RYAN BALILI, BRYAN NELSEN, DAVID SNOKE, University of Pittsburgh, LOREN PFIEFFER, KENNETH WEST, Bell Labs, Lucent Technologies, UNIVERSITY OF PITTSBURGH TEAM, BELL LABS, LUCENT TECHNOLOGIES COLLABORATION — Evidence for Bose Einstein condensation (BEC) of exciton-polaritons have been presented recently by several groups in a variety semiconductor microcavity geometries (eg. [1]. Objections nevertheless remain as experimental evidence for polarization BEC bear striking similarity to observed behavior in a regular photon laser or micromaser in weak coupling regime. [2]. Latest results however show that a both BEC and lasing transitions can occur and are distinguishable in the stress trapped case [3].

1:27PM J23.00012 Optical Bistability in Coupled Microdisks

S.N. GHOSH, Y.K. VERMA, School of Natural Sciences, University of California, Merced, CA 95344, B.B. BUCKLEY, Department of Physics, University of California, Santa Barbara, California 93106, USA, X. LI, N. SAMARTH, Materials Research Institute, Penn State University, University Park, Pennsylvania 16802, USA, D.D. AWSCHALOM, Department of Physics, University of California, Santa Barbara, California 93106, USA, S. GHOSH, School of Natural Sciences, University of California, Merced, CA 95344, USA — Semiconductor microcavities offer unique means of controlling light-matter interactions in confined geometries, resulting in a wide range of applications in optical communications. We report bi-stable lasing in coupled GaAs microdisks with quantum wells and interface-fluctuation quantum dots in the active region. The inter-disk coupling results in mode-splitting, with the higher energy resonance persistently achieving higher mode Q (~ 4000). The bi-stability manifests in the form of hysteresis in the intensity of the coupled modes on non-uniform excitation and can be attributed to saturable absorption. This property in the lasing characteristics of coupled cavities gives us a control on the gain modulation and mode-switching and would be useful for applications in optical memories and computing, and in next generation of low-threshold optoelectronic devices.

we study the polarization of the current as a function of the average spin orientation of iron atoms randomly dispersed over the nanotubes in a realistic setup. In particular, nanotube plus iron atom - has a magnetic moment of \(3\, \mu_B\) and recursive Green’s functions calculations we study the transport properties of disordered one-dimensional systems [1] composed of such units. In particular, nitrogen defects. We demonstrate that the Fe atoms bind to the four N defects in a configuration similar to a porphyrin molecule. Moreover, this system - CN sites of molecules, such as ammonia, and to be associated with the behavior of these sensors. In this work we study the adsorption of iron atoms onto these be used in a variety of nanoscopic electronic devices, and their functionality can be greatly enhanced by the introduction of defects. It has been shown that magnetic read-write heads. We report on the nano-electron beam assisted fabrication of atomically sharp iron-based tips and on the creation of a nano-soldering modify desired nanostructures for technological applications and to form molecular junctions and interconnections between carbon nanotubes. The development of the next generation of miniaturized electronic systems demands the integration of nanoelectronic components creating reliable mechanical and electrical contacts. At the same time, the development of scanning probe techniques and magnetic recording media require an ever decreasing tip size of ultrasharp magnetic read-write heads. We report on the nano-electron beam assisted fabrication of atomically sharp iron-based tips and on the creation of a nano-soldering iron for nano-interconnects using Fe-filled multiwalled carbon nanotubes (MWNTs). Our technique allows also carving a MWNT into a nanosoldering iron that was demonstrated capable of joining two separated halves of a tube. This approach could easily be extended to the interconnection of two largely dissimilar CNTs, between a CNT and a nanowire or between two nanowires.

11:51AM J24.00002 Carbon nanotube based sharp tips and soldering irons, ABHA MISRA, Graduate Aeronautical Laboratories (GALCIT), California Institute of Technology, Pasadena, CA, 91125, CHIARA DARAIO, Graduate Aeronautical Laboratories (GALCIT), and Applied Physics, California Institute of Technology, Pasadena, CA, 91125 — High energy electron beam machining has been proven a powerful tool to modify desired nanostructures for technological applications and to form molecular junctions and interconnections between carbon nanotubes. The development of the next generation of miniaturized electronic systems demands the integration of nanoelectronic components creating reliable mechanical and electrical contacts. At the same time, the development of scanning probe techniques and magnetic recording media require an ever decreasing tip size of ultrasharp magnetic read-write heads. We report on the nano-electron beam assisted fabrication of atomically sharp iron-based tips and on the creation of a nano-soldering iron for nano-interconnects using Fe-filled multiwalled carbon nanotubes (MWNTs). Our technique allows also carving a MWNT into a nanosoldering iron that was demonstrated capable of joining two separated halves of a tube. This approach could easily be extended to the interconnection of two largely dissimilar CNTs, between a CNT and a nanowire or between two nanowires.

12:03PM J24.00003 Broken chiral symmetry in nanotube sliding1, GIUSEPPE ERNESTO SANTORO, XIAOHUA ZHANG, International School for Advanced Studies (SISSA), UGO TARTAGLINO, Pirelli Tires, Milan, ERIO TOSATTI, International School for Advanced Studies (SISSA) — We discovered, in simulations of the frictional sliding of coaxial nanotubes, an unanticipated example of dynamical symmetry breaking – in fact a family of examples – taking place at the nanoscale. While both nanotubes are armchair, thus perfectly left-right symmetric and nonchiral, a nonzero angular momentum appears spontaneously at a series of critical sliding velocities, in correspondence with large peaks of the sliding friction. The angular momentum is not connected with real bodily rotations, but rather to breathing phonon pseudorotations. The nonlinear equations governing this phenomenon turn out to share common elements with another classical problem exhibiting a dynamical chirality breaking, that of forced oscillations of a string or a rope. Several new elements that are exquisitely “nano” appear in the nanotube case making it a richer, more elegant and intricate case, with a variety of different phenomena, and the crucial involvement of umklapp and of sliding nanofriction. 1This research was supported by Miur PRIN 2006022847 and by CNR/ESF/EUROCORES/FANAS/AFRI

12:15PM J24.00004 Porphyrin-like defects in CN\(_n\) nanotubes1, ANTONIO J.R. DA SILVA, Physics Institute - USP, JAMES ALMEIDA, A.R. ROCHA, Centro de Ciências Naturais e Humanas, UFABC, A. FAZZIO, Physics Institute - USP — Carbon nanotubes (CNT) can be used in a variety of nanoscopic electronic devices, and their functionality can be greatly enhanced by the introduction of defects. It has been shown that CNTs doped with nitrogen atoms can act as sensors. Pyridine–like defects, where four N atoms surround a divacancy, have been shown [1] to act as binding sites of molecules, such as ammonia, and to be associated with the behavior of these sensors. In this work we study the adsorption of iron atoms onto these nitrogen defects. We demonstrate that the Fe atoms bind to the four N defect in a configuration similar to a porphyrin molecule. Moreover, this system - CN\(_n\) nanotube plus iron atom - has a magnetic moment of \(3\, \mu_B\), which is almost entirely localized on the Fe atom. With a combination of density functional theory and recursive Green’s functions calculations we study the transport properties of disordered one-dimensional systems [1] composed of such units. In particular, we study the polarization of the current as a function of the average spin orientation of iron atoms randomly dispersed over the nanotubes in a realistic setup. 1A. R. Rocha, M. Rossi, A. Fazzio and A. J. R. da Silva, Phys. Rev. Lett. 100, 176803 (2008).

12:27PM J24.00005 Dislocation Onset and Glide in Carbon Nanotubes under Torsion, TRAIAN DUMITRICEA, DONG-BO ZHANG, RICHARD JAMES, University of Minnesota — The torsional plastic response of carbon nanotubes is comprehensively described in the objective molecular dynamics framework [1-3]. It is shown that an (n,m) tube is prone to slip along a nearly-axial helical path, which introduces a distinct (+1,-1) change in the wrapping index. The low energy realization occurs without loss of mass, via nucleation of a 5-7-7-5 dislocation dipole, followed by a nearly-axial glide of the 5-7 dislocation. The onset of plasticity depends not only on chirality but also on handedness. For a given handedness of the applied twist, chiral tubes of opposed handedness are most susceptible to yield. A right-handed applied twist on an armchair (zig-zag) tube leads to a right- (left-) handed tube.

12:39PM J24.00006 Electrochemical Charging of Carbon Nanotubes for Tunable Field Emission Cathodes, ALEXANDER KUZNETSOV, NORMAN BARISCI, NanoTech Institute, University of Texas at Dallas, ANVAR ZAKHIDOV, ALEXANDER ZAKHIDOV, Cornell University, Ithaca, New York — Carbon nanotubes (CNTs) have very promising applications as electron field emitters. Work function of CNTs greatly affects the performance of such cold electron emitters. It is possible to change emission currents by several orders of magnitude by electrochemical charging. Electrochemical charging changes work function of CNTs by creating so called double layer. It was recently demonstrated that double layer structure remains for several hours after removing the CNTs from an electrolyte [1]. The extensive study of charging single wall carbon nanotube (SWNT) paper in different electrolytes has been performed at different charging potentials Vch. Field emission currents and threshold fields dependence on the charging potential and polarity is studied for various ions, with different valency and size: Na, Mg, Cs. Clear dependence of work function on Vch is demonstrated. AFM micro-imaging with a Kelvin probe allowed to study the micropatterns of work function modulation. Also dissipation of positive charge in air was investigated and its stability was significantly increased. 1. Suh Dong-Seok, Baughman Ray, Zakhidov Anvar, US Patent 20070170071 (2007)

12:51PM J24.00007 Interaction of water and methanol with graphene, C60 and (10,10) nanotube1, VIJAY KUMAR, Dr. Vijay Kumar Foundation, Gurgaon, India, M. AMAR, Wright State Univ., J.F. MAGUIRE, Air Force Research Laboratory, Y. KAWAZOE, IMR, Tohoku Univ. Sendai, Japan — We study interaction of water and methanol molecules with graphene, C60 and (10,10) carbon nanotube using plane wave pseudopotential method and GGA. The interaction energies, ∆E, of H2O and CH3OH molecules on a (10,10) SWCNT, C60 and a graphene sheet are quite small (a few tens of meV) and are weakly dependent on the orientation of the molecules. The different electronic structures of graphene, nanotubes, and C60 lead to the differences. For (10,10) nanotube ∆E of water (39 meV) is favorable outside the nanotube and it increases for a water dimer. For methanol ∆E outside as well as inside the nanotube is nearly the same (40 meV). A competition between molecules-molecule and molecule-nanotube wall interaction could, however, lead to interesting molecular ordering behavior. ∆E of water on C60 is significantly smaller presumably due to its large HOMO-LUMO gap but for a graphene sheet the band gap vanishes and ∆E has an intermediate value between C60 and (10,10) nanotube. For methanol on graphene sheet ∆E increases to 60 meV due to more significant overlap of the molecular orbitals with those of the graphene sheet.

1:03PM J24.00008 Hydrogen adsorption on metal coated Multiwalled Carbon nanotubes, XIANFENG ZHANG, DINESH RAWAT, TOYOHISA FURUHASHI, RAKESH SHAH, ALDO MIGONE, Department of Physics, Southern Illinois University at Carbondale, SAIKAT TALAPATRA — We present results of volumetric adsorption measurements of hydrogen, on Palladium-Gold (Pd-Au) coated multiwalled carbon nanotubes (MWNT). The nanotubes were prepared using air assisted chemical vapor deposition technique and were subsequently purified (acid treatment) before coating them with Pd-Au. Hydrogen adsorption measurements were performed at 77.3 K on as produced MWNTs as well as purified MWNT and compared with the adsorption isotherm obtained on Pd-Au coated MWNT samples under same experimental conditions. The effect of coating the MWNTs with Pd-Au on the adsorption behavior of hydrogen on these nanotubes will be discussed.

1:15PM J24.00009 Enhancement of In Vivo Anticancer Effect of Cisplatin by Incorporation Inside Carbon Nanohorns, MASAKO YUDASAKA, AIST, KUMIKO AJIMA, JST, TATSUYA MURAKAMI, YOSHIKAZU MIZOGUCHI, KUNIHIO TSUCHIDA, Fujita Health Univ., TOSHIHARI ICHIHASHI, NEC, SUMIO IIJIMA, JST, NEC, AIST, Meijo Univ. — We have been studying potential applications of single-wall carbon nanohorns (SWNHs) to drug delivery systems. SWNHs are multiply functionalized with proteins, magnetites, tumor targeting molecules, and others. Various drugs are easily incorporated, and the incorporated drugs are slowly released. Almost no acute toxicity of SWNHs was found through various animal tests. We show in this report that anticancer effect of cisplatin was enhanced by incorporation inside SWNHs (CDDP@SWNH) as evidenced by in vivo tests: CDDP@SWNH was locally injected to tumors subcutaneously transplanted on mice. CDDP@SWNH inhibited the tumor growth more effectively than CDDP. This anticancer enhancement was achieved by large CDDP-quantity incorporated inside SWNH, slow release of CDDP from SWNH, and a distinct (+1,-1) change in the wrapping index. The onset of plasticity depends not only on chirality but also on handedness. For a given handedness of the applied twist, chiral tubes of opposed handedness are most susceptible to yield. A right-handed applied twist on an armchair (zig-zag) tube leads to a right- (left-) handed tube.

1:27PM J24.00010 Fabrication of ZnPc/Protein Nanohorns for Double Photodynamic and Hyperthermic Cancer Phototherapy, MINFANG ZHANG, AIST, JST, TATSUYA MURAKAMI, Fujita Health Univ., KUMIKO AJIMA, JST, KUNIHIO TSUCHIDA, Fujita Health Univ., ATULA S. SANDANAYAKA, OSAMU ITO, Tohoku Univ., SUMIO IIJIMA, AIST, NEC, Meijo Univ., MASAKO YUDASAKA, AIST, JST, NEC — We developed double photodynamic and hyperthermic phototherapy systems [1] by loading zinc phthalocyanine (ZnPc) on single-wall carbon nanohorns (SWNHs). A protein of bovine serum albumin (BSA) was also attached to the surface of SWNHs. ZnPc performed photodynamic therapy (PDT) effect and SWNH had photothermogenic (PHT) effect. BSA endowed hydrophilic property to the system. Previous results in vitro showed that the efficiency of phototherapy using ZnPc-SWNH-BSA was higher than that of ZnPc or SWNHs. We show in this report that mouse tests also exhibited the similar tendency. ZnPc-SWNH-BSA was locally injected in tumors subcutaneously transplanted on mice. And the laser (670 nm) was irradiated for 15 minute everyday for 10 days. By this phototherapy, the tumors completely disappeared. The phototherapy using ZnPc or SWNHox-BSA exhibited weaker antitumor effects, and the tumors continued to grow. [1] Zhang et al. PNAS, 2008, 105, 14773.
1:39PM J24.00011 Terahertz Plasmon Oscillations at Room Temperature in Nanotube Transistors, DIEGO KIENLE, FRANÇOIS LÉONARD, Sandia National Laboratories, California — We present a theoretical study of the high-frequency properties of carbon nanotube transistors. We employ a new theory for AC quantum transport based on a self-consistent Non-Equilibrium Green Function formalism. The theory is applied to calculate the frequency dependent response of a semi-conducting \((17,0)\) nanotube FET device in the ballistic limit applying a time harmonic signal at the gate terminal. We show that in the ON-state the dynamical conductance exhibits divergent resonant peaks at discrete frequencies in the terahertz regime even at room temperature. These conductance peaks can be associated with the excitation of the charge eigenmodes (plasmons) of the quantum cavity formed by the nanotube channel and its surrounding gate, and shows up as pronounced spatial periodic large amplitudes in the AC charge and potential, respectively. The resonant features vanish when the device is operated in the OFF-state in which case the conductance displays smooth oscillations, a signature of single particle quantum interference. Our results indicate that low dimensional devices with nanometer channel length might show potential as novel detectors and emitters of THz radiation operating at room temperature.

1:51PM J24.00012 Effects of substrate relaxation on adsorption in pores, SILVINA GÁTICA, Howard University, HYE-YOUNG KIM, Southeastern Louisiana University, GEORGE STAN, University of Cincinnati, MILTON COLE, Pennsylvania State University — Fluids in porous media are commonly studied with analytical or simulation methods, usually assuming that the host medium is rigid. Large qualitative effects are found for several systems, for which substrate relaxation may not be neglected. One application is a determination of the ground state of 3He in slit and cylindrical pores, where the relaxation effects vanish when the device is operated in the OFF-state in which case the conductance displays smooth oscillations, a signature of single particle quantum interference. Our results indicate that low dimensional devices with nanometer channel length might show potential as novel detectors and emitters of THz radiation operating at room temperature.

11:15AM J25.00001 Quantum and transport scattering times in graphene, X. HONG, K. ZOU, J. ZHU, Department of Physics, Penn State University, A. POSADAS, J. HOFFMAN, C. H. AHN, Department of Applied Physics, Yale University — We study the quantum\((\tau_q)\) and transport\((\tau_t)\) scattering times of single layer graphene mechanically exfoliated on SiO\(_2\) and polycrystalline Pb(Zr,Ti)O\(_3\) (PZT) substrates. The PZT substrate exhibits a gating efficiency of \(2 \times 10^{11}\,\text{cm}^2/\text{V} \times \text{s}\), corresponding to a dielectric constant of \(\sim 12\). We extract \(\tau_q\) from the magnetic field dependence of Shubnikov de Haas oscillations and \(\tau_t\) from the zero gate mobility, respectively. For the PZT-gated graphene, in the density range of \(2 \times 10^{12}/\text{cm}^2 < n < 6 \times 10^{12}/\text{cm}^2\), the transport scattering time \(\tau_t\) exhibits a clear crossover from a \(n^{1/2}\) dependence to a very weak density dependence at \(n \approx 4 \times 10^{12}/\text{cm}^2\). This observation is consistent with the theoretical prediction of a transition from long to short-ranged impurity scattering in graphene. On the other hand, the quantum relaxation time \(\tau_q\) shows a \(n^{1/2}\) dependence for the whole carrier density range. The ratio \(\tau_q/\tau_t\) changes from 2.5 to 1.8. Similar measurements are carried out on SiO\(_2\)-gated graphene. We compare data obtained from both substrates.

11:27AM J25.00002 Electrical and structural properties of chemically modified graphene sheets, ANDREA C. FERRARI, University of Cambridge, Engineering Department, Cambridge, CB3 OFA, UK — The chemical exfoliation of graphite through oxidation and then dispersion in a solvent is one of the methods of achieving scalable production of single graphene sheets. We use this method for making chemically modified graphene (CMG) sheets with tunable electronic properties, which can be placed flat on any surface or dispersed in various matrices. CMG sheets share some similarities with pristine graphene and with carbon nanotubes, e.g. tunable electron- and hole-type conductivity is observed in single CMG sheets just above the percolation threshold. CMGs may also be considered as a template for a bottom up development of a new class of materials. We have performed electrical measurements of individual CMG sheets and will discuss their electronic properties and the possible mechanisms of the charge transport in relation to their atomic structure and chemical composition.

11:39AM J25.00003 Doping, Strain, Orientation and Disorder of Graphene by Raman Spectroscopy, ANDREA C. FERRARI, University of Cambridge, Engineering Department, Cambridge, CB3 OFA, UK — Raman spectroscopy is a fast and non-destructive method for the characterization of carbons [1]. These show two features: the G and D peaks, around 1580 and 1350 cm\(^{-1}\), respectively. The G peak corresponds to the doubly degenerate \(E_2g\) phonon at the Brillouin zone centre. The D peak is due to the breathing modes of sp\(^2\) atoms and requires a defect for its activation [1-5]. It is common for as-prepared graphene not to have enough structural defects for the D peak to be seen [4,6], so that it can only be detected at the edges [6]. The most prominent feature in graphene is the second order 2D peak [6]. This is always seen, since no defects are required for its activation. Its shape changes single and multi-layers [6]. Raman spectroscopy also monitors doping [7-9]. We report the evolution of the Raman spectra of single [7,9] and bi-layer [9] graphene as a function of doping. A Fermi level shift is induced either by applying a bottom gate [7], or by a polymeric top gate [8,9], or naturally happens as a result of charged impurities [7]. This induces a stiffening of the Raman G peak for both hole and electron doping [7]. This is explained, including dynamic corrections to the adiabatic Born-Oppenheimer approximation [7]. The phonon renormalization of bilayer graphene has characteristic features compared to single layer. This allows a direct estimation of the interlayer coupling [7-9]. We then consider the effects strain. Uniaxial strain lifts the \(E_2g\) degeneracy and splits the G peak in two: \(G^+\) and \(G^-\). The peaks downshift as a function of strain allows a direct measurement of the Gruneisen parameter [10]. The polarization dependence of the \(G^+/G^-\) mode is a probe of the crystallographic orientation of the sample [10]. Finally, we consider the effect of disorder [3,4,11] and show how to discriminate between disorder, strain and doping [11]. We will also discuss how the D peak is a signature of \(\pi\) electron localisation, and thus, of gap opening in chemically modified graphene [12].
transport properties of epitaxial graphene on Si-face SiC and 3-inch SiC wafers, an agenda that we are now pursuing.

12:27PM J25.00005 Frictional Characteristics of graphene, CHANGGU LEE, Columbia University, ROBERT CARPICK, University of Pennsylvania, JAMES HONE, Columbia University — The frictional characteristics of graphene were characterized using friction force microscopy (FFM). The frictional force for monolayer graphene is more than twice that of bulk graphite, with 2,3, and 4 layer samples showing a monotonic decrease in friction with increasing sample thickness. Measurements on suspended graphene membranes show identical results, ruling out substrate effects as the cause of the observed variation. Likewise, the adhesion force is identical for all samples. The frictional force is independent of load within experimental uncertainty, consistent with previous measurements on graphite. We consider several possible explanations for the origin of the observed thickness dependence.

12:39PM J25.00006 Using Defects as Local Electronic Probes of Epitaxial Graphene on SiC, GREGORY M. RUTTER, KEVIN D. KUBISTÅ, DAVID L. MILLER, MING RUAN, WALTER A. DE HEER, PHILLIP N. FIRST, School of Physics, Georgia Institute of Technology, Atlanta, GA, JOSEPH A. STROSCIO, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD — Defects play an important role in the transport properties of epitaxial graphene, and understanding this role is essential for realizing potential nanoelectronics based on graphene. In this study, scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) performed at 4.2 K are used to measure the local electronic behavior of defects in epitaxial graphene grown on both SiC(0001) and SiC(000-1). Energy-resolved maps of the differential conductance reveal defect-induced standing-wave modulations related to the unique nature of the graphene band structure. In this talk, I will discuss how these defects can be used as a local probe of the graphene electronic properties with the inclusion of an applied magnetic field and the resulting Landau quantization. Supported in part by NSF, NRI-INDEX, and the W. M. Keck Foundation.

12:51PM J25.00007 ABSTRACT WITHDRAWN —

1:03PM J25.00008 Crystallographic Cuts in Single Layer Graphene, LEONARDO CAMPOS, VITOR MANFRINATO, JAVIER SANCHEZ, JING KONG, PABLO JARILLO-HERRERO, MIT — Graphene consists of a single monolayer of carbon atoms in a honeycomb 2D crystal. It is unique because the electrons are described by the Dirac equation, like relativistic particles with zero rest mass. According to theoretical predictions, it is possible to create field effect transistors just using narrow (d<10nm) nanoribbons. With zigzag edges, graphene nanoribbons can have a large magneto-resistance or could be used to produce a spin valve. With armchair edges it is possible to have an energy gap controllable by electric field. In this work we will show how to use Ni nanoparticles to create crystallographic oriented cuts in exfoliated graphene. Using Raman spectroscopy and electronic measurements of Dirac peaks, we have verified that the graphene, after the high temperature nanocut etching process, are still high quality 2D crystals, indicating that this process can be used to produce graphene nanodevices. Using this method we fabricate oriented nanoribbons and equilateral triangles with varying size. We also present a detailed analysis of the fabrication conditions for controlling the etching characteristics. Last, we present our analysis of the chirality of our nanocuts.

1:15PM J25.00009 Chiral tunneling of Dirac electrons in strained graphene, A. GARCIA-SARAVIA, G. CORDOURIER-MARURI, M.E. CIFUENTES-QUINTAL, E. MARTINEZ-GUERRA, R. DE COSS, Departamento de Fisica Aplicada, CINVESTAV-Mérida, A. P. 73 Cordemex, Mérida, Yucatan, Mexico — The behavior of the electrons in graphene is like massless Dirac fermions, which is a consequence of the characteristic energy spectrum of this material (E= k). Perfect chiral tunneling is expected when Dirac electrons pass through a step barrier (Klein paradox). However, in a two-dimensional system like graphene, the perfect tunneling is obtained only in a small range of incident angles. In the present work, we have studied the uniaxial deformation as a method of tuning the electronic transmittance in graphene. The effect of the armchair and zigzag strain on graphene was studied by means of first principles calculations, using the Density Functional Theory. For the calculations we used the pseudopotential-LCAO method. We found that the uniaxial deformations, induce an ellipsoidal distortion of the Dirac cones and isotropy breaking of the Fermi velocity. Finally, we used the Dirac–like equation to model the electronic transmittance as a function of the incident angle. We obtain that the strain induces a strong changes in the transmittance when the deformation is perpendicular to the incident axis.

1:27PM J25.00010 Strain and adhesion of graphene sheets in shallow trenches, CONSTANTZ METZGER, SEBASTIAN REMI, SILVIA KIJSMINSKY, ANTONIO CASTRO NETO, ANNA SWAN, BENNETT GOLDBERG, Boston University — Detailed high resolution micro Raman mapping of graphene exfoliated over shallow trenches demonstrates that single layer graphene adheres to the bottom of shallow trenches instead of remaining freely suspended. The analysis shows that the strain is surprisingly uniform. The high resolution Raman mapping of G and 2D Raman modes are consistent with uniaxial strain measurements, and the strain map concurs with our theoretical calculations that predict that a graphene sheet reaches minimal free energy sticking to the trench bottom even if that leads to moderate strain of about 0.6% in the sheet.

1:39PM J25.00011 ABSTRACT WITHDRAWN —

1:51PM J25.00012 Correlation of optical and topographical measurements with electronic transport properties of epitaxial graphene on Si-face SiC, PAUL M. CAMPBELL, Naval Research Laboratory, Washington DC, JOSHUA ROBINSON, Pennsylvania State University, University Park PA, JAMES C. CULBERTSON, JOSEPH L. TEDESCO, ROY A. MABOUDIAN, CARLO CARRARO, University of California at Berkeley, JASON KAWASAKI, Princeton University, ROYA MABOUDIAN, CARLO CARRARO, University of California at Berkeley — The early stages of epitaxial graphene layer growth on the Si-terminated 6H-SiC(0001) are investigated by depolarized Raman spectroscopy and electron channeling contrast imaging. The selection of the depolarized component of the scattered light results in a significant increase in the C=C bond signal over the second order SiC Raman signal, which allows us to resolve submonolayer growth, the formation of the buffer layer and a strained graphene layer. The linear strain, measured at room temperature (RT), is found to be compressive, which can be attributed to the large difference between the coefficients of thermal expansion of graphene and SiC. Whereas film thickness is determined by growth temperature, both the magnitude of the compressive strain and film morphology can be varied by adjusting the growth time at fixed annealing temperature. Annealing times in excess of 8-10 minutes lead to an increase in the mean square roughness of SiC step edges to which graphene films are pinned, resulting in compressively stressed films at RT. Shorter annealing times produce minimal changes in the morphology of the terrace edges and result in nearly stress-free films under cooling to RT.

1:51PM J25.00014 Controlled Structural Strain in Epitaxial Graphene Layers on 6H-SiC and Effects on Surface Morphology, NICOLA FERRALIS, University of California at Berkeley, JASON KAWASAKI, Princeton University, ROYA MABOUDIAN, CARLO CARRARO, University of California at Berkeley — The early stages of epitaxial graphene layer growth on the Si-terminated 6H-SiC(0001) are investigated by depolarized Raman spectroscopy and electron channeling contrast imaging. The selection of the depolarized component of the scattered light results in a significant increase in the C=C bond signal over the second order SiC Raman signal, which allows us to resolve submonolayer growth, the formation of the buffer layer and a strained graphene layer. The linear strain, measured at room temperature (RT), is found to be compressive, which can be attributed to the large difference between the coefficients of thermal expansion of graphene and SiC. Whereas film thickness is determined by growth temperature, both the magnitude of the compressive strain and film morphology can be varied by adjusting the growth time at fixed annealing temperature. Annealing times in excess of 8-10 minutes lead to an increase in the mean square roughness of SiC step edges to which graphene films are pinned, resulting in compressively stressed films at RT. Shorter annealing times produce minimal changes in the morphology of the terrace edges and result in nearly stress-free films upon cooling to RT.
2:03PM J25.00013 Reconstruction of Vacancy Defects in Graphene and Carbon Nanotube
GUN-DO LEE, EUJOOON YOON, NONG-MOON HWANG, Seoul National University, CAI-ZHUANG WANG, KAI-MING HO, Iowa State University — Recently, various structures of vacancy defects in graphene layers and carbon nanotubes have been reported by high resolution transmission electron microscope (HR-TEM) and those arouse an interest of reconstruction processes of vacancy defects. In this talk, we present reconstruction processes of vacancy defects in a graphene and a carbon nanotube by tight-binding molecular dynamics (TBMD) simulations and by first principles total energy calculations. We found that a structure of a dislocation defect with two pentagon-heptagon (5-7) pairs in graphene becomes more stable than other structures when the number of vacancy units is 10 and over. The simulation study of scanning tunneling microscopy reveals that the pentagon-heptagon pair defects perturb the wavefunction of electrons near Fermi level to produce the \( \sqrt{3} \times \sqrt{3} \) superlattice pattern, which is good agreement with experiment. It is also observed in our tight-binding molecular dynamics simulation that 5-7 pair defects play a very important role in vacancy reconstruction in a graphene layer and carbon nanotubes.

Session J26 DMP DCOMP: Focus Session: Computational Nanoscience IV: Carbon- and Silicon-based Nanostructures 328

FENG LIU, University of Utah — The nanotechnology of the future demands controlled and consistent fabrication of different classes of nanostructures. Computational nanoscience can play an important role in the development of novel nanofabrication techniques. By revealing the fundamental differences in the mechanical bending behavior of nanofilms from that of micro- and macro-films, we have carried out atomistic simulations making significant contributions to advance a novel nanofabrication approach, the so-called “nanomechanical architecture” of thin films. This approach allows fabrication of different types of nanostructures, with a high level of control over their size and shape based on a priori theoretical/computational designs. The simulations have revealed a self-bending mechanism of Si (Ge) nanofilms leading to formation of pure Si (Ge) nanotubes, which greatly broadens the repertoire of nanotubes that can be made from multilayer films. Furthermore, applying the principle of nanomechanical architecture to the extreme case of the thinnest film possible, a single atomic layer of patterned graphene sheet, a new method for synthesizing carbon nanotubes with an unprecedented control over their size and chirality was proposed.

12:03PM J26.00007 Thermal activation of interlayer bonding and its effect on properties of multiwalled carbon nanotubes
CHUN TANG, Department of Physics & High Pressure Center, University of Nevada, Las Vegas, WANLIN GUO, Institute of Nano Science, Nanjing University of Aeronautics & Astronautics, CHANGFENG CHEN, Department of Physics & High Pressure Science and Engineering, University of Nevada Las Vegas — We report molecular dynamics simulations of multiwalled carbon nanotubes (MWCNTs) at high temperatures. Our results show that thermally activated interlayer bonding have significant influence on structural, mechanical and electronic properties of MWCNTs and lead to new behaviors with implications for their applications. We examine the effect of strain and temperature conditions on the formation of interlayer bonding in MWCNTs and unveil the underlying atomistic mechanisms.

12:15PM J26.00004 Effective Hamiltonian approach to bright and dark excitons in single-walled carbon nanotubes
SANGKOOK CHOI, JACK DESLIPPE, STEVEN G. LOUIE, University of California at Berkeley and Lawrence Berkeley National Lab — Recently, excitons in single-walled carbon nanotubes (SWCNTs) have generated great research interest due to the large binding energies and unique screening properties associated with one-dimensional (1D) materials. Considerable progress in their theoretical understanding has been achieved by studies employing the ab initio GW-Bethe-Salpeter equation methodology. For example, the presence of bright and dark excitons with binding energies of a large fraction of an eV has been predicted and subsequently verified by experiment. Some of these results have also been quantitatively reproduced by recent model calculations using a spatially dependent screened Coulomb interaction between the excited electron and hole, an approach that would be useful for studying large diameter and chiral nanotubes with many atoms per unit cell. However, this previous model neglects the degeneracy of the band states and hence the dark excitons. We present an extension of this exciton model for the SWCNT, incorporating the screened Coulomb interaction as well as state degeneracy, to understand and compute the characteristics of the bright and dark excitons, such as the bright and dark level splittings. Supported by NSF #DMR07-05941, DOE #DE-AC02-06NA26274 and computational resources from Teragrid and NERSC.

12:27PM J26.00005 First-principles studies of the optical properties of carbon nanohoops
JOYDEEP BHATTACHARJEE, JEFFREY B. NEATON, Lawrence Berkeley National Laboratory — First proposed 70 years ago, cycloparaphenylenes — cyclic aromatic molecules that are the shortest possible segment of an armchair nanotube — have been only recently synthesized [1]. Using first-principles density functional theory and a Bethe-Salpter equation approach, we study structural, electronic, and optical properties of this novel class of materials, coined "carbon nanohoops." Remarkably, we find, in agreement with experiments, that smaller hoops have smaller optical absorption gaps. This counterintuitive trend, opposite to that expected from ordinary quantum confinement, reflects a large increase in electron-hole interaction strength with decreasing hoop diameter. The diameter dependence of this interaction is thoroughly explored for several nanohoops, compared with an acyclic series, and discussed in the context of possible applications. [1] R. Jasti, J. Bhattacharjee, J. B. Neaton, and C. R.Bertozzi, submitted (2008).

12:39PM J26.00006 First-principles study of methane adsorption on defective graphitic nanomaterials. BRANDON WOOD, Theoretical Sciences Unit, JNCASR, Bangalore, India, DEBOSRUTI DUTTA, MANAPATHY AYAPPA, Department of Chemical Engineering, Indian Institute of Science, Bangalore, India, SHOBHANA NARASIMHAN, Theoretical Sciences Unit, JNCASR, Bangalore, India — Efficient storage of methane represents a significant challenge to large-scale implementation of natural gas-based consumer transportation. Activated carbons and related carbon-based nanoporous structures have garnered tremendous interest as storage media due to their unusually high absorptive capacities. However, systematic improvement of these materials relies on a fundamental understanding of the physical and chemical processes involved. We present here extensive energetic calculations of methane adsorption in model carbonaceous systems using density-functional techniques. As exact nanostructures of activated carbons are difficult to obtain, we have attempted to isolate likely model nanostructures and defects, including surfaces, edges, point defects, and chemical functionalization. For each of these cases, we analyze changes in the structural, magnetic, and electronic properties upon adsorption. The defect structures exhibiting strongest methane adsorption are isolated, and the relevant mechanisms dominant in binding are identified. The impact of our results in terms of increasing methane absorptive capacity in activated carbons is discussed.

12:51PM J26.00007 Effects of hydrogen chemisorption on the structure of carbon nanotubes. ANDRE MUNIZ, TEJINDER SINGH, DIMITRIOS MAROUDAS, University of Massachusetts at Amherst — We report results of a computational atomic-scale analysis of the effects of atomic hydrogen chemisorption on the structure of single-walled and multi-walled carbon nanotubes (SWCNTs and MWCNTs). The analysis combines classical molecular-dynamics simulations with first-principles density functional theory calculations. We find that H chemisorption induces structural changes in SWCNTs associated with sp²-to-sp³ bonding transitions; increasing the H coverage beyond a critical level leads to axial and radial expansion of the SWCNTs that increases monotonically with H coverage. We also investigated the possibility of H-induced inter-shell sp³ C-C bond formation in MWCNTs. We find several pathways that lead to stable inter-shell bonded structures, which can act as seeds for nucleation of various crystalline carbon phases embedded into the MWCNTs. Finally, we show how the chiralities and relative alignments of adjacent graphene walls in MWCNTs determine the resulting crystalline structures.

1:03PM J26.00008 First principles study of NH₃ adsorption on carbon nanowires. JORGE-ALEJANDRO TAPIA, ALVARO-DANIEL SANCHEZ, CESAR ACOSTA, Facultad de Ingeniería (UADY), GABRIEL CANTO, Centro de Investigaciones en Corrosion (UACAM) — Recently has been reported a new type of one-dimensional carbon structures. Carbon nanowires formed by a linear carbon-atom chain inside an armchair (5,5) carbon nanotube has been observed using high-resolution transmission electron microscopy. Theoretical and experimental studies of the NH₃ adsorption in the carbon nanotubes report changes in the electronic properties of the carbon nanotubes. In the present work we have studied the electronic and structure properties of carbon nanowires (chain@SWCNT) when NH₃ atoms are adsorbed. We used the Density Functional Theory and the calculations where performed by the pseudopotentials LCAO method (SIESTA code) and the Generalized Gradient Approximation (GGA) for the exchange-correlation potential. We have analyzed the changes in the atomic structure and density of states (DOS). We found that the electronic character of the carbon chain of the chain@SWCNT system can be modulated by NH₃ adsorption. This research was supported by SEP under Grant No. PROMEP/103.5/07/2595 and the Consejo Nacional de Ciencia y Tecnología (Conacyt) under Grants No. 82497 and 60534.

1:15PM J26.00009 First-Principles Studies of Octacyclopropylcubane: A Novel High-Energy Density Material. STEVEN L. RICHARDSON, Howard University, REESHEMAH N. ALLEN, DANIEL FINKENSTADT, Naval Research Laboratory, MICHAEL J. MEHL, MARK R. PEDERSON, Naval Research Laboratory — The ongoing quest for synthesizing novel high-energy density materials (HEDMs) is clearly motivated by a search for new propellants and explosives. Recently de Meijere et al. have synthesized a new HEDM, octacyclopropylcubane (C₃₂H₄₀), in which the eight hydrogen atoms of cubane were replaced by cyclopropyl groups. In this work we report the results of a first-principles density-functional theory (DFT) calculation using the suite of codes known as NRLMOL (Naval Research Laboratory Molecular Orbital Library) to compute the structural, electronic, and vibrational properties of octacyclopropylcubane. We have calculated the vibrational properties of C₃₂H₄₀ and compare our results with experiment. We have also employed a DFT-based tight-binding scheme to compute the vibrational density of states for octacyclopropylcubane and compare our results with our full DFT-based results. Interesting enough, the geometry of the cyclopropyl groups in C₃₂H₄₀ does not allow for the quartic- concerted torsional mode (QCTM) that we and other workers have previously studied in octanitrocubane.

1:27PM J26.00010 Efficient first-principles simulation of non-contact atomic force microscopy for structural analysis. JAMES CHELIKOWSKY, TZU-LIANG CHAN, University of Texas at Austin, CAIL-ZHUANG WANG, Ames Laboratory-U.S. DOE, KAI-MING HO, Iowa State University — Non-contact atomic force microscopy (nc-AFM) has made significant advances that have allowed one to image a surface at atomic resolution. However, first-principles simulations of nc-AFM images remain a challenge because they involve calculations of the sample together with an atomic model of the AFM tip. We propose an efficient scheme to simulate nc-AFM images by using a first-principles self-consistent potential from the sample as input and without explicit modeling of the AFM tip. Our method is applied to various types of semiconductor surfaces including Si(111) (7 x 7), TiO₂(110) (1 x 1), Ag/Si(111)-(√3 x √3)/R30°, and Ge/Si(105) (1 x 2) surfaces. Our method takes into account electronic effects of the tip-sample interaction, which are important for predicting the bright spot positions and the contrast change with AFM tip height. In addition, we obtain good agreement with experimental results and previous theoretical studies.

This work was supported by the National Science Foundation under DMR-0551195 and the U.S. DOE under DE-FG02-06ER46286 and DE-FG02-06ER15760.

1:39PM J26.00011 Ab initio calculation of Stokes shifts of hydrogenated silicon clusters. MARIE LOPEZ DEL PUERTO, University of St. Thomas, St. Paul, MN, MANISH JAIN, University of California, Berkeley, CA, JAMES R. CHELIKOWSKY, University of Texas, Austin, TX — There is experimental evidence that hydrogenated silicon clusters may have large Stokes shifts. The absorption and emission processes in these clusters are not symmetric because the clusters may undergo structural changes while in an excited state. Several theoretical methods have been used to study this problem, resulting in an array of predicted Stokes shifts that differ in energy by several eVs, and different predicted minimum-energy structures with either relaxed cores or relaxed outer shells. We calculate Stokes shifts using three different methods: density functional theory within the local density approximation (LDA), density functional theory within the generalized gradient approximation (GGA), and time-dependent density functional theory within the local density approximation (TDLDA). We find that these three different methods give similar results both for magnitude of Stokes shift and excited-state structures. The Stokes shift of hydrogenated silicon clusters of 5 to 35 silicon atoms range from 5.5eV to 0.8eV, decreasing with increasing cluster size.

This work was supported in part by NSF under DMR-0551195 and the U.S. Department of Energy under DE-FG02-06ER46286 and DE-FG02-06ER15760.
1:51PM J26.00012 Calculated Polarizabilities of Diamond and Silicon Nanoclusters¹. SUDHA SRINIVAS, Physics Department, Northeastern Illinois University, Chicago, IL 60625, KOBLAR JACKSON, Physics Department, Central Michigan University, Mt. Pleasant, MI 48859, MINGLI YANG, Institute for Nanobiomedical Technology and Membrane Biology, Sichuan University, Chengdu 610041, China, JULIUS JELLINEK, Chemistry Division, Argonne National Laboratory, Argonne, IL 60439 — A scheme for decomposing the electric polarizability of a system into site-specific contributions is applied to hydrogenated nanoclusters of carbon and silicon. Site-specific dipole moments and polarizabilities are obtained from the response of charge densities to external electric fields, and decomposed into local and charge transfer components. We study changes in the polarizabilities of the C and Si atoms as the clusters grow in size. We find that exterior atoms have larger polarizabilities than interior atoms and that the charge transfer contribution to the total cluster polarizability increases with cluster size. We examine the relationship between the atomic polarizabilities in these clusters and bulk polarizability in carbon and silicon.

¹This work was supported by the Office of Basic Energy Sciences, Division of Chemical Sciences, Geosciences, and Biosciences, U. S. Department of Energy under grant number DE-FG02-03ER15489 (KAI, SS, and MY) under contract number DE-AC-02-06CH11357 (JJ).

2:03PM J26.00013 The Role of Vacancies on the Doping in Silicon Nanocrystals¹. JAE-HYEON EOM, TZU-LIANG CHAN, JAMES CHELIKOWSKY, University of Texas at Austin — We will present results for the effect of intrinsic defects (vacancies) on the doping of silicon nanocrystals by using first-principles calculations, i.e., pseudopotentials in real space. We calculated the total energy of a B doped silicon nanocrystal as a function of the vacancy position and the nanocrystal size. We found that the most stable B site strongly depends not only on the cluster size, but also on the position of the vacancy. We also explored the evolution of the interaction between the vacancy and the B dopant by comparing the total energy for several nanocrystal sizes and configurations.

¹This work was supported in part by NSF under DMR-0551195 and the U.S. Department of Energy under DE-FG02-06ER46286 and DE-FG02-06ER15760.

Tuesday, March 17, 2009 11:15AM - 1:51PM –
Session J27 GIMS: Focus Session: X-ray and Neutron Instruments and Sciences I 329

11:15AM J27.00001 Synchrotron X-ray Ultrafast Phase-Contrast Imaging Study of Fluids. YUJIE WANG, Argonne National Laboratory — Visible light imaging has been the traditionally dominant technique for study of fluid mechanical systems. However, it suffers from strong refraction, reflection and scattering effects under various occasions. X-ray phase-contrast imaging technique with its inherent generation synchrotron can offer a great tool for studying fluid mechanical systems with microsecond temporal and micron spatial resolutions. Several examples on dynamic multiphase flows and fluid singularities will be demonstrated. Future applications for other soft-condensed matter systems will also be discussed.

11:51AM J27.00002 Implicit spatial averaging in inversion of inelastic x-ray scattering data¹. P. ABBAMONTE², Frederick Seitz Materials Research Laboratory, University of Illinois — Inelastic x-ray scattering (IXS) is usually said to measure the imaginary part of the dynamical density response of a material. However this is not rigorously true. The density response χ, which describes the response of the system to a point charge source, is a function of two spatial coordinates and the time, i.e. χ = χ(x₁, x₂, t). Its Fourier transform χ(k₁, k₂, ω) is therefore a function of two, rather than just one, momenta. IXS does not probe this full response, but only its longitudinal or “diagonal” part Im{χ(k, k, ω)}. In this talk I will show that recently developed IXS inversion algorithms [2], which have shown promise for imaging attosecond dynamics in real space, yield a specific spatial average of the response, i.e. χ(x₁, t) = ∫ dx₂′ χ(x₁, x₂ + x₂′, t). This can be thought of as an average over all possible source locations, a real space projection, or a specific type of Fourier space filtering. I will show, within a simple model, that the salient real space dynamics nonetheless survive, and that IXS inversion is still a useful and well-posed technique for imaging attosecond dynamics.

¹This work was supported in part by NSF under DMR-0551195 and the U.S. Department of Energy under DE-FG02-06ER46286 and DE-FG02-06ER15760.

12:03PM J27.00003 Quasi-zero dimensional CuB₂O₄ as an archetype for resonant inelastic X-ray scattering. JASON HANOCO, GUILLAUME CHABOT-COUTURE, YUAN LI, Stanford, GUERMAN PETRAKOVSKI, Kirenski Institute, Siberia, KENJI ISHII, IGNACE JARRIGE, JUN-ICHIRO MIZUKI, JAEA, SPring8, MARTIN GRENEN, TOM DEVEREAUX, Stanford — We explore the general phenomenon of resonant inelastic scattering (RIXS) using CuB₂O₄, a network of CuO₂ plaquettes electronically isolated by B³⁺ ions. Spectra show a small number of well-separated features, and we exploit the simple electronic structure to explore RIXS phenomenology by developing a calculation allowing for intermediate-state effects ignored in standard approaches. These effects are found to be non-negligible and good correspondence between our model and experiment leads to a simple picture of such phenomenology as the genesis of d−d excitations at the K edge and intermediate-state interference effects.

12:15PM J27.00004 Inelastic Neutron Scattering Study of Ce₃Sn and Ce₃In. C.H. WANG, J. M. LAWRENCE, University of California, Irvine, CA. 92697 USA, A.D. CHRISTIANSON, Oak Ridge National Laboratory, Oak Ridge 37831, TN USA, E.A. GOREMYCHKIN, ISIS Facility, Rutherford Appleton Laboratory, Chilton, Didcot, OX11 0QX, United Kingdom, E.D. BAUER, Los Alamos National Laboratory, Los Alamos, NM, 87545 USA, N.R. DE SOUZA, A.I. KOLESNIKOV, Argonne National Laboratory, Argonne, IL 60439 USA — In Ce₃Sn and Ce₃In, the linear coefficients of specific heat γ are 260 mJ/mol CeK² and 700 mJ/mol CeK², respectively. The Wilson ratio is 7.0 for Ce₃Sn and 11.5 for Ce₃In. Such large values suggest the presence of ferromagnetic correlations in the ground state. Hence, this system is a potential candidate for studying the magnetic instability at a quantum critical point (QCP). As an initial measurement, we have measured the magnetic inelastic neutron scattering line shape of polycrystalline samples to determine the crystal field (CF) excitations. The low temperature spectrum of both Ce₃Sn and Ce₃In consist of a quasi-elastic line and two obvious inelastic lines resulting from the two excited crystal field doublets of Ce⁺⁺ in the tetragonal symmetry. The quasi-elastic linewidth which is related to the Kondo scale, is 3.2mEV for Ce₃Sn and 1.5mEV for Ce₃In, consistent with the linear coefficients of specific heat. For Ce₃Sn the two CF excitations are at 20mEV and 35mEV while for Ce₃In, the splitting is much larger giving the two excitations at 15mEV and 47mEV.
12:27PM J27.00005 Resonant Multi-Wave X-Ray Diffraction Study on Iron Oxides System. SHIH-CHANG WENG, YEN-RU LEE, JHENG-GANG CHEN, CHIA-HUNG CHU, SHIH-LIN CHANG, National Tsing Hua University — The resonant X-ray scattering occurs when the incident photon energy is close to an absorption edge of a constituent atom. Under such circumstances, the corresponding atomic scattering factor will be modified due to anomalous dispersion, which is directly related to unoccupied states, magnetic moment, charge distribution, and the types of near-neighbor atoms. Therefore, the resonant X-ray scattering is widely used to investigate crystal structure, electronic structure, magnetic property and charge distribution, etc. On the other hand, the multi-wave diffraction can provide more information about reflection phase than the normal (two-beam) Bragg diffraction. In this paper, we will show that resonant multi-wave diffraction profiles in the vicinity of iron k-edge give the information about charge-ordering/charge distribution of iron oxide systems, such as Fe3O4.

12:39PM J27.00006 X-ray Diffuse Scattering from Ultrafast Laser Excited Solids. MARIANO TRIGO, YU-MIIN SHEU, JIAN CHEN, DAVID REIS, University of Michigan, STEPHEN FAHY, EAMONN MURRAY, University College, Cork, Ireland, TIMOTHY GRABER, ROBERT HENNING, University of Chicago — Intense, ultrashort laser pulses can be used to excite and detect coherent phonons in solids. However, optical experiments can only probe a reduced fraction of the Brillouin zone and hence most of the decay channels of such coherent phonons become invisible. In contrast, time-resolved x-ray diffuse scattering (TRXDS) has the potential to be the ultimate tool to study these phonon decay processes throughout the Brillouin-zone of the crystal. In our work, performed at the BioCARS beamline at the Advanced Photon Source, we use synchrotron time-resolved diffuse x-ray scattering to study Si and Bi under intense laser excitation with 100 ps resolution. We show that reasonable signal levels can be achieved with incident flux of $10^{12}$ photons comparable to the flux that will be available at future 4th generation sources such as the LCLS in a single pulse. These sources will also provide three orders of magnitude shorter pulses; thus, this experiment serves as a test of the feasibility of time-resolved X-ray diffuse scattering as a tool for studying nonequilibrium phonon dynamics in solids.

12:51PM J27.00007 Antiferromagnetism in a Fe50Pt40Rh10 thin film investigated using neutron diffraction1. GARY MANKEY, University of Alabama, DIETER LOTT, JOCHEN FENSKE, ANDREAS SCHREYER, GKSS Research Center, PRAKASH MANI, University of Alabama, FRANK KLOSE, Australian Nuclear Science and Technology Organization, WOLFGANG SCHMIDT, KARIN SCHMALZL, Juelich Research Center, ELENA TARTAKOVSKAYA, National Ukrainian Academy of Science — The temperature-dependent magnetic structure of a 200 nm thick single-crystalline film of Fe50Pt40Rh10 was studied by unpolarized and polarized neutron diffractions. By applying structure factor calculations, a detailed model of the magnetic unit cell was developed. In contrast to former studies on bulk samples, our experimental results show that the film remains in an antiferromagnetic state throughout the temperature range of 10–450 K. Remarkably, it can be demonstrated that the antiferromagnetic structure undergoes a smooth transition from a dominant out-of-plane order with the magnetic moments oriented in-plane to an in-plane order with the magnetic moments oriented perpendicular to the film plane. Theoretically, this can be explained by the existence of two competing anisotropy contributions with different temperature dependencies.

1:03PM J27.00008 Following Transient Phases at the Air/Water Interface1. MATI MERON, JEFF GEBHARTD, HAROLD BREWER, P. JAMES VICCARO, BINHUA LIN, CARS, The University of Chicago — A fast pixel array detector, the Pilatus 100K, has been used in studies of organic monolayers at the air-water interface. The area sensitivity and large dynamic range of the detector, in combination with a “one dimensional pinhole” geometry, make it possible to observe surface processes which were inaccessible to the previous generation of experimental techniques. Especially, time dependent phenomena acting on time scales ranging from seconds to minutes can be observed and analyzed.

1 This work is supported by ChemMatCARS, University of Chicago, which is funded by a NSF and DOE grant number CHE-0535644.

1:15PM J27.00009 Detecting Hidden Symmetries with Coherent X-Ray Diffraction1. THOMAS DEMMER, ALEJANDRO DIAZ ORTIZ, PETER WOCHNER, HELMUT DOSCH, Max Planck Institute for Metals Research — An approach to analyze x-ray coherent diffraction patterns of amorphous systems is presented. We have investigated archetype hard-sphere systems where the local environment is simulated using different hundreds of geometric structures (i.e., regular and irregular polyhedra). The effect of positional and orientation randomness on the coherent diffraction pattern is studied numerically for samples containing up to 107 particles. A library of such simulated diffraction data is then used to retrieve the underlying symmetries in amorphous systems. A discussion of the relevant experimental work is also presented.

1 This work has been funded by the Alexander von Humboldt Foundation

1:27PM J27.00010 Measuring phonon dispersion relations with momentum- and energy-resolved x-ray calorimetry. RUQING XU, U. of Illinois at Urbana-Champaign, HAWOONG HONG, Argonne National Lab, T.-C. CHIANG, UIUC — X-Ray Thermal Diffuse Scattering (TDS) is a powerful method for determining phonon dispersion relations, as has been demonstrated in a number of experiments. However, most previous studies employed a fitting procedure based on presumed atomic force constant models, and the results could be susceptible to systematic errors. In view of this issue, we have developed a new method based on momentum-resolved x-ray calorimetry. The phonon frequencies at specific wavevectors are determined directly from the temperature dependence of the TDS intensities, with no force constant models needed. A test of this method on Cu has yielded excellent results. However, a limitation exists for this method, as it requires data taken over a wide temperature range, and the minimum temperature must be significantly lower than the Debye temperature. This can be a problem for materials with phonon frequencies that change significantly with temperature. To overcome this problem, we are experimenting with another method: the scattered x-rays are energy analyzed, and the TDS intensity is determined relative to the Compton scattering intensity. With this internal intensity calibration, phonon frequencies can now be determined from TDS data with temperature. To overcome this problem, we are experimenting with another method: the scattered x-rays are energy analyzed, and the TDS intensity is determined relative to the Compton scattering intensity. With this internal intensity calibration, phonon frequencies can now be determined from TDS data over a narrow temperature range. Results of a test study on chromium will be presented.

1:39PM J27.00011 Infrared emission induced by x-rays1. RICHARD ROSENBERG, MOHAMMAD ABU HALA, Argonne National Laboratory, SIMON WATKINS, Simon Fraser University — Two of the most powerful methods for studying the properties of matter are Fourier transform infrared (FTIR) spectroscopy and synchrotron radiation (SR) based x-ray techniques. Having the ability to perform both types of research on the same samples at the same time would be a significant synergism. Furthermore, the spatial resolution of conventional FTIR microscopes is limited by diffraction, which in the mid IR is 2-20 μm, while SR based x-ray microscopes are capable of <30 nm diameter resolution. Thus, by utilizing nanometer sized x-ray beams to produce IR emission it should be possible to extend the spatial resolution of IR microscopy by orders of magnitude and simultaneously perform x-ray studies. To test the feasibility of this approach we have incorporated a commercial FTIR instrument into an existing ultra-high vacuum end station on an insertion device beamline at the Advanced Photon Source and measured the bandgap, exciton luminescence (0.4 eV) from InAs thin films. Results using both high intensity, near-zero-order and low intensity, monochromatic x-rays will be presented.

11:15AM J28.00001 Electronic properties of graphene and its operation at GHz frequencies
YU-MING LIN, IBM T. J. Watson Research Center — Graphene, a two-dimensional carbon crystal, possesses great potential for applications in nanoelectronics because of its high intrinsic carrier mobility and the possibility of being processed using the well-established planar top-down technology in semiconductor industries. The former makes graphene an ideal candidate for electronic devices operating at high frequencies, while the latter allows us to tailor the transport properties of graphene devices by controlling their channel geometry. For example, it is, in principle, possible to create metallic and/or semiconducting graphene nanostuctures if a precise edge termination can be achieved. In this talk, I will present our recent experimental studies on transport properties of graphene nanoribbons and high-frequence characteristics of graphene transistors operated at GHz frequencies. High-quality graphene nanoribbons with widths down to 30 nm are fabricated by e-beam lithography. In these graphene nanoribbon devices, clear plateau features are observed in the measured conductance as a function of gate voltage at T \( \lesssim 80 \) K, indicating the formation of subbands due to quantum confinement in nanoribbons. This conductance quantization behavior is observed in both metallic and semiconducting nanoribbons, and provides the direct experimental evidence of quantum size confinement effects and the formation of subbands for 1D graphene nanoribbons. To explore the high-frequency transport in graphene, top-gated graphene field-effect transistors are fabricated and S- parameter measurements are performed to obtain their transport properties at microwave frequencies. In these graphene transistors, we found that the measured intrinsic current gain shows the ideal 1/f frequency dependence, indicating an FET-like behavior in these devices. The cutoff frequency \( f_T \) at which the current gain becomes unity is proportional to the dc transconductance \( g_m \) of the device, and is consistent with the relation \( f_T = g_m/(2\pi C) \). The peak \( f_T \) was found to increase with a reducing gate length, and a cut-off frequency beyond 20GHz was measured in a graphene transistor with a gate length of 150 nm. This work is done in collaboration with Ph. Avouris, D. Farmer, K. Jenkins, A. Valdes-Garcia, V. Perebeinos, J. Small.

11:51AM J28.00002 Graphene Frequency Multipliers1. HAN WANG, DANIEL NEZICH, JING KONG, TOMAS PALACIOS, Massachusetts Institute of Technology — In this paper we demonstrate a new application for graphene: full-wave signal rectification and frequency doubling. Due to its ambipolar transport properties, graphene field-effect transistors (GFET) show a V-shaped transfer characteristic about the minimum conduction point. Frequency doubling can be realized with a single GFET by biased the gate to the minimum conduction point and superimposing a sinusoidal input signal to the gate. Electrons and holes will conduct in alternative half cycles to produce an output signal at the drain, whose fundamental frequency is twice that of the input. Sub-linear IV characteristics of the GFET near minimum conduction point help improve the conversion efficiency and spectrum purity of the output signal. In our experiments, for an input frequency of 10 KHz, the output signal showed excellent spectrum purity (94% of RF power at 20 KHz) in the absence of any filtering elements. Given the extremely high electron mobility in graphene (>100,000 cm^2/Vs at room-temperature), such ambipolar devices have the potential to operate at very high frequencies and allow the fabrication of new THZ sources and sensors, as well as high speed transmitters and receivers.

12:03PM J28.00003 Chemically derived graphene nanoribbons: physical properties and electronics1, XINRAN WANG, Stanford University, YIJIAN OUYANG, University of Florida, XIAOLIN LI, LI ZHANG, HAILIANG WANG, Stanford University, JING GUO, University of Florida, HONGJIE DAI, Stanford University — Graphene electronics is a promising field of graphene research due to extremely high carrier mobility and the ability to fabricate true nanometer scale devices. We show that sub-10nm graphene nanoribbons, which are semiconductors with suitable bandgap for nanoelectronics, can be synthesized via chemical methods. Electrical transport measurements show that GNRs have finite bandgaps which are inversely proportional to widths. Unlike carbon nanotubes, all the sub-10nm GNRs are semiconductors and afford graphene field-effect transistors (FETs) with on-off ratio higher than 10^6 at room temperature. The performance of individual GNRFET is assessed and compared with CNTFETs. The scattering free path of carriers in GNRs is estimated, and the limiting factors are discussed. The performance of chemical GNRs and plasma etched GNRs are also compared and discussed.

12:15PM J28.00004 Non-volatile memory devices using graphene and ferroelectric thin films1, YI ZHENG, National University of Singapore — The unique linear energy band dispersion and its purely 2D crystalline structure have made graphene a rising star not only for fundamental research but also for nanoscale device applications. Here we demonstrate a novel non-volatile memory device using a combination of graphene and a ferroelectric thin film. The binary information, i.e., “1” and “0”, is represented by the high and low resistance states of the graphene working channels and is switched by the polarization directions of the ferroelectric thin film. A highly reproducible resistance change exceeding 300% is achieved in our graphene-ferroelectric hybrid devices under ambient conditions. The experimental observations are explained by the electrostatic doping of graphene by the remnant electrical field at the ferroelectric/graphene interface.

1In collaboration with Dr. Kui Yao, Institute of Material Research and Engineering, Singapore, and Dr. Barbara Oezylmar, National University of Singapore.

12:51PM J28.00005 Tuning Disorder and Interactions in Graphene1. JIANHAO CHEN, Department of Physics, University of Maryland — One (of many) unique aspects of graphene is that it is an atomically-thin two-dimensional electron system, open to manipulation and study using surface science techniques. This aspect of graphene has allowed us to tune both the disorder strength the interaction strength, allowing unprecedented control over a condensed matter system. Experiments are performed on atomically-clean graphene on SiO\(_2\) in ultra-high vacuum. Addition of potassium to graphene is used to study the dependence of the mobility and minimum conductivity point on charged impurity density. Tuning the dielectric environment through addition of an ice overlayer has two effects: charged impurity scattering is reduced, due to reduced Coulomb interaction between impurities and carriers, while short-range scattering is increased, due to reduced screening. In sharp contrast to graphene with charged impurity disorder, which remains metallic at low temperature, even a small amount of irradiation-induced point disorder produces a divergence of the resistivity and insulating behavior at low temperature.

1Supported by the NSF Maryland MRSEC, Nanoelectronics Research Institute, and Office of Naval Research.

1:27PM J28.00006 Graphene electronics: joule heat and charge density in active devices. MARCUS FREITAG, MATHIAS STEINER, YVES MARTIN, VASILI PEREBEINOS, ZHIHONG CHEN, JAMÉS C. TSANG, PHAEDON AVOURIS, IBM TJ Watson Research Center — We use Raman scattering microscopy to measure the shifts of the 2D and G-bands resulting from the electronic power dissipation in the graphene sheet. Extracted images of the temperature distribution show peak temperatures of up to 1000K in the middle of the graphene device. The metallic contacts act as the dominant heat sinks, because the thermal conductivity of graphene is far greater than the gate-oxide thermal conductivity. We model thermal transport and obtain excellent agreement in peak temperature and functional form. Velocity saturation due to phonons with 50meV energy is observed, suggesting that substrate polar phonons limit the high-bias conduction in graphene. Trapped charges are also detected and we find that application of a high current is associated with drain-induced barrier lowering in back-gated graphene devices.
1:39PM J28.00007 n-Type Behavior of Graphene Supported on Si/SiO2 Substrates1, HUMBERTO GUTIERREZ, HUGO ROMERO, NING SHENG, JORGE SOFO, PETER EKLUND, Physics Department, Penn State University, PARSOON JÔSHI, SRINIVAS TADIGADAPA, Electrical Engineering Department, Penn State University — Results are presented from an experimental and theoretical study of electronic properties of back-gated graphene field effect transistors (FETs) on Si/SiO2 substrates. The excess charge on the graphene was observed by sweeping the gate voltage to determine the charge neutrality point in the transistors. Devices exposed to laboratory environment for several days were always found to be initially p-type. After \( \sim 20 \) h at 200 °C in \( \sim 5 \times 10^{-7} \) Torr vacuum, the FET slowly evolved to n-type behavior with a final excess electron density on the graphene of \( 4 \times 10^{12} \) electrons/cm\(^2\). This value is in excellent agreement with our theoretical calculations on SiO\(_2\), where we have used molecular dynamics to build the SiO\(_2\) and then density functional theory to compute the electronic structure. The essential theoretical result is that SiO\(_2\) has a significant surface state density just below the conduction band edge that donates electrons to the graphene to balance the chemical potential at the interface. An electrostatic model for the FET is also presented that produces an expression for the gate bias dependence of the carrier density.

1:51PM J28.00008 Photocurrent imaging and efficient photon detection in a graphene transistor1, FENGNIAN XIA, THOMAS MUELLER, IBM TJ Watson Research, ROKSANA GOLIZADEH-MOJARAD, ECE Department, Purdue University, MARCUS FREITAG, YU-MING LIN, JAMES TSANG, VASILI PEREBEINOS, PHAEDON AVOURIS, IBM TJ Watson Research — We measure the channel potential of a graphene transistor using a scanning photocurrent imaging technique. In this approach, the photon-induced current between the source and drain is measured when the excitation laser beam is scanned across device at various gate biases. Potential profiles are then inferred from photocurrent measurements. We show that at a certain gate bias, the impact of the metal on the channel potential profile extends into the channel for more than 1/3 of the total channel length from both source and drain sides, hence most of the channel is affected by the metal. The barrier height between the metal and graphene interface is experimentally determined to be around 95 meV from transport and photocurrent measurements. As the gate bias exceeds the Dirac point voltage, \( V_{\text{Dirac}} \), the original p-type graphene channel turns into a p-p-n channel. When laser beam from He-Ne laser with a wavelength of 632.8 nm is focused on the p-n junctions, an impressive external responsivity of \( \sim 0.001 \) A/W is achieved, given that only a single layer of atoms are involved in photon detection. The possibility of using graphene p-n junctions in high-bandwidth photonic applications is discussed.

2:03PM J28.00009 Quantum capacitance measurement in high performance graphene field-effect devices1, ZHIHONG CHEN, IBM T.J. Watson, JOERG APPENZELLER, Electrical Engineering, Purdue University — We demonstrate first quantum capacitance measurements on single-layer graphene devices and elucidate on their relevance for the extraction of mobility for scaled graphene FETs. We also show experimentally that multi-layer graphene devices can be easily distinguished from single-layer graphene within our capacitance measurement approach, a previously unnoticed fact.

Tuesday, March 17, 2009 11:15AM - 2:15PM –
Session J29 GMG DMP FIAP: Focus Session: Spin Currents in Metals - New and Miscellaneous Topics 333

11:15AM J29.00001 Electronic transport in ferromagnetic conductors1, CHRISTIAN WICKLES, WOLFGANG BELZIG, University of Constance — We theoretically study ferromagnetic conductors using the Stoner model to describe the interaction between electron spin and magnetization. The latter can, in general, depend on time and space. We include impurity scattering processes for the electrons that lead to momentum relaxation, spin-flip and spin-dephasing. Utilizing Keldysh theory, we derive transport equations which allow to access interesting quantities such as domain wall resistance, electronic contribution to the magnetization damping coefficients and forces induced by non-equilibrium electron distributions in the presence of current flow. On the other side, a magnetization that shows temporal and spatial variation can induce current flow in the electron system.

11:27AM J29.00002 Bulk Spin Pumping and Bulk Spin Transfer Torque in Two-band Magnetic Conductors1, WAYNE SASLOW, Texas A&M University — For nonmagnetic materials, irreversible thermodynamics shows that thermal conduction and electrical conduction have a new and independent cross-coupling that yields a thermoelectric and an electrothermal effect. All of these terms are dissipative. However, for nonuniform two-band conducting magnets (e.g., within domain walls), electrical conduction and magnetization dynamics are cross-coupled by the up-band and down-band conductivities, without a need for a new cross-coupling. This yields both a bulk spin pumping term driving the current and a bulk spin transfer torque term driving the magnetization. Adiabatic in space, these terms are dissipative. In addition to these spin transfer and spin pumping terms corresponding to existing transport coefficients, for each spin component there are two types of additional transport coefficients. One type modifies the dissipative conductivity-driven terms in spin pumping and spin transfer torque, and itself is dissipative. The other type, non-adiabatic in space, is non-dissipative. We consider the situation where there is a spin current but no net current. Thermal effects are also considered, with temperature gradients having the same symmetry as gradients in the up and down spin electrochemical potentials.

2This work supported by the DOE through grant #DE-FG02-06ER46278.

11:39AM J29.00003 Influence of a Transport Current on Magnetic Anisotropy1, ION GARATE, ALLAN MACDONALD, University of Texas at Austin — The microscopic understanding of the spin transfer torque (STT) is an essential ingredient in the quest to develop optimized spintronic devices. It is well-known that STT occurs whenever electric currents travel through non-collinear magnetic systems. In contrast, it is often overlooked that current-induced torques may also arise in uniformly magnetized systems due to the intrinsic spin-orbit coupling in the band structure of the ferromagnet. We relate this effect to the change in magnetic anisotropy in presence of a current, and use simple models to estimate the possible role of transport currents to modify the direction of the ferromagnetic easy axis and assist magnetization reversal.

11:51AM J29.00004 Quantifying Spin Hall Effects in Gold Hall Bars1, GORAN MIHAJLOVIC, JOHN E. PEARSON, SAMUEL D. BADER, AXEL HOFFMANN, Materials Science Division and Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL 60439 USA, MIGUEL ANGEL GARCIA, Universidad Complutense, Madrid, Spain — Spin Hall effects manifest the fundamental interdependence between charge and spin transport. We studied these effects experimentally by measuring the non-local resistance, \( R_{nl} \), in mesoscopic Au Hall bars where spin current generation and detection are spatially separated in two side arms, while a bridging arm acts as the spin conduit. The measured \( R_{nl} \) decreases monotonically with decreasing temperature, changing sign from positive to negative. This can be understood by modeling \( R_{nl} \) as a sum of two components: a positive, ohmic component, arising from the charge current, and a negative component, due to spin Hall effects and spin diffusion. By varying the spacing between the side arms, the components can be separated. We determined the spin diffusion length, thespin Hall angle and the spin Hall conductivity. We found spin Hall angles of order 0.1, with a temperature dependence proportional to the resistivity, while the spin Hall conductivity was almost temperature independent.

3Work at Argonne is supported by the U.S. Department of Energy Office of Science under Contract No. DE-AC02-06CH11357.
12:03PM J29.00005 Investigation of Spin-Torque Effects on the Exchange Bias of Ferromagnet/Antiferromagnet Bilayers, KIRAN V. THADANI, R.A. BUHRMAN, D.C. RALPH, Cornell University — Spin-polarized current, generated by one ferromagnetic layer in a magnetic multilayer structure, can deposit spin angular momentum into a second ferromagnetic layer, causing it to either reversibly switch its orientation or oscillate in steady state at microwave frequencies. Recent calculations and experiments have investigated the possibility that spin torque might also alter the structure of an antiferromagnet [1], thereby affecting the exchange-bias field produced by the antiferromagnet on an adjacent ferromagnetic layer [2, 3]. Here we report studies made using nanopillar samples in which the free magnetic layer is exchange-biased to an antiferromagnet, which allow a direct measurement of the magnitude of the exchange bias and its current dependence. We will also investigate the degree to which the exchange bias alters the damping of the free-layer magnet and the extent to which the effective damping can be controlled with current. [1] A. S. Nunez et al., Phys. Rev. B 73, 214426 (2006). [2] Z. Wei et al., Phys. Rev. Lett. 98, 116603 (2007). [3] S. Urazhdin et al., Phys. Rev. Lett. 99, 046602 (2007).

12:15PM J29.00006 Tunnel barrier enhanced voltage signals generated by magnetization precession of a single ferromagnetic layer¹, TAKAHIRO MORIYAMA, University of Delaware — A variety of experimentally observed phenomena involving nonlocal magnetization dynamics in magnetic multilayers are due to two complementary effects: (i) the transfer of spin angular momentum accompanying charge currents driven by the applied bias voltage between ferromagnetic layers results in torques that (for sufficiently high current densities) generate spontaneous magnetization precession and switching; and (ii) the precessing magnetization of a ferromagnet (FM) pumps spins into adjacent normal metal layers (NM) with no applied bias. In particular, the spin pumping effect is a promising candidate for realizing a spin battery device [1] as a source of elusive pure spin currents (not accompanied by any net charge transport) emitted at the FM/NM interface, where steady magnetization precession of the FM layer is sustained by the absorption of external rf radiation under the FMR conditions. We report the electrical detection of magnetization dynamics in an Al/AI0₂/Ni₈₀Fe₂₀/Cu tunnel junction, where a Ni₈₀Fe₂₀ ferromagnetic layer is brought into precession under the ferromagnetic resonance (FMR) conditions. The dc voltage generated across the junction by the precessing ferromagnet is enhanced about an order of magnitude compared to the voltage signal observed in Cu/FeNi/Pt structures [2]. A structure of Cu (100nm)/Al (10nm)/AlOₓ (2.3nm)/Ni₈₀Fe₂₀ (20nm)/Cu (70nm)/Au (25nm) was fabricated on a Si substrate with a 1µm thick thermal oxide layer. The bottom-most 100 nm Cu layer was patterned into a coplanar waveguide (CPW) and the rest of the structure was patterned into a pillar structure on the signal line of the CPW. Dc voltages ~ µV were observed in the Al/AlO₂/Ni₈₀Fe₂₀/Cu tunnel junction when the Ni₈₀Fe₂₀ is in the ferromagnetic resonance. The dc voltages increase as the precession cone angle and frequency increase. We discuss the relation of this phenomenon to magnetic spin pumping and speculate on other possible underlying mechanisms responsible for the enhanced electrical signal. [1] A. Brataas et al. PRB 66, 060404 (2002) [2] M. V. Costache et al. PRL 97, 216603 (2006)

12:51PM J29.00007 FMR and voltage induced transport in normal metal-ferromagnet-superconductor trilayers, HANS JOAKIM SKADSEEM, ARNE BRATAAS, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway, JAN MARTINEK, Institute of Molecular Physics, Polish Academy of Science, 60-179 Poznan, Poland — In recent years, hybrid nanoscale circuits containing normal conductors, ferromagnets, and superconductors have been realized. These structures allow observation and understanding of the competition between ferromagnetism and superconductivity. In this talk, we consider charge and spin transport in normal metal-ferromagnet-superconductor trilayers induced by bias voltage and/or magnetization precession. Transport properties are discussed in terms of time-dependent scattering theory. We compute the charge and spin current response to bilinear order in precession frequency and bias voltage and express the results in terms of spin-dependent conductances. Simplified conductance expressions are obtained when the ferromagnet is longer than the transverse spin coherence length.

1:03PM J29.00008 Spin torque from tunneling through impurities in a magnetic tunnel junction, TURAN BIROL, PIET BROUWER, Cornell University — We study impurity-mediated transport in a magnetic tunnel junction (MTJ) in the sequential tunneling regime. We address the conductance of the MTJ as well as the spin transfer torque. We show that the torque from impurity-mediated tunneling can be distinguished from that from direct tunneling through its dependence on the barrier thickness and the angle between the ferromagnetic moments.

1:15PM J29.00009 Thermoelectric transport and thermal spin currents in ferromagnetic films and nanostructures, AZURE AVERY, RUBINA SULTAN, BARRY ZINK, University of Denver — For fundamental physics, understanding the mechanisms behind giant magnetoresistance (GMR) and its related properties, magnetoresistance (MR) and magnetothermopower (MTEP), is crucial, especially for nanoscaled structures. Though progress has been made in understanding electron transport through magnetic thin films and multilayers, far less is understood about the mechanisms behind thermal transport in these systems. This is due, in part, to the difficulty of measuring thermal properties of these low-dimensional systems. We present a robust technique for accurately measuring thermal conductivity (kₜ), thermopower (α), and MTEP in nanoscale magnetic materials using micromachined silicon nitride thermal isolation structures. We outline the fabrication of the structures and present our measurement results for ferromagnetic thin films and nanowires. Finally, we present how this technique is applied to testing the validity of current models explaining the mechanisms of thermal transport, such as thermal spin currents, in ferromagnetic films and nanostructures.

1:27PM J29.00010 ABSTRACT WITHDRAWN —

1:39PM J29.00011 Magneto resistive junctions based on epitaxial graphene and h-BN, OLEG YAZYEV, ALFREDO PASQUARELLO, Ecole Polytechnique Federale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland — Using a first-principles approach, we investigate the structural, magnetic and transport properties of interfaces based on epitaxially grown monolayer graphene and hexagonal boron nitride (h-BN) in combination with ferromagnetic transition metals (Fe, Co and Ni). Such structurally well defined interfaces based on (111) fcc or (0001) hcp transition metal thin films can be produced using simple manufacturing processes. Our calculations predict magnetoresistance ratios over 100% for certain junction compositions. In addition, such systems feature strong antiparallel (Fe and Co) and parallel (Ni) exchange coupling across the interface combined with low junction resistance. The predicted properties position such magneto resistive junctions as an interesting alternative to the currently used giant and tunneling magnetoresistive systems and make them suitable for practical applications.
and this in turn produces coupling to the electric dipole moments. The oxygen distortions induced with the spin reorientations below $T_N$ distorts the MnO$_5$N in the Lu-O bonds. This suggests an enhancement of the net electric polarization below $T_N$ hereby show that it is the ferroelectric motion of the Lu ions coupled with O distortions that exhibits a strong temperature dependence below $T_N$. While in previously reported neutron diffraction data, it was shown that all atomic coordinates changed based on symmetry considerations with $T_N$, the multiferroic LuMnO$_3$ give systems such as YING ZOU, SHISHIR RAY, SOMADITYA SEN, MARK WILLIAMSEN, Dept of Physics, University of Wisconsin-Milwaukee, USA — Unconventional magnetic switching, in spin based electronics, and as materials with negative refractive index, make them important candidates for device applications. Here we present Rietveld and XAFS analysis will be made. The detailed temperature dependent structure on multiple length scales will be presented with implications for the method based on high-q data. Temperature dependent measurements reveal anomalies in the short range structure involving oxygen atoms. Comparison with Rietveld and XAFS analysis will be made.

2:03PM J30.00003 Magnetic Field Dependent Changes in the Local Structure of ReMn$_2$O$_5$. M. DELEON, T.A. TYSON, Z. CHEN, NJIT, S.-W. CHEONG, Rutgers University — The temperature dependent structure of the ReMn$_2$O$_5$ (Re=rare earth) system has been examined by the x-ray pair distribution function method based on high-q data. Temperature dependent measurements reveal anomalies in the short range structure involving oxygen atoms. Comparison with Rietveld and XAFS analysis will be made. The detailed temperature dependent structure on multiple length scales will be presented with implications for the observed low temperature ferroelectric properties. This work is supported by DOE Grant DE-FG02-07ER46402.

12:15PM J30.00004 Studies of Competing Order in Multiferroic RMnO$_3$. PRASENJIT GUPTASARMA, YING ZOU, SHISHIR RAY, SOMADITYA SEN, MARK WILLIAMSEN, Dept of Physics, University of Wisconsin-Milwaukee, USA — Unconventional magnetic order, a ferroelectric background and the possibility of coupled ground states, together with competing spin, charge, lattice and orbital degrees of freedom, give systems such as RMnO$_3$ (R=Rare Earth), an ABO$_3$-type compound, a rich and fascinating phenomenology. The possibility of using these materials in switching, in spin based electronics, and as materials with negative refractive index, make them important candidates for device applications. Here we present a review of our studies of the detailed phenomenology of a series of single crystals of RMnO$_3$ grown from a floating zone, for different Rare Earths $R$, and by inducing structural distortions and charge disproportionation through substitutions at both the A and the B sites.

2:27PM J30.00005 Enhanced local lattice distortions with the antiferromagnetic transition in the multiferroic LuMnO$_3$. DESPINA LOUCA, University of Virginia, THOMAS PROFFEN, Los Alamos National Laboratory, SEUNG-HUN LEE, University of Virginia, SANG-WOOK CHEONG, Rutgers University — The ferroelectric hexagonal manganite, LuMnO$_3$, has been investigated via neutron scattering and the pair density function analysis to determine the nature of the local atomic distortions with the antiferromagnetic transition, $T_N$, of the Mn ions. While in previously reported neutron diffraction data, it was shown that all atomic coordinates changed based on symmetry considerations with $T_N$, we hereby show that it is the ferroelectric motion of the Lu ions coupled with O distortions that exhibits a strong temperature dependence below $T_N$ as reflected in the Lu-O bonds. This suggests an enhancement of the net electric polarization below $T_N$. At the same time, the motion of the apical O1 and O2 ions distorts the MnO$_5$ bipyramids, leading to more buckling of the ab-layers. However, the Mn ions do not appear to distort significantly away from their equilibrium position. The oxygen distortions induced with the spin reorientations below $T_N$ may be the cause for the Lu ion displacements through electrostatic interactions and this in turn produces coupling to the electric dipole moments.
Laboratory, Carnegie Institution of Washington, JINZHU HU, X17 of NSLS, CARS, University of Chicago, Upton, NY, CHENGLIN ZHANG, SUNG-BAEK KIM, R MnO.

In order to induce multiferroic behaviour in other magnetic members of the orthorhombic $R_{3d}$, and Ho 5d and Y 4d spectral features, the corresponding features in the Y

The effect of hydrostatic pressure on the ferroelectric properties of these systems will be given based on comparisons with density functional calculations.

12:39PM J30.00006 Pressure Dependence of Structure Stability of Multiferroic Hexagonal-RMnO$_3$, ZHIQIANG CHEN, PENG GAO, TREvor A. TYSOn, Department of Physics, New Jersey Institute of Technology, ZHENXIAN LIU, Geophysical Laboratory, Carnegie Institution of Washington, JINZHU HU, X17 of NSLS, CARS, University of Chicago, Upton, NY, CHENGLIN ZHANG, SUNG-BAEK KIM, SANG-WOOK CHEONG, Dept. of Physics and Astronomy, Rutgers University — We present high pressure IR and X-ray diffraction measurements of the hexagonal multiferroic systems HoMnO$_3$, YMnO$_3$ and LuMnO$_3$. Measurements were conducted over the pressure range ambient to $\sim$20 GPa. No phase changes were observed over this broad range of hydrostatic pressures. These suggest that the hexagonal structure is stable at higher pressures. The thermal treatment is necessary to overcome the barrier (breaking and reconnection of bonds) to achieve the hexagonal to orthorhombic phase change. A discussion of the effect of hydrostatic pressure on the ferroelectric properties of these systems will be given based on comparisons with density functional calculations.

This work is supported by DOE grant DE-FG02-07ER46402.

12:51PM J30.00007 X-ray absorption spectroscopy studies of YMnO$_3$, HoMnO$_3$, and Y$_3$Ho$_{0.5}$MnO$_{1.5}$, RELJA VASIC, North Carolina State University, DARIO ARENA, JOSEPH DVORAk, Brookhaven National Laboratory, HAILDong ZHOU, CHRIS R. WIEBE, National High Magnetic Field Laboratory, GERALD LUCOVSKY, North Carolina State University, MARC ULRICH, Army Research Office — We have investigated three hexagonal perovskites, YMnO$_3$, HoMnO$_3$, and Y$_3$Ho$_{0.5}$MnO$_{1.5}$ by O K$\alpha$ and Mn L$_{3,2}$ edge X-ray absorption spectroscopy. In YMnO$_3$ and HoMnO$_3$ the lowest energy transitions are predominantly Mnp 4p and 3d states with a least five distinct states occurring at approximately the same X-ray energies in both samples. We associate this portion of electronic structure with the trigonal bipyramidal bonding symmetry of a five-fold coordinated Mn. Higher energy transitions in the XAS OK$\alpha$ spectra are broader and associated with Ho 5d and Y 4d orbitals. Compared with YMnO$_3$ and HoMnO$_3$ Mn 3d, and Ho 5d and Y 4d spectral features, the corresponding features in the Y$_3$Ho$_{0.5}$MnO$_{1.5}$ K$\alpha$ spectrum exhibit broader features fewer in number. These are consistent with random alloy bonding in which the Ho and Y are randomly distributed on the A-atom sub-lattice. We will discuss the electronic structure of these empty states in the context of symmetry adapted linear combinations of molecular orbital O 2p*, and Mn 3d*, Ho 5d* and Y 4d* nearest neighbor states.

1:03PM J30.00008 Competing Magnetic Interactions in Magnetoelectric YbMnO$_3$, SHISHIR RAY, YING ZOU, MARK WILLIAMSEN, SOMADITYA SEN, LARRY BUROKER, PRASENJIT GUPTASARMA, Physics Dept, University of Wisconsin-Milwaukee, USA — The (RE)MnO$_3$ (RE = Rare Earth) series of magnetoelectrics exist as both hexagonal and orthorhombic lattice structures. These have recently attracted much attention due to possible applications in spintronics, in switching, and as media with negative refractive index. YbMnO$_3$ is hexagonal with ferroelectricity (Tc $\sim$ 970K) and antiferromagnetism (T N $\sim$ 80K). Comprehensive resonant X-ray scattering at variable temperatures (200-1000K) in a single crystal of magnetoelectric orthorhombic TbMnO$_3$ has been extensively studied both experimentally and theoretically about its fascinating properties (e.g., magneto-electric coupling, spiral magnetic order). Understanding these empty states in the context of symmetry adapted linear combinations of molecular orbital O 2p*, and Mn 3d*, Ho 5d* and Y 4d* nearest neighbor states.

Detailed description will be dealt with this presentation.

3:39PM J30.00011 Emergence of the multiferroic state in R$\text{MnO}_3$, G. BALAKRISHNAN, D. O'FLYNN, C.V. TOMY, M.R. LEES, Department of Physics, University of Warwick, Coventry CV4 7AL, UK — In order to understand the emergence of multiferroic behaviour in the R$\text{MnO}_3$ compounds, it is educational to study the relationship between ferroelectricity and magnetoelectrically enhanced lattice modulations in $\text{R MnO}_3$. Lattice modulations in $\text{R MnO}_3$ are strongly dependent on the Mn-O-Mn bond angle (\(\phi\)), which in turn is determined by the ionic radii (\(r_{\text{i}}\)) of the R atoms. Multiferroic properties have been observed in the orthorhombic R$\text{MnO}_3$ (R = Tb/Dy) compounds, in which \(\phi\) is close to 145°. In order to induce multiferroic behaviour in other magnetic members of the orthorhombic R$\text{MnO}_3$, and to tune the structure to be in the same region of the phase diagram as Tb/DyMnO$_3$, it is necessary to substitute at the R site with a suitable (smaller) atom. We have achieved this in SmMnO$_3$ and NdMnO$_3$ by substitutions at the Sm and Nd sites with smaller R ions. In the optimally substituted compounds (40 to 50%), we observe an additional magnetic transition. Investigations of the dielectric properties of the crystals reveal anomalies in the dielectric properties coincident with this magnetic transition, analogous to those exhibited by Tb/DyMnO$_3$, indicative of multiferroic behaviour. We present detailed investigations of the magnetic, dielectric and structural properties in single crystals of selected compositions.
11:15AM J31.00001 400-Fold Reduction in Saturation Field by Stress Relief in Multilayers. WILLIAM EGGLEHOF, JOHN BONEVICH, CARLOS BEAUCHAMP, GERY STAFFORD, JOHN UNGURIS, NIST, PHILIP PONG, University of Hong Kong, ROBERT EICMAEL, NIST — A common problem in soft magnetic thin films is increased saturation field due to stress build-up with increasing thickness. We have found a solution to the problem using multilayers of a magnetic thin film and a film that is either not lattice matched or has a different crystal structure. Reductions in the saturation field as large as 400 fold are found. The ultra-soft Ni$_2$Fe$_{14}$Cu$_8$Mo$_4$ alloy can have saturation fields as small as 0.05 mT (0.05 Os) for 10 nm thick films. However, for films 400 nm thick (which is needed for some applications) the saturation field is typically 20 mT. Splitting this magnetic thin film up into segments 100 nm thick separated by a 5 nm Ag film reduces the saturation field to 0.05 mT. Alternatively, using a 2 nm CoFe film yields a saturation field of 0.1 mT. A tensile stress of $7.35 \times 10^7$ dynes/cm$^2$ was measured in the 400 nm film and $3.7 \times 10^7$ dynes/cm$^2$ for the multilayer with Ag. The highly-stressed Ni$_2$Fe$_{14}$Cu$_8$Mo$_4$ develops a magnetostriction coefficient of $-5$ ppm, although in the unstressed state its magnetostriction coefficient is near zero. In conclusion, we have found a solution to the stress-induced large saturation fields in an otherwise soft magnetic film. The results should be important for ultra-low-magnetic-field tunnel-junction sensors and magnetic flux concentrators.

11:27AM J31.00002 Structure and magnetic properties of magnetron-sputtered FePt/Au superlattice films. YONGSHENG YU, University of Nebraska, HAIBO LI, Jilin Normal University, XINGZHONG LI, LANPING YUE, University of Nebraska, WEILI LI, Habbin Institute of Technology, MEI LIU, YUMEI ZHANG, Jilin Normal University, WEIDONG FEI, Habbin Institute of Technology, DAVID J. SELLMYER, University of Nebraska — FePt/Au multilayer films were prepared with sputtering and the effects of Au thickness and annealing temperature on the structure and magnetic properties were investigated. Superlattice structure was induced by thicker Au layer. The interatomic spacing d(220) in the fcc FePt lattice increases with increasing Au thickness, indicating increasing strain energy in fcc FePt lattice. After annealing at 300°C, FePt films with Au layer of 3.5 nm became ordered and the multilayer structure was retained. The strain energy in fcc FePt lattice appears to be responsible for lowering the ordering temperature of the FePt phase. For films annealed at higher temperatures, thicker Au layer restrained the ordering of FePt phase, which led to a decrease of coercivities. — This research is supported by DOE and NCMN.

11:39AM J31.00003 Controlling Interlayer exchange coupling in ultra narrow Fe/Pt multilayered nanowire: an ab initio study. PUSPAMITRA PANIGRAHI, RANJIT PATI, Michigan Technological University, Houghton, MI 49931 — Interest in the study of magnetic/non-magnetic multilayered structures took a giant leap since Grünberg and his group established that the value of interlayer exchange coupling (IEC) depends upon the non-magnetic spacer width. The recent increase in demand for device miniaturization compelled researchers to look for novel nanoscale multilayered structures. Towards this effort, we have studied IEC in one dimensional Fe/Pt multilayered nanowires using first principles density functional approach. Our result shows the exchange coupling energy (J) to switch sign as the width of the non-magnetic Pt spacer varies. The competition among short and long range direct exchange and the super exchange is recognized to play an important role for the non-monotonic sign of IEC depending upon the width of the Platinum spacer layer.

11:51AM J31.00004 Design of Co/Pd multilayer system with antiferromagnetic-to-ferromagnetic phase transition. JAN-ULRICH THIELE, Seagate Technology — Among the known magnetic material systems there are only very few examples of materials that undergo a temperature dependent antiferromagnetic-to-ferromagnetic phase transition, and of these only the chemically ordered alloy FeRh exhibits this transition near room temperature [1, 2]. Here we present a perpendicular anisotropy multilayer structure that mimics FeRh. The basic idea is to use two stacks of Co/Pd multilayers with large perpendicular magnetic anisotropy and high Curie temperature, $T_C$, separated by a layer providing antiferromagnetic coupling, and a CoNi/Pd multilayer with perpendicular anisotropy with a lower $T_C$, interlayer, in the range of the desired AF-FM transition temperature, $T_{AF-FM}$. At room temperature this system behaves as two antiferromagnetically coupled layers with a low perpendicular remanent magnetic moment. As the temperature is raised to approach $T_{C,interlayer}$ the magnetization of the interlayer is gradually reduced to zero, and consequently its coupling strength is reduced. Eventually, the effective coupling between the two high-$K_{c,interlayer}$, high-$T_C$ layers becomes dominated by their dipolar fields, resulting in a parallel alignment of their moments and a net remanent magnetic moment equal to the sum of the moments of the two high-$T_C$ layers [2].

12:27PM J31.00005 Graded Magnetic Anisotropy in Co/Pd Multilayers. B. J. KIRBY, J. E. DAVIES, National Institute of Standards and Technology, S. M. WATSON, R. D. SHULL, J. A. BORCHERS, National Institute of Standards and Technology, G. T. ZIMANYI, KAI LIU, University of California - Davis — As the magnetic recording industry looks beyond perpendicular recording, multilayered exchange coupled media have demonstrated potential for increased storage density. Recent work has shown further enhancements when the anisotropy is gradually increased from a soft top to a hard bottom region. However, creating graded anisotropy structures is difficult, and convincingly demonstrating such a gradient is also challenging. Since the coercivity of Co decreases with increasing thickness, we attempted to create graded anisotropy structures by sputtering Co/Pd superlattices with progressively varying Co layer thicknesses. We probed the depth dependent anisotropy of the samples using polarized neutron reflectometry (PNR), a technique sensitive to the depth-dependent magnetic composition of thin films. The sample magnetization vector M was bent away from the out-of-plane easy axis direction by an applied magnetic field H, and the depth profile of the in-plane component of M(H) was measured. Our results clearly demonstrate that samples with graded Co thickness also exhibit graded anisotropy. Further, comparisons of samples with different levels of gradient discretization shed light on the nature of the interlayer exchange coupling in a graded anisotropy system. [1] D. Suess, Appl. Phys. Lett. 89, 189901 (2006).

12:39PM J31.00006 Coercivity enhancement in (Co/CoO)$_n$ superlattices. SRINIVAS POLISSETTY, CHRISTIAN BINEK, University of Nebraska-Lincoln — The temperature dependence of the coercivity is studied in (Co/CoO)$_n$ periodic multilayer thin film superstructures below and above the exchange bias blocking temperature. The ferromagnetic Co thin films are grown with the help of MBE at a base pressure of 10E-10 mbar whereas antiferromagnetic CoO thin films are grown from in-situ oxidized Co. The thicknesses of these films are monitored by reflection high energy electron diffraction (RHEED). A mean-field theory is outlined which provides an analytic and intuitive expression for the enhancement of the coercivity of the ferromagnet which experiences the exchange coupling with a neighboring antiferromagnet. An experimental approach is developed allowing to determine the interface susceptibility of an individual antiferromagnetic pinning layer by systematic change in the thickness of the antiferromagnet thin films in various sets of superlattice samples measured at different temperatures, respectively. The experiment enables us to separate out the intrinsic coercivity from the contribution induced by exchange coupling at the interface. It is the goal of our study to evidence or disprove if it is simply this susceptibility of the reversible interface magnetization creating the spin drag effect and by that the coercivity enhancement. Financial support by NSF through CAREER DMR-0547887, NRI and Nebraska MRSEC.
12:51PM J31.00007 Antiferromagnetic coupling in Fe/Si/Fe structures with Co “dusting” layers , RASHID GAREEV, MATTHIAS KIESLING, Uni Regensburg, MATTHIAS BUCHMEIER, Uni Muenster, GEORG WOLTERSDORF, CHRISTIAN BACK, Uni Regensburg, UNI REGENSBURG TEAM, UNI MUEENSTER COLLABORATION — Artificial antiferromagnetic (AF) tunneling Si-based structures are attracting a spatial interest due to extremely strong AF coupling, which exceeds 5μemu/m², low resistance-area product and resonant-type tunneling magnetoresistance (TMR) [1]. A promising way to regulate the spin polarization in TMR structures is to insert Co “dusting” layers at interfaces [2]. We present AF coupling in Fe/Co/Si/Co/Fe epitaxial structures with sub-monolayer—thick Co “dusting” layers at interfaces and different thicknesses of the Si spacer. We determined the strength of AF coupling from spin-wave frequencies and angular dependence of the resonance field of the ferromagnetic resonance, as well as MOKE hysteresis. We found the AF coupling near 0.1μemu/m² which decays with the spacer thickness and detectable for 2nm-thick Si spacers. The presented results can open an avenue for magnetotransport studies in AF-coupled structures using interface engineering. [1]. R.R. Gareev et al, JMMM 240, 235 (2002), R.R. Gareev et al, APL 88, 172105 (2006). [2]. Y. Wang, X.F. Han, and X.-G. Zhang, APL 93, 172501 (2008).

1:03PM J31.00008 Probing Magnetic Configurations in Buried Cobalt/Copper Multilayered Nanowires1, KAI LIU, University of California - Davis — Multilayered magnetic nanowires have been a model system for heterostructured junctions that exhibit a host of fascinating perpendicular spin transport phenomena, such as giant and tunneling magnetoresistance (MR), and spin-transfer torque effects. Due to the extremely small physical dimensions the magnetic components in these nanowires or junctions often exhibit complex magnetization reversal behaviors, which are difficult to probe by magnetic imaging since the entities are buried deep inside a matrix. Conventional hysteresis loop measurement alone cannot reliably distinguish the reversal mechanisms either. In this work we have captured magnetic and MR “fingerprints” of Co nanodiscs in Co/Cu multilayered nanowires as they undergo a single domain to vortex state transition, using a first-order reversal curve (FORC) method [1]. The nanowires have been electrochemically deposited into nanoporous polycarbonate membranes. In 50 nm diameter [Co(5nm)/Cu(8nm)]20 nanowires, a 10% MR effect is observed at 300 K. In 200 nm diameter nanowires, the magnetic configurations can be tuned by adjusting the Co nanodisc aspect ratio. Nanowires with thinnest Co exhibit single domain behavior. The nanowires show nucleation and annihilation of the vortices are manifested as butterfly-like features in the FORC distributions, similar to those observed in arrays of Fe nanodots [2]. They also show a superposition of giant and anisotropic magnetic interaction, which corresponds to the specific magnetic configurations of the Co nanodiscs.

1Work done in collaboration with Jared Wong, Peter Greene, Randy K. Dumas, Daniel Masiel, Nigel D. Browning, and June W. Lau, supported in part by NSF (ECCS-0725902 and PHY-0649297), CITRIS and the Alfred P. Sloan Foundation.

1:39PM J31.00009 Controlled formation of double-vortex configurations in a shape-engineered F/N/F trilayer stack studied by quantitative off-axis electron holography , LEI HUANG, MARVIN SCHOFIELD, YMEI ZHU, Department of Condensed Matter Physics and Material Science, Brookhaven National Lab — Vortex domain state, widely existing in submicron size patterned magnetic structures, can be very useful in high density magnetic magnetic data storage devices. In this report, we designed a shape engineered ferromagnetic-nonmagnetic-ferromagnetic (F/N/F) trilayer stack that would generate four different vortex-based remnant states by applying defined sequences of in-plane magnetic field. These four states are distinguished by different relative chirality orientations of two vortices stabilized in the ferromagnetic layers. Experimentally, we lithographically patterned 400nm sized prototype device, and studied in-situ the switching behavior by off-axis electron holography. Using the integrated approach including single element hysteresis loop, induction contour mapping and quantitative electron phase shift measurement, we revealed the underlying reversal mechanism as separate vortex formation and annihilation in two magnetic layers. We also confirmed the field-control feasibility of such structure by distinguishing unambiguously the presence of all four states after each field recipe was applied.

1:51PM J31.00010 Magnetic properties of ion-etched magnetic nanodot arrays , IOAN TUDOSA, KEITH CHAN, ERIK SHIPTON, ERIC FULLERTON, University of California San Diego — One pathway for increasing the density in magnetic recording media is to have bits stored as single patterned magnetic islands. While promising, this method has been hindered by the failure to reduce the island to island variation which decays with the spacer thickness and detectable for 2nm-thick Si spacers. The presented results can open an avenue for magnetotransport studies in AF-coupled structures using interface engineering. [1]. R.R. Gareev et al, JMMM 240, 235 (2002), R.R. Gareev et al, APL 88, 172105 (2006). [2]. Y. Wang, X.F. Han, and X.-G. Zhang, APL 93, 172501 (2008).

2:03PM J31.00011 Magnetic multilayers and Nanomagnetic Patterns , P. PANYAIJIRAWUT, M.S. RZ-CHOWSKI, University of Wisconsin-Madison — We have grown Ni/Co magnetic multilayers by sputtering, finding that the multilayers have in-plane uniaxial magnetic anisotropy. This is induced during growth by the sputtering geometry, and by the interaction between layers. We pattern the multilayers into sub-micron dots and networks using the nanosphere lithography technique, forming well-ordered two dimension arrays of magnetic nanoparticles. We use an oxygen plasma etch to adjust the size of the polystyrene spheres after spin coating. Using self-assembled close-packed monolayer of polystyrene spheres as deposition mask, the magnetic material is deposited through the interstitial areas to form networks. We also form isolated nanoparticles using the polystyrene spheres as aetch mask. We discuss the magnetic behavior of patterned multilayers.

Tuesday, March 17, 2009 11:15AM - 2:15PM
Session J32 GMAG: Artificial Structured or Self-Assembled Magnetic Materials 336

11:15AM J32.00001 Surface-state mediated indirect exchange interaction between magnetic nanodots on metallic substrates1, DI XIAO, LIFENG YIN, Oak Ridge National Laboratory, WENGUANG ZHU, U of Tennessee-Knoxville and Oak Ridge National Laboratory, G. MALCOLM STOCKS, JIAN SHEN, Oak Ridge National Laboratory, ZHENYU ZHANG, Oak Ridge National Laboratory and U of Tennessee-Knoxville — We investigate theoretically the ferromagnetic ordering of magnetic nanodots grown on flat or vicinal metal substrates. We first show that, on a flat substrate, the surface state-mediated indirect exchange interaction between the nanodots can be significant enough to account for the high ferromagnetic transition temperature observed in recent experiments. We obtain the quantitative coupling strength and characteristic length scale of the magnetic interaction via detailed Monte Carlo simulations. We then study how the reduced dimensionality of the surface state on vicinal surfaces affects the collective magnetic behavior of the systems, and discuss the findings in connection with latest experimental observations.

1Supported by DMSE/BES of DOE and NSF.
11:27AM J32.00002 Artificial Nanomagnet With Lateral Confinement1. LIFENG YIN, ZHENG GAI, Oak Ridge National Laboratory, NOPPI WIDJAIA, Oak Ridge National Laboratory / The Univ. Tennessee, DI XIAO, Oak Ridge National Laboratory, ZHENYU ZHANG, Oak Ridge National Laboratory / The Univ. Tennessee, WARD PLUMMER, The Univ. Tennessee / Louisiana State University, JIAN SHEN, Oak Ridge National Laboratory / The Univ. Tennessee — We introduce a novel way—curved Cu(111) substrate—to smoothly modify the surface states by introducing a miscut angle and study the impact of modifying vicinal surface states on the ferromagnetic behavior of Fe dots. With this curved substrate, the same growth parameter can be ensured in the whole miscut angle studied. When the Fe dot assemblies have an in-plane easy axis, two distinct regimes and a critical terrace width, separating these two regimes, can be identified. There are three contributing factors: the vicinal surface state, the competition between the Fe dots diameter and the terrace width, and the in-plane uniaxial magnetic anisotropy. The couplings between these three factors lead to the interesting behavior observed in the Fe/vicinal Cu(111) nanodot assemblies.

1Supported in part by the Division of Materials Science and Engineering, U. S. DOE.

11:39AM J32.00003 Multiple Quantum Transitions In Magnetic Nanoparticles. NATALIA NOGINOVA, NSU, Norfolk, VA, ADRIAN RADOCEA, Cornell University, Ithaca, NY, VADIM A. ATSARKIN, IRE, Moscow, Russia — Absorption at multiple resonance transitions of Fe/vicinal Cu(111) nanodot assemblies.

11:51AM J32.00004 SEMPA Measurements of Ferromagnetic Nanodisk Phase Diagrams. SEOK-HWAN CHUNG, CNST, NIST / Maryland NanoCenter. U. of Maryland, ROBERT MCMICHAEL, DANIEL PIERCE, JOHN UNGURIS, CNST, NIST — We use Scanning Electron Microscopy with Polarization Analysis (SEMPA) to image the magnetic domain structures of ferromagnetic nanodisks with different diameters and thicknesses, and thereby determine the phase diagram of the ground state in these technologically important magnetic structures. Depending on the nanodisk dimensions, one of three distinct ground state magnetic configurations is observed: a single domain in-plane, a single domain out-of-plane, or a vortex state. In contrast to previous work, the magnetic states of individual nanodisks are determined using simultaneous SEMPA measurements of both the in-plane and out-of-plane magnetization components. By systematically imaging Permalloy nanodisks with diameters that range from 35 nm to 190 nm and with thicknesses that range from 10 nm to 65 nm, we are able to locate phase boundaries and the triple point between these three phases. Near the phase boundaries and triple point we observe a mixture of the different phases. A model magnetic phase diagram generated by using the OOMMF micromagnetic simulator is found to agree well with the phase diagram determined by the SEMPA measurements. This work is supported by the NIST-CNST/UMD-NanoCenter Cooperative Agreement.

12:03PM J32.00005 Ordering, Texture and Magnetism in Ultrathin FePt Films. TOM GEORGE, XINGZHONG LI, RALPH SKOMSKI, DAVID J. SELLMYER, Nebraska Center for Materials and Nanoscience, University of Nebraska — Non-epitaxially grown L1₀ FePt ultrathin films have been fabricated and investigated. All films were magnetron sputtered onto SiO₂ substrates in the form [Fe/Pt]ₙ, with individual layer thicknesses from about 0.1 to 0.4 nm. The films' nominal total thickness ranged from 5 to 20 nm and was controlled by varying the number of bi-layer repetitions. The L1₀ phase and (001) texture were obtained by post-deposition annealing for 300 seconds at 600 °C. Transmission electron microscopy showed all as-deposited films as continuous; but after annealing, all films except the thickest ones showed agglomeration into a connected island-like morphology. L1₀ ordering and texture were confirmed by x-ray and electron diffraction, and the degree of order tended to decrease with increasing nominal film thickness. The (001) texture was greatest when the nominal film thickness was 12.5 nm, coinciding with an island thickness of the same value. SQUID magnetometry shows a relatively unusual trend of coercivity increasing with island thickness, with the highest value corresponding to the most ordered sample. The process of film agglomeration and the effects of bi-layer thickness and annealing temperature and time are also discussed. – This research is supported by NSF-MRSEC (RS), INSIC, DOE (DJS), and NCMN.

12:15PM J32.00006 Numerical Studies of Magnetization Reversal in Thin Anular Nanorings. GABRIEL CHAVES-O'FLYNN, ANDREW KENT, DANIEL STEIN, DANIEL BEDAU, New York University, NEW YORK UNIVERSITY TEAM — The rate of thermally activated magnetization reversal in thin ferromagnetic nanorings has been found analytically in a 1D model in which the demagnetization energy is approximated by a local surface term [1]. Numerical micromagnetic calculations confirm all aspects of the analytic model for narrow thin rings, such as peramally rings of 200 nm mean radius, 40 nm width and 2 nm thickness [2]. However, the model breaks down in for extremely wide rings, when the ring width approaches its mean diameter. Here we present numerical micromagnetic results for the transition states between the clockwise and counterclockwise state in this limit. We describe how the two transition configurations of narrow rings cease to be saddles of the energy functional. Also, a new low energy metastable state is found to exist for a narrow range of fields. We discuss the results of applying the String Method [3] to determine the transition states and energy barriers between the lowest magnetization configurations of rings. [1] K. Martens, D.L. Stein, and A.D. Kent, PRB 73, 054413 (2006) [2] G. D. Chaves-O’Flynn, D.L. Stein, and A.D. Kent, arXiv:0811.0440 (2008) [3] W. E, W. Ren, E. Vanden-Eijnden, J. Chem. Phys 126, 164103 (2007)

12:27PM J32.00007 Onset of magnetism in supported transition metal encapsulated silicon cages2. ROBERTO ROBLES, SHIV N. KHANNA, Dept. of Physics, Virginia Commonwealth University, Richmond, VA 23284 — In the past few years, silicon based clusters have attracted a lot of attention as building blocks of nanomaterials. Some of the most promising candidates are the transition metal encapsulated silicon cages, which have been shown to be specially stable, both experimentally and theoretically. However, for the use of these materials in fields like spintronics, it is not only necessary to be semiconductor based, but also that they present a finite magnetic moment. However, it has been shown that the magnetic moment of the transition metal atom encapsulated in silicon cages is quenched due to the hybridization with silicon. By performing density functional calculations in the generalized gradient approximation, we show that the magnetic moment of these clusters can be recovered by depositing them on a surface. Using CrSi₁₂ on Si(111) as an example, we have deposited the cluster in different orientations. The studies show that, for most of them, a finite magnetic moment is preserved in the system after a geometrical relaxation. The origin of this behavior is discussed in terms of hybridization, comparing to the unsupported situation.

12:39PM J32.00008 Metamaterials with tunable refractive index fabricated from amorphous ferromagnetic microwires and optical Magnus effect\textsuperscript{1} , ANDREY IVANOV, ANATOLY VEDYAYEV, VLADIMIR GALKIN, ALEXANDER SHALYGIN, VALERY IVANOV, M.V. Lomonosov Moscow State University — For homogeneous NPVM (negative phase–velocity mediums) [V. G. Veselago, Soviet Physics - Uspekhi 10 (1968) 509; T. G. Mackay, A. Lakhtakia, Phys. Rev. E 69 (2004) 026602] anomalous effects such as negative refraction, light pressure, Doppler shift. Cherenkov-Vavilov radiation, Goos – Hänchen effects have been discovered in different frequency ranges. In this presentation the optical circular polarized effect is calculated for inhomogeneous mediums (optical Magnus effect) and it is shown that it is anomalous in NPVM with respect to “right-handed” materials. The proposed metamaterials fabricated from glass coated amorphous ferromagnetic Co-Fe-Cr-B-Si microwires are shown to exhibit a negative refractive index for electromagnetic waves over scale of GHz frequencies [A.V. Ivanov, A.N. Shalygin, A.V. Vedayev, V.A. Ivanov, JETP Letters 85 (2007) 565]. The magnetoelastic interaction between microwires has been taken into account. The phase and group velocities in proposed metamaterial have been calculated. The ratio of thereof depends monotonically on the size of the microwires. Optical properties of such metamaterials are tunable by an external magnetic field and mechanical stress.

12:51PM J32.00009 Magnetism in 1D Cobalt-Cyclopentadienyl Sandwich Molecular Wire\textsuperscript{1} , HANNES ALLMAIER, Technical Univ. Graz, AT, C. MORARI, Univ. Catholique Louvain, DICE, Elect, BE, L. CHIONCEL, E. ARRIGONI, Technical Univ. Graz, AT, F. BEIUȘEANU, Univ. of Oradea, RO, A. LICHTENSTEIN, Univ. of Hamburg, DE, M. KATSNELSON, Univ. of Nijmegen, NL — A challenge for technological applications at the nanometer scale is to find magnetic materials with reduced dimensionality. Recent theoretical studies have predicted ferromagnetic and half-metallic behavior for the 1D-organic magnetic benzen vanadium wire. Here we discuss a variety of magnetic orderings such as antiferromagnetic and ferromagnetic half-metallicity in the cobaltocene Co2(C5H5)2 nanowire. We performed DFT-calculations to optimize its geometry and used the NMO downfolding technique to construct the real-space low energy Hamiltonian. To describe electronic correlations beyond the mean-field, we used the developed Variational Cluster Approach. Our preliminary results show that non-quasiparticle states appear in the half-metallic gap, which reduce considerably the spin polarization of such a wire. Ab-initio electron transport calculations are in progress to establish the role of cobaltocene nanowire as part of a future spin filter.

\textsuperscript{1}H.A., L.C and E.A. acknowledge support by FWF project P18505-N16.

1:03PM J32.00010 Comparative Density Functional study of Ti on CuN/Cu(100)\textsuperscript{1} , JESUS CRUZ, Georgetown University, PUSHPA RAGHANI, Stanford University, BARBARA JONES, IBM Almaden Research Lab — We have performed a Density Functional Theory (DFT) calculation using the Projector Augmented Wave (PAW) technique to study the electronic structure of adatoms of Ti placed on a single layer of copper nitride (CuN) surface grown on top of Cu(100). The insulating CuN surface mediates superexchange interactions between the magnetic adatoms, and also can strongly affect electronic properties. The PAW technique allows us to have elements of the precision of an all-electron (AE) calculation and the performance of an Ultrasonic Pseudopotential (USPPs) calculation. We compare results obtained of the magnetic moment, atomic positions, and charge densities of Ti adatoms with both USPPs and PAW methods, and discuss the similarities and differences between the methods. We also report studies of the effect of the Coulombic repulsion U in the PAW methodology, and compare some of these results to an all-electron calculation.

1:15PM J32.00011 Characteristics of Co islets on Cu(111) from first principles calculations\textsuperscript{1} , DUY LE, TALAT RAMAN, University of Central Florida — Through first principles electronic calculations, based on the spin-polarized density functional theory using the generalized gradient approximation and the ultrasoft pseudopotential method in the plane wave representation, we have examined the structure and magnetic properties of Co monomer, dimer and several n-mers on Cu(111). We find that the monomer has slight preference for the fcc site as compared to the hcp (about 0.02eV) while there is no such preference in the case of the Co dimer. The dimer bond length is found to be about 2.15\textdegree. For the 6 atoms cluster, we find that it prefers to be antiferromagnetic and absolute magnetic moment of each Co atom is about 0.07-0.08\textmu B. The monomer is non-magnetic while a high magnetic moment of 1.94\textmu B per Co atom is found in the case of dimer. We discuss our results in the context of recent experimental and theoretical findings [1,2].

Superconductivity at $T_c$=38 K in Pristine and Sulfur Doped Amorphous Carbon

ZHIPING YIN, UC Davis, FRAÇOIS GYGI, Dept. of Applied Science, UC Davis, WARREN PICKETT, Department of Physics, UC Davis — The high temperature superconductivity (up to 25 K) observed in elemental Ca at high pressure extends across several phase boundaries, making understanding the crystal structures of Ca under high pressure of great importance. Above 100 GPa, both experiment and theory indicate three possible structures, having space groups $P4_{2}1_{2}1, Cmca$ and $Pnma$. The reported room temperature structure, primitive simple cubic in the 32-109 GPa range, is consistent with the calculations of multilayer crystallographic anisotropy. MOKE from these structures can have different sign depending on incidence angle; this is consistent with calculations of multilayer model. We found that the sign of MOKE can change also versus azimuthal angle, which was unexpected. Physics behind this phenomenon will be presented.

Competing s and d-wave superconducting order in V$_3$Si

SHANTANU MUKHERJEE, DANIEL AGTERBERG, University of Wisconsin-Milwaukee — Competing phases have generated a lot of interest in the study of cuprate and pnictide superconductors. Here we examine the competition between s and d-wave superconducting order in V$_3$Si. We provide microscopic arguments as to why both of these phases have a comparable transition temperature in this material. We further argue that many experimental probes provide evidence for this competition.

Theoretical study of FFLO phases and related phases in non-centrosymmetric superconductors

ZHICHAO ZHENG, DANIEL AGTERBERG — Superconducting order can break translational invariance, leading to a phase in which the Cooper pairs develop a coherent periodic spatially oscillating structure, such as in a FFLO phase. Some superconductors break inversion symmetry, leading to helical and multiple-q (FFLO-like) phases. We study these related phases with and without vortices. We show that for a FFLO phase, a crisscrossing lattice solution arises from the decay of conventional Abrikosov vortices into pairs of fractional vortices. We further show that the fractional vortex solution can also exist in the multiple-q phase of non-centrosymmetric superconductors.
12:15PM J33.00006 Non-centrosymmetric superconductor La$_3$Bi$_2$Pt$_3$, GABRIEL SEYFARTH, UCI & UdM, CIGDEM CAPAN, UCI, ANDREA BIANCHI, UdM, ZACHARY FISK, UCI, PIERRE RODIERE, CHRISTINE OPAGISTE, Institut Neel, Grenoble — Recently, we have discovered that the metallic La$_3$Bi$_2$Pt$_3$ (Y$_3$Au$_4$Sb$_5$ structure) becomes superconducting below a transition temperature $T_c$ of about 1.4K. Our interest in the superconducting phase of La$_3$Bi$_2$Pt$_3$ stems from the fact that it lacks a center of inversion, which may lead to unconventional superconductivity, including nodes in the superconducting gap function, even if the pair wave function exhibits the full spatial symmetry of the crystal. Compared to other non-centrosymmetric magnetic compounds in which superconductivity has recently been discovered, like CePt$_3$Si, UIr, CeRhSi$_3$ (under pressure), the nature of the superconducting state in La$_3$Bi$_2$Pt$_3$ is not complicated by strong electron correlations nor the coexistence of magnetism. This makes it a good model system to study superconductivity without inversion symmetry. In our presentation we will focus on the first basic characterization of our La$_3$Bi$_2$Pt$_3$ single crystals (X-ray, specific heat, resistivity, penetration depth, etc.).

12:27PM J33.00007 On d-Wave Superconductors with a Zeeman or Exchange Splitting of the Spin-Up and -Down Fermi Surfaces, CHIA-REN HU, Texas A&M University — For a given Zeeman (or exchange) energy $\hbar$, we used the Fermi-surface splitting, $\Delta_q$, as a variational parameter, and showed: (1) For an s-wave superconductor, the Sarma state is actually an unstable equilibrium state, which is known to exist for $0.5 < \hbar < 1$ only, and has energy higher than the un-polarized BCS state and the normal state. (2) For a d-wave superconductor, the Sarma-like state can actually exist down to $h=0$, and is a stable equilibrium state up to some $h_{\text{max}}$, if not considering other possible deformations of the order parameter (possibly symmetry breaking, such as going toward the FFLO state, which is known to exist at higher $h$ only), and its energy is lower than those of the un-polarized BCS state and the normal state. (3) The state can be further improved by introducing more variational parameters, which are still not symmetry-breaking. Thus we predict that for CeCoIn$_5$ and other d-wave superconductors the low-field superconducting state in a magnetic field parallel to the layers should already show some bulk spin-polarization, ad is NOT the usual un-polarized BCS state.

12:39PM J33.00008 Superconductivity from two dimensional interfaces: CuCl/Si, GaP/Si, ZnS/Si, S.H. RHIM, R. SANIZ, A. J. FREEMAN, Northwestern University — Two-dimensional (2D) interfaces of hetero-bonded semiconductor superlattices are studied using the highly precise FLAPW method. The 2D system, of metal-insulator-metal, is one of the candidate geometries to realize the excitonic mechanism of superconductivity, where $T_C$ can be greatly enhanced over phonon mediation. Epitaxially grown CuCl on Si (111) was reported to exhibit an anomalous diamagnetic susceptibility at 60-150 K. For all superlattices, 2D metallicity was found at the interfaces due to charge transfer from the polarity mismatch, as evidenced by their bands, Fermi surfaces, and charge densities. The $T_C$, calculated within the crude RMTA and the McMillan-Hopfield formula, is 0.5-4K in CuCl/Si. The $T_c$ vanishes for the other cases. To pursue the excitonic mechanism, we are determining the Kernel function $K(\omega)$, i.e. the average of the effective Coulomb interaction, with q dependent dynamic screening. First results for CuCl/Si show $K(\omega)$ to be attractive for a certain energy range.

12:51PM J33.00009 Standard Model for Superconductivity in Graphite Intercalation Compounds: Prediction of Optimum Standard $T_c$, YASUTAMI TAKADA, ISSP, University of Tokyo — Based on the model that was successfully applied to the explanation of superconductivity with the transition temperature $T_c$ of about 0.1K or less in the alkali-intercalated graphite compounds such as K$_x$C, Rb$_x$C, and Cs$_x$C in 1982 [Y. Takada, J. Phys. Soc. Jpn. 51, 63 (1982) ], we have calculated $T_c$ for the alkaline-earth-intercalated graphite compounds including Ca$_y$C, Ba$_y$C, and Sr$_y$C, with $T_c$ of about 10K or less to find that the same model reproduces the observed $T_c$ in those compounds as well, indicating that it is a standard model for superconductivity in the graphite intercalation compounds with $T_c$ ranging over three orders of magnitude. The difference in $T_c$ by two orders between K$_x$C and Cs$_x$C can be accounted for by (i) doubling the valency of the metal ions, which enhances $T_c$ by one order, and (ii) tripling the effective mass of the superconducting three-dimensional electrons in the interlayer band, which also enhances $T_c$ by one order. Enhancement of $T_c$ well beyond 10 K is also predicted in this model, if intercalant metals are judiciously chosen so that both $Z$ and $m^*$ are increased further.

10:03PM J33.00010 Crystal structure and physical properties of new layered oxysulfides (Cu$_2$S$_2$)(Sr$_5$Sc$_2$O$_6$)$_3$, (Cu$_2$S$_2$)(Ba$_3$Sc$_2$O$_6$) and (Cu$_2$S$_2$)(Ba$_3$In$_2$O$_5$), HIARUKO OGINO, KOICHI USHIYAMA, YUKARI KATSURA, SHIGEORI HORII, JUN-ICHI SHIMOYAMA, KOJII KISHIO — Recently high-$T_c$ superconductors were discovered in layered oxynitride systems with stacking of fluorescent oxide layers and anti-fluorite-like nitride layers. Materials having similar stacking structure with perovskite-based oxide layers. Structural features and physical properties of these new materials will be presented.

1:15PM J33.00011 High-$T_c$ superconductivity in nanostructured Na$_x$WO$_{3-y}$; Sol-gel route, ALI ALIEV, NanoTech Institute, University of Taxis at Dallas, Richardson, TX 75083 — Tungsten trioxide, WO$_3$, infiltrated into various nanoporous matrix structures such as carbon inverse opal, carbon nanotubes paper, or platinum sponge and then intercalated with alkaline ions (Li$, Na$) exhibits a pronounced diamagnetic onset in ZFC magnetization in a wide range of temperatures, 125-123 K. Resistivity measurements show non zero jump and intensive fluctuations of electrical resistance below observed transition points. The observed magnetic and electrical anomalies in nanostructured tungsten bronzes (Li$^x$WO$_{3-y}$, Na$^x$WO$_{3-y}$) suggest the possibility of localized non-percolated superconductivity. The direct evidence of polaron formation from temperature dependence of EPR and photoemission spectra and formation of bipolarons in weakly reduced to WO$_{3-y}$, with y typically in the order of 2.95 suggest bipolarons mechanism of a Bose-Einstein condensation of trapped electron pairs in doped WO$_{3-y}$. On the other hand the strong lattice instabilities in 2D systems like layered cuprates and tungsten bronzes place the upper limit on $T_c$. Than, the percolative self-organized mechanism on the metal/insulator interface like Na$^x$WO$_3$ and NaWO$_3$/nanostructured matrix can facilitate the high $T_c$ obtained in sodium bronzes infiltrated into inverted carbon opal or carbon nanotube matrices.
deposited on the surface at room temperature, and the resultant Na\(^+\)WO\(_3\) state drastically increased. The same behavior was observed for pure WO\(_3\). Charge transfer to the WO\(_3\) superconductivity in surface-doped WO\(_3\).

HAMMOND, THEODORE GEBALLE, MALCOLM BEASLEY, Geballe Laboratory for Advanced Materials, Stanford University — We report the search for superconductivity in surface-doped WO\(_3\) films. Possible evidence for high temperature superconductivity in this system has been reported in the literature. In our work, WO\(_3\) films were grown by MBE and characterized by in-situ XPS, UPS, and ex-situ XRD and resistivity measurements. For some films, Na was deposited on the surface at room temperature, and the resultant Na\(^+\)WO\(_3\) films annealed in vacuum (\(\sim 10^{-8}\) Torr) for 1h at various temperatures (300 – 800°C). With increasing thickness of Na, the intensity of the Na\(^+\) peak in XPS spectra and area of the W5d state in UPS spectra increased, suggesting some charge transfer to the WO\(_3\) film. After annealing below 500°C, XPS and UPS spectra did not change, while after annealing above 500°C, the area of the W5d state drastically increased. The same behavior was observed for pure WO\(_3\) films, however, suggesting that oxygen vacancies are created during the annealing. The films started to decompose above 700°C. The resistivity of our films decreased with increasing annealing temperature. However, so far we have not observed any sign of superconductivity down to 2 K in any of our films. Session J34 DCMP: Focus Session: Iron Pnictides and Other Novel Superconductors VII: Pressure Effects and Thermal Expansion 404

11:15AM J34.00001 Effects of pressure on CaFe\(_2\)As\(_2\) and related materials\(^1\), PAUL CANFIELD, Ames Lab / Iowa State University — The discovery of CaFe\(_2\)As\(_2\)\(^2\) and its extreme pressure dependence \(^2\) (even for pressures below 1 GPa) has lead to it being used as a model system for understanding the effects of pressure on the (AE)Fe\(_2\)As\(_2\) (AE = Ba, Sr, Ca) compounds.\(^3\) We have found that the combination of extreme pressure sensitivity with a first order structural phase transition that involves significant changes in the unit cell dimensions makes CaFe\(_2\)As\(_2\) very sensitive to the pressure medium used. In liquid medium, self clamping cells the higher temperature transitions, while generally detectable and highly reproducible\(^4\) are smeared and broadened, especially near the first order phase transition between the low temperature orthorhombic and collapsed tetragonal phases. In He-pressure cells these transitions remain extremely sharp.\(^5\) Superconductivity is detected between \(\sim 0.3\) and \(\sim 0.7\) GPa in the liquid medium cells and is essentially absent in the He-pressure cell.\(^5\) This superconducting region can be associated with a coexistence of low temperature phases brought on by non-hydrostatic components associated with the medium’s inability to respond to the high-temperature structural phase transitions.\(^5\) The origin of the superconductivity in this mixed region remains a topic of keen experimental and theoretical interest.

\(^{1}\)Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

11:51AM J34.00002 Discovery of a pressure-induced “collapsed” phase in CaFe\(_2\)As\(_2\), A. KREYSSIG,\(^1,2\),\(^2\)
\(^{1}\)Ames Laboratory; \(^^{2}\)Dep. of Materials Science and Engineering, University of Maryland, College Park, Y. LEE, G.D. SAMOLYUK, Z. JIANG, B. NIST Center for Neutron Research, Gaithersburg; \(^{4}\)Dep. of Physics, San Diego State University, San Diego, N. NI, S. NANDI, J.B. LEÃO, S.J. POULTON, D.N. ARGYRIOU, \(^{6}\)Helmholtz-Zentrum Berlin fuer Materialien und Energie, Germany, B.N. HARMON, R.J. MCQUEENI, A.I. GOLDMAN, — Recent investigations of the superconducting iron-arsenide families have highlighted the role of pressure, be it chemical or mechanical, in forming superconductivity. \(^{5}\) We report that CaFe\(_2\)As\(_2\) undergoes a pressure-induced transition to a non-magnetic, volume “collapsed” tetragonal phase, which becomes superconducting at lower temperature. Spin-polarized total-energy calculations on the collapsed structure reveal that the magnetic Fe moment itself collapses, consistent with the absence of magnetic order in neutron diffraction. – The support by U.S. DOE (DE-AC02-07CH11358) and NSF (DMR-0306165 and DMR-0805335) is acknowledged.

12:03PM J34.00003 Pressure-induced superconducting state of CaFe\(_2\)As\(_2\) from an antiferromagnetic spin-density wave state, HANOH LEE, EUNSUNG PARK, TUSON PARK, F. RONNING, E.D. BAUER, J.D. THOMPSON, Los Alamos National Laboratory — The spin-density-wave (SDW) antiferromagnet CaFe\(_2\)As\(_2\) has been reported as superconducting under pressure. By measuring electrical resistivity and magnetic susceptibility under pressure in silicon fluid as a pressure medium, we show that bulk superconductivity is present in a narrow pressure range where orthogonal and collapsed tetragonal state coexist. At higher pressures, where the collapsed tetragonal structure is proposed, distinctive electrical resistivity and magnetic susceptibility under pressure are observed, consistent with the absence of magnetic order in neutron diffraction. – The support by U.S. DOE (DE-AC02-07CH11358) and NSF (DMR-0306165 and DMR-0805335) is acknowledged.

12:15PM J34.00004 Structural changes in pressure induced superconducting BaFe\(_2\)As\(_2\), SIMON KIMBER, Helmholtz-Zentrum Berlin fur Materialien und Energie (HZB), ANDREAS KREYSSIG, Ames Laboratory, US DOE, Iowa State University, Ames, IA 5001, USA, FABIANO YOKAIKIYAMA, DIMITRI ARGYRIOU, Helmholtz-Zentrum Berlin fur Materialien und Energie (HZB), JIAQIANG YAN, Ames Laboratory, US DOE, Iowa State University, Ames, IA 5001, USA, THOMAS HANSEN, Institute Max von Laue-Paul Langevin, 6 rue Jules Horowitz, TAPAN CHATTERJI, JCNS, Forschungszentrum Julich Outstation at Institut Laue-Langevin, ROBERT MCQUEENI, PAUL CANFIELD, ALAN GOLDMAN, Ames Laboratory, US DOE, Iowa State University, Ames, IA 5001, USA — We have determined the crystal structure of BaFe\(_2\)As\(_2\) as a function of pressure (0 – 150 kbar) and pressure (0 – 6 GPa) using neutron powder diffraction. The structural features important to superconductivity, namely suppression of the T-O phase transition and reduction in the As-Fe-As bond angle and Fe-Fe distance, show exactly the same behaviour under pressure up to the optimal \(T_c\) value, as found in chemical doped samples. This result suggests that chemical doping and pressure have similar effects on the electronic degrees of freedom in this family of iron pnictide superconductors.
12:27PM J34.00005 Diffraction Studies of the P-T Phase Diagram with Single-Crystal Ca122
A.I. GOLMAN, A. KREYSSIG, Ames Laboratory/Department of Physics and Astronomy, K. PROKES, Helmholtz-Zentrum Berlin für Materialien und Energie, D.K. PRATT, Ames Laboratory/Department of Physics and Astronomy, D.N. ARGYRIOU, Helmholtz-Zentrum Berlin für Materialien und Energie, J.W. LYNN, NCNR, Gaithersburg, MD 20899, S. NANDI, Ames Laboratory/Department of Physics and Astronomy, S.A.J. KIMBER, Helmholtz-Zentrum Berlin für Materialien und Energie, Y. CHEN, NCNR, Gaithersburg, MD 20899, Y.B. LEE, G. SAMOLYUK, Ames Laboratory/Department of Physics and Astronomy, J.B. LEAO, S.J. POURTON, NCNR, Gaithersburg, MD 20899, S.L. BUDKO, N. NI, P.C. CANFIELD, B.N. HARMON, R.J. MCQUEENEY, Ames Laboratory/Department of Physics and Astronomy — Single crystal neutron and high-energy x-ray diffraction have identified the phase lines corresponding to transitions between the ambient-pressure tetragonal (T), the antiferromagnetic orthorhombic (O) and the nonmagnetic collapsed tetragonal (cT) phases of CaFe2As2. We find no evidence of additional structures for pressures up to 2.5 GPa (at 300 K). Both the T-c and O-c transitions exhibit significant hysteresis effects and we demonstrate that coexistence of the O and cT phases can occur if a non-hydrostatic component of pressure is present.

12:39PM J34.00006 Pressure-induced shift of $T_c$ in $K_xSr_{1-x}Fe_2As_2$ ($x = 0.2, 0.4, 0.7$): Analogy to the high-Tc cuprate superconductors, MELISSA GOOCH, Texas Center for Superconductivity at the University of Houston and Department of Physics, BING LV, Texas Center for Superconductivity at the University of Houston and Department of Chemistry, BERND LORENZ, Texas Center for Superconductivity at the University of Houston and Department of Physics, ARNOLD GULOY, Texas Center for Superconductivity at the University of Houston and Department of Chemistry, CHING-WU CHU, Texas Center for Superconductivity at the University of Houston; Lawrence Berkeley National Laboratory; Hong Kong University of Science and Technology — Through a systematic study of $K_xSr_{1-x}Fe_2As_2$ ($x = 0.2, 0.4, 0.7$), by pressure shifts of the $T_c$, similarities between the FeAs and high Tc superconductors can be observed. These similarities develop directly from the layered structure seen in both superconductors, which consists of an active superconducting layer and a charge reservoir block. The pressure coefficient of $T_c$ depends on the doping level: $dT_c/dp > 0$ (underdoped, $x = 0.2$), $dT_c/dp = 0$ (optimally doped, $x = 0.4$), and $dT_c/dp < 0$ (overdoped, $x = 0.7$). This is understood in terms of a pressure-induced charge transfer between the active and charge reservoir layers. In addition to the measured pressure shift in the $T_c$, the suppression of the spin density wave can clearly be demonstrated for the $x = 0.2$ case.

12:51PM J34.00007 Pressure Effect on the Structural and Magnetic Transition in CaFe$_2$As$_2$, SHILIANG LI, University of Tennesse, YING CHEN, NIST Center for Neutron Research, University of Maryland, JEFFREY LYNN, NIST Center for Neutron Research, XIANHUI CHEN, University of Science and Technology, PENGCHENG DAI, University of Tennessee, RK. BEWLEY, T. GUIDI, ISIS, Rutherford University Lab. — Application of ~2.5 kbar pressure induces superconductivity in CaFe$_2$As$_2$ with a $T_c$ of ~12K that remains constant up to ~7kbar, where superconductivity is again suppressed. This modest pressure enables the use of neutron scattering to study in detail changes of the spin and lattice correlations between normal and superconducting state as a function of pressure. The elastic part of the scattering measured on the MERLIN spectrometer utilizing a He gas pressure cells shows that at 4kbar pressure and 2k only ~50% of the sample has transformed to the collapsed tetragonal phase. The inelastic spectra show a suppression of spectral weight at low energies and small momentum transfer on going from ambient pressure to the superconducting state at 4kbar and 2k. The spectral weight is transferred to higher energies and wavevectors, leading to a V-shaped excitation branch in the collapsed tetragonal phase. Work supported by US DOE BES-DEMS-AC02-06CH11357.

1:03PM J34.00008 Pressure dependence of the inelastic neutron scattering response of CaFe$_2$As$_2$, S. ROSENKRANZ, R. OSBORN, E. GOREMYCHKIN, I.S. Todorov, D.Y. CHUNG, H. CLAUS, J.A. SCHLUETER, Argonne Nat. Lab., C.D. MALLIAKAS, M.G. KANATZIDIS, Northwestern Univ., A.D. CHRISTIANSON, Oak Ridge Nat. Lab., R.I. BEWLEY, T. GUIDI, ISIS, Rutherford University Lab. — Application of ~2.5 kbar pressure induces superconductivity in CaFe$_2$As$_2$ with a $T_c$ of ~12K that remains constant up to ~7kbar, where superconductivity is again suppressed. This modest pressure enables the use of neutron scattering to study in detail changes of the spin and lattice correlations between normal and superconducting state as a function of pressure. The elastic part of the scattering measured on the MERLIN spectrometer utilizing a He gas pressure cells shows that at 4kbar pressure and 2k only ~50% of the sample has transformed to the collapsed tetragonal phase. The inelastic spectra show a suppression of spectral weight at low energies and small momentum transfer on going from ambient pressure to the superconducting state at 4kbar and 2k. The spectral weight is transferred to higher energies and wavevectors, leading to a V-shaped excitation branch in the collapsed tetragonal phase. Work supported by US DOE BES-DEMS-AC02-06CH11357.

1:27PM J34.00010 High-Resolution Thermal Expansion Measurements of CaFe$_2$As$_2$, ARIANA DE CAMPOS, M.S. DA LUZ, J.J. NEUMEIER, Montana State University, E.D. BAUER, F. RONNING, J.D. THOMPSON, HANOH LEE, TUSON PARK, Los Alamos National Laboratory, EUNSYUNG PARK, Sungkyunkwan University — The discovery of superconductivity in doped LaFeAsO initiated a surge of interest in layered FeAs systems. The recent discoveries in CaFe$_2$As$_2$ [1,2] of: (i) suppression of the first-order structural phase transition under modest hydrostatic pressure, (ii) superconductivity under pressure and (iii) at higher pressures the suppression of superconductivity with stabilization of a potentially different high temperature phase, establish pressure as a valuable parameter for tuning the behavior of these fascinating compounds. In this work, thermal expansion measurements of a high-quality single crystal of CaFe$_2$As$_2$ are reported. A sharp transition was observed between the high temperature tetragonal and low temperature orthorhombic structures at $T_s = \approx 180$ K. [1] M.S. Torikachvili, et al. PRL 101, 057006(2008). [2] Park T., et al., J. Phys.Cond.Matter, 20, 32204 (2008). Work at LANL was performed under the auspices of the U.S. DOE Office of Basic Energy Sciences and supported by the LDRD program.

1:39PM J34.00011 Magnetic Ordering and Negative Thermal Expansion in PrFeAsO, D.N. ARGYRIOU, S.A.J. KIMBER, F. YOKAICHYA, K. HABICH, S. GERISCHER, Helmholtz-Zentrum Berlin für Materialien und Energie (HZB), Glienicker Strasse 100, D-14109, Germany, R. KLINGELER, C. HESS, G. BEHR, A. KONDRAT, B. BUCHNER, Leibniz-Institute for Solid State and Materials Research (IFW) Dresden, Germany, T. HANSEN, T. CHATTERJI, Institute Max von Laue-Paul Langevin, 6 rue Jules Horowitz, BP 156, F-38042, Grenoble Cedex 9, France — We report the structure and magnetism of PrFeAsO; one of the parent phases of the newly discovered Fe-As superconductors, as measured by neutron powder diffraction. In common with other REFeAsO materials, a tetragonal-orthorhombic phase transition is found on cooling below 136 K and striped Fe magnetism with $k = (1,0,1)$ is detected below $\sim 85$ K. Our magnetic order parameter measurements show that the ordered Fe moment along the $a$ axis reaches a maximum at $\sim 40$ K, below which an anomalous expansion of the $c$ axis sets in, which results in a negative thermal volume expansion of 0.015% at 2 K. We propose that this effect, which is suppressed in superconducting samples, is driven by a delicate interplay between Fe and Pr ordered moments.

Session J35 DMP: Focus Session: Iron Pnictides and Other Novel Superconductors VIII: Magnetism (Experiment) 405

11:15AM J35.00001 Nuclear and Magnetic structures of CeFeAs$_1$-$x$P$_x$O. CLARINA DELA CRUZ, PENGCHENG DAI, Univ. of Tennessee and NSSD-ORNL, HERBERT MOOK, NSSD-ORNL, Q. HUANG, M. GREEN, J. LYNN, NIST NCNR, N.L. WANG, G.F. CHEN, J.L. LOU, IPCAS — A new class of superconductors (RO$_1$-$x$F$_x$FeAs) has been discovered very recently which has resulted to a flurry of activities in the scientific community. Our initial work on the La based parent compound successfully revealed, for the first time, the AFM order which is preceded by a structural distortion from tetragonal to orthorhombic nuclear structures. A model for the magnetic structure was also proposed. Both magnetic order and structural distortion are suppressed in lieu of the superconducting phase. Our systematic study of the doping dependence of both the nuclear and magnetic structure of CeO$_1$-$x$P$_x$FeAs as well as in the La system has established the nature of the competition between the static AFM order of the Fe spins and the superconductivity. This work looks at the effects of the tuning of the structural parameters in the compounds without doping carriers into the system. This is motivated by the belief that structurally driven electronic effects are very important in these highly correlated systems. We study the parent compound CeFeAsO and change the particulars about the structural distortion by substituting P on the As site until it’s approach to CeFePO which is a nonmagnetic heavy Fermion. We present interesting details of the phase diagram of CeFeAs$_1$-$x$P$_x$O with respect to the As/P concentration.

11:27AM J35.00002 Lattice and magnetic instabilities in CaFe$_2$As$_2$. SHIBABRATA NANDI, ALAN GOLDMAN, Ames Laboratory, US DOE and Iowa State University, DIMITRI ARGYROIU, Helmholtz-Zentrum Berlin fur Materialien und Energie, BACHIR OULADDIF, Institute Laue-Langevin, TAPAN CHATTERJI, Forschungszentrum Julich Outstation at Institute Laue-Langevin, ANDREAS KREYSSIG, NI NI, SERGEY BUD’KO, PAUL CANFIELD, ROBERT MCQUEENEY, Ames Laboratory, US DOE and Iowa State University. Neutron diffraction measurements of a high quality single crystal of CaFe$_2$As$_2$ are reported. A sharp peak in the high temperature tetragonal and low temperature orthorhombic structures at $T_S=172.5$ K (on cooling) and 173.5 K (on warming). Concomitant with the structural transition we observe a rapid, but apparently continuous, ordering of the Fe moments, in a commensurate antiferromagnetic structure, with a saturated moment of 0.80(5) $\mu_B$/Fe directed along the orthorhombic a-axis. The hysteresis of the structural transition is 1 K between cooling and warming and is consistent with previous thermodynamic, transport and single crystal x-ray studies. The temperature onset of magnetic ordering shifts rigidly with the structural transition providing clearest evidence to date of the coupling between the structural and magnetic transitions in this material and the broader class of arsenides.

11:39AM J35.00003 High Energy Spin Waves in CaFe2As2 Single Crystals, SOULEYMANE DIALLO, VLADIMIR ANTROPOV, Ames Laboratory, COLLIN BROHOLM, Johns Hopkins University, TOBY PERRING, ISIS Neutron Facility, SERGEY BUD’KO, Ames Laboratory, NI NI, Iowa State University, PAUL CANFIELD, Ames Laboratory, ANDREAS KREYSSIG, kreyssig@ameslab.gov, ALAN GOLDMAN, ROBERT MCQUEENEY, Ames Laboratory — We present neutron scattering measurements of the magnetic excitations in single crystals of antiferromagnetic ordered CaFeAs$_2$ (TN = 172 K), the parent compound of the newly discovered iron-arsenide based superconductors. The data reveals steeply dispersive and well-defined spin waves up to an energy of approximately 120 meV. The data below 120 meV can be fit to a Heisenberg model consisting of nearest-neighbor interactions (J$_1$a, J$_1$b and J$_1$c) and next-nearest neighbor interaction (J$_2$), yielding constraining values on the magnetic exchange coupling constants. Above 120 meV, the excitations appear weaker or strongly damped. Ab-initio calculations of the dynamic magnetic susceptibility show that the high energy behavior arises from the damping of itinerant spin waves by particle-hole excitations.

11:51AM J35.00004 Neutron Scattering Study of the Fe Oxypnictide Superconductors NdFeAsO$_{1-x}$F$_x$ and LaFeAsO$_{0.87}$F$_{0.13}$. YIMING QIU, NIST Center for Neutron Research and Univ. of Maryland, WEI BAO, QINGZHENG HUANG, TANER YILDIRIM, JASON SIMMONS, MARK GREEN, YING CHEN, JEFF LYNN, MAIKO KOFU, SEUNGHUN LEE, T. WU, G. WU, XIANHUI CHEN — We report the neutron scattering studies of NdFeAsO$_{1-x}$F$_x$ ($x=0, 0.2$)[1] and LaFeAsO$_{0.87}$F$_{0.13}$[2]. In NdFeAsO, there is a tetragonal to orthorhombic structural transition at $T_S=150$ K, where an anomaly in resistivity also occurs. A long range magnetic order with the wave-vector (1/2, 1/2, 0) forms below $T_N=1.96$ K. This long range order is dominated by the rare earth Nd ions, however, both the Nd and smaller Fe moments contribute to the antiferromagnetic structure. Neither the magnetic ordering nor the structural distortion occurs in the superconducting samples NdFeAsO$_{0.80}$F$_{0.20}$ and LaFeAsO$_{0.87}$F$_{0.13}$ at temperatures down to 1.6 K. In LaFeAsO$_{0.87}$F$_{0.13}$, no magnetic-resonance peak was observed in the superconducting state at 1.6 K. Two phonon peaks at 12 and 17 meV were observed, consistent with theoretical calculation. 12:03PM J35.00005 The crystalline electric field as a probe for long range antiferromagnetic order and superconductivity in CeFe$_2$As$_2$. SONGXUE CHI, University of Tennessee, Knoxville, DEVASHIBHAI ADROJA, ISIS Facility, Rutherford Appleton Laboratory, TITIANA GUIDI, ROBERT BEWLEY, ISIS Facility, Rutherford Appleton Laboratory, SHI LIANG LI, JUN ZHAO, University of Tennessee, JEFFREY LYNN, CRAIG BROWN, YIMING QIU, NIST Center for Neutron Research, GEN FU CHEN, JIAN LIN LUO, NAN LIN WANG, Institute of Physics, Chinese Academy of Sciences, PENGCHENG DAI, University of Tennessee, Knoxvill — We use inelastic neutron scattering to study the crystalline electric field (CEF) excitations of Ce$^{3+}$ in CeFeAs$_{1-x}$F$_x$($x=0,0.10$). For nonsuperconducting CeFeAsO, the Ce CEF levels have two magnetic doublets in the paramagnetic state, but these doublets split into six singlets when Fe ions order antiferromagnetically. For superconducting CeFeAsO$_{0.84}$F$_{0.16}$ ($T_c=41$ K), where the static AF order is suppressed, the Ce CEF levels have three magnetic doublets at all temperatures. Careful measurements of the intrinsic linewidth and the peak position of the 18.7 meV mode reveals clear anomaly at $T_c$. These results suggest that CEF excitations in the rare-earth oxypnictides can be used as a probe of spin dynamics in the nearby FeAs planes.

12:15PM J35.00006 Inelastic neutron scattering studies on spin excitations of Fe Pnictides. JUN ZHAO, Department of Physics and Astronomy, The University of Tennessee, DAO-XIN YAO, Department of Physics, Purdue University, SHI LIANG LI, Department of Physics and Astronomy, The University of Tennessee, TAO HONG, Neutron Scattering Science Division, Oak Ridge National Laboratory, YING CHEN, SUNG CHANG, WILLIAM RÄTLIFF, JEFF LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology, HERBERT MOOK, Neutron Scattering Science Division, Oak Ridge National Laboratory, GENFU CHEN, JIANLIN LUO, NANNING WANG, Institute of Physics, Chinese Academy of Sciences, JINGCHUN HU, Department of Physics, P. CARL UNÖVER, JUN ZHAO, ZHANGHONG LIU, Department of Physics, P. CARL UNÖVER, JUN ZHAO, ZHANGHONG LIU, Department of Physics, Oak Ridge National Laboratory, The University of Tennessee & Neutron Scattering Science Division, Oak Ridge National Laboratory — We used inelastic neutron scattering to study the evolution of spin excitations in the FeAs superconductors and their parent compounds. We show here not only the antiferromagnetic order is suppressed by the doping; the spin excitations also change dramatically with doping. We observed sharp spin-wave excitations in the antiferromagnetically ordered parent compound. Based on the observed dispersion relation, we estimate the effective magnetic exchange coupling using a Heisenberg model. We also studied the spin excitation spectrum in the superconducting sample and its relationship to the superconductivity.
12:27PM J35.00007 Resonant spin excitation in Ba$_{1-x}$K$_x$Fe$_2$As$_2$†, R. OSBORN, S. ROSENKRANZ, E.A. GORE-MYCHKIN, D.Y. CHUNG, I.S. TODOROV, H. CLAUS, Argonne National Laboratory, A.D. CHRISTIANSON, M.D. LUMSDEN, Oak Ridge National Laboratory, C.D. MALLIAKAS, M.G. KANATZIDIS, Northwestern University, R.I. BEWLEY, T. GUIDI, ISIS Pulsed Neutron and Muon Facility — In the iron arsenides, superconductivity occurs when the antiferromagnetism of a parent compound has been suppressed by chemical doping. We have investigated the evolution of the magnetic response with potassium doping in Ba$_{1-x}$K$_x$Fe$_2$As$_2$. In the parent compound (x = 0), there is evidence of a column of inelastic scattering at the AF wavevector, Q$_{AF}$ = 1.2Å$^{-1}$, consistent with a steep dispersion of gapped spin waves. A similar inelastic column is seen in the normal phase in the z = 0.4 compound, but it persists to lower energy transfer. However, at the superconducting transition of 38K there is a transfer of spectral weight into an excitation localized at Q$_{AF}$ = 1.2Å$^{-1}$ and ω = 14meV [A. D. Christianson et al, Nature, in press]. Such resonant spin excitations, which are a universal feature of the copper oxide superconductors and seen in several heavy fermion superconductors, provide evidence that the energy gap has unconventional symmetry, with opposite sign on portions of the Fermi surface connected by the resonance wavevector.

12:39PM J35.00008 Antiferromagnetic spin correlations in the tetragonal phase of CaFe$_2$As$_2$‡, R.J. MCQUEEN, S.O. DIALLO, J.L. ZARESTKY, Ames Laboratory, US DOE and Iowa State University, C. BROHOLM, Johns Hopkins University, T.G. FERRING, Rutherford Appleton Laboratory, S.L. BUD’KO, N. NI, A. KREYSSIG, P.C. CANFIELD, A.I. GOLDMAN, Ames Laboratory, US DOE and Iowa State University — We present neutron scattering measurements of magnetic excitations in the tetragonal phase of CaFe$_2$As$_2$. Below T$_S$ = 173 K, CaFe$_2$As$_2$ undergoes a first-order transition to an orthorhombic structure with columnar antiferromagnetic ordering with a wavevector Q$_{AFM}$ = (101). This phase is characterized by strong magnetic interactions giving rise to steep spin waves. In the tetragonal phase above T$_S$, broad quasi-elastic excitations are observed near Q$_{AFM}$ that display a weak dependence on L, indicating two-dimensional antiferromagnetic correlations. These correlations are observed to persist up excitation energies of ~50 meV and temperatures of at least 300 K. Our results indicate that strong magnetic interactions exist above T$_S$, and ordering is likely suppressed by magnetic frustration.

12:51PM J35.00009 Magnetic order the iron spins in NdOFeAs, YING CHEN, NCNR and Univ. of Maryland, J.W. LYNN, NCNR, J. LI, NCNR and Univ. of Maryland, G. LI, G.F. CHEN, J.L. LUO, N.L. WANG, Chinese Academy of Sciences, PENGCHENG DAI, C. DELA CRUZ, Univ. of Tennessee & ORNL, H.A. MOOK, ORNL — Polarized and unpolarized powder neutron-diffraction measurements have been carried out to investigate the magnetic order in one of the highest Tc system, NdFeAsO. Antiferromagnetic order is observed below 141 K [1], which is in close proximity to the structural distortion observed in this material [2]. The magnetic structure consists of chains of parallel spins that are arranged antiparallel between chains, which is the same in-plane spin arrangement as observed in all the other iron oxypnictide materials. Nearest-neighbor spins along the c axis are antiparallel like LaFeAsO [3]. The ordered moment is 0.25 (7) μB, which is the smallest ordered moment found so far in these systems.

1:03PM J35.00010 Coexistence of the spin-density-wave and superconductivity in the Ba$_{1-x}$K$_x$Fe$_2$As$_2$ system, YANG REN, APS, Argonne National Laboratory, H. CHEN, University of Science and Technology of China, Y. QIU, NIST Center for Neutron Research & Univ. of Maryland, WEI BAO, Los Alamos National Laboratory, R.H. LIU, G. WU, T. WU, Y.L. XIE, X.F. WANG, University of Science and Technology of China, Q. HUANG, NIST for Neutron Research, NIST, X.H. CHEN, University of Science and Technology of China — The relation between the spin-density-wave (SDW) and superconducting order is a central topic in current research on the FeAs-based high Tc superconductors. Conflicting results exist in the FeAs(111) class of materials, for which whether the SDW and superconductivity are mutually exclusive or they can coexist has not been settled. Here we show that for the (Ba$_1$K$_2$)Fe$_2$As$_2$ system, the SDW and superconductivity can coexist in an extended range of compositions. The availability of single crystalline samples and high levels of energy gaps would make the materials a model system to investigate the high Tc ferropnictide superconductivity. [arXiv:0807.3950 (2008)]

1Work at APS/ANL was supported by U.S. DOE/OS/BES, under Contract No. DE-AC02-06CH11357; at USTC by National Science Foundation of China & Ministry of Science and Technology of China & National Basic Research Program of china; at LANL by U.S. DOE/OS.

1:15PM J35.00011 High magnetic field vortex torque magnetometry in SmFeAsO$_{0.8}$F$_{0.2}$ single crystals, LUIS BALICAS, ALEX GUREVICH, YOUNJUNG JO, JAN JAROSZYNSKI, DAVID LABALESTIER, National High Magnetic Field Laboratory, Florida State University, Tallahassee-FL 32310, USA, R.H. LIU, H. CHEN, XIANHUI H. CHEN, Hefei National Laboratory for Physical Science a Microscale and Department of Physics, University Science and Technology of China, Hefei, Anhui, N.D. ZHIGADOLO, S. KATRYCH, Z. BUKOWSKI, J. KARPINSKI, Laboratory for Solid State Physics, ETH Zürich, CH-8093 Zürich, Switzerland — To probe manifestations of multiband superconductivity in oxypnictides, we measured the angular dependence of magnetic torque τ(θ) in the mixed state of SmO$_{0.8}$F$_{0.2}$FeAs single crystals as functions of temperature T and high magnetic field H up to 30 T. We show that the effective mass anisotropy parameter γ extracted from τ(θ), can be greatly overestimated if the strong paramagnetism of Sm or Fe ions is not properly taken into account. The correctly extracted γ depends on both T and H, saturating at γ ≃ 9 at lower temperatures. Neither the London penetration depth nor the superfluid density is affected by high fields up to the upper critical field. Our results indicate two strongly-coupled superconducting gaps of nearly equal magnitudes.

1:27PM J35.00012 Inelastic Neutron Scattering from Fe Pnictide Superconductors, ANDREW CHRISTIANSON, Oak Ridge National Laboratory — We present inelastic neutron scattering data from both single crystal and polycrystalline specimens of several of the new Fe-based superconducting materials. The phonon density of states (PDOS) was determined for LaFeAsO$_{1-x}$F$_x$. The PDOS for the nonsuperconducting parent compound LaFeAsO was found to be nearly identical to that of superconducting LaFeAsO$_{0.8}$F$_{0.2}$. Good agreement was found between first principal calculations and the experimentally determined PDOS with the exception of a small difference in some of the Fe mode frequencies. The experimental PDOS is not consistent with conventional phonon mediated superconductivity. In the case of Ba$_2$(Fe$_{1−$x}Co$_x$)$_2$As$_2$, a magnetic excitation appears below Tc that is not present at any temperature in the parent compound Ba$_2$Fe$_2$As$_2$. The excitation occurs at an energy of 14 meV and at a wave vector consistent with antiferromagnetic correlations in the FeAs plane. The existence of this excitation is strong evidence for an unconventional superconducting gap symmetry and demonstrates that the superconducting order parameter is strongly coupled to magnetic degrees of freedom in the Fe-based superconductors.

Tuesday, March 17, 2009 11:15AM - 2:15PM Session J36 DCMP: Si and Ge Nanowires: Electrical Transport and Simulation 408
11:15AM J36.00001 Epitaxial growth of Ge-Si,Ge$_{1-x}$ core-shell nanowire heterostructures with tunable shell content. KAMRAN VARAHRIAMYAN, DOMINGO FERRERE, EMANUEL TUTUC, SANJAY BANERJEE. The University of Texas at Austin — Core-shell nanowire heterostructures are an interesting testbed for band engineering at the nanoscale. Here we present the growth of germanium (Ge) – silicon-germanium (Si,Ge$_{1-x}$) epitaxial core-shell nanowire (NW) heterostructures, with tunable Si and Ge shell content. The Ge NWs were grown using the Au-catalyzed vapor-liquid-solid (VLS) growth mechanism. Subsequently, the Si,Ge$_{1-x}$ shells are grown in-situ, conformal onto the Ge NW using ultra-high-vacuum chemical vapor deposition. We use transmission electron microscopy to confirm that both the core and shell are single crystal, and cross-sectional transmission electron microscopy energy dispersive x-ray spectroscopy to determine the shell thickness and content. Our data show that the Si and Ge shell content can be tuned depending on the SiH$_4$ and GeH$_4$ partial pressures during the shell growth, effectively enabling band engineered core-shell nanowire heterostructures.

11:27AM J36.00002 The Effects of Strain and Quantum Confinement on the Electronic Properties of Germanium Nanowires$^1$. PAUL LOGAN, Arizona State University, XIHONG PENG, Arizona State University — Germanium nanowires are expected to play an important role as both interconnects and functional components in future nanoscale electronic and optical devices, such as light-emitting diodes, field-effect transistors, chemical and biological sensors. The study of quantum confinement on the band gap of Ge nanowires has been addressed both using theoretical methods and experimental techniques. In the present work, using first principles density-functional theory we studied the uniaxial strain effects on the electronic properties in Ge wires along [110] direction with lateral diameter up to 5 nm. Ge [110] nanowires demonstrate a direct band gap, in contrast to the nature of indirect band gap in bulk. We discovered that the uniaxial strain modulates the band gap of Ge nanowires: compressive strain increases the gap while tensile strain reduces the gap. In addition, the strain also modifies the effective masses of the electron and the hole of Ge wires. Expansion increases the effective mass of the hole, while compression increases the effective mass of the electron. Our results suggest both strain and size can be used to tune the band structure of nanowires, which may help in design of future nanoelectronic devices.

$^1$Prof. Jeff Drucker and his research group are acknowledged for experimental data.

11:39AM J36.00003 Atomic scale structure of Si nanowire. TAO XU, JEAN PHILIPPE NYS, MAXIME BERTHE, BRUNO GRANDDidier, DIDIER STEVENARD, Institut d’Electronique, de Microélectronique et de Nanotechnologie, WANGHUA CHEN, RODRIGUE LARDE, EMMANUEL CADEL, PHILIPPE PAREIGE, University and INSA of Rouen — In this work, we have succeeded to observe the atomic structures of Au assisted Vapor-liquid-solid grown Si nanowire facetten sidewalls by scanning tunnelling microscopy (STM) at low temperature. By combining transmission microscopy observations with STM measurements, we were able to identify the different facets along the growth direction of the nanowires. For nanowires with diameters larger than 150 nm, the facets orientation alternates between the [111] and [113] directions, whereas for smaller diameters, the [113] facets are replaced by facets with an orientations making a larger angle with the [111] direction. Imaging the facets at the atomic resolution clearly revealed that the facet reconstructions are induced by Au atoms. From the spectroscopic measurements, the facets are found to be metallic. In order to obtain the impurity distribution below the surface, 3D atom probe tomography analyses were performed. A uniform distribution of Boron impurities is observed in the core of the nanowire and the impurity concentration agrees well with the ratio of the flow rates between silane and diborane. Finally, such results are compared to the conductivities of single nanowires measured in field effect transistor devices.

11:51AM J36.00004 Structural and Electronic Properties of Boron Doped Multiply Twinned Silicon Nanowires. C.S. JAYANTHI, PAUL TANDY, M. YU, S.Y. WU, University of Louisville, Y. ZHAO, NREL, UNIVERSITY OF LOUISVILLE/NATIONAL RENEWABLE ENERGY LAB COLLABORATION — Previous studies of undoped multiply twinned (MT) silicon nanowires (SiNWs) have found these structures to be more stable than the bulk-cut single crystal SiNWs for diameters < 6 nm$^1$. The five segments that form the MT-SiNWs result in a strain field, causing the interior region of the MT-SiNW to compress while stretching its exterior. In fact, the distribution of the internal stress field in MT-SiNWs offers a unique opportunity for doping the MT-SiNW, including bi-polar doping, and thus opening doors to novel designs of photovoltaic elements. In this work, we will use highly efficient quantum mechanical simulations based on the semi-empirical Hamiltonian developed in Ref.$^2$ to investigate the electronic structure of boron doped MT-SiNWs of different diameters. We will first determine the most favorable locations for placing boron atoms by mapping uniaxial strain effects on the electronic properties in Ge wires along [110] direction with lateral diameter up to 5 nm. Ge [110] nanowires demonstrate a direct band gap, in contrast to the nature of indirect band gap in bulk. We discovered that the uniaxial strain modulates the band gap of Ge nanowires: compressive strain increases the gap while tensile strain reduces the gap. In addition, the strain also modifies the effective masses of the electron and the hole of Ge wires. Expansion increases the effective mass of the hole, while compression increases the effective mass of the electron. Our results suggest both strain and size can be used to tune the band structure of nanowires, which may help in design of future nanoelectronic devices.

12:03PM J36.00005 Nanometer-resolution studies of “end-on” metal contacts to vertical Si nanowires. W. CAI, Y.L. CHE, J.P. PELZ, The Ohio State Univ., E. HEMESATH, L.J. LAUHON, Northwestern Univ. — There is great interest in semiconducting nanowires (NWs) and carbon nanotubes (NTs) for future electronic devices and fundamental studies of low-dimensional systems. However, the critical contacts to NWs and NTs are still poorly understood. For example, it is predicted (but not yet demonstrated) that Fermi level pinning should be much weaker at small “end-on” NWs or NT Schottky contacts.$^1$ We have previously used cross-sectional ballistic electron emission microscopy (BEEEM) to quantify small-size effects in Schottky contacts to cleaved quantum wells.$^2$ Here we describe on-going work to study individual end-on contacts to Si NWs. Vertical Si NWs were grown on Si(111) substrates, embedded in spin-on-glass, and planarized with a chemical mechanical polish. A brief HF etch and thin Au film deposition were then used to make end-on NW contacts. Initial studies with AFM, SEM, internal photoemission spectroscopy, and BEEEM demonstrate we can make and measure end-on Schottky contacts to 80nm diameter Si NWs. We will discuss on-going work to optimize sample processing (to reduce roughness near the NWs) and then to quantify the dependence of local contact properties on Si NW diameter. Work supported by NSF Grant No. DMR-0805237.$^1$ F. Leonard et al., Phys. Rev. Lett. 84, 4693 (2000).$^2$ C. Tivarus et al., Phys. Rev. Lett. 94, 206803 (2005).

12:15PM J36.00006 First-Principles Simulations of Silicon Nanowires with Different Surface Passivations. JUNWEN LI, JOHN W. MINTMIRE, Department of Physics, Oklahoma State University — We report first-principles simulation results for the electronic band structure of silicon nanowires along $<$100$>$ and $<$110$>$ directions with different surface passivating groups such as hydrogen, hydroxyl, and methyl within an all-electron, Gaussian type orbital, local density functional approach. We discuss how these different groups affect the band gaps and electron distribution of silicon nanowires. And from the band structures we find that the carrier effective masses of $<$100$>$-oriented silicon nanowires exhibit much more dependence on the diameter and passivation compared to those of $<$110$>$-oriented nanowires.$^1$ This work was supported by the US Department of Energy Grant DE-FG02-07ER46362.

$^1$This work was supported by the US Department of Energy Grant DE-FG02-07ER46362.
12:27PM J36.00007 Study of Electronic Charge Distribution in Silicon Nanowire Transistors: An Atomistic Approach\(^1\), ABHIJEEET PAUL, SAUMITRA MEHROTRA, GERHARD KLIMECK, Purdue University — Atomistic modeling has been performed to investigate the spatial electronic charge distribution in silicon nanowire cross-sections. The modeling approach involves solution of electronic bandstructure using the 20 band sp\(^{3d5s*}\)-SO nearest neighbor Tight-binding (TB) method with spin orbit (SO) interaction (LCAO) solved self-consistently with a two dimensional Poisson equation. Nanowires with rectangular, circular and triangular cross-section shapes have been investigated, with cross-section size of 3.1 nm and 5.1 nm for three different crystal orientations namely [100], [110] and [111]. The observed charge distribution as observed in these wires, is a strong function of cross-section shape, size and crystal orientation. [100] and [110] wires show strong corner effects, however, [111] oriented wires have centralized charge distribution. Charge distribution is sensitive to the structural and crystal symmetry of the nanowire. Structural confinement breaks the symmetry that manifests in the 1D energy dispersion of these wires by lifting up the degeneracy at the gamma valley. Finally, we enable the understanding of atomistic treatment for charge distribution in the capacitance measurements in these ultra-scaled silicon nanowire transistors.

\(^1\)Computational resources from NCN, nanoHUB has been used. Also SRC and NSF funding has been provided to the authors.

12:39PM J36.00008 Interface State Disorder Dominated Microwave Conductance in Silicon Nanowires, CLARK HIGHSTRETRE, MARK LEE, Sandia National Laboratories, DAVID H. DUNLAP, University of New Mexico, AARON L. VALLETT, SARAH M. EICHELF, JOAN M. REDWING, THERESA S. MAYER, The Pennsylvania State University — We have developed a technique to measure the microwave conductance spectra of nanostructures at frequencies from 100 MHz to 50 GHz and at temperatures between 4 K and 300 K. We have used this technique to measure the microwave conductance spectra of doped silicon nanowires (SiNWs) which are found to increase sublinearly with frequency as \( f^{-0.5} \) to \( f^{-0.45} \), indicative of disordered conduction. Additionally, the exponents are found to be nearly independent of temperature suggesting that structural disorder in nanowire morphology, rather than energetic trapping, dominates the AC transport. A model was developed that explains the SiNW conductance in terms of carrier confinement in a disordered electrostatic potential caused by charged Si/SiO\(_2\) interface states. These results highlight the importance of topological effects in the microwave properties of nanomaterials. Results from the measurement of other nanomaterials will also be briefly presented. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

12:51PM J36.00009 Effect of hydrogen passivation on the structure and energetics of silicon nanowires, ABRAHAM AHMIEL, YONGQIANG XUE, SUNY Albany — In this work we explore systematically the structure, energetics and electronic properties of silicon nanowires (SiNWs) with different surface structures and growth directions, and the trend of such property variation with increasing nanowire diameters using first principles density functional theory with both local atomic basis and plane waves. Both passivated and unpassivated systems were studied. The unpassivated (100) and (111) wires are found to be metallic with the unpaired electrons on the surface of these wires acting as conducting channels. Hydrogen passivation of these surfaces introduces a direct band gap by confining the electrons to localized bonds. The nature of the electronic states is examined through local density of states and electron density distributions. The relative stability of SiNWs with different growth directions and surface structures are evaluated from the free energy of formation.

1:03PM J36.00010 Semiconducting nanowire devices in out-of-plane geometry, PRADEEP MANANDHAR, SAMUEL T. PICRAUX, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — Semiconducting nanowires are attractive components in the field of nanoelectronics, photonic and sensing applications. Experiments with nanowires have usually been performed in planar geometry. Here, we demonstrate the fabrication of nanowire devices in out-of-plane geometry by taking advantage of inherent growth direction of nanowire using the vapor-liquid-solid (VLS) method. Highly epitaxial semiconducting nanowires are grown on doped Si (111) substrate from Au nanoparticle seeds assembled in e-beam lithography patterns. The directed assembly of Au nanoparticles is achieved by molecular recognition through silanization process, or electrophoretic assembly. The versatility of the VLS method allows the growth of a wide range of semiconducting nanowires with controlled in-situ doping. The post-growth processes include CVD of SiO\(_2\) filler layer, chemical mechanical polishing and light etching of the SiO\(_2\) layer to expose nanowire tips. Top metal contacts are then deposited for electrical characterization and sensing applications. We will present the results of the vertical nanowire device performance.

1:15PM J36.00011 Top-gate Ge\(_{1-x}\)Si\(_x\)Ge\(_{1-y}\) core-shell nanowire field effect transistors with highly doped source and drain,\(^1\) JUNGHYO NAH, E.-S. LIU, D. SHAHRJERDI, K. M. VARAHRAMYAN, S. K. BANERJEE, E. TUTUC, University of Texas at Austin — Semiconductor nanowires (NWs) field effect transistors (FETs) have been considered as candidates for aggressively scaled complementary metal-oxide-semiconductor (CMOS) devices. In particular, germanium (Ge) NW have been of interest thanks to their higher carrier mobility, compared to silicon (Si). Most of the reported semiconductor NW FETs to date are measured on devices with metal (Schottky) contacts, where the carrier injection efficiency into the channel is significantly limited by the Schottky barrier at the metal/NW interface. Using low (3keV) energy boron ion implantation, we demonstrate here top-gate Ge\(_{1-x}\)Si\(_x\)Ge\(_{1-y}\) core-shell NW p-type FETs, with highly doped source (S) and drain (D). The highly doped, up to \(10^{20}\) cm\(^{-3}\) levels, S/D regions of the NW FETs allow an efficient carrier injection into the NW and a low contact resistance. Compared to similar top gated NW FETs, but with undoped S/D and with metal-semiconductor contacts, the electrical characteristics of the top-gated NW FETs with doped S/D exhibit up to two orders of magnitude higher current, and an improved ON/OFF current ratio.

1:27PM J36.00012 Precision transport and assembly of nanowires in suspension by electric fields, D.L. FAN, ROBERT CAMMARATA, C.L. CHIEN, Johns Hopkins University. MATERIALS TEAM, PHYSICS TEAM — We describe a method of precision transport of nanowires in suspension using a combination of dielectrophoretic force and electrophoretic force, which, respectively, aligns and transports the nanowires. We revealed the effect of electroosmosis flows on the nanowires and determined the ratio of viscous coefficients for nanowires moving parallel or perpendicular to the orientations. The transport of nanowires can be made to follow any prescribed trajectory with any orientation by the voltages applied to the patterned electrodes. As a demonstration of the high precision of manipulation, we have joined end-to-end two oppositely charged nanowires originally separated by 200 \(\mu\)m into a microelectromechanical device.

1:39PM J36.00013 Thermal properties measurements of silicon nanowires at low temperature, HERON JEAN-SAVIN, FOURNIER THIERRY, BOURGEOS OLIVIER, Neel Institut, CNRS, Grenoble, France — Phonons transport in nanowires and nanotubes is an effervescent field for theoretician as well as experimentalist. Especially at low temperature, where the dimension of the sample approximate the dominant phonon wave length, the low dimensionality of these systems has strong impact on the thermal transport. Specific regimes have to be considered: transmission coefficient to the heat bath, quantum regime, transition between diffusive and specular regime etc. . Firstly, we have performed measurements with the 3\(\mu\)m method on various suspended silicon nanowires with a section of the order of 100\(\mu\)m and a length of 10\(\mu\)m. Above 2 K, the thermal conductance varies like \(T^{-1}\)(Casimir Regime); however at lower temperature, a quadratic regime in temperature appears: the signature of a change in the phonon transport regime. Secondly, we have measured nanowires with various geometries, to deduce the impact of geometrical factors at the mesoscopic scale on the thermal transport. All these results will be discussed in view of the different models describing the heat transfer at the nanoscale.
1:51PM J36.00014 ABSTRACT WITHDRAWN

2:03PM J36.00015 Donor-pair defects and doping efficiency in silicon nanowires , BYUNGKI RYU, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon, 305-701, CHANG-YOUN MOON, Department of Physics and IPAP, Yonsei University, Seoul 120-701, WON-JIN LEE, KEE JOO CHANG, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon, 305-701 — We investigate the doping efficiency of dopants in Si nanowires through first-principles density-functional calculations. For hydrogen- passivated Si nanowires doped with group-V elements such as P, As, and Sb, we consider wire diameters in the range of 8 - 30 Å and axis orientations along the [111] and [110] directions. A single substitutional donor prefers to locate on the wire center and acts as a shallow donor. When wire diameters are below a critical value, a donor-pair defect which consists of two dopants at the first-nearest distance can be stabilized, in contrast to bulk Si. The stability of the donor-pair defect is attributed to the confinement effect in nanostructures, which results in the increase of the band gap and thereby the destabilization of the shallow donor level. As the donor-pair defect with a deep level in the band gap is electrically inactive, the doping efficiency expected to be low in small-diameter nanowires. The formation of the donor-pair defect is found to be more favorable for the P dopants, which have a smaller atomic radius than the As and Sb dopants.

Session J37 DCP: Focus Session: Spectroscopic Probes of Biomolecular Structure and Function
II 409

11:15AM J37.00001 Structures of Amyloid Fibrils and Protein Folding Intermediates: New Insights from Solid State NMR, ROBERT TYCKO, National Institutes of Health — I will present recent results from two projects: (1) We are using a combination of solid state NMR techniques and electron microscopy techniques to develop full molecular models for amyloid fibrils formed by the beta-amyloid peptide of Alzheimer’s disease and by other peptides and proteins. Amyloid fibrils are often polymorphic, so that the detailed molecular structure depends on growth conditions or other factors. I will describe two structural models for beta-amyloid fibrils with two distinct morphologies. I will also describe efforts to determine which fibril structure develops in the brains of Alzheimer’s disease patients, and solid state NMR methods that contribute to our amyloid studies; (2) Structural properties of unfolded or partially folded states of proteins are not well understood. In principle, solid state NMR measurements on freeze-dried trapped-ideal-state samples reveal idealized structures and provide access to the structural properties of proteins in the unfolded states (i.e., denatured states) and on transient states that are trapped by freezing on the microsecond time scale. Both types of experiments reveal structural properties that are unanticipated and could not be detected by more conventional protein folding measurements.

11:51AM J37.00002 Two-Dimensional Infrared Probes of Peptide Conformations: the 3α-Helical Secondary Structure, NIEN-HUI GE, Department of Chemistry, University of California, Irvine — The 3α-helix is a secondary structure that has important biological functions and has been proposed as a picosecond intermediate in the folding of α-helices. Two-dimensional infrared (2D IR) spectroscopy with its high structural sensitivity and time resolution is a powerful approach for investigating the structure and dynamics of peptides and proteins. In this talk, we will describe how we are using 2D IR and isotope labeling to study 3α-helical oligopeptides that are rich in C13-methylated amino acids. These peptides are attractive models for developing and refining new and theoretical approaches to peptide conformational analysis. By manipulating networks of vibrational modes using judicious choices of laser polarizations and pulse ordering, we demonstrate that 2D IR can provide diagnostic cross-peak patterns for distinguishing different helical structures and probe the onset of 310-helical secondary structure. Using a series of peptides with 13C=18O and 15N isotope labels, we observe cross-peak signatures that reveal vibrational couplings between amide-I and amide-II modes across a 310-helical hydrogen bond. The results provide a direct evidence for local helical structure formation. Experimental spectra are compared to simulations based on nonlinear response theory, vibrational eigenstates and couplings derived from DFT-optimized structures, and trajectories from molecular dynamics simulations.

12:27PM J37.00003 Earle K. Plyler Prize Talk: Using High Resolution Electronic Spectroscopy to Probe Reactive Chemical Intermediates, TERRY MILLER, Ohio State University — Gas phase chemical reactions, such as occur in atmospheric chemistry, combustion, plasma processing, etc. are of great importance to our economy and society. These reactions are typically very complex involving up to 1000's of elementary steps with a corresponding number of reactive chemical intermediates. Spectroscopic diagnostics, based upon well analyzed and well understood spectra of the intermediates, are crucial for monitoring such reactions and unraveling their mechanisms. These spectral analyses often benefit from the guidance provided by quantum chemical calculations and conversely the molecular parameters, experimentally determined from the spectra, serve as “gold standards” for benchmarking such calculations. Such standards are especially valuable for reactive intermediates whose electronic structures are particularly complex because of electronic-spin interactions, Jahn-Teller effects or other vibronic interactions, hindered internal motions, large molecular size and weight, etc. The organic alkoxyl, RO-, and peroxy, ROO2-, (R=alkyl group) free radicals are excellent examples of such species. The talk will focus on our recent characterization of these radicals via their “high-resolution,” mostly rotationally resolved, electronic spectra utilizing the techniques of laser induced fluorescence, stimulated emission pumping, and cavity ringdown spectroscopy. Selected spectra, their analysis, and the molecular information resulting therefrom will be discussed.

1:03PM J37.00004 Solvent induced fluctuations and the collective librational dynamics of myoglobin, hemoglobin, and lysozyme studied with infrared spectroscopy, KRISTINA WOODS, Carnegie Mellon University — We will discuss the use of [THz and Mid-] infrared spectroscopy to investigate the dynamics of several globular proteins under varying hydration and temperature conditions. Analysis of the experimental spectra has revealed that the amount of solvent in the hydration shell has a strong influence on the amplitude and the rate of relaxation associated with the low frequency protein conformational fluctuations and also the arrangement of hydrogen bonds in the protein secondary structure. At a hydration level > 0.2 we identify modes in the secondary structure of all of the proteins investigated that suggest extra mobility in the protein structure that is not present at low hydration. We will discuss how greater insight into the origin and nature of these detected solvent induced fluctuations may be important for developing a better understanding about energy localization and its relationship with biological function.

1:15PM J37.00005 Label-Free Determination of Protein Binding in Aqueous Solution using Overlayer Attenuated Total Reflectance Fourier Transform Infrared Spectroscopy (OE-ATR-FTIR), TRAVIS RUTHENBURG, TOLULOPE AWEADA, SIMON PARK, CLAUDE MEARES, DONALD LAND, Department of Chemistry, University of California, Davis — Protein binding/affinity studies are often performed using Surface Plasmon Resonance techniques that don’t produce much spectral information. Measurement of protein binding affinity using FTIR is traditionally performed using high protein concentration or deuterated solvent. By immobilizing a protein near the surface of a gold-coated germanium internal reflection element interactions can be measured between an immobilized protein and free proteins or small molecules in aqueous solution. By monitoring the on and off rates of these interactions, the dissociation constant for the system can be determined. The dissociation constant for the molecule Yttrium-DOTA binding to the antibody 2D12.5 system was determined to be 100M. Results will also be presented from our measurements of Bovine Serum Albumin (BSA) binding to anti-BSA.
1:27PM J38.00006 Solute-protein interactions: Variations in correlation times and spin label mobility. MANDY BLACKBURN, LUIS GALIANO, ANGELO VELORO, GAIL FANUCCI, University of Florida — Using EPR, NMR and fluorescence spectroscopy, the effects of several viscogen monomers (sucrose, glycerol, and ethylene glycol) and macromolecular crowding polymers (Ficoll400 and various size polyethylene glycols (PEG)) on the mobility of spin labels at aqueous exposed sites in the flap of HIV-1 protease, the correlation time of this protein, as well as conformation of the hair pin flaps were investigated. Results show that, as expected, protein correlation time is more strongly altered by the small viscogens compared to the macromolecular crowders. On the other hand, EPR line shapes reveal that the chemistry (ie hydrophobicity) and not the size of the solutes correlates to changes seen in the spectra. The conformations of the β-hair pin flaps in HIV-1 protease were unchanged by any of solutes as determined by pulsed EPR distance measurements. Thus, indicating that specific solute interactions with the surface of the protein are responsible for the changes observed in the EPR spin label spectra.

1:39PM J38.00007 On The Electronic Properties of Photoacoids In The Gas Phase. Electric Dipole Moments of CIS- and TRANS-2-Naphthal当地 M. HAMERS, J. STOKBRO, University of Pittsburgh — The permanent electric dipole moments (μ) of two conformers of 2-naphthol (2HN) in their ground and electronically excited states have been experimentally determined by Stark-effect measurements in a molecular beam. Upon UV excitation, little change in the magnitudes of μ is observed, but the orientation of the dipole moment within each conformer shifts significantly, indicating photon-induced rearrangements in electronic distributions. cis-2HN has Δμ = -0.17 D and Δθ = -28° and trans-2HN has Δμ = 0.05 D and Δθ = +28° (trans-2HN). The Δθ values for the two conformers differ in sign. The small changes in the magnitudes of the dipole moments suggest that the isolated molecules do not undergo large charge separations upon excitation. Our study, void of solvent perturbations, is of importance to the larger community currently describing aromatic biomolecule and “super” photoacoid behavior via theoretical modeling and condensed phase solvatocromism.

1:51PM J38.00008 Threading of Binuclear Ruthenium Complex Through DNA Bases THAYA-PARAN PARAMANATHAN, Department of Physics, Northeastern University, Boston, MA, USA., FREDRIK WESTERLUND, Nano-Science Center, University of Copenhagen, Copenhagen, Denmark., MICAIA MCCAULEY, Department of Chemistry, Northeastern University, Boston, MA, USA., PER LINCOLN, Department of Chemical and Biological Engineering, Chalmers University of Technology, Goteborg, Sweden., IOULLA ROUZINA, Department of Biochemistry, Molecular Biology and Biophysics, University of Minnesota, Minneapolis, MN, USA., MARK WILLIAMS, Department of Physics, Northeastern University, Boston, MA, USA. — Due to steric constraints the dumb-bell shaped binuclear ruthenium complex can only intercalate DNA by threading, which requires local melting of the DNA to occur. By mechanically manipulating a single DNA molecule held with optical tweezers, we lower the barrier to threading compared to bulk experiments. Stretching single DNA molecules with different drug concentrations and holding a constant force allows the binding to reach equilibrium. We can obtain the equilibrium fractional ligand binding and length of DNA at saturation. Fitting these results yields quantitative measurements of the binding thermodynamics and kinetics. In addition, we obtain the minimum binding site size, which may be determined by either electrostatic repulsion or steric constraints.

2:03PM J38.00009 Raman Spectral Signatures as Conformational Probes of Biomolecules1. ILANA BAR, AMIR GOLAN, NITZAN MAYORKAS, SALMAN ROSENWAKS, Ben Gurion University of the Negev — A first application of ionization-loss stimulated Raman spectroscopy (ILSRS) monitoring the spectral signatures of four conformers of a gas phase neurotransmitter (2-phenylethylamine) is reported. The Raman spectra of the conformers show bands that uniquely identify the conformational structure of the molecule and are well matched by density functional theory calculations. The measurement of spectral signatures by ILSRS in an extended spectral range, with a relatively convenient laser source, is extremely important, allowing enhanced accessibility to intra- and inter-molecular forces, which are significant in biological structure and activity.

Session J38 DCP: Focus Session: Theory of Electron Transport Through Molecules II

11:15AM J38.00001 Transport in Molecular Junctions: Thoughts Coherent and Incoherent . MARK RATNER, Northwestern University — Current experimental efforts are clarifying quite beautifully the nature of charge transport in so-called molecular junctions, in which a single molecule provides the channel for current flow between two electrodes. The theoretical modeling of such structures is challenging, because of the uncertainty of geometry, the nonequilibrium nature of the process, and the variety of available mechanisms. The talk will center on the formulation of the problem in terms of non-equilibrium theory, and then on the generalizations needed to make that simple picture relevant to the real experimental situation. These include antiresonances, vibronic coupling and its control, structural disorder and representations for the electronic structure. Comments will be made on the measurements of inelastic spectra, and the information to be gained from them.

11:51AM J38.00002 Theoretical aspects of modeling the conductance of molecular junctions . KURT STOKBRO, QuantumWise A/S — In this talk I will discuss different semi-empirical and ab initio approaches for modeling the coherent electron transport of molecular junctions using the non-equilibrium Greens function formalism [1]. The most important effects for determining the conductance are the energies and coupling of the frontier molecular orbitals to the electrodes. I will discuss the accuracy of different levels of theory for calculating the HOMO-LUMO gap of various molecules, and present a simple correction that improves the accuracy of Density Functional based mean field theories [2]. The physical origin of the correction is illustrated using the Moshinsky atom as test system, and the accuracy is illustrated for a number of small molecules [3]. The coupling of the molecule to the electrodes is controlled by the terminal group on the molecule. We illustrate how a molecule with C60 terminal groups can have a very strong coupling with the electrodes [4].

12:27PM J38.00003 ABSTRACT WITHDRAWN

1Work supported by NSF (CHE-0615755).
12:39PM J38.00004 Many-body theory of electron transport in single-molecule junctions. CHARLES STAFFORD, JUSTIN BERFIELD, University of Arizona — Currently, there is no general theory to treat the many-body problem of a single molecule coupled to metallic electrodes. Mean-field approaches such as density-functional theory—the dominant paradigm in quantum chemistry—have serious shortcomings because they do not account for important interaction effects like Coulomb blockade. We develop a systematic theoretical framework for this nonequilibrium many-body problem, starting from an exact diagonalization of the few-body problem of an isolated molecule, and including lead-molecule coupling perturbatively in a novel application of nonequilibrium Green’s functions.

12:51PM J38.00005 Quantum theory of image potential and resonant tunneling in molecular junctions. LUDUMYLA ADAMSKA, IVAN OLEYNIK, University of South Florida, MORTIKO KOZHUSHNER, Institute of Chemical Physics, Russian Academy of Sciences, Russia — It has recently been realized that the image potential plays an important role in charge transport through single organic molecules. In most cases, the classical image potential -1/4z is used to calculate the modified energy spectrum of the charge carriers in the molecule. In this talk, we will present the theory of resonant tunneling transitions that include the quantum mechanical effects of dynamic image potential due to the polarization interaction of the tunneling charge carrier (electron or hole) with surface plasmons. The application of this theory to organic molecular junctions of experimental interest will be discussed.

1:03PM J38.00006 Charge and Spin Memory Effects in Molecular Junctions1, P. D’AMICO, D.A. RYNDYK, Regensburg Uni, G. CUNIBERTI, T.U. Dresden, K. RICHTER, Regensburg Uni — In the field of molecular electronics, effects like charge-memory, bistability and switching between charged and neutral states have been observed in STM [1] and single-molecule junctions [2] experiments. In this work we use model Hamiltonians to describe molecular junctions, including electron-electron and electron-vibron interactions as well as tunneling coupling to the leads. For a molecular level coupled to a vibron and in the presence of leads, we show that upon applying gate or bias voltage, it is possible to observe charge-bistability and hysteretic behavior. Physical quantities like lifetimes, charge-voltage and current-voltage curves are calculated by the master equation method for weak coupling to the leads [3] and at stronger coupling by the equation-of-motion method for noneq. Green functions, performing a systematic analysis of the bistable behaviour of the system for different internal parameters such as the electron-vibron and the lead-molecule coupling [4]. In the case of a spin-degenerate level in a single and double dot molecule with vibrational coupling and in presence of ferromagnetic leads, we consider the possibility to obtain a spin-memory effect. 1We acknowledge support from the DFG project “Quantum Transport from the Molecular Scale.”

1:15PM J38.00007 A simple model for the description of correlation effects in molecular conductors1, MATTHIAS ERNZERHOF, FRANCOIS GOYER, Department of Chemistry, University of Montreal — To model transport through molecular electronic devices (MDEs), we use a non-Hermitian Hamiltonian [1] for the description of open systems that exchange current density with their environment. The infinite contacts are replaced by complex source-sink potentials (SSPs) [1]. Employing a Hubbard interaction term, we include electron-correlation effects in our approach [2]. Electron interaction is considered in the molecule and neglected in the contacts. Among other strongly correlated problems, we discuss the change in conductance upon bond breaking. In the limit where the electron repulsion is strong compared to the binding energy (as it is the case in a stretched bond) a strong suppression of conductance is observed due to the localization of electrons. Other interesting phenomena, which cannot be accounted for with conventional (independent electron) approaches, are discussed as well. [1] F. Goyer, M. Ernzerhof, and M. Zhuang, J. Chem. Phys. 126, 144104 (2007); [2] M. Ernzerhof, J. Chem. Phys. 127, 204709 (2007). [2] A. Goker, F. Goyer, and M. Ernzerhof, J. Chem. Phys. 129, 194901 (2008); M. Ernzerhof, J. Chem. Phys. 125, 124104 (2006).

1:27PM J38.00008 Effects of dephasing on molecular conduction1, JESSE MAASSEN, FERDOWS ZAHID, HONG GUO, Centre for the Physics of Materials and Department of Physics, McGill University, Montreal, Canada — In this work, we theoretically investigate effects of dephasing on electron transport in molecular wires. The quantum transport analysis is carried out using the density functional theory (DFT) combined with the non-equilibrium Green’s function framework (NEGF). The dephasing effect is included at a phenomenological level by introducing fictitious voltage probes to the NEGF-DFT formalism that mimics the randomisation of quantum phase information of the charge carriers. For three systems: (i) a 1,4-benzenedithiol (BDT) molecule connected to Al(001) leads; (ii) an atomic gold chain in contact with Au(001) leads; and (iii) a very narrow Al(001) nanowire, our results indicate that there are two behaviours. When the wires are not conductive as (i,ii), the dephasing effects can increase conduction for a range of system parameters; while for (iii) the dephasing on electron transport in molecular wires. The quantum transport analysis is carried out using the density functional theory (DFT) combined with the non-equilibrium Green’s function framework (NEGF). The dephasing effect is included at a phenomenological level by introducing fictitious voltage probes to the NEGF-DFT formalism that mimics the randomisation of quantum phase information of the charge carriers. For three systems: (i) a 1,4-benzenedithiol (BDT) molecule connected to Al(001) leads; (ii) an atomic gold chain in contact with Au(001) leads; and (iii) a very narrow Al(001) nanowire, our results indicate that there are two behaviours. When the wires are not conductive as (i,ii), the dephasing effects can increase conduction for a range of system parameters; while for (iii) the dephasing effect is small. These effects can increase conduction for a range of system parameters; while for (iii) the dephasing effect is small. These effects can increase conduction for a range of system parameters; while for (iii) it is comparable to the case of a perfectly conductive wire.

Tuesday, March 17, 2009 11:15AM - 2:03PM — Session J39 DBP: Lipid Bilayers: Structure and Function II 411

11:15AM J39.00001 Membrane curvature sensitively by the actin cytoskeleton. GHEE HWEE LAI, ABHUJIT MISHRA, NATHAN SCHMIDT, University of Illinois at Urbana-Champaign, DANIEL KAMEI, TIMOTHY DEMING, University of California, Los Angeles, GERARD C. L. WONG, University of Illinois at Urbana-Champaign — Biological active molecules such as proteins and oligonucleotides can be transduced across cell membranes with high efficiency by cell penetrating peptides. It has been recently demonstrated using synchrotron x-ray diffraction that such peptides induce saddle-splay (negative Gaussian) membrane curvature, which is the topological requirement for pore formation. Here, we show how the actin cytoskeleton ‘senses’ and responds to negative Gaussian defects on a membrane, by examining the interaction between cell penetrating peptides and an active polymerizing cytoskeleton encapsulated within giant unilamellar vesicles, and compare the results to cell based studies.

11:27AM J39.00002 Optically Induced Rotation of Laser-trapped Chiral Lipid Tubules by Linearly Polarized Light. NATTAPORN CHATTHAM, THANATE NA WICHAN, APICHART PATTANAPORKRATANA, JANMRAS LIMTRAKUL, Kasetsart University, KASETSART UNIVERSITY TEAM — Chiral Phospholipids are found self-assembled into fascinating cylindrical tubules of 500 nm in diameter by helical winding of bilayer stripes under cooling in ethanol and water solution. Theoretical prediction and experimental evidence reported so far confirmed the modulated tilt direction in a helical striped pattern of the tubules. This molecular orientation morphology results in optically birefringent tubules. We investigate them under optical trap of 532 nm linearly polarized optical tweezers. We observed spontaneous rotation of lipid tubules induced by radiation torque. The tubule direction can be controlled by the alignment of polarization direction, and thus the rotation angle can be specified. Other related aspect on optical activity of the lipid tubules is also studied. This work is supported by Kasetsart University Research and Development and National Nanotechnology Center, Thailand.
and revealed a good agreement with the FTIR and Raman spectroscopic results. Synthetic lipids with a hydrophilic oligomer covalently coupled to the substrate serve as membrane anchors while forming a nm-thick aqueous reservoir. This property can be exploited to investigate protein-membrane interactions at the molecular length scale. The anchor is chemisorbed to a self-assembled monolayer, either as a pure compound (densely tethered) or laterally diluted (sparingly tethered) by β-mercaptoethanol (β-ME), a small spacer. Phospholipids are then precipitated to complete the bilayer structure. Diffusion measurements were performed using both one-photon and two-photon fluorescence correlation spectroscopy using the Z-Scan approach[2]. While the aqueous reservoir decouples the bilayer from the substrate, we expect the presence of tethers in the inner leaflet to inhibit the free diffusion of lipids. Indeed, we see a drop in the apparent diffusion coefficient by a factor of 2 when comparing a densely tethered membrane to a sparsely-tethered membrane. Importantly, the diffusion coefficients in tBLMs compare favorably with those observed in giant unilamellar vesicles, indicating that tBLM dynamics are similar to those of free bilayers. [1] McGillivray et al., Biointerphases 2007(2): 21–33 [2] Benda et al., Langmuir 2003(19): 4120-4126.

**11:51AM J39.00004 Cholesterol Perturbs Lipid Bilayers Non-Universally**¹, JOHN NAGLE, JIANJUN PAN, THALIA MILLS, STEPHANIE TRISTRAM-NAGLE, Physics Department, Carnegie Mellon University, Pittsburgh, PA 15213 — Cholesterol is well known to modulate the physical properties of biomembranes. Using modern X-ray scattering methods, we have studied the effects of cholesterol on the bending modulus Kc, the thickness Dhm, and the orientational order parameter Szz of lipid bilayers. We find that the effects are different for at least three classes of phospholipids characterized by different numbers of saturated hydrocarbon chains. Most strikingly, cholesterol strongly increases Kc when both chains of the phospholipid are fully saturated but not at all when there are two mono-unsaturated chains.

**12:03PM J39.00005 Barrier Function of Lipid Membrane in the Interaction with Nanostructures**, SERGIY MINKO, Clarkson University, YURY ROITER — Tiny details of the phospholipid (DMPC) membrane morphology in close vicinity to nanostructured silica surfaces have been discovered in the atomic force microscopy experiments. The structural features of the silica surface were varied in the experiments by the deposition of silica nanoparticles of different diameter on plane and smooth silica substrates. It was found that, due to the barrier function of the lipid membrane; only particles larger than 22 nm in diameter, with a smooth surface were completely enveloped by the lipid membrane. However, nanoparticles with bumpy surfaces (curvature diameter of bumps that as that of particles <22 nm) were only partially enveloped by the lipid bilayer. For the range of nanostructure dimensions between 1.2 nm and 22 nm, the lipid membrane underwent structural rearrangements by forming pores (holes). The nanoparticles were accommodated into the pores but not enveloped by the lipid bilayer. The study also found that the lipid membrane conformed to the substrate with surface structures of dimensions less than 1.2 nm without losing the membrane integrity.

**12:15PM J39.00006 Direct nm-scale observation of lipid membrane fluctuations**, SUNG CHUL BAE, YAN YU, Department of Materials Science and Engineering, University of Illinois, STEPHEN M. ANTHONY, Department of Chemistry, University of Illinois, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois — Thermal fluctuation of giant unilamellar phospholipid vesicles (GUVs) was observed by a combination of direct imaging using epifluorescence microscopy and forward laser beam scattering of a laser beam from the vesicle edge. The latter technique allows for the quantitative measurement of lipid membrane fluctuations due to the presence of rafts. Using high performance microscopy and a specialized data analysis scheme, we were able to extract information about lipid membrane fluctuations at nanometer length scales over a range of temperatures. These results are consistent with previous lipid dynamics experiments, and provide a valuable tool for understanding membrane structure and function.

**12:27PM J39.00007 Effects of mobile membrane proteins on the structure and dynamics of lipid rafts**, JUN FAN, MARIA SAMMALKORPI, Mechanical and Aerospace Engineering, MIKKO HAATAJA, Mechanical and Aerospace Engineering, Princeton Institute for the Science and Technology of Materials, Program in Applied and Computational Mathematics — Compositional lipid domains (“lipid rafts”), which reside in the plasma membrane, are thought to facilitate many important cellular processes, including signal transduction and viral entry. Experimentally, raft dynamics have been probed mainly indirectly through observations of raft-associated membrane proteins, and the interpretation of the data relies heavily on assumptions about raft shape and viscosity. Previously, we have shown that strong interactions between rafts and immobile protein clusters may induce the formation of spatially extended raft aggregates [J. Fan et al., PRL 100, 178102 (2008)], thus complicating the interpretation of experimental data. In this work, we present a novel model that explicates the dynamics of membrane proteins with the underlying time-dependent raft domain structure via a hybrid continuum-particle simulation scheme, and develop strategies for extracting quantitative information about raft dynamics from observations of the membrane proteins alone.

**12:39PM J39.00008 Multiscale Modeling of supported bilayers**, ROLAND FALLER, CHENYUE XING, MATTHEW I. HOOPES, UC Davis — Supported Lipid Bilayers are an abundant research platform for understanding the behavior of real cell membranes as they allow for additional mechanical stability. We studied systematically the changes that a support induces on a phospholipid bilayer using the coarse-grained Martini model. It turns out that there is at equilibrium about a 2-3% higher density in the proximal leaflet. These results are in favorable agreement with recent data obtained by very large scale modeling using a water free model where flip-flop can be observed directly. We compare results of the free energy of transfer obtained by pulling the lipid across the membrane in different ways. There are small quantitative differences but the overall picture is consistent. We are additionally characterizing the intermediate states which determine the barrier height and therefore the rate of translocation.

**12:51PM J39.00009 Thermotrophic vibrational spectroscopy of newly developed self-forming PEGylated lipids**, RAJAN BISTA, REINHARD BRUCH, AARON COVINGTON, University of Nevada, Reno, Nevada, USA — Vibrational spectroscopy can provide valuable structural information about lipids, which are important molecular components of biological membranes. In the present study, we have focused on the thermotropic vibrational spectroscopy of two newly developed synthetic PEGylated lipids trademarked as QuSomes to investigate the phase behaviors and associated changes in the conformational order. In contrast to conventional phospholipids, this new kind of lipid forms liposomes spontaneously upon hydration, without the supply of external activation energy. Variable-temperature thin-layered Fourier Transform Infrared (FTIR) spectroscopy and Raman spectroscopy have been developed and employed in order to plot the transition temperature profiles showing the phase behavior of these new lipids composed of 1,2-dimyristoyl-rac-glycerol-3-dodecylamine glycol (GDM-12) and 1,2-distearyl-rac-glycerol-3-tricosylamine glycol (GGS-23). Furthermore, several spectral indicators were calculated and correlated which allowed for the deduction of various aspects of molecular structure as well as intramolecular motion and intermolecular interactions occurred during temperature change. To confirm the observations, differential scanning calorimetry (DSC) was applied and revealed a good agreement with the FTIR and Raman spectroscopic results.
The results elucidate the mechanism by which PG-1 uses to induce leakage in bacterial cells. The structural transformation can be understood in the framework of the action of 1d detergent, with PG-1 acting as a line in model membranes via atomic force microscopy for the first time. PG-1 induces structural transformations in supported lipid bilayers, progressing from bilayer separation of charged and neutral lipid molecules in mixed lipid monolayers, and discuss the dependence on pH, salt concentration and ion valency.

To study the mechanism of action of PG-1, we directly visualize the topological changes induced by PG-1 forming pores which increase membrane permeability to ions or larger molecules. It has been proposed that PG-1 selectively induces stable membrane pores in bacterial membranes over mammalian membranes. To investigate the mechanism of action of PG-1, we directly visualize the topological changes induced by PG-1.

1:03PM J39.00010 Theory of Disk-to-Vesicle Transformation, Jianfeng Li, An-Chang Shi, Department of Physics and Astronomy, McMaster University — Self-assembled membranes from amphiphilic molecules, such as lipids and block copolymers, can assume a variety of morphologies dictated by energy minimization of system. The membrane energy is characterized by a bending modulus ($\kappa$), a Gaussian modulus ($\kappa_G$), and the line tension ($\gamma$) of the edge. Two basic morphologies of membranes are flat disks that minimize the bending energy at the cost of the edge energy, and enclosed vesicles that minimize the edge energy at the cost of bending energy. In our work, the transition from disk to vesicle is studied theoretically using the string method, which is designed to find the minimum energy path (MEP) or the most probable transition path between two local minima of an energy landscape. Previous studies of disk-to-vesicle transition usually approximate the transitional states by a series of spherical cups, and found that the spherical cups do not correspond to stable or meta-stable states of the system. Our calculation demonstrates that the intermediate shapes along the MEP are very different from spherical cups. Furthermore, some of these transitional states can be meta-stable. The disk-to-vesicle transition pathways are governed by two scaled parameters, $\kappa G/k$ and $\gamma R_0/4k$, where $R_0$ is the radius of the disk. In particular, a meta-stable intermediate state is predicted, which may correspond to the open morphologies observed in experiments and simulations.

1:15PM J39.00011 Hybrid Lipid as Biological Surfactant, Robert Brewster, Weizmann Institute of Science, Phil Pincus, University of California- Santa Barbara, Sam Safran, Weizmann Institute of Science — Systems capable of forming finite-sized, equilibrium domains are of biological interest in the context of membrane rafts where it has been observed that certain cellular functions are mediated by small (nanometric to tens of nanometers) domains with specific lipid composition that differs from the average composition of the membrane. These small domains are composed mainly of lipids with completely saturated hydrocarbon tails that show good orientational order in the membrane. The surrounding phase consists mostly of lipids with at least one unsaturated bond in the hydrocarbon tails which forces a “kink” in the chain and inhibits ordering. In vitro, this phase separation can be replicated; however, the finite domains coarsen into macroscopic domains with time. We have extended a model for the interactions of lipids in the membrane, akin to that developed in the group of Schick (Elliott et al., PRL 2006 and Garbes Putzel and Schick, Biophys. J. 2007), which depends entirely on the local ordering of hydrocarbon tails. We generalize this model to an additional species and identify a biologically relevant component, a lipid with one fully saturated hydrocarbon chain and one chain with at least one unsaturated bond, that may serve as a line-active component, capable of reducing the line tension between domains to zero, thus stabilizing finite sized domains in equilibrium.

1:27PM J39.00012 Distribution of Drug Molecules in Lipid Membranes: Neutron Diffraction and MD Simulations, Mohan Boggara, University of Houston, Ella Mihailescu, University of California, Irvine, Ramanan Krishnamoorti, University of Houston — Non-steroidal anti-inflammatory drugs (NSAIDs) e.g. Aspirin and Ibuprofen, with chronic usage cause gastro intestinal (GI) toxicity. It has been shown experimentally that NSAIDs pre-associated with phospholipids reduce the GI toxicity and also increase the therapeutic activity of these drugs compared to the unmodified ones. In this study, using neutron diffraction, the DOPC lipid bilayer structure (with and without drug) as well as the distribution of a model NSAID (Ibuprofen) as a function of its position along the membrane normal was obtained at sub-nanometer resolution. It was found that the bilayer thickness reduces as the drug is added. Further, the results are successfully compared with atomistic Molecular Dynamics simulations. Based on this successful comparison and motivated by atomic details from MD, quasi-molecular modeling of the lipid membrane is being carried out and will be presented. The above study is expected to provide an effective methodology to design drug delivery nanoparticles based on a variety of soft condensed matter such as lipids or polymers.

1:39PM J39.00013 Calcium-induced domain formation in mixed lipid monolayers, Wouter G. Ellenbroek, Department of Physics and Astronomy, University of Pennsylvania, David A. Christian, Chemical & Biomolecular Engineering and the Laboratory for Research on the Structure of Matter, University of Pennsylvania, Ilya Levtental, Institute for Medicine and Engineering, University of Pennsylvania, Andrea J. Liu, Department of Physics and Astronomy, University of Pennsylvania, Paul A. Janney, Departments of Physics and Astronomy, and Bioengineering, University of Pennsylvania — Multivalent ions such as calcium play an important role in soft matter and biological systems. This role cannot be captured by a mean field treatment of the electrostatics such as the Poisson-Boltzmann equation, which neglects, for example, the fact that $Ca^{2+}$ ions can mediate attractions between negatively-charged objects. We show both experimentally and theoretically, that $Ca^{2+}$-mediated attractions lead to phase separation of charged and neutral lipid molecules in mixed lipid monolayers, and discuss the dependence on pH, salt concentration and ion valency.

1:51PM J39.00014 Membrane Disruption Mechanism of Antimicrobial Peptide, Kin Lok H. Lam, University of Chicago, Ting Ann Siah Team, Yuji Ishitsuka Team, Ka Yee C. Lee Team — PG-1, a cationic antimicrobial peptide, kills bacteria by forming pores which increase membrane permeability to ions or larger molecules. It has been proposed that PG-1 selectively induces stable membrane pores in bacterial membranes over mammalian membranes. To study the mechanism of action of PG-1, we directly visualize the topological changes induced by PG-1 in model membranes via atomic force microscopy for the first time. PG-1 induces structural transformations in supported lipid bilayers, progressing from bilayer edge instability, to the formation of pores, and finally to a network of wormlike micelles in a zwitterionic dimyristoylphosphatidylcholine model membrane with increasing PG-1 concentrations. The structural transformation can be understood in the framework of the action of 1d detergent, with PG-1 acting as a line active agent. The results elucidate the mechanism by which PG-1 uses to induce leakage in bacterial cells.

Tuesday, March 17, 2009 11:15AM - 2:15PM
Session J40 DBP: Biological Physics II 412
11:15AM J40.00001 Cell Rheology and Embryogenesis Using the Subcellular Element Model, Timothy Newman, Arizona State University — I will present recent work on grid-free computational modeling of both cell biomechanics and multicellular collective dynamics, the latter in the context of gastrulation in the chick embryo. Mechanics at both subcellular and multicellular scales is modeled seamlessly with the Subcellular Element Model (SEM). The SEM is able to capture basic viscoelastic properties of cells at a semi-quantitative level, and is efficient enough to simulate thousands of cells in three dimensions allowing computational analysis of biological hypotheses regarding collective cell motion during gastrulation. Work done in collaboration with Sebastian Sandersius, Arizona State University.

1 Funding provided by the Human Frontier Science Program.
11:51AM J40.00002 The effects of viscoelastic polymer substrates on adult stem cell differentiation. CHUNGHEUE CHANG, ADAM FIELDS, ALEX RAMEK, VLADIMIR JURUKOVSKI, MARCIA SIMON, MIRIAM RAFAILOVICH — Dental Pulp Stem Cells (DPSCs) are known to differentiate in either bone, dentine, or nerve tissue by different environment signals. In this study, we have determined whether differentiation could only through modification of the substrate mechanics. Atomic Force Microscopy (AFM) on Shear Modulation Force Microscopy (SMFM) mode indicated that the spun-cast polybutadiene (PB) thin films could be used to provide different stiffness substrates by changing the thicknesses of thin films. DPSCs were then plated on these substrates and cultured in standard media. After 28 days incubation, Laser Scanning Confocal Microscopy (LSCM) with mercury lamp indicated that the crystals were observed only on hard surfaces. The Scanning Electron Microscopy (SEM) and Energy Dispersive X-ray analysis (EDX analysis) indicated that the crystals are calcium phosphates. The Glancing Incidence Diffraction (GID) was also used to determine the structure of crystals. These results indicate that DPSCs could be differentiated into osteoblasts by mechanical stimuli from substrate mechanics.

12:03PM J40.00003 Translocation of double strand DNA into a biological nanopore¹. SUNITA CHATKAEW, LAMIA MLAYEH, MARC LEONETTI, FABRICE HOMBLE, SFMB COLLABORATION — Translocation of double strand DNA across a unique mitochondrial biological nanopore (VDAC) is observed by an electron transport chain. Characteristics of opened and sub-conductance states of VDAC are studied. When the applied electric potential is beyond 20 mV, VDAC transits to a sub-conductance state. Plasmids (circular double strand DNA) with a diameter greater than that of the channel shows the current reduction into the channel during the interaction but the state with zero-current is not observed. On the contrary, the interaction of linear double strand DNA with the channel shows the current reduction along with the zero-current state. These show the passages of linear double strand DNA across the channel and the electrostatic effect due to the surface charges of double strand DNA and channel for circular and linear double strand DNA.

¹FNRS, Ecole Centrale de Marseille

12:15PM J40.00004 On-chip growth of polymeric nanowires for electro-mechanical probing of live cells. BRET FLANDERS, PREM THAPA, Kansas State University — This study characterizes the directed electrochemical nanowire assembly of amorphous polythiophene nanowires on micro-electrode arrays. In this approach, a long range component of an applied voltage signal defines a channel of maximum flux in the laboratory reference frame. Amorphous wires lack a natural growth axis. However, because polymerization is restricted to the channel-region, such materials may be grown with wire-like geometries, and the growth path of these wires may be controlled. The wire-laden electrode arrays are useful substrates for cell physiological studies. To this end, non-invasive methodology for inducing single Dictyostelium cells to approach and attach individual pseudopods to the tips of the polymeric wires will be presented.

12:27PM J40.00005 What do cell rheology experiments really measure? JOHN C. CROCKER, Chemical and Biomolecular Engineering, University of Pennsylvania — It is now widely appreciated that normal tissue morphology and function rely upon cells' ability to sense and generate forces appropriate to their correct tissue context. While the effects of forces on cells have been studied for decades, our understanding of how those forces propagate through and act on different cell structures remains at an early stage. The last decade has seen a resurgence of interest, with a variety of different micromechanical methods in current use that probe cells dynamic deformation in response to a time varying force. Recently, it has been shown that the seemingly disparate findings from different labs can be fit into a single, workable consensus description. The ability of researchers to carefully measure the mechanical properties of cells subjected to a variety of pharmacological and genetic interventions, however, currently outstrips our ability to quantitatively interpret the data in many cases. Despite these challenges, the stage is now set for the development of detailed models for cell deformability, motility and mechano-sensing that are rooted at the molecular level.

1:03PM J40.00006 Cargo transport by several molecular motors. STEFAN KLUMPFF, Center for Theoretical Biological Physics, UC San Diego, MELANIE MÜLLER, JANINA BEEG, RUMIANA DIMOVA, REINHARD LIPOWSKY, MPI of Colloids and Interfaces, Potsdam, Germany — In cells, cargoes are often transported by small teams of molecular motors rather than by a single motor. Furthermore, many cargoes perform bidirectional movements, which are based on the presence of two motor species on the cargo. We study the transport by several motors theoretically using a model that describes the stochastic binding and unbinding of motors from filaments and that is based on the properties of individual motors as observed in single molecule experiments. We find that the cooperation of several motors leads to a strongly increased run length, which is confirmed experimentally for beads pulled by several kinesin motors. Furthermore, such cargoes exhibit a non-linear force-velocity relation. For the case of two motor teams pulling into opposite direction we find that a stochastic tug-of-war model, where the motors interact only by pulling their common cargo into opposite directions, leads to surprisingly complex motility. In particular, even for two motor teams with equal strength, we find that a tug-of-war leads to fast bidirectional motion similar to what is observed in cells and usually taken as evidence for some unknown coordination mechanism. This behavior is due to a dynamic instability, which arises from the strong force-dependence of the rate with which motors unbind from filaments.

1:15PM J40.00007 Adverse Effects of TiO₂ Nanoparticles on Human Dermal Fibroblasts and How to Protect Cells. ZHI PAN, WILSON LEE, LENNY SLUTSKY, Stony Brook University, SOWMYA SANDARESH, Hixville High School, NICOLE ELSTEIN, Bayport-Bluepoint High School, RICHARD CLARK, NADINE PERNODET, MIRIAM RAFAILOVICH, Stony Brook University — We have studied the effects of exposure of human dermal fibroblasts to rutile and anatase TiO₂ nanoparticles. We found that these particles can impair cell functions, with the latter being more potent at producing damage. We showed that the exposure to nanoparticles decreases cell area, cell proliferation, mobility, and ability to contract collagen. Individual particles are shown to penetrate easily through the cell membrane, in the absence of endocytosis, while some endocytosis is observed for larger particle clusters. Once inside, the particles are sequestered in vesicles, which continue to fill up with increasing incubation time till they rupture. We also tested particles that were coated with a dense grafted polymer brush and, using flow cytometry, showed that the coating prevented the particles from adhering to the cell membrane and hence penetrating the cell, which effectively decreases reactive oxygen species (ROS) formation and protects cells, even in the absence of light exposure. Considering the broad applications of these nanoparticles in personal health care products, the functionalized polymer coating can potentially play an important role in protecting cells and tissue from damage.

1:27PM J40.00008 Surface Morphological Studies on Nerve Cells by AFM. GOKSEL DURKAYA, Department of Physics & Astronomy, Georgia State University, LEI ZHONG, VINCENT REHDER, Department of Biology, Georgia State University, NIKOLAUSS DIETZ, Department of Physics & Astronomy, Georgia State University — Surface morphological properties of fixed and living nerve cells removed from the buccal ganglion of Helisoma trivolvis have been studied by using Atomic Force Microscopy (AFM). Identified, individual neurons were removed from the buccal ganglion of Helisoma trivolvis and plated into poly-L-lysine coated glass cover-slips. The growth of the nerve cells was stopped and fixed with 0.1% Glutaraldehyde and 4% Formaldehyde solution after extension of growth cones at the tip of the axons. Topography and softness of growth cone filopodia and overlying lamellipodium (veil) were probed by AFM. Information obtained from AFM’s amplitude and phase channels have been used for determination of softness of the region probed. The results of structural studies on the cells are linked to their mechanical properties and internal molecular density distribution.
The four systems and comparisons with available data will be presented and discussed. The charge and spin distributions over them, and the associated hyperfine interactions of the nuclei of the atoms. Results and trends of these properties over aims in mind, we have studied quantitatively at a first principles level the electronic structures of all four halogen five liganded heme compounds, the natures of this purpose an in depth understanding at the electronic level of the heme units, the protein chains, and the interactions between the two, is vital. With these sign problem remains significant. I will discuss the different attempts we have made to reduce it.

For the composite excitations when momentum, such excitations have non-zero spectral weight at two distinct energy scales separated by the on-site repulsion are gapped composite excitations generated by the dynamics of the charge of Illinois, Urbana, Illinois 61801 — We show exactly that the only charged excitations that exist in the strong-coupling limit of the half-filled Hubbard model of Illinois, Urbana, Ilinois 61801 — We show exactly that the only charged excitations that exist in the strong-coupling limit of the half-filled Hubbard model of particles. The universal character of this theory is analogous to the van der Waals model for a liquid-gas transition. This work is supported by NIH R01 GM073082.

The four systems and comparisons with available data will be presented and discussed. The charge and spin distributions over them, and the associated hyperfine interactions of the nuclei of the atoms. Results and trends of these properties over

1:39PM J40.00009 Study of Charge and Spin Distribution Properties in Five-Liganded Halogen-Heme Systems, ARCHANA DUBEY, UCF Orlando, MINAKHI PUJARI, K. RAMANI LATA, SUNY Albany, ALYSSA GARCIA, A.F. SCHULTE, UCF Orlando, S.R. BADU, R.H. PINK, SUNY Albany, R.H. SCHEICHER, Uppsala University, Sweden, T.P. DAS, SUNY Albany, UCF Orlando — The current emphasis in biological physics is on the study of the functions of important systems, like for instance hemoglobin and cytochromes at a quantitative level. For these studies an accurate knowledge of the electronic structures of the entire molecules as well as parts of them are very important. In the heme proteins there is great current interest in both electron transport and in attachment and detachment of O₂, CO, and NO molecules to the iron. For this purpose an in depth understanding at the electronic level of the heme units, the protein chains, and the interactions between the two, is vital. With these aims in mind, we have studied quantitatively at a first principles level the electronic structures of all four halogen five liganded heme compounds, the natures of the charge and spin distributions over them, and the associated hyperfine interactions of the nuclei of the atoms. Results and trends of these properties over the four systems and comparisons with available data will be presented and discussed.

1:51PM J40.00010 Kalman meets neuron - the intersection of control theory and neuroscience, STEVEN SCHIFF, Penn State University — Since the 1950s, we have developed mature theories of modern control theory and computational neuroscience with almost no interaction between these disciplines. With the advent of computationally efficient nonlinear Kalman filtering techniques, along with improved neuroscience models which provide increasingly accurate reconstruction of dynamics in a variety of important normal and disease states in the brain, the prospects for a synergistic interaction between these fields are now strong. I will show recent examples of the use of nonlinear control theory for the assimilation and control of single neuron dynamics, a novel framework for dynamic clamp, the modulation of oscillatory wave dynamics in brain cortex, a control framework for Parkinsonian dynamics and seizures, and the use of optimized parameter model networks to assimilate complex network data.

2:03PM J40.00011 Protein Thermodynamics from Maxwell Constraint Counting, DONALD JACOBS, Department of Physics and Optical Science, UNC-Charlotte, DENNIS LIVESAY, Department of Bioinformatics and Genomics, UNC-Charlotte, OLEG VOROV, Department of Physics and Optical Science, UNC-Charlotte — Topological properties of network rigidity explain essential aspects of structural phase transitions and thermodynamic stability in proteins [1]. We present an exact transfer matrix method within a Distance Constraint Model (DCM) that maps interactions into distance constraints having energy and entropy contributions. Conformational entropy is reduced by interactions that rigidify structure, associated with independent constraints. Here, we solve the DCM using a mean-field treatment that assumes distance constraints are well distributed throughout the structure, meaning a distance constraint is independent until the structure is globally rigid. Experimental heat capacity curves are described markedly well with a few adjustable parameters. The universal character of this theory is analogous to the van der Waals model for a liquid-gas transition. This work is supported by NIH R01 GM073082.

2:17AM J41.00001 Origin of the Mott Gap, PHILIP PHILLIPS, ROBERT G. LEIGH, Loomis Laboratory of Physics, University of Illinois, Urbana, Illinois 61801 — We show exactly that the only charged excitations that exist in the strong-coupling limit of the half-filled Hubbard model of Fermi gas at unitarity, obtained through DiagMC simulation.

2:27AM J41.00002 Diagrammatic Monte Carlo, KRIS VAN HOUCKE, FELIX WERNER, UMASS Amherst, EVGENY KOZIK, ETH Zurich, LODA POLLET, NIKOLAY PROKOF’EV, BORIS SVISTUNOV, UMASS Amherst, DARPA OLE COLLABORATION — Diagrammatic Monte Carlo (DiagMC) is an exact technique that allows one to simulate quantities specified in terms of diagrammatic expansions, the latter being a standard tool of many-body quantum statistics. The sign problem, that is typically fatal to Monte Carlo approaches, appears to be manageable with DiagMC. We introduce a general DiagMC scheme for strongly interacting fermions. As an illustrative example, we discuss the application of DiagMC to the Fermi-Hubbard model, and benchmark the technique against state-of-the-art numerical tools for strongly correlated fermions. In addition, we discuss the thermodynamic properties of a Fermi gas at unitarity, obtained through DiagMC simulation.

2:39AM J41.00003 Unconventional soft gaps in strongly-correlated systems with coexisting short-range interaction and disorder, HIROSHI SHINAOKA, MASATOSHI IMADA, Dept. of Applied Physics, Univ. Tokyo — We report a theoretical study of the Anderson-Hubbard model under coexisting short-range interaction and disorder, which is one of the minimum models of real strongly-correlated materials. We determined the ground-state phase diagram in three dimensions within the unrestricted Hartree-Fock approximation. Although only short-range interaction is present, we found a soft gap in the single-particle density of states of the insulating phases [1]. This unconventional soft gap (soft Hubbard gap) cannot be explained within the conventional theory [2] which ascribes the formation of soft gaps to the long-range part of the Coulomb interaction. We present a phenomenology to clarify the origin of the soft Hubbard gap. We propose a multi-valley energy landscape as their origin. Further support by the exact diagonalization in one dimension beyond the mean-field level is given. Possible experiments to verify the present theory are also proposed. [1] H. Shinaoka and M. Imada, arXiv:0811.2492v1. [2] A. L. Efros and B. I. Shklovskii, J. Phys. C 8, L49 (1975).

2:51AM J41.00004 Determinant Quantum Monte Carlo method applied to the t-J model, ALEKSANDER ZUJEV, UC Davis, RICHARD FYE, 825 La Charles NE Albuquerque, NM 87123, RICHARD SCALETTAR, UC Davis — The usual approach to simulating the t-J model with the Determinant Quantum Monte Carlo (DQMC) method starts with the Hubbard model with a finite on-site interaction $U$ which is then increased to “almost” infinity. This approach, however, has considerable difficulties with large round-off errors (stability) and variances, and also a very bad fermion sign problem. In this talk, we will describe a different approach which starts with (almost) infinite $U$ by means of a projector operator and further prohibiting double occupancy by using a modified creation operator. The new technique will be shown to solve some of these difficulties. Unfortunately, the sign problem remains significant. I will discuss the different attempts we have made to reduce it.
We consider a coupled non-interacting and spin-density-wave (SDW) chains as an example. We find that the interchain hopping induces a short-rang SDW order in the extended Anderson-Hubbard model. Since the phase transition is believed to be of Kosterlitz-Thouless type, no local order parameter can describe such a transition. We find instead that the nodal regions and a pseudogap in the antinodal regions at lower dopings \( x \) (induced by strong short ranged order) than as a Mott phenomenon. Doping the gapped phase leads to a non-Fermi-liquid state with a Fermi surface only in theory is used to investigate the metal-insulator transition in the Hubbard model. At half filling a gap-opening transition is found to occur as the interaction increases beyond a critical value. The gapped behavior found in the 4-site DCA approximation is shown to be associated with the onset of strong antiferromagnetic and singlet correlations and the transition is found to be potential energy driven. It is thus more accurately described as a Slater phenomenon (induced by strong short ranged order) than as a Mott phenomenon. Dopping the gapped phase leads to a non-Fermi-liquid state with a Fermi surface only in the nodal regions and a pseudogap in the antinodal regions at lower dopings \( x \leq 0.15 \) and to a Fermi liquid phase at higher dopings.

This work is supported by an Earmarked Grant for Research from the Research Grants Council of HKSAR, China (Project No. CUHK 400906).

1:03PM J41.00010 Effect of nonlocal interactions on the disorder-induced zero-bias anomaly in the extended Anderson-Hubbard model1, RACHEL WORTIS, HONGYI CHEN, W.A. ATKINSON, Trent University — Adding disorder to a system of correlated electrons moves single-particle states away from the Fermi surface. In the weakly correlated regime, consensus exists on the evolution of the resulting density of states anomaly between the limits of weak and strong disorder. Recently a number of groups have made progress in understanding the strongly correlated regime, mostly in the context of purely local interactions. We study the extended Anderson-Hubbard model using exact diagonalization on two-dimensional 12-site clusters, exploring the evolution of the zero-bias anomaly with the strength of the nonlocal interaction and with doping. At half filling, an exchange-driven Altshuler-Aronov-like anomaly develops Efros-Shklovskii-like atomic character and moves to a regime of strong charge-density correlations, whereas at quarter filling both the Efros-Shklovskii-like behavior and the charge density correlations are much weaker.

1:15PM J41.00011 Local Order and the gapped phase of the Hubbard model: a plaquette dynamical mean field investigation. EMANUEL GULL, PHILIPP WERNER, ETH Zurich, XIN WANG, Columbia University, MATTHIAS TROYER, ETH Zurich, ANDREW MILLIS, Columbia University — The four-site DCA method of including intersite correlations in the dynamical mean field theory is used to investigate the metal-insulator transition in the Hubbard model. At half filling a gap-opening transition is found to occur as the interaction increases beyond a critical value. The gapped behavior found in the 4-site DCA approximation is shown to be associated with the onset of strong antiferromagnetic and singlet correlations and the transition is found to be potential energy driven. It is thus more accurately described as a Slater phenomenon (induced by strong short ranged order) than as a Mott phenomenon. Dopping the gapped phase leads to a non-Fermi-liquid state with a Fermi surface only in the nodal regions and a pseudogap in the antinodal regions at lower dopings \( x \leq 0.15 \) and to a Fermi liquid phase at higher dopings.

12:03PM J41.00005 Ordering and Frustration in a Strongly Correlated Chain system. SIDDHARTHA LAL, Department of Physics, University of Illinois at Urbana-Champaign, MUKUL LAAD, Max Planck Institute for Complex Systems, Dresden, Germany — We present recent results of our study on the one-dimensional extended Hubbard model with longer-range Coulomb interactions at quarter-filling in the strong coupling limit. With the complex phase diagram of the TMTSF and TMTTF organic charge transfer salts as motivation, we explore the possible charge and spin ordered states that arise from frustrating interactions. We find a quantum critical point in the phase diagram of the single chain and present results for some response functions in the quantum critical regime. RPA studies of coupled chains reveal a phase diagram with the ordered phase extended to finite temperatures and a phase boundary again ending at a quantum critical point. Critical quantum fluctuations at the QCP enhance the transverse dispersion, leading to a dimensional crossover and a low temperature transition from insulating chains to anistropic metallic bulk behaviour. These results have been reported in arxiv:0708.2156 and are in press at Int. J. Mod. Phys. B.

12:15PM J41.00006 Mott and Wigner-Mott transition away from half-filling. CHUNHUA LI, ZIQIANG WANG, Boston College — We study the Mott transition in strongly correlated electron systems away from half-filling in the presence of finite-range Coulomb interaction and/or a superstructure associated with an inhomogeneous electronic state. Using a cluster Gutzwiller approach, we map a minimal single band \( t-t'V-\Delta \) model with nearest neighbor Coulomb repulsion \( V \) and superlattice potential \( \Delta \), to a two-orbital Hubbard model with intra and interorbital Coulomb repulsion \( U \) and \( U' \) and a crystal field splitting \( \Delta \). We obtain the Mott transition at quarter-filling from both uniform and \( \sqrt{x}+\sqrt{1-x} \) charge density wave metals and discuss the physics of the Mott and Wigner-Mott metal-insulator transition.

12:27PM J41.00007 Effect of Interchain Hopping on Nonequivalent Hubbard Chains. TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University, Japan, HIROYUKI YOSHIZUMI, TAKAO MORINARI — Motivated by recent report on the presence of different orders in each CuO\(_2\) plane and their coexistence in multi-layered high-temperature superconductors, we examine a simple model with two nonequivalent Hubbard chains coupled by interchain hopping, employing the density-matrix renormalization group (DMRG) and a mean-field calculation. We consider a coupled non-interacting and spin-density-wave (SDW) chains as an example. We find that the interchain hopping induces a short-rang SDW order from adjacent SDW chain and the induced order decreases with increasing the original SDW order of the adjacent chain. We discuss the finding in connection with the multi-layered cuprates.

12:39PM J41.00008 High Precision QMC Study of the 2D Hubbard Model. CHRISTOPHER VARNEY, SIMONE CHIESA, RICHARD SCALETTAR, University of California, Davis — The Hubbard model has provided insight into a wide variety of strongly correlated systems, including the cuprates and manganites. Recent advances in the generation of optical lattices allow for the possibility of experimentally studying the 2D Hubbard model in a new context. To enhance our understanding of the model, we examine the magnetic correlations on a rectangular lattice using Determinant Quantum Monte Carlo. In this talk, we discuss high precision calculations of the anti-ferromagnetic order parameter as a function of interaction strength and the effect of the aspect ratio on finite size scaling.

12:51PM J41.00009 Quantum phase transition in the one-dimensional half-filled asymmetric Hubbard model. YANG LIU, WEN-LING CHAN, SHI-JIAN GU, HAI-QING LIN, Department of Physics, The Chinese University of Hong Kong — We study the quantum phase transition in the one-dimensional asymmetric Hubbard chain at half-filling in terms of spin stiffness by the exact diagonalization method. Since the phase transition is believed to be of Kosterlitz-Thouless type, no local order parameter can describe such a transition. We find instead that spin stiffness might be able to describe the quantum phase transition since the spin degree of freedom is gapless in the Hubbard region, while gapful in the Falicov-Kimball region.
1:30PM J41.00003 One-dimensional periodic Anderson model at partial band filling , MIKLÖS GULACSI, IAN MCCULLOCH, Max Planck Institute for the Physics of Complex Systems — An effective Hamiltonian is derived for the one-dimensional periodic Anderson model via bosonization. The effective Hamiltonian is shown to reproduce all the features of the model as identified by DMRG and provides new information on the ferromagnetic to paramagnetic phase transitions and the paramagnetic phase. We are using a non-Abelian DMRG to determine numerically the phase diagram of the one-dimensional periodic Anderson model. We found very good agreement between the bosonization approach and the DMRG results.

1:51PM J41.00014 The Marginal Fermi Liquid-A Derivation Based on Dirac’s Constraints , D. SCHMELTZER, CCNY — Dirac’s method for constraints is used for enforcing the exclusion of double occupancy for Correlated Electrons. The constraint is given by the pair $Q(\mathbf{x}) = \psi(\mathbf{x})\psi(\mathbf{x})$ which annihilates the ground state $|\Psi\rangle$. Away from half fillings $Q(\mathbf{x})$ is replaced by a set of first class constraints $Q_{\mu}^{\alpha}Q_{\mu}^{\beta}$ which are restricted to negative energies. The propagator for the single hole is determined by a measure which is a function of time duration for the hole propagator. a)-The imaginary part of the self energy - is linear in the frequency. b)-In the superconducting phase the tunneling density of states is asymmetric.

Session K1 Poster Session II (2-5:00pm): Education; SPS/Undergrad Research; Metals; Magnetism; Instrumentation and Measurements; Chemical Physics; Artificially Structured Materials; Surfaces, Interfaces and Thin Films; AMO Physics; Quantum Information; Bio Physics Exhibit A

K1.00001 PHYSICS EDUCATION —

K1.00002 Stokes analysis of an optical system , GEORGI GEORGIEV, Assumption College, THOMAS SLAVKOVSKY, Assumption College, ASSUMPTION COLLEGE TEAM — As a transfer from research to teaching we are using stokes analysis to represent changes in the vectors for polarization of light as acted upon by the matrices of optical elements in undergraduate physics lab. The goal is to integrate students’ knowledge for matrix analysis with an experimental determination of the changes in the polarization of light. This method allows students to learn how to design an optical system by using mathematical analysis, a skill necessary for future scientists or engineers in the fields of optics. We have tested and implemented the lab. The results are that it is well accepted by the students, but is very involved computationally, and needs to be shortened. The Stokes analysis needs to be introduced earlier in the curriculum in order to make the students comfortable with the formalism.

K1.00003 The Doppler Effect in Sound Waves, Light Waves, and Quantum Waves , ALAN M. KADIN, Princeton Junction, NJ — In undergraduate modern physics courses, special relativity and quantum mechanics are generally introduced as a series of sharp breaks from classical physics. An alternative approach is suggested, focusing on the Doppler effect, closely related to changes in reference frames. In the classical acoustic Doppler effect with a source or observer moving with speed $u$, the frequency $f$ shifts while the wavelength $\lambda$ must remain fixed for classical transformations. Hence the phase velocity $v_{ph}=f\lambda$ must also shift. In the optical Doppler effect, $f$ also shifts for $u$ approaching $c$, but this must be accompanied by a corresponding shift in $\lambda$ (from the Lorentz transformation) in order to maintain $v_{ph}=c$ constant. The Doppler effect is usually not considered for quantum waves, but this clearly requires a non-classical shift in the de Broglie wavelength $\lambda=h/mv$ even for $u<c$. This shift is fully explained by the Lorentz transformation if one takes $f=mc^2/h$, as was shown by de Broglie in his original 1924 paper. This is a dispersive wave with $v_{ph}=c^2/v$, but a group velocity $v_g=v$, as required for a consistent physical interpretation. This emphasizes the relativistic basis of quantum waves.

K1.00004 Kinematic analysis of the Cretaceous Era dinosaur footprints near the Paluxy River, Texas: Predation event or not? , SCOTT LEE, University of Toledo — Motivation is enhanced by challenging students with interesting and open-ended questions. In this talk, a methodology for studying the locomotion of extinct animals based on their footprint tracks is developed and applied to a possible predation event recorded in Cretaceous Era deposits Students usually love learning about dinosaurs, an unexpected treat in a physics class. This example can be used in the classroom to help build critical thinking skills as the students decide whether the evidence supports a predation scenario or not.

K1.00005 Locomotion speeds of various dinosaurs , MARY DOUGHERTY, SCOTT LEE, University of Toledo — Most students have a passing curiosity about dinosaurs. Piquing this interest is an excellent tool to engage students. A methodology for estimating the locomotion speed of an animal based upon their footprint tracks is developed. Using this technique, an analysis of the locomotion speeds of various dinosaurs is performed. The tracks studied include 28 theropods (meat-eating dinosaurs), 23 sauropods (the “long-necked” herbivores), 28 non-armored, non-sauropod herbivores and 10 armored, non-sauropod herbivores. The theropods show the fastest locomotion speed as well as the greatest variety of speeds while the armored dinosaurs are the slowest.

K1.00006 Avogadro: Free, Open Source, Cross-Platform Computer Program for Building Molecules and Visualizing Structure , MARCUS HANWELL, GEOFFREY HUTCHISON, University of Pittsburgh — The Avogadro project is a free, open source approach to building chemical structures. It has integrated analysis, and three-dimensional visualization capabilities. Avogadro also uses external packages to perform quantum structure calculations. The work presented here illustrates a novel approach to working with the results of quantum calculations by visualizing possible molecular orbitals and allowing the user to select orbitals of interest. The Avogadro program allows the user to prepare new jobs for various quantum codes such as GAMESS-US, Q-Chem, Gaussian and Molpro. Due to the plugin-based nature of the Avogadro project many specialized options can be added, such as raytracing the electronic structure of the molecule to produce high quality output, building carbon nanotube structures, or designing solid-state structures. Avogadro is already being used by educators and researchers. Due to the free and open source nature of the project, it can be readily downloaded and used by all students in and out of the classroom. It can also be tailored to particular institutions and/or courses.
K1.00007 Gaps and Tails: The restricted N-body problem in colliding galaxies and the asteroid belt . ANNA PANCOAST, SHEA GARRISON-KIMMEL, PETER LOVE, Haverford College — We report simulations of the restricted n-body problem performed in the class Computational Physics at Haverford College. We simulated gravitational interactions in a large system in which nearly all of the particles, such as asteroids or stars, are assumed to have no effect on the trajectories of other particles. We begin by simulating the emergence of Kirkwood Gaps in the asteroid belt. We then modify the code to include the extensive initial conditions necessary to model the parabolic collision of two galaxies. We explored both direct and retrograde passages between the galaxies, reproducing the results of the 1972 paper by Toomre and Toomre, specifically the formation of galactic bridges and tails.

K1.00008 Understanding Statistical Mechanics and Biophysics Using Excel , PETER NELSON, Benedictine University — A new approach to teaching statistical mechanics and biophysics is presented using the classic two-box system from statistical mechanics as an example. This approach makes advanced physics concepts accessible to a broad audience including undergraduates with no calculus background. Students develop a simple Excel spreadsheet that implements a kinetic Monte Carlo (kMC) simulation algorithm “from scratch”. The students discover for themselves the properties of the system by analyzing the simulation output in a directed, activity-based exercise. By changing the number and initial distribution of the particles, students see how the system approaches equilibrium and how system variability changes with system size. A finite difference solution is also implemented in Excel, and students compare its predictions with the kMC results. This approach is quite different from using “canned” computer demonstrations, as students design, implement and debug the simulation themselves – ensuring that they understand the model system intimately.

K1.00009 Computational Physics Undergraduate Research Experience (A case Study) , HOMEYRA SADAGHIANI, ALEX SAML, California Polytechnic University Pomona — There is a growing trend of inclusion of more research programs into undergraduate education. In spite of that, the assessment of undergraduate-research experience in physics is limited. This presentation describes a ten weeks undergraduate summer research experience in computational physics in the field of biophysics for two upper division physics students at Cal Poly Pomona. The analysis of Pre/post test data suggests more gains on research methodologies and skills than actual physical concepts underlying the research project. We also discuss student attitude change measured by survey and interviews.

K1.00010 Scientific Inquiry: A Problem-Based Approach for Improving Teaching and Learning , PETER SHELTON, PEGGY SCHIMMOELLER, TATIANA TOTEVA, Randolph College — We describe a research project that had two goals: (1) to design and develop a content specific science inquiry institute to improve teachers’ instructional practices in the sciences and thus students’ achievement in science; and (2) to investigate students’ perception of scientists as a measure of their attitude toward science, and to see whether an inquiry science curriculum can improve attitudes. We report that certain stereotypical images of scientists are prevalent among students. Teacher participants increased content knowledge and familiarity with using inquiry and hands-on methods in the classroom.

K1.00011 To Click or Not to Click1 , NINA ABRAMZON, HOMEYRA SADAGHIANI, California Polytechnic University Pomona — A comparison of clickers v. flashcards in a controlled setting was done to test a) whether clickers show an improvement over flashcards in students learning the following concepts: i) Coulomb’s force law and ii) magnetic fields caused by currents, and b) if students using clickers are more open towards conceptual questions and the peer instruction method compared to students using flashcards. Two classes taught concurrently by the same instructor were taught identically, except that in one class parach-goldenrod paradigm was used to ask conceptual questions using clickers, and in the other using flashcards. To test which students learned the concepts better, a few multiple choice questions from a standard exam used in physics education were included in the final exam of both classes, and the performance of the two classes was compared. In addition, a questionnaire was given to each class to evaluate students’ opinions about the benefits of lectures including conceptual TPS questions and the use of related conceptual questions on exams. The results of the survey were compared between the two classes. The experimental design and results of the study will be presented.

1Sponsored by the Faculty Center for Professional Development at Cal Poly Pomona.

K1.00012 SOCIETY OF PHYSICS STUDENTS AND UNDERGRADUATE RESEARCH –

K1.00013 Flexible Solution-Processed TiO2-Based Memory1 , BARBARA DUNLAP, NADINE GERGEL-HACKETT, BEHRANG HAMADANI, JOHN SUEHLE, CHRISTINA HACKER, DAVID GUNDLACH, CURT RICHTER — We have fabricated flexible titanium dioxide memory devices using a room temperature spin-on titanium dioxide (TiO2) sol gel technique. These devices show a non-volatile memory behavior with on/off ratios up to 10,000:1 and can be switched between low and high current states by applying an adequate bias (less than 10 V). Once switched, the state can be read by applying a small bias (0.5 V). The device can then be set back to the previous current state by applying a bias that is equal in magnitude but opposite in polarity to the initial bias. Devices maintain on/off ratios greater than four orders of magnitude when flexed 4,000 times, still switch after being flexed 8,000 times, and hold their set state for longer than 1x10^6 seconds. The advantages of our devices include that they are low power, rewritable, nonvolatile, lightweight, physically flexible, and they have a simple, inexpensive, two-terminal, room temperature processed device design.

1Work was done at the National Institute of Standards and Technology. Barbara Dunlap was a summer intern working at NIST through an internship with the Society of Physics Students.

K1.00014 Hydrogen storage media through nanostructured polymeric materials1 , SCOTT KIRKLIN, BRIAN DORNEY, SHENGWEN YUAN, PETER ZAPOL, Argonne National Laboratory, LUPINC YU, University of Chicago, Di-JIA LIU, Argonne National Laboratory, ARGONNE NATIONAL LABORATORY COLLABORATION, UNIVERSITY OF CHICAGO COLLABORATION — On-board hydrogen storage is critical to future transportation technologies such as H2-powered fuel cell vehicles. Reported here is our current effort in developing nanostructured polymeric materials as the non-dissociative hydrogen adsorbents for the transportation application. Various porous polymers were prepared. The discussion will be focused on the surface structural characterization using BET approach and hydrogen adsorption capacities and physical properties using a Sieverts type isotherm measurement. Details on improving the accuracy of measurement as well as data analysis will also be reported.

1This project is funded by the Department of Energy, Office of Energy Efficiency and Renewable Energy
A few percent. The results are relevant to recent experiments on the wetting of cesium by helium/hydrogen solutions, and may also have astrophysical applications. The results are relevant to recent experiments on the wetting of cesium by helium/hydrogen solutions, and may also have astrophysical applications.

We have been a number of reports on CNT based membrane electrode assembly (MEA) in PEMFC, but CNTs in these electrodes are oriented randomly and the advantages associated with the structural properties of CNTs were not fully utilized. We report here our progress in fabricating and evaluating MEAs made of catalyst decorated, vertically aligned carbon nanotube (ACNT) layers. For comparison, a commercial MEA prepared through the ink-based process was also tested under similar conditions. Improved performance was observed for ACNT-based MEAs, particularly at high current densities, suggesting enhancement in mass transport and improved water management.

This work was supported by the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy.

K1.000080 K1.00015 Polymer Electrolyte Membrane Fuel Cell with Vertically Aligned Carbon Nanotube Electrode, ANN CALL, GABRIEL GOENAGA, JUNBING YANG, DI-JIA LIU, Argonne National Laboratory — Carbon nanotubes (CNTs) have been considered a promising material for various applications. Electro-catalyst support for polymer electrolyte membrane fuel cells (PEMFCs) is one of them. There have been a number of reports on CNT based membrane electrode assembly (MEA) in PEMFC, but CNTs in these electrodes are oriented randomly and the advantages associated with the structural properties of CNTs were not fully utilized. We report here our progress in fabricating and evaluating MEAs made of catalyst decorated, vertically aligned carbon nanotube (ACNT) layers. For comparison, a commercial MEA prepared through the ink-based process was also tested under similar conditions. Improved performance was observed for ACNT-based MEAs, particularly at high current densities, suggesting enhancement in mass transport and improved water management.

K1.000080 K1.00016 Measuring and Using the dn/dc of HPC Polymer and Microgel Solutions, KRISTA FREEMAN, KIRIL STRELETZKY, Cleveland State University — The specific refractive index increment (dn/dc), the change in index of refraction with concentration, is essential for accurate light scattering (SLS) experiments on polymer solutions. With a reliable value for dn/dc, SLS yields basic polymer properties such as radius of gyration, molecular weight, and second virial coefficient. This study focuses on determining dn/dc values of hydroxypropylcellulose (HPC) polymer and microgel solutions and practically applying these values in SLS. Using a differential refractometer, HPC solutions were analyzed at a range of concentrations, molecular weights, wavelengths, temperatures, and filtration protocols. It was determined that dn/dc of HPC polymer is independent of temperature in good solvents, slightly dependent on molecular weight, inversely proportional to wavelength squared, and sensitive to polymer solution’s filtration protocol. HPC microgel testing produced dn/dc values one order of magnitude larger than those of HPC polymer solutions and did not support the expected wavelength dependence. These findings were analyzed and used to obtain a molecular weight, radius of gyration, and second virial coefficient for HPC polymer and microgel solutions.

K1.000080 K1.00017 Measuring Insulation in Walls Using a Thermocouple to Measure Temperature Differences, BETH PARKS, CLAYTON BROWN, Colgate University — It would be useful to develop tools to measure building insulation non-invasively and inexpensively. The temperature difference across an exterior wall and the center of the room is a sensitive measure of the amount of insulation in the wall. We describe measurements using a thermocouple to determine the insulation in a mock house.

K1.000080 K1.00018 Lasing in Superconducting Qubits, ALYSSA WILSON, ROBERTO RAMOS, Drexel University — Qubits are superconducting circuits that have many interesting quantum properties similar to those displayed by atoms. One such behavior is lasing, as manifested in a resonator coupled to a qubit. I will review experiments in which lasing was exhibited in charge qubits and three-Josephson-junction flux qubits. I will also examine the similarities between these systems and compare these to properties of the Josephson phase qubit. In the presentation, I will discuss the feasibility of demonstrating this phenomenon in the phase qubit.

K1.000080 K1.00019 Evaluation and Redesign of Introductory Undergraduate Physics Series for Use with USB Devices, LEAH PARSONS, GARY BEDROSIAN, Allegheny College — The introductory physics laboratory series at many colleges suffers from several problems, including a large time commitment, inflexibility of lab set-ups, and lack of accommodation of multiple learning styles. It is difficult in a conventional lab set-up, in which students follow a carefully specified series of steps, to be able to generalize findings to more than one specific case. In this paper, we propose changes that will allow students to form the labs to their own learning styles better than the traditional approach. The integration of USB devices will allow this. We have reduced the current introductory physics labs at Allegheny College to their basic principles in order to apply them to a new, more flexible, lab paradigm. Using a USB device designed by Rensselaer Polytechnic Institute, labs that reflect the core concepts of introductory physics will be able to be performed in a more agreeable environment: the student’s own home, at a time of their choice, with use of a personal computer and simple additional materials. This project will present the method of lab design as well as proposed testing of lab effectiveness.

K1.000080 K1.00020 Measuring Proper Motion of Barnard’s Star, KATRINA WIECHMANN, TOM MICHALIK, Randolph College — Stars of the night sky are generally considered to be fixed points, not changing noticeably over generations of observations. While most stars seem to appear in the same place year after year, some change location noticeably, the best example being Barnard’s Star. Barnard’s star is closer to Earth than any other star except Proxima Centauri. It also appears to move across the sky faster than any other star. This change in apparent location is caused by the movements of our Solar System and the motion of the star in question, and is known as proper motion. Using the astrometric capabilities of the MIRA software along with precise positional information for reference stars from the Tycho satellite star catalogue, the position of Barnard’s star is computed relative to the reference stars. We calibrate a series of images of Barnard’s Star taken in the Randolph College Observatory between 2001 and 2008 in order to independently determine the proper motion of Barnard’s star and compare this measurement to the accepted value of \( 10.25 \)" per year.

K1.000080 K1.00021 Sync-map Description of Coupled Oscillators, GILAD BARLEV, Kenyon College, EDWARD OTT, MICHELLE GIVAN, University of Maryland, College Park — The Kuramoto model describes the tendency of coupled oscillators to synchronize when the coupling strength is above a critical value. Through Monte Carlo simulations, we study the behavior of a variation on the discrete-time Kuramoto model and verify certain properties of the model, namely the critical coupling value and the rate of relaxation towards synchronization. We then apply the model to non-directed networks with community structure to investigate synchronization within communities. Further, we propose a method for the discovery of community structure within networks based on observations of the time-averaged degree of synchronism between pairs of oscillators within our system.

K1.000080 K1.00022 Partial Molar Volume of Helium Dissolved in Hydrogen, MADELINE SMITH, M.S. PETTERSEN, Washington and Jefferson College — We have determined the partial molar volume \( v' \) of helium dissolved in hydrogen, by analyzing existing data on the concentrations of the liquid and the coexisting vapor phase at high pressures. The partial molar volume can be found from the chemical potential of the helium in solution \( (\mu_2 = \mu_{2s} + \mu_{2g}) \), where \( \mu_2 \) is the chemical potential of the helium in solution, and \( \mu_{2g} \) its concentration, and the chemical potential can be determined from pressure and the concentration of the vapor phase, after applying virial corrections. Both \( v' \) and the virial terms lead to corrections to Henry’s law. Over the range studied (0-50 bar and 15.5-29 K), we find that the partial molar volume of helium is equal to the molar volume of pure hydrogen, within a few percent. The results are relevant to recent experiments on the wetting of cesium by helium/hydrogen solutions, and may also have astrophysical applications.

K1.00031 Synthesis of Nanosized Silicon Powders and Characterization of Their Electrical Properties
K1.00032 Electron Paramagnetic Resonance Spectroscopic Studies of Cyanide-Bridged Fe/Os and Fe/Ru Clusters, KATLYN MEIER, TANYA NOCERA, R. ABOOD, Allegheny College, Dept. of Physics, M. CHEN, Carnegie Mellon University, Dept. of Chemistry, M. HILFIGER, Texas A&M University, Dept. of Chemistry, D. PETASIS, Allegheny College, Dept. of Physics, C. ACHIM, Carnegie Mellon University, Dept. of Chemistry, K. DUNBAR, Texas A&M University, Dept. of Chemistry — The pertunecular, cyanide-bridged metal clusters with the general formula \([M(tmphen)2][M'(CN)6]2\) \((tmphen = 3, 4, 7, 8\text{-tetrathemethyl-1, 10-phenanthroline})\) have a core with trigonal bipyramidal geometry with equatorial \([M(tmphen)2](CN)2]\) and axial \([M'(CN)6]\) ions and contain M-CN-M' or M-NC-M' units, depending on the relative preference of the M and M' ions for the C or N terminus of the cyanide bridge. Spin-crossover behavior has been observed in these clusters and has motivated the current study. A series of Electron Paramagnetic Resonance (EPR) spectra of solid samples of the complexes with M/M' = Fe/Os and Fe/Ru were obtained between the temperatures of 2K and 300K. EPR spectra were also collected for samples dissolved in MeCN and MeOH. The EPR signals observed from Os (III) ions in the Fe/Os cluster and the signals from the Fe/Ru cluster indicating changes in oxidation and spin states of the metal ions as a function of temperature will be presented.

K1.00033 METALS —

K1.00034 Low energy positron sticking on surfaces — comparison of experiment and calculations, S. MUKHERJEE, K. SHASTRY, U. Texas at Arlington, N. G. FAZLEEV, U. T. Arlington, A. H. WEISS, U. Texas at Arlington — Recent measurements have provided evidence that low energy positrons incident upon a metal surface can make a single step transition from an unbound scattering state to an image potential bound state resulting in the creation of an electron-hole pair. Because the transition into the surface state results in the release of an additional \(\sim 3\) eV of energy as compared to a transition into a bulk state, the direct transition from scattering state to surface state can result in the creation of secondary electrons even at beam kinetic energies below the energy threshold necessary to generate secondary electrons in scattering processes in which the positron final state is a bulk state. In this poster we present a comparison of the experimental results with model calculations from which the rate of the direct process is estimated and the implications of these measurements in the understanding of quantum-sticking of positrons to surfaces are considered.

K1.00035 The Surface Dynamics of the Initial Oxidation Behavior of CuNi Alloys, STEVE ZIEMACK, LI SUN, JUDITH YANG, JEFF EASTMAN, GUANGWEN ZHOU, UNIVERSITY OF PITTSBURGH COLLABORATION, ARGON NATIONAL LABORATORY COLLABORATION, EUGENE, WASHINGTON — As an extension of our previous work on the initial oxidation stages of pure Cu and CuAu alloy, we are currently visualizing the oxidation of CuNi alloys by in-situ ultra high vacuum transmission electron microscope (UHV-TEM) and X-ray diffraction. We investigated systematically a range of CuNi (001) compositions, including 2.8,15 and 24 at\%Ni at P (O2) =5x10-4 torr and T=500-700°C. The initial oxidation behavior is similar to that of Cu (001) AND CuAu (001), where oxide islands rapidly nucleate, grow and coalesce. However, remarkable differences exist: 1) a second rapid nucleation of compact and dense oxide islands occurred and 2) polycrystalline oxides formed, where only cube-on-cube epitaxial Cu2O islands nucleated on Cu (001) and CuAu (001) for all temperature and pressures studied. The surface segregation behavior of Cu and Ni may explain these surprising results.

K1.00036 Creation and Characterization of Gold Coated Slides with a Home Built Deposition Chamber, NATE RIEDERS, ADELE POYNOT, Allegheny College — I discuss the creation of gold slides as part of a physics senior thesis at Allegheny College. The device used for making the gold slides was constructed as part of this project. Gold wire was placed in an evacuated chamber along with an array of glass slides. The gold wire is heated and evaporated onto the glass slides, leaving a thin deposition layer. The gold slides are created for the study of hydrophobic materials using surface plasmon resonance (SPR). The use of SPR as the experimental method requires the thickness of the gold layer to be precisely determined. Thus, the thickness of the gold slides is characterized using scanning tunneling microscopy.

K1.00037 Surface Layer Availability Approach to Systems with Solid-Fluid Surfaces, ROBERT CAMMARATA, Johns Hopkins University — Although the dividing surface method as devised by Gibbs can be used to completely describe the surfaces of fluid systems, in the case of fluid-solid interfaces with a finite size crystal the approach is generally restricted to systems where the solid is a single phase material. This is a result of the fact that the surface chemical potential of the solid component is not well-defined. As a result, Gibbs chose a dividing surface location where the surface excess amount of that component is zero so that the corresponding surface chemical potential was never needed. However this approach cannot be extended to systems containing multicomponent solids. It is proposed that for such systems a surface availability function, analogous to the thermodynamic availability function used in engineering thermodynamics, can be employed. It will be shown that such an approach can be used without the need of a particular dividing surface location, and that more generally the dividing surface construction can be dispensed with in favor of a finite volume surface layer. It is shown that by using this surface layer formulation a variety of problems, including surface adsorption and nucleation during solidification, can be rigorously treated for multicomponent systems.

K1.00038 Dielectric function trajectory of ultrathin gold films, XUEFENG WANG, DAVID NOLTE, Purdue University — There have been attempts to study the complex refractive index \(n_0\) of gold films by ellipsometry, but the measurements become unreliable when the average film thickness is below several nanometers, presumably because of optical anisotropy of the thin film. Here, we apply interferometric picoellometry to measure \(n_0\) by analyzing the Fourier-domain anisotropic diffraction of a normal-incidence scanning Gaussian laser beam reflected by a stripe-patterned gold film. The \(n_0\) and dielectric constant \(\varepsilon_g\) of the gold film were measured for thicknesses ranging continuously from 0.1 nm to 10 nm at a wavelength of 488 nm. Three distinct regimes of the \(\varepsilon_g\) trajectory on the complex plane were observed as the gold thickness increased. The first regime (gold thickness: 0.1 nm ~ 0.7 nm) reveals an evolution from sparse clusters to dense clusters. The real part of \(\varepsilon_g\) changes from 2.3 to 7.0 and the imaginary part changes from 0 to 0.7. The Maxwell-Garnett equation is applied for this regime by treating the film as an effective medium consisting of air and gold clusters. The second regime (0.7 nm~ 2 nm) is a linear curve of \(\varepsilon_g\) suggesting a transition from isolated clusters into a continuous thin film. The third regime (2 nm ~ 10 nm) shows a circular trajectory of \(\varepsilon_g\) moving towards the bulk value, which can be interpreted by the Drude equation.

K1.00039 The Variational Calculation for Small Cylindrical Metallic Cluster, CHIN-SHENG WU, Yuan Ze University — We use the Hohenberg-Kohn principle to calculate the density of the surface electronic charge around small cylindrical metallic cluster. The surface potential is varied in order to get the minimum total energy, which is the summation of electro-static energy and exchange-correlation energy. We use the availability function used in engineering thermodynamics, can be employed. It will be shown that such an approach can be used without the need of a particular dividing surface location, and that more generally the dividing surface construction can be dispensed with in favor of a finite volume surface layer. It is shown that by using this surface layer formulation a variety of problems, including surface adsorption and nucleation during solidification, can be rigorously treated for multicomponent systems.

K1.00039 The Variational Calculation for Small Cylindrical Metallic Cluster, CHIN-SHENG WU, Yuan Ze University — We use the Hohenberg-Kohn principle to calculate the density of the surface electronic charge around small cylindrical metallic cluster. The surface potential is varied in order to get the minimum total energy, which is the summation of electro-static energy and exchange-correlation energy. We use the local approximation for the inhomogeneous dielectric function around the surface. Therefore this surface charge can be applied to find dielectric constant, which is a function of the electron density. The dielectric constants are calculated on the cylindrical surface for various metal densities.
K1.00040 A Green Hydrothermal Synthesis for Iron-Doped, Carbon-Coated Tellurium Nanostructures and an Analysis of the Effects of the Molecular Weight and Ratio of Poly(vinylpyrrolidone) on Nanostructure Morphology¹, T. MULLIGER, Clemson University, S. MISHRA, The University of Memphis, S. GUHA, University of Missouri — A poly(vinylpyrrolidone) (PVP)-assisted hydrothermal process was used to synthesize tellurium nanostructures, as well as carbon-coated tellurium nanostructures (Te@C) in the presence of glucose as a carbon source. The thickness of ultra-thin tellurium nanostructures in the presence of PVP was found to depend upon the molecular weight of the polymer, as well as the ratio of polymer to tellurium source (Na2TeO3) used as starting materials. Structures ranging from 3-15nm were synthesized using four different molecular weights of PVP polymer (10,000; 29,000; 40,000; and 55,000) as well as different ratios of polymer to sodium tellurite, and their difference are compared. Varying the reaction time of the carbon-coating hydrothermal process yielded carbon-shell thickness ranging 20-60nm. As-prepared Te@C nanostructures were decorated with iron nanoparticles through an ultrasonication process at 70°C. Under a flow of Ar, hollow carbon nanostructures were also synthesized through a mild chemical treatment process at room temperature. Samples were extensively characterized using transmission electron microscopy (TEM), scanning electron microscopy and energy dispersive x-ray analysis (SEM/EDAX), ultraviolet visible, and PL.

¹Authors like to thank RC, PRF, and REU for the support of this project.

K1.00041 Polymer Assisted Core-shell Ag-C nanoparticles Synthesis via Green hydrothermal Technique, JAMES WILLIAMS, SANJAY MISHRA, The University of Memphis, Memphis, TN — Core-Shell Ag-C nanoparticles were synthesized in the presence of glucose through a one-pot green hydrothermal wet chemical process. An aqueous solution of glucose and Ag nitrate was hydrothermally treated to produce porous carbonaceous shell over silver core nanoparticles. The growth of carbon shells was regulated by either of the polymers (poly) vinyl pyrrolidone (PVP) or poly vinyl alcohol (PVA). The two polymers were compared to take a measure of different tunable sizes of cores, and shells. The effects of hydrothermal temperature, time, and concentration of reagents on the final formation of nanostructures were studied using UV-vis extinction spectra, transmission electron microscope, and Raman spectroscopy. The polymer molecules were found to be incorporated into carbonaceous shell. The resulting opacity of the shell was found to be hydrothermal time and temperature dependent. The shell structure was found to be more uniform with PVP than PVA. Furthermore, the polymer concentration was found to influence size and shape of the core-silver particles as well. The core-shellled nanoparticles have surfaces with organic groups capable of assembling with different reagents that could be useful in drug-delivery, optical nanodevices or biochemistry.

K1.00042 Growth Mechanism Study of Carbon Nanospheres Synthesized using Green Hydrothermal Technique, M. DOORLEY, Southwest Community College, Memphis, TN, S.R. MISHRA, M. MARADJI, S.K. KARNA, The University of Memphis, Memphis, TN, N. DUBENKO, N. ALI, Southern Illinois University, Carbondale, IL, E. GUNAPALA, K. MARASINGHE, University of North Dakota, Grandforks, ND — FeNi nanoparticles (NP) in the size range of 50 to 250 nm were synthesized via a wet chemical method. The precursor, sulfate salts of iron and nickel were reduced in alkaline media and in the presence of either polymers PEG (200-20,000 MW) or PVP (10,000 to 55,000 MW). The synthesis process was studied to understand the role of polymers in the growth of NP. TEM and XRD studies show formation of highly crystalline and well dispersed FeNi NP in polymer matrix. A decrease in particle size with an increase in PVP MW and increase in particle size with increase in PEG MW was observed. Furthermore, increase in PVP concentration leads to increase in particle size while increase in PEG concentration did not affect the particle size. Low temperature ZFC magnetization study show decrease in saturation magnetization value with the increase in polymer MW. It is concluded that the polymer mediated growth of FeNi NP involved 1) the formation of coordinative bonds between polymer and metal ions, 2) polymer-promoted nucleation, which produce small FeNi nanoparticles, and 3) steric shielding of the FeNi nanoparticles surfaces through chemical bonding to polymer which inhibited particle-particle contact and, thus the agglomeration of NP.

K1.00043 Polymer assisted synthesis of FeNi nanoparticles, S.K. KARNA, S.R. MISHRA, The University of Memphis, Memphis, TN, I. DUBENKO, N. ALI, Southern Illinois University, Carbondale, IL, E. GUNAPALA, K. MARASINGHE, University of North Dakota, Grandforks, ND — FeNi nanoparticles (NP) in the size range of 50 to 250 nm were synthesized via a wet chemical method. The precursor, sulfate salts of iron and nickel were reduced in alkaline media and in the presence of either polymers PEG (200-20,000 MW) or PVP (10,000 to 55,000 MW). The synthesis process was studied to understand the role of polymers in the growth of NP. TEM and XRD studies show formation of highly crystalline and well dispersed FeNi NP in polymer matrix. A decrease in particle size with an increase in PVP MW and increase in particle size with increase in PEG MW was observed. Furthermore, increase in PVP concentration leads to increase in particle size while increase in PEG concentration did not affect the particle size. Low temperature ZFC magnetization study show decrease in saturation magnetization value with the increase in polymer MW. It is concluded that the polymer mediated growth of FeNi NP involved 1) the formation of coordinative bonds between polymer and metal ions, 2) polymer-promoted nucleation, which produce small FeNi nanoparticles, and 3) steric shielding of the FeNi nanoparticles surfaces through chemical bonding to polymer which inhibited particle-particle contact and, thus the agglomeration of NP.

K1.00044 Adiabatic Electron-Phonon Coupling in the A15 Compounds V3Si, V3Ge and V3Co, OLIVIER DELAIRE, M. LUCAS, ORNL, M. KRESCH, B. FULTZ, Caltech — The phonon density of states (DOS) of the A15 compounds V3Si, V3Ge, and V3Co was measured as a function of temperature between 10K and 1273K with inelastic neutron scattering. The temperature dependence of the phonon DOS strongly departs from the predictions of the quasiharmonic model in the superconducting compounds V3Si and V3Ge, but behaves more normally in the non-superconducting V3Co. Using first-principles electronic structure calculations, the observed anomalies are related to the details of the band structure in these compounds. It is shown that sharp features in proximity to the Fermi level lead to anomalous phonons through a sensitivity to thermal disorder, or adiabatic electron-phonon coupling. In the case of V3Co, the sharp peak in the electronic DOS leads to a stiffening of the phonons with increasing temperature. It is shown that V3Si and V3Ge, a sharp peak in the electronic DOS leads to a stiffening of the phonons with increasing temperature. These results are compared to recent measurements of the phonon DOS and its temperature dependence in the B20 compounds Fe(1-x)Co(x)-Si.

K1.00045 Impurity Studies in CeCoIn5, ABBEKE KEBEDE, NC A&T State University, TERELL DIAL, NC A&T State University, NHHPL-LOS ALAMOS COLLABORATION — Systematic alloy studies of CeTIn5 (T = Co, Rh, Ir) reveal the stability of superconductivity in a wide range of composition; and in some cases it coexists with a magnetically ordered phase. We extended these studies to include (R, Ce)(Co,M)n; are (R= Pr and M= Fe, Mn). Our preliminary measurements indicate that the samples are single phase, and they exhibiting a wide range of transport and magnetic properties. In this communication we present the results of our resistivity and magnetic susceptibility measurements.

K1.00046 The 0.7 anomalous conductance¹, D. SCHMELTZER, Ccny-Cuny, A. KUKLOV, Csi-Cuny — At low electronic densities and finite temperatures the method of one dimensional Bosonization is not applicable. We introduce the zero modes method to incorporate Fermi Dirac Statistics. We compute the conductance at finite temperatures in the presence of long range Coulomb and biased umklapp interactions. We show that the 0.7 conductance anomaly appears at low densities when the Fermi energy and the temperature are of the same order of magnitude.

¹Ccny Collaborative grant -2007-2008
K1.00047 Quantum critical fluctuations in the itinerant antiferromagnet Nd$_2$O$_2$$_{29}$. JINGUANG CHENG, JIANSHI ZHOU, JOHN GOODENOUGH. TMI. University of Texas at Austin, HAIDONG ZHOU, NMHFL, Florida State University — Monoclinic Nd$_2$O$_2$$_{29}$ is a metallic antiferromagnet with $T_N \approx 12$ K. [1] We have studied critical behaviors near $T_N$ by measuring the resistivity ($\rho$), specific heat ($C_p$), and thermoelectric power ($S$). As $T_N$ is approached from $T_N^-$, critical behaviors used in ferromagnetic metals, $\rho/dT = (\alpha/\alpha)(T)-\beta + c^1 T + c^2 T$ provide the best description for $\rho/dT$ and $C_p$, respectively. We found an identical $\alpha \approx 0.2(2)$ in both $\rho/dT$ and $C_p$, as predicted by Fisher and Langer in a ferromagnetic metal. [2] These observations indicate strong critical scattering of conduction electrons by short-range spin fluctuations near $T_N$. In addition, the $S$ is strongly enhanced at low temperatures. The temperature dependence of $S$ above $T_N$ follows closely the formula $S/T \propto -lnT$, which suggests that quantum critical fluctuations [3] plays a role in enhancing the thermoelectric power on top of the classic critical fluctuations.

K1.00048 The Superconducting Phase Diagram of V3Si0.98X0.02, X=Ni, Mn, Co, Fe, Cu. M.D. ALMEIDA, C.P. OPEIL, Boston College, J.C. LASHLEY, J.L. SMITH, Los Alamos National Laboratory — We report on the results of AC Resistivity measurements of V$_{3}$(Si$_{0.98}$X$_{0.02}$) in the presence of a magnetic field, where the dopants include Ni, Fe, Mn, Co, and Cu. From this we see a clear shift in the superconducting critical temperature of the materials in response to increasing in field strength. Additionally, diammetry measurements provide information on the thermal expansion coefficients of these materials.

K1.00050 DFT Calculation of the Electronic Properties and EEL Spectrum of NiSi$_2$$^1$. ROBERTO NUÑEZ-GONZÁLEZ, Departamento de Matematicas, Universidad de Sonora, ARMANDO REYES-SERRATO, DONALD H. GALVAN, Centro de Nanociencias y Nanotecnologia, UNAM, ALVARO POSADA-AMARILLAS, Departamento de Investigacion en Fisica, Universidad de Sonora — In this work we present theoretical band structure, total and projected density of states (DOS), dielectric function and electron energy-loss spectrum (EELS) of NiSi$_2$. The calculations were carried out using the Full-Potential Linearized Augmented Plane Waves (FLAPW) method, within the Density Functional Theory (DFT) with the Local Density Approximation (LDA). Our theoretical EELS results are in excellent agreement with recent experimental findings, indicating that the main peak corresponds to a plasmon. Additional peaks in our calculations are identified as interband transitions (at 2.67 eV, 4.77 eV and 6.1 eV) associated to transitions between Ni d to Si p states, and low magnitude plasmons (at 1.3 eV and 4.02 eV).

$^1$APA acknowledges CONACYT-Mexico for financial support through project 24060. ARS is grateful to CONACYT Project 52927 and UNAM-PAPIIT IN107508.

K1.00051 Using Image Processing Techniques for Cluster Analysis, and Droplet Formation in Phase Separating Fluids. GREGORY SMITH, ANA OPRISAN, College of Charleston, JOHN HEGSETH, University of New Orleans, SORINEL OPRISAN, College of Charleston, CAROLE LECOUTRE, YVES GARRABOS, DANIEL BEYSENS, University of Bordeaux, France, COLLEGE OF CHARLESTON TEAM, UNIVERSITY OF NEW ORLEANS COLLABORATION, UNIVERSITY OF BORDEAUX COLLABORATION — A series of experiments in Phase Separating Fluids

K1.00052 Insights on copper coordination and reactivity of endonuclease EcoRI by ESR spectroscopy and modeling. MING JI — The cleavage of DNA by restriction endonuclease EcoRI is catalyzed by metal ions such as Mg$^{2+}$. However, Cu$^{2+}$ does not catalyze the cleavage of DNA by EcoRI. In order to understand the functional difference between Cu$^{2+}$ and Mg$^{2+}$ coordination of Cu$^{2+}$ in the EcoRI-DNA complex was clarified by ESR and MD simulation. There are two Cu$^{2+}$ components in the specific EcoRI-DNA complex. Each component has one N atom from histidine imidazole and one oxygen atom from the phosphate backbone of DNA coordinate to Cu$^{2+}$ based on the ESR experimental results. MD simulation further confirmed that the Ni atom of His114 imidazole and one oxygen atom from the phosphate backbone of DNA coordinate to Cu$^{2+}$. Difference in the coordination of Cu$^{2+}$ and Mg$^{2+}$ explains their different functional behaviors.

K1.00053 Twist Defect in an Imprinted Cholesteric Elastomer$^1$. PAOLA CASTRO-GARAY. Departamento de Investigación en Física, Universidad de Sonora, Hermosillo, México, JUAN ADRIAN REYES, Departamento de Física Química, Instituto de Física, Universidad Nacional Autónoma de México, D.F, México, ADALBERTO CORELLA-MADUEÑO, Departamento de Física, Universidad de Sonora, Hermosillo, Son., México — We have found that a chiral twist defect inserted in a cholesteric elastomer gives rise to circularly polarized localized modes of both handedness. This defect enhances the resonance mode amplitude whose handedness is opposite to the cholesteric helix for high cross-linked density. Complementarily, for low cross-linked density, the circular polarization opposite to helix cholesteric of the elastomer is decoupled with the defect mode so that the resonance mode disappears. Finally, the resonance mode of the circularly polarization of the same handedness to elastomer helix is maintained either, for high or low cross-linked density.

$^1$P. Castro-Garay acknowledges the support form CONACYT.
Meso-scale Harmonic Analysis of Homogenous Dislocation Nucleation. ASAD HASAN, CRAIG MALONEY, Carnegie Mellon University — Under sufficiently high load dislocations will be nucleated in perfect crystals. A typical scenario is the nano-indentation of a defect-free metal. An outstanding issue is the prediction of where and under what loads nucleation will occur. Many criteria have been put forward which address this question, some in terms of the local stress field, others in terms of the local tangent stiffness of the material. More recently it has been questioned whether a local criterion can be used at all [1]. We address the locality of the nucleation process via analysis of molecular dynamics simulations in terms of the vibrational eigenmodes of the mesoscale regions of the crystal for various model systems. [1] R.E. Miller and D. Rodney, J. Mech. Phys. Solids 56(4) 1203-1223, 2008.

MAGNETISM: OXIDES AND NANOSTRUCTURES —

The origin of the double-triangle hysteresis loops in ErFeO₃ near the low temperature erbium ordering transition L.T. TSYMBAŁ, O. Galkin Donetsk Physics & Technology Institute, YA. B. BAZALIY, University of South Carolina and Institute of Magnetism, Kyiv Ukraine, G.N. KAKAZEI, Universidade do Porto, Porto, Portugal and Institute of Magnetism, Kyiv Ukraine — Magnetic properties of an orthoferrite ErFeO₃ are determined by the iron and the rare-earth magnetic ions. Interactions between magnetic sub-systems of ErFeO₃ lead to a sequence of orientation phase transitions observed in this material. In this work hysteresis loops in single crystal ErFeO₃ samples were studied below the spin-rotation transition region, T < 80 K. Above and around the compensation point Tcomp = 46 K the hysteresis loops are rectangular, with the coercive force diverging at Tcomp. As the temperature is lowered towards the erbium ordering transition Tₓₓᵧᵧ = 4.1 K, the shape of the loops experiences a dramatic change. At 20 K the loops develop triangular “tails.” At 10 K the triangles become prominent while the central rectangular part near H = 0 collapses. A double-loop hysteresis pattern with two triangular loops emerges. We explain this behavior by a domain wall motion reversal mechanism with negligible pinning of the walls in the sample. The transition from the rectangular to the double-triangle loops is due to the competition between the energy barrier of wall nucleation and the demagnetization energy gain achieved by placing the wall inside the sample. Our model explains well the correlation of the loop’s shapes and sizes with the total magnetization of ErFeO₃.

Impact of transition metal buffer layers on Magnetite thin film growth and properties1, PRIYANGA JAYATHILAKA, DARYL WILLIAMS, CHRIS BAUER, DUSTIN BELJEY, CASEY MILLER, University of South Florida, Department of Physics — Magnetite thin films were grown on MgO single crystals with 3nm buffer layers of Fe, Cr, Mo, and Nb. An in situ masking system allowed the deposition of the individual buffer layers on separate substrates, followed by the simultaneous growth of 100nm thick magnetite films on all substrates via reactive sputtering. We are thus able to demonstrate the impact of the resulting lattice strain on the magnetite films’ structure, and temperature dependent resistivity and magnetization.

Origin of multiferroicity in hexagonal Y₁₋ₓDyₓMnO₃, A.K. SINGH, School of Physical Sciences, Jawaharlal Nehru University, New Delhi-110067 India, S.D. KAUSHIK, V. SRIRUGURI, UGC-DAE-CSR Mumbai Centre, Bhabha Atomic Research Centre, Mumbai 400085, India, S. PATNAIK, School of Physical Sciences, Jawaharlal Nehru University, New Delhi-110067 India — Multiferroic materials, that offer the possibility of manipulating an ordered electric state by applying magnetic field, have attracted considerable attention in the recent past. Here we report a detailed analysis of structural, magnetic and dielectric properties of polycrystalline samples of Y₁₋ₓDyₓMnO₃ (0 ≤ x ≤ 0.2). These materials belong to space group P6₃mc with hexagonal crystal structure and were synthesized by solid state reaction method. We have carried out extensive zero field and in-field neutron diffraction, and dielectric measurements. Our study provides evidence for change in the lattice parameters, buckling of Y (Dy) layers, Mn-O-Mn bond angles and tilting of MnO₆ polyhedra as a function of temperature and magnetic field. We also study the magnetoelectric coupling in YMnO₃ as well as doped samples by in-field dielectric measurements. A distinct anomaly near Néel temperature is observed in these measurements that vary with the application of magnetic field. In essence, we develop a model to understand the magnetoelectric coupling of these antiferromagnetic multiferroics with their field dependent magnetic structure.

Anomalous magnetic transition in multiferroic BiMnO₃ under high pressure, CHIH CHIEH CHOU, S. TARAN, J.L. HER, C.P. SUN, C.L. HUANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, H. SAKURAI, A.A. BELIK, E. TAKAYAMA-MUROMACHI, Advanced Nano Materials Laboratory (ANML), National Institute for Materials Science (NIMS), 1-1 Namiki, Tsukuba, Ibaraki 305-0044, Japan, H.D. YANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan — The magnetic-field-dependent dc magnetization and the pressure-dependent (pmax ~ 16 kbar) ac susceptibilities χp(T) on both powder and bulk multiferroic BiMnO₃ samples, synthesized in different batches under high pressure, are reported. The ferromagnetic (FM) transition (Tc ~ 100 K) increases with higher magnetic field. The magnetic hysteresis shows the behavior as a soft ferromagnet. Ac susceptibility data indicate the following phenomena. (I) The FM peak (peak I) and its temperature (Tc) decrease simultaneously with increasing pressure. (II) Above a certain pressure (9 -11 kbar), another peak (peak II) appears at (Tc ~ 93 K). (III) Peak II also decreases with increasing pressure. (IV) Both these peaks persist over some intermediate pressure range (9-13 kbar). (V) Peak I disappears with further application of pressure; however, the second peak survives until present pressure limit (pmax ~ 16 kbar). These features are considered to originate from the complex interplay of the magnetic and orbital structure of BiMnO₃ being affected by pressure.

Magnetic frustration and spin glass behaviour in layered lithium oxide, LiNi₀.₆₅Co₀.₂₅Mn₁₀O₂, MAGNUS WIKBERG, PETER SVEDE LINDB, Dep. Eng. Sciences, Uppsala University, MOHAMMED DAHBI, ISMAEL SAADOUNE, ECME, LP2E2M, FST Marrakech, University Cadi Ayyad, PORTBORG JÖNS GUSTAFSSON, KRISTINA EDSTROM, Dep. of Materials Chemistry, Uppsala University — Samples of LiNi₀.₆₅Co₀.₂₅Mn₁₀O₂ with different amount of Li (x) have been investigated with ac and dc SQUID magnetometry, X-ray diffraction as well as with neutron scattering. The LiₓNi₀.₆₅Co₀.₂₅Mn₁₀O₂ exhibit a rhombohedral structure (space-group Rh3m) with non-magnetic Li⁺ layers alternating with transition metal (TM) slabs with edge-sharing oxygen octahedras. The nickel slabs contain several intralayer interactions of both antiferromagnetic (AFM), ferromagnetic (FM) type, e.g. 90° Ni₂⁺⁻Mn⁺⁺ and 90° Ni⁺⁻Ni⁺⁻, respectively. Also, the presence of Ni²⁺ in the Li-plane further induces AFM and FM couplings due to 180° superexchange interactions between Ni²⁺ ions in the Li-plane and TM⁺ ions present in the slabs. The resulting magnetic structure shows no evidence of long range order due to a high degree of spin frustration, thus yielding magnet properties reminiscent of a spin glass.

Spin and charge orderings in single layered cobaltate Laₓ−₁CaₓCoO₄ (0.3 < x < 0.8), KAZUMASA HORIGANE, HARUHIRO HIRAKA, TORU UCHIDA, KAZUYOSHI YAMADA, JUN AKIMITSU — Neutron scattering experiments were performed on single crystals of layered cobalt-oxides Laₓ−₁CaₓCoO₄ (LCCO) to characterize the charge and spin order in a wide hole-doping range of 0.35 ≤ x ≤ 0.8. For a commensurate value of x = 0.5 in (H,0,L) plane, two types of superlattice reflections concomitantly appear at low temperature; one corresponds to a checkerboard charge ordered pattern of Co²⁺/⁺ ions and the other is magnetic in origin. Further, the latter magnetic-superlattice peaks show two types of symmetry in the reflections, suggesting antiferromagnetic-stacking (AF-S) and ferromagnetic-stacking (F-S) patterns of spins along the c direction. From the hole-doping dependence, the in-plane correlation lengths of both charge and spin orders are found to give a maximum at x = 0.5. These features are the same with those of x = 0.5 in Laₓ−₁Srₓ+₁MnO₄ (LSMO), a typical checkerboard and spin ordered compound.
K1.00062 Electronegativity and Valence Electron Spectrum of Room Temperature Ferromagnets\(^1\) O. PAUL, ISIKAKU-IRONKWE, The Center for Superconductivity Technologies, Abuja FCT, Nigeria — Materials that exhibit room temperature ferromagnetism (RTFM) are of interest in the fabrication of spintronic devices. RTFM has been observed in semiconductors, oxides and other non-magnetic materials and nanocrystals. There is yet no consensus on the origin of RTFM or how to predict the next RTFM. Here we study the electronegativity and valence electron count of known RTFMs as a step to understanding this fascinating family of materials. Understanding the process of RTFM may aid the search for *room temperature superconductivity* (RTS) — a similar phenomenon.

\(^1\)Research support from ISEM, University of Wollongong, New South Wales 2522, Australia.

K1.00063 Molecular nanomagnets for information technologies\(^1\) MARCO AFFRONTI, CNR-INFN-S3 — I have recently reviewed challenges, achievements and perspectives in the field of molecular magnets in a review article in J. of Mat. Ch. DOI: 10.1039/b809251f (2008) focusing on quantum information. Molecular magnets are indeed quantum objects, with well-defined spin states at low temperature. The challenge is to obtain scalable quantum hardware with long coherence time. A paradigmatic case is that of AF rings in which an extra spin was introduced to have a S=1/2 as ground state (Phys. Rev. Lett. 94, 190501 (2005) and use excited states as a resource for implementing two-qubit gates (Phys. Rev. Lett. 94, 190501 (2005), Phys. Rev. B 76, 024408 (2007)). The mechanism of decoherence can be studied in details by considering hyperfine interactions with finite number of nuclear spins (Physical Review B 77, 054428 (2008). Cr7NI are stable in solution, can be functionalized to be grafted on surface (Inor. Chem. 46, 4968-4978 (2007) or to be linked each other by forming supramolecular complexes (Angew. Chem Int. Ed. 44, 6496 (2005) and Nature Nanotechnology 2008) with tuneable entanglement of spin states.

K1.00064 Correlation effects on the properties of small cobalt clusters\(^1\) YVETTE HANCOCK, MARI IJÄS, Department of Engineering Physics, Helsinki University of Technology, Finland — Demands for higher-density magnetic storage media and smaller memory devices require atomic-scale magnetic components with stable magnetic properties. One such candidate for this application is a small transition metal cluster. The magnetic properties of transition metal clusters are often strongly sensitive to the geometry of the cluster, the local atomic and structural environments, and to the system size. In this work, the GGA + U DFT method is used for the first time to study the system properties of small cobalt clusters consisting of 2 to 5 atoms. Previous studies using DFT and tight-binding approaches have been found to overestimate the binding energies, dissociation energies and vibrational frequencies of the clusters against their known experimental values. By including a Hubbard U correction between 2 – 3 eV, the DFT method can then be fitted to reproduce the experimental results, thereby improving upon previous theoretical descriptions of these systems. The effect of U on the calculated magnetic and structural properties of the clusters is also discussed.

K1.00065 Temperature and size dependence of electron magnetic resonance spectra of Ni nanoparticles chemically dispersed in silica\(^1\) VIVEK SINGH, MOHINDAR SEEHRA, West Virginia University — The temperature dependence (5K to 300K) of the electron magnetic resonance (EMR) lines observed at 9.28 GHz in Ni:SiO\(_2\) (15:85) nanocomposites with mean diameter D of the Ni nanoparticles (NPs) of D=3.8, 11.7, 15 and 21 nm are reported. The sizes of the Ni NPs were determined by TEM and XRD, with SiO\(_2\) being in the amorphous state. The procedures for the synthesis of the samples along with their DC and AC magnetization behavior were reported recently [1]. In EMR, three resonance lines are observed: (i) Line 1 with linewidth \(\Delta H \approx 50\) Oe and \(g \approx 2\), and Curie-like variation of the line-intensity, with \(\Delta H \approx H\) being temperature and size-independent; (ii) Line 2 with \(\Delta H \approx 950\) Oe and \(g \approx 2.2\) for \(D=3.8\)nm at 300K with both \(\Delta H\) and \(g\) increasing with decreasing \(T\) and \(\Delta H\) size-dependent; and (iii) weak line 3 with \(g \sim 4\) at 300K, with \(g\) also increasing with decreasing \(T\). We argue that the line 1 is due to dangling bonds in SiO\(_2\) as a similar line with \(\Delta H \approx 9\) Oe is also observed in SiO\(_2\) without Ni doping. Lines 2 and 3 are attributed to magnetic Ni NPs and large Ni clusters respectively whose anisotropy is both size and temperature-dependent [2], leading to the observed \(\Delta H\) and \(g\) values of the lines.

K1.00066 Synthesis and Characterization of Gd and Nd Nanoparticles\(^1\) DULCE G. ROMERO, PEI-CHUN HO, Department of Physics, Cal. State U., Fresno, SAEED ATTAR, Department of Chemistry, Cal. State U., Fresno — Due to the reduced dimensionality, nano-sized materials have physical properties significantly different from the bulk material, such as, superparamagnetic behavior, enhanced magnetization, and self-organization [1-3]. Nano-sized materials have great potential for technical applications, for example, magnetic information storage, imaging, medical devices, and magnetic refrigeration. In this report, we will present the growth and filtration of rare-earth Gd and Nd nanoparticles by the inverse micelle technique [4]. The results of the characterization of these clusters by X-ray diffraction, scanning electron microscope, and energy-dispersive x-ray spectroscopy will be presented.

K1.00067 Development of ferromagnetism in Pd nanoparticles with reduction in size\(^1\) MOHINDAR SEEHRA, JAMES RALL, West Virginia University, J. LIU, C. ROBERTS, Auburn University — Bulk fcc Pd is a paramagnet just missing the Stoner criterion for ferromagnetism (\(N(E_F)\| > 1\)) [1]. Several groups have reported weak ferromagnetism in 2-4 nm Pd nanoparticles (NPs) [2]. We report systematic development of weak ferromagnetism in Pd NPs with reduction in size. Magnetic measurements (\(M vs. T\)) are compared for bulk Pd with those of size \(D\) \(\approx 50, 70, 80\) and 60 nm. The samples of size \(D=7, 6, 5, 4, 3, 2, 1, 0\) and 6 mm were prepared by an aqueous seed-mediated growth and characterized by TEM and x-ray diffraction with the latter showing expansion of the lattice with decrease in size. Compared with the low-field magnetic susceptibility of bulk Pd, the 7 and 6 nm NPs are enhanced by an order of magnitude. For the 50 nm NPs, \(\chi\) follows nearly the Curie law. The hysteresis loops (\(M vs. H\)) for the 7 and 6 nm NPs shows a decrease in coercivity and remanence from 3K to 300K suggesting \(\Delta H > 300K\). Origin of this ferromagnetism in terms of surface magnetism and lattice expansion is discussed.

\(^1\)Research is supported by Fresno State start-up fund.

K1.00068 Mössbauer and magnetic studies of \((\text{Ni}_{0.6-x}\text{Co}_x)\text{Zn}_{0.4}\text{Fe}_2\text{O}_4\) nanoparticles\(^1\) J.C. HO, Wichita State University, M.M. EL-TABEY, Menoufia University, H.H. HAMDEH, R. ASMATULU, Wichita State University, S.H. WU, Y.Y. CHEN, Academia Sinica Mixed-ferrites (\(\text{Ni}_{0.6-x}\text{Co}_x)\text{Zn}_{0.4}\text{Fe}_2\text{O}_4\) with \(x = 0, 0.1, 0.2, 0.3, 0.4, 0.5\) and 0.6 were synthesized by co-precipitation of Ni-, Co-, Zn- and Fe-sulfates. Structural characterization of the approximately 10-nm particles was made by x-ray powder diffraction. Through Mössbauer spectroscopic measurements, the composition- and temperature-dependence of magnetic blocking temperature and anisotropic constant were obtained. SQUID data yielded corroborative results, in addition to magnetization and saturation values.
K1.00069 Effect of Anisotropy in Two-dimensional Dimer model of magnetic ferrofluids1. ABDALLA OBEIDAT, WESAM AL-SHARO, Jordan University of Science and Technology — The magnetization and the Initial susceptibility have been calculated using statistical mechanics for two-dimensional structured dilute ferro-fluid taking the effect of the magnetic anisotropy and inter-particle interaction. We assumed the assembly consists of N/2 non-interacting systems. Each system is composed of 2 interacting single domain fine magnetic spherical particles. We referred to this model as a Dimer-model. We found that when the easy axis is fixed with respect to the external magnetic field, the ordering temperature depend on the anisotropy constant K in both parallel and perpendicular cases.

1Jordan University of Science and Technology

K1.00070 Magnetic Nanoparticle Arrays prepared via Coaxial Electrospinning, NIKHIL SHARMA, HASSNAIN JAFFARI, ISMAT SHAH, DARRIN POCHAN, University of Delaware — One dimensional nanoparticle (1D NP) arrays display strong anisotropy in their physical properties making them interesting from a fundamental as well as applications perspective. 1D arrays of Fe3O4 nanoparticles have been constructed by encapsulating magnetite nanoparticles within Poly(ethylene oxide) nanofibers, by a modified solution spinning process. Electrospinning is a facile process for creating 1D nanostructures and a simple modification to the process renders a coaxial delivery mechanism that facilitates the construction of nanoparticle arrays. These hybrid 1D nanomaterials were structurally characterized by electron microscopy and the magnetic characteristics of these fiber encapsulated particle arrays were studied using vibrating sample magnetometry. Anisotropic magnetic behavior along different orthogonal axes (parallel and perpendicular) was observed even at room temperature with an appreciable increase in coercivity in the perpendicular configuration. Experimental work is underway to use these particle arrays as precursor materials for the creation of magnetite nanorods.

K1.00071 Initiating magnetization switching in computational Fe nanopillars via local heating, SAM THOMPSON, GREG BROWN, Florida State University, MARK NOVOTNY, Mississippi State University, PER RIKVOLD, Florida State University — The use of high-coercivity materials in recording media assists in extending the areal information density by allowing smaller, more closely spaced bits. To achieve densities greater than one terabit per square inch, however, the necessary coercivity of the particles challenges the maximum applied field that can be attained by the write head. One proposed technique to overcome this dilemma is heat-assisted magnetization reversal (HAMR), in which a locally applied heat pulse lowers the coercivity, allowing the applied field to initiate switching. To model this, we employ micromagnetic simulations of iron nanoparticles with thermal fluctuations that depend spatially and temporally on a solution of the heat equation corresponding to an initial heat pulse applied to the end of the pillar. For the case of an applied magnetic field parallel to the easy axis, the magnetization-switching behavior is explored as a function of total heat input and applied-field magnitude.

K1.00072 Fabrication of magnetic trilayer stripes using interference lithography, MENG ZHU, NIST, Gaithersburg, MD, 20899 / University of Maryland, College Park, MD, 20742, JAMES MACARTHUR, Swarthmore College, Swarthmore, PA, 19081, ROBERT MCMICHAEL, NIST, Gaithersburg, MD, 20899-8412 — Both theoretical (PRB, 74, 024424, 2006) and experimental (APL, 90, 232504, 2007) studies of a single layer magnetic film edge have shown that the edge-mode of magnetization precession detected by ferromagnetic resonance (FMR) is an effective tool to probe magnetic properties of thin film edges. To extend the measurement technique to realistic devices such as spin-valves or tunnel junctions, magnetic multilayer stripes have to be fabricated. Here, we present the fabrication of Py/Cu/Co magnetic trilayer stripes by interference lithography. A resist stack consisting of positive photoresist 1805 and WIDE-B anti-reflective coating (ARC) is exposed by a blue laser at 405nm using Lloyd’s mirror interferometer. Optimal soft-baking temperature of ARC results in an undercut during the development of the photoresist. This undercut facilitates the lift-off process after the evaporation of Py/Cu/Co trilayer. A uniform array of trilayer stripes with a period of ~620nm was obtained. This work has been supported in part by the NIST-CNST/UMD-NanoCenter Cooperative Agreement and NIST CNST-NSF REU #DMR-0754115.

K1.00073 Enhanced magneto-optical effect in two-dimensional spin photonic crystals, JINBAE KIM, WONCHANG NAM, NISHAD DESHPANDE, XINGRI JIN, MINSOO SEO, SUNG-JAE LEE, YOUNGPAK LEE, Hanyang University, Korea, JOOYULL RHEE, Sungkyunkwan University, Korea, KIWON KIM, Sungmoon University, Korea — Patterned arrays of magnetic nanostructures have become one of the key issues in recent years because of their potential application to the information technology which utilizes optical and magnetic storage devices. In this study, we have successfully fabricated two-dimensional patterned arrays of Co by using the photolithography and the wet-etching process. The magnetic anisotropy, the magnetic domain structures, and the magnetization reversal process are investigated by means of magnetic-force microscopy and magneto-optical Kerr effect. The in-plane magnetization reversal process could be understood through a detailed investigation the field-dependent magnetic domain structures. The magneto-optical response is measured for both reflected and diffracted beams, and compared with the results of micromagnetic simulation.

K1.00074 Fabrication and characterization of rectangular thin film planar loops for transformer applications, GREGORY A. TOPASNA, DANIELA M. TOPASNA, FRANK R. POWELL, Virginia Military Institute — This study focuses on optimizing the configuration and performance of a thin film planar loop that is flux linked to a short straight wire. Our calculations for the mutual inductance show its dependence on the geometry of the planar loop as well as on its location relative to the wire. We have fabricated and characterized various geometries and compared the data to the solutions predicted by our model. These results are used in designing the next generation of devices which will incorporate magnetic nanoparticles.

K1.00075 MAGNETISM: DYNAMICS AND TRANSPORT —

K1.00076 Laser-induced orbital and spin excitations in ferromagnets: Insights from a two-level system1, GUOPING ZHANG, Department of Physics, Indiana State University, Terre Haute, Indiana 47809, YIHUA BAI, Center for Instruction, Research and Teaching, Indiana State University, Terre Haute, Indiana — A recent element-specific and time-resolved measurement in Fe/Gd multilayers showed the laser-induced orbital and spin excitations proceed in unison and the spin-orbit ratio is held constant during the demagnetization. Here a two-level model shows that these orbital and spin excitations originate from state population and state interference effect. For an addressed state, spin and orbital dynamics are solely from the state interference, where the spin and orbital momenta oscillate with the laser frequency and match the dipole moment exactly, an unambiguous test case for time-resolved magneto-optical Kerr effect. For an undressed state, the inference effect introduces a rapid beating in orbital momentum, which is observed in the first-principles calculation in fcc Ni. The state population change leads to a constant spin-orbit ratio, which explains the linear dependence between spin and orbital momentum changes within 2 ps upon the arrival of pump pulse in ferromagnetic iron.

K1.00077 Origin of light-induced precession of magnetization in ferromagnetic (Ga,Mn)As. 
EVA ROZKOTOVA, PETR NEMEC, DANIEL SPRINZL, NADA TESAROVA, PETR MALY. Charles University in Prague, Ke Karlovu 3, 121 16 Prague 2, Czech Republic, VIT NOVAK, KAMIL OLEJNIK, JAN ZEMEN, MIROSLAV CUJKR, TOMAS JUNGWIRTH, Institute of Physics ASCR v.v.i., CuKovnická 10, 162 53 Prague, Czech Republic, JOERG WUNDERLICH, Hitachi Cambridge Laboratory, Cambridge CB3 0HE, United Kingdom — The impact of femtosecond laser pulse leads to the precession of magnetization in (Ga,Mn)As, which can be detected by the time-resolved Kerr rotation (KR) technique. Even though this phenomenon is known for several years [1], the exact physical mechanism inducing the precession is still not clear [2,3]. We show, by a detailed comparison of the KR experimental results and the microscopic calculations of the magnetic anisotropy, that the precession is a consequence of the anisotropy field modification due to the laser pulse-induced change of hole concentration and lattice temperature. [1] A. Oiwa, H. Takechi, H. Munekata. J. Supercond. 18, 9 (2005).[2] Y. Hashimoto, S. Kobayashi, H. Munekata, PRL 100, 067202 (2008).[3] E. Rozkotova, P. Nemec, P. Horodyiska, D. Sprinzel, F. Trojane, P. Maly, V. Novak, K. OleJNIK, M. CuK, T. Jungwirth, Appl. Phys. Lett. 92, 122507 (2008).

K1.00078 Longitudinal Field µSR Study of Spin Dynamics and Onset of Magnetic Correlations in LiY_{1-x}Ho_{x}F_{2} with 0.002 ≤ x ≤ 0.101. R.C. JOHNSON, K. CHEN, M.J. GRAF. Department of Physics, Boston College, Chestnut Hill, MA 02467 USA — The Ho^{3+} ions in LiY_{1-x}Ho_{x}F_{2} exhibit a crossover from single ion to spin glass behavior with increasing x. We have studied the longitudinal field depolarization rate for samples with 0.002 ≤ x ≤ 0.10 over the temperature range 50 mK ≤ x ≤ 50 K and for magnetic fields up to 0.1 T. For low concentrations, we find a peak in the temperature-dependent depolarization, as often observed in 1/T1 NMR measurements on single molecule magnets (SMM); at high concentrations the depolarization rate increases monotonically with decreasing temperature. These results suggest that the difference in behavior of SMMs systems as seen in NMR and µSR measurements may be due to differences in the strength of the interactions between the magnetic clusters.

1Supported by National Science Foundation grant DMR-0710525.

K1.00079 A $^{51}$V NMR Investigation of the Quasi-1D Antiferromagnet BaCo_{5}V_{2}O_{14}: Is there a New ordered Phase?. T. BESARA, Department of Chemistry, Florida State University, Tallahassee, FL, USA, L.L. LUMATA, Department of Physics, Florida State University, Tallahassee, FL, USA, K.-Y. CHOI, Department of Physics, Chung-Ang University, Seoul, Republic of Korea, A.P. REYES, P.L. KUHNS, National High Magnetic Field Laboratory, Tallahassee, FL, USA, N.S. DALAL, Department of Chemistry, Florida State University, Tallahassee, FL, USA, J.S. BROOKS, H.D. ZHOU, C.R. WIEBE, Department of Physics, Florida State University, Tallahassee, FL, USA — We report on detailed $^{51}$V (I=7/2) NMR spectral and spin-lattice relaxation time (T1) measurements on the quasi-1D antiferromagnet BaCo_{5}V_{2}O_{14}. Our major focus was on probing the possible existence of the new ordered state in its field-induced phase above the critical field H_{c}. This phase is believed to be of the incommensurate type, and thus quite amenable to investigation by NMR line shape and T1 measurements. T1 data were obtained using a spin-echo pulse sequence. Measurements were done on a single crystal, with the field parallel to the easy axis (c-axis). Details of the lineshape and T1 analysis in terms of the evolution of the anticipated new phase will be presented.

K1.00080 NMR and Spin Relaxation in Systems with Magnetic Nanoparticles: Effects of Size and Molecular Motion, NATALIA NOGINOVA, TRACEE WEAVER, NSU, Norfolk, VA, ALEXANDR ANDREYEV, Virginia Tech, Blacksburg, VA, VADIM A. ATSARKIN, IRE, Moscow, Russia — To better understand the specifics of nuclear magnetic resonance and spin relaxation in systems with magnetic nanoparticles and test the limits of the outer sphere model for the diffusion related relaxation, iron oxide nanoparticle suspensions were studied in the dependence of the particle size, and for different degree of molecular motion. For the liquid suspensions with relatively small particles or clusters, spin relaxation rates well correspond to the theory, which predict maximum and decrease of the longitudinal rate and increase in the transverse rate with the increase in the effective radius, R. For the larger particle size > 20 nm, as well as in cases of strong aggregation or slowdown of molecular motion, the relaxation rates are significantly lower than theoretical predictions. We discussed the results and frames of the fast-motion and fast-diffusion approximations.

K1.00081 Magnetic properties of MnCrO_{4} investigated by NMR. DONG YOUNG YOON, SOONCHIL LEE, Department of physics, Korea Advanced Institute of Science and Technology, YOON SEOK OH, KEE HOON KIM, Department of physics and astronomy, Seoul National University — We investigated the magnetic properties of spinel MnCrO_{4} by nuclear magnetic resonance (NMR) and superconducting quantum interference device (SQUID). The magnetization vs. temperature curves under zero field cooling and field cooling show the ferrimagnetic spiral structure below 20 K and the collinear ferrimagnet from 40 K to 20 K. The magnetization vs. time curve show the spin-glass-like behavior below 9 K. The canting angles of Mn and Cr spins at liquid He temperature are determined by NMR to be 50° and 110°, respectively. In the ferrimagnetic spiral state, the nuclear spin-spin relaxation rate steeply increases with increasing temperature above 12 K, which expected to come from the fast fluctuation of electron spins. The NMR shows that the volume of the ferrimagnetic spiral domain decreases faster than the local magnetization as temperature increases. Furthermore, the domain volume shows the differences between cooling and warming processes. We depict that the ferrimagnetic spiral is embedded in the collinear ferrimagnet matrix.

K1.00082 Direct Observation of Orbital Reorientation in MnV_{2}O_{4} by NMR. JEONG HYUN SHIM, EUNA JO, JOOSEOEP LEE, SOONCHIL LEE, Department of Physics, Korea Advanced Institute of Science and Technology, DAEJONG 305-701, KOREA, TAKEHITO SUZUKI, TAKUYO KATSUFUJI, Department of Physics, Waseda University, Tokyo 169-8555, Japan — The effect of magnetostriction on the orbital states on the MnV_{2}O_{4} was investigated by rotating the direction of magnetic field. The microscopic evidence of the orbital reorientation process, induced by the rotation, was found from the variation of V^{3+} NMR spectrum. Despite the magnetic field is rotated from z axis to y axis, NMR spectrum of 0° is almost identical to that of 90°, which reveals the reorientation of the orbital states of V^{3+} ions following deformation of lattice. It was also observed that the reorientation process takes place suddenly when the magnetic field made 45° with respect to the z axis. Such a sudden behavior implies that the orbital-lattice coupling is much stronger than the spin-orbital coupling in MnV_{2}O_{4}.

K1.00083 In-plane and out-of-plane ferromagnetic resonance investigations of epitaxial CrO_{2}(110). HWACHOL LEE, KRISHNA CHETRY, CLAUDIA MEWES, ARUNAVA GUPTA, TIM MEWES. The University of Alabama — We report on in-plane and out-of-plane ferromagnetic resonance experiments to determine the magnetization damping in epitaxial CrO_{2}(110) thin films. The films were grown on TiO_{2} (110) substrates using chemical vapor deposition (CVD) with a CrO_{3} precursor [1]. Ferromagnetic resonance experiments as a function of the in-plane angle confirm a uniaxial in-plane anisotropy with the easy axis aligned parallel to the in-plane easy axis of the film and along the film normal. Both measurements show a weak dependence of the linewidth on the microwave frequency once the sample is fully saturated. The effective damping constant as determined by the frequency dependent measurements is very small. Over the experimentally accessible frequency range (4-60 GHz) the dominant contribution to the ferromagnetic resonance linewidth is therefore extrinsic in nature. References: [1]: X. W. Li, A. Gupta, and G. Xiao, Appl. Phys. Lett. 75, 713 (1999).

3We gratefully acknowledge support from the NSF (DMR 0804243).
EID, Miami University — We have measured the contact resistance between the ferromagnetic semiconductor GaMnAs and each of the metals silver, aluminum, and copper. We have observed giant positive magnetoresistance with its saturation field increasing with increasing temperature, which is well explained by the Zeeman splitting of the localized states that suppresses the spin dependent hopping paths in the presence of magnetic field.

This work is supported by the NSF DMR-0547036.

K1.00085 Excitations in the chiral spin liquid

DARRELL SCHROETER, Reed College — Recently, a spin-Hamiltonian was presented [Schroeter et al., Phys. Rev. Lett. 99, 097202 (2007)] for which the chiral spin liquid is the exact ground state. This poster will present a numerical study of the excitations of the model, including results obtained by exact diagonalization of the model on 16 and 25-site lattices.

K1.00086 Electrical and Optical Characterization of Spin Transfer Torques

JOSHUA EMERICK, S.C. PARKS, K. LI, A. HAUSER, J. E. THOMPSON, J. CIRALDO, J. LUCY, F. Y. YANG, E. JOHNSTON-HALPERIN, Department of Physics, The Ohio State University — The spin-transfer torque (STT) phenomenon is a direct outgrowth of giant magnetoresistance (GMR) in the regime of high current density. Investigations of this phenomenon have contributed to improved understanding of fundamental processes and revealed the potential for technological innovation. To further this exploration, we have constructed an instrument that simultaneously measures microwave electrical response and magnetization in an external magnetic field of up to 1 T. The microwave probe is sensitive at frequencies up to 30 GHz and the magneto-optical Kerr effect (MOKE) magnetometer is configured to measure the magnetization of the active region during operation (resolution of ~ 100 µm). We present the experimental configuration of this instrument and calibration data from prototype samples. The ability to directly measure layer orientation for active devices provides a powerful tool for the investigation of STT.

K1.00087 Pure Spin Current Injection through Superconductive/Normal Metal Ohmic Interface

KOHEI OHNISHI, ISSP University of Tokyo, TAKASHI KIMURA, YOSHICHIKA OTANI, ISSP University of Tokyo, ASI RIKEN — In past few years, spin-dependent transport properties in nano-structured systems have drawn considerable attention owing to potential applications in spintronics. Spin transport has so far been investigated both experimentally and theoretically much more intensively in normal- or semi-conductors than in superconductors. However recent theoretical studies on the spin transport in superconductor predict the intriguing phenomena such as the non-linearity and the control of superconductivity that may lead to functional superconductive spintronic devices. Therefore, it is urgent to elucidate experimentally the spin transports in superconductor. Here, we investigate the influence of pure spin currents on superconductivity in a lateral structure consisting of superconductive Nb, normal metal Cu and ferromagnetic Ni-Fe wires. Using nonlocal spin injection technique, we found that pure spin current injection into the superconductive Nb wire induces the voltage drop along the wire. This can be understood as conversion from the spin current to the supercurrent via the quasi-particle current.

K1.00088 Spin-dependent conductance switching in organic molecular junctions

YUN-WEN CHEN, LUIS A. AGAPITO, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — We use density-functional theory to calculate the electronic transport through single molecules attached to capped (5,5) carbon nanotubes (CNT's) as leads. We observed a strong variation in the electrical conductance with respect to the spin-state of the junction. The singlet state exhibits high conductance whereas the triplet low. The deformation of the CNT's cap structure, upon covalent adsorption of the phenyl rings, triggers the spin dependence in the organic junctions. Two different π-conjugated phenylene-vinylene-containing molecules were tested, yielding similar behavior.

K1.00089 Giant positive magnetoresistance in Co@CoO nanoparticle array

HUI XING, WENJIE KONG, CHAEHYUN KIM, University at Buffalo-SUNY, SHOUHENG SUN, Brown University, ZHUAN XU, Zhejiang University, HAO ZENG, University at Buffalo-SUNY — The spin-dependent charge transport has been extensively studied due to its technological applications in information industry. Of particular interests are magnetic granular systems consisting of magnetic grains embedded in a nonmagnetic matrix, which typically exhibits negative granular MR. Interestingly, anomalous positive MR in granular systems has been reported in different materials [1]. Possible origins that can account for the positive MR include: ordinary MR caused by the curvature of the carrier trajectories in the magnetic field, shrinkage of the wave functions of localized electronic states due to the external field, and suppression of hopping paths due to the Zeeman splitting of the localized state. Here we present magnetotransport studies in self-assembled Co@CoO nanoparticle arrays which provide model granular systems. Efros Shklovskii variable range hopping to Mott variable range hopping crossover occurs at around 25 K. Giant positive MR with its saturation field increasing with increasing temperature is observed, and is well explained by the Zeeman splitting of the localized states that suppress the spin dependent hopping paths in the presence of magnetic field.

K1.00090 ABSTRACT WITHDRAWN

K1.00091 Measurements of the Contact Resistance Between GaMnAs and Different Metals

NOAH OPOONDO, GRANT RILEY, ROBERT TOLLEY, TYLER BREST, Miami University, XINYU LIU, JACEK FURDYNA, Notre Dame University, KHALID EID, Miami University — We have measured the contact resistance between the ferromagnetic semiconductor GaMnAs and the metals, yet the very high carrier concentration in GaMnAs causes the contact resistance to be quite small and ohmic. We will also discuss the possible mechanisms of conduction at the interface. Determining the contact resistance of GaMnAs is important for spin injection experiments. This work is supported by the Research Corporation for Science Advancement.

K1.00092 Vortex-core reversal by rotating currents , THOMAS KAMIONKA, MICHAEL MARTENS, MARKUS BOLTE, GUIDO MEIER, Institute of Applied Physics and Microstructure Research Center, University of Hamburg, Germany, KANG WEI CHOU, TOLEK TYLISZCZAK, Advanced Light Source, LBNL, Berkeley, CA, USA, MICHAEL CURCIC, BARTEL VAN WAENENBERGE, HERMANN STOLL, Max Planck Institute for Metals Research, Stuttgart, Germany — The investigation of the interaction between a spin-polarized current and the magnetization of a ferromagnet is of great interest. One concept for data storage is to use the current-induced switching of the vortex-core polarization, i.e. the out-of-plane component of the magnetization in the center of a micromized permalloy element. It has been shown both theoretically [1] and experimentally [2] that the polarization can be switched selectively by resonant field excitation. We carried out time-resolved scanning transmission X-ray microscopy while exciting the vortex core with rotating currents of varying frequency, amplitude and rotation sense. We observed vortex core switching, and by analyzing the gyration phase with respect to the exciting current we derive whether the Oersted-field or the spin torque mainly contributes to the excitation and causes the switching process. [1] S. K. Kim et al., Appl. Phys. Lett. 92, 022509 (2008). [2] M. Curcic et al., Phys. Rev. Lett. 101, 197204 (2008).

K1.00093 Antivortex-core switching as write process in random access memories , ANDRE DREWS, TORU MATSUYAMA, LARS BOCKLAGE, MARKUS BOLTE, GUIDO MEIER, Institute of Applied Physics and Microstructure Research Center, University of Hamburg, Germany, BENJAMIN KRUEGER, STELLAN BOHLENS, Institute of Theoretical Physics, University of Hamburg, Germany — Magnetic vortices observed in ferromagnetic thin films have received a great deal of interest in recent years. The topological counterpart of a vortex, the antivortex, has not been investigated as intensively so far. Like vortices, magnetic antivortices gyrate when excited by alternating fields or spin-polarized currents. When excited by alternating currents and fields simultaneously, the superposition of the forces leads to an enhancement or suppression of the gyration amplitude, depending on the orientation of the in-plane magnetization, i.e. the c-value of the antivortex, and the antivortex-core polarization p. Thus the c-p-dependent amplitude variation of antivortex core gyration can lead to antivortex-core switching and thus to write binary data. Reading out of the data can be done by detecting the amplitude of gyration, e.g. by inductive loops. A logical zero (one) is represented by a small (large) gyration amplitude, i.e., suppression (enhancement) of the gyration. Due to the c-p-dependence of the excitation amplitude, an ensuing toggle switching is impossible. This technique allows bringing the antivortex into a distinct binary state without the need of a reading process before writing the bits.

K1.00094 MAGNETISM: GENERAL AND THEORY –

K1.00095 Local hyperfine field systematic of sp impurities on (001) and (111) Ni Surfaces , MARCUS TOVAR COSTA, Universidade do Estado do Rio de Janeiro, Instituto de Aplicacaoo, Brazil, ALEXANDRE DE OLIVEIRA, Centro Federal de Educacao de Quimica de Nilopolis, Brazil — A self-consistent calculation of the local magnetic moments and the hyperfine fields is performed, considering a systematic of n-sp, (n=4,5) impurities on (001)Ni and (111)Ni surfaces and sub-layers. A simple model is adopted which is, in principle, an extension on that of Daniel and Friedel. The behavior obtained for the hyperfine fields for each one of the series namely above is drastically different from that obtained for the bulk. The calculations of the electronic structure of the systems are based on a full multi-orbital tight-binding model and using the Green function formalism. The effect of next-neighbor perturbation on the magnetic properties, due to the lost of translational invariance introduced by the impurity, is taken into account in the present picture. The theoretical results are in agreement with known experimental data.

K1.00096 Long-range behavior of exchange bias in CoFe/FeMn-based multilayers , NAM DAO, Department of Materials and Engineering, University of Virginia, WEI CHEN, Department of Physics, University of Virginia, KEVIN WEST, DAVID KIRKWOOD, JIWEI LU, Department of Materials and Engineering, University of Virginia, STUART WOLF, Department of Materials and Engineering and Department of Physics, University of Virginia — CoFe/FeMn-interface-based multilayers were grown in magnetic field and at room temperature. The exchange bias field $H_{EB}$ depends strongly on the order of depositions and is much higher for CoFe/FeMn than FeMn/CoFe bilayers. By combining the two bilayer structures into symmetric CoFe/FeMn ($f_{pMn}$)/CoFe trilayers, $H_{EB}$ is enhanced for both the top and bottom CoFe layers. Enhancements of exchange bias are also observed by reducing the FeMn thickness $t_{pMn}$ of the trilayers. These results evidence the propagation of exchange bias between the two CoFe/FeMn and FeMn/CoFe interfaces mediated by the FeMn antiferromagnetic order. Furthermore, the exchange bias is even considerably increased when a thin Al or Mg layer is inserted into the CoFe/FeMn interface (i.e., CoFe/Al/FeMn or CoFe/Mg/FeMn) and persists for the insertion layer thicknesses of up to about 1.5 nm. These results strongly indicate that exchange bias is not a pure interfacial phenomenon, but mainly governed by possible long-range couplings such as dipole-dipole and RKKY between the antiferromagnetic uncompensated spins and the ferromagnetic layer.

K1.00097 Direct Measurement of the Bose-Einstein Condensation Universality Class in NiCl$_2$-4SC(NH$_2$)$_2$ at Ultralow Temperatures$^1$, LIANG YIN, J.S. XIA, N.S. SULLIVAN, Department of Physics, University of Florida, and NHHMF, V.S. ZAPF, NHMF, Los Alamos National Laboratory, A. PADUAN-FILHO, Universidade de Sao Paulo — In this work, we demonstrate field-induced Bose-Einstein condensation (BEC) in the organic compound NiCl$_2$-4SC(NH$_2$)$_2$ using ac susceptibility measurements down to 1 mK. The Ni S=1 spins exhibit 3D XY antiferromagnetism between a lower critical field $H_{c1} \sim 2$ T and a upper critical field $H_{c2} \sim 12$ T. The results show a power-law temperature dependence of the phase transition line $H_{c1} (T) - H_{c1} (0) \approx \alpha T^\gamma$ with $\alpha = 1.47\pm 0.0$ and $H_{c2} (0) = 2.05 T$, consistent with the 3D BEC universality class. Near $H_{c1}$, a kink was found in the phase boundary at approximately 150 mK.$^1$This work was supported by NSF Cooperative Agreement No. DMR 0654118, the Department of Energy and the State of Florida, the Brazilian Agencies CNPq and FAPESP.

K1.00098 Magnetization Plateau of Classical Ising Model on Shastry-Sutherland Lattice$^1$, MINGCHE CHANG, National Taiwan Normal University, MIN-FONG YANG, Tunghai University — Magnetization of the classical antiferromagnetic Ising model on the Shastry-Sutherland lattice is investigated using the tensor renormalization group approach. We find a single magnetization plateau at 1/3 of the saturation value and investigate its dependence on temperature and frustration. The spin configuration of this plateau has also been determined.$^1$Supported by the National Science Council of Taiwan

K1.00099 Phase transitions in site diluted systems of Ising dipoles , JUAN J. ALONSO, Universidad de Malaga, JULIO F. FERNANDEZ, ICMA, CSIC-Universidad de Zaragoza — By Monte Carlo simulations, we study dilute systems of Ising magnetic dipoles on simple cubic lattices. Dipoles are restricted to point along the z axis and are randomly placed in a fraction $x$ of the $L^3$ sites of the lattice. For $x_c \approx 0.6$ we find a thermally driven second order transition between a paramagnetic and a dipolar antiferromagnetic (AF) phase at a temperature $T_{c}$ which can be fitted by $k_BT_{c}/E_g \approx 4.3(x-x_c)^{0.6}$, where $E_g$ is a nearest neighbor dipole-dipole interaction energy. We explore whether an equilibrium spin glass phase exists for $x < x_c$. To this end, we study the spin glass overlap parameter $q$ between equilibrium configurations which we obtain from tempered Monte Carlo simulations for systems of $N$ dipoles in the range $40 \leq N \leq 500$. For $x < x_c$ we find no AF phase transition. However, we observe rather large AF correlations at low temperatures for $0.2 < x < x_c$. For $x = 0.35, 0.5$ and 0.6 and temperatures below $k_BT/T_{c} \approx 0.9$ we find double-peaked distributions of $q/\langle q^2 \rangle^{1/2}$. Their shape does not change appreciably with $N$. For smaller values of $x$, for which previous results exists, we have not been able to obtain clear cut results.
K1.00100 Ab-Initio Study of Magnetic Properties of M-doped (M = Cr or V) ZnGeN\textsubscript{2} \textsuperscript{1} — J. RUFINUS, Science Division, Widener University, Chester, PA 19013 — The current interest in the emerging field of semiconductor spintronics is mostly focused on transition metal-doped binary materials. Recently, however, the explorations of transition metal-doped ternary semiconductors have intensified, due to some experimental confirmations of high Curie temperature in chalcopyrite compounds. In ternary materials, there are possibilities of having ferromagnetic or antiferromagnetic configurations, depending on which metal site was substituted by the dopant. A donor (i.e. releasing electrons) will be produced when a metal atom substitutes a lower valent site, while an acceptor (i.e. releasing holes) will be produced when a metal atom substitutes a higher valent site. Only holes are expected to lead to ferromagnetism. A density functional theory within generalized gradient approximation study was performed on M-doped (M = Cr or V) ternary material ZnGeN\textsubscript{2}. The objective of this study is to determine whether substitutional transition metal in a group II (Zn) site and in a group IV (Ge) site will be ferromagnetic or antiferromagnetic. Our results show that both Cr- and V-doped ZnGeN\textsubscript{2} to be ferromagnetic, independent of the substitution sites. Additionally, formation of half-metallic ferromagnetism is possible in this type of material.

\textsuperscript{1}Work supported by NSF, Teragrid, and Widener University Grants

K1.00101 Spin-glass transition of magnetic dipoles with random anisotropy axes \textsuperscript{4} — JULIO F. FERNANDEZ-DEZ, ICMA, CSIC-Universidad de Zaragoza, JUAN J. ALONSO, Universidad de Malaga — We study partially occupied lattice systems of classical magnetic dipoles which point along randomly oriented axes. Only dipolar interactions are taken into account. From Tempered Monte Carlo simulations, we obtain equilibrium results for xL\textsuperscript{3} dipoles, randomly located on L\textsuperscript{3} simple cubic lattice sites, for L = 4, 6, 8 and 12, with an x = 0.35, 0.5 and 1 fraction of occupied sites. The numerical evidence we obtain supports the existence of an equilibrium spin glass phase below a transition temperature T\textsubscript{SG}, given by k\textsubscript{B}T\textsubscript{SG} = \langle 0.9 \pm 0.1 \rangle x \epsilon d, where \epsilon d is a nearest neighbor dipole-dipole interaction energy. The spin glass overlap parameter q is statistically distributed, and its mean square deviation follows the rule, \langle q^2 \rangle \approx 0.25 \langle q \rangle^2 \langle x \rangle in the spin-glass phase.

K1.00102 A Finite Temperature First-Principles Model for Spin Fluctuations \textsuperscript{5} — YI WANG, SHUNLI SHANG, LONG-QING CHEN, ZI-KUI LIU — In the past decades, the steady increasing in both computer power and the efficiency of computational methods has made it realistic the accurate first-principles calculations of material properties at finite temperature. The current frontier is how to extend the first-principles approach when it becomes important of the role of the internal degrees of freedom, which is beyond the spatial degrees of freedom of a material. One of important examples is the interplay between magnetic and lattice fluctuations at finite temperature. Solution of this enigma can reveal the microscopic origin of the novel properties of many materials. Hereby we propose a general framework to calculate the Helmholtz energy for system with spin fluctuations. The theory has been applied for EuTiO\textsubscript{3}. The energetics includes 256 spin configurations, of a 2x2x2 supercell, which are reduced to 14 not equivalent ones. We find a Schottky anomaly in the specific heat at T = 5.8 K which is matching closely to the Neel Temperature of 5.5 K for EuTiO\textsubscript{3}.

K1.00103 Study of the magnetic structures of the atacamite and botallackite forms of Cu\textsubscript{2}(OH)\textsubscript{3}Cl in terms of first principles DFT calculations \textsuperscript{6} — JINHEE KANG, CHANGHOON LEE, MIKE H. WHANGBO, Department of Chemistry, North Carolina State University — The atacamite and botallackite forms of Cu\textsubscript{2}Cl(OH)\textsubscript{2} are made up of edge- and corner-sharing Cu(OH)\textsubscript{2}Cl\textsubscript{2} octahedra. Each polymorph consists of two slightly different types of Cu\textsubscript{2}Cl\textsubscript{2} octahedra, with their Cu\textsuperscript{2+} magnetic orbitals contained in the Cu(OH)\textsubscript{2} square planes. Atacamite and botallackite are different in the way the Cu(OH)\textsubscript{2} square planes are connected, but their magnetic properties of atacamite and botallackite are quite similar. To explain these observations, the crystal structures of the two polymorphs were optimized by first principles DFT calculations. We then evaluated the spin exchange interactions of the two polymorphs using the optimized structures on the basis of DFT calculations. To a first approximation, both polymorphs were found to be described by a uniform 1D antiferromagnetic chain model with spin frustration arising from the next-nearest-neighbor interactions. Implications of these observations were explored.

\textsuperscript{6}DMSE, OBES, and DOE

K1.00104 Electromagnetic response of the planar metamaterial consisting of cut-wire pair and continuous wire \textsuperscript{7} — VU DINH LAM, NGUYEN THANH TUNG, JINWOO PARK, SEONGJAE LEE, YOUNGPAK LEE, Hanyang University, Korea — The left-handed materials (LHMs) attract more and more attention in recent years because of their intriguing physical properties and applications. Recently, a simple structure, the so-called cut-wire pair (CWP) was proposed and successfully used as the magnetic component in fabricating the LHMs. The simple geometry of CWPs means that such structures can be scaled down to the nanometer dimension much more easily than those based on the conventional split-ring resonator structures. In addition, the main advantages of the CWP structure comparing to the other structures is its ability to produce a strong magnetic resonance for the normal-to-plane propagation with only one CWP layer. In this report, we present the influence of lattice constants on the electromagnetic properties of CWP structures in the microwave frequency regime. In addition, we also discussed on how the lattice constants affect the LH behavior of combined structure consisting of CWP and continuous wire. A good agreement between the measurement and the numerical simulation is achieved.

K1.00105 Magneto-optical imaging of magnetic domain pattern produced by intense femtosecond laser pulse irradiation \textsuperscript{8} — JAIVARHAN SINHA, SHYAM MOHAN, S.S. BANERJEE, Department of Physics, Indian Institute of Technology, Kanpur-208 016, U. P., India, S. KAHALY, G. RAVINDRA KUMAR, Tata Institute of Fundamental Research, 1 Homi Bhabha Road, Mumbai- 400 005, India — An important and intriguing area of research is laser plasma generated giant magnetic field pulses. Interaction of ultrashort high intensity laser pulses with matter involves several mechanisms for generating ultrastrong magnetic fields. By irradiating a magnetic recordable tape constituting of Fe\textsubscript{3}O\textsubscript{4} particles with an intense p-polarized femtosecond laser pulses (\sim 10\textsuperscript{16} W cm\textsuperscript{-2}, 100fs), we have found complex magnetic field patterns stored in the tape. We image the local magnetic field distribution around the irradiated region \textsuperscript{1} using the high sensitivity magneto-optical imaging technique. We understand the complex magnetic domains patterns recoded on the tape in terms of interesting instabilities \textsuperscript{1} generated in the plasma produced during the irradiation of the tape with intense laser pulses.\textsuperscript{1}

\textsuperscript{8}Jaivardhan Sinha, Shyam Mohan, S. S Banerjee, S. Kahaly, G. Ravindra Kumar, Phys. Rev. E 77, 046118(2008), *srayaji@itik.ac.in

K1.00106 INSTRUMENTATION AND MEASUREMENT SCIENCE —

K1.00107 Low Temperature Conducting Probe Microscopy of Carbon Nanotubes — IVAN BORZENETS, HENOK MEBRAHTU, ULAS COSKUN, MATTHEW PRIOR, GLEB FINKELSTEIN, Duke University Physics — In order to measure local electrical properties of nano-devices at liquid He temperatures, we have built an atomic force microscopy. The instrument is outfitted with a conducting tip, which allows us to acquire both topography and electrical signals at the same time. The AFM has a scan window of up to 10 microns at low temperature and allows one to translate the sample laterally by up to a millimeter. To find a specific device within this range, the samples structure has to be specially optimized by addition of the "search pattern". The electrically conducting tip of the AFM allows us to make a variety of measurements such as: gating and tunneling, and to apply a mechanical force to the sample.
K1.00108 Fabrication Of Nickel-tipped Cantilevers for Magnetic Resonance Force Microscopy, STEVEN HICKMAN, E.W. MOORE, S. LEE, S.R. GARNER, J.C. ONG, S. KUEHN, J.A. MARÖHN, Dept of Chemistry, Cornell University — Magnetic resonance force microscopy (MRFM) is a technique that may one day allow us to acquire magnetic resonance images of single molecules. To date we have demonstrated that MRFM can achieve a sensitivity of ~10^8 proton spins, using a custom-fabricated silicon cantilever with a 9 micron diameter magnet tip. By making improved magnetic tips and mitigating surface dissipation, it may be possible to achieve single-proton sensitivity. Achieving the atom-scale force sensitivity necessary to image single proton spins requires custom-fabricating cantilevers with extreme dimensions. In MRFM the force exerted on the cantilever, per proton, is proportional to the field gradient from the cantilever's magnetic tip. Achieving single proton sensitivity requires a very small, densely packed array of magnet tips. We have developed an electron-beam-lithography (EBL) process for batch fabricating nanoscale tip magnets on ultrasensitive silicon cantilevers. Research by our group has shown that surface induced dissipation is a major source of noise, which can be minimized by fabricating the magnets overlapping the end of the cantilever. We will present 50-600 nm wide nickel overlapping magnets fabricated by EBL and isotropic plasma etching. With our designed cantilever, we expect a sensitivity of better than 10^7 protons.

K1.00109 Controlling and measuring substrate stiffness for cell motility studies, LINDSAY RUNYAN, PETER HOFFMANN, Wayne State University, KAREN BENINGO, Wayne State University — Cell motility and differentiation is generally considered to be controlled by an appropriate extracellular matrix (ECM). However, recent evidence has shown that mechanical cues may be just as important. Here, we present a study to create patterned substrates that allow us to test the hypothesis that cells prefer substrates of certain mechanical moduli and will migrate towards these substrates. In this context, we present a discussion of optimal methods to measure substrate moduli at the local level and compare different methods with respect to ease of implementation, data interpretation and reliability.

K1.00110 Measuring the energy landscape of complex bonds using AFM, ESSA MAYYAS, PETER HOFFMANN, LINDSAY RUNYAN, Wayne State University, HOFFMANN TEAM — We measured rupture force of a complex bond of two interacting proteins with atomic force microscopy. Proteins of interest were active and latent Matrix metalloproteinases (MMPs), type 2 and 9, and their tissue inhibitors TIMP1 and TIMP2. Measurements show that the rupture force depends on the pulling speed; it ranges from 30 pN to 150 pN at pulling speeds 300m/s to 48000m/s. Using timeresolved AFM, we studied the time evolution of the rupture force of studied MMP-TIMP interaction; we determined all physical parameters that form the landscape energy of the interaction, in addition to the life time of the bond and its length. Moreover, we used the pulling experiment to study the interaction of TIMP2 with the receptor MT1-MMP on the surface of living cells.

K1.00111 Scanning tunneling microscope-cathodoluminescence (STM-CL) imaging of the GaAs/AlGaAs (110) cross-section: evaluation of spatial resolution and imaging area shift, KENTARO WATANABE, Department of Applied Physics, School of Engineering, The University of Tokyo, YOSHIKI NAKAMURA, Quantum-Phase Electronics Center, Department of Applied Physics, School of Engineering, The University of Tokyo and CREST-JST, SHIGEYUKI KUBOYA, RYUJI KATAYAMA, KENTARO ONABE, Department of Advanced Materials Science, School of Frontier Sciences, The University of Tokyo, MASAKAZU ICHIKAWA, Quantum-Phase Electronics Center, School of Applied Physics, School of Engineering, The University of Tokyo and CREST-JST — We studied local optical properties of AlGaAs/GaAs multilayer structures by scanning tunneling microscope cathodoluminescence (STM-CL) spectroscopy, where low-energy (~100 eV) electrons field-emitted from STM tips were used as bright excitation sources. The STM-CL measurements were performed at the (110) cross-sectional surface of the AlGaAs/GaAs multilayer structure. We found that the field-emitted electron beam (FEEB) diameter mainly determine the spatial resolution of this system in STM-CL spectroscopy by evaluating some contributors: the thermalization length and the diffusion length of generated hot electrons. We also clarified that the shift of the STM-CL measurement position from the STM tip position was caused by the FEEB angled from the surface normal.

K1.00112 Twisted Pair Cryogenic Low Pass Filters, WOON SONG, Korea Research Institute of Standards and Science, MUSHTAQ REHMAN, SANG-WAN RYU, Chonnam National University, Korea, YOUNUK CHONG, Korea Research Institute of Standards and Science — For precise electronic-transport measurement at low temperatures, low pass filters are usually required to block external interference. However, since filters designed for the RF are not suitable for the field gradient from the cantilever's magnetic tip. Achieving single proton sensitivity requires a very small, densely packed array of magnet tips. We fabricated a low pass filter consisting of twisted pair of manganin wires wrapped in a copper tape, which can be made compact. We measured its microwave transmission characteristics with various filter parameters such as length, insulation thickness and twisted turns per unit length and compared the result with copper powder filter. The constructed filter with length of one meter showed a higher attenuation (more than 60 dB at 1 GHz) with cutoff frequency of about 8 MHz. This result is in good agreement with the theoretical model, which assumes the cable as a resistive transmission line.

K1.00113 Data Encoding on Continuous Wave THZ Signals for Sensing, KE SU, ZHIWEI LIU, Department of Physics, New Jersey Institute of Technology, Newark, NJ 07102, LOTHAR MOLLER, Bell Laboratories, Alcatel-Lucent, Holmdel, NJ 07733, USA, JOHN F. FEDERICI, Department of Physics, New Jersey Institute of Technology, Newark, NJ 07032 — The intrinsic advantages of potentially ultra-high bandwidth, unrestricted frequency bands, and relative secure channels lead to a steadily increasing interest in THz communications. Other than for communication purposes, data modulation on THz signals could find application in sensing. When imprinting code sequences on pulse trains, ranging information from far distance scattering objects can be obtained to define selective measurement intervals. This technique is known from M-sequence radar and ultra-high bandwidth, multi-carrier modulation. A novel method of data encoding is described which combines these approaches with ultra-wideband, single-carrier modulation. The encoded signal is transmitted as a frequency modulated continuous wave (FM-CW) signal. The encoded data modulation is achieved by a digital phase modulation. An electro-optic phase modulator is used to directly modulate the THz wave through a τπ phase shift. While data rates in the MB/s range are demonstrated, it is possible to transmit data rates in the hundreds of MB/s range. Applications of the data modulation to sensing applications will be discussed.

K1.00114 Metal embedded Fiber Bragg Grating Sensors, CHOODA KHANAL, FIU, GARMAN VARGAS, KANTESH BALANI, ANUP KESHRI, CARMEN BARBOSA, ARVIND AGARIVAL, ROBERTO PANEPUCCI, FIU — A novel method of embedding optical fibers and optical fiber sensors, inside metallic structures will be discussed. We specifically report results for embedding fiber bragg grating sensors in an aluminum coating onto a steel plate. Characterization of an embedded FBG sensor and its effects on the sensor operation are also presented. Temperature sensitivity and the strain sensitivity will be discussed. The novel high throughput deposition method show the potential of embedding optical sensors onto metallic structures which make it suitable for many engineering applications in biomedical, civil, mechanical and aeronautical, among other fields.

K1.00115 Image contrast dependence on the field emitter in near field emission scanning electron microscopy, OLIVIER SCHOLDER, TARYL KIRK, LORENZO DE PIETRO, THOMAS BAELHER, URS RAMSPERGER, DANIELO PESCIA, Swiss Federal Institute of Technology Zurich (ETHZ) — In conventional scanning electron microscopy (SEM) the lateral resolution is limited by the electron beam diameter impinging on the specimen surface. Near field emission scanning electron microscopy (NFSEM) provides a simple means of overcoming this limit; however the most suitable field emitter remains to be determined. NFSEM has been used in this work to investigate the W (110) surface with single crystal tungsten tips of (310), (111), and (100)-orientations. The topographic images generated from both the electron intensity variations and the field emission current indicate higher resolution capabilities with decreasing tip work function than with polycrystalline W tips. Moreover the electron intensity images show more detail with higher resolution than field emission current imaging. This implies that the electron yield is more sensitive to additional parameters, which may be the local work function, specimen curvature, primary beam energy, and detector sensitivity.
Quantitative analysis of scattering force microscopy data using harmonic models

Thomas Henze, Klaus Schroeter, Albrecht Petzold, Thomas Thurn-Albrecht,
Institute of Physics, Martin-Luther-University Halle-Wittenberg, D-06099 Halle, Germany — The separate identification of dissipative and elastic force contributions in Atomic Force Microscopy (AFM) is discussed. We show that within a harmonic approximation the interaction of the AFM tip with the sample surface can be described by average interaction parameters, namely an effective elastic tip-sample interaction $k_{eff}$ and an effective dissipation $\alpha_{eff}$, which can be extracted in a simple way from measured data. The method is applied to force spectroscopy curves on hard and soft polymeric model surfaces. The approach enables a thorough discussion of the influence of experimental parameters on the measured data. In imaging a clear identification of phases in systems with hard-soft contrast as for instance in semicrystalline polymers is made possible.

A nanoscopic study of degradation of optical recording media

Kwonjae Yoo, H.R. Kang, K.J. Kim, B.C. Woo, D.A. Ha, N.H. Lee, Wan S. Yun, KriSS, Daejeon 305-340, Korea, M.Y. Yun, Joongb University, Chungnam 312-702, Korea — The life expectancy of optical recording media usually depends on loss of physical property, that is, optical elements in digital recording unit cells eventually will be disappeared by physical and chemical degradation. Nevertheless, the study of information loss in the element by natural degradation is not so many, which need a practical and scientific investigation in detail. Here we present the results of the life expectancy estimation method of optical recording media studies on the recording unit cells by employing accelerated aging tool. Our results showed that archiving DVDs, which have double reflective layers, indicate the acceptable life expectancy over one hundred years. Additional optical, Surface Kelvin probe microscopy (SKPM) and electrostatic force microscopy (EFM) measurements clearly reveal the degradation of dye layer depending on accelerated aging time. The correlation between those physical quantities and PI errors might lead a key factor for the development of new life expectancy estimation method of optical recording media.

In-situ TEM observation on STM tunneling gap

Suhyun Kim, Yasumasu Tanishiro, Kunio Takayanagi, Tokyo Institute of Technology — Transmission Electron Microscope and Scanning Tunneling Microscope in an ultra high vacuum environment (UHV-TEM-STM) have been combined to simultaneously perform both high resolution TEM and atomically resolved STM experiments. This system was constructed for in-situ investigation of physical property of impurity atoms embedded below semiconductor surface. To image TEM and STM at the same time, crucial requirement is that, the STM image must be acquired under the electron beam irradiation. As a preliminary test, we used HOPG (Highly Oriented Pyrolytic Graphite) sample and tungsten tip as schematically shown in Fig 1(a). Fig 1(b) shows an atomic resolution STM image of HOPG obtained with 300mV sample bias and 3nA tunneling current even in the condition of the electron beam irradiation on the tip. TEM image can be simultaneously acquired by performing In-situ TEM observation on STM tunneling gap formed between the tip and a thin sample. Fig 1(a) Geometry of STM observation on STM tunneling gap Fig 1(b) STM image of HOPG obtained with 300mV sample bias and 3nA tunneling current

Micromechanical devices for magnetization measurements at high magnetic fields and low temperatures

J. Paster, K. Ninios, H.B. Chan, University of Florida, L. Balicas, Florida State University — We constructed micromechanical faraday balance magnetometers for measuring the absolute value of the magnetization of very small samples (~ 1ugram) at high magnetic fields and a wide range of temperatures. The magnetometers consist of a movable polycrystal silicon plate (500 by 500 micrometers) suspended by four springs above a fixed electrode. When small samples of the magnetic material are placed at the center of the movable plate, the magnetic field gradient creates a force on the sample that changes the capacitance between the plate and electrode. The absolute magnetization of the sample can be determined provided that the magnetic field gradient is known. Springs with different shapes are designed to minimize the response to magnetic torque. Experimental results will be compared to numerical simulation.

X-ray Young’s double slit experiment and other aspects of kinoform X-ray prism arrays

A.F. Isakovic, K. Evans-Lutterodt, BNL-NSLS, A. Stein, J.B. Warren, BNL-CFN, S. Narayanan, A.R. Sandy, ANL-APS — Numerical design and large aspect ratio nanofabrication techniques [1] were employed to produce kinoform prisms and lenses for the purpose of focusing, deflecting and characterizing hard X-ray synchrotron radiation. Purely refractive prisms are hampered by the effects of absorption, which limits the numerical aperture of the lens and hence the optic resolution. Kinoform lenses allow one to circumvent these limitations, with the trade-off of an energy bandwidth for the optic. Purely refractive prisms have similar limitations due to absorption, and consequently we choose to fabricate kinoform prisms and study their properties experimentally. In particular we analyze theoretically the extent to which the kinoform prism can be modeled by a simple prism, and the effect of nano-fabrication precision on the prism performance. The focus of the nano-fabrication efforts is in balancing out patterning of a large area and a deep anisotropic etch. Experimental characterization is performed at APS 8-ID beamline. We observed, controlled and measured interference fringes, in analogy with the Young’s double slit experiment. [1] A. F. Isakovic et al., JVST-A 26, 1182 (2008) and J. Synchr. Rad. 16.
Characterization of the Throughput of Short Fiber-Optic Arrays as a Function of the Angle of Incidence

An instrument was constructed to measure the light distribution at the back of a thin fiber-optic array as a function of the angle of incidence and the location at which the incoming 633 nm light strikes a fiber. The f-number of the incoming light is 10 and the diameter of the focal spot is 8 microns. The input optics are mounted on a rail that rotates in such a manner that the focal location remains fixed. Images of the light distribution at the back of the array are recorded using a 12-bit 2.5 megapixel camera. Data recorded using commercial face plates is presented.

Nano-scale Spin State in Invar Alloy Fe-36at%Ni

PENG ZHAO, P. CHRIS HAMMEL, Department of Physics, Ohio State University, JI-CHENG ZHAO, Department of Material Science and Engineering, Ohio State University — We use high-resolution ferromagnetic resonance force microscopy (FMRFM) to image the nano-scale spin structure of an Invar alloy (Fe-36at%Ni) to test the well-known two-spin-state hypothesis proposed by Weiss. Weiss proposed that the two-spin-state model could explain the Invar effect; but to our knowledge this has not been experimentally confirmed. With nano-scale spatial resolution of FMRFM, we intend to experimentally examine the existence or absence of such states in the Fe-36at%Ni Invar alloy.

Chemical Physics

Salt-induced overcharging, charge inversion and reentrant condensation in polyelectrolyte solutions

The behavior of highly-charged polyelectrolytes (PE) in multivalent salt solutions is investigated by computer simulations. By studying the charge distribution function around a chain, we show that PE is charge-overcompensated near its surface by condensed multivalent counterions when salt concentration is high. Nonetheless, the effective chain charge, computed by the ratio of the electrophoretic mobility to the diffusive mobility, can be positive or negative, depending sensitively on the ion size. This finding violates our intuitive thinking that an overcharging on the surface of a charged macromolecule leads inevitably the sign inversion of its effective charge. Moreover, the reentrant condensation of PE is studied by calculating the mean distance between chains. Chain aggregation happens only when salt concentration is intermediate and the ion size is comparable to the monomer size. The results demonstrate the importance of ion excluded volume and suggest a disconnection of the salt-induced segregation of PE chains at high salt concentrations with charge inversion.

Free energy landscapes of short polyproline peptides in vacuo and solvated environments

MAHMOUD MORADI, CHRISTOPHER ROLAND, VOLODYMYR BABIN, CELESTE SAGUI, CHIPS and Department of Physics, North Carolina State University — Polyproline peptides are known to occur in two different conformations, including right-handed PPI and left-handed PPII. Depending on the solvated environment and the peptide length, either PPI or PPII is favored. Specifically, we calculated the free energy landscapes of short polyproline peptides (length 6, 9, 13-mers) in vacuo, in implicit water, and in the solvents hexane and propanol as a function of the radius of gyration and handedness. To calculate the free energies, the recently developed Adaptively Biased Molecular Dynamics (ABMD) method, which belongs to the general category of umbrella sampling methods with a time-dependent potential, was used.

In situ sum-frequency generation spectroscopy of ethylene-glycol and poly-N-isopropylacrylamide films

VOLKER KURZ, PATRICK KOELSCH, University Heidelberg — Ethylene-glycol(EG)-based self-assembled monolayers (SAMs) are often used as a model systems for thin liquid films. Temperature series in heavy water were measured using a unique sample cell developed for in situ sum-frequency generation (SFG) spectroscopy experiments. Results obtained from model EG-SAMs with different lengths and terminations groups in various ion solutions showed temperature-dependent changes in the molecular order. Films of poly-N-isopropylacrylamide(pNIPAM) were also characterized by in situ SFG spectroscopy in the CH, OH, OD and amide spectral regions under different polarization combinations. These systems have many applications as thermo-responsive polymers due to their ability to change solubility in water at the biologically relevant temperature of 32 °C. This so-called lower critical solution temperature (LCST) phase transition was characterized in depth, allowing for the identification of the molecular groups involved in this process.

The Effects of Multiwalled Carbon Nanotube Doped Poly(Ethyl Methacrylate) on Optical Field Induced Nematic Liquid Crystal Reorientation

MATTHEW KERR, DAVID STATMAN, Allegheny College — We have been investigating photoinduced gliding of the easy axis at the nematic liquid crystal/polymer interface. Gliding of the easy axis on polyethylene methylacrylate (PEMA) surfaces has been observed when magnetic or electric fields are applied to the bulk liquid crystal. We have studied similar gliding when the surface is coated with a carbon nanotube/PHEMA composite. Our experiments utilize polarimetry techniques and cross-polarized microscopy. The results of photoinduced gliding experiments on PEMA surfaces doped with multiwalled carbon nanotubes will be presented.

Mapping hydration dynamics and coupled water-protein fluctuations around a protein surface

LUYUAN ZHANG, LIUJAN WANG, YA-TING KAO, WEIHONG QIU, YI YANG, OGHAGHARE OKOBIAH, DONGPING ZHONG, The Ohio State University — The behavior of highly-charged polyelectrolyte solutions is investigated by computer simulations. By studying the charge distribution function around a chain, we show that PE is charge-overcompensated near its surface by condensed multivalent counterions when salt concentration is high. Nonetheless, the effective chain charge, computed by the ratio of the electrophoretic mobility to the diffusive mobility, can be positive or negative, depending sensitively on the ion size. This finding violates our intuitive thinking that an overcharging on the surface of a charged macromolecule leads inevitably the sign inversion of its effective charge. Moreover, the reentrant condensation of PE is studied by calculating the mean distance between chains. Chain aggregation happens only when salt concentration is intermediate and the ion size is comparable to the monomer size. The results demonstrate the importance of ion excluded volume and suggest a disconnection of the salt-induced segregation of PE chains at high salt concentrations with charge inversion.

K.00132 Quantized ionic conductance in nanopores, MICHAEL ZWOLAK, Los Alamos National Laboratory, JOHAN LAGERQVIST, MASSIMILIANO DI VENTRA, University of California - San Diego — We study ion transport through nanopores via molecular dynamics calculations. Due to the confined geometry and large local field of a single ion, the nanoscale atomic configurations of species influence the ionic conductance. In particular, hydration layers that form around ions in aqueous solution create a series of energy barriers to ion transport. As an ion enters the pore, these hydration layers have to be partially broken due to steric restrictions of the pore. The breaking of the layers proceeds in a highly nonlinear, step-like fashion, giving rise to a strong nonlinear dependence of the electrostatic energy barrier on the pore diameter and therefore also a step-like conductance. We discuss this effect as well as the conditions under which it may be experimentally observed. 1

K.00133 Base sequence dependence and backbone-induced effects on charge transport through DNA, YONG JOE, SUN LEE, ERIC HEDIN, Ball State University — We investigate quantum mechanical electron transmission along the long axis of the DNA molecule using a tight-binding model. Specifically, we use two different DNA models to study the charge transfer efficiency of synthetic ds-DNA. First, the generic form of a simple one-conduction channel model, called the fishbone model, is used. The sugar-phosphate backbone and the coupling amplitude between each site of the base and the backbone are incorporated into an energy-dependent on-site potential in the main DNA site. Here, individual sites represent a base-pair formed by either AT (TA) or GC (CG) pairs coupled via hydrogen bonds. Second, we employ a two-dimensional three-chain model where the backbone on-site energy, the coupling amplitude between the bases and the backbone, and a possible hopping of charge carriers between the successive backbone sites are used as key parameters. The overall transmission and the current-voltage characteristics are calculated to determine the influence of mismatch (impropriety) effects in the DNA sequence. Finally, we discuss the transmission gap as a function of coupling between the bases and between the bases and the backbone. *One of the authors (E.R.H) is partially supported by a grant from the Center for Energy Research, Education, and Service (CERES) at Ball State University.

K.00134 Lanthanide Metal-Organic Framework Materials, PING-YEN HSIEH, University of Maryland-College Park, MARK A. GREEN, National Institute of Standards and Technology, ROBERT M. BRIBER, University of Maryland-College Park — A series of lanthanide metal-organic framework materials (MOF) with variable organic linkages including benzene-dicarboxylic acid (BDC), 1,3,5-benzene-tricarboxylic acid (BTC), and 1,3,5-tris(4-carboxyphenyl)benzene (BTB) have been synthesized. The low density and high porosity of MOFs make them candidates molecular sieve or hydrogen storage materials. The crystal structures have been determined using a combination of single crystal X-ray diffractometer and synchrotron powder X-ray diffraction work. Holmium with the BDC ligand material (Ho-BDC) crystallizes in a monoclinic C2/c space group, with lattice parameters of a = 17.06 Å, b = 10.67 Å, c = 10.57 Å, β = 96.12°. The crystal structure of Ho-BTC is in tetragonal P 41 2 2 space group and Ho-BTB is in a triclinic P-1 space group. A comprehensive examination of Ho-MOF with different ligands by x-ray and thermogravimetric analysis shows that there is a stable nanoporous structure for dehydrated Ho-BTC up to 250°C. The same phenomenon is not observed in the Ho-BDC and Ho-BTB materials. The collapsed structure with BDC and BTB indicates the stability of dehydrated samples is strongly related to the interactions between the metal and the organic linkers.

K.00135 Ultrafast Spectroscopy of Single-Stranded Adenine Oligomers, CHARLENE SU, The Ohio State University, CHRIS MIDDLETON, University of Wisconsin-Madison, BERN KOHLER, The Ohio State University — The excited-state dynamics of single-stranded homo-oligomers containing a variable number of adenine bases have been studied by femtosecond transient absorption technique within the ground state absorption band. The bleach recovery signals show that all the adenine oligomers decay with a long-lived component of a hundred picosecond in addition to a short-lived component, which is also observed in the adenine mononucleotide, 2'-deoxyadenosine 5'-monophosphate. The latter component is attributed to vibrationally cooling to the electronic ground state and the former one is associated with intrastrand excimer formation between stacking bases. It is found that the amplitude of long-lived component increases with the elongation the of adenine oligomers in comparison to the short-lived one. Excimer yields estimated on the basis of relative amplitude show that adenine oligomers have higher excimer formation in longer strands, indicating a greater degree of base stacking.

K.00136 Homogeneous bubble nucleation in liquids: a molecular dynamics study, ZUN-JING WANG, Carnegie Mellon University, CHANTAL VALERIANI, University of Edinburgh, DAAN FRENKEL, University of Cambridge — We have studied homogenous bubble nucleation in a Lennard-Jones fluid by performing Molecular Dynamics simulation coupled with Forward-Flux Sampling (MD-FFS). The MD-FFS estimate of bubble-nucleation rate is higher than predicted on the basis of Classical Nucleation Theory (CNT). Although this discrepancy is consistent with earlier findings, our simulations show that bubble nuclei are compact rather than ramified as had been suggested by Shen and Debenedetti (J. Chem. Phys. 1999, 111:3581). We find bubble nucleation starts with local spots much hotter than superheated environment, and the local temperature correlates strongly with subsequent bubble formation - this mechanism is not taken into account in CNT.

K.00137 Investigation into the Mpemba Effect: Variation in the Freezing Time of Water Dependent on Initial Temperature and Purity, INGRID THVEDT, MARTHA ROSEBERRY, SUSAN LEHMAN, The College of Wooster — The observation that hot water sometimes appears to freeze more quickly than cold water, known as the Mpemba effect, has generated vigorous debate. Prior research [1] into the Mpemba effect has resulted in conflicting results, due to a variety of observation techniques, multiple definitions of freezing, and different water treatments. To clarify the previous results, we have tested multiple types of water and improved the sample monitoring. During cooling and freezing, each 50 g water sample is continually monitored by three thermistors at different depths. Samples of tap, distilled, and nanopure water were heated, heated and cooled, or boiled before being frozen. We monitor the time to reach freezing, the duration of freezing, and the total time to reach -7°C. We observe the Mpemba effect most consistently in the length of the freezing transition in tap water. Observations of temperature variation during freezing will also be presented. [1] See the review by M. Jeng, Am.J.Phys. 74 S14 (2006).

K.00138 Clockwork Rotation and Rotation Transduction in 2D crystals of Janus amphiphilic colloidal spheres, SHAN JIANG, STEPHEN ANTHONY, STEVE GRANICK, University of Illinois at Urbana and Champaign — Colloidal spheres with one side hydrophilic and the other side hydrophobic can self-assemble into clusters owing to amphiphilicity. When the particle concentration is high enough, 2D crystals with hexagonal translational order and additional orientational order will form. By using the Fourier Transform and particle tracking techniques, the position and the rotation of each single particle can be tracked. Long-range clockwork rotation behaviors were observed for the particles inside the clusters. In other words, when one particle rotates by Brownian motion, the particle next to it is impelled to counter-rotate. This transduction extends for a distance up to half a dozen particles.
K.100139 Modeling Chemical Reactions on Metal Oxide Surfaces, HAITAO LIU, University of Pittsburgh, MICHAEL FALCETTA, Grove City College, KENNETH JORDAN, University of Pittsburgh — Photocatalytic conversion of carbon dioxide to methanol has been observed at titanium dioxide interfaces, but the detailed mechanisms are unknown. Computer simulations can prove valuable in elucidating the mechanisms and aid in improving the efficiency. Two major computational strategies for treating such systems are slab and cluster models. The present work uses both periodic slab and embedded cluster models to elucidate the important factors in developing an embedding scheme that properly treats the system and allows the treatment of excited electronic states. Ground state adsorption energies are calculated for a variety of basis sets, cluster sizes, electronic structure methods and embedding schemes to demonstrate convergence with respect to all of these variables. Detailed comparisons of the electrostatic potential obtained from periodic and embedded cluster models are presented to clarify the importance of various effects in the embedding scheme.

K.100140 Spontaneous spreading of particle monolayers from unstable Pickering emulsions, HSIN-LING CHENG, SACHIN VELANKAR, Chemical Engineering, University of Pittsburgh — Partially-wettable particles can adsorb at liquid/liquid interfaces and give stable Pickering emulsions. However, if there are insufficient particles, then the emulsion is unstable. In such an unstable emulsion, we document a remarkable phenomenon, viz. coalescence of an oil/water/particle Pickering emulsion contained in a vial induces a particle film to climb up the walls of the vial. While this has been noted previously with nanoparticles, we show that such film-climbing is highly general and can be induced by a variety of particle types, particle sizes ranging from a few nm to a few microns, and different emulsion types. Many of the features of film growth described previously with nm-sized particles are found to remain true even with the far larger particles studied here. Binks et al., Langmuir, 22, 4100, 2006, have postulated that the particle films that climb up the walls of a vial are actually comprised of one oil layer and one water layer, with particles adsorbed at the interface between them. We confirmed this “sandwich” structure experimentally and also show that such interfacially-adsorbed particles can easily exert the very modest surface pressure necessary to sustain the weight of the film. Finally, while some climbing films are tightly-packed particle monolayers, tight packing is not essential; even sparsely-populated monolayers can display film climbing.

K.100141 Kinetics and Cross-Stream Migration of Polymer Solutions in Nanoscale Channel Undergoing Shear Flow, JAIME A. MILLAN, SIDY DANIOKO, MOHAMED LARADJI, University of Memphis — Polymer solutions confined to nanoscale slit pores are investigated in detail via generalized dissipative particle dynamics. We focus both on Poiseuille and planar Couette flows. In both cases, we investigated the effect of Schmidt number through the modification of both random and dissipative forces. The trend of the cross-stream migration of the polymer chains depends strongly on the value Schmidt number of the solution. In particular, we found a migration towards the walls for relatively low Schmidt number. However, polymer migration toward the channel centerline is observed for relatively high Schmidt number, in agreement with experimental observations and simulations based on other numerical approaches. The polymer chains kinetics is characterized by tumbling with well-defined characteristic time scale that decreases with increasing shear rate. The power spectra of both polymer stretch and tilt are in agreement with recent experiments.

K.100142 Synthesis, characterization and optical properties of magnesium hydroxide micro-/nanostructures, LATHA KUMARI, WENZHI LI, Florida International University, CHARLES H. VANNOY, ROGER M. LEBLANC, University of Miami, DEZHI WANG, Boston College, DEPARTMENT OF PHYSICS, FLORIDA INTERNATIONAL UNIVERSITY, MIAMI, FL 33199, USA TEAM, DEPARTMENT OF CHEMISTRY, UNIVERSITY OF MIAMI, CORAL GABLES, FL 33124, USA COLLABORATION, DEPARTMENT OF PHYSICS, BOSTON COLLEGE, CHESTNUT HILL, MA 02467, USA COLLABORATION — Magnesium hydroxide (Mg(OH)2) crystals of various shapes and sizes (micron to nano) were synthesized by single step hydrothermal route at different reaction conditions. The as-prepared hexagonal (Mg(OH)2) particles were converted to cubic MgO by calcination at 450°C. The Mg(OH)2 and MgO nanostructures showed optical band gaps of 5.7 and 3.43 eV, respectively. Broad band photoluminescence emission spectra were observed in the vicinity of UV and visible region. Mg(OH)2 and MgO nanostructures with wide optical band gap and short-wavelength luminescence emission can be used as a luminescent material for photonic applications.

1W.Z. Li acknowledges the support by National Science Foundation under grant DMR-0548061.

K.100143 Fabrication of zinc oxide microstructures and their properties, LATHA KUMARI, WENZHI LI, Florida International University, CHARLES H. VANNOY, ROGER M. LEBLANC, University of Miami, DEZHI WANG, Boston College, DEPARTMENT OF PHYSICS, FLORIDA INTERNATIONAL UNIVERSITY, MIAMI, FL 33199, USA TEAM, DEPARTMENT OF CHEMISTRY, UNIVERSITY OF MIAMI, CORAL GABLES, FL 33124, USA COLLABORATION, DEPARTMENT OF PHYSICS, BOSTON COLLEGE, CHESTNUT HILL, MA 02467, USA COLLABORATION — The bitter-melon-like and prism-like zinc oxide (ZnO) microstructures have been synthesized by hydrothermal route. Besides these microstructures, the ZnO material also consists of spherical nanoparticles with narrow size distribution. The as-synthesized ZnO material depicts hexagonal crystal structure. An optical band gap of 2.95 eV is determined from the UV-vis absorption band edge. The prism-like ZnO microstructure shows an ultraviolet near-band-edge emission at about 3.27 eV (380 nm) at room temperature which can be assigned to the radiative annihilation of excitons. The wide-band gap oxide materials like ZnO with short-wavelength PL emission can find application in light emitting devices.

K.100144 Size dependent thermalization time of Ag nanoparticles and the surface density profile, CATALINA LOPEZ-BASTIDAS, Centro de Nanociencias y Nanotecnologia, Universidad Nacional Autonoma de Mexico, Ensenada, Baja California, Mexico — It is well known that the lack of d-electron screening in the s-electron spill-out region at the surface of Ag nanoparticles increases the electron-electron interaction in this region compared to the bulk. Therefore when comparing the electron-electron interaction contribution to the thermalization time of Ag nanoparticles of varying radius, smaller particles thermalize faster due to the increased surface to bulk ratio. One aspect which has not been addressed is the effect of the spatial distribution of charge at the surface of the nanoparticle. In this work it is shown that the size dependence of the thermalization time is very sensitive to the surface density profile. The electron thermalization time of conduction electrons in Ag nanoparticles as a function of the radius is calculated. The sensitivity of the scattering rate to the spatial distribution of charge at the surface of the nanostructure is analyzed using several model surface profiles. The change in surface charge distribution via charging or coating of the nanospheres is shown to be a tool for control and probing of the ultra-fast electron-electron dynamics in metallic nanoparticles.
K1.00145 A General Route to Inorganic Nanoparticles Using a Condensed Electron Beam, MARISSA CALDWELL, Stanford University, SHAUL ALONI, JEFFREY URBAN, DELIA MILLIRON, LBLN, H.-S. PHILIP WONG, Stanford University — Inorganic nanoparticles are of interest to study the size dependence of various material properties. However, current colloidal synthetic routes are limited in the scope of accessible inorganic materials. Here we present a facile route to inorganic nanoparticles of a wide range of material compositions and sizes. Using the beam from an electron microscope, 2 – 100nm particles were formed from micron sized pieces of a wide range of materials including: semiconductors, metals, insulators. Using this route, we have produced nanoparticles of over 25 different compositions. Each material demonstrated an energetic threshold barrier to particle formation. To help elucidate the formation mechanism, we collected cathodoluminescence spectra which, when correlated with known temperature-dependent bandgap data, showed a large increase in temperature due to the e-beam-to-material interaction. The temperature rise dependence on the e-beam current and acceleration voltage was studied. We conclude that the temperature rise is large enough to compare with vaporization energies and is a plausible mechanism for the production of nanocrystals.

K1.00146 Can isolated Au nanoclusters catalyze CO oxidation?, P.-S. LIN, A.-L. CHIN, C.-P. CHANG, F.-K. MEN, Department of Physics, National Chung Cheng University, Chia-Yi, Taiwan, R.O.C. — It has been more than twenty years since the discovery of oxide-layer supported Au nanoclusters (<5 nm) capable of catalyzing CO oxidation. This discovery has attracted a lot of attention owing to possible practical applications as well as a model system for understanding nanoscale catalysis. One mechanism that has been proposed to explain this observation is that the process takes place entirely on Au nanoclusters. Since most experiments performed on this topic have been done in complicated environments, it would be difficult to fully justify/dismiss the validity of a particular mechanism. We have chosen a clean and inert support, highly oriented pyrolytic graphite, to grow Au nanoclusters via molecular beam epitaxy under ultrahigh vacuum conditions. We measured the change in CO$_2$ partial pressure after leaking high-purity CO and O$_2$ gases into the vacuum chamber with and without the presence of Au nanoclusters. To perform a systematic investigation, we also prepared Au nanoclusters of different densities and sizes. With the presence of Au nanoclusters we could not find any discernible increase in the CO$_2$ partial pressure, thus rules out the possibility that Au nanoclusters would take a full credit in catalyzing CO oxidation.

K1.00147 Chemical Synthesis and Characterization of Self-Assembled Nanoparticles Prepared in the Presence of Citrate Ions, KARL UNRUH, THOMAS EKIERT, University of Delaware — Iron(II) ions in aqueous solutions containing various concentrations of citrate ions have been reduced to metallic Fe using sodium borohydride. In comparison to the 10-20 nm diameter Fe particles formed in the absence of citrate, the presence of citrate results in the formation of 100–200 nm spherical (or in some cases cubical) particles self-assembled from much smaller Fe nanoparticles. Structural, chemical, and magnetic measurements indicate that for appropriate citrate/Fe ratios, air stable powders that exhibit a room temperature saturation magnetization of nearly 200 emu/g and a coercivity less than 100 Oe – even without deoxygenating the reaction solution or an explicit surface passivation step – can be obtained. Thermal treatments at temperatures between 350 and 450 °C result in the sintering of the Fe nanoparticles within the larger aggregates while heat treatments at higher temperatures result in the sintering of the aggregates themselves into a continuous porous matrix.

K1.00148 Brownian Motion of an Ellipsoid in Correlated Fluids, SHAOQING ZHANG, University of Pennsylvania, WU-PEI SU, University of Houston — To account for the correlation in the fluctuation force due to the surrounding media, we analytically study the diffusive behavior of an anisotropic Brownian particle by introducing an exponentially correlated colored noise in the rotational motion. The crossover from anisotropic to isotropic diffusion slows down, and the increase in the translational diffusion coefficient induced by an external force is enhanced. These results are of great interest in the research on biological physics and soft matters.

K1.00149 Enantiospecific Interaction of Histidine with Planes of Single Crystalline alpha Quartz, DANISH FARUQUI, PAUL J. SIDES, VLADIMIR V. PUSHKAREV, ANDREW J. GELLMAN, Carnegie Mellon Univ — Chiral chemistry profoundly affects living organisms because they are homochiral environments. The origin of life itself trace to enantiospecific interactions. Chiral purity is an important scientific and technological goal. Adsorption of chiral compounds on ‘powdered’ quartz is sometimes enantioselective. Here we offer positive evidence of diastereomeric, chiral recognition at the interface between ‘single crystal’ alpha quartz and aqueous histidine and verification of the effect for three principal crystallographic orientations of quartz. Characterizing the electrostatic environment, the zeta potential of (0001) L-quartz decreased by approximately 40 mV±5 as R-histidine was added incrementally to a concentration of 400 u molar; the zeta potential of the same L-quartz sample, however, decreased by only 20 mV±5 in an otherwise identical experiment with L-histidine. Results of all diasteriomeric and control experiments on each plane were consistent, the zeta-potential provides evidence that adsorption on quartz is enantiospecific; is influenced by the chirality of quartz but not necessarily by the crystallographic orientation of the surface.

K1.00150 Electronic Structure of Ti substituted hydroxypatite: TiHap, SHUXIA YIN, DONALD ELLIS, Northwestern University — Hydroxyapatite (Hap), with the chemical formula Ca$_{10}$(PO$_4$)$_6$(OH)$_2$, is the main mineral constituent of mammal tooth enamel and bone and has become an important biomaterial with medical applications. Hap also attracts increasing interest for use in environmental adsorbents and catalysts due to its porous nature and highly active ion-exchange character. Ti-modified Hap (TiHap) has been proved to possess high affinity to organic molecules and bacteria as well as high photocatalytic activity for their oxidative decomposition. The concentration of Ti$^{4+}$ is a key factor controlling TiHap crystallinity and catalytic efficiency. Here we studied the sorption mechanism of Ti$^{4+}$ on Hap using Density Functional Theory within periodic slab models. Ti$^{4+}$ or (Ti(OH)$_2$)$^{2+}$, as the most likely ion exchange species with Ca$^{2+}$, were first considered in bulk Hap. A second charge compensated model considered includes both surface Ca ion vacancies and substitutional Ti$^{4+}$. To obtain insight of the energetic stability and microscopic crystal structure of TiHap, Ti substitution on different Ca sites and distributions at different atomic ratios are investigated in both bulk and surface models.

1 Supported by US DOE, at Northwestern Institute for Catalysis in Energy Processes.
K1.00151 Time-Dependent Density Functional Theory Applied for Pulse Laser Shot: Criterion of the Numerical Stability1. YOSHIYUKI MIYAMOTO, CREST-JST, Nano Electronics Res. Labs. NEC, HONG ZHANG, Sichuan University — In this talk, applications of TDDFT [1] for irradiation of pulse laser to materials and subsequent structural change are shown. Contrary to the pioneering works [2-3], we present a way of judging numerical stability which can be confirmed by the energy conservation rule. The conserved quantity is the DFT total energy plus kinetic energy of ions minus work done by the pulse shot [4], which can simply be demonstrated with use of adiabatic exchange-correlation functional and time-varying electric field generated by a time-varying fictitious charge. As an example, structural change on graphite surface induced by pulse laser shot is demonstrated with use of 10-layer AB-stacked slab model. After irradiating laser shot with wavelength of 800 nm, pulse width of 50 fs, and a power about 90 mJ/cm² per pulse, the top graphene monolayer spontaneously leaves while other layers remain.

1All calculations were performed by using the Earth Simulator.

K1.00152 Enhanced Surface Plasmon Resonance. WEIQIANG MU, Northwestern University, JOON JANG, Northwestern University, MAXIM SUKHAREV, Arizona State University, DONALD BUCHHOLZ, ROBERT CHANG, JOHN KETTerson, Northwestern University, KETTERSON TEAM, CHANG TEAM, SUKHAREV TEAM — We have studied the surface plasmon resonances in thin silver films sandwiched between silica. This is the so-called Sarid geometry which supports a (short-range) symmetric and a (long-range) anti-symmetric mode. The coupling is achieved diffusively via an approximately sinusoidal surface etched in the underlying silica prior to deposition of a 20nm Ag film and a 400nm silica capping layer; the modulation amplitudes were 10, 30 and 50nm. FDTD simulations of the transmission (T) and reflection (R) coefficients show that for perpendicular incidence strong coupling occurs to the two plasmon modes along with a much weaker electromagnetic Woods anomaly. We will present data on both T and R showing evidence of coupling to the antisymmetric and symmetric Sarid modes as well as observations of waveguiding effects in the silica capping layer. Data will be compared with FDTD calculations for corresponding film parameters.

K1.00153 Changing What Science Is and How It’s Done. ROBERT JONES — Knowledge is of an approximate character. Our formalisms abstract and simplify. Each formalism is an idealization, often times approximating in its own DIFFERENT ways, each offering somewhat different coverage of the domain. Having MULTIPLE overlapping theories of a knowledge domain is then better than having just one theory (R. Jones, APS Gen. Meeting, March 2008 and refs. therein). In the future each field will possess multiple theories of its domain and scientific work and engineering will be performed based on the ensemble predictions of ALL of these. This idea can be considered an extension of Bohr’s notion of complementarity, “...different experimental arrangements...described by different physical concepts...together and only together exhaust the definable information we can obtain about the object.” Although finding the “correct” or “most probable” theory has been the goal of scientific investigation in the past we now know that the pluralistic science that I am describing here is more successful (Peter Cheeseman in The Mathematics of Generalization, D. H. Wolpert, Ed, 1995, pg. 315 and Michael Weisberg, J. of Philosophy, 2007, pg. 646). This is not postmodernism. Theories are accepted based upon experimental evidence not human opinion. Over the years I have tried to keep with this new pluralism in both my fusion energy and artificial intelligence work.

K1.00154 The Role of the Element Rhodium in the hyperbolic law of the Periodic Table of Elements. ALBERT KHAZAN — The method of equilateral hyperboles assumes that their tops should be certain with high accuracy by means of Lagrange’s theorem. On this basis the scaling factor for transition from the coordinate system usual to mathematicians to that which is to be used in chemistry is calculated. Such an approach has allowed calculating parameters of the last element. The calculation can be checked by means of the first sequel from the hyperbolic law, proceeding only from the atomic mass of the element Rhodium. As it has appeared, the direct and adjacent hyperboles are crossed in a point with the coordinates 205.811; 0.5, which abscissa makes a half of the last element’s atomic mass (the deviation is about 0.01%). The real axes of the hyperboles coincide with the tangents and normals, and the scaling factor differs from the first calculation as 0.001%. However these insignificant divergences are so small to the most important conclusion that the validity of the Hyperbolic Law, as calculation on Rhodium our data consists of (Progr. Physics, 2007, v.1, 38; v.2, 83; v.2, 104; 2008, v.3, 56).

K1.00155 Coordination of Swarmed Unmanned Ground Vehicles using Self Organization Mapping with Generic Algorithm1. SHEKHAR PRADHAN, DeVry College of New York — The methodologies for path planning for individual UGVs have been well studied and modeled. The Simultaneous Localization and Mapping (SLAM) is an example of such study. However, there is no reliable method of communication among swarmed UGVs. The author along with other collaborators, Dr. Wei Cao of NASA Research Center and Dr. James Burghart of Cleveland State University, proposes a Master-slave approach for the coordinated management of UGVs using Neural Networks. SOM is used to work with the coordinates 205.811, 0.5, which abscissa makes a half of the last element’s atomic mass (the deviation is about 0.01%). The real axes of the hyperboles coincide with the tangents and normals, and the scaling factor differs from the first calculation as 0.001%. However these insignificant divergences are so small to the most important conclusion that the validity of the Hyperbolic Law, as calculation on Rhodium our data consists of (Progr. Physics, 2007, v.1, 38; v.2, 83; v.2, 104; 2008, v.3, 56).

1The research is supported by NAVY and NASA grants.

K1.00156 Effects of Aggregation on the Electronic Properties of Polyyiophene and its Oligomers. KELLY ZEWE, LINDA PETEANU, WYNEE LEE — Polyyiophene is a commonly used component of organic electronics and solar cells. Polyyiophene chains are readily aggregated under the processing conditions used to form thin films for applications in devices. This aggregation can drastically alter the charge transfer and optical properties of the material. In order to better understand these effects, oligomers of polyyiophene were studied. Because oligomers have shorter, well-defined chain lengths and are free of defects, the effects of aggregation on their electronic properties are easier to interpret than those of the polymer systems and are more readily modeled using electronic structure theory. Bulk and single-molecule fluorescence methods are used to explore the emission properties as a function of aggregate size, precipitating solvent, and monomer properties and to correlate these to the polymer properties. Stark spectroscopy is used to measure the change in charge separation and in excited-state delocalization caused by aggregation and the consequent increase in chain-chain contacts.
K1.00157 Adsorption on Nanotubes With Repulsive First Neighbors\textsuperscript{1}. ALAIN PHARES, Villanova University, DAVID GRUMBINE, St. Vincent College, FRANCIS WUNDERLICH, Villanova University — We consider adsorption on nanotube lattices with zigzag triangular geometry. In Langmuir, Vol. 24, pp. 11722-11727 (2008), we studied such adsorptions with first- and second-neighbor interactions and attractive first-neighbors. The nanotube energy phase diagram is independent of \( M \), the number of atoms in the nanotube circumference, and holds for infinite \( M \), reproducing the infinite width limit of a triangular terrace [Langmuir, Vol. 24, pp. 124-134 (2008)]. Here, we consider repulsive first-neighbors. The phase characteristics, \( \{\theta_0, \theta, \beta\} \), are the coverage, and the numbers per site of first and second neighbors, respectively. Particle-hole symmetry holds for all nanotube diameters and the energy phase diagram is \( M \) dependent. In the infinite-\( M \) limit, the non-trivial phases with their complements are: \( \{1/4, 0, 0\} \), or \( \{2 \times 2\} \), and \( \{3/4, 3/2, 3/2\} \); \( \{1/3, 1/3, 0\} \), or \( \{3 \times 1\} \), and \( \{2/3, 4/3, 1\} \); \( \{1/3, 0, 1\} \), or \( \{\sqrt{3} \times \sqrt{3}\} \); \( \{2/3, 1, 2\} \); and \( \{1/2, 1/2, 1/2\} \), which is its own complement. This infinite-\( M \) limit should be the same as the infinite width limit of a triangular terrace. We found that we had missed the \( \{2/3, 4/3, 1\} \)-phase in Langmuir, Vol. 23, pp. 1928-1936 (2007).

\textsuperscript{1}Work supported by NSF and the Pittsburgh Supercomputing Center.

K1.00158 Fast algorithms for classical X− >0 diffusion-reaction processes. FABRICE THALMANN, University of Strasbourg and Insitut Charles Sadron CNRS,Strasbourg,France, NAM-KYUNG LEE, Department of Physics, Sejong University, Seoul, South-Korea — The Doi formalism [J.Phys.A 9, p1465, 1976] treats a reaction-diffusion process as a quantum many-body problem. We use this second quantized formulation as a starting point to derive a numerical scheme for simulating X− >0 reaction-diffusion processes, following a well-established time discretization procedure. In the case of a reaction zone localized in the configuration space, this formulation provides also a systematic way of designing an optimized, multiple time step algorithm, spending most of the computation time to sample the configurations where the reaction is likely to occur.

K1.00160 Vibrational spectroscopic study of newly developed self-forming lipids and nanovesicles. RAJAN BISTA, REINHARD BRUCH, University of Nevada, Reno, Nevada, USA — We present the first experimental study of self-forming synthetic nanovesicles, trademarked as QuSomes\textsuperscript{TM}, using vibrational spectroscopic techniques namely near-infrared (NIR) and laser tweezers Raman spectroscopy. Raman spectra of these new artificial nanovesicles suspended in Phosphate Buffered Saline (PBS) have been obtained by using an inverted confocal laser-tweezer-Raman-microscopy system in the spectral range of 3100 to 500 cm\textsuperscript{-1}. This spectrometer works with an 80 mW diode-pumped solid-state laser, operating at a wavelength of 785 nm in the TEM\textsubscript{00} mode. The laser is used both for optical trapping and Raman excitation. Similarly, NIR absorption spectra of these novel nanovesicles have been recorded in the spectral range of 9000-4800 cm\textsuperscript{-1} by using a new miniaturized micro-mirror spectrometer based on micro-optical-electro-mechanical systems (MOEMS) technology. In this work, we have found that the most prominent bands in the studied spectral region of Raman spectra are dominated by vibrational modes arising from C-C and CH\textsubscript{2} bonds. Similarly, NIR spectra are primarily assigned as first and second overtone of C-H stretching mode and second overtone of C=O stretching mode. These spectroscopic techniques have proven to be an excellent tool to establish the fingerprint region revealing the molecular structure and conformation of QuSomes\textsuperscript{TM} nanoparticles.

K1.00161 Effects of Aggregation on the Properties of Individual Conjugated Oligomers and Polymers Probed by Fluorescence Microscopy. GIZELLE SHERWOOD, LINDA PETEANU, JURJEN WILDEMAN — The recent upsurge in use of conjugated polymers in photovoltaic devices and in displays drives the need for understanding how morphology affects important functional features such as emission and charge migration. Due to the inherent complexity of polymers, a parallel effort to ‘build-up’ understanding of their features via a detailed study of important electronic and photo-physical properties of oligomer aggregates is needed. These exhibit remarkably uniform spectral properties that defy analysis via standard exciton coupling models. Fluorescence microscopy is used to probe both variations in vibronic structure and emission lifetime between individual aggregates and trends in these properties as a function of aggregate size.

K1.00162 ARTIFICIALLY STRUCTURED MATERIALS —

K1.00163 Template assisted synthesis and optical properties of gold nanoparticles,\textsuperscript{1}. PETRU FODOR, VINCENT LA SALVIA, Cleveland State University — A hybrid nanofabrication method (interference lithography + self assembly) was explored for the fabrication of arrays of gold nanoparticles. To ensure the uniformity of the nanoparticles, a template assisted synthesis was used in which the gold is electrodeposited in the pores of anodized aluminum membranes. The spacing between the pores and their ordering is controlled in the first fabrication step of the template in which laser lithography and metal deposition are used to produce aluminum films with controlled strain profiles. The diameter of the pores produced after anodizing the aluminum film in acidic solution determines the diameter of the gold particles, while their aspect ratio is controlled through the deposition time. Optical absorbance spectroscopy is used to evaluate the ability to tune the nanoparticles plasmon resonance spectra through control over their size and aspect ratio.

K1.00164 Structural and Electrical Study of ZnO Nanowires Grown on Silicon and Titanium Substrates. EDWARD LIKOVICH, ERIC PETERSEN, VENKATESH NARAYANAMURTI, Harvard University School of Engineering and Applied Sciences — We studied the VLS (vapor-liquid-solid) growth of ZnO nanowires on catalytically patterned Silicon and Titanium foil substrates. We provide evidence for VLS growth from the formation of a eutectic liquid between Au catalyst particles and the Si or Ti substrate. In order to further understand conduction in nanowires, we present preliminary data from electrical measurements on wires grown on each substrate and provide a comparison. We show that the use of metal foil substrates exhibits promise for future nanowire applications in large-area light emitters, collectors, and thermoelectrics.

This work was supported through a Cottrell College Science Award ID 7347 from the Research Corporation for Science Advancement.
K1.00165 Electronic properties of boron nano-ribbons: - DFT study, SUMIT SAXENA, TREVOR A. TYSON, Department of Physics, New Jersey Institute of Technology, Newark, NJ. — Electronic properties of boron nano-ribbons have been studied using density functional techniques employing ultra-soft pseudo-potentials. Spin restricted calculations were performed for boron nano-ribbons constructed from stable boron sheet structures. Different stable edge configurations of nano-ribbons were observed. Band structure analysis was performed and Density of states was calculated to determine the electronic phase of these nano-ribbons. Comparisons with the carbon systems will be made. This work is supported in part by NSF DMR-051219.

K1.00166 Fundamentals of magneto-optics of single Rashba spintronic quantum dots, MANVIR KUSHWAHA, University of Puebla, Mexico — We report on the theoretical investigation of the effect of the Rashba-type spin-orbit interaction (SOI) on the Fock-Darwin energy spectrum in the parabolically confined quantum dots in the presence of a perpendicular [to the original two-dimensional electron gas (2DEG)] magnetic field. The study is based on the formal (analytical) results without resorting to any numerical simulation. We observe that the SOI modifies drastically the optical, thermodynamic, as well as magneto-optical properties of the (narrow-gap InAs) quantum dots. We discuss the dependence of the Fock-Darwin spectrum, Fermi energy, optical transitions, and magnetization on all the important parameters involved in the theory such as, for example, the orbital quantum number, the magnetic field, the confinement potential, and the Rashba parameter that characterizes the strength of the SOI. The illustrative examples include the results both with and without the SOI, for the sake of comparison. One of the most important observation is that the Rashba SOI causes the band mixing and band shifting in the quantum dots and the Fock-Darwin energy spectrum becomes richer but complex. This complexity seems to arise due to an intricate interplay between the SOI and the Zeeman energy.

K1.00167 Quantum Wire Fano Resonance in an Electric Field, V. VARGIAMIDIS, Aristotle University, Thessaloniki, Greece, V. FESSATIDIS, Fordham University, Bronx, USA, N.J.M. HORING, Stevens Institute of Technology, Hoboken, USA — Electronic transport through a straight parabolically confined quantum wire with an attractive impurity and a transverse electric field is investigated via the Feshbach coupled-channel theory. The impurity is modeled by a δ-function potential in the propagation direction while it is Gaussian in the transverse direction. In the presence of an impurity, the transmission probability of the wire may exhibit resonances of the Fano type (which is the result of the interference between background transmission and transmission via a quasibound state created in the impurity). It is shown here that increasing the field strength from zero causes displacement of the confining potential, thereby inducing a “shifting” of the impurity across the channel and therefore influencing the resonance structure. As the center of the confining potential approaches the center of the impurity, the coupling of the (first) propagating state with the quasibound state of the second channel gradually decreases, resulting in a decrease of the resonance width. For a particular value of the field strength the resonance width shrinks to zero and the Fano profile collapses. The resonance energy is also examined as a function of the electric field strength.

K1.00168 Fabrication and Electrical Characterization of Zinc Oxide Nanowires, DAQING ZHANG, CHUN-HONG LEE, CSU Fresno, CHRIS VERVEN, Univ. of Idaho, VANVILAI KATKANANT, CSU Fresno — One dimensional semiconducting zinc oxide (ZnO) nanowires have drawn attractive attentions in the past years. The unique electrical, optical, and piezoelectric properties of ZnO nanowires make them broad applications ranging from light emitting diode and lasers, solar cells, photodetectors, electron transporters and transistors, to piezoelectric generators. In our research, two-terminal current-voltage (I-V) measurements were conducted to determine the electrical conductivity alternation of the ZnO nanowires under laser irradiation, and various gaseous surroundings. The I-V curves at the temperature ranged from 150 to 300 K were recorded in vacuum. The Arrhenius plot shows perfect linear relation between I and T. The donor lever of the semiconducting nanowire is about 326 meV. We observed that the current increased by 50% with laser on in comparison to that with it off; it raised by a factor of four under ambient reductive gas CO. In addition, the I-V behaviors were found to be reversible with those various environments. Further studies on the possible nano-devices such as optical switches and chemical sensors are undergoing.

K1.00169 Elementary process of electromigration investigated by novel spectroscopic approach to electrical break junctions, Akinori Umeno, Kazuhiako Hirakawa, IIS, Univ. of Tokyo, INQIE TEAM, CREST-JST TEAM — We have investigated electromigration process at gold nanojunctions by introducing a novel spectroscopic analysis. Gold nanojunctions were broken into nanogaps by passing large current, which was controlled by monitoring the evolution of junction conductance. We observed that, for the junctions as small as few tens of atoms, the junction conductance showed successive drops by one quantum (e^2/h), corresponding to one-by-one removal of gold atoms, only when the junction voltage exceeded certain critical values. The histogram of the observed critical voltages showed a clear peak, V_p, and eV_p was found to agree with the activation energy for surface diffusion of gold atoms. The result indicates that the elementary process of electromigration in such small junctions is the self-diffusion of metal atoms driven by microscopic kinetic energy transfer from a single conduction electron to a single metal atom. Technological implications of this new finding are also discussed in terms of reproducible formation of nanogap electrodes for single molecular junctions and also failure-tolerant interconnections for VLSIs.

K1.00170 Band structure of core-shell semiconductor nanowires, MATS-ERIK PISTOL, Dept. of Solid State Physics, Lund University, Sweden, CRAIG PRYOR, Dept. of Physics and Astronomy, University of Iowa — We present band structures of strained core-shell nanowires composed of zincblende III-V (binary) semiconductors. We consider all combinations of AIN, GaN, InN, and all combinations of AIP, GaP, AIA, GaAs, InP, AlSb, GaSb, and InSb. We compute the Γ- and X-conduction band minima as well as the valence band maximum, all as functions of the core and shell radii. The calculations were performed using continuum elasticity theory for the strain, eight-band strain-dependent k·p theory for the Γ-point energies, and single band approximation for the X-point conduction minima. We identify structures with type-I, type-II and type-III band alignment, as well as systems in which one material becomes metallic due to a negative band-gap. We identify structures that may support exciton crystals with and without photocoexcitation. We have also computed the effective masses, from which the confinement energy may be estimated. All the results [Pistol and Pryor, Phys. Rev. B 78, 115319] are available in graphical and tabular form at www.semiconductor.physics.uiowa.edu

K1.00171 Analysis of electron transport through quantum dots using the Hidden Markov Model (HMM), MATTHEW HOUSE, HONG WEN JIANG, Department of Physics, University of California Los Angeles — The number of electrons present on a quantum dot defined in a two-dimensional electron gas in a semiconductor heterostructure can be observed using a nearby quantum point contact (QPC), but counting the number of electrons present in the dot does not directly reveal the presence of multiple allowed states that contain the same number of electrons; i.e. different orbital or spin states. Two or more states with the same number of electrons may have different rates of transition to other, directly observable states. In this case they may be indirectly distinguishable, by analysis of the statistics of a time series of data. We present a new approach to analysis of QPC data based on the Hidden Markov Model (HMM). HMM theory provides a mathematical framework for optimally estimating the rates of transition between a system with various states, which may include states that cannot be directly distinguished from one another by observation (they are “hidden”). Statistical tests can be applied to determine if the hypothesis of a “hidden” state is justified by the data. The application of the HMM framework to the quantum dot analysis problem and preliminary results of the application of this approach to electron transport data is presented.
K1.00172 Si$_{0.7}$Ge$_{0.3}$ Nanorings Mediated By Ag Nanodots: Structural Evolution and Enhanced Photoluminescence Properties

CHIN HO, CHENG-YING CHEN, JR-HAU HE, Natl Taiwan Univ, INSTITUTE OF PHOTONICS AND OPTOELECTRONICS TEAM — Currently nanorings (NRs) are attractive because there is a great deal of interest in nanostructures from theoretical, experimental, and device perspectives. The feasible NR fabrication is demanded in the field of electronic and optoelectronic devices at the nanoscale. In the present study, the growth of high-density Si$_{0.7}$Ge$_{0.3}$ NRs has been achieved on ultrathin Ag films on Si$_{0.7}$Ge$_{0.3}$ substrate. In situ ultrahigh-vacuum transmission electron microscopy revealed that the formation of nanorings involves a mechanism mediated by Ag NDs and evaporation of Ag-Si-Ge eutectic liquid at high temperature. Si$_{0.7}$Ge$_{0.3}$ NRs exhibit the enhanced PL intensity over Si$_{0.7}$Ge$_{0.3}$ thin film due to quantum size effects. The luminescence efficiency as a function of the size of Si$_{0.7}$Ge$_{0.3}$ NRs has been investigated. Power-dependent PL demonstrates that the NR mediated by Ag NDs is type-I band alignment. The process promising the availability of type-I Si$_{0.7}$Ge$_{0.3}$ NRs can serve as a useful platform for the fundamental understanding and future practical applications of NRs.

K1.00173 Experimental demonstration of reflection minimization at 2D photonic crystal interfaces via antireflection structures

TEUN-TEUN KIM, SUN-GOO LEE, MYEONG-WOO KIM, JAE-EUN KIM, HAE YONG PARK, Department of Physics, KAIST, 373-1 Guseong-dong, Yuseong-gu, Daejeon, Korea, PHOTONIC CRYSTAL LAB. DEPARTMENT OF PHYSICS, KAIST TEAM — We experimentally confirm that the antireflection structures effectively minimize the unnecessary reflections of self-collimated microwave beams in a two-dimensional square lattice photonic crystal composed of alumina rods. The optimized design parameters for the antireflection parameters are obtained from the one-dimensional antireflection coating theory and the finite-difference time-domain simulations. Measurements of the transmission through the photonic crystal samples with and without the antireflection coating structures agree well with the simulation results. Measured results show that the photonic crystal with an antireflection coating structure yields transmission of more than 80% of the incident power near the self-collimation frequency, which is more improved transmittance with wider band compared to the case without the antireflection coating structure.

K1.00174 Localized and Resonant elastic sagittal modes in one-dimensional phononic crystals

1, L. CASTRO-ARCE, Department of Research in Physics, University Sonora; Department Physics, Mathematics and Ingeering, unity Regional Sorth, Navojoa Sonora Mexico, F. RAMOS-MENDIETA, Department of Research in Physics, University of Sonora, Hermillos, Sonora Mexico — By incorporating a defect Zn layer in an Epoxy/Sn one-dimensional phononic crystal we found transmission peaks associated to localized longitudinal and transverse elastic states. The same localized modes of orthogonal polarizations are excited by incident longitudinal or transverse waves; thus, the transmission spectrum of localized vibrations does not depend on the polarization of the incident wave. The phenomenon can be explained on basis of mode conversion. In addition, resonant modes with frequencies lying inside a bulk band were also found. It is interesting that as function of both the size of the phononic sample and the angle of incidence, the polarization of the transmission resonant peaks change; for example, for a sample of seven cells with the defect at the center, the mode can change from quasitransverse to quasilongitudinal when the angle of incidence changes from 30 to 40 degrees. The variation of polarization is also independent of the polarization of the incident wave.

2The firt author has a scholarship from CONACYT (Mexico).

K1.00175 Transport Properties of Nanoscale Materials by First-principles Calculations

K1.00176 ThermoElectric and Structural Properties of Sintered LaCoO$_3$ Ceramics

1, A. CORTES, W. LOPERA, Thin Film Group Department of Physics, Universidad del Valle, Cali, Colombia, P. PRIETO, Excellence Center for Novel Materials — Electrical and thermal transport properties of LaCoO$_3$ in bulk are reported in the temperature range from 10 to 390 K. The crystalline structure of the samples was determined by x-ray diffractionometry (XRD). XRD measurements indicated that the formation of LaCoO$_3$ was completed, and it was verified that a pure phase with rhombohedral crystalline structure was obtained. The results of the thermoelectric measurements show that the Seebeck coefficient ($S$) initially grow with the increasing of temperature up to a maximum value around of 650 $\mu$V/K at 230 K. After this temperature $S$ decrease slowly up to a value of 520 $\mu$V/K, at room temperature. The polycrystalline LaCoO$_3$ samples show thermal conductivity around 0.4 W/mK at room temperature, that is a lower value than the reported for single crystal samples of this material. Electrical resistivity measurements show typical semiconducting behavior, with a large value of resistivity, close to 2.6 $\Omega$. Finally the thermoelectric figure of merit have a maximum value of 0.09, at room temperature, that is comparable to previous reported values for this material.

K1.00177 Accurate thermopower measurement of quasi-one dimensional nanomaterials

1, YI-BIN GAO, YE WANG, JUN-YI WANG, Department of Physics, Peking University, LIAN-MAO PENG, SHENG-YONG XU, Department of Electronics, Peking University — To measure accurate thermopower (Seebeck coefficient) of a nanomaterial is of importance for developing low-dimensional thermoelectrics and energy-conversion devices. We have built up sample stages with copper bulks and 25 micron-diameter gold wires, and assembled multi-wall carbon nanotubes (MWCNT) and individual nanowires onto these stages using in situ nano-probe manipulation in a scanning electron microscope. We can establish a temperature difference as high as 80K between two ends of a nanomaterial sample with this kind of stage, thus obtain a measurement accuracy of 2%-5%. For MWCNT bundles, we have observed a trend that, when the number of individual tubes in a bundle varies from several millions to around a thousand, the thermopower almost remains as a constant value around 10 microvolt per Kelvin. But when the tube number in the bundle is further reduced to less than a hundred, the thermopower increases steeply to a value near 20 microvolt per Kelvin. The result is attributed to the effect of surface adsorption of oxygen on the thermopower of the bundle.

**K1.00178** Phonon Thermal Conductivity of Si/Ge Nanostructures, SHANG-FEN REN, Illinois State University. WEI CHENG, Beijing Normal University — Phonon thermal conductivities of various Si/Ge nanostructures (NSs), including nanocrystals, nanowires, nanowires, and Si/Ge nanocomposites, are investigated with three different models: macroscopic approximation, semi-microscopic model that calculates the heat capacity of NSs with a microscopic Valence-Force-Field Model (VFFM), and a full microscopic description of phonon thermal conduction that calculate both heat capacity and phonon group velocity by the VFFM. The results are compared, and the advantages and limitations of each of the models are discussed. It is shown that with full microscopic description, phonon thermal conductivity in Si/Ge nanostructures might be quite different from those obtained with the macroscopic description, mainly depending on the roughness of the interfaces and the size of the nanostructures. This further indicates that it is critically important to investigate phonon thermal conductivities in nanostructures with microscopic models when the roughness is important to consider and the size of the nanostructures is small.

**K1.00179** High Pressure Structural and Electrical Transport Properties of the Ca$_3$Co$_4$O$_7$ System, T. WU, T.A. TYSON, Z. CHEN, Department of Physics, New Jersey Institute of Technology, Q. JIE, Q. LI. Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, J.J. TU, Department of Physics. The City College of New York — High pressure and temperature dependent resistivity measurements were conducted on the Ca$_3$Co$_4$O$_7$ system to understand the influence of internal pressure by doping on the properties of these materials. To directly probe the effect of pressure on the structure, x-ray diffraction measurements under pressure were also conducted with diamond anvil cells at ambient temperature. The results are compared with ambient pressure chemically materials. The influence of the atomic structure on the thermolectric properties will be discussed.

**K1.00180** Magnetism in ZnO, CHANYONG HWANG, W. KIM, Korea Research Institute of Standards and Science, JISANG HONG, Department of Physics, Pukyung National University, H.J. KIM, Chungnam National University, Y.P. LEE, Department of Physicis and q-Psi, Hanyang University — DMS has drawn a lot of attention for the possible use in spintronics. Ferromagnetic order showed up after the doping the oxide such as ZnO with transition metals. The origin of this ferromagnetic order is still controversial. Especially addition of Cu as a dopant material for ferromagnetic order raises the question on the role of transition metal dopant for the existence of ferromagnetic order. We have used high energy electron beam to build the Zn vacancy. SQUID and MCD results will be presented for the existence of long range ferromagnetic order. First principles calculation also supports our model for the origin of this ferromagnetism. (Supported by KOSEF)

**K1.00181** Fabrication of Si nanowires on Si (100) using a scanning probe tip, JOSHUA SMITH, ROBERT DAVIS, YING YI DANG, GARY FEDDER, JIM BAIN, DAVID RICKETTS, Carnegie Mellon University — Reliable fabrication on the nanoscale is becoming increasingly important. The co-author team is investigating a nanolithography technique for the deposition of nanoscale features entitled “Tip-directed, field-emission assisted nanomanufacturing” (TFAN). The TFAN process involves the adsorption of a layer of silicon-containing gas, such as disilane, to a substrate and the selective patterning of the surface with field-emitted electrons from a scanning probe tip. The electrons crack the Si containing molecules, which results in the deposition of Si on the substrate. The adsorption of Si-containing molecules to the substrate surface is critical to the success of this approach. The investigation involves the determination of the coverage, sticking coefficient, and temperature constant of disilane on the Si(100) surface using temperature programmed desorption and scanning tunneling microscopy.

**K1.00182** Excitation energy dependence of fluorescence intermittency in CdSe/ZnS core-shell nanocrystals, ROBERT MOHR, THOMAS EMMONS, CATHERINE CROUCH, Swarthmore College — We report measurements of the excitation energy dependence of the fluorescence intermittency of single CdSe/ZnS core/shell nanocrystals (NCs) using two different excitation energies. The lower excitation energy, at 532 nm, corresponds to excitation of 270 meV above the band gap. The higher energy, at 405 nm, corresponds to excitation of 1.0 eV above the bandgap. At each excitation energy, 77 individual NCs were measured for 1500 s. The on-times from each individual NC follow a power-law distribution with the same exponent regardless of excitation energy. The on-times follow a truncated power law distribution with an exponent that is independent of energy, but the distribution of truncation times obtained from the individual NCs at the higher energy is peaked at shorter values than the distribution obtained with the lower excitation energy.

**K1.00183** Polarization-independent extraordinary optical transmission in three-dimensional metallic gratings, YUEHUI LU, MINHYUNG CHO, YOUNGPAK LEE, Hanyang University, Korea, JOOYULL RHEE, Sungkyunkwan University, Korea — Extraordinary optical transmission (EOT) is a unique effect that light is transmitted with an efficiency greater than unity when it is normalized to the area of grooves or holes. In this work, the EOT of both transverse-electric (TE) and transverse-magnetic (TM) polarizations was investigated for sub-wavelength metallic gratings by the rigorous coupled-wave analysis, implemented as the Airy-like internal reflection series. Generally, the EOT is achievable for TM polarization due to the excitation of coupled surface plasmon polaritons (SPPs), whereas the SPP-produced EOT for TE polarized light is impossible because of the absence of SPPs for this polarization. However, the TE-polarized EOT produced by cavity modes is available. In this work, the polarization-independent EOT is exhibited in the pure metallic gratings with broad slits without need for a specific dielectric filler in the grooves. The design proposed in this work simplifies the realization of gratings that possess the polarization-independent EOT.

**K1.00184** On Static and Dynamic Properties of Solitons in Molecular Chains, IRINA BARIAKHTAR, Boston College — The cross section for scattering of x-rays by solitons is calculated for the solitons corresponding to the formation of kinks in quasi-one-dimensional systems, e.g. molecular chains. Obtained is the temperature dependence of the soliton density, the shape of the particle density distribution in the soliton, based on the study of the x-ray scattering cross section by solitons, and other static and dynamic properties of the solitons in quasi-one-dimensional systems.

**K1.00185** SPP resonance and transmission enhancement of 1D slit array on aluminum film at microwave regime, MYEONG-WOO KIM, TEUN-TEUN KIM, JAE-EUN KIM, HAE YONG PARK, Department of Physics, KAIST, 373-1 Guseong-dong, Yuseong-gu, Daejeon, Korea, DEPARTMENT OF PHYSICS, KAIST TEAM — In this presentation, we show the transmission enhancement through periodically slit arrays on a metallic film experimentally measured in the microwave regime. Enhanced transmission peaks and sharp transmission dips are clearly observed near the surface plasmon polariton(SPP) resonance frequencies calculated theoretically. The measured transmittance spectra exhibit considerable dependence on the geometrical properties of slits such as slit width, slit periodicity and metallic film thickness. Transmission peaks and dips are originated from the coupling between the incident light and SPPs which are caused by the slit array which acts like a grating coupler. Obtained results are theoretically explained by solving the Maxwell’s equations and the diffraction theory with appropriate boundary conditions, which are in excellent agreement with those calculated by the finite-difference time-domain method.
Photoresponse in large area multi-walled carbon nanotube/polymer nanocomposite films, Paul Stokes, Jianhua Zou, Lei Zhai, Qun Huo, Saiful I. Khondaker, University of Central Florida, Nanoscience Technology Center, Department of Physics, Chemistry, Materials and Aerospace Engineering. Recently, photoresponse of CNTs (both in visible and near infrared (NIR) regime) have generated considerable debate in terms of whether the photoresponse is (i) due to photon induced charge carrier (excitonic), (ii) due to heating of the CNT network (bolometric), or (iii) caused by photodesorption of oxygen molecules at the surface of the CNT. In addition, the role of the metal electrode - CNT contact's effect on the photoresponse has also been debated. Here, we will present near IR photoresponse study of large area multi-walled carbon nanotube/poly(3-hexithiophene)-b-polystyrene polymer (MWNT/P3HT-b-PS) nanocomposite films for different loading ratio of MWNT in polymer matrix. We show that, compared to pure MWNT film, there is a large enhancement of photocurrent in MWNT/polymer composite film. The photocurrent strongly depends on the position of the laser spot with maximum response occurring at the metal - film interface. The time constant for the photoresponse is slow and varies between 0.6 and 1.2 seconds. We explain the photoresponse of the composite film by Schottky barrier modulation at the metal – film interface and discuss reasons for the slow time response.

Enhanced 1540 nm emission from ZnO:Er nanorod arrays via Ag island films, JIANG-WEI LO, CHIN-AN LIN, JR-HAUE HE, Natl Taiwan Univ. Self-assembled nanorod arrays (NRAs) heterostructures that consist of a single-crystalline Er-doped ZnO NRAs grown on Ag nanodot films have been synthesized by a chemical method and proposed as one of the promising optoelectronic materials since the Er intra-4f shell transition leads to 1540 nm emission for optical communication. The enhancement of 1540-nm emission of Er-doped ZnO NRAs via enhanced deep level emission of ZnO host resulted from local field enhancement effects of Ag nanodot films, and subsequent energy transfer to Er has been demonstrated. The microstructural analysis, electronic structure analysis, and photoluminescence characterizations have been performed to clarify the mechanism of enhanced 1540 nm emission. This paves the way to electrical pumping in a nano-system that forms NRAs of high-quality optical cavity.

Influence of Negative-Bias Voltage on Mechanical Properties of Quaternary Ti(Nb)(C)(N) Coatings, M.E. GOMEZ, J.C. CAicedo, C. AMAYA, G.A. MENDOZA, J. ALVARADO-RIVERA, J. MUNOZ-SALDANA, P. PRIETO, UNIVERSIDAD DEL VALLE, COLOMBIA TEAM, UNIVERSIDAD NACIONAL DE COLOMBIA, BOGOTA TEAM, CINVESTAV, IPN, QUERETARO, MEXICO TEAM, CENM, COLOMBIA COLLABORATION. Mechanical properties of quaternary Ti-Nb-C-N films via r.f magnetron sputtering process were studied by nanoindentation. The r.f. bias voltage was systematically varied from 0, -50, -100 V, keeping all other growth parameters fixed. Active vibration modes were analyzed by using Fourier transformed infrared spectroscopy (FTIR), where bands associated to Ti-N, Nb-C-N and Ti-C-N bonds, and to Ti-Nb-C-N stretching vibrations were found. Nanindentation results reaching the elastic-plastic behavior of the Ti-Nb-C-N films indicate that both hardness and elastic modulus increase from 22 to 30 GPa and from 220 to 306 GPa, respectively. Thus, increasing the bias-voltage from 0 to -100V a clear improvement of hardness and elastic modulus were obtained.

Electrical and Optical characterization of GaN$_x$As$_{1-x}$ fabricated using Ion Implantation and Pulsed Laser Melting, TAESEOK KIM, MICHAEL J. AZIZ, VENKATESH NARAYANAMURTI, School of Engineering and Applied Sciences, Harvard University, KIRSTIN ALBERI, National Renewable Energy Laboratory, OSCAR D. DUBON, Dept. of Materials Science and Engineering, University of California, Berkeley. We present a systematic investigation of the band structure of GaN$_x$As$_{1-x}$ alloys synthesized using nitrogen ion implantation followed by pulsed laser melting and rapid thermal annealing. The evolution of the nitrogen concentration-depth profile is consistent with liquid-phase diffusion, solute trapping at the rapidly moving solidification front, and surface evaporation. The reduction of the Schottky barrier height at nitrogen composition up to $x = 0.06$ is studied by ballistic electron emission microscopy (BEEM) and determined quantitatively using second voltage derivative (SD) BEEM spectra. This composition effect on the barrier height is consistent with the bandgap narrowing measured on the same samples by photomodulated reflectance and is also consistent with the band anti-crossing model for the splitting of the conduction band in GaN$_x$As$_{1-x}$ alloys. Lithographically patterned GaN$_x$As$_{1-x}$ dots are imaged by BEEM. Analysis of BEEM spectra from the locally confined dots indicates an alloying-induced decrease in the Schottky barrier height of four times the thermal energy at room temperature.

SURFACES, INTERFACES AND THIN FILMS

Ab-initio study of the O covered Cu(100), Cu(110), and Cu(111) surfaces, N.G. FAZLEEV, Department of Physics, University of Texas at Arlington. The study of adsorption of oxygen on transition metal surface is important for the understanding of oxidation, heterogeneous catalysis, and metal corrosion. The structures formed on transition metal surfaces vary from simple adlayers of chemisorbed oxygen to oxygen diffusion into the sub-surface region and the formation of oxides. In this work we present an ab-initio investigation of stability and associated physical and electronic properties of different adsorption phases of oxygen on Cu(100), Cu(110) and Cu(111) as well as of the clean Cu surfaces using density functional theory in the generalized gradient approximation and a four-layer slab to model the ideal Cu surfaces. In particular, we fully optimize the geometry of the surfaces with adsorbed oxygen and study the electronic structure, the changes in electron work function, surface energy, and interlayer spacings as a function of coverage. Furthermore, we study the chemistry of the metal-adsorbate bonding. Results and analysis are also presented for the Cu20(100) surface. We compare our results to both experimental data and other theoretical models.

Adsorption and Dissociation of Water on the (0001) Surface of DHCP Americium, PRATIK DHOLABHAI, ASOK RAY, The University of Texas at Arlington. Ab initio total energy calculations within the framework of density functional theory have been performed for water molecule adsorption on the (0001) surface of double hexagonal closed packed americium. Subsequent partial dissociation (OH-H) and complete dissociation (H=O-H) of the water molecule have been examined. The completely dissociated configuration exhibits the strongest binding with the surface followed by partially dissociated species, with all molecular H2O configurations showing weak physisorption. The change in work functions and net magnetic moments before and after adsorption will be presented for all the cases studied. The adsorbate-substrate interactions will be elaborated using the difference charge density distributions and the local density of states. The effects of adsorption on Am 5f electron localization-delocalization in the vicinity of the Fermi level will be discussed.
K.00193 Hydrogen adsorption on the (020) surface of α-Pu — A computational Study

RAY, MD ISLAM, University of Texas at Arlington, TX 76019 — We have studied the hydrogen adsorption on (020) surface of α-Pu and the effect of surface relaxation on chemisorption using relativistic full-potential augmented plane wave with local orbital basis method. The surface is modeled with four-layer slab consisting of 32 atoms with layer by layer anti-ferromagnetic arrangements. We have investigated the adsorption properties for four different adsorption sites, namely the top, the hollow, the short bridge and the long bridge sites. All the computations are carried out both at scalar relativistic level where spin-orbit interaction is ignored and where it is included, to study the effect of SO interaction on the adsorption properties. The effect of relaxation is also studied by calculating adsorption properties both on the relaxed and the non-relaxed surfaces. Our studies show that the short bridge is the most favorable site for hydrogen adsorption with chemisorption energy of 2.75 eV. Our study also shows that the spin-orbit coupling and the surface relaxation have very little impact on adsorption.

K.00194 Ab initio Calculation of optical properties of II-VI semiconductor surfaces

VAZQUEZ-NAVA, NORTERNO ARZATE, Centro de Investigaciones en Optica A. C., B.S. MENDOZA, Centro de Investigaciones en Optica — In this work we present some ab initio calculations of reflectance anisotropy spectra (RAS) of VI-II semiconductor surfaces having different surface reconstructions. We use an ab initio pseudopotential formalism in the framework of the density functional theory and within the local density approximation (DFT-LDA). We study the (001) polar surface of cadmium telluride (CdTe) and zinc telluride ZnTe with different reconstructions. Also we obtain RAS using a microscopic formulation based on a semi-empirical tight binding (SETB) approach which includes spin-orbit (SO) interactions [1]. We show RAS of each surface reconstruction and compare both theoretical results with experimental results [2]. We find a good agreement between experimental and theoretical spectra.

K.00195 Structure, composition and optical band gap of TiO₂ films prepared by d.c. magnetron sputtering

GOMEZ, A. ARIAS, E. CAMPS, L. ESCOBAR-ALARCON, F. ESPINOZA, J. MUÑOZ-SALDANA, G.A. MENDOZA, G. ZAMBRANO, UNIVERSIDAD DEL VALLE, COLOMBIA TEAM, INSTITUTO DE INVESTIGACIONES NUCLEARES (ININ), MEXICO TEAM, CINVESTAV, QUERÉTARO, MEXICO TEAM, UNIVERSIDAD NACIONAL DE COLOMBIA, BOGOTA TEAM — Titanium dioxide (TiO₂) thin films have been grown on silicon (001) substrate by d.c. magnetron sputtering. In an gas mixture at different Ar/O₂ ratio flow and at two different substrate temperatures (400 and 550 °C). Samples were characterized by X-ray diffraction, XRD, Raman spectroscopy, Scanning Electron Microscopy (SEM), Fourier Transformed Infrared Spectroscopy (FTIR) and UV-Vis analysis. Results showed that we obtained TiO₂-Anatase phase for the 90/10 of Ar/O₂ ratio in the gas mixture and at substrate temperature of 400 °C. The anatase phase proportion in the films decreases by increasing the oxygen concentration in the Ar/O₂ gas mixture. Optical band gap of 2.9 and 2.7 eV was calculated from UV-Vis spectra for sample grown at 90/10 and 80/20 of Ar/O₂ ratio, respectively.

Acknowledgments: This work has been partially supported by CENM-COLCIENCIAS contract 043-2005. Authors thank Department of Chemistry at Universidad del Valle for FTIR measurements.

K.00196 Growth and characterization of EuO thin films

BRENNER, M. EBLEN-ZAYAS, Carleton College — Eu-rich EuO is a ferromagnetic semiconductor that exhibits an insulator-metal transition associated with the onset of ferromagnetism and a colossal magnetoresistance response. In addition, the material is of interest for its possible use in spintronics. The materials properties are extremely sensitive to the stoichiometry of films. We will compare the properties of these films as a function of growth parameters, and discuss the stability of these films over time. In addition, we will present work comparing the properties of EuO thin films grown via reactive evaporation of Eu in the presence of an oxygen partial pressure with EuO films grown by Eu deposition followed by oxidation.

This work is supported by the Research Corporation and NSF DMR-0804715.

K.00197 Evolution of size distribution of Cobalt Silicide islands on (5x2) reconstructed Au/Si(111) surfaces

HUNG-CHIH KAN, TI-LI LIN, AN-LI CHIN, FU-KWO MEN, Department of Physics, National Chung Cheng University, Chia-Yi, Taiwan, ROC — We report our preliminary result on the observation of the evolution of Cobalt silicide islands on (5x2) reconstructed Au/Si(111) surfaces during high temperature annealing with snap-shot scanning tunneling microscopy (STM). At room temperature, we deposited Co on (5x2) reconstructed Au/Si(111) surfaces in an ultra-high vacuum (UHV) environment. We then annealed the surface at temperatures around 500 °C, and first observed the formation of cobalt silicide islands on the terraces and across the steps. Subsequent annealing causes the islands to evolve: the islands across the step continued to grow while those on the terraces eventually disappeared. The ripening process clearly favors the islands cross the steps. We developed our own image processing algorithm to segment the STM images scanned from the surface into individual islands and terraces. With that we analyze and compare the statistical trend of the evolution of the islands across the steps and that of those on the terraces.

This work is supported by the National Science Council, Taiwan, ROC.

K.00198 Atomic Modeling of the Grain Boundary in Silicon

MIZUSEKI, HIROSHI, SAHARA, RYOJI, KAWAZOE, YOSHIIKU, Institute for Materials Research, Tohoku University — By combining empirical potential approach with first-principles calculations, we investigate the atomic and electronic structures of grain boundary in silicon to estimate the deleterious effect on photovoltaic properties. Optimized geometries of several boundary structures are determined by using a Tersoff potential. Moreover, the electronic structures of boundary have been examined using the density-functional theory with the plane-wave pseudopotential method. Calculations show that the electronic properties depend strongly on the atomicistic structures, their properties are corresponding to efficiency of photovoltaic cell. This work was supported by the New Energy and Industrial Technology Development Organization (NEDO)
K1.00199 First principles study of Cu on Zn(0001): Resolution of the \((\sqrt{3} \times \sqrt{3})\)-R30° – Cu/ZnO(0001) surface phase, KAWATUT CHUASIRIPATTANA, OLIVER WARSCHKOW, University of Sydney, BERNARD DELLEY, Paul-Scherer-Institut, CATHY STAMPFL, University of Sydney — The Cu/ZnO system is a well known catalyst for methanol synthesis as well as hydrogen production from methanol by the reverse water gas-shift reaction. Despite many years of effort to clarify the characterization and the synergetic mechanisms between Cu and ZnO, there still exists considerable novelty associated with the active phase of this combination catalyst. Recently, a \((\sqrt{3} \times \sqrt{3})\)-R30° phase has been reported on the Cu/ZnO(0001) surface (Dulub et al., Topics in Catalysis, 34, 65 (2005)). This reconstruction appears in the LEED pattern after annealing the pre-deposited Cu-clusters on the ZnO(0001) surface at 350 °C in a 10^-6 mbar O_2 environment for 10 minutes. In this work, we perform first-principles total-energy calculations within the framework of ab initio atomistic thermodynamics to investigate the atomic geometry and relative stability of this structure. We have extensively surveyed many possible atomic geometries, from which we are able to propose the atomic structure of this \((\sqrt{3} \times \sqrt{3})\)-R30° phase. To provide an overall understanding of this system, we also construct a two-dimensional phase diagram as a function of the Cu and O chemical potential, thus displaying the most stable surface structures.

K1.00200 Halomethane Adsorption on Graphite and Silica surfaces1, C. LAMSAL, G. LEUTY, Southern Illinois University at Carbondale, JONATHAN NEHRING, North Park University, MESFIN TSIGE, Southern Illinois University at Carbondale — Owing to their simple nature and number of practical applications, the adsorption of halomethanes onto various substrates has been a topic of study in materials science for a number of decades. While many studies have been directed towards the exploration of halomethanes as potential lubricant additives, the fundamental understanding of these compounds is still not well understood in general is the behavior of similar adsorbates on other, possibly widely different substrates. How the choice of substrate affects the manner in which these compounds are adsorbed as well as the effects of the substrate on the structure of the adsorbate more than a monolayer thick is less understood. In this presentation, we report the results of a recent molecular dynamics study comparing the structure and dynamics of systems composed separately of three tetra substituted halomethanes - CF3, CF2Cl, and CF2Br - adsorbed onto two different substrates - graphite and silica (α-quartz) - along a range of temperatures to examine how these systems evolve and change according to the characteristics of the substrate surface.

K1.00201 Structure analysis and Physical property of Multiferroic LuFe2O4 Thin films, MINHWAN JUNG, SANGYOUN PARK, YOONHEE JEONG, POSTECH, Pohang, 790-784, S. Korea — Multi-ferroic materials have stimulated considerable interest because of technical applications in modern electronic devices such as memory elements and charge devices. LuFe2O4 was reported to have both ferrimagnetism and charge-ordering-induced ferroelectricity with the charge and spin frustrations. Since the material must be grown in thin film form before one would utilize the physical phenomena in practical applications, we have attempted to grow thin films of LuFe2O4. We have successfully obtained LuFe2O4 thin films on sapphire (0001) substrates by PLD method. Through XRD and PFMS measurements, their structure and magnetic property were characterized. In pole figure result, it showed 6 fold symmetry and there was a 30 degree rotation between the in-plane film and substrate direction. As for magnetic properties, we ascertained that the critical temperature was near 250K and it was identical to that of the bulk system.

K1.00202 Optical and structural analysis of In0.5−x,Ga,N alloys grown by HPCVD, GOKSEL DURKAYA, MAX BUEGLER, ENNO MALGUTH, Department of Physics & Astronomy, Georgia State University, WILL FENNICK, IAN FERGUSON, School of ECE, Georgia Institute of Technology, KONSTANTS E. DZIATK, Department of Physics & Astronomy, Georgia State University — The In0.5−x,Ga,N ternary alloy system has potential for development of high efficiency solar energy conversion and advanced optoelectronic device applications. InGaN hetero-structures of various compositions can be engineered to the responsive from UV to IR wavelength range, so that devices based on such heterostructures can cover the whole visible spectrum. However, the growth of such ternary In0.5−x,Ga,N alloys is challenging. This contribution focuses on the structural and optical characterization of In0.5−x,Ga,N layers and heterostructures grown by high pressure chemical vapor deposition (HPCVD), a growth technique that enables the stabilization of indium-rich In0.5−x,Ga,N alloys at elevated temperatures using 15 to 20 bar nitrogen overpressure. We will present the structural analysis of In0.5−x,Ga,N layers studied by Raman spectroscopy (RS), X-Ray Diffraction (XRD) and atomic force microscopy (AFM). The effects of composition and growth conditions on the layer surface topography and growth modes are studied by AFM.

K1.00203 Two Different Types of Single Crystal Morphologies of the γ-Phase and Their Conversion in Isotactic Polypropylene, YAN CAO, RYAN VAN HORN, CHI-CHUN TAI, MATTHEW GRAHAM, KWIANG-UN JEONG, CLAUDIO DE ROSA, BERNARD LOTZ, STEPHEN Z.D. CHENG — In the past, the crystallographic relationship between the γ-phase and the α-phase in isotactic polypropylene was extensively studied via oligomers of iPP. We attempt to investigate how the crystal morphological changes take place in the γ-phase using high molecular weight iPP-co-polystyrene samples. Due to the specific epitaxial growth of the γ-phase on the elongated α-phase single crystals, two different morphologies were identified via transmission electron and atomic force microscopies. The first γ-phase crystal morphology is needle-like. Selective area electron diffraction results showed that their [T10] or [110] zone axis was parallel to the thin film normal. The growth of this type of epitaxial γ-phase crystal was due to the step direction in the initial α-phase single crystal being parallel to the thin film normal. The second γ-phase crystal morphology was flat lamellae. This requires that the initial α-phase single crystal had to have a stem orientation tilted away from the thin film normal. Therefore, the sufficient and necessary condition for the γ-phase morphological conversion from the needle-like crystal to the flat crystal is the change of the stem orientation direction of the initial α-phase single crystals.

K1.00204 Reactive properties of chemically modified Pd(100) surface revealed by Kinetic Monte Carlo simulations, DOMINIC ALFONSO, National Energy Technology Laboratory — The interaction of H2 and CO with sulfur-covered Pd(100) surface represents a prototype model for understanding the various reasons for the poisoning of palladium by sulfur compounds. The use of Kinetic Monte Carlo method to investigate this system was explored. A Kinetic Monte Carlo code was developed and used to monitor the hosts of competing elementary steps associated with the adsorption, diffusion and desorption of H2 and CO on the metal surface. The input parameters such as rate of reactions and lateral interactions were obtained from density functional theory calculations within the generalized gradient approximation. We demonstrate that Kinetic Monte Carlo simulation is a powerful tool for elucidating the microscopic details of the behavior of H2 and CO on the poisoned surface.

K1.00205 Adsorption of Dimethyl Disulfide (DMDS) on a Metallic Quantum Well System, LEVAN TSISKURITI, SYLVIE RANGAN, ROBERT BARTYNSKI, Rutgers University — We have studied the bonding of the thiol molecule dimethylsulfide (SC(H)2)2 on ultrathin Cu films that exhibit metallic quantum well (MQW) states using inverse photoemission (IPE), reflection-absorption infrared spectroscopy (RAIRS) and temperature programmed desorption (TPD). This thiol is similar to more complex organic molecule which exhibits the self-assembled properties on metal surfaces. After a room temperature exposure of the Cu surface to the thiol molecule at a dose of ~ 2.5 L, a c(2 x 2) low energy electron diffraction (LEED) pattern confirmed that the adsorbate forms an ordered overlayer. A large sulfur signal is observed in Auger electron spectroscopy (AES) and the C-H stretch mode was observed in IR with a frequency of 2915 cm^-1 confirming molecular adsorption. Changes in the IPE spectrum upon adsorption are dominated by suppression of the substrate-related features, although some weak adsorbate-induced peaks are also observed. Both experimental and theoretical evidence indicates that the bonding of this thiol molecule is characterized by the formation of the C-S bond with the Cu substrate. The position of the C-S bond in the LEED pattern shows the self-assembled properties of the thiol molecule will be discussed.
K1.00206 Surface-state Emission of Si(111)-(7x7) Induced by Scanning Tunneling Microscopy

Hiroshi Imada, Masashi Ohta, Naoki Yamamoto. Condensed Matter Physics, Tokyo Institute of Technology — The luminescence measurement method we employ which utilizes a phenomenon called scanning tunneling microscope light emission (STM-LE) enables us to investigate surface structures with atomic resolution. However, STM-LE has not been well established, because the involved physics leaves many problems to be solved. In the present work, we studied STM-LE from Si(111)-7x7 surface to elucidate the nature of STM-LE of semiconductor surface. All the experiments were performed in an UHV-STM. Ag-covered Mo tips were used. Photon mapping and spectral measurement were performed. Emission spectra of Si(111)-7x7 at both bias polarities show very similar shape and behavior. The peaks are at 1.4eV, 2.3eV and around 1.6eV and do not shift with applied voltage. Since the position of the peak around 1.6eV shifts with tip shape but those of the 1.4eV and 2.3eV peaks are intrinsic to Si(111)-7x7 surface. Whole emission mechanism includes excitation of localized surface plasmon (LSP), excitation and decay (light emission) of surface electron and enhancement of the light. The photon maps show so high spatial resolution that individual adatoms can be clearly recognized.

K1.00207 Confined states in metallic thin films analyzed with a one-dimensional-pseudo-potential approach

Dah-Ann Luh, National Central University, Cheng-Maw Cheng, Ku-Ding Tsuei, National Synchrotron Radiation Research Center, Jian-Ming Tang, University of New Hampshire — An approach based on a one-dimensional pseudo-potential (1DPP) is proposed to analyze the confined states in metallic thin films. The potential of a thin-film system near the Fermi level is approximated with a pseudo-potential that is constructed with periodic potentials in the substrate and the film and with an image potential in the vacuum. The confined states are obtained by solving the Schrödinger equation. The result from applying the 1DPP approach to analyze the bound states in Ag/Au(111) thin films will be presented.

K1.00208 ABSTRACT WITHDRAWN

K1.00209 A First Principles Study of the Adsorption and Dissociation of CO2 on the δ-Pu (111) Surface

Raymond Atta-Fynn, Asok Ray. Department of Physics, The University of Texas at Arlington — Ab initio calculations within the framework of density functional theory have been used to study the adsorption of molecular CO2 and the corresponding partially dissociated (CO+O) and completely dissociated (C+O+O) products on the δ-Pu (111) surface. The completely dissociated C+O+O configurations exhibit the strongest binding with the surface (5.85 eV), followed by partially dissociated products CO+O (4.34 eV), with molecular CO2 adsorption having the lowest binding energies (2.98 eV). For all initial vertically upright orientations the CO2 molecule is physisorbed and its geometry and orientation does not change. For all initial flat lying orientations chemisorption occurs, with the final state corresponding to a bent CO2 molecule with bond angles of 118°-130° except one case where spontaneous partial dissociation from the atop site occurs. The interactions of the CO2 and CO with the Pu surface have been analyzed using the energy density of states and different charge density distributions.

K1.00210 Delta zeta: Improvement of the reproducibility of zeta potential measurements by transformation

Danish Faruqui, Paul J. Sides, Andrew J. Gellman. Carnegie Mellon Univ — When measuring the zeta potential of planar substrates as a function of pH, the results sometimes varied day by day even for the same sample treated exactly the same way. The shapes of the titration curves, however, were consistent despite apparent offsets. When data acquired on fused silica were transformed by subtracting the zeta potential measured at the initial condition from each subsequent measurement, however, data from many experiments fell on the same curve with a much reduced variance. Examination of the fundamental relationship between charge density and the zeta potential, derived from the Gouy Chapman theory of the electrical double layer, revealed that subtraction of the initial datum from each subsequent point amounted to cancellation of the total number of ionizable sites from the measurement. The transformed data reflected only chemical information such as equilibrium constants and activities. The principle assumptions are that the number of ionizable sites are fixed during a given experiment and the zeta potential magnitude is 100 mV or higher. Model expressions were verified for different mineral surfaces in range of aqueous solutions.

K1.00211 Operando Positron Annihilation Gamma Spectrometer (OPAGS)

S. Satyal, K. Shastry. University of Texas at Arlington, S. Mukherjee, University of Texas at Arlington, A.H. Weiss. University of Texas at Arlington — Surface properties measured under UHV conditions cannot be extended to surfaces interacting with gases under realistic pressures due to surface reconstruction and other strong perturbations of the surface. Surface probing techniques require UHV conditions to perform efficiently and avoid data loss due to scattering of outgoing particles. This poster describes the design of an Operando Positron Annihilation Gamma Spectrometer (OPAGS) currently under construction at the University of Texas at Arlington. The new system will be capable of obtaining surface and defect specific chemical and charge state information from surfaces under realistic pressures. Differential pumping will be used to maintain the sample in a gas environment while the rest of the beam is under UHV. Elemental content of the surface interacting with the gas environment will be determined from the Doppler broadened gamma spectra. This system will also include a time of flight (TOF) Auger spectrometer which correlates with the results of the Doppler measurements at lower pressures. By employing the unique capabilities of OPAGS together with those of the TOF PAES spectroscopy the charge transfer mechanisms at the surface in catalytic systems can be understood.

K1.00212 Temperature Programmed Desorption Study of Dodecanethiol Self-Assembled Monolayers on Ag

Simona Riemann, Nicholas Clark, Jennifer Walters, Daniel Field, Heike Geisler, Carl Venticello. Texas State University — The desorption kinetics of dodecanethiol self-assembled monolayers grown on Ag films has been studied using temperature programmed desorption. The self-assembled monolayers have been grown either in solution or by vapor deposition in UHV. The direct detection of dodecanethiol by the residual gas analyzer gives a complex spectrum due to multiple cracking fragments that are produced during the ionization of the molecule. The temperature programmed desorption measurements indicate that desorption of the self-assembled monolayer occurs in a two-stage process: dissociation of the alkane chain followed by desorption of the sulfur from the surface. Alkane chain fragments other than methane are observed to desorb over a range of ~150°C to ~220°C. Methane desorption starts at ~100°C and persists to ~350°C. In addition, the desorption of sulfur is observed starting at ~220°C.

K1.00221 Charge Exchange in Slow Collisions of O+ with He — L.B. ZHAO, D.C. JOSEPH, B.C. SAHA, Department of Physics, Florida A&M University, Tallahassee, FL-32307, H.P. LEBERMAN, P. FUNKE, R.J. BUENKER, Bergische Universität Wuppertal, D-42097 Wuppertal, Germany — A comparative study is reported for the charge transfer in collisions of O+ with He using the fully quantal and semiclassical molecular-orbital-coupling (MOCC) approaches in the adiabatic representation. The electron capture processes O+→(1S0, 2D0, 3P0) + He → O(1P0) + He+ are recalculated. The semiclassical MOCC approach was examined by a detailed comparison of cross sections and transition probabilities from both the fully quantal and semiclassical MOCC approaches. The discrepancies reported previously between the semiclassical and the quantal MOCC cross sections may be attributed due to the insufficient step-size resolution of the semiclassical calculations. Our results are also compared with the experimental cross sections and found good agreements. This work is supported by NSF, CREST program (Grant#0630370).

K1.00222 K-Shell Ionization of Neutral Targets by Electron Impact — A.K.F. HAQUE, M.S.R. SARKER, M.A.R. PATOARY, M. SHAHJAHAN, M.I. HOSSAIN, M.A. UDDIN, A.K. BASAK, Department of Physics, University of Rajshahi, Bangladesh, B.C. SAHA, Department of Physics, Florida A&M University, Tallahassee, FL-32307. — The electron impact K-shell ionization cross sections (EIKICS) are needed in diverse fields, such as plasma-, radiation-, astrophysics. For plasma modeling the demand of EIKICS is enormous; this can only be fulfilled by simple analytical or semi-classical models that can generate efficiently accurate results over wide ranges of projectile energies and target species. We modified the Deutsch-Mark [1] model by incorporating ionic and relativistic corrections and applied to evaluate K-shell ionization cross sections for 30 atomic targets, 1Z<92 for 1<Z<2 GeV with very encouraging results as compared to available experimental findings. Work is supported by NSF, CREST project.

K1.00223 Gold cluster beyond hollow cage: Double-shell Au58 — CHUAN-DING DONG, XIN-GAO GONG, Fudan University, Shanghai, PR China — Gold clusters were found to have planar and hollow cage-like structures due to the strong relativistic effect. By using first principles calculation, we take Au58 as an example to demonstrate that gold cluster can show shell structure. Au58 reaches its highest stability with an optimal inner core of 10 atoms. Particularly, a double-shell structure with a hollow inner shell shows remarkable robustness. It is significant to consider this shell structure as a descendant of the hollow cage structures found previously, such as tetrahedral Au40, icosahedral Au122, tubular Au183 and so on, for this implies a possible evolution from planar, to cage, to shells and finally to the compact structure as the number of atoms in the cluster increasing.

K1.00224 An Investigation of Methanol Transitions at Cold Temperatures through Collisonal Cooling — KELLY SALB, DANIEL WILLEY — The detection of molecular transitions in the interstellar medium (ISM) has long been of interest to astrophysicists. If molecules and their interactions can be understood, then scientists may better understand the workings of space such as star formation. Methanol, CH3OH, has long been detected by astrophysicists in the ISM as an important constituent with a rich spectrum as a result of its asymmetry and that its low-energy torsional vibrations of the methyl group against the OH top can be excited under interstellar conditions. We investigate collisions of methanol with helium, a prominent constituent of the ISM, at temperatures between 5-30K through spectroscopy to better understand the interaction in the ISM.

K1.00225 Non-Linear Interactions in Pump-Probe Optical Phenomena1 — VERNE JACOBS, Naval Research Laboratory — Reduced density matrix descriptions are developed for pump-probe optical phenomena in atomic systems, taking into account atomic collisions as environmental phenomena. Time-domain (equation-of-motion) and frequency-domain (resolvent- operator) formulations are developed in a unified manner. In a semiclassical perturbative treatment of the electromagnetic interaction, compact Liouville-space operator expressions are derived for the linear and the general (n'th order) non-linear electromagnetic-response tensors. These expressions are valid for coherent atomic excitations and for the full tetradic-matrix form of the collision operator in the Markov approximation.

K1.00226 Efficient and Selective Photon Detection using Amplification Without Inversion.1 — KEVIN MERTES, MICHAEL DI ROSA, Los Alamos National Laboratory — We describe ongoing theoretical and experimental research at Los Alamos National Laboratory of a new technology for photon detection that exploits quantum processes to attain an unrivaled combination of high quantum efficiency and sharp discrimination. The amplification without inversion (AWI) scheme we are exploring consists of a Λ system found in the excited states of 264Hg. The 63P0 ⇒ 1 and 63P2 ⇒ 2 states form the lower 2 levels of the Λ system, and 73S1 ⇒ 3 forms the upper level. By incoherently pumping Hg vapor into [3] while simultaneously driving [3] ⇒ [2], approximatly 50% of the population will reside in [1]. Under these conditions, the system is radiating along [3] → 1 with an emission spectrum with a narrow dark line centered precisely on the [3] → 1 resonance. A faint light signal that is resonant with the [3] ⇒ 2 transition that enters the system would precipitate a coherent pulse of photons. This gain occurs from the coherent redistribution of population through level [3]. The expected spectral width for gain is a narrow 20 MHz. Due to spontaneous-emission quenching the noise added from this scheme should be significantly less than ordinary laser amplifiers.

K1.00227 Improved test of the standard model of elementary particles with atomic parity violation1 — KYLE BELOY, Univ. of Nevada, Reno, SERGEY PORSEV, Petersburg Nuclear Physics Institute, ANDREI DEREVIANKO, Univ. of Nevada, Reno — Atomic parity violation places powerful constraints on new physics beyond the Standard Model (SM) of elementary particles. The measurements are interpreted in terms of the nuclear weak charge, quantifying the strength of the electroweak coupling between atomic electrons and quarks of the nucleus. We report the most accurate to-date determination of this coupling strength by combining previous measurements by the Boulder group with our high-precision calculations in cesium atom. Our result is in a perfect agreement with the prediction of the SM. In combination with the results of high-energy collider experiments, our work confirms the predicted energy dependence (or “running”) of the electroweak interaction over an energy range spanning four orders of magnitude (from ∼10 MeV to ∼100 GeV) and places new limits on the masses of extra Z bosons (Z′). Our raised bound on the Z′ masses carves out a lower-energy part of the discovery reach of the Large Hadron Collider. At the same time, a major goal of the LHC is to find evidence for supersymmetry (SUSY), one of the basic, yet experimentally unproven, concepts of particle physics. Our result is consistent with the R-parity conserving SUSY with relatively light (sub-TeV) superpartners. This raises additional hopes of discovering SUSY at the LHC.

1Work supported by NIST, NSF, and RFBR.

K1.00228 Micromagic clock: microwave clock based on atoms in an engineered optical lattice — KYLE BELOY, ANDREI DEREVIANKO, Univ. of Nevada, Reno, VLADIMIR DZUBA, VICTOR FLAMBAUM, Univ. of New South Wales, Sydney — We propose a new class of atomic microwave clocks based on the hyperfine transitions in the ground state of aluminum or gallium atoms trapped in optical lattices. For these elements magic wavelengths exist at which both levels of the hyperfine doublet are shifted at the same rate by the lattice laser field, cancelling its effect on the clock transition. This work represents an elegant piece of theoretical physics containing a challenge to the experimentalist to realize a new frequency standard based on these proposed clocks.

1Fundings are provided from the Laboratory Directed Research and Development program of the Los Alamos National Laboratory.
K1.00220 Precession in Atomic Mechanics , ALFRED PHILLIPS, JR., Source Inst / Cornell U — With Atomic Mechanics we have been able to accurately calculate the measured values of the NIST He I and He II energy levels. Our model requires much less mathematical tedium than does the Schrödinger method but with equal accuracy. We made the conjecture that the angular momentum for excited electrons is \( n + \delta n \) h-bar. We had hypothesized that the delta \( n \) was a fractal. We have subsequently found a more conventional quantum mechanical explanation for delta \( n \). We model the delta \( n \) by assuming that the excited electron undergoes precession with a quantum number, \( l \), having values of 1, 2, 3, . . . . We will discuss the precession model. We expect that our model may be used in calculating the spectra of more complex atoms, lithium onward, that have been formillable mathematically using the Schrödinger theory.

K1.00230 COLD GAS —

K1.00231 Faraday patterns in interference experiments with one dimensional gases of ultracold atoms , SUSANNE PIELAWA, VLADIMIR GRITSEV, EUGENE DEMLER, Harvard University — We analyze a quantum analogue of the Faraday instability in one dimensional ultracold gases. Temporal periodic modulation of the interaction strength parametrically excites collective modes and gives rise to standing wave patterns in interference experiments. We discuss both bosonic and fermionic systems and demonstrate that such experiments can be used to probe spin charge separation.

K1.00232 Phase Separation in Bose-Superfluid Fermi Mixtures , B. RAMACHANDRAN, S.G. BHONGALE, H. PU, Department of Physics and Astronomy, and Rice Quantum Institute, Rice University, Houston, TX 77005, USA — We study the phase diagram of 3-dimensional mixtures of BEC and a two-component superfluid fermi gas, referred to as Bose-Superfluid fermi mixtures, at zero and finite temperature. At zero temperature, we identify regimes at equilibrium in which the mixture exists either as a pure superfluid phase coexisting with a mixed phase or as a single homogenous phase. We identify critical boson densities at which phase separation occurs for different values of the fermi-fermi interaction strength. As a potential application of this phase separation phenomenon, we consider BEC to be in a realistic cigar-shaped double-well trap acting as a probe of the superfluid state. We show that the critical boson densities obtained from the phase diagram can be used to map the spatial density profile of the bosons using Local Density Approximation (LDA) in the trap setting. We show a methodology to robustly detect the “local” value of the superfluid Gap parameter by observing the boson density profile in the trap. We also explore the more challenging problem of phase separation in these mixtures at finite temperature. We show that, under proper conditions, this spatial phase separation phenomenon occurring in the presence of the BEC probe can be used to potentially detect the onset temperature of the BCS superfluidity.

K1.00233 Fermionic quantum gases with tunable interactions in optical lattices , ULRICH SCHNEIDER, LUCIA HACKERMÜLLER, Universität Mainz, Germany, THORSTEN BEST, SEBASTIAN WILL, SIMON BRAUN, MARIA MORENO CARDONER, BELEN PAREDES, Universität Mainz, IMMANUEL BLOCH, Universität Mainz, Max Planck Institut für Quantenoptik, Garching, Germany — Fermionic atoms in optical lattices can serve as a model system for condensed matter physics, as they present an implementation of the Hubbard hamiltonian with high experimental control of the relevant parameters. In our system we sympathetically cool \( ^{87}\text{Rb} \) and \( ^{40}\text{K} \) in an optically plugged quadrupole trap and an optical dipole trap. After evaporation, a balanced spin mixture of \( 40\text{K} \) atoms is loaded into a blue detuned optical lattice where the interactions can be changed via a Feshbach resonance. We present experimental and theoretical studies of the behaviour of fermionic atoms for both attractive and repulsive interactions. For repulsive interactions we show a transition from compressible, metallic states to Mott-insulating and finally band insulating states. On the attractive side we investigate an anomalous expansion when the interaction is strongly attractive and study the dynamics of atoms and repulsively and attractively bound pairs.

K1.00234 Interacting Mixtures of Bosons and Fermions in Optical Lattices , SEBASTIAN WILL, THORSTEN BEST, SIMON BRAUN, ULRICH SCHNEIDER, LUCIA HACKERMÜLLER, IMMANUEL BLOCH, Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudinger Weg 7, 55128 Mainz, Germany — Mixtures of ultracold atomic quantum gases in optical lattices form novel quantum many-body systems offering unique controllability. In particular, degenerate Bose-Fermi mixtures have only recently come into experimental reach and are the topic of fruitful theoretical investigation. Among the most prominent predictions are the formation of charge-density waves, polaron-like quasi-particles and even supersolid ordering. We have prepared a mixture of bosonic \( ^{87}\text{Rb} \) and fermionic \( ^{40}\text{K} \) in a 3D optical lattice potential and investigated its properties depending on the interspecies interaction. We found a marked shift in the superfluid to Mott-insulator transition and were able to fully explain our findings in terms of an effective Bose-Hubbard model, employing renormalized Hubbard parameters. In recent measurements of the absolute intra- and interspecies interaction energies on individual lattice sites, we were able to further elucidate the effects of interaction in the optical lattice a thorough understanding of which may be an important step on the way towards complex quantum many-body states.

K1.00235 Spin-imbalance of ultracold Fermions in quasi-1D1, 2, ANN SOPHIE C. RITTNER, YEAN-AN LIAO, WENHUI LI, TOBIAS PAPROTTA, RANDALL G. HULET, Department of Physics and Astronomy and Rice Quantum Institute, Rice University, Houston, TX 77005 — After the success of BCS theory, more exotic forms of superfluidity have generated large interest in the condensed matter and cold atoms community. One prominent example is the elusive Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) phase, a polarized superfluid that is predicted to occur when superconductors are subjected to a strong magnetic field. At present, there is no experimental evidence for the FFLO phase in a 3D system, but it is predicted to occupy a larger region of the phase diagram in a quasi-1D system. We have implemented a 2D optical lattice in order to explore the phase diagram of a quasi-1D polarized Fermi gas.

1 Work supported by NSF, DARPA, ONR, and the Welch and Keck foundations.

K1.00236 Wavepacket Dynamics in Energy Space of a Chaotic Trimeric Bose-Hubbard System , MORITZ HILLER, Department of Physics, Albert Ludwigs University of Freiburg, Germany, TSAMPIKOS KOTTOS, Department of Physics, Wesleyan University, Middletown CT-USA and MPI for Dynamics and Self-Organization, Goettingen-Germany , THEO GEISEL, MPI for Dynamics and Self-Organization, Goettingen-Germany — We study the energy redistribution of interacting bosons in a ring-shaped quantum trimer as the coupling strength between neighboring sites of the corresponding Bose-Hubbard Hamiltonian undergoes a sudden change \( \delta \). In the framework of (ultra-)cold atoms on optical lattices this perturbation corresponds to a modulation of the trapping potential height. Our analysis is based on a three-fold approach combining linear response theory calculations as well as semiclassical and random matrix theory considerations. The \( \delta \)-borders of applicability of each of these methods are identified by direct comparison with the exact quantum mechanical results. We find that while the variance of the evolving quantum distribution shows a remarkable quantum-classical correspondence (QCC) for all \( \delta \)-values, other moments exhibit this QCC only in the non-perturbative \( \delta \)-regime.
Quantum nucleation and macroscopic quantum tunneling in cold-atom boson-fermion mixtures

Dmitry Solenov, Dmitry Mozrytsky, Theoretical Division, Los Alamos National Laboratory

We present the results on kinetics of phase separation transition in boson-fermion cold atom mixtures. The parameters at which the transition is governed by quantum nucleation mechanism are identified. We demonstrate that for low fermion-boson mass ratio the density dependence of quantum nucleation transition rate is experimentally observable. The crossover to macroscopic quantum tunneling regime is analyzed. Based on a microscopic description of interacting cold atom boson-fermion mixtures we derive an effective action for the critical droplet and obtain an asymptotic expression for the nucleation rate in the vicinity of the phase transition and near the spinodal instability of the mixed phase. We show that dissipation due to excitations in fermion subsystem play a dominant role close to the transition point.

Quantum information, concepts, and computation

Quantum manipulation of low-frequency fluctuators with a superconducting resonator

Lin Tian, School of Natural Sciences, University of California, Merced, CA 95344, Kurt Jacobs, Department of Physics, University of Massachusetts at Boston, 100 Morrissey Blvd, Boston, MA 02125 USA

Spurious two-level systems (fluctuators) in superconducting devices have demonstrated long coherence time and can be considered as qubits instead of sources of decoherence. Coherent coupling between two-level system (TLS) and superconducting phase qubit has been observed in experiments. Here, we show that universal quantum logic gates on the TLS qubits can be implemented via the coupling between the TLSs and a superconducting microwave resonator in a cavity QED setup. By adjusting the driving on the resonator mode, parameters of individual TLS can be controlled to realize single qubit gates. Meanwhile, effective coupling can be generated between TLSs via their simultaneous coupling to the resonator mode. We present concrete designs for the gate operations and our numerically simulation shows that high fidelity can be achieved for the gate operations in the presence of resonator decay even at decay rates of a few megahertz. The nonlocal nature of the resonator mode also makes the TLSs intrinsically scalable for testing quantum algorithms.

Higher Energy Levels in Qubit Networks

Zechariah Thrailkill, Joseph Lambert, Roberto Ramos, Drexel University

Josephson junctions can be capacitively coupled together to form qubit networks capable of carrying out quantum logic operations. In order to fully utilize these systems, the influence of energy levels higher than the ground and first excited states in the qubits must be examined. We have analyzed such networks with three, four, and more qubits biased to both anharmonic and harmonic regimes. As the qubits become harmonic, the higher energy levels will interact more strongly with the computational basis. Allowing the system to pass through these higher energy levels can allow quantum state transfers where, in the anharmonic regime, it would not occur. We will discuss the impact these higher energy levels have on the natural state evolution of the systems, quantum information transfer, and state manipulation using a time independent, or adiabatically changing Hamiltonian.

Quantum hacking: Experimental demonstration of time-shift attack against practical quantum-key-distribution systems

Yi Zhao, Chi-Hang F. Fung, Bing Qi, Christine Chen, Hoi-Kwong Lo, Center for Quantum Information and Quantum Control, Department of Physics and Department of Electrical & Computer Engineering, University of Toronto

We have demonstrated the applicability of ground-state and time-dependent density functional theory to quantum computing systems by proving the Hohenberg-Kohn and Runge-Gross theorems for a fermion system representing N qubits. Time-dependent density functional theory is used to determine the minimum energy gap Δ(N) arising from application of the quantum adiabatic evolution algorithm to the NP-Complete problem MAXCUT. As density functional theory has been used to determine the minimum energy gap for a quantum gas microscopic to experimentally realize high resolution imaging and spatial addressability of a rubidium atom ensemble loaded into an optical lattice. Very good optical access to the atoms combined with solid immersion-like geometry is expected to provide an imaging resolution of about 0.5 microns. We realize a long lived two-dimensional quantum gas inside a novel opto-magnetic surface trap using an evanescent wave potential. To create the lattice potential we developed a projection approach using holographic phase masks. We have loaded a quantum gas into the lattice potential and are working on resolving single atoms on the lattice sites.

Efficient local implementation of bipartite nonlocal unitaries

Li Yu, Robert Griffiths, Carnegie Mellon University, SCOTT COHEN, Duquesne University

By definition, nonlocal unitaries cannot be implemented locally. However, if spatially separated parties share nonlocal resources (i.e., entanglement), they may be able to implement a nonlocal unitary by performing only local operations and sharing classical information. We provide protocols for doing so, which generalize previously published methods and in many cases allow tasks to be accomplished with fewer nonlocal resources than is required when using teleportation. We also discuss our insight into how and why entanglement allows such a task to be accomplished, an insight which arises from a diagrammatic approach allowing one to picture the processing of quantum information.

Density functional theory and quantum computation

Frank Gaitan, Southern Illinois University, FRANCO NORI, RIKEN/University of Michigan

We present our implementation of a quantum gas microscopic to experimentally realize high resolution imaging and spatial addressability of a rubidium atom ensemble loaded into an optical lattice. Very good optical access to the atoms combined with solid immersion-like geometry is expected to provide an imaging resolution of about 0.5 microns. We realize a long lived two-dimensional quantum gas inside a novel opto-magnetic surface trap using an evanescent wave potential. To create the lattice potential we developed a projection approach using holographic phase masks. We have loaded a quantum gas into the lattice potential and are working on resolving single atoms on the lattice sites.
K1.00246 Electronic and Magnetic Properties of B$_5$CX (X=V, Cr, Mn, Fe, Ni, and Co): a Theoretical Study, DAYNE SHIELDS, Department of Physics, University of Nebraska at Omaha, WAI-NING MEI, JING LU, Department of Physics, Peking University, PETER A. DOWBEN, Department of Physics, University of Nebraska at Omaha COLLABORATION, DEPARTMENT OF PHYSICS, PEKING UNIVERSITY COLLABORATION, DEPARTMENT OF PHYSICS, UNIVERSITY OF NEBRASKA-LINCOLN COLLABORATION — We used on-site correlation corrected density functional theory to investigate the structure and magnetic properties of the recently synthesized B$_5$CX-Co and many other substitutions. We found that the Co and Ni molecules were non-magnetic. Other than that, Cr had both stable ferro- and antiferromagnetic structures. The V, Mn, and Fe molecules are not stable, we have to treat them as infinitely long chain molecules.

K1.00247 Scattering in Quantum Lattice Gases, ANDREW O’HARA, PETER LOVE, Haverford College — Quantum Lattice Gas Automata (QLGA) are of interest for their use in simulating quantum mechanics on both classical and quantum computers. QLGAs are an extension of classical Lattice Gas Automata where the constraint of unitary evolution is added. In the late 1990s, David A. Meyer as well as Bruce Boghosian and Washington Taylor produced similar models of QLGAs. We start by presenting a unified version of these models and study them from the point of view of the physics of wave-packet scattering. We show that the Meyer and Boghosian-Taylor models are actually the same basic model with slightly different parameterizations and limits. We then implement these models computationally using the Python programming language and show that QLGAs are able to replicate the analytic results of quantum mechanics (for example reflected and transmitted amplitudes for step potentials and the Klein paradox).

K1.00248 Novel approach to the dynamics of a dissipative two-state system, PETER P. ORTH, ADILET IMAMBIEKOV, KARYN LE HUR, Yale University — A two-state system in contact with a harmonic oscillator bath is frequently used to describe the process of decoherence in physical systems, such as a spin in a solid-state environment or a qubit coupled to external and uncontrolled degrees of freedom. The problem in general cannot be solved exactly, and several approximative methods have been devised such as Bloch-Redfield master equations, which are limited to weak-coupling, or the Non-Interacting Blip Approximation (NIBA), that neglects the system’s backaction onto the bath. We study the dissipative two-state dynamics in a novel way, rephrasing the problem as that of (non-)unitary time evolution of a quantum state vector exposed to a random Gaussian perturbation Hamiltonian. Our formalism goes beyond the NIBA and is particularly well suited to study the case of time-dependent system parameters. We compare it to common approaches such as the (extended)-NIBA, or stochastic wave-function methods. Furthermore, we investigate dissipative Landau-Zener tunneling in the so-called scaling limit.

K1.00249 Classical Derivation of Fermion Operators and Correlations, ROBERT CLOSE, None — A second-order wave equation is derived for an ideal elastic solid. The Klein-Gordon equation is a special case of this equation in which the mass term replaces the nonlinear rotation and convection terms. The second-order wave equation is factored to yield a first order bispinor equation. This equation is similar to the Dirac equation. The corresponding Lagrangian is constructed in terms of bispinors. The quantity conjugate to angular velocity is the quantum mechanical angular momentum. The quantity conjugate to velocity includes the quantum mechanical wave momentum and also the momentum of the medium. Along a given axis there are two independent solutions corresponding to forward- and backward-propagating waves. Since these independent states are separated by 180 degrees, their bispinor wave functions transform under rotation with spin one-half. Potentials are derived from consideration of wave interference. Parity is conserved. The conventional Dirac parity operator is incorrect because it represents a 180 degree rotation rather than inversion of velocity space. Correlations between classical bispinor wave functions are identical to the quantum correlations.

K1.00250 Modeling and Simulation of Fault Tolerant Quantum-dot Cellular Automata Devices, BENJAMIN PADGETT, Ball State University, GABRIEL ANDUWAN, Papua New Guinea University of Technology, MICHAEL KUNTZMAN, University of Texas, IOAN STURZU, Texas A&M University — We present a theoretical study of fault tolerant properties in Quantum-dot Cellular Automata (QCA) Devices. The study consists of modeling and simulation of various possible manufacturing, fabrication and operational defects. We will present specifically the effects of temperature and manufacturing defects at the cell level and array level of various QCA devices. Results of simple devices such as quantum wire, logical gates, inverter, cross-over and XOR will be presented. The cell defects would include displaced dots and missing defects. We will present specifically the effects of temperature and manufacturing defects at the cell level and array level of various QCA devices. Results of simple devices such as quantum wire, logical gates, inverter, cross-over and XOR will be presented. The cell defects would include displaced dots and missing defects.

K1.00251 Fault-Tolerant Characteristics of Quantum-dot Cellular Automata Devices, MAHUZA KHATUN, Ball State University, GABRIEL ANDUWAN, Papua New Guinea University of Technology, IOAN STURZU, Texas A&M University — The operational behavior of the Quantum-dot Cellular Automata (QCA) devices has been investigated regarding both dot displacement and temperature effects. Each of the breakdown characteristics displayed unique features for every particular QCA device. We have found that the characteristic features of the basic logic QCA devices are inherited by the higher or complicated QCA devices, such as the full adder. It was observed that the presence of a crossover of QCA lines in a full adder was a major factor for the breakdown. Thus, a proposed full adder QCA device without a crossover was seen to improve the successful operation of a full adder.

K1.00252 Extraction of correlated 2-photons with near unity efficiency, ALEXANDER LING, JUN CHEN, JINGYUN FAN, ALAN MIGDALL, JQI/NIST — We report a source of 2-photons that can be extracted with near unit efficiency. The reduced mode area of solid-core microstructure fibers lets a light pulse induce significant nonlinear optical interaction inside a short fiber, making it easy to generate 2-photon entanglement. However, the photon extraction efficiency is low due to the small core size ($d \approx 1 \mu m$) that requires high numerical aperture (NA) lenses to couple light in and out of the fiber. Tapering the core at the fiber end to 10 µm allows the use of anti-reflection-coated lenses of smaller NA, to achieve a single-photon extraction efficiency of $\eta = 96\%$. Using a pair of volume holographic gratings for selecting any wavelength of interest increased our spectral transmittance for that wavelength to $\eta_g = (98\%)^2$, enabling a near unit efficiency in extracting a single photon from the fiber source: $\eta \eta_g = 92.2\%$. The final 2-photon detection efficiency of 10% also extends the efficiency of single-photon detection modules (~70% each) and single-mode fiber collection (~50% per channel). At an average pump power of $P = 50 \mu W$ and a laser repetition rate of $R = 76$ MHz, we detect 50 photon pairs $s^{-1}$ with $g^{(2)}(0) = 0.0055$ and a coincidence-to-accidental ratio of 900:1. Higher pairs rates at the same $g^{(2)}$ level can be achieved by increasing R. With better photon detection, this source may enable loophole-free Bell tests.
K1.00253 Negativity for spin one anisotropic Heisenberg clusters in magnetic field, ARMEN KOCHARIAN, California State University, Los Angeles, NERSES ANANIKYAN, LEV ANANIKYAN, YAHAQN AGBARYAN, Yerevan Physics Institute — The quantum and thermal phase transitions are studied for spin $s=1$ in anisotropic (ferromagnetic and antiferromagnetic) XXZ and Heisenberg small clusters with longitudinal crystalline and magnetic fields. We investigate the concept of entanglement. The grand canonical ensemble of Heisenberg clusters is also used for exact analytical and numerical calculations of thermal properties and negativity as a function of magnetic and anisotropic fields. We study the negativity, magnetic phase transitions and crossovers in small clusters of various topologies driven by exchange interaction, external field and temperature. The negativity effect as a function of temperature and magnetic field is studied for both ferromagnetic and antiferromagnetic cases. The thermal behavior of negativity can capture the important properties in single molecule magnets, the dynamic magnetization and these our results can be useful for interpretation of the phase diagram in molecular nanomagnets and nanometer-sized magnetic particles.

K1.00254 Cavity -Quantum Dot interactions and mode coupling in a nanocavity, VIJAY KASIO-MAYAULJ, ONOFRIO RUSSO, New Jersey Institute of Technology — We describe an approach for realizing effective manipulation of single electron state level transitions for quantum dots mediated by a nano-cavity. The two quantum dots interact with the cavity for the two dot system in the coulomb blockade energy region. Because of the zero dimensional structure of the quantum dots, the system can be implemented to be a characteristic entity for an efficient generator of single photons. This process is emphatically more selective in the coulomb/spin blockade region, where also, the system efficiency of the single photon event is most likely more probable. Whereas, it is clear that the photon efficiency is small, the cavity quantum electrodynamics (CQED) nature suggests an enhancement in the electron energy state being occupied by the second quantum dot. This is more likely with very strong coupling of the quantum dots to the cavity with cavity quality factors larger than perhaps $10^5$. Quality factors in excess of $10^5$ have been demonstrated experimentally. 1. K. Srinivasan, M. Barselli, T. J. Johnson, P. E. Barclay, O. Painter, A. Stintz, and S. Krishna, Appl. Phys. Lett. 86, 151106 (2005). [ISI]

K1.00255 Linear, Rotational and Vibrational KInetic Energies Must Be Included in Mass-Energy Calculations, STEWART BREKKE, Northeastern Illinois University (former grad student) — All bodies have no motion, have linear, rotational and/or vibrational motion, singly or in some combination. Curvilinear motion is linear motion influenced by an external force field. The total energy of a body therefore must include the linear rotational and vibrational kinetic energies if present besides just the mass-energy conversion which may reconcile experimental data with theory even though these extra energies may be very small in comparison. If $k$ is a force constant, $x$ is the amplitude of vibration and $\omega$ is the angular speed, the formula for $E$ zero is as follows.

$$E_{0} = m\omega^{2} + 1/2m\omega^{2} + 1/2I\omega^{2} + 1/2kx^{2}$$

K1.00256 Consciousness Can Change the Output Signals of a Solar Cell and the Photoelectric Conversion Equation of Slow Mass Wave, DAYONG CAO, Beijing Natural Providence Science & Technology Development Co., LTD — The experiment's results show that human consciousness can change output signals such as $V_{oc}$ (open-circuit voltage) and $I_{sc}$ (short circuit current) of a solar cell placed some distance from a participant. For the first time, a consciousness signal is able to be recorded through the experiment conducted in Oct 2002. The order and rhythm of the changing wave pattern of $V_{oc}$ is related to the action of consciousness. The order and rhythm of slow brain signal of ERP and EEG are related to the cognized objects. Consciousness is independent and self-determined while brain signal is passive and driven. Consciousness is spiritual and Intelligence while brain signal is physical, corporality and mechanic. So consciousness is different from the brain signal. And consciousness effect is different from physical effect of light. Because consciousness can choose the object which it acts on. The light have a pair of mass wave of low frequency and energy wave of high frequency. In photoelectric conversion process, We only use the energy wave to get the $\eta$ (photoelectric transformation efficiency) which is little. If being used a pair of wave, we will get a larger $\eta$. The photoelectric conversion equation of slow mass wave are being put forward.

K1.00257 Quantum Quasi-Paradoxes and Quantum Sorites Paradoxes, FLORENTIN SMARANDACHE, University of New Mexico, Gallup Campus — There can be generated many paradoxes or quasi-paradoxes that may occur from the combination of quantum and non-quantum worlds in physics. Even the passage from the micro-cosmos to the macro-cosmos, and reciprocally, can generate unsolved questions or counter-intuitive ideas. We define a quasi-paradox as a statement which has a prima facie self-contradictory support or an explicit contradiction, but which is not completely proven as a paradox. We present here four elementary quantum quasi-paradoxes and their corresponding quantum Sorites paradoxes, which form a class of quantum quasi-paradoxes.

K1.00258 BIOLOGICAL PHYSICS —

K1.00259 Nonmonotonic Behavior of Nonnative Contacts in Small Proteins: An Exact Study on a Square Lattice, CHONG, CHEN, PURUSHOTTAM GUJRATI — Nonnative contacts are defined as contacts absent in the native state, and can be used to study the process of folding. They are expected to increase with temperature or energy. By exactly generating all possible conformations on a square lattice, we have investigated nonnative contacts for proteins in the standard HP model and its modified versions introduced by our group. This enables us to carry out exact calculation for the nonnative contact density $n_n(e)$ as a function of the energy density $e$ as well as its canonical average $\bar{n}_n(T)$ as a function of temperature $T$ from which we construct $\bar{n}_n(T)$ to compare with $n_n(e)$. The sequence dependence of $n_n(e)$ and $\bar{n}_n(T)$ are also investigated. Some new understandings of the role for nonnative contacts play in the protein folding process, as will be discussed during the talk. 1) The density $n_n(e)$ is always monotonically increasing in the standard model. This need not be true for all kinds of interactions. 2) The density $\bar{n}_n(T)$ is usually monotonically increasing. A few violations can be seen. 3) The protein property is sequence dependent, as expected. Reference [1] P. D. Gujrati, B. Lambeth, Jr., A. Corsi, and E. Askanazi, arXiv: 0708.3739 (2007).

K1.00260 Photoreceptor rearrangement and vision restoration in eyes with outer retinopathy: Quantitative assessment by fractal analysis, DELIA CABRERA DEBUC, Bascom Palmer Eye Institute, University of Miami Miller School of Medicine, ROBERT TCHTINGA, University of Dschang, Faculty of Science, Department of Physics, P.O.Box 67 Dschang, Cameroon, MEDICAL IMAGING COLLABORATION, FRACTAL ANALYSIS COLLABORATION — The differentiation between normal and abnormal photoreceptor rearrangement with outer retinopathy before and after treatment may improve understanding on the sequence of events involved in the visual field defects. In this study, we evaluated a fractal analysis approach to quantify photoreceptor rearrangement and vision restoration. We analyzed Optical Coherence Tomography (OCT) data from an individual with outer retinopathy before and after treatment. The outer nuclear layer (ONL) was delineated from the rest of the retinal structure by using a custom-built segmentation algorithm. We then determined the fractal box dimension of the ONL's outline using the box counting method. Thickness and reflectance of the ONL were also calculated. Our results showed that the ONL's fractal dimension, thickness and relative reflectivity decreased after treatment. These early results showed that ONL's fractal dimension could be used as an index of photoreceptor rearrangement, which might lead to a more effective approach to therapy and improved diagnosis.
**K1.00261 Statistical Characterization of a 1D Random Potential Problem— with applications in score statistics of MS-based peptide sequencing**

GELIO ALVES, YI-KUO YU, National Center for Biotechnology Information/NIH — We provide a complete thermodynamic solution of a 1D hopping model in the presence of a random potential by obtaining the density of states. Since the partition function is related to the density of states by a Laplace transform, the density of states determines completely the thermodynamic behavior of the system. We have also shown that the transfer matrix technique, or the so-called dynamic programming, used to obtain the density of states in the 1D hopping model may be generalized to tackle a long-standing problem in statistical significance assessment for one of the most important proteomic tasks--peptide sequencing using tandem mass spectrometry data.

This work was supported by the Intramural Research Program of the National Library of Medicine at the National Institutes of Health.

**K1.00262 ABSTRACT WITHDRAWN**

**K1.00263 Single Molecule Study on Incorporation Efficiency of DPO4 and Klenow Fragment to BPDE Adduct**

LU SONG, UC Davis, LLNL, YIN YEH, ROD BALHORN, MONIQUE COSMAN, UC Davis — DNA synthesis involving high fidelity A-family polymerases such as Klenow fragment is blocked by DNA adducts, while Y-family DNA polymerases such as Dpo4 can bypass the DNA adducts to resume DNA synthesis. So understanding the functional relationship between A-family and Y-family DNA polymerases in DNA replication and the mechanism of bypassing DNA adducts is of great help to explain the cause of mutagenesis. We introduce a flow cell on modified surface to study the incorporation efficiency of Dpo4 and Klenow fragments to benzo[α]pyrene-diol-epoxide (BPDE) adduct at single molecule level. Specifically, we anchor the labeled DNA onto the modified surface with adduct site open in nucleotide incorporation and flow the polymerases and labeled nucleotides into flow cell. With Total Internal Reflection Fluorescence Microscopy (TIRFM) we identify the incorporation of the nucleotides onto the anchored DNA template by identifying the co-localization of the template position and that of the labeled nucleotide. We further quantify the signal densities of the images obtained from the two different polymerases, thus examining whether incorporation reactions have been executed and quantifying the incorporation efficiency of the polymerases. We can also identify, on the specific adduct site, which nucleotide, if any, is incorporated by each of the two polymerases.

**K1.00264 Mechanical Properties of Type IV Pili in *P. Aeruginosa***

SHUN LU, AHMED TouHAMI, University of Guelph, EDIE SCHEURWATER, HANJEOng HARVEY, LORI BURROWS, McMaster University, JOHN DUTCHER, University of Guelph — Type IV pili (Tfp) are thin flexible protein filaments that extend from the cell membrane of bacteria such as *Pseudomonas aeruginosa* and *Neisseria gonorrhoeae*. The mechanical properties of Tfp are of great importance since they allow bacteria to interact with and colonize various surfaces. In the present study, we have used atomic force microscopy (AFM) for both imaging and pulling on Tfp from *P. aeruginosa* (PAO1) and from its PilA, PiIIT, and PiIc mutants. A single pilus filament was mechanically stretched and the resulting force-extension profiles were fitted using the worm-like-chain (WLC) model. The statistical distributions obtained for contour length, persistence length, and number of pili per bacteria pole, were used to evaluate the mechanical properties of a single pilus and the biogenesis functions of different proteins (PilA, PilIT) involved in its assembly and disassembly. Importantly, the persistence length value of ~ 1 µm measured in the present study, which is consistent with the curvature of the pilus observed in our AFM images, is significantly lower than the value of 5 µm reported earlier by Skerker et al. (1). Our results shed new light on the role of mechanical forces that mediate bacteria-surface interactions and biofilm formation. 1- J.M. Skerker and H.C. Berg, Proc. Natl. Acad. Sci. USA, 98, 6901-6904 (2001).

**K1.00265 Inhibition of Oncogenic functionality of STAT3 Protein by Membrane Anchoring**

BAOXU LIU, STEVEN FLETCHER, PATRICK GUNNING, CLAUDIU GRADINARU, University of Toronto, GRADINARU/GUNNING COLLABORATION — Signal Transducer and Activator of Transcription 3 (STAT3) protein plays an important role in oncogenic processes. A novel molecular therapeutic approach to inhibit the oncogenic functionality of STAT3 is to design a prenylated small peptide sequence which could sequester STAT3 to the plasma membrane. We have also developed a novel fluorescence derivative label (F-NAC), which is much more photostable compared to the popular fluorescein label FITC. Remarkably, the new dye shows fluorescent properties that are invariant over a wide pH range, which is advantageous for our application. We have shown that F-NAC is suitable for single-molecule measurements and its properties are not affected by ligation to biomolecules. The membrane localization via high-affinity prenylated small-molecule binding agents is studied by encapsulating F-NAC-labeled STAT3 and inhibitors within a liposome model cell system. The dynamics of the interaction between the protein and the prenylated ligands is investigated at single molecule level. The efficiency and stability of the STAT3 anchoring in lipid membranes are addressed via quantitative confocal imaging and single-molecule spectroscopy using a custom-built multiparameter fluorescence microscope.

**K1.00266 Towards real-time 3D Tracking of Structural Transitions in Adenylate Kinase by Thermal Noise Imaging**

ARND PRAALLE, VIJAY RANA, YUNSHIANG HSU, University at Buffalo, SUNY — Proteins in contrast to macroscopic machines are subject to thermal fluctuations in shape which provide both opportunities and challenges. They have to be flexible enough to support turn-over rates up to hundreds per second, yet stable enough to maintain their three-dimensional structure over hours and days. As result of thermal excitation they fluctuate between structural conformations. We measured thermally excited structural fluctuations in the Adenylate Kinase using a site-specifically attached nanoparticle and a laser trap based position sensing scheme. This ‘Thermal Noise Imaging’ (TNI) can provide real-time tracking of 3D structural transitions. TNI uses scattering of laser light to locate a nanoparticle with Ångström spatial and microsecond temporal resolution. We present details of the technique and a comparison of thermally excited structure fluctuations with functional transitions.

**K1.00267 Single molecule study of ClpP enzymatic activity**

AMIR MAZOUCHi, University of Toronto, Department of Physics, ANGELA YU, WALID HOURY, University of Toronto, Department of Biochemistry, CLAUDIU GRADINARU, University of Toronto, Department of Physics, GRADINARU TEAM, HOURY TEAM — Elementary processes that form the basis of biological activities pass through a number of short-lived intermediate states while progressing from initial state to final state. Single-molecule techniques, unlike ensemble averaging measurements, are often able to resolve these transient states. ClpP, a known target of antibacterial drugs like acycepidopes (AEDPs), is a classical representative of serine proteases, enzymes that cleave peptide bonds in proteins. We performed single-molecule fluorescence measurements including burst spectroscopy and fluorescence correlation spectroscopy (FCS) to address unknown aspects of this degradation process. Our study reveals important molecular details of protein degradation, such as the enzyme-substrate binding rate, the lifetime distribution of the conjugated state and the probability of substrate cleavage upon conjugation.
K1.00268 The effect of macromolecular crowding on reaction rates: a computational and theoretical study1, JUN SOO KIM, ARUN YETHIRAJ, Theoretical Chemistry Institute and Department of Chemistry, University of Wisconsin-Madison — The effect of macromolecular crowding on the rates of association reactions was investigated using theory and computer simulations. Reactants and crowding agents are both hard spheres, and when two reactants collide they form product with a reaction probability, \( p_{\text{reac}} \). A value of \( p_{\text{reac}} < 1 \) crudely mimics the fact that proteins must be oriented properly in order for an association reaction to occur. The simulations show that the dependence of the reaction rate on the volume fraction of crowding agents varies with the reaction probability. For reaction probabilities close to unity where most of encounters between reactants lead to a reaction, the reaction rate always decreases as the volume fraction of crowding agents is increased due to the reduced diffusion coefficient of reactants. On the other hand, for very small reaction probabilities where in most of encounters the reaction does not occur, the reaction rate increases with the volume fraction of crowing agents, in this case, due to the increase probability of a re-collision. The Smoluchowski theory is in quantitative agreement with simulations for the reaction rate constant and allows the quantitative analysis of both effects separately.

K1.00269 Polymer translocation induced by bad solvent, CHRISTOPHER LORSCHER, ANIKET BHATTACHARYA, University of Central Florida, TAPIO ALA-NISSILA, Helsinki University of Technology — We report Langevin dynamics simulation studies of a translocating homopolymer through a nano pore induced by different existing solvent conditions at the cis and trans compartments of the pore. Specifically, we study the mean first passage time \( \tau \) as a function of the chain length \( N \) and determine the scaling exponent \( \alpha \sim N^{-\alpha} \). We also look at the mean force experienced by the chain and its conformations as a function of the translocated segments. Our studies also reveal detail picture of the translocation process which may provide insights relevant for the entry of a DNA into a host cell.

K1.00270 Statistical test of a null hypothesis: Taser® shocks have not caused or contributed to subsequent in-custody deaths, MARJORIE LUNDQUIST1, Bioelectromagnetic Hygiene Institute — Since 1999 over 425 in-custody deaths have occurred in the USA after law enforcement officers (LEOs) used an M26 or X26 Taser®, causing Amnesty International and the ACLU to call for a moratorium on Taser use until its physiological effects on people have been better studied. A person’s Taser dose is defined as the total duration (in seconds) of all Taser shocks received by that person during a given incident. Utilizing the concept of Taser dose for these deaths, TASER International’s claim of Taser safety can be treated as a null hypothesis and its validity scientifically tested. It shows that the null hypothesis should be rejected; i.e., model M26 and X26 Taser®s are capable of producing lethal effects non-electrically and so have played a causal or contributory role in a great many of the in-custody deaths following their use. This implies that the Taser® is a lethal weapon, and that LEOs have not been adequately trained in its safe use!

K1.00271 Computing Transitions in Macromolecular Systems: Dynamic Importance Sampling, JUAN PERILLA, Johns Hopkins University, OLIVER BECKSTEIN, ANU NAGARAJAN, THOMAS WOOLF — Understanding and predicting conformational changes in macromolecules is central to linking structure and function. Performing straight-forward all-atom molecular dynamics would, in principle, enable sampling of conformational changes, but the time-scale for functionally important transitions, exceeds the usual MD timescales by several orders of magnitude. Thus to sample on longer time-scales requires the development of biased molecular dynamic methods, where the bias can be applied and corrected for at the end. In our approach, called ‘Dynamic Importance Sampling’ we generate a series of independent trajectories that are conditioned on starting and ending in defined conformations. Trajectories are generated using two different algorithms: one that uses an adaptive soft-ratcheting scheme, based on stochastic trajectories and, the other uses information from the set of normal modes. Both algorithms do not require a previous knowledge on the reaction coordinate, furthermore using this framework we are also able to introduce a generalized reaction coordinate in order to guide the transitions for virtually any system. The algorithms, which require no initial pathway, are capable of rapidly determining multiple pathways between known states. The associated probability scores allow us to rank order the most likely pathways.

K1.00272 The Origin of Power Law Distributions in Protein Synthesis, JEFFREY BARKER, CHUCK YEUNG, Pennsylvania State Univ. at Erie, XIAO-LUN WU, EMILY CHAPMAN-MCUYSTON, University of Pittsburgh — A genetically identical bacteria population will show heterogeneous gene expression due to the stochastic nature of the protein production mechanism. Therefore, the probability distribution of the resulting protein(s) can be used to gain information about these underlying processes. The experiments of Chapman-McQuiston et. al. show that under certain circumstances the protein probability distribution has a power law form \( p(n) \sim n^{-\alpha} \) at small \( n \). Our simulations and analysis find, in agreement with work by Friedlander and Brenner, that a linear protein production rate will produce a power law distribution with the exponent depending on the amplitude of the bubble (bubble) dynamics of 80 bp long promoter DNA sequences. We suggest that three dynamic quantities: bubble probability, bubble lifetime, and average strand is likely to be a requirement for transcription initiation in several promoters. We present molecular dynamic simulations of DNA to analyze the strand separation site.

K1.00273 Toward a Detailed Description of the Thermally Induced Dynamics of the Core Promoter, BOIAN ALEXANDROV, Theoretical Division, Los Alamos National Laboratory, VLADIMIR GELEV, Beth Israel Deaconess Medical Center and Harvard Medical School, KIM RASMUSSEN, ALAN BISHOP, Theoretical Division, Los Alamos National Laboratory, ANNY USHEVA, Beth Israel Deaconess Medical Center and Harvard Medical School — Experimental data suggest that a spontaneous dsDNA strand separation at the transcriptional start site (TSS) is likely to be a requirement for transcription initiation in several promoters. We present molecular dynamic simulations of DNA to analyze the strand separation (bubble) dynamics of 80 bp long promoter DNA sequences. We suggest that three dynamic quantities: bubble probability, bubble lifetime, and average strand separation, together represent an adequate characterization of the bubble formation at TSS’s of eight mammalian gene promoters. The TSS is distinguished by large, frequent, and long-lived transient openings in the double helix. In support of these results are our experimental transcription data demonstrating that an artificial DNA template, viz., a bubble-template of 5 bp mismatch at the TSS, is transcribed bi-directionally by human RNA polymerase alone in the absence of any other transcription factors.

K1.00274 In Silico Docking of Ligands to Drug Oxidation Enzymes Cytochrome P450 3A4 and Cytochrome P450 1A2, DAVID SMITH, JONATHAN GUGLIELMONE, MARSCH GLENN, GUENGERICH F. PETER, GROVE CITY COLLEGE BIOPHYSICS RESEARCH TEAM — Cytochrome P450 3A4 (CYP3A4) and Cytochrome P450 1A2 (CYP1A2) oxidize most drugs in humans. Protein modeling toolkits from OpenEye Scientific Software were used to examine the interaction of drug substrates with CYP3A4 and CYP1A2. Conformers and partial atomic charges were generated for each drug molecule. User-defined volumes were defined around CYP3A4 and CYP1A2 active sites. Ligands were docked assuming protein and substrates as rigid bodies. To assess rigid docking accuracy, x-ray diffraction coordinates of CYP3A4-erythromycin and CYP3A4-metyrapone complexes were obtained. Rigid re-docking of erythromycin and metyrapone into CYP3A4 yielded poses similar to the crystal structures. Rigid docking revealed two other energetically-favorable CYP3A4-metyrapone poses. The best poses were obtained by using all the Open Eye scoring functions. Optimization of protein-ligand interactions within 5-10 Angstroms of the docked ligand was then performed using the Merck Molecular Force Field in which the protein was assumed to be flexible and the ligand to be rigid. Nearby protein residues pulled slightly closer to the substrate, reducing the volume of the active site.
K1.00275 Examination of mathematical models for voltage attenuation in dendritic trees of geniculate neurons, KEEGAN HINES, Washington and Lee University, WILLIAM GUIDO, Virginia Commonwealth University — An examination of Rall’s model of Electrotonic Compactness in neuronal dendritic trees was conducted. The principal power of this model is a prediction for dendritic morphology as it is related to voltage attenuation and efficient transmission of electrical signals. In particular, this study tested the validity of Rall’s “3/2 power rule” with precision and accuracy not previously sought. Cells were imaged using fluorescent tagging and multi-photon confocal microscopy in order to render three dimensional images of cells in vivo. Dendritic diameters and lengths were measured on either side of junction points and these values were compared to Rall’s predictions. Cells of varying ages were measured in order to simultaneously investigate whether deviations from Rall’s model increased or decreased with brain development. Cells of age P8 tend to adhere closely to Rall’s predictions while mature cells (∼P90) show morphologies which would lead to inefficient signal flow. These data coincide well with previous studies which indicate that as cells grow, membranes mature and acquire ion channels which lead to non-linear conductances across the membrane. This is a possible explanation for why, from a purely morphological standpoint, cells grow into a less electrically efficient formation.

K1.00276 The Interaction of Photon Beams with the DNA Molecules: Genomic Medical Physics, V. ALEXANDER STEFAN, Institute for Advanced Physics Studies (Stefan University), 1010 Pearl Street, La Jolla, CA 92038-2946 — I propose a novel method for the modification of the corrupted human DNA code that causes particular genetic disease. The method is based on the nonlinear interaction between the DNA molecule and the “modulation photons” generated by the BW-FEL. The BW-FEL frequencies are given by ε=ω−2γΩe(γ is the free electron beam relativistic factor, n is the harmonic number of the electron Bernstein plasma mode, and Ωe is the electron cyclotron frequency). The “carrier photons” are focused on the area of the brain, the source-center of a genetic disease. For the BW-FEL parameters: the free electron beam guiding d.c. magnetic field ~ 1kG, γ ~10^3, and n=10, the keV “modulation photons” are generated, which are easily focused on the nucleotides. By modulating the frequency of the BW-FEL, the parametric resonance with the different DNA (sub-DNA) eigen molecular oscillation-modes are achieved, leading to the “knock-on” of the unwanted (corrupted) nucleotides.

K1.00277 A kinetics study of the activation energy for the desorption of water from guanosine, MEGAN SCHWENKER SMITH, SCOTT LEE, University of Toledo — The interactions of the nucleic acids with their water of hydration are of fundamental importance but are still poorly characterized. As an initial effort, we have studied the nucleoside guanosine (G), composed of the ribose sugar and the guanine base, which is a component of RNA. We have measured the interactions of the water of primary hydration with G via thermogravimetric measurements and differential thermal analysis by studying the kinetics of the dehydration process. These data yield the activation energy for the desorption of the water of primary hydration from G.

K1.00278 Novel techniques for study of the nucleosome core particle ionic atmosphere and its role in electrostatically-driven DNA packing, KURT ANDRESEN, Colgate University — The nucleosome core particle (NCP) is the primary mechanism for DNA compaction. While the wrapping of the DNA around the histone core is thought to be at least partially sequence-dependent, the packing of the nucleosome cores is believed to be almost entirely electrostatic in nature. Using novel techniques to probe the ionic atmosphere, we hope to elucidate details of this compaction and provide a quantitative description of the positive and negative ions that surround the nucleosome. Results of these experiments will be presented. This work should have implications for nucleosome compaction, chromatin remodeling, and more generally electrostatics of highly charged biomolecules.

K1.00279 Hill Parameters and Heterogeneity of alpha-Naphthoflavone Binding to Human Cytochrome P450 3A4 by Fluorescence Spectroscopic Analysis, BENJAMIN CARLSON, GLENN MARSCH, Grove City College, MARTHA MARTIN, P. F. BEER GUENGERICH, Vanderbilt University School of Medicine — Human cytochrome P450 3A4 (CYP 3A4) is an alpha-helical membrane-bound protein that metabolizes approximately 50% of all drugs. The interaction between CYP450 3A4 and alpha-naphthoflavone (ANF) was characterized using fluorescence methods. ANF quenched fluorescence from tryptophan residues in CYP 3A4, and CYP 3A4 quenched bound ANF. The ANF emission energy was unchanged upon binding to CYP 3A4, implying that enzyme-bound 3A4 is completely quenched. Fluorescence difference spectra were fit to the Hill equation by varying the parameters Kd and n. For quenching of tryptophan fluorescence by ANF, no significant sigmoidal behavior was observed with n=1.1, and the spectral dissociation constant revealed a strong ANF-CYP 3A4 interaction with Kd=27nM. Modest cooperativity and very tight binding was observed in the quenching of ANF by CYP 3A4, with n=1.4 and Kd=4.9nM. Fluorescence polarization anisotropy decreased at low ANF/CYP 3A4 molar ratios; then < r > increased at higher ratios. Compared to substrate-free CYP 3A4, adding substrate at low molar ratios increases the CYP 3A4 rotation, suggesting the molecular volume decreases.

K1.00280 Residue mobility and energy profiles of an HIV-1 protease (1DIFA) chain by a coarse-grained Monte Carlo simulation, RAS PANDEY, University of Southern Mississippi, BARRY FARMER, Air Force Research Laboratory — HIV-1 protease (1DIFA), an enzyme consists of two polypeptides, 99 amino acids each. Aspartic acid residue (Asp) forms the active catalytic site. Specificities of residues are captured via an interaction matrix (residue-residue, residue-solvent) of the Lennard-Jones potential. Simulations are performed for a range of interaction strength (J) with the solvent-residue interaction describing the quality of the solvent. Snapshots of the protein show considerable changes in the conformation of the protein on varying the interaction. From the mobility and energy profiles of the residues, it is possible to identify the active (and not so active) segments of the protein and consequently their role in proteolysis. Contrary to interaction thermodynamics, the hydrophobic residues possess higher configurational energy and lower mobility while the electrostatic and polar residues are more mobile despite their lower interaction energy.

K1.00281 Interaction of Human Cytochrome P450 3A4 with Hydrophobicity Probe Nile Red Shows Heterogeneous, Strong Binding, JENNIFER HANSEN, F. GUENGERICH, MARTHA MARTIN, GLENN MARSCH, PHYSICS DEPARTMENT, GROVE CITY COLLEGE, GROVE CITY PA 16127 TEAM, CENTER IN MOLECULAR TOXICOLOGY, VANDERBILT UNIVERSITY, NASHVILLE, TN, 37232 TEAM — Human cytochrome P450 3A4 (CYP 3A4) binds an unusually wide variety of substrates, and metabolizes about 50% of all drugs. Steady-state fluorescence spectra were acquired for complexes of CYP 3A4 and the fluorescence probe Nile Red. Difference fluorescence spectra showed the quenching of CYP 3A4 tryptophan fluorescence by Nile Red. CYP 3A4 was also added to Nile Red, and changes in the Nile Red fluorescence spectra were monitored. The dissociation constant showed tight binding, with Kd = 44nM. Good fits to the Hill plots were obtained with n = 1, suggesting non-cooperative binding. This study revealed strong, heterogeneous, non-cooperative binding of Nile Red to CYP 3A4.
The Effect of Electric and Magnetic Fields on Protein Self-Organization and Osteoblast Biomineralization

The Effect of Titanium Dioxide Nanoparticles on Keratinocyte Cell (KC) and Squamous Cell Carcinoma (SCC) - Investigation on mineralization behaviour of Type I collagen and noncollagenous extracellular matrix protein immobilized on polymer thin film. XIAOLAN BA, Stony Brook University, ARIELLA KRISTAL, Solomon Schechter Highschool, ELAINE DIMISI, Brookhaven National Laboratory, MIRIAM RAFAILOVICH, Stony Brook University — The effects of the components of extracellular matrix on the bone formation and the kinetics of crystal growth of calcium phosphate have remained unknown. Here we reported a method to investigate the role of Type I collagen and the interactions with other ECM proteins such as fibronectin and elastin during biomineralization process. The early stage of mineralization was characterized by atomic force microscopy (AFM) and shear modulation force microscopy (SMFM). The late stage of mineralization was investigated by scanning electron microscopy (SEM), grazing incident x-ray diffraction (GIXD). The results showed the calcium phosphate biomineralization only occurred when the collagen interacted with fibronectin or elastin.

K1.00288 The Effect of Electric and Magnetic Fields on Protein Self-Organization and Osteoblast Biomineralization

Coarse-graining of the membrane lipids and surface allow for the larger system size necessary for membrane shape studies. Supported lipid bilayers (SLB) continue to be an important means of measuring the thermodynamic and mechanical properties of phospholipid membranes, which are the basis of compartmentalization in living cells. Understanding SLB systems with respect to their substrates enhances the understanding of the measurements taken thereon and promotes design of new substrates to expand the usefulness of these systems. We present data for the interaction of coarse-grained lipid membranes with nanopatterned surfaces, showing the effect of the balance between bending energy and adsorption energy on membrane topology.

The Effect of Titanium Dioxide Nanoparticles on Keratinocyte Cell (KC) and Squamous Cell Carcinoma (SCC) cells. Confocal microscope shows that the particles in keratinocyte culture are sequestered in membranes between the cell colonies. The particles penetrated into the cells in the case of the SCC cells. TEM revealed very few particles in the keratinocyte, many more particles were observed sequestered in vacuole of the SCC cells. These results indicate that the keratinocyte layer behaves very different from the fibroblast layers which are much more senescent to TiO₂ nanoparticle damage and may suggest a protection mechanism of the dermal tissue. The effect of UV exposure in the presence of DNA was also investigated. We found that adsorbed proteins, as well as grafted polymer provided a measure of protection against free radical formation. The effects of low level UV exposure when the particles are near in-vitro cell culture will be presented.

Substrate interactions with adsorbed membranes modify the intrinsic mechanics of supported lipid bilayers. Coarse-graining of the membrane lipids and surface allow for the larger system size necessary for membrane shape studies. Supported lipid bilayers (SLB) continue to be an important means of measuring the thermodynamic and mechanical properties of phospholipid membranes, which are the basis of compartmentalization in living cells. Understanding SLB systems with respect to their substrates enhances the understanding of the measurements taken thereon and promotes design of new substrates to expand the usefulness of these systems. We present data for the interaction of coarse-grained lipid membranes with nanopatterned surfaces, showing the effect of the balance between bending energy and adsorption energy on membrane topology.

The Effect of Titanium Dioxide Nanoparticles on Keratinocyte Cell (KC) and Squamous Cell Carcinoma (SCC-13) - CHIENHSIU LIN, SUNY-Stony Brook U., MARCIA SIMON, VLADIMIR JURUKOVSKI, WILSON LEE, MIRIAM RAFAILOVICH, DEPARTMENT OF MATERIALS SCIENCE & ENGINEERING, STONY BROOK UNIVERSITY, STONY BROOK, NEW YORK COLLABORATION — We have investigated the effects of TiO₂ nanoparticles on cell keratinocytes and SCC (Squamous Cell Carcinoma) cells. We found that the concentration of particles required to adversely affect the cells was many times higher for keratinocytes than SCC cells. Confocal microscope shows that the particles in keratinocyte culture are sequestered in membranes between the cell colonies. The particles penetrated into the cells in the case of the SCC cells. TEM revealed very few particles in the keratinocyte, many more particles were observed sequestered in vacuole of the SCC cells. These results indicate that the keratinocyte layer behaves very different from the fibroblast layers which are much more senescent to TiO₂ nanoparticle damage and may suggest a protection mechanism of the dermal tissue. The effect of UV exposure in the presence of DNA was also investigated. We found that adsorbed proteins, as well as grafted polymer provided a measure of protection against free radical formation. The effects of low level UV exposure when the particles are near in-vitro cell culture will be presented.

Theoretical Description of Microtubule Dynamics in Fission Yeast During Interphase - YUNG-CHIN OEI, ANDREA JIMÉNEZ-DALMARONI, University College London, UK, ANDREJ VILFAN, Jozef Stefan Institute, Ljubljana, Slovenia, THOMAS DUKE, University College London, UK — Fission yeast (S. pombe) is a unicellular organism with a characteristic cylindrical shape. Cell growth during interphase is strongly influenced by microtubule self-organization - a process that is experimentally well characterized. The microtubules are organized in 3 to 4 bundles, called “interphase microtubule assemblies” (IMAs). Each IMA is composed of several microtubules, arranged with their dynamic “plus” ends facing each other. Coarse-graining of the membrane lipids and surface allow for the larger system size necessary for membrane shape studies. Supported lipid bilayers (SLB) continue to be an important means of measuring the thermodynamic and mechanical properties of phospholipid membranes, which are the basis of compartmentalization in living cells. Understanding SLB systems with respect to their substrates enhances the understanding of the measurements taken thereon and promotes design of new substrates to expand the usefulness of these systems. We present data for the interaction of coarse-grained lipid membranes with nanopatterned surfaces, showing the effect of the balance between bending energy and adsorption energy on membrane topology.

The Effect of Electric and Magnetic Fields on Protein Self-Organization and Osteoblast Biomineralization - XIAOLAN BA, Stony Brook University, LARA FOURMAN, Plainview Old Bethpage Highschool, SANCITA SINGAL, Herricks Highschool, YIZHI MENG, MIRIAM RAFAILOVICH, Stony Brook University — The induction of bone formation to an intentional orientation is a potentially viable clinical treatment for bone regeneration. Among the many chemical and physical factors, electric and magnetic fields are an essential way to regulate the behavior of cells and matrix fibers. The aims of this study are to investigate the effects of electric and magnetic fields on protein self-organization and osteoblast biomineralization on polymer surfaces in vitro. To this end, we use atomic force microscopy (AFM) to characterize the morphology of protein fiber and ECM by cells. The mechanical property of protein fibers was investigated by shear modulation force microscopy (SMFM). The late-stage of mineralization was characterized by scanning electron microscopy (SEM) and grazing incident x-ray diffraction (GIXD). The primary data indicated that the magnetic field could enhance the biomineralization of osteoblast.
K1.00289 Elastic properties of vimentin networks1, YI-CHIA LIN, AMY C. ROWAT, Harvard University, HARALD HERRMANN, German Cancer Research Center, CHASE C. BROEDERSZ, FREDERICK C. MACKINTOSH, Vrije Universiteit, ELEONAR A. MILLMAN, DAVID A. WEITZ, Harvard University — We measure the mechanical properties of in vitro networks of the intermediate filament protein vimentin by rheometry. Vimentin networks are highly elastic even for small volume fractions of protein and exhibit dramatic stiffening with strain. We find that divalent ions such as Ca2+ and Mg2+ act as effective cross-linkers in the vimentin network. The observed linear and nonlinear elastic responses at intermediate strains can be explained quantitatively by affinely stretching the entropic fluctuations of single semiflexible filaments; at high strains, enthalpic stretching of the individual filaments contributes to the observed nonlinear response.

K1.00290 In Vitro Migration of Human Dermal Fibroblasts on the Electrospun Fibrous Scaffold, YING LIU, DILIP GERSASPE, ALICIA FRANCO, Stony Brook University, SARAJANE GROSS, ELIAS GOODMAN, North Shore Hebrew Academy High School, RICHARD CLARK, MIRIAM RAFAILOVICH, Stony Brook University — Cell migration has become the focus of much research due to its importance through out cell life. We hypothesized that the aligned scaffold obtained from electrospinning would enhance the rate of cell migration and ultimately the rate of new tissue ingrowth. An in vitro en-masse assay was used to study the effects of fiber diameter and alignment on the cell migration. It was found that, while the cells were spreading out on the fibers with diameter of 200nm, nearly all the cells were oriented along the fibers for the 1 and 8 micron surfaces. In addition to fiber diameter, orientation is another crucial parameter which can determine cell migration. Cell migration rates and persistence increased on the aligned PMMA fibers compared to the random fibers. The role of focal adhesions during cell migration was detected by staining the Vinculin after 6 and 24h of cell culture time. The computational model used to stimulate cell migration on the aligned scaffold, and it was turned out that various cellular parameter were integrated to accomplish the specific cell locomotion pattern on the aligned scaffold.

K1.00291 Nanoscale Mechanics of Type I Collagen, H. HARPER, E. CROPPER1, A. BULGER, U. CHOKSI, T. J. KOOB, S. PANDIT, W.G. MATTHEWS, University of South Florida — Collagen is the most abundant protein in the body by mass. Type I collagen fibrils provide mechanical strength and cellular housing within tissues exhibiting a broad range of mechanical properties. This diversity in the mechanics of tissues with similar underlying components warrants detailed study of the process by which structure and mechanics develop. While collagen mechanics have been studied at the tissue level for decades, surprising little is known about collagen mechanics at the fibril and molecular level. Presented herein is a multi-scale experimental and computational investigation of collagen I mechanics, bridging the single molecule and fibril hierarchical forms. The mechanics of single collagen molecules are explored using AFM and force spectroscopy. Moreover, atomistic molecular-dynamics simulations are performed to provide structural information not accessible to the experimental system. Fibrils then are grown from molecular collagen, and the mechanics of these fibrils are investigated using AFM. Based upon the single molecule and fibril results, a coarse-grain computational model is being developed. The outcomes include a better understanding of how the mechanics of filamentous self-organizing systems are derived and how their hierarchical forms are established.

K1.00292 Self-assembly of FKE8 peptides using CHARMM, ABBDELHALLAH OUAZZANI, ABDULKADER KARA, ANIKET BHATTACHARYA, University of Central Florida — We investigate the molecular self-assembly of FKE8 peptides (with a sequence FKFEFKFE) using CHARMM. Previous studies1,2 of the FKE8 peptides have shown helical ribbon structures during the formation of β-sheets. In order to understand this supramolecular structure, first we investigate the stable configuration of two FKE8 molecules as a function of the orientation of the long axis of the molecules. We find that stable configuration of these two molecules (based on energy minimization) occurs when the long axes of the two molecules are orientated at an angle ≃ 51.5° with respect to each other. This angle may be relevant to understand the pitch of the helical structure. Next we study the self-assembly of several FKE8 molecules starting with an initial configuration where two successive FKE8 molecules are oriented at an angle ≃ 51.5° with respect to each other. It was found that, while the cells were spreading out on the fibers with diameter of 200nm, nearly all the cells were oriented along the fibers for the 1 and 8 micron surfaces.

K1.00293 Simulation of Peptide Binding to Silica and Silica Mineralization, F.S. EMAMI, H. HEINZ, Department of Polymer Engineering, The University of Akron, Akron, Ohio, 44325, USA, R.J. BERRY, V. VARSHNEY, B.L. FARMER, R.R. NAIK, AFRL/RXB, WPAFB, Dayton, OH 45433, USA, S.V. PATWARDHAN, C.C. PERRY, Department of Chemistry, Nottingham Trent University, Nottingham, NG11 8NS, U.K. — The purpose of this study is to identify the nature of the interaction of peptides with silica surfaces and their effect on mineralization. Classical force fields (CVFF, PCFF) have been extended for silica aiming at the computation of surface properties in quantitative agreement with experiment, taking explicitly into account water molecules, pH, and surface coverage with peptides. We focus on the interaction of five short peptides (pep1, pep4, 82-4, H4, R5) identified by biopanning with regular and amorphous silica surfaces (Q3 and Q2) to understand the relation between peptide sequence and affinity to the surface. Results of the atomistic molecular dynamics simulation indicate adsorption energies, binding constants and conformational changes upon adsorption. The comparison of NMR chemical shifts in solution and on the surface in computation and experiment further aids in understanding the mechanism of binding.

K1.00294 NMR Studies in Macromolecular Solutions1, ANAND YETHIRAJ, SULIMAN BARHOUUM, Memorial University — We use diffusion nmr to characterize the dynamics of multi-component macromolecular solutions. Diffusion coefficients of all components are obtained simultaneously. We also present a scheme to extract the diffusion coefficients associated with transient aggregates in solution. Applications and limitations of this scheme are discussed.

1This work is being supported by NSERC

K1.00295 Surface imprinting of proteins: from mechanism to application, YANTIAN WANG, STEFFEN MUELLER, JONATHAN SOKOLOV, Stony Brook University, KALLE LEVON, Polytechnic University, BASIL RICAS, MIRIAM RAFAILOVICH, Stony Brook University — Protein adsorption properties on different surfaces have been of great interest due to their importance in biomedical applications. In this study, adsorption of proteins on gold, thiol self-assembled monolayer (SAM), and molecularly imprinted thiol SAM was studied. Alkaline phosphatase (AP), an enzyme that can catalyze p-nitrophenyl phosphate and produce a yellow end product which has light absorbance at 405nm, was co-adsorbed with 11-mercapto-1-undecanol to fabricate the imprinted surface. Different washing methods were used to remove AP and create re-adsorption sites. The adsorption amount of AP before and after washing was measured by spectrophotometer after enzyme reaction. Re-adsorption of AP onto the three substrates was measured by spectrophotometer after enzyme reaction. Re-adsorption of AP onto the three surfaces was compared and showed that the imprinted surface re-bound the protein molecules at the template site. Potentiometric response of the three substrates to AP was measured at different pH, the charge effect on the potential response was studied. The selective binding of the template proteins made it a useful technique as a protein sensor.
K1.00296 Single Molecule Optical Signal Comparison of Fluorescent Molecules and Raman Active Nanopores. EDWARD ALLGEYER, University of Maine Department of Physics, ADAM PONGAN, GARY CRAIG, MICHAEL MASON, University of Maine Department of Chemical Engineering. MASON LAB GROUP TEAM — In recent years various enhancement techniques have been used to greatly improve the effective cross section of all flavors of raman spectroscopy. Further, coupling specific probe molecules to metal nanoparticles allows for a nanoprobe with an enhanced effective raman cross section making raman probes a viable technique for imaging and spectroscopy in biological and material systems. However, it has been claimed that intensity variations of raman nanopores are to large for raman nanopores to be useful. Here we report on a study of intensity variations of novel raman active nanoprobes and contrast this with intensity variations of typical single molecule fluorescent probes. In both cases an intensity distribution is built from the single molecule level. 

K1.00297 Atomic Force Microscope Investigations of Biofilm-Forming Bacterial Cells Treated with Gas Discharge Plasmas1. KURT VANDERVOORT, ANDREW RENSHAW, NINA ABRAMZON, Physics Department, California State Polytechnic University, Pomona, GRACIELA BRELLES-MARINO, Biological Sciences Department, California State Polytechnic University, Pomona — We present investigations of biofilm-forming bacteria before and after treatment from gas discharge plasmas. Gas discharge plasmas represent a way to inactivate bacteria under conditions where conventional disinfection methods are often ineffective. These conditions involve bacteria in biofilm communities, where cooperative interactions between cells make organisms less susceptible to standard killing methods. Chromobacterium violaceum were imaged before and after plasma treatment using an atomic force microscope (AFM). After 5 min. plasma treatment, 90% of cells were inactivated, that is, transformed to non-culturable cells. Results for cell surface morphology and micromechanical properties for plasma treatments lasting from 5 to 60 minutes were obtained and will be presented.

K1.00298 Electrostatic perturbation in neurons and endothelial cells under stress using Atomic Force Microscopy-assisted Electrostatic Nanolithography. VICTORIA NEDASHKIVSKA, SERGEI LYUKSYUTOV, The University of Akron, LOIS-MAY BEZUIDENHOUT, CORNELIS VAN DER SCHYF, NEUOCOM — The morphological and membrane properties of neuronal and vascular endothelial cells need to be studied to reveal their possible role in neurodegeneration after injury. Atomic Force Microscopy Electrostatic Nanolithography (AFMEN) offers an opportunity to measure cellular perturbations during stress conditions. AFMEN is based on electrostatic manipulations of macromolecules and biological tissues at a nanoscale level which generates electric fields of the order of magnitude $10^{-9}$ - $10^{-12}$ V m$^{-1}$ and studies membrane changes in vitro cell culture systems. Two cell culture systems were selected based on their ability to represent neurons on the one hand, and vascular epithelial cells differentiated to model the blood-brain barrier, on the other. The imaging was completed for cells in wet (natural) and also in dry conditions. Changes in membrane behavior will be compared between stressed cells and controls that have not undergone exposure to pathologic conditions. 

K1.00299 Ballistics and Biophysics of Fatal Lesion in Thorax. SAAKI J. SHAIBANI, Independent Modeling, Algorithms & Analytical Studies (IMAAS) — The examination of body-related factors does not always provide the level of insight required to resolve the mechanism of death for major chest injury. Indeed, many autopsy findings are limited when environmental information is either not available at all or is incomplete. Such was the case when a gunshot wound was inflicted upon a standing adult male whose torso was rotated by a forward pitch and a rightward yaw. Highly accurate values for these angles were derived by a process independent from any standard medical approach, along with precise measurements for various anatomical landmarks, so that a meticulous analysis could be performed to determine all plausible bullet trajectories. A combination of physics and medicine then allowed only one viable set of conditions to be identified. The interdisciplinary nature of the research described here was responsible for its success; without such a collaborative study, a full understanding of the relevant issues could not have emerged. Physics-based techniques can also be of benefit in many other applications when the appropriate protocol is defined properly and then implemented correctly.

K1.00300 How are static magnetic fields detected biologically? . LEONARD FINEGOLD, Department of Physics, Drexel University — There is overwhelming evidence that life, from bacteria to birds to bats, detects magnetic fields, using the fields for orientation or navigation. Indeed there are recent reports (based on Google Earth imagery) that cattle and deer align themselves with the earth’s magnetic field. [1]. The development of frog and insect eggs are changed by high magnetic fields, probably through known physical mechanisms. However, the mechanisms for eukaryotic navigation and alignment are not clear. Persuasive published models will be discussed. Evidence, that static magnetic fields might produce therapeutic effects, will be updated [2]. 

K1.00301 Raman Spectroscopy Study of Prostatic Adenocarcinoma Bulk Tissues S. DEVPURA, H. DAI, J.S. THAKUR, R. NAiK, A. CAO, A. PANDYA, G.W. AUNER, Wayne State University, F. SARKAR, W. SAKR, Karmanos Cancer Institute, V. NAiK, University of Michigan-Dearborn — Prostate cancer is one of the most common types of cancer among men. The mortality rate for this disease can be dramatically reduced if it can be diagnosed in its early stages. Raman spectroscopy is one of the optical techniques which can provide fingerprints of a disease in terms of its molecular composition which changes due to the onset of disease. The aim of this project is to investigate the differences in the Raman spectra to identify benign epithelium (BE), prostatic intraepithelial neoplasia (PIN) and adenocarcinoma of various Gleason grades in archived bulk tissues embedded in paraffin wax. For each tissue, two adjacent tissue sections were cut and dewaxed, where one of the sections was stained using haematoxylin and eosin for histological examination and the other unstained adjacent section was used for Raman spectroscopic studies. We have collected Raman spectra from 10 prostatic adenocarcinoma dewaxed tissue sections using Raman microscope (785 nm excitation laser). The data were analyzed using statistical methods of principal component analysis and discriminant function analysis to classify the tissue regions. The results indicate that Raman Spectroscopy can differentiate between BE, PIN and Cancer regions.

K1.00302 Biophysical modeling of mismatch repair proteins1. FREDDIE SALSbury, Wake Forest University — Mismatch repair proteins play a vital role in the biology of cancer due to their dual functions as repair proteins and as sensors of DNA damage. Computational modeling of mismatch repair proteins in conjunction with biological experimentation has demonstrated the role of long-range communication in the functions of these proteins. Furthermore, different conformations have been shown to be associated with different cellular functions, and these differences are being exploited in drug discovery. The latest results in this modeling will be presented.

K1.00303 *In vivo* determination of the structure of oligomers of a G protein-coupled receptor.

SASMITA RATH1, VALERICA RAICU, Department of Physics, University of Wisconsin, Milwaukee, WI 53211 — Resonance Energy Transfer (RET) is a process of nonradiative energy transfer between a donor and an acceptor molecule, which is widely used for studies of protein-protein interactions in living cells. Here we report on the results of a spectrally-resolved two-photon microscopy study of image-pixel level RET in yeast cells (*S. cerevisiae*) expressing a G-protein-coupled receptor called Sterile 2 α factor protein (Ste2P). The number of pixels showing RET were plotted against the RET efficiency to obtain distributions of RET efficiency in the cells. These distributions were simulated with models for plausible geometries and sizes of protein complexes (V. Raicu, 2007, *J. Biol. Phys.* 33:109–127). From all the models tested we found that a parallelogram-shaped tetramer is the most likely structure for the Ste2p oligomers.

Session L1 DPOLY: John H. Dillon Medal Symposium in Honor of Venkat Ganesan

Spirit of Pittsburgh Ballrom A

2:30PM L1.00001 Dillion Medal Prize Lecture. VENKAT GANESAN, The University of Texas at Austin — Many aspects of polymer research have undergone a paradigm shift in the past decade, with an increased emphasis on technological applications which propose the use of materials and devices created by controlling matter from the atomic scales to the bulk commodity level. This talk will focus on multicomponent polymeric materials (block copolymers, rod-coil polymers and mixtures like polymer blends and polymer nanocomposites), which have played a central role in enabling this paradigm shift in the context of polymeric materials. In this talk, I will discuss our recent researches on developing simulation tools that can predict the structure, morphology and flow behavior of such multicomponent polymers. In contrast to conventional ("particle-based") Monte Carlo and Molecular dynamics approaches, our methods work at a coarse-grained level of the system to predict the thermodynamics and dynamics of such multicomponent materials. This talk will focus on an outline of the simulation strategies and present some results concerning both the equilibrium and dynamical properties of such materials.

3:06PM L1.00002 Chain Stretching and Order-Disorder Transitions in Block Copolymer Monolayers and Multilayers. EDWARD J. KRAMER, VINDHYA MISHRA, GILA E. STEIN, KAREN E. SOHN, SUMI HUR, GLENN H. FREDRICKSON, UCSB, ERIC W. COCHRAN, Iowa State University — Both monolayers of block copolymer cylinders and spheres undergo order to disorder transitions (ODT) at temperatures well below those of the bulk. Monolayers of PS-b-P2VP cylinders undergo a “nematic” to “isotropic” transition at temperatures about 20 K below the bulk ODT while monolayers of PS-b-P2VP with P2VP spheres undergo a 2D crystal to hexatic transition at temperatures about 10 K below the bulk ODT. Bilayers of each structure disorder at temperatures well above that of the monolayers. While one is tempted to attribute all of the difference to the fact that ordered monolayers are quasi 2 dimensional while bilayers are not, an alternative explanation exists. In the cylinder monolayer the corona PS chains must stretch to fill a nearly square cross-section domain rather than a hexagonal one in the bulk, while the corona PS chains in a sphere monolayer must stretch to fill a hexagonal prism rather than an octahedron in the bulk. The more non-uniform stretching of the chains in the monolayer should increase its free energy and decrease its order-disorder temperature.

3:18PM L1.00003 Free Energy Estimation in Field-Theoretic Simulations. GLENN FREDRICKSON, ERIN LENNON, KIRILL KATSOY, UC Santa Barbara — A new technique is presented for computing absolute and relative free energies of polymeric fluids in the context of field-theoretic simulations. Complex Langevin sampling is combined with a thermodynamic integration scheme to provide access to free energies of homogeneous and inhomogeneous polymer phases. The scheme utilizes a harmonic crystal reference state whose free energy can be computed analytically. The method is demonstrated in the context of the order-disorder transition of diblock copolymer melts.

3:30PM L1.00004 Directed Crystallization in polymer solutions. MURUGAPPAN MUTHUKUMAR, University of Massachusetts — Theoretical considerations of amyloid fibrillation in protein solutions and polymer-mediated crystallization of nanoparticles will be presented.

3:42PM L1.00005 The O52 Network by Molecular Design: CEC D Tetra block Terpolymers. FRANK S. BATES, MICHAEL BLUEMLE, GUILLAUME FLEURY, TIMOTHY LODGE, U. Minnesota — Varying the length of poly(dimethylsiloxane) in poly(cyclohexylethylenethylene-b-ethylene-b-cyclohexylethylenylene-b-dimethylsiloxane) (CECD) terablock terpolymers between 0 and 20% produces the sequence of ordered phases: cylindrical-to-network-to-cylindrical. Small-angle X-ray scattering and transmission electron microscopy demonstrate Pnma space group symmetry and a unique network morphology stabilized by the asymmetric molecular architecture and block interactions. These results establish a new design principle for the generation of triply periodic and multiply continuous nanostructured soft material.

3:54PM L1.00006 Suppression of Segmental Relaxation as the Origin of Strain Hardening in Polymer Glasses. KENNETH SCHWEIZER, KANG CHEN, University of Illinois — A nanometer scale dynamical theory is proposed for the post-yield large amplitude strain hardening phenomenon in polymer glasses. The physical picture is that external deformation induces anisotropic chain conformations which modifies interchain packing, resulting in density fluctuation suppression and intensification of localizing dynamical constraints and activation barriers. The strain amplitude dependence of the resulting stresses are well described by classic rubber elasticity form. However, the hardening stress is of interchain origin and arises primarily from prolongation of segmental relaxation, not single strand entropic elasticity. Theoretical predictions for the magnitude, temperature and deformation rate dependence of the hardening modulus are consistent with experiments and simulations.

4:06PM L1.00007 Disappearance of high frequency modes in polymer dilute solution viscoelasticity. RONALD LARSON, University of Michigan, SEMANT JAIN, Praxair — We address the problem of the “missing modes” in the high frequency rheology of dilute polymer solutions. According to the Rouse-Zimm theory, the slow viscoelastic response of dilute polymers is dominated by the collective motion of the chain, as described by a bead-spring model. However, one expects this description to break down at high frequencies at which chain motion on scales too small to be represented by beads and springs should be evident; this motion should be controlled by rotations of individual backbone bonds of the polymer. The viscoelastic response produced by these “local modes” is observable in polymer melts; however, for dilute polymer solutions, the “local modes” are absent from viscoelastic spectra, as shown by Schrag and coworkers (Peterson, et al., *J. Polym. Sci.* B, 39:2860 (2001)). Here we address this problem by directly simulating single polymer chains using Brownian dynamics simulations, with realistic bending and torsional potentials. We show using these simulations that the “missing modes” result from barriers to bond rotation that make the chain “dynamically rigid” at high frequencies. As a result, the “dynamical Kuhn length” of the chain exceeds the static one, and the chain at high frequencies is not able to explore local conformations as fast as would be needed for their relaxation to contribute to the mechanical relaxation spectrum.
4:18PM L1.00008 Polymer Conductivity through Particle Connectivity. YUEH-LIN LOO, Princeton University — To promote solution processability of conductive polymers, polymer acids, instead of small-molecule acids, are frequently used as dopants. Generally, the conductive polymer is synthesized in the presence of the polymer acid; sub-micron size particles that are electrostatically stabilized result during polymerization. We discovered that the molecular characteristics of the polymer acid have great implications on the structure of these conductive polymer particles. Templating the synthesis of the conductive polymer with a higher molecular weight polymer acid results in larger particles, and templating with a polymer acid having a larger molecular weight distribution results in a large size distribution in the particles. Because conduction in such conductive polymers is governed by how these particles pack, we show that the macroscopic conductivity of these films is dictated by a single parameter, i.e., the particle density, that is reducible from the various molecular characteristics of the polymer acid we explored. In the specific case of polyaniline that is doped with poly(2-acylamido-2-methyl-1-propane sulfonic acid), the particles are structurally and chemically inhomogeneous. The conductive portions of the polymer preferentially segregate to the particle surface. Conduction in these materials are therefore mediated by the particle surface and conductivity thus scales superlinearly with particle surface area per unit film volume.

4:30PM L1.00009 Modeling the Self-Assembly of Nanoparticle Amphiphiles. SANAT KUMAR, Columbia University, ATHANASSIOS PANAGIOTOPoulos, Princeton University — We demonstrate that spherical nanoparticles, uniformly grafted with macromolecules, robustly self-assemble into a range of anisotropic superstructures when they are dispersed in the corresponding homopolymer matrix. Theory and simulations both suggest that this self-assembly process reflects a balance between the energy gain when particle cores approach and the entropy of distorting the graft polymers. The effectively directional nature of the particle interactions is thus a many-body emergent property.

4:42PM L1.00010 Confinement Effects on Polymer Dynamics in Nanocomposites. RAMANAN KRISHNAMOORTI, University of Houston, TIRTHA CHATTERJEE, UC Santa Barbara, Mansour Abdolbaki, University of Houston, Madhusudan Tyagi, NIST — The dynamics of polymers in systems with dispersed nanoparticles is studied using inelastic and quasi-elastic neutron scattering. In this study, the role of confinement between nanoparticles and the role of nanoparticle topology are examined by considering dispersions with spherical C60 buckyballs, rod-like single walled carbon nanotubes and plate-like graphene. The polymers examined here include bisphenol A epichlorohydrin and bisphenol F epichlorohydrin. Significant changes in the dynamics of the polymer are observed and these will be examined in the context of mode coupling theories.

4:54PM L1.00011 Long-time dynamics of chains in polymer nanocomposites. Peter Green, University of Michigan — In polymer nanocomposites (PCNs), the presence of the nanoparticles has a marked effect on the dynamics and the Tg. In one limit, the chains become strongly attached to the particles, and two glass transitions, and bimodal dynamics, may be observed. In the other, where the chain/particle interactions are weak, the chain friction factor, z(T), can undergo significant changes, manifested in the translational diffusion and viscosity. In the polystyrene-methacrylate (PMMA)/C60 system, the dynamics slow down, accompanied by an increase in the glass transition. At the same time, the temperature dependence of the relaxations remains the same as pure PMMA. In polystyrene/Au-thiol capped PS ligands, the dynamics and the glass transition could be induced to increase or decrease, through manipulation of molecular parameters in the system. In this presentation, we propose a mechanism to describe translational diffusion and Tg in PCN systems in which the polymer chain/nanoparticle interactions are weak.

5:06PM L1.00012 Self-Assembly of Conjugated Rod-Coil Block Copolymers for Photovoltaic Applications. R. A. Segalman, B.D. Olsen, Y. Tao, B. McCulloch, UC Berkeley and Lawrence Berkeley National Laboratories — The phase behavior of conjugated rod-coil block copolymers is significantly different from that of traditional block copolymers due to the interplay between liquid crystalline interactions of the rod blocks and microphase separation of the rods and coils. A universal phase diagram for rod-coil diblock copolymers depends on the strengths of the rod aligning interactions and the rod-coil repulsive interactions as well as the geometrical ratio of rod volume to coil and aspect ratios. In this talk, the experimental phase diagram of a weakly segregated model block copolymer will be compared to that predicted by self-consistent field theory. Conjugated rod-coil block copolymers with electron donating and accepting blocks are promising for photovoltaic applications. The self-assembly of poly(thiophene-b-acylate perylene diimide) block copolymers as well as block copolymer-nanocrystal composites result in photovoltaic active layers with controllable degrees of order. We demonstrate that short range order on the nanoscale is beneficial to device performance.

5:18PM L1.00013 Confinement Effects on Glassy-State Polymer Behavior in Thin Films, Nanocomposites, Tethered Nanoparticles, and Nanostructured Systems. John Torkelson, Perla Ritigstein, So Young Kim, Rodney Priestley, Connie Roth, Manish Mundra, Northwestern University — Confinement of polymers at the nanoscale and even the microscale can lead to significant deviations in glass transition temperature, physical aging rate, and alpha-relaxation dynamics from bulk polymer behavior. Here we illustrate how model experiments involving several techniques applied to simple, thin polymer films help us to understand and predict qualitatively or semi-quantitatively the glassy-state response of more complex, confined systems, including nanocomposites, tethered nanospheres, nanostructured homopolymer films, and nanostructured systems consisting of more than one polymer component. We shall illustrate how the glass transition temperature can be altered by as much as 60 K and how physical aging can be nearly totally suppressed via confinement. The discovery of new confinement effects and implications for new applications of confined polymer systems will be discussed.

Tuesday, March 17, 2009 2:30PM - 5:30PM — Session L2 DCMP: Buckley and Lilienfeld Prize Spirit of Pittsburgh Ballroom BC

2:30PM L2.00001 Oliver E. Buckley Prize Talk: Birth of tunnel magnetoresistance and its development. Terunobu Miyazaki, 2-1 Katahira, Aoba-ku, Sendai 980-8577 — Nowadays usually we use the word, tunnel magnetoresistance, but it required a long time to combine both words tunnel and magnetoresistance. The study of tunnel junction may originate p-n junction studied first around 1950. On the other hand, magnetoresistance effect was reported first in 1857 which was about 100 years earlier than the start of tunnel junction study. The research of tunnel magnetoresistance has been mainly developed first for Al-oxide tunnel barrier junctions and made a big progress by the appearance of MgO barrier junctions for both basic research and applications. More recently Heusler electrode tunnel junctions exhibits a large TMR ratio up to about 750 %, so we will focus on the Heusler electrode junctions and also application of tunnel magnetoresistance junctions.

3:06PM L2.00002 Oliver E. Buckley Prize Talk: Spin-dependent tunneling. Robert Meservey, MIT

Francis Bitter Magnet Laboratory — This abstract not available.
3:42PM L2.00003 Oliver E. Buckley Prize Talk: Spin polarized tunneling and tunnel magnetoresistance – Learning from the past and moving forward\(^1\), JAGADEESH MOODERA, Massachusetts Institute of Technology — Electron tunneling phenomenon has contributed enormously to our understanding of various branches of physics over the years. The technique of spin polarized tunneling (SPT), sensing the spin polarization of tunneling electrons using a superconducting spin detector, discovered by Meservey and Tedrow in the early seventies has been successfully utilized over the years to understand many aspects of magnetism and superconductivity. Electrical spin injection/detection in a semiconductor is strongly believed to succeed through such an approach. The successful observation of a large change in tunnel current in magnetic tunnel junctions (MTJ) in the mid nineties has brought extreme activity in this field – both from fundamental study as well as extensive application in mind (as sensors, nonvolatile memory devices, logic elements etc.). From the early history of this field that led to the discovery of room temperature TMR effect to the observation of many novel phenomena to the exciting recent work on spin filtering, spin transport in semiconductors to toggling of the superconducting state with spin current will be highlighted and reviewed. Work done in collaboration with Drs. Meservey and Tedrow, PhD students, postdoctorals, as well as high school students and undergraduates. NSF, ONR, DARPA and KIST-MIT project funds supported the research over the years.

\(^1\) NSF, ONR, DARPA and KIST-MIT project funds supported the research over the years.

3:42PM L2.00004 Oliver E. Buckley Prize Talk: Discovery and exploration of spin-dependent tunneling\(^1\), PAUL TEDROW\(^2\), Francis Bitter Magnet Laboratory, MIT — Experiments on thin-film superconductors in intense magnetic fields by R. Meservey and P. M. Tedrow led to the discovery of spin-polarized tunneling. Measurements of the critical magnetic of very thin aluminum films for temperatures down to 0.45 K verified that spin-orbit scattering had to be included in the BCS description of the critical field. Theory predicted a first order transition at low temperature, and, although measurements of the shape of the resistive transition of the films strongly implied the existence of such a transition, magnetic field-dependent tunneling measurements of the energy gap of the aluminum were undertaken to observe directly the first-order nature of the transition. Splitting of the superconducting density of states by the applied magnetic field, i.e., spin-dependent tunneling, was observed in these measurements. Subsequent tunneling experiments demonstrated the spin polarization of tunnel currents from ferromagnets. The extension of these tunneling studies to include a wide range of superconductors and magnetic materials produced new qualitative and quantitative information about the behavior of conduction electron spins in such materials. Although experimental technique and theory have improved from these early times, there remain unanswered questions concerning electron tunneling into ferromagnets. An overview of these early experiments will be presented\(^3\).

\(^1\) We acknowledge the theoretical support by Dr. Brian Schwartz, Professors Peter Fulde and Dierk Rainer, the work of Dr. Jagadeesh Moodera, the contributions of graduate students and technical staff, and the financial support of the AFOSR, NSF, and NASA.

Tuesday, March 17, 2009 2:30PM - 4:54PM — Session L3 DCMP: Fe-based Superconductors: Competing Orders 301/302

3:06PM L3.00001 Competing orders and spin density wave instabilities in FeAs-based systems , NANN LIN WANG, Institute of Physics, Chinese Academy of Sciences, Beijing 100190 — The discovery of superconductivity with T\(_c\) up to 55 K in layered FeAs-based compounds has generated tremendous interest in the scientific community. Except for relatively high T\(_c\), the Fe pnictides display many interesting properties. Among others, the presence of competing orders is one of the most intriguing phenomena. In the early stage of our study on the compounds, we identified a spin-density-wave (SDW) ordered state for the parent compound with a stripe (or collinear) type spin structure based on the transport, specific heat, optical spectroscopy measurements and the first- principle calculations. The proposed spin structure is in a nesting of the Fermi surfaces is confirmed by subsequent neutron experiments. However, it could also be explained by a local superexchange picture. In this talk I shall focus on our recent optical data on single crystal samples, trying to address the debating issue about itinerant or localized approaches to the SDW order. We found that the undoped compounds are quite metallic with relatively high plasma frequencies above T\(_{SDW}\). Upon entering the SDW ordered state, a large part of the Drude component is removed by the gapping of Fermi surfaces. Meanwhile, the carrier scattering rate is even more dramatically reduced. Those observations favor an itinerant description for the driving mechanism of SDW instability. Nevertheless, our experiments also indicate that Fe pnictides are not simple metals. A high energy gap-like feature is present even above T\(_{SDW}\), which seems to be linked with the antiferromagnetic spin fluctuations. For the superconducting samples, a superconducting pairing energy gap is clearly observed in the far-infrared reflectance measurement. The Ferrell-Glover- Tinkham sum rule is satisfied at a low energy scale. Work done in collaboration with: G. F. Chen, J. L. Luo, Z. Fang, X. Dai, W. Z. Hu, J. Dong, G. Li, Z. Li, P. Dai, J. Lynn, H. Q. Huang, J. Singleton.

3:30PM L3.00002 Magnetic order close to superconductivity in the iron-based layered RFeAsO\(_x\)F\(_{1-x}\) (R = La, Ce) systems , PENGCHENG DAI, Univ of Tennessee, Knoxville — No abstract available.

3:42PM L3.00003 Competing Magnetic Interactions, Structural Phase Transition, and the Unprecedented Giant Coupling of Fe-spin State and the As-As Interactions in Iron-Pnictide , TANER YILDIRIM, NIST and University of Pennsylvania — From all-electron fixed-spin-moment calculations \([1]\), we showed that the ferromagnetic and checkerboard antiferromagnetic ordering in LaOFeAs were not stable and the stripe Fe-spin configuration (i.e. SDW) was the only stable ground state. The main exchange interaction between Fe ions are large, antiferromagnetic, and frustrated. The magnetic stripe SDW phase breaks the tetragonal symmetry, removes the frustration, and causes a structural distortion. We unravel surprisingly strong interactions between arsenic ions, the strength of which is controlled by the Fe-spin state in an unprecedented way \([2]\). Reducing the Fe-magnetic moment, weakens the Fe-As bonding, and in turn, increases As-As interactions, causing giant reduction in the c-axis. For Ca\(_2\)Fe\(_2\)As\(_2\) system, this reduction of c-axis with the loss of the Fe-moment is as large as 1.4 Å, an unheard of giant coupling of local spin-state of an ion to its lattice. Since the calculated large c-reduction has been recently observed only under high-pressure, our results suggest that the iron magnetic moment should be present in Fe-pnictides at all times at ambient pressure. Implications of these findings on the mechanism of superconductivity in iron-pnictides will be discussed.

Extending the NMR work to lower temperatures we find evidence for a deviation of the T³⁻¹ behaviour of the spin lattice relaxation, which would agree with the extended s-wave symmetry suggested in recent theoretical work. In the paramagnetic normal state, NMR on all three nuclei shows that the local electronic susceptibility rises with increasing temperature. This had led to suggest the presence of a pseudogap, which I will discuss in detail. The scaling of all NMR shifts with respect to the macroscopic susceptibility indicates that there is no apparent multiband effect through preferential hyperfine couplings. Relaxation measurements indicate a similar temperature-dependence for (T₁T)⁻¹ and suggest that the dynamical susceptibility changes uniformly in q space with varying temperature. The transport properties show some striking similarities to the findings in cuprates [6] and, finally, susceptibility [4] as well as NMR studies point to the antiferromagnetic fluctuations, whose relevance is also discussed in many theoretical models of the superconducting pairing mechanism. In collaboration with Hans-Joachim Grafe, Christian Hess, Rüdiger Klingeler, Günther Behr, Agnieszka Kondrat, Norman Leps, and Guillaume Lang, IFW Dresden; Hans-Henning Klauss, TU Dresden; and Hubertus Luetkens, PSI Villigen.

Tuesday, March 17, 2009 2:30PM - 5:30PM –
Session L4 COM: The Dynamics of Diversity in Astrophysics 306/307

2:30PM L4.00001 Probing Beyond Einstein: The Joint Dark Energy Mission, LARRY GLADNEY, Department of Physics and Astronomy, University of Pennsylvania — The discovery of the acceleration of the expansion of the universe in 1998 represents perhaps the most profound challenge to our current understanding of physics and astronomy. The observation of acceleration requires either that more than 70% of the contents of the universe be an exotic form of energy (the so-called “dark energy”) or that there is a flaw in general relativity. The failure of present theories to convincingly explain the effect leads many experts to expect that elucidating the cause of the expansion will lead to fundamental breakthroughs that impact cosmology, astrophysics, and particle physics. The NASA/DOE Joint Dark Energy Mission (JDEM) will be the first of the Beyond Einstein probes. This mission will determine whether the acceleration of the expansion of the universe has varied over time in an attempt to determine the equation of state for dark energy or whether predictions from general relativity fail to adequately explain the acceleration. This talk will present the rationale for a space-based study of dark energy and the techniques likely to be used as part of JDEM.

3:06PM L4.00002 Thermodynamics of the Universe, SAMINA MASOOD, University of Houston-Clear Lake — Properties of fundamental particles are changed in hot and dense media. This fact helps to determine the thermodynamics of the universe from the changed properties of particles in the early universe. We study the behavior of light particles including neutrinos in thermal media to find out the details about the early universe. The neutrino oscillation and the magnetic moment of neutrino, however, do not seem to change significantly enough in thermal background to fully justify the big bang model. We have to look for other properties of neutrinos including entanglement to support the standard model.

3:42PM L4.00003 Space Weather and Global Warming, GEORGE CARRUTHERS, Naval Research Laboratory — This presentation will give discussions of the broad topic of Space Weather, and of Global Warming (these have some associations, as well as differences). Both have the Sun as the major energy source; short-term differences in solar activity are the sources of space weather (which affects the entire solar system, not just our Earth), whereas global warming is a longer-term event which depends on both the Sun and on the lower regions of the Earth’s atmosphere, and (more recently) human activities. In particular, the major gas of interest for global warming is the addition of carbon dioxide to the atmosphere by combustion of coal and oil. Means for decreasing the latter will be discussed, as well as of the effects of space weather on further human exploration of near-Earth and solar system environments.

4:18PM L4.00004 The Accelerating Universe, RUTH DALY, Penn State University — Several different types of observations indicate that the universe is accelerating at present, and was decelerating in the recent past. These observations and a model-independent analysis of the data will be discussed. The model-independent, or assumption-free, data analysis method will be applied to determine the expansion and acceleration rates of the universe as functions of redshift, independent of the contents of the universe and of a theory of gravity. A new model-independent function, the dark energy indicator, which provides a measure of deviations of the equation of state at different redshift from predictions in the standard model, will be presented and discussed. The data will be used to solve for the pressure, energy density, equation of state, and potential and kinetic energy densities of the dark energy as functions of redshift without assuming a model or functional form for the dark energy.

4:54PM L4.00005 Participation and Research of Astronomers and Astrophysicists of Black African Descent, HAKEEM OLUSEYI, Florida Institute of Technology — No abstract available.

Tuesday, March 17, 2009 2:30PM - 5:30PM
Session L5 DCMP: Competing Ground-States and Novel Excitations in Strongly Correlated Metals 401/402
2:30PM L5.00001 Quantum criticality in a cubic heavy fermion cage compound

Silke Paschen, Vienna University of Technology — Matter at the absolute zero in temperature may reach a highly exotic state: Where two distinctly different ground states are separated by a second order phase transition the system is far from being frozen; it is undecided in which state to be and therefore undergoes strong collective quantum fluctuations. Quantum criticality describes these fluctuations, their extension to finite temperatures, and the resulting unconventional physical properties. Heavy fermion compounds have been much investigated in the past few years as model systems. An important recent finding is that in the tetragonal compound YbRh$_2$Si$_2$ [1] a new energy scale vanishes at the quantum critical point and is in addition to the second-order phase transition scale that governs the behavior of conventional quantum critical points [2,3]. New theoretical scenarios can account for this finding if 2-dimensional spin fluctuations are assumed [4]. Here similar behaviour of the new heavy fermion compound Ce$_3$Pd$_{20}$Si$_6$ [5] is discussed in which the cubic crystal structure and the highly symmetric local environment of the Ce atoms in molecular “cages” makes 2-dimensional spin fluctuations rather unlikely.

Financial support of the Austrian Science Fund (project P19458-N16) is gratefully acknowledged.

3:06PM L5.00002 A New Route to Quantum Criticality in Yb$_3$Pt$_4$

Meigan Aronson, Brookhaven National Laboratory/Stony Brook University — The vanishing of magnetic order at a quantum critical point (QCP) is a central feature of virtually all classes of correlated electron systems, and may be accompanied by unconventional ordered states such as superconductivity, and by anomalous critical scattering. Some of the most detailed studies have focused on f-electron heavy electron compounds, and here the picture has emerged that magnetic order requires the formation of moments, provided by the divergence of the quasiparticle mass at the QCP. We combine specific heat, magnetization, and electrical resistivity measurements on the new compound Yb$_3$Pt$_4$, to argue that alternative routes to quantum criticality are also possible. The weakly first order antiferromagnetic transition in Yb$_3$Pt$_4$ can be tuned by field to a critical end point, which is extended to a quantum critical point at 1.62 T. Both the ordered and paramagnetic phases are Fermi liquids at low temperatures, but the quasiparticle mass does not diverge at the QCP. Instead, a divergence of the zero temperature susceptibility and the quasiparticle scattering is observed, controlled by a zero field fixed point and not the nearby QCP. We argue that Yb$_3$Pt$_4$ is the first example of a heavy electron system where magnetic order occurs at the QCP due to increasingly strong quasiparticle interactions, much as is found in $^3$He, Stoner ferromagnets, and spin density wave systems.

Work at Stony Brook University carried out under NSF-DMR-0405961

3:42PM L5.00003 Magnetism and the Fermi surface in heavy fermion metals

Seiji Yamamoto, Rice University — With a plethora of different phases and quantum critical points, heavy fermion materials should reign supreme as the prototype for competing order, a major contemporary theme in condensed matter physics. One key feature that differentiates the types of magnetic phases/critical points is the presence or absence of Kondo screening. This singlet formation is dramatically manifested in the Fermi surface, which provides important experimental insight into the problem. The size of the Fermi surface therefore becomes an important issue. To provide a theoretical basis for the different types of magnetism, we have recently carried out asymptotically exact studies of the Kondo lattice model inside both the antiferromagnetic [1] and ferromagnetic [2] phases. A fundamental aspect of the approach is to map the magnetic Hamiltonian for the local f-moments onto a quantum nonlinear sigma model (QNLSm). The Kondo interaction results in an effective coupling between the QNLsM fields and the conduction electrons. Renormalization group analyses show that the Fermi surface in the corresponding ordered states is small (not incorporating the f-moments) for both the ferromagnetic and antiferromagnetic cases. These results are of relevance to a number of materials, including YbRh$_2$Si$_2$ and CeRu$_2$Ge$_2$, where experimental measurements of magnetotransport and de Haas van Alphen effects [3,4] have provided evidence for the small Fermi surface phases. The implications of our results for the heavy fermion quantum critical points will also be discussed.

4:18PM L5.00004 How Do Heavy Fermions Get Polarized And Die?

Stephen Julian, University of Toronto — In paramagnetic heavy fermion systems the f-spins dissolve into Kondo singlets and reappear within the Fermi volume, producing a “large” Fermi surface populated by heavy quasiparticles. According to theory, when a very large magnetic field is applied to such a system the Kondo singlets are broken and the fully polarized bare f-spins vanish from the Fermi volume, leaving behind a “small” Fermi surface populated by light quasiparticles. How the system passes from the low-field to the high-field limit is not clear. This talk will discuss recent transport and de Haas van Alphen studies of the archetypal heavy fermion compounds CeRu$_2$Si$_2$ [1] and YbRh$_2$Si$_2$ [2], which are interpreted as showing that the f-electron disappears from the Fermi volume via two successive Lifshitz transitions: in the first transition a major spin band sinks below the Fermi level, while in the second a new minority spin band appears at the Fermi level. While this interpretation is in accord with recent theoretical work of Kusminskiy et al. [3], it could be criticized on the grounds that only the first of the two postulated Lifshitz transitions have so far been observed.

4:54PM L5.0005 Electron spin resonance in Kondo systems

Peter Woelfle, Brookhaven National Laboratory — In heavy fermion compounds, in which ferromagnetic correlations appear to be present [1], the spin lattice relaxation and quasiparticle interaction processes.

proteins or other cellular machinery. We also show that it is unlikely to be the result of a hypothetical “open” conformation of the repressor.

short DNA loops (around 95 bp) the experiments show more looping than is predicted by the linear-elasticity model, echoing other recent experimental results.

tethered particle motion (TPM) experiments; e.g. it accounts for all the entropic forces present in such experiments. Our model has no free parameters; it characterizes DNA elasticity using information obtained in other kinds of experiments. It can compute both the “looping J factor” (or equivalently, looping free energy) for various DNA construct geometries and repressor concentrations, as well as the detailed probability density function of bead excursions. We also show a new method to correct observed data for finite camera shutter time. The model successfully reproduces the detailed distributions of bead excursion, including those obtained in TPM experiments, confirming that the repressor tetramer is a rigid body. A new approach for investigating turbulent nonlinear dynamics is presented. The scaling exponents that are observed in the Lagrangian description of turbulence is also presented. The magnetic Reynolds number in the outer core is about 20 times the critical value for sustained dynamo action and the Reynolds number is about $10^7$, implying turbulent conditions. Fluctuations in the turbulence induce continuous changes in the geomagnetic field, including occasional polarity reversals. Geomagnetic polarity reversals have occurred about once every 250 kyr on average over the past 5 Myr, the last reversal occurred around 780 ka and there have been several long constant- polarity superchrons. The axial dipole collapses before a reversal, exposing the complex non-dipolar transition field, then the axial dipole is regenerated in the opposite polarity, the entire process lasting 10-20 kyr. Spontaneous polarity reversals have been observed in at least one liquid sodium dynamo experiment. Downward-extrapolated measurements from Earth-orbiting satellites reveal the axial dipole comes mostly from a few high-latitude concentrated flux spots on the core boundary. About 15% of the core boundary has reversed-direction magnetic field, mostly in the southern hemisphere. Proliferation and growth of reversed flux regions are major reasons why the axial dipole is in decline, decreasing at 10 times its free decay rate and suggesting (to some) that the geomagnetic field may be in early stage of a polarity reversal. 

3:06PM L6.00002 Flows and jets around compact astrophysical objects , JOHN HAWLEY, University of Virginia — No abstract available.

3:42PM L6.00003 Fluid Mechanics of the Geodynamo , PETER OLSON, Johns Hopkins — Fluid dynamical processes in the molten, iron-rich, electrically conducting core sustain Earth’s magnetic field. Convection driven by secular cooling and chemical differentiation is the primary energy source for the geodynamo. Earth’s rotation imparts helicity to the convection, which amplifies the geomagnetic field, balancing losses from Ohmic dissipation. Both the Ekman and Rossby numbers are very small in the outer core, so the convection is partly aligned with the planetary spin axis, which tends to orient the geomagnetic dipole axis in the north-south direction. The magnetic Reynolds number in the outer core is about 20 times the critical value for sustained dynamo action and the Reynolds number is about $10^7$, implying turbulent conditions. Fluctuations in the turbulence induce continuous changes in the geomagnetic field, including occasional polarity reversals. Geomagnetic polarity reversals have occurred about once every 250 kyr on average over the past 5 Myr, the last reversal occurred around 780 ka and there have been several long constant- polarity superchrons. The axial dipole collapses before a reversal, exposing the complex non-dipolar transition field, then the axial dipole is regenerated in the opposite polarity, the entire process lasting 10-20 kyr. Spontaneous polarity reversals have been observed in at least one liquid sodium dynamo experiment. Downward-extrapolated measurements from Earth-orbiting satellites reveal the axial dipole comes mostly from a few high-latitude concentrated flux spots on the core boundary. About 15% of the core boundary has reversed-direction magnetic field, mostly in the southern hemisphere. Proliferation and growth of reversed flux regions are major reasons why the axial dipole is in decline, decreasing at 10 times its free decay rate and suggesting (to some) that the geomagnetic field may be in early stage of a polarity reversal. 

4:18PM L6.00004 Statistics and scaling in magnetohydrodynamic turbulence , WOLF-CHRISTIAN MÜLLER, Max-Planck-Institut für Plasmaphysik, 85748 Garching, Germany — The nonlinear cascade of energy is one of the most prominent processes in turbulent systems. The associated self-similarity of two- point statistics leads to the appearance of inertial-range scaling laws, e.g. in the energy spectrum of turbulence. The scaling exponents that are observed in experiments or direct numerical simulations allow to verify the validity of cascade phenomenologies. Currently, controversial findings have led to a confusing situation in the phenomenological understanding of nonlinear inertial-range dynamics of magnetohydrodynamic turbulence which is discussed using recent results of direct numerical simulations. A new approach for investigating turbulent nonlinear dynamics which is based on the Lagrangian description of turbulence is also presented. 

4:54PM L6.00005 Turbulence in the interstellar and interplanetary medium , GARY ZANK, University of Alabama — No abstract available.
3:06PM L7.00002 Modulation of membrane mechanical properties by Sar1, a vesicle trafficking protein. , RAGHVUEER PARTHASARATHY, University of Oregon — The trafficking of cargo in cells involves dramatic changes in membrane shape and topology. Though trafficking is widely studied and the identities and interactions of the responsible proteins are well mapped, remarkably little is known about the mechanics involved. We focus on Sar1, the key regulator of the coat protein complex II (COPII) family that ferries newly synthesized proteins from the ER to the Golgi. Sar1 is the only member of the COPII coat that interacts directly with the ER lipid bilayer membrane. It has an amphiphatic N-terminal helix; when Sar1 is GTP-bound, the helix is exposed and the hydrophobic semi-cylinder can insert into the bilayer. To investigate whether Sar1 has a role beyond merely localizing the other COPII proteins, we directly measure the force involved in membrane deformation as a function of its presence or absence, using optically trapped microparticles to pull tethers from lipid membranes whose composition and large surface area mimic the composition and geometry of the ER. Tether measurements allow extraction of the membrane bending modulus, the parameter that governs the energetics of deformation. We find that the bending modulus measured in the presence of Sar1 with a non-hydrolyzable GTP analogue is half that measured without Sar1 or with Sar1-GDP. These results reveal a paradigm-altering insight into COPII trafficking: Sar1 actively alters the material properties of the membranes it binds to, lowering the energetic cost of curvature generation.

3:42PM L7.00003 ABSTRACT WITHDRAWN —

4:18PM L7.00004 “Double Bubble” and other trouble with DNA looping, ALEXEI TKACHENKO, Physics Department, University of Michigan — DNA looping is essential for such biological processes as regulation of gene expression and DNA packaging into nucleosomes. Classical theory of looping, based on the elastic description of DNA, was proposed more than two decades ago by Shimada and Yamakawa. However, a number of puzzles related to the problem remain largely unresolved to date. For instance, DNA loops in nature tend to be significantly shorter than the optimal one once predicted theoretically, and the looping probability appears to be much larger. Even in vitro experiments conflict with each other and with the theory. In my talk, I will review a number of mechanisms which may be responsible for these discrepancies, and which add complexity to the overall problem. I will briefly discuss possible roles of bending-induced and protein-induced structural defects (such as kinks and bubbles), as well as effects of boundary constraints. I will then focus on two phenomena: the effect of sequence disorder, and the loop formation in a supercoiled DNA. The former results in the lack of self-averaging of looping probabilities. The supercoiling may explain the smaller optimal loop size observed in vivo.

4:54PM L7.00005 Push or Pull? – Cryo-Electron Microscopy of Microtubule’s Dynamic Instability and Its Roles in the Kinetochores, HONG-WEI WANG, Department of Molecular Biophysics and Biochemistry, Yale University — Microtubule is a biopolymer made up of alpha-beta-tubulin heterodimers. The tubulin dimers assemble head-to-tail as protofilaments and about 13 protofilaments interact laterally to form a hollow cylindrical structure which is the microtubule. As the major cytoskeleton in all eukaryotic cells, microtubules have the intrinsic property to switch stochastically between growth and shrinkage phases, a phenomenon termed as their dynamic instability. Microtubule’s dynamic instability is closely related to the types of nucleotide (GTP or GDP) that binds to the beta-tubulin. We have biochemically trapped two types of assembly states of tubulin with GTP or GDP bound representing the polymerizing and depolymerizing ends of microtubules respectively. Using cryo-electron microscopy, we have elucidated the structures of these intermediate assemblies, showing that tubulin protofilaments demonstrate various curvatures and form different types of lateral interactions depending on the nucleotide states of tubulin and the temperature. Our work indicates that during the microtubule’s dynamic cycle, tubulin undergoes various assembly states. These states, different from the straight microtubule, lend the highly dynamic and complicated behavior of microtubules. Our study of microtubule’s interaction with certain kinetochore complexes suggests that the intermediate assemblies are responsible for specific mechanical forces that are required during the mitosis or meiosis. Our discoveries strongly suggest that a microtubule is a molecular machine rather than a simple cellular scaffold.

Tuesday, March 17, 2009 2:30PM - 5:30PM — Session L8 DCMP GSNP: Jamming at Nonzero Temperature and Stress 414/415

2:30PM L8.00001 Simple scaling of the glass transition temperature with pressure 1, NING XU, University of Pennsylvania and University of Chicago — Zero-temperature packings of frictionless spheres have been used as a starting point for understanding granular materials, foams, colloids and even glass-forming liquids. Such packings exhibit a jamming transition, known as Point J, with increasing packing fraction. This symposium presents recent work that explores the implications of Point J for systems at nonzero temperature, shear stress, or friction. In this talk, I present results that push beyond zero temperature to explore the connection between Point J and the glass transition. We performed molecular dynamics simulations of several three-dimensional models of glass-forming liquids, and measured the relaxation time from the intermediate scattering function along several trajectories to the glass transition, such as lowering temperature at fixed packing fraction, or raising pressure at fixed temperature. Along each trajectory, we extrapolated the relaxation time using the form $\tau = \exp(A/(T - T_0))$ or $\tau = \exp(A/(p' - p_0))$, depending on whether temperature or pressure was varied, where $p'$ is the contribution to the pressure from repulsive forces, only. Here, $A$, $\alpha$, $T_0$ and $p_0$ are fit parameters. We find that $T_0$ is linear in the repulsive contribution to the pressure, $p'_r$: $T_0 = \nu p'_r$. The fit parameter $\nu$ is approximately $0.035\nu_0 = 0.37\sigma^{-1}$, independent of potential, where $\nu_0$ is the average volume per particle and $\sigma$ is the diameter of the particle. This linear scaling of $T_0$ with $p'$ holds very well at low $p'$, which corresponds to the vicinity of Point J in purely repulsive systems where jamming transition at $T = 0$ exists. This suggests that Point J marks the onset of a nonzero value of the glass transition temperature, $T_0$. Experimental data for glycerol (K. Z. Win and N. Menon, Phys. Rev. E 73, 040501 (2006)) also show that $T_0$ is linear in pressure, with a prefactor of $0.04 \times$ the molecular volume.

3:06PM L9.00002 Noisy Transport in Reaction-Diffusion Systems with Quenched Disorder, ANDREW MISSEL, KARIN DAHMEN, University of Illinois, Urbana-Champaign — Reaction-diffusion (RD) models are useful tools for studying a wide variety of natural phenomena. The effects of quenched disorder in the reaction rates on RD models is not completely understood, especially in parameter regimes where internal noise or stochasticity is also important. In this talk, I will discuss an RD model in which both quenched disorder and stochasticity are important. I will show how ideas from the theory of hopping conduction in doped semiconductors and first passage percolation can be used to make predictions for a number of important transport-related features in the model: the infection time, or time needed for the population to traverse the system; the velocity of the front moving through the system; and the dynamic roughening of the coarse-grained front. I will also present the results of simulations of the model that largely confirm these analytical predictions.

3:18PM L9.00003 Monte Carlo simulation and linear stability analysis of Turing pattern formation in noisy reaction-subdiffusion systems, KENG-HWEE CHIAM, A*STAR Institute of High Performance Computing, JIAWEI CHIU, MIT — Subdiffusion is an important physical phenomenon observed in many systems. However, numerical techniques to study it, especially when coupled to noisy reactions, are lacking. In this talk, we develop an efficient Monte Carlo algorithm based on the Gillespie algorithm and the continuous-time random walk to simulate noisy reaction-subdiffusion systems. Using this algorithm, we investigate Turing pattern formation in the Schnakenberg model with subdiffusion. First, we show that, as the system becomes more subdiffusive, the homogeneous state becomes more difficult to destabilize and Turing patterns form less easily. Second, we show that, as the number of particles in the system decreases, the magnitude of noise increases and again the Turing patterns form less easily. Third, we show that, as the system becomes more subdiffusive, the ratio between the two diffusive constants must be higher in order to observe Turing patterns. Finally, we also carry out linear stability analysis to validate the results obtained from our algorithm.

3:30PM L9.00004 Continuous Time Random Walks with Internal Dynamics, STEPHAN EULE, Max-Planck-Institute for Dynamics and Self-Organization, Goettingen, Germany, RUDOLF FRIEDRICH, Institute of Theoretical Physics, Muenster, Germany, FRANK JENKO, Max-Planck-Institute for Plasmaphysics, Garching, Germany — We formulate a generalized master equation for a class of Continuous Time Random Walks (CTRWs) in the presence of a prescribed deterministic evolution between the successive transitions. This formulation is exemplified by means of a generalized advection-diffusion and a jump-diffusion scheme. Based on the generalized master equation the corresponding fractional evolution equations are presented.
3:42PM L9.00005 Unusual finite-size crossover features in driven lattice gases¹. GEORGE L. DAQUILA, UW E C. TAUBER, Virginia Tech — We study the temporal scaling behavior of the autocorrelation function for the asymmetric exclusion process (ASEP) on a ring in one dimension as function of system size and hopping bias. We have performed extensive Monte Carlo simulations using standard and continuous time algorithms to extract the long-time asymptotic scaling behavior for some very large systems. Even for the totally asymmetric exclusion process (TASEP), the effective exponent for the temporal autocorrelation function displays an extremely slow crossover towards the asymptotic value 2/3, with unusual features. For the ASEP, the crossover time grows with increasing backwards hopping rates. In contrast, we observe standard crossover behavior and much shorter crossover times in two- and three-dimensional lattice gases.

¹Research in part supported through NSF DMR-0308548.

3:54PM L9.00006 Contact process with mobile disorder. RONALD DICKMAN — I study scaling properties of the absorbing-state phase transition in the one-dimensional contact process with mobile disorder via numerical simulation and the pair approximation. In this model, the dilution sites are permanently inactive but are free to diffuse, exchanging positions with the other sites, which host a basic contact process. Even though the disorder variables are not quenched, the critical behavior is drastically affected: the critical exponent $\delta$ and the ratio $\beta/\nu$ are found to vary continuously with vacancy concentration and hopping rate. At the critical point, the mean lifetime $\tau$ scales with system size $L$ as $\tau \sim (\ln L)^2$, rather than as a power law; the anomalous scaling of the lifetime is associated with fluctuations in the vacancy density.

4:06PM L9.00007 Fluctuation ratios in reaction-diffusion systems, SVEN DOROSZ, MICHEL PLEIMLING, Virginia Polytechnic Institute and State University — We study fluctuations in diffusion-limited reaction systems driven out of their stationary state. Using a numerically exact method, we investigate fluctuation ratios in various systems which differ by their level of violation of microscopic time reversibility. Studying a quantity that for an equilibrium system is related to the work done to the system, we observe that under certain conditions oscillations appear on top of an exponential behavior of transition fluctuation ratios. We argue that these oscillations encode properties of the probability currents in state space.

4:30PM L9.00009 Stochastic current switching behavior in semiconductor superlattices. STEPHEN TEITSWORTH, HUIDONG XU, Duke University — Numerical simulation results are presented for a discrete drift-diffusion model that describes electronic transport in weakly-coupled semiconductor superlattices under voltage bias and also includes shot noise in the tunneling currents. Sequential resonant tunneling between quantum wells is the primary conduction mechanism and noise terms are treated as delta-correlated in space and time. We study the response of this system to abrupt steps in applied voltage in a range for which the current-voltage characteristics exhibit bistability. The system switches from a metastable state to a stable state with a stochastically varying delay time, a process corresponding to relocation of charge density from one (critical) quantum well to an adjacent one. We find that the mean delay time $\tau$ varies as $\ln \tau \propto V - V_{ch}^{1/2}$ where $V$ and $V_{th}$ denote, respectively, the system voltage and the voltage at the boundary of the bistability range [1]; $\tau$ also depends exponentially on the cross-sectional area of the superlattice. An effective one-dimensional potential energy is constructed for the charge density in the critical quantum well. We find that noise contributions of the quantum wells far from the critical well have a significant effect on the switching process. [1] O. A. Tretyakov and K. A. Matveev, Phys. Rev. B. 71, 165326 (2005).

4:42PM L9.00010 Fluctuation relations in a driven, nonlinear micromechanical torsional oscillator. COREY STAMBAUGH, H.B. CHAN, University of Florida — Fluctuation relations in a periodically driven micromechanical oscillator are investigated. The system is first studied in a linear regime by applying a weak drive. The ratio of the work variance to the mean work is shown to be independent of the driving frequency, consistent with standard fluctuation relations for a steady state system near thermal equilibrium. When a strong drive is applied to the system the response becomes nonlinear and the system displays bistability. The work variance in this nonlinear system, driven far from equilibrium, is predicted to show a strong frequency dependence not seen in the linear case. For such bistable system the total variance has two contributing components. The first component, involving intrastate fluctuations about one stable attractor, is expected to scale with a power law dependence as the system approaches the bifurcation point where the occupied state disappears. The second component of the work variance for interstate fluctuations is shown to have a strong frequency dependence near the kinetic phase transition where the populations of the two states are comparable. The relationship between the work and variance is compared to experimental observations, and to theory.

4:54PM L9.00011 ABSTRACT WITHDRAWN —

5:06PM L9.00012 Work distributions in the T=0 Random Field Ising Model. XAVIER ILLA, Helsinki University of Technology, JOSEP MARIA HUIGUET, EDUARD VIVES, Universitat de Barcelona — The T=0 Random Field Ising Model is a prototype model for the study of collective phenomena in disordered systems. The model can be numerically studied from two different points of view: on the one hand, the exact ground state calculation provides an approach to the equilibrium phase diagram. On the other the use of a local relaxation dynamics based on single spin-flips provides a good framework for the understanding of avalanche dynamics and hysteresis, which is closer to experimental observations. In this sense, the model is a good workbench for the comparison of equilibrium and out-of-equilibrium trajectories. We perform a numerical study of the three-dimensional Random Field Ising Model at T=0. We compare work distributions along metastable trajectories obtained with the single-spin flip dynamics with the distribution of the internal energy change along equilibrium trajectories. The goal is to investigate the possibility of extending the Crooks fluctuation theorem to zero temperature when, instead of the standard ensemble statistics, one considers the ensemble generated by the quenched disorder. We show that a simple extension of Crooks fails close to the disordered induced equilibrium phase transition due to the fact that work and internal energy distributions are very asymmetric.
3:06PM L10.00004 Quasiparticle Gaps and Exciton Coulomb Energies in Si Nanoshells, KIMBERLY FREY, JUAN C. IDROBO, SERDAR OGUZ\textsuperscript{1}, University of Illinois at Chicago, MURILLO L. TIAGO, FERNANDO A. REBOREDO\textsuperscript{2}, Oak Ridge National Laboratory — Quasiparticle gaps and exciton Coulomb energies are calculated in Si nanoshells passivated by H at the inner and outer surfaces. We consider spherical nanoshells with inner radii \( R_1 \) up to 1 nm and outer radii \( R_2 \) up to 1.6 nm. Quasiparticle gaps are calculated using the \( \Delta SCF \) and \( GW \) methods. While the single-band effective mass approximation predicts that the gap should depend only on the thickness \( t = R_2 - R_1 \), we find that first principles calculations that depend on both \( R_1 \) and \( R_2 \). The dependences of the quasiparticle gap on \( R_1 \) and \( R_2 \) are mostly consistent with electrostatics of a charged metallic shell. We also find that the (unscreened) Coulomb energy in Si nanoshells has a somewhat unexpected size dependence at fixed outer radius \( R_2 \). Namely, the exciton Coulomb energy decreases as the nanoshell becomes more confining, contrary to what one would expect from quantum confinement effects. We show that this is a consequence of an increase in the average electron-hole distance, giving rise to reduced exciton Coulomb energies in spite of the reduction in the confining nanoshell volume.

3:42PM L10.00007 Photoluminescence from core/multiple-shell GaAs/AlGAs Nanowires, M.A. FICKENSCHER, S.D. PERERA, H.E. JACKSON, L.M. SMITH, University of Cincinnati, J.M. YARRISON-RICE, Miami University, H.J. JOYCE, Y. KIM, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University — We use photoluminescence (PL) and photoluminescence excitation spectroscopy (PLE) to study the electronic structure of GaAs/AlGaAs core-shell multi-shell NWs. Using Au-catalyst assisted MOCVD, a nominally 2 nm GaAs quantum well tube (QWT) with AlGaAs barriers is formed surrounding a central 50 nm GaAs nanowire core. PL measurements on single nanowires reveal a line at the expected exciton energy for the core and, in addition, several higher energy lines not observed in simple core/shell structures. PLE measurements suggest a coupling of the confined states in the QWT and the core states. A broad PLE response centered at 1.67 eV is suggestive of an AlGaAs shell concentration of approximately 12%. We acknowledge the support of the NSF (0701703 and 0806700) and the Australia Research Foundation.

3:54PM L10.00008 Polarization Dynamics of Twin Free GaAs/AlGaAs Core-Shell Nanowires, S. PERERA, L.M. SMITH, H.E. JACKSON, University of Cincinnati, J.M. YARRISON-RICE, University of Miami, H.J. JOYCE, Y. KIM, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University, X. ZHANG, J. ZOU, University of Queensland — We use polarized time-resolved photoluminescence to study exciton dynamics in GaAs/AlGaAs core-shell nanowires (NWs) at 20 K. By pumping the nanowires with lasers polarized parallel and perpendicular to the nanowire, the polarization dynamics reflect the exciton dipole distributions within the nanowires. The NWs were prepared by Au catalyzed MOCVD and excited by a pulsed titanium-sapphire laser at 798 nm. The polarization of the emitted PL was monitored at the exciton emission peak (1.515 eV) as a function of time after excitation by a polarized pulse. The diameter of the nanowire is much larger than the exciton Bohr radius so that the exciton dipoles are degenerate regardless of orientation; thus in thermal equilibrium the density of excitons parallel and perpendicular dipoles should be equal. At low excitation intensities we find that the exciton dipoles are created out of thermal equilibrium, but relax within several hundred picoseconds. At higher excitation powers, the exciton dipoles relax much more rapidly within a time interval. This suggests that exciton dipole relaxation is very sensitive to carrier-carrier scattering. We acknowledge the support of the NSF (0701703 and 0806700) as well as the Australia Research Foundation.

4:06PM L10.00009 Polarization dependent photoluminescence studies of InP nanowires, LEI FANG, XIANWEI ZHAO, FENGYUAN YANG, EZEKIEL JOHNSTON-HALPERIN, Department of Physics, The Ohio State University — Control of the polarization anisotropy observed in measurements of single NWs has the potential to enable both fundamental studies of polarization-sensitive electronic states and potential applications in polarization-sensitive photodetectors. This anisotropy is caused by the large dielectric mismatch between the semiconductor nanowire and the environment (air), which suggests that with appropriate dielectric matching it is possible to minimize or eliminate polarization anisotropy. In order to explore this possibility, we measure the polarization dependence of ensemble InP nanowires grown by pulsed laser deposition. The measured polarization response of these ensembles correlates well with the straightforward extension of previous models developed to describe single wire measurements. Further, initial studies involving coating InP nanowires with tantalum oxide, whose dielectric constant (5.76 to 8.41) is close to that of InP (9.61), reduces the polarization anisotropy by 20%. These preliminary results will be presented and proposed strategies for more dramatic suppression will be discussed.

3:40PM L10.00010 Photocurrent spectroscopy of single InP nanowires, A. MAHARJAN, H.E. JACKSON, L.M. SMITH, A. KOGAN, University of Cincinnati, J.M. YARRISON-RICE, Miami University, S. PAIMAN, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University — We use photocurrent spectroscopy of single InP nanowires at room temperature to study nanowires having either zinc-blende (ZB) or wurtzite(WZ) crystal structures. Photolithography is used to fabricate the Ti/Al metal contact pads separated by ~4 microns on several ZB or WZ InP nanowires. The metal- semiconductor-metal contacts are modeled based on thermionic emission and field emission theory. Analysis of the dark I-V characteristics of these devices determines important intrinsic properties including donor density, barrier heights and electrical conductivity. Current-voltage (I-V) photocurrent curves for a nanowire are obtained by broad illumination of the device from a Ti-Sapphire laser with energies ranging from 1.30 eV to 1.55 eV. The photocurrent at a given bias voltage is plotted as a function of photon energy to determine the band edge of given semiconductor nanowire. The photocurrent drops exponentially below the band edge reflecting Urbach’s rule. We find that the energy band gaps of wurzite and zinc blende nanowires are 1.42 eV and 1.34 eV respectively at room temperature showing that the energy band gap of wurzite structure is about ~80 meV higher than zinc blende structure. Supported by the NSF (# 0701703, # 0806700 and # 0804199) and the Australian Research Foundation.

4:30PM L10.00011 Photoluminescence Study of Type II ZB-WZ InP nanowire homostructures, K. PEMASIRI, M. MONTAZERI, R. GASS, H.E. JACKSON, L.M. SMITH, University of Cincinnati, J.M. YARRISON-RICE, Miami University, S. PAIMAN, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University, X. ZHANG, J. ZOU, University of Queensland — We use CW and time-resolved photoluminescence (TRPL) from single InP nanowires containing both wurzite (WZ) and zincblende (ZB) crystalline phases to study the quantum confinement of excitons in a Type-II homestructure. We observe strong excitation power dependence, with a change in PL emission energy from the ZB edge to the WZ edge confirming the confinement of the electric field within the space charge region due to the applied bias voltage. Photogenerated electrons and holes are collected at forward and reverse biased contacts, respectively. Polarization analysis shows that the photocurrent is maximized for laser excitation polarized perpendicularly to the c-axis of the nanosheet. Supporte by the NSF (#0701703 and #0806700), KIST Research Foundation and KIST.
4:54PM L10.00013 Raman Stress Mapping of Cds Nanosheets, M. MONTAZERI, J.M. YARRISON-RICE, L.M. SMITH, H.E. JACKSON, University of Cincinnati, H. RHO, Y. LEE, Chonbuk National University, Y.J. CHO, J. CHOJ, J.G. PARK, Korea Institute of Science and Technology — We present results of spatially resolved room temperature second order Raman scattering measurements for single ~3 micron wide CdS nanosheets. The sheets, grown by pulsed laser deposition using vapor-phase transport, are uniform in size and shape and exhibit hexagonal wurtzite structure. The orientation of the c-axis is determined by Raman polarization analysis. Spatially-resolved Raman scattering reveals a stress gradient across the nanosheets, with the 2LO phonon energy at the center of nanosheet being higher by ~2 cm\(^{-1}\) with respect to the edges which indicates that nanosheets are relaxed at the edges with a strain gradient toward the center. Support provided by NSF (#0701763 and #0806700), Korea Research Foundation and KIST.

5:06PM L10.00014 Ultrafast spatially-resolved carrier dynamics in single CdSe nanobelts, LARS GUNDLACH, PIOTR PIOTROWIAK, Department of Chemistry, Rutgers University-Newark, 73 Warren St, Newark, NJ, 07102 — A recently constructed Kerr-gated microscope was applied to spatially, temporally, and spectrally resolve the ultrafast non-linear excitation relaxation dynamics in single CdSe nanobelts. Luminescence movies with a 100 fs frame resolution were constructed. The ability to spatially resolve the femtosecond dynamics in a single emitting object gives insights which would be impossible to obtain in an ensemble measurement. By applying the Kerr-gated microscope we are able to monitor the dynamics in a single nanobelt with a sufficient time resolution to reveal the different pathways that compete with the dissociation of multiple excitons. We will show that ensemble averaging methods give results that are complicated because of ensemble inhomogeneities. Indeed, already a different orientation of the nanoparticles with respect to the light-field leads to different dynamic response and difficult to interpret results. The onset of nonlinear behavior and the subsequent dynamics are particularly sensitive to the most subtle inhomogeneities in composition and morphology and hence most difficult to study under the condition of ensemble averaging making time-resolved wide-field fluorescence microscopy a perfect aid in disentangling the complex response.

Tuesday, March 17, 2009 2:30PM - 5:18PM — Session L11 DMP: Focus Session: Transport Properties of Nanostructures III: Molecular Junctions II 305

2:30PM L11.00001 Electron Transport in Single Molecule Junctions: Stability, Electron-Phonon Interactions and Current-Induced Local Heating, N.J. TAO, Arizona State University — Understanding electron transport in a single molecule connected to two electrodes is as basic task in molecular electronics. A widely used approach is to attach the molecule with two linkers that can bind to the electrodes. Thiol is the most studied linker because of its well known capability to bind strongly to metal electrodes, such as Au, although several other linkers, such as isocyanide, amine, pyridine, carbon-carbon and carboxylic acid, have also been used to establish a molecule-electrode contact. It has been concluded that the linkers can play an important or even dominant role in the conductance and other electron transport properties of molecular junctions. Since the molecule-electrode contact is often the weakest link in a molecular junction, an important question that has not yet been well studied is: How stable is a molecular junction due to the finite lifetime of the linker-electrode bond? Another important question is: How hot does a molecular junction get when passing a current through it? In the present work, we investigate the stability and breakdown mechanism of a single molecule covalently attached to two gold electrodes via Au-S bonds. We report on an experimental study of current-induced local heating in single molecules covalently attached to two gold electrodes as a function of applied bias and molecular length. We also discuss the related electron-phonon interactions in single molecule junctions.

3:06PM L11.00002 Electron Transport and Thermoelectricity in Alkanethiol Molecular Junctions, YU-CHANG CHEN, CHUN-LAN MA, DIU NGHIEIM, YU-SHEN LIU, Department of Electrophysics, National Chiao Tung University, Taiwan — We investigate the electron transport properties of alkanethiol molecules in the two- and three-terminal junctions by using first-principles approaches. We observe that novel states around the Fermi levels are introduced in the amino-substituted butanethiol junction. It leads to a sharp increase of the current owing to the resonant tunneling. We also describe a field-theoretic theory combined with first principles approaches to calculate the thermoelectricity. The dependence of the Seebeck coefficient on the biases, gate voltages, and temperatures is systematically investigated. Due to the novel states introduced by the amino-substituted butanethiol junction, the Seebeck coefficient could be easily controlled by using gate voltages and biases. When the temperature in one of the electrodes is set to zero, the Seebeck coefficient could vary pronouncedly with the temperature in the other electrode, and such dependence could be enhanced by varying gate voltages. At finite biases, we also find richer features in the Seebeck coefficient related to the density of states in the vicinity of the left and right Fermi levels.

3:18PM L11.00003 Ab initio transport calculations of molecular wires with electron-phonon couplings, KENJI HIROSE, NEC Corp., NOBUHIKO KOBAYASHI, Univ. of Tsukuba — Understanding of electron transport through nanostructures becomes important with the advancement of fabrication process to construct atomic-scale devices. Due to the drastic change of transport properties by contact conditions to electrodes in local electric fields, first-principles calculation approaches are indispensable to understand and characterize the transport properties of nanometer-scale molecular devices. Here we study the transport properties of molecular wires between metallic electrodes, especially focusing on the effects of contacts to electrodes and of the electron-phonon interactions. We use an ab initio calculation method based on the scattering waves, which are obtained by the recursion-transfer-matrix (RTM) method, combined with non-equilibrium Green's function (NEGF) method including the electron-phonon scatterings. We find that conductance shows exponential behaviors as a function of the length of molecular wires due to tunneling process determined by the HOMO-LUMO energy gap. From the voltage drop behaviors inside the molecular wires, we show that the contact resistances are dominant source for the bias drop and thus are related to local heating. We will present the electron-phonon coupling effects at contact on the inelastic scattering and discuss on the local heating and local temperature, comparing them with those of metallic atomic wires.

3:30PM L11.00004 Transport properties and stability of molecular break junctions, NIKOLAI SERGUEEV, Vanderbilt University, LEONIDAS TSETSERIS, Vanderbilt University, Aristotele University of Thessaloniki, KALMAN VARGA, Vanderbilt University, SOKRATES PANTELIDES, Vanderbilt University, Oak Ridge National Laboratory — The electrode-molecule interface in a break junction is known to be crucial to understand its electronic and transport properties. Using first-principles calculations we first probe a comprehensive set of mechanisms responsible for the stability of the prototype junction of a benzene-dithiol (BDT) between gold electrodes. We find that by pulling the electrodes apart the geometry of the molecule depends drastically on the electrode-surface morphology. We next report results of the quantum transport calculations for several stable junction configurations. The calculations are performed using the recently developed technique based on density functional theory and complex absorbing potentials[1]. The molecular junction is treated as a closed system with a set of complex potentials mimicking the source and the drain electrodes. We will present the results of recent experiments on BDT break junctions. We will compare the results with recent experiments on BDT break junctions.

3:42PM L11.00005 Electrical Conductance and Reversible Conductance Switching in Molecular Junctions

BERT DE BOER, Molecular Electronics, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands — A technology is demonstrated to fabricate reliable molecular metal-molecule-metal junctions with unprecedented device diameters up to 100 µm. The yield of these molecular junctions is close to unity. Stability investigations have shown a shelf life of years and no deterioration upon cycling. Key ingredients are the use of a conducting polymer layer (PEDOT:PSS) sandwiched between the self-assembled monolayer (SAM) and the top electrode to prevent electrical shorts, and processing in lithographically defined vertical interconnects (vias) to prevent both parasitic currents and interaction between the environment and the SAM [1–3]. Furthermore, a fully functional solid-state molecular electronic switch is manufactured by conventional processing techniques. The molecular switch is based on a monolayer of photochromic diarylethene molecules sandwiched between two electrodes. The monolayer reversibly switches the conductance by more than one order of magnitude between the two conductance states via optical addressing. This bidirectional conductance switch operates as an electronic ON/OFF switch and as a reprogrammable data storage unit that can be optically written and electronically read [4].

The research was financially supported by the Zernike Institute for Advanced Materials, NWO via the VIDI grant, and NanoNed, a national nanotechnology program coordinated by the Dutch Ministry of Economic Affairs.

4:18PM L11.00006 Reversible, mechanically-activated switching in pyridine single molecule junctions

MARIA KAMENETSKA, Columbia University (CU), SU YING QUEK, Lawrence Berkeley National Lab (LBNL), MICHAEL L. STEIGERWALD, CU, HYOUNG JOON CHOI, Yonsei University, STEVEN G. LOUIE, LBNL, MARK S. HYBERTSEN, Brookhaven National Lab, J.B. NEATON, LBNL, LATHA VENKATARAMAN, CU — We measured the conductance of single pyridine-terminated molecules by mechanically forming and breaking Au point contacts with a modified STM in a solution of molecules. Conductance traces recorded while stretching the junction reveal two distinct steps at different conductance, both due to the formation of a single molecule junction between gold electrodes. To better understand the origin of this bi-stable conductance signature, we devise a new method to experimentally determine the distance between the gold electrodes for any given molecular conductance. We find a clear correlation between the level of conductance and the distance between gold electrodes, with the lower conductance corresponding to a molecule fully stretched between the contacts and the higher conductance to a molecule bound at an angle. The dependence of conductance on metal-molecule contact geometry allows us to reversibly switch between conductance states by elongating and compressing the junction.

1. Support: NSF-CHE-0641523 and NYSTAR.

4:30PM L11.00007 First-Principles Studies of Single-Molecule Junctions: Conductance and Mechanically-Controlled Switching

SU YING QUEK, Molecular Foundry, Lawrence Berkeley National Lab, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University, Seoul; STEVEN G. LOUIE, Department of Physics, University of California, California, Berkeley and Lawrence Berkeley National Lab, MARK S. HYBERTSEN, Center for Functional Nanomaterials, Brookhaven National Lab, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics and Center for Transport in Nanostuctures, Columbia University, J.B. NEATON, Molecular Foundry, Lawrence Berkeley National Lab — We explore the conductance of amine- and pyridine-Au single-molecule junctions, in the context of recent experiments, with a density-functional theory (DFT)-based scattering state approach. Using a physically motivated self-energy correction, we compute conductance values in good agreement with experiment, in contrast to DFT values that are too large[1]. We investigate quantitatively conductance trends, and demonstrate, together with experiment, that reversible conductance switching can result from mechanically-induced changes in the metal-molecule contact geometry in pyridine-Au junctions. [1] Quek et al, Nano Lett 7, 3477 (2007)

1. Support: DOE (DE-AC02-05CH11231, DE-AC02-98CH10886), NSF (DMR-0551195, DMR04-39768, CHE-0117752), NYSTAR, NERSC

4:42PM L11.00008 Conductance of Molecular Wires Measured by STM- Break Junction

JONATHAN R. WIDAWSKY, MARIA KAMENETSKA, ADAM C. WHALLEY, JENNIFER E. KLARE, COLIN NUCKOLLS, MARK S. HYBERTSEN, LATHA VENKATARAMAN, Columbia University and CFN, Brookhaven National Laboratory — We present a comparison of the measured conductances of short molecular wires attached to gold electrodes in ambient conditions. The junctions are fabricated using a modified STM to repeatedly form and break Au point contacts, characterized by the quantum of conductance, in a solution of molecules. Specifically, we characterized the conductance of three molecules – 4,4’-diaminoazobenzene, 4,4’-diaminostilbene, and bis-(4-aminophenyl)acetylene – by measuring the voltage bias applied across the electrodes. In order to determine a statistically most probable value of conductance, each measurement is obtained from data sets of approximately 10,000 individual conductance pull-out traces obtained over a few hours. In addition, we measure the conductance of solutions irradiated with ultraviolet light to detect photodesorption of the azobenzene and stilbene from their trans to the cis configurations.

4:54PM L11.00009 Molecular orbital theory of ballistic electron transport through molecules

Tuesday, March 17, 2009 2:30PM - 5:30PM –
Session L12 DMP DCMP: Focus Session: Photocatalysis and photovoltaic: Excitation, Trapping, and Transport of Charge Carriers at Surfaces and Interfaces

2:30PM L12.00001 Polynuclear Metal Oxide Photocatalysts in Nanoporous Silica Scaffolds for Artificial Photosynthesis, HEINZ FREI, LBNL — No abstract available.

3:06PM L12.00002 Understanding and Controlling Photovoltaic Effects in Complex Oxide Thin Films, STEVEN BYRNES, THOMAS CONRY, SOURAV ROGER BASU, LANE MARTIN, DREW PARAN, VARADA BAL, JOEL W. AGER, R. RAMESH, UC Berkeley and Lawrence Berkeley National Laboratory — Thin-film oxide heterostructures are a promising material system for large-scale photovoltaic energy conversion, as oxides can be cheap, abundant, stable, and highly light-absorbing. As a model system, we have investigated the room-temperature ferroelectric BiFeO$_3$ (BFO). Heteroepitaxial BFO films are grown by both metal-organic chemical vapor deposition (MOCVD) and pulsed laser deposition (PLD), allowing for a wide range of control over thickness, composition, and ferroelectric domain structure. BFO has been measured to have a direct bandgap at 2.6 eV; moreover its bandgap and other material properties can be controlled by alloying and by modification of stoichiometry. In this work, we will demonstrate the photovoltaic properties of BFO thin films (100–1000 nm) grown heteroepitaxially on oxide bottom electrodes with transparent ITO top contacts. Electrical and external quantum efficiency measurements prove that the photovoltaic effect comes from a Schottky barrier between ITO and p-type BFO, but time-dependent and capacitance-voltage measurements show that ferroelectric, ion motion, and/or trap states also play an important role in the electrostatics of the device.

3:18PM L12.00003 Ultrafast Time-Resolved Spectroscopy of Photoinduced Electron Transfer in Novel Photovoltaic Devices, L.M. MIER, Department of Chemistry, The Ohio State University, Columbus, OH 43210-1185, A.R. CARTER, Department of Physics, The Ohio State University, Columbus, OH 43210, T.L. GUSTAFSON, Department of Chemistry, The Ohio State University, Columbus, OH 43210-1185, A.J. EPSTEIN, Departments of Physics and Chemistry, The Ohio State University, Columbus, OH 43210 — We present work toward an understanding of the fundamental photophysics of photoinduced electron transfer between 9-anthracenecarboxylic acid (9-AC) and TiO$_2$ nanoparticles in order to apply the techniques to a novel photovoltaic device. The active layer of a proposed device consist of a broad-spectrum, metal-organic absorbent covalently bound through a carboxylic acid to a nano-porous TiO$_2$ structure. To study the electron transfer, a model compound, 9-AC, is covalently bound to TiO$_2$ nanoparticles. Ultrafast electron transfer from the excited 9-AC to the TiO$_2$ is observed within 50 fs using ultrafast broadband spectroscopy. Further evidence of this transfer is shown from quenching of the fluorescence of the 9-AC with increasing concentrations of TiO$_2$ with no effects on the lifetime of the fluorescence.

3:42PM L12.00005 Interfacial charge dynamics studied by ultrafast electron diffraction, RYAN MURDICK, RAMAKANTALAYAN RAMAN, Michigan State University, YOSHI MURUOKA, Osaka University, RICHARD WORTHATCH, CHONG-YU RUAN, Michigan State University — Of central importance to nanoscale device technology is the role of charge transfer at interfaces. Using ultrafast electron diffraction, which has recently emerged as a new technique in determining transient surface photovoltages with nanometer sensitivity (Murdick et al., PRB 77, 245329, 2008), we investigate the surface charge and space-charge dynamics at the Si/SiO$_2$ interface. By varying the excitation wavelength, fluence, and pulse duration, we explore various pathways inducing electron tunneling through an insulating barrier to reach the surface states. We show that the surface states have relatively long lifetimes (~100 ps), but are rechargeable, thus ideal for serving as a charge pump for interfacial devices. Using the Si/SiO$_2$ platform, we extend this diffractionic potentiometry approach to study nanoparticle charging and molecular transport.

3:54PM L12.00006 TiO2 nanowire sensitized by organic dyes for photovoltaic applications: influence of binding groups and molecular dimension

SHENG MENG, EFTHIMIOS KAXIRAS, Harvard University Physics Department — We investigate the electronic couplings including charge separation, injection, and recombination processes between a TiO2 nanowire and a set of organic dye sensitizers, based on the full time-dependent density functional theory treatment of electron excitation and atomic vibrations. For all the cases the highest occupied molecular orbital (HOMO) of dye molecules are found being located in the middle of the TiO2 bandgap and the lowest-unoccupied molecular orbital (LUMO) close to the TiO2 conduction band minimum, leading to enhanced visible light absorption and ultrafast electron injection into the TiO2 conduction band. The influences of the anchoring groups and molecular dimensions to the dye injection dynamics and electron-hole recombination process are discussed.

This work was supported in part by DOE CMSN Grant DE-FG02-05ER46226 and the Harvard University Center for the Environment.

4:06PM L12.00007 Analysis of Quasiparticle Energy Band Shifts Resulting from Introduction of Nitrogen into Titanates

WEI KANG, Center for Functional Nanomaterials, Brookhaven National Laboratory, MARK S. HYBERTSEN, Center for Functional Nanomaterials, Brookhaven National Laboratory — Titanium oxides and many titanates, such as rutile (TiO2) and SrTiO3, are promising in photocatalysis for water splitting and photo-degradation of hazardous materials in the environment, although their large band gaps limit utilization of the solar spectrum to the UV region. Experiments show that introduction of nitrogen by various means can significantly affect the band gap. However, catalytic action also depends on individual conduction and valence band alignments. We address these issues by performing theoretical calculations of the energy spectrum for titanium oxides, titanates and various structures introducing nitrogen into the crystals using the GW method. In contrast to density functional theory approaches, the GW method generally leads to energy levels and band gaps that agree well with experiments. We here use this approach to illustrate the mechanism of band shifting in titanates due to the introduction of nitrogen, in particular the differences in correlation effects for nitrogen related energy bands in these materials. This work is supported by the DOE.

4:18PM L12.00008 Nanocrystal-based Dyads for Solar to Electric Energy Conversion

LEI WANG, MINGYAN WU, DAVID WALDECK, University of Pittsburgh — We describe a new project which aims to develop a systematic and modular approach to creating a new generation of Gratzel-inspired solar energy conversion devices with the following novel advantages: the ability to capture the entire available range of solar irradiance by employing sets of linked nanoparticles, fabrication by self-assembly, enhanced robustness, and lowered cost through use of nanostuctured, rather than molecular, charge transfer elements. The project team is designing, creating, and characterizing linked-nanoparticle dyads, which will act as the charge separation "engine" in new generation solar cells. By employing a mixture of dyads it should be possible to efficiently capture the entire solar spectrum. The proposed device architecture has two important advantages over existing solar conversion devices: It can be produced by a self-assembly process. Because of its modularity, each of its components (nanoparticles or organic linker) can be optimized separately.

4:30PM L12.00009 Energy level alignment of zinc tetrphenylporphyrins derivatives adsorbed on wide band gap semiconductor oxides

SYLVIE RANGAN, ROBERT ALLEN BARTYNSKI, ELENA GALOPPINI, Rutgers University — Metalloporphyrins play an essential role in photosynthetic mechanisms and therefore are natural candidates for electron transfer mediator in dye sensitized solar cells (DSSCs). Among the possible metalloporphyrins, the zinc tetrphenylporphyrins (ZnTPP) derivatives have been found to have similar electron injection and charge recombination properties as the important standard ruthenium dye N3 for DSSCs, as well as reasonable performances using TiO2 or ZnO as substrates. We have investigated the electronic structure, energy level alignment, and their changes with altered surface bonding geometries, using a selective functionalization with carboxylic anchoring groups of the meso-phenyl, of functionalized ZnTPP on single crystal TiO2 and ZnO surfaces. Occupied and unoccupied electronic states were determined using direct (ultra-violet and x-ray) photoemission and inverse photoemission in the same ultra-high vacuum analysis chamber. Energy level alignment of the ZnTPP molecular orbitals with respect to the substrates band edges will be compared to the available literature.

CHRISTOPHER MERCHANT, NINA MARKOVIC, Johns Hopkins University — We have studied photocurrent generation in large carbon nanotube (CNT) films using electrodes with different spacings. We observe that the photocurrent depends strongly on the position of illumination, with maximum observed response occurring upon illumination at the electrode edges. The rate of change of the response decays exponentially, with the fastest response occurring for samples with the smallest electrode spacing. We show that the time response is due to charge carrier diffusion in low-mobility CNT films.

also serve as a guide for the hybrid DFT itself. For instance, it provides hints how the weight is changed/screened when a crystal is compressed.

The weight of the exact exchange term optimized in this way can serve as a variational parameter that is optimized with the density-functional-based orbitals. Presented possibilities to improve variational freedom of Slater-Jastrow trial wave function by using one-body orbitals from the hybrid density-functional theory (DFT) to construct its determinantal Slater part. The weight of the exact exchange term in the hybrid DFT functional serves as a variational parameter that is optimized with respect to the total energy calculated within the fixed-node diffusion Monte Carlo method. This approach is certainly less powerful than direct optimization of one-body orbitals within a basis-set expansion, but its modest computational requirements make it suitable for large-scale simulations of solids. Presented method will be illustrated on several materials with emphasis on transition-metal compounds. The weight functional terms in the variational Monte Carlo calculations compared to those given by the density-functional-based orbitals. Advantages of using the optimized orbitals in the diffusion Monte Carlo calculations are also discussed.

We explore possibilities to improve variational freedom of Slater-Jastrow trial wave function by using one-body orbitals from the hybrid density-functional theory (DFT) to construct its determinantal Slater part. We analyze the fixed-node errors for a diverse set of atoms and molecules. In some cases, our simple wavefunctions have almost the exact atomic total energies in the variational Monte Carlo calculations compared to those given by the density-functional-based orbitals. Advantages of using the optimized orbitals in the diffusion Monte Carlo calculations are also discussed.

Improved Algorithm for Calculating Observables in Diffusion and Reptation Monte Carlo. Unlike previous attempts [1], our technique assumes no knowledge about derivatives of the trial or exact ground state wavefunction with respect to the perturbation. We will outline the derivation of the operator and show examples for DMC by comparing to forward walking, and within RMC by showing faster convergence to the unbiased, ground state observable. [2]Assaraf and Caffarel, J. Chem. Phys. 119, 10536 (2003).

Analysis of fixed-nodes errors in quantum Monte Carlo calculations of atoms and molecules, SHUMING HU, KEVIN RASCH, MINYI ZHU, MICHAL BAJDICH, LUBOS MITAS. Center for High Performance Simulation, Department of Physics, North Carolina State University — The accuracy of fixed-node QMC calculation is determined by the fermion nodes of the trial wavefunction. We analyze the fixed-node errors for a diverse set of atoms and molecules. In some cases, our simple wavefunctions have almost the exact nodes. But in other cases, it is very difficult to find the exact nodes even with wavefunctions of correlated many-body forms, such as extensive multi-reference expansions, pairing and backflow. We try to elucidate the impact of the size and extent of the basis sets as one of the factors influencing fixed-node biases. The testing systems also include transition metal atoms with all-electron and Ne-core pseudopotential calculations.

The accuracy of fixed-node QMC calculation is determined by the fermion nodes of the trial wavefunction. We analyze the fixed-node errors for a diverse set of atoms and molecules. In some cases, our simple wavefunctions have almost the exact nodes. But in other cases, it is very difficult to find the exact nodes even with wavefunctions of correlated many-body forms, such as extensive multi-reference expansions, pairing and backflow. We try to elucidate the impact of the size and extent of the basis sets as one of the factors influencing fixed-node biases. The testing systems also include transition metal atoms with all-electron and Ne-core pseudopotential calculations.

Geometry of fermion nodes and its impact on many-body effects in quantum Monte Carlo, LUBOS MITAS, North Carolina State University — Fermion nodes, which are zero sets of stationary fermionic many-body wavefunctions, play an important role in quantum Monte Carlo calculations. In the diffusion Monte Carlo method the so-called fixed-node approximation allows us to avoid well-known inefficiencies of the fermion sign problem and to use the method for large systems. Besides this practical importance fermion nodes are also related to spectral properties of second order differential operators and to several physical effects and quantities. In order to understand these relationships, we study fermion nodal hypersurfaces, both their topologies and shapes, as determined by wavefunctions built from different types of correlations such as pairing orbitals and backflow many-body coordinates. We analyze the impact of particle interactions on the changes of nodal topologies and the conditions under which such changes can occur. We investigate impact of nodal topologies on properties of wavefunctions with periodic boundary conditions as well as relationship of the nodal surfaces to kinetic energy and some other quantities. We further attempt to elucidate the nodal properties on examples of exactly solvable models.

Hybrid DFT orbitals as a means of reduction of fixed-node errors in diffusion Monte Carlo simulations, JINDRICH KOLORENC, SHUMING HU, LUBOS MITAS, North Carolina State University — We explore possibilities to improve variational freedom of Slater-Jastrow trial wave function by using one-body orbitals from the hybrid density-functional theory (DFT) to construct its determinantal Slater part. Weight of the exact exchange term in the hybrid DFT functional serves as a variational parameter that is optimized with respect to the total energy calculated within the fixed-node diffusion Monte Carlo method. This approach is certainly less powerful than direct optimization of one-body orbitals within a basis-set expansion, but its modest computational requirements make it suitable for large-scale simulations of solids. Presented method will be illustrated on several materials with emphasis on transition-metal compounds. The weight of the exact exchange term optimized in this way can also serve as a guide for the hybrid DFT itself. For instance, it provides hints how the weight is changed/screened when a crystal is compressed.

Geometry optimization using Quantum Monte Carlo, LUCAS WAGNER, JEFFREY GROSSMAN, University of California, Berkeley — There are many molecular and solid systems where correlation effects need to be treated very accurately to obtain correct geometries. Current density functionals often do not perform sufficiently well in excited states, weak-binding, and transition-metal oxide systems. Quantum Monte Carlo (QMC) offers very accurate total energies due to explicit treatment of electron correlation, but its stochastic nature makes precise geometry optimization challenging. We present a method that uses noisy total energies to perform a stochastic series of line minimizations. This method is efficient for multiple degrees of freedom and is effective in both the excited state and when the trial function is relatively poor—two regimes in which forces in QMC have not been developed. Details of the approach will be presented as well as a number of applications.
4:18PM L13.00010 Quantum Monte Carlo calculations of the energy-level alignment at organic-inorganic hybrid interfaces†, ZHICANG WU, YOSUKE KANAI, JEFFREY GROSSMAN, University of California at Berkeley — Understanding interface properties of nano- and hybrid-composite materials is of critical importance for fostering technological advancements. While the density functional theory (DFT) continues to be an important method for investigating opto-electronic and excitation properties of materials, the DFT calculations in some cases fail to provide an accurate description. One such difficult case is computing the energy-level alignment at a hybrid interface, composed of two distinct materials with very different electronic characteristics. In this work we present a quantum Monte Carlo approach to correct the Kohn-Sham (KS) level alignment, and we demonstrate this approach for hybrid interfaces between the silicon (001) surface and several organic molecules. Our calculations show that for some molecules there is a qualitative difference with the DFT-KS level alignment, completely changing the character of the heterojunctions formed. We will discuss its implication for understanding the opto-electronic behaviors of hybrid interfaces, along with some computational/theoretical challenges in extending this approach further.

†This work was supported by the National Science Foundation (NSF) by University of California at Berkeley under Grant No. 0425914.

4:30PM L13.00011 QMC Study of Optical Switching of Azobenzene Molecule†, RENE DERIAN, MATUS DUBECKY, Inst. of Phys., Slovak Academy of Sciences, Bratislava, Slovakia, LUBOS MITAS, Dept. of Phys., NCSU, Raleigh, IVAN STICH, Inst. of Phys., Slovak Academy of Sciences, Bratislava, Slovakia — Optical Switching of photochromic azobenzene (AB) molecule via first excited singlet-state is studied. AB features two photoswitchable conformations, cis and trans with very different geometries and properties. Using QMC techniques we compute excitation/exoexcitation ground-state — first singlet-excitestate spectra of AB. By a careful QMC optimization of the ground/excited-state wave functions with up to 500 determinants chemical accuracy is obtained for the cis and trans conformers. Our QMC results are significantly superior to DFT results with proper spin symmetry (ROKS) and surpass also the available standard quantum chemistry results such as CAS SCF. These results open up the possibility of simulation of anchored AB opto-mechanical switches.

†Work supported by APVV (APVV-0091-07, LPP-0252-07).

4:42PM L13.00012 Multideterminant quantum Monte Carlo calculations of benzene dimers†, RICHARD G. HENNIG, KATHLEEN A. SCHWARZ, Cornell University, Department of Materials Science and Engineering, CYRUS UMIRIGAR, Cornell University, Department of Physics, JULIEN TOULOUSE, Université Pierre et Marie Curie, France — Benzene dimers represent the prototypical system for weak π-π interactions that determine the bonding for various organic materials and carbon nanostructures. Several previous studies using coupled-cluster and quantum Monte Carlo methods have determined the binding energy of parallel, perpendicular and parallel-shifted configurations of the benzene dimer. Here we present multi-determinant variational and diffusion Monte Carlo calculations for the various benzene dimer configurations. The total energy of the benzene dimers depends strongly on basis set size, orbital coefficients and number of determinants in the trial wave function. The binding energy converges faster than the total energy with basis set size and number of determinants due to partial cancellation of errors. While orbital optimization lowers the total energy, the large number of orbital parameters and hence large computational cost limits orbital optimizations to wave functions with small basis sets and small numbers of determinants. In comparison the optimization of the Jastrow and determinant coefficients can efficiently converge the energy of benzene dimers and enables accurate predictions of the binding energies.

†Funded by the DOE petascale initiative.

4:54PM L13.00013 A Quantum Monte Carlo investigation of dispersion interactions in graphite†, LEONARDO SPANU, UC Davis Chemistry Department, Davis CA, GIULIA GALLI, UC Davis, Chemistry Department, Davis CA, SANDRO SORELLA, SISSA-ISAS, Trieste Italy — We present a series of Quantum Monte Carlo (QMC) calculations of graphite, aimed at describing on the same footing the strong C-C covalent bonds and the weaker interlayer interactions. In particular, we carried out calculations of binding energies, bond lengths and compressibility by using the Variational Monte Carlo and Lattice Regularized Diffusion Monte Carlo techniques [1]. We use as a variational ansatz the Jastrow Antisymmetrized Wave function, including a pairing determinant and a Jastrow correlation factor [2]. Our results allow for a detailed analysis of dispersion forces between graphite layers, including their behavior at long distances, and yield a quantitative estimate of the layer binding energy.

5:06PM L13.00014 Auxiliary-Field Quantum Monte Carlo Studies of Pressure-Induced Phase Transitions in Silicon and MnO†, WIRAWAN PURWANTO, HENRY KRAKAUER, ERIC WALTER, SHIWEI ZHANG, College of William and Mary — Accurate theoretical predictions across structural phase transitions are challenging, as they typically involve different electronic structures on the two sides of the transition. We use the phaseless auxiliary-field quantum Monte Carlo (AFQMC) method—which yields accurate many-body wave functions by means of importance sampled random walks in the space of Slater determinants—to calculate the equation of state near two phase transitions: in Si, from the diamond to metallic β-tin transition at ~ 11 GPa; and in MnO, the volume and magnetic moment collapse at ~ 100 GPa. The Si phase transition serves as a test case to study the accuracy of the AFQMC method; the calculated transition pressure is in good agreement with the experiment. Applications to the MnO phase transition will then be presented.

5:18PM L13.00015 A Quantum Monte Carlo Study of Molecular Titanium Dihydride†, TODD D. BEAUDET, JEONGNIM KIM, KENNETH ESLER, RICHARD M. MARTIN, University of Illinois at Urbana-Champaign — Recently there has been interest in the possibility of reversibly storing molecular hydrogen on titanium decorated carbon-nanostructures. The possibility of storing molecular hydrogen on titanium decorated carbon nanostructures is of critical importance for fostering technological advancements. While the density functional theory (DFT) continues to be an important method for investigating opto-electronic and excitation properties of materials, the DFT calculations in some cases fail to provide an accurate description. One such difficult case is computing the energy-level alignment at a hybrid interface, composed of two distinct materials with very different electronic characteristics. In this work we present a quantum Monte Carlo approach to correct the Kohn-Sham (KS) level alignment, and we demonstrate this approach for hybrid interfaces between the silicon (001) surface and several organic molecules. Our calculations show that for some molecules there is a qualitative difference with the DFT-KS level alignment, completely changing the character of the heterojunctions formed. We will discuss its implication for understanding the opto-electronic behaviors of hybrid interfaces, along with some computational/theoretical challenges in extending this approach further.

2:30PM L14.00001 The equilibrium colloidal crystal/colloidal liquid interface, ERIC R. WEEKS, JESSICA HERNANDEZ-GUZMAN, Physics Dept., Emory University — We use confocal microscopy to study an equilibrated crystal-liquid interface in a colloidal suspension. The surface shows spatial fluctuations due to capillary waves. Local measurements of the structure and dynamics near the rough surface reveal that the intrinsic surface, while meandering in space, is locally sharply defined. Examining different quantities finds slightly different widths of this intrinsic surface.

2:42PM L14.00002 Janus particles at the liquid-liquid interface, QIAN CHEN, STEPHEN ANTHONY, STEVE GRANICK, University of Illinois Urbana Champaign — Dipolar Janus particles (negatively charged on one side, positively charged on the other), deposited on PDMS droplets in water, are studied in real time by fluorescence and phase contrast microscopy. Crystals form, under some conditions with long-range hexagonal order, but this self-assembled structure depends strongly on particle size and ionic strength of the water phase. Their provocative translational and rotational dynamics is studied using single-particle tracking.

2:54PM L14.00003 Short-time self-diffusion of nearly hard spheres at an oil-water interface, PENGER TONG, YUAN PENG, WEI CHEN, Department of Physics, Hong Kong University of Science and Technology, THOMAS FISCHER, Institute of Experimental Physics V, University of Bayreuth, DAVID WEITZ, Department of Physics and School of Engineering and Applied Sciences, Harvard University — Optical microscopy and multi-particle tracking are used to study hydrodynamic interactions of monodisperse polymethylmethacrylate (PMMA) spheres at a decal-win-water interface. The short-time self-diffusion coefficient measured at low surface coverage has the form, \( D_S^2(n) = \alpha D_0 (1 - \beta n) \), where \( n \) is the area fraction occupied by the particles and \( D_0 \) is the Stokes-Einstein diffusion coefficient in the bulk suspension of PMMA spheres in decal. The measured values of \( \alpha \) are found to be in good agreement with the numerical calculation for the drag coefficient of interfacial particles. The measured values of \( \beta \) differ from that obtained for bulk suspensions, indicating that hydrodynamic interactions between the particles have interesting new features at the interface.

3:06PM L14.00004 Observing the three-dimensional motion of colloids at an oil-water interface, RYAN MCGORTY, DAVID KAZ, Harvard University, SHANKAR GHOSH, Tata Institute of Fundamental Research, V.N. MANOHRAN, Harvard University — Our experimental system allows us to place micron-sized colloids at a flat oil-water interface. Using digital holographic microscopy we track the motion of particles at the interface in all three dimensions. Of particular interest is the out-of-plane motion of an adsorbed particle. I will present data of such motion and what it reveals regarding the energy and length scales of a particle attached to an interface. Introducing a laser tweezer and customized colloids (such as core-shell particles) into our experiment allows us to further investigate this system.

3:18PM L14.00005 Self-assembled Capillary Arrows, JEAN-CHRISTOPHE LOUDET, BERNARD POULIGNY, Centre de Recherche Paul Pascal, CNRS 115 avenue A. Schweitzer 33600 Pessac, France — Anisotropic particles adsorbed at a water-air interface are known to aggregate due to capillary interactions. We show that the packing configuration of a pair of prolate ellipsoids critically depends on their relative size and/or aspect ratio mismatch. While identical particles simply pack side-by-side, particles of slightly different sizes are observed to systematically self-assemble into characteristic arrows, i.e. with a finite angle between their axes. The occurrence of such arrows cannot be explained within the far-field approximation of interacting polar quadrupoles. A numerical analysis is worked out which allows us to explore the near-field characteristics of the capillary interaction. Results clearly show the destabilization of the side-by-side configuration due to a size mismatch, in agreement with experimental observations.

3:30PM L14.00006 Impact of Surfactant Sorption Kinetics on Microscale Tipstreaming, WINGKI LEE, LYNN WALKER, SHELLEY ANNA, Carnegie Mellon University — A microfluidic flow focusing system has been used to synthesize submicron sized droplets via a thread formation mode of drop breakup. This process utilizes the interaction of fluid motion and surfactant transport to draw out a thin thread, which then fragments into a stream of tiny droplets whose sizes are orders of magnitude smaller than the size of the device. In this work, we use a homologous series of C\(_n\)E\(_S\) (\( n = 10, 12 \) and 14) surfactants to probe the impact of surfactant sorption kinetics on this process. To characterize the effects of these surfactants on the thread formation process, we measure the relevant timescales for the formation of a cone-like interface, the drawing and disintegration of a fine thread, and the period with which the process repeats. We then relate these timescales to the characteristic timescales for transport of surfactants to the oil-water interface. These measurements and simple scaling analyses suggest ways to extend the thread length and optimize the overall yield of submicron droplets.

3:42PM L14.00007 Network Formation at the Air-Water Interface, ALINE MILLER, MARIA SIMON SAENZ DE SAMANIEGO, University of Manchester — A series of dicarboxylic end functionalised peptides have been designed to form beta-sheet rich monolayers at the air-water interface and their structure, rheological properties and ability to polymerize in response to UV light have been studied using a Langmuir trough and dilatational rheology. Surface pressure-area isotherms as well as compression-expansion cycles reveal all our peptide monolayers organise into the three distinct organisational states typically observed for surfactants at the air-water interface: gaseous (G), liquid expanded (LE) and liquid condensed (LC) and the limiting area per molecule suggests the alternating amphiphilic structure of the peptide causes the molecule to orient with its long axes parallel to the air-water interface. The presence of the dicarboxylic group enhances surface activity and stability over time. Here we will discuss how peptide sequence, UV exposure strength and time, as well as peptide concentration (and hence organisation) influence the kinetics of network formation, and the morphology and mechanical properties of the final network formed.

3:54PM L14.00008 Kinetically Controlled Adsorption to Freshly Formed Interfaces, NICOLAS ALVAREZ, Chem. Eng. Dept., LYNN WALKER, Chem. Eng. Dept., SHELLEY ANNA, Mech. Eng. Dept., Carnegie Mellon University — The coefficients of diffusion, adsorption, and desorption are fundamental properties of surfactant molecules and should be independent of the nature in which they are applied. However, the approaches currently used to obtain these parameters are highly context dependent and can lead to unphysical trends such as a concentration dependent diffusion coefficient and large mismatches between predicted and observed dynamic behavior. In pendant drop studies one is restricted to diffusion or mixed controlled adsorption at small concentrations, but in reality to get at the kinetic coefficients it would be more advantageous to probe the kinetic controlled regime. Recently it was shown that a characteristic length scale, \( R_{D-K} \), governs the transition from diffusion controlled adsorption to kinetically controlled adsorption for spherical interfaces. If the spherical interface has a radius smaller than \( R_{D-K} \) the adsorption process is kinetically limited. This paper uses a micro-tensiometer to probe the adsorption dynamics to micron diameter spherical interfaces to test the transition from diffusion limited to kinetic limited adsorption. Using this method we measure kinetic adsorption constants directly. We also describe a new timescale for diffusion, which better describes the adsorption of surfactants onto spherical interfaces.

Structures formed by colloidal particles on a droplet at small particle number. Jerome Fung, Ryan J. McGorty, Harvard University, Dept. of Physics, Vinothan M. Manoharan, Harvard University, Dept. of Physics and SEAS — We discuss 3D imaging studies of the self-assembled structures formed by small numbers (∼10) of micron-sized polymethylmethacrylate (PMMA) colloids pinned to the surface of a ∼10 micron oil droplet in an aqueous solution. In the low N limit, these structures are governed by the interactions between the constituent colloidal particles on a given droplet. We prepare these droplets using a capillary microfluidic device. Since the droplets are not density matched to the continuous phase, we study them with a time-averaged zero gravity apparatus, based on a rotary stage. Specifically, we image the 3D structures formed by the colloidal particles on the droplets using digital holographic microscopy (DHM). DHM records the 2D interference patterns, or holograms, formed by light scattered from the colloidal particles and unscattered light. Subsequent analysis of the holograms, based on the Lorenz-Mie solution for light scattering by spheres, allows us to determine the 3D particle positions with time resolution limited by the camera frame rate.

Interfacial rheology in complex flow. Jeffrey Martin, Steven Hudson, National Institute of Standards and Technology — Multiphase liquid systems are omnipresent in and essential to everyday life, e.g. foods, pharmaceutics, cosmetics, paints, oil recovery, etc. The morphology and stability of such systems depend on dynamic interfacial properties and processes. Typical methods utilized to measure such interfacial properties often employ drops that are much larger and flows that are much simpler than those encountered in typical processing applications. A microfluidic approach is utilized to measure dynamic structure and kinetics in multiphase systems with drop sizes comparable to those encountered in applications and flow complexity that is easily adjustable. The internal circulation and deformation of an aqueous droplet in clear mineral oil is measured using particle tracers and a detailed shape analysis, which is capable of measuring sub-micron deviations in drop shape. Deformation dynamics, detailed drop shape, interfacial tension, and internal circulation patterns and velocities are measured in Poiseuille and transient elongational flows. Flow kinematics are adjusted by varying the microchannel geometry, relative drop size, and drop height. The effects of confinement on interfacial dynamics and circulation patterns and velocities are also explored.

Reverse coffee-ring effect. Byung Mook Weon, Lei Xu, Department of Physics, University of Pennsylvania Amherst, T. Prisk, J. Zhou, A. Dinsmore — We measure the contact forces at the bottom of a container of frictionless liquid droplets as a function of compression and of distance to the container wall. Glass cylinders are used to contain 20-micron-radius droplets of silicon oil; Brownian motion is not significant for this size. Reflection interference contrast microscopy is used since we are particularly interested in contacts with the bottom surface. By looking at the Newton’s ring interference pattern, we measure the deformation of each droplet, which arises from gravity and pressure from the whole pile transmitted through droplet contacts. We also measure the radius of each droplet and thereby obtain the vertical contact force. We vary the pile height to change the compressive stress and then measure the corresponding forces, probability distributions, and correlations of rearrangements. The results elucidate the roles that friction and confining walls play in granular systems and also shed light on force chains in bulk of the material.

Sticking colloids to liquid-liquid interfaces one by one. David Kaz, Ryan McGorty, Harvard University, Shankar Ghosh, Vinothan Manoharan, Harvard University — We investigate the dynamics of placing individual colloidal particles (~2 microns) onto a flat oil-water interface using optical tweezers. By monitoring the strength and position of the trap, we are able to measure the forces acting on a particle as it encounters the liquid-liquid interface. Digital holographic microscopy affords us three dimensional position information at high frame rates (> 500fps), allowing us to probe short timescale behavior. We vary parameters such as particle surface chemistry, dissolved ion concentration, and pH in order to pursue questions about the nature of interface penetration dynamics.

Controlled Crystal Growth and Solid-Liquid Interface in temperature-sensitive colloidal systems. Duc Nguyen, University of Amsterdam, The Netherlands, Zhbing Hu, University of North Texas, Peter Schall, University of Amsterdam, The Netherlands — We use temperature-sensitive colloidal NIPA systems to study crystal growth at the “atomic scale”. By applying a temperature gradient we are able to control the growth of large colloidal single crystals. We visualize the nucleation of these crystals and solidification at the crystal-liquid interface in three dimensions by using confocal microscopy. Trajectories of particles on both the crystal and liquid side of an advancing interface are determined. These elucidate the mechanism of particle assembly at the interface of a growing crystal. At later stages of crystal growth, the interface becomes stationary, and we use the fluctuations of the stationary interface to determine the interface stiffness. Our data suggests a strong anisotropy of the interface tension. These microscopic observations provide unique insight into the mechanism of solidification.

A Surface Plasmon Resonance Investigation of How Water Meets a Hydrophobic Surface. Adele Poynor, Allegheny College, Physics Department. Corey Shemelya — By definition hydrophobic substances hate water. Water placed on a hydrophobic surface will form a droplet in order to minimize its contact area. What happens when water is forced into contact with a hydrophobic surface? One theory is that an ultra-thin low- density region forms near the surface. We have employed the surface-sensitive, quantum-optical technique of Surface Plasmon Resonance (SPR) to verify the existence of this region at the boundary.

2:30PM L15.00001 Thermal Convection in the Presence of Internal Heating. Gabriel Seiden, Stephan Weiss, Eberhard Bodenschatz, Max Planck Institute for Dynamics and Self-Organization — Thermal convection in the presence of internal heat sources is an important mechanism of heat transport in geophysics, particularly in planetary mantle convection. Carefully controlled laboratory studies of this mechanism are, however, scarce. We present experimental results on the effect of internal heating on Rayleigh-Bénard convection, where the heat sources are induced by IR absorption. The results are compared with available theoretical predictions.
2:42PM L15.00002 Chaotic three particle dynamics in a viscous liquid filled rotating drum . JAMES E. DAVIDHEISER, ERIC R. WEEKS, PHIL SEGRE, Physics Dept., Emory University — We conduct experiments to study the motions of three heavy spheres moving within a viscous liquid filled rotating cylindrical drum. Numerous works, in other geometries, demonstrated that assemblies of non-Brownian particles in viscous liquids have the potential to exhibit chaotic motion. We find that as the drum rotation rate ω is varied, there are several distinct periodic states as well as fully chaotic states. We track the motion of the spheres using a digital camera and custom particle tracking software. From our data, we characterize the chaotic trajectories as ω is varied.

2:54PM L15.00003 Chaotic Dynamics of an Elastically Bouncing Dumbbell . COLIN REES, SCOTT FRANKLIN, Rochester Institute of Technology — The dynamics of an elastically bouncing dumbbell is analogous to that of a ball bouncing on a sinusoidally deforming surface with an important exception: the dumbbell’s angle, analogous to the surface’s oscillation frequency, changes with each bounce, making the subsequent motion significantly more complicated. We investigate this dynamical system over a range of aspect ratios and initial energy, finding periodic, quasi-periodic and chaotic motions. As the initial energy is increased, the dumbbell can flip over and tumble. We find for large aspect ratios, however, narrow bands of energies well above this minimum where tumbling suddenly ceases. Because energy is conserved, the dynamics of a bounce are uniquely determined by the angle and angular velocity. The Lyapunov exponents of paths in this two dimensional phase space can be calculated, with the hope of identifying periodic islands within the chaotic sea. Finally, for certain parameters, the angle at each collision moves from its initial value in a subdiffusive manner, and we determine the characteristic exponents.

3:06PM L15.00004 ABSTRACT WITHDRAWN —

3:18PM L15.00005 Fixed point of a renormalization group approach for oscillator synchronization. TONY LEE, GIL REFAEL, MICHAEL CROSS, OLEG KOGAN, Department of Physics, California Institute of Technology. JEFFREY ROGERS, Control and Dynamical Systems, California Institute of Technology — We apply a recently developed renormalization group method to a 1-dimensional chain of phase-coupled oscillators in the regime of weak randomness. The RG predicts how oscillators with randomly distributed frequencies and couplings form frequency-synchronized clusters. Although the RG was originally intended for strong randomness (distributions with long tails), we find good agreement with numerical simulations even in the regime of weak randomness. We also show analytically and numerically the existence of a stable fixed point in the functional RG space. At late stages of the RG, there is a universal approach to the fixed point regardless of the initial distributions of frequency and coupling.

3:30PM L15.00006 Cell refinement and growing misorientations from a continuum dislocation density theory . YONG CHEN, WOOSONG CHOI, STEFANOS PAPANIKOLAOU, JAMES P. SETHNA, Laboratory of Atomic and Solid State Physics, Cornell University, SURACHATE LIMKUMNERD, Physics Department, Chulalongkorn University, Bankok, Thailand — At low temperatures, climb-free plastic behavior of BZ gels through mechanical deformations opens up the possibility of using these materials in novel chemo-mechanical sensors.

3:42PM L15.00007 Dynamic self-assembly in far-from-equilibrium magnetic granular ensembles at the liquid/liquid interface . ALEXEY SNEZHKO, IGOR ARANSON, Argonne National Laboratory — Magnetic particles suspended over an interface of two immiscible liquids and energized by a vertical alternating magnetic fields give rise to novel dynamic self-assembled structures (“pulsating magnetic stars,” “clams”) which are not accessible at the liquid/air interface. These novel structures is attributed to the interplay between surface waves, generated at the liquid/liquid interface by the collective response of magnetic microparticles to the alternating magnetic field, and hydrodynamic fields induced in the boundary layers of both liquids forming the interface. We show that while the onset of the dynamic self-assembly is controlled by the external driving magnetic field parameter the viscosity of the liquids forming the interface plays an essential role. Transition between different self-assembled structures with the parameters of the external excitations is observed.

3:54PM L15.00008 Investigation on dynamics of colloidal particles with optically-controlled electrode patterns1 . Kwan HyOung Kang, HyunJin Park, Horim Lee, Jiwoo Hong, Pohang Univ. Sci. and Tech. — We investigated the dynamics of colloidal particles under ac electric fields. We used an optoelectronic substrate in which the conductivity of substrate can be changed optically. The shape of electrode pattern thus can be changed freely by controlling the optical pattern which is produced by a conventional projector. Interaction between particles showed a various patterns depending on applied electrical frequency, and rich dynamic characters are captured by dynamically changing the electrode pattern. Particle behaviors are in general governed by the balance between the dielectrophoresis and induced charge electroosmosis.

4:06PM L15.00009 Memories in paste: their applications to control crack patterns . AKIO NAKAHARA, YOUSUKE MATSUO, Nihon University — We experimentally find that a paste, i.e., a densely packed colloidal suspension with plasticity, has memories of external mechanical fields it suffered, such as flow and vibration. These memories are sustained as microscopically anisotropic network structures of colloidal particles. By drying these pastes, we find that the memories in pastes can be visualized as macroscopically anisotropic crack patterns. By using the memory effects of paste, we can imprint flow and vibration patterns into pastes to produce various crack patterns, such as lamellar, radial, ring, spiral, and so on [1]. [1] Physics Today 60 (2007), no. 9, p. 116.

4:18PM L15.00010 Controlling chemical oscillations in heterogeneous BZ gels via mechanical strain . VICTOR YASHIN, Chemical Engineering Department, University of Pittsburgh, KRYSNTYN J. VAN VLIES, Department of Materials Science and Engineering, Massachusetts Institute of Technology, ANNA C. BALAZS, Chemical Engineering Department, University of Pittsburgh — We performed theoretical and computational studies to determine the effect of an applied mechanical strain on the dynamic behavior of heterogeneous polymer gels undergoing the oscillatory Belousov-Zhabotinsky (BZ) reaction. In these gels, the catalyst for the reaction is localized in specific patches within the polymer network and the BZ reaction only occurs within these BZ patches. We focused on a 1D model for the system, and considered two scenarios, in which the BZ reaction did or did not affect the degree of swelling within the gel. For gels having one and two BZ patches, we found that a longitudinal strain could induce transitions between the oscillatory and steady state regimes. For certain values of the BZ stoichiometric parameter f, these transitions could exhibit a hysteresis. In systems having two oscillating BZ patches, a strain could switch between the in-phase and out-of-phase synchronization of the oscillations. The ability to alter the dynamic behavior of BZ gels through mechanical deformations opens up the possibility of using these materials in novel chemo-mechanical sensors.
of a quantum phase transition where \( \Omega \) is possible, by choosing the parameters of the system appropriately, to produce an interacting 1D bose gas with sharp momentum distribution, and show the momenta through parametric resonance with the oscillations of the population imbalance observed at small times. We show that through this resonance it of 1D coupled gases we find similar behavior for short times, but quantum fluctuations destroy the self trapped state by production of particle pairs of opposite is caused by singular \( \pm \pi n \) scattering processes and can be understood by analogy to the Kondo effect, both at strong and weak coupling, with the possibility scattering processes and can be understood by analogy to the Kondo effect, both at strong and weak coupling, with the possibility of a quantum phase transition where \( \Omega(\pm\pi n) \) jumps to zero with increasing coupling. The low energy singularities in the impurity spectral function can be understood on the same footing.

This work is in part supported by the office of the Dean of Science, UBC, NSERC (Canada), Canadian Institute for Advanced Research, and the A. P. Sloan foundation.

2:42PM L16.00002 Vortex lattice locking in rotating two-component Bose-Einstein Condensates, RYAN BARNETT, EDWARD CHEN, Caltech, MASON PORTER, Oxford, HANS PETER BUCHLER, Stuttgart, GIL REFAEL, Caltech — The vortex density of a rotating superfluid, divided by its particle mass, dictates a superfluid’s angular velocity through the Feynman relation. To find how the Feynman relation applies to superfluid mixtures, we investigate a rotating two-component Bose-Einstein condensate, composed of bosons with different masses. We find that in the case of sufficiently strong interspecies attraction, the vortex lattices of the two condensates lock and rotate at the drive frequency, while the superfluids themselves rotate at two different velocities, whose ratio is that of the particle masses of the two species. In this talk, I will characterize the vortex-locked state, establish its regime of stability, and find that it survives within a disk smaller than a critical radius, beyond which vortices become unbound. Finally, numerical solution of the coupled Gross-Pitaevskii equations in support of this will be presented.

2:54PM L16.00003 Quantum fluctuations of a Bose-Josephson junction on a quasi-one-dimensional ring trap, NICOLAS DIDIER, ANNA MINGUZZI, Université Joseph Fourier, Laboratoire de Physique et de Modélisation des Milieux Condensés, C.N.R.S., ROBERTA CITRO, Università degli Studi di Salerno, Dipartimento di Fisica “E. R. Caianiello”, 84081 Baronissi (Sa), Italy, FRANK W.J. HEKKING, Université Joseph Fourier, Laboratoire de Physique et de Modélisation des Milieux Condensés, C.N.R.S. — Ring traps for ultracold atomic gases are becoming experimentally feasible. We study the theory of quantum fluctuations of a Bose-Einstein condensate confined to a quasi-one-dimensional ring trap where a Josephson junction is realized with a localized barrier potential. We consider the situation where the transverse confinement of the trap is so tight that only longitudinal quasi-1D motion is allowed along the ring. The condensate is treated as a Luttinger liquid and the low energy properties are described within the bosonization formalism. For a very large barrier, we study the one-particle density-matrix including the correction due to the density fluctuations. Our analysis reveals different power law decays depending on the location of the probed points, i.e. whether they are chosen in the bulk or at the edge of the ring under consideration. This quasi-long range order could be probed using an interference measurement. In the Tonks-Girardeau limit, the density-density correlation function tends to the exact result obtained from the Bose-Fermi mapping. The momentum distribution is calculated and compared to the result for a very small barrier. Furthermore, for a barrier of finite height, within the renormalization group approach, we study how quantum fluctuations reduce the effective Josephson coupling strength.

3:06PM L16.00004 Detecting statistics of quasiparticles using dynamical probes, CLAUDIA DE GRANDI, ROMAN BARANKOV, ANATOLI POLKOVNIKOV, Boston University — We study a time-dependent sine-Gordon model in the range of the coupling constant (Luttinger parameter) where the quasiparticles excitations change from massive bosons to free fermions. We find that, if we include the effects of finite temperature, the non-adiabatic response to slow perturbations is enhanced for the bosonic case and reduced for the fermionic one with respect to zero temperature. The signature of this bunching (anti-bunching) behaviour can also be seen at zero temperature by analyzing the second order corrections of a perturbative approach in the number of quasiparticles created. This suggests the existence of a crossover (for the Luttinger parameter) that separates systems with Bose-like statistics from systems with fermi-like statistics, and therefore time-dependent perturbations to the system can be used to probe the statistics of the quasiparticles. We show how this model is relevant for cold atoms experiments that realize splitting and merging of two one-dimensional Bose gases.

3:18PM L16.00005 Motion of an impurity in a one-dimensional quantum liquid, AUSTEN LAMACRAFT, University of Virginia — We consider the motion of an impurity particle in a general one-dimensional quantum fluid at zero temperature. The dispersion relation \( \Omega(P) \) of the impurity is strongly affected by interactions with the fluid as the momentum approaches \( \pm \pi n \hbar, \pm 3\pi n \hbar, \ldots \), where \( n \) is the density. This behavior is caused by singular \( \pm 2\pi n \hbar \) scattering processes and can be understood by analogy to the Kondo effect, both at strong and weak coupling, with the possibility of a quantum phase transition where \( \Omega(\pm\pi n) \) jumps to zero with increasing coupling. The low energy singularities in the impurity spectral function can be understood on the same footing.

3:30PM L16.00006 Breakdown of Macroscopic Quantum Self Trapping in Coupled 1D Bose Gases, RAFAEL HIPOLITO, ROMAN BARANKOV, ANATOLI POLKOVNIKOV, Boston University — Two coupled 1D Bose-Einstein condensates with a large population imbalance exhibit macroscopic quantum self-trapping if the ratio of interaction energy to the coupling energy between the two gases is above a critical value. Above the self trapping transition, one sees only small amplitude high frequency oscillations of the population difference. In the analogous case of 1D coupled gases we find similar behavior for short times, but quantum fluctuations destroy the self trapped state by production of particle pairs of opposite momenta through parametric resonance with the oscillations of the population imbalance observed at small times. We show that through this resonance it is possible, by choosing the parameters of the system appropriately, to produce an interacting 1D Bose gas with sharp momentum distribution, and show the conditions that the system must satisfy in order to produce such a state.
3:42PM L16.00007 The Mass of a Spin Vortex, in a Bose Einstein Condensate. ARI TURNER, University of California Berkeley — Ferromagnetic condensates can have both spin-current and charge-current vortices. A moving charge-vortex experiences the Magnus force, perpendicular to its motion, when it moves. This effective “magnetic field” is so strong that it dominates the inertial term in Newton’s law; therefore it is not possible to set a charge-vortex moving at an arbitrary speed relative to the condensate. As we will show, a spin-vortex can move “inertially” through a condensate and resists acceleration with a mass.

3:54PM L16.00008 Unusual states of vortex matter in interacting multicomponent Bose-Einstein condensates, EGOR BABAEEV, University of Massachusetts Amherst, ESKIL DAHL, ASLE SUDBO, NTNU Trondheim — A striking property of a single-component superfluid under rotation, is that a broken symmetry in the order parameter results in a broken translational symmetry, a vortex lattice. If translational symmetry is restored by means of rotation disorder, as for example in a laser driven superfluid, then the broken translational symmetry is restored. We show that for interacting mixtures of Bose-condensate (with a dissipationless intercomponent drag), new situations arise. A phase disordered nonsuperfluid component can break translational symmetry in response to rotation due to interaction with a superfluid component. In a different regime instead of a vortex lattice, the system forms a highly disordered vorticity which completely undergoes merger and reconnecting processes involving different types of vortices, with a breakdown of translational symmetry only in a statistical sense.

4:06PM L16.00009 Normal modes of a ring-shaped BEC with vortices, SUNGJONG WOO, Univ of Mass Lowell, YOUNG-KYUN KWON, Kyung Hee University, Univ of Mass Lowell — Recently, a ring-shaped BEC was realized experimentally at NIST and long lasting perpetual current was observed. Using Bogoliubov-de Gennes equations, we have analyzed dynamics of such a non-simply connected rotating condensate system with quantized vortices. Surface modes of a simply connected rotating BEC are known to be associated with driven vortices that can make interactions with the vortex lattice that exists due to the rotation. In our current work, it has been found that stable vortex dipoles or velocity dipoles that do not exist in a normal mode for a simply connected BEC, exist in a non-simply connected case generating “inner” surface modes. The interactions of such inner surface modes with quantized changes as well as the stability of the perpetual current related to the low lying excitations will be discussed. How the angular dispersion relation changes as a BEC makes a transition from a simply connected to a ring-shaped one will also be presented.

4:18PM L16.00010 Hierarchies of Supercurrents in Multicomponent Atomic Josephson Vortices, VITALIY KAUROV, CSI, CUNY — We show that a quasi-1D long atomic Josephson junction [1,2] containing a mixture of BECs can sustain multi-component Josephson vortices (mJV). A new exact soliton solution is given to describe a stationary mJV in the general N-component case. Depending on system parameters (scattering lengths, tunneling strengths, and chemical potentials) Josephson supercurrents of different components form a hierarchy according to their intensity and proximity to phase slip. By tuning the parameters it is possible to turn off or on particular currents using the JV – dark soliton interconversion effect [1,2]. Inside the mJV different components may circulate either in the same or opposite directions resulting in bulk super-counter-flow in the latter case. The weak tunneling limit can be described by a modified Sine-Gordon model. An approximate solution for mJV propagating along the junction is found for the two-component case. The degeneracy of stationary mJV with respect to co-flow or counter-flow configurations is lifted by the uniform motion of mJV. Which configuration is energetically preferable depends on the interspecies scattering length. [1] V. M. Kaurow and A. B. Kuklov, Phys. Rev. A 71, 016101-R (2005). [2] V. M. Kaurow and A. B. Kuklov, Phys. Rev. A 73, 013632 (2006).

4:30PM L16.00011 Rotating Bose-Einstein condensates at the phase transition point, MAHIR HUSSEIN, Max Planck Institut fur Physik Komplexer Systeme, Dresden, Germany, PIET VAN ISACKER, Grand Accelerateur National d’Ions Lourds, KLAUS BARTSCHAT, Drake University, OLEG VOROV, University of North Carolina, Charlotte — Here we give analytic description of the phase transitions in the rotating Bose-Einstein condensate of weakly interacting atoms in a magnetic trap [1,2]. The analytic solution allows one to classify the instabilities in the condensates which occur when the rotational speed is increased [3]. In the case of predominantly repulsive interactions, the transition corresponds to the vortex entry the condensate. The transition to the Abrikosov state has follows if the rotational speed is increased further. In the case of predominantly attractive interactions, the transition corresponds to the escape of the condensate from the trap at the critical speed. [1] O. K. Vorov, P. Van Isacker, M. S. Hussein and K. Bartschat, Phys. Rev. Lett. 95, 230406 (2005). [2] O. K. Vorov, M. S. Hussein and P. Van Isacker, Phys. Rev. Lett. 90, 200402 (2003). [3] O. K. Vorov, P. Van Isacker, M. S. Hussein and K. Bartschat, to be submitted to Nature (2007). Supported by NSF (USA), CEA (France).

4:42PM L16.00012 Strongly Interacting Quantum gases using spin-Coherent state Representation, RADHA BALAKRISHNAN, Institute of Mathematical Sciences, Chennai, India, INDUBALA SATIJA, George Mason University, Fairfax, VA — For strongly interacting boson gas, spin-coherent states representation may provide a useful description of the Bose-Einstein Condensate as it encodes fluctuations and depletion. We investigate the the non-linear evolution equation for the order parameter obtained using spin-coherent states. The equation is not of the GPE-type and exhibits local fluctuations and in the limit of small order parameter, it reduces to the GPE equation. We compare and contrast the quasi-particle excitation and the vortex excitations of this system with that of weakly interacting quantum gases described by GPE equation. For a variety of problems, implication of this description of quantum gases will be discussed.

4:54PM L16.00013 Dynamics of spinor condensates near point-group symmetric ground states, GIL REFAEL, RYAN BARNETT, Caltech. DANIEL PODOLSKY, University of Toronto — The mean-field ground state of spin- S BEC’s often exhibits a high degree of symmetry, which only becomes apparent when considering the 25 reciprocal spin-states: coherent spin-states orthogonal to the ground state. Our presentation will concentrate on a description of the dynamics of spinor-condensates using these reciprocal states. First, we will present the resulting hydrodynamic Euler equations, which generalize Mermi-Nico relations to higher spin. Second, we will use the reciprocal states and their hidden point-group symmetry to construct the Goldstone and optical spin-wave modes of the spinor condensates. Finally, we will present a mapping between the spin-wave modes, and the wave functions of electrons in atoms, where the spherical symmetry is degraded by a crystal field.

Tuesday, March 17, 2009 2:30PM - 5:30PM —
Session L17 GQI: Superconducting Flux Qubits and Qubit Amplifiers and Readouts 318

2:30PM L17.00001 Behavior of a Josephson Flux Qubit on a Sapphire Substrate, ANTHONY PRZYBYSZ, E. CROWE, H. KNOW, B.K. COOPER, R.M. LEWIS, University of Maryland, JQI, CNAM, B.S. PALMER, The Laboratory for Physical Science, JQI, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, University of Maryland, JQI, CNAM — We discuss the design, fabrication, and testing of a Nakamura-style [1] flux qubit. The device consists of a four-Josephson junction qubit loop that is directly coupled to a small dc SQUID, which is used for detection. The device was built on a sapphire substrate using electron beam lithography and double angle evaporation to form the Al/Alo/Al tunnel junctions. A 200 nm thick layer of aluminum was deposited on the e-beam resist in order to prevent charge effects during the lithography. Three of the junctions in the qubit loop were 100 nm x 250 nm, and the fourth was 100 nm x 150 nm. The large junctions are the main contribution to the inductance of the qubit loop, and the smaller junction creates an energy splitting of 1-10 GHz between the two circulating current states. The SQUID junctions were 100 nm x 2000 nm, and the critical current of the detection SQUID was 240 nA. We present the results of ongoing measurements on the behavior of the device at 25 mK. This project was funded by the JQI, LPS, and CNAM. [1] F. Yoshihara, Y. Nakamura, et al., “Decoherence of Flux Qubit Due to 1/F Flux Noise,” PRL 97, 167001 (2006).

2:42PM L17.00002 Josephson Vortices in a Strongly Interacting Bose-Einstein Condensate, DMITRII GORELKO, Srinivas KOTILRA, University of Maryland, JQI, CNAM — We discuss the design, fabrication, and testing of a Josephson vortex qubit. The device consists of a Josephson vortex loop that is coupled to a small dc SQUID, which is used for detection. The device was built on a sapphire substrate using electron beam lithography and double angle evaporation to form the Al/Alo/Al tunnel junctions. A 200 nm thick layer of aluminum was deposited on the e-beam resist in order to prevent charge effects during the lithography. Three of the junctions in the qubit loop were 100 nm x 250 nm, and the fourth was 100 nm x 150 nm. The large junctions are the main contribution to the inductance of the qubit loop, and the smaller junction creates an energy splitting of 1-10 GHz between the two circulating current states. The SQUID junctions were 100 nm x 2000 nm, and the critical current of the detection SQUID was 240 nA. We present the results of ongoing measurements on the behavior of the device at 25 mK. This project was funded by the JQI, LPS, and CNAM. [1] F. Yoshihara, Y. Nakamura, et al., “Decoherence of Flux Qubit Due to 1/F Flux Noise,” PRL 97, 167001 (2006).
2:42PM L17.00002 IBM’s experimental quantum computing effort. MATTHIAS STEFFEN, IBM, DAVID DIVINCENZO, MATTHEW FARINELLI, GEORGE KEEFE, MARK KETCHEN, SHWETANK KUMAR, FRANK MILLIKEN, MARY BETH ROTHWELL, JIM ROZEN — We present our experimental quantum computing effort and discuss results on flux and phase qubits.

2:54PM L17.00003 Tuning the gap of the superconducting flux qubit. ARKADY FEDOROV, FLOOR PAAUW, KEES HARMANS, HANS MOOIJ, Kavli Institute of Nanoscience, Delft University of Technology, PO Box 5046, 2600 GA Delft, The Netherlands — Recent advances in experiments with the flux qubits include demonstration of single and two qubit quantum gates as well as a coupling between the flux qubit and a harmonic oscillator. It was also experimentally confirmed that the best coherence properties were achieved when the qubit was kept at the symmetry point. For these conditions the qubit’s energy level splitting is minimal (the gap) and determined solely by the quantum tunnelling in the double-well potential. However, since the potential barrier and the gap of the conventional flux qubit are fully fixed by the fabrication, one needs to tune the qubits out of the symmetry point in order to bring it in resonance with another quantum system. We overcome this limitation by introducing the change in the qubit design and demonstrated the tuning of the gap over a range of several Gigahertz within a few nanoseconds. We believe this could be an important step toward the coupling of the flux qubit to another qubit or the quantum bus. This control also allows a more extensive study of the relaxation time of the qubit as a function of the gap size within a constant environment.

3:06PM L17.00004 Ultra-strong coupling regime of cavity QED with flux qubits. JEROME BOURASSA, ALEXANDRE BLAIS, Universite de Sherbrooke — With improved dephasing rate and coupling strength, the transmon qubit has recently been used to reach the strong coupling regime of cavity QED [1,2]. With the transmon however, these improvements are done at the expense of lower anharmonicity compared to the Cooper-pair box. Here we present an alternative approach where a flux qubit is coupled to the transmission line. As was recently shown experimentally [1], very strong coupling can be obtained by directly connecting the qubit loop to the center conductor of the resonator whose local inductance is tuned to maximize the coupling. We will discuss how this system can be used to study the breakdown of the rotating-wave approximation and how the Λ-configuration of the energy levels of the flux qubit can be exploited.

3:18PM L17.00005 Amplitude spectroscopy of a superconducting artificial atom. WILLIAM OLIVER, MIT Lincoln Laboratory, DAVID BURNS, MIT, SERGIO VALENZUELA, CIN2-ICN Barcelona, MARK RUDNER, Harvard; LEONID LEVITO, TERRY ORLANDO, MIT — We introduce and demonstrate amplitude spectroscopy in a superconducting artificial atom [1]. A harmonic field at a fixed frequency drives the artificial atom through its energy-level avoided crossings. Spectroscopic information is obtained from the amplitude dependence of the system response. The resulting ‘spectroscopy diamonds,’ regions of parameter space in which state transitions occur, exhibit quantum interference patterns and population inversion which serve as a fingerprint of the atom’s energy spectrum. Using this approach, we determined the energy spectrum of a manifold of states with energies from hω 0.01 GHz to hω 120 GHz for a fixed driving frequency near only 0.16 GHz. The amplitude spectroscopy technique is complementary to frequency spectroscopy, providing a means to access, manipulate, and characterize quantum systems over broad bandwidths while using only a single drive frequency that may be orders of magnitude smaller than the energy scales being probed. [1] Berns et al., Nature 455, 51 (2008)

3:30PM L17.00006 Phase tomography of a strongly driven superconducting artificial atom. MARK RUDNER, Harvard University, ANDREI SHYTOV, University of Utah, LEONID LEVITO, DAVID BURNS, MIT, WILLIAM OLIVER, MIT Lincoln laboratory, TERRY ORLANDO, SERGIO VALENZUELA, MIT — In a recent experiment [1], amplitude spectroscopy of a superconducting qubit was demonstrated by driving the system with a strong rf field through a manifold of states spacing energies up to 120 GHz. The interference between repeated Landau-Zener transitions in a qubit swept through an avoided level crossing results in Stueckelberg oscillations in qubit magnetization. The resulting oscillatory patterns are a hallmark of the coherent strongly-driven regime in qubits, quantum dots and other two-level systems. The two-dimensional Fourier transforms of these patterns are found to exhibit a family of one-dimensional curves in Fourier space [2], in agreement with experiment [1]. We interpret these images in terms of the time evolution of the quantum phase of the qubit state and show that they can be used to probe dephasing mechanisms in the qubit. [1] D. M. Berns et al., Nature 455, 51 (2008). [2] M. S. Rudner et al., Phys. Rev. Lett. 101, 190502 (2008)

3:42PM L17.00007 Simultaneous cooling of an artificial atom and its neighboring quantum system. JIANQIANG YOU, Fudan University & RIKEN, YU-XI LIU, RIKEN, FRANCO NORI, University of Michigan & RIKEN — We propose an approach for cooling both an artificial atom (e.g., a flux qubit) and its neighboring quantum system, the latter modeled by either a quantum two-level system or a quantum resonator. The flux qubit is cooled by manipulating its states, following an inverse process of state population inversion, and then the qubit is switched on to resonantly interact with the neighboring quantum system. By repeating these steps, the two subsystems can be simultaneously cooled. Our results show that this cooling is robust and effective, irrespective of the chosen quantum systems connected to the qubit.

3:54PM L17.00008 Chirped nonlinear cavity for digital quantum state readout without switching. OFER NAAMAN, QNL, UC Berkeley, JOSÉ AUMENTADO, NIST, Boulder, LAZAR FRIEDLAND, Racah Institute of Physics, Hebrew University, Jerusalem, Israel, JONATHAN WURTELE, Department of Physics, University of California, Berkeley, IRFAN SIDDIQI, QNL, UC Berkeley — We observe a new phase-locking effect in a high-Q cavity embedding a Josephson junction driven with a chirped microwave signal. Above a critical drive amplitude, the cavity phase-locks to the drive and its oscillation amplitude grows with time. Below threshold, the cavity dephases from the drive and its amplitude remains small. The transition to phase-locking is associated with a sharp threshold sensitive to the junction IO, and can be used for digital detection of quantum states. This detector smoothly evolves into one oscillation state or the other without relying on any switching process.

4:06PM L17.00009 Lumped-element microwave resonant circuit with a dc SQUID. M.P. DEFEO, C. SONC, T.W. HEITMANN, K. YU, B.L.T. PLOURDE, Syracuse University, R. MCDERMOTT, University of Wisconsin — We have fabricated lumped-element microwave resonant circuits consisting of a dc SQUID shunted with a capacitor formed from superconducting layers. Adjusting the SQUID bias conditions changes its Josephson inductance, thus varying the resonant frequency. We discuss the possibility of time-domain monitoring of the oscillations in these circuits and their potential use in a new readout scheme for superconducting qubits.

4:18PM L17.00010 Qubit decoherence due to a Josephson bifurcation amplifier trapped in one of... FRANK WILHELM, IOANA SERBAN, University of Waterloo, MARK DYKMAN, Michigan State University — We investigate the relaxation of a superconducting flux qubit for the case when its detector, the Josephson bifurcation amplifier, remains latched in one of its two (meta)stable states. We observe a qualitatively different behavior for the two different attractors, and interpret the result as the combined effect of the amplitude of the detector’s response to external driving and the effective curvature of the detector’s basins of attraction in a rotating frame, in the proximity of the stable points. We address the question of the proper version of detailed balance for the qubit.

1Work supported in parts by NSERC and NSF
4:30PM L17.00011 Parametric Resonators for Quantum Information Applications, C.M. WILSON, M. SANDBERG, F. PERRSON, I. HOI, G. JOHANSSON, V. SHUMEIKO, P. DELSING, Chalmers University, T. DUTY, U. Queensland — We have fabricated and characterized tunable superconducting transmission line resonators. To change the resonance frequency, we modify the boundary condition at one end of the resonator through the tunable Josephson inductance of a SQUID. We demonstrate a large tuning range, high quality factors and that we can change the frequency of a few-photon field on a time scale orders of magnitude faster than the photon lifetime. When parametrically pumped at twice their resonance frequency, the devices can act as parametric amplifiers. When pumped strongly, a threshold is crossed where the resonators oscillate spontaneously. Within this regime of parametric oscillations, the devices can exist in a variety of dynamical states. We observe a rich pattern in the dynamics of switching between these states. We study the possibility of using this dynamical bifurcation for qubit readout. Finally, recent theoretical work has suggested that it may be easier to observe dynamical tunneling in this system than in the Duffing oscillator.

4:42PM L17.00012 The effects of higher-harmonic mode coupling in quarter-wave SQUID parametric amplifiers, MINHYEA LEE, LAFE SPIETZ, JOSE AUMENTADO, National Institute of Standards and Technology — Recent interest in quarter-wave SQUID-based parametric amplifiers has motivated concerns regarding the coupling of higher harmonic modes to the operating frequency mode. We will present experiments in which the harmonic mode coupling is attempted to measure. We will also discuss the effect of higher mode coupling on noise performance and gain, focusing on whether this mode coupling limits practical amplifier performance.

4:54PM L17.00013 Nonlinear dissipative filters for measurement protection on superconducting qubits1, POL FORN-DIAZ, RAYMOND SCHOUTEN, KEES HARMANS, HANS MOOIJ, TU Delft. Kavli Institute of Nanoscience — Measurements on superconducting qubits require the system to be well isolated from noise sources if its quantum state is not being accessed. This ensures that decoherence induced by the measurement apparatus is minimized. The need to have slow (sub-GHz) and fast (GHz) lines to measure and control the state of the qubit is difficult to combine with the requirement to attenuate the noise over a broad spectral range. To overcome this problem, we have built a new type of non-linear coaxial copper powder filter with a Josephson junction in its inside. The junction in the filter acts as a shorting switch. For low frequencies, the junction acts as a shortcut to ground, and high frequencies are absorbed in the metallic powder. The Josephson junction critical current is taken such that when sending a pulse to probe the measurement device (a DC SQUID in our case), the junction in the filter switches to the voltage state, thus reaching the SQUID to perform the measurement. A minimum noise suppression of 40 dB is obtained, while allowing ns pulses to be transported.

5:06PM L17.00014 Development of a Microwave Resonator for Qubit Read-out1, ZAEILL KIM, V. ZARETSKEY, Department of Physics, University of Maryland, K. D. OSBORN, Laboratory for Physical Sciences, F. C. WELSTOOD, IQI, CNAM, Department of Physics, University of Maryland, B. S. PALMER, Laboratory for Physical Sciences — We have designed and fabricated a “lumped-element” thin-film superconducting Al microwave resonator on sapphire to be used to read out a Cooper-pair box. The resonator consists of a meandering inductor and an interdigitated capacitor coupled to a transmission line. At T=30 mK and on resonance at 5.578 GHz, the transmission through the transmission line decreases by 15 dB and the loaded quality factor is 60,000. We have studied the temperature dependence of our resonator at temperatures as high as 500 mK and compared it to the Mattis-Bardeen theory. Coupling of this resonator to a Cooper-pair box qubit will be discussed.

5:18PM L17.00015 Resolving Vacuum Fluctuations in an Electrical Circuit by Measuring the Lamb Shift, ANDREAS FRAGNER, MARTIN GOPPL, ETH Zurich, ALEXANDRE BLAIS, Universite de Sherbrooke, ANDREAS WALLRAFF, ETH Zurich, ETH QUANTUM DEVICE TEAM — Quantum theory predicts that empty space is not truly empty. Even in the absence of any particles or radiation, in pure vacuum, virtual particles are constantly created and annihilated. In an electromagnetic field, the presence of virtual photons manifests itself as a small renormalization of the energy of a quantum system, known as the Lamb shift. We present an experimental observation of the Lamb shift in a solid-state system. The strong dispersive coupling of a superconducting electronic circuit acting as a quantum bit (qubit) to the vacuum field in a transmission-line resonator leads to measurable Lamb shifts of up to 1.4% of the qubit transition frequency. The qubit is also observed to couple more strongly to the vacuum field than to a single photon inside the cavity, an effect that is explained by taking into account the limited anharmonicity of the higher excited qubit states.

5:30PM L18.00001 Recent Advances in X-Ray Free Electron Lasers1, KWANG-JE KIM, Argonne National Laboratory — X-ray free electron lasers(FELs) are undergoing an exciting development. They will soon become a reality with the commissioning of the LCLS in early next year, soon followed by Spring 8 X-FEL and the European XFEL at Hamburg. Intense, coherent pulses of x-rays from these machines will permit exploration of the atomic world with spatial and temporal precisions hitherto not feasible. After these first generation x-ray FELs based on self-amplified spontaneous emission (SASE) in a single pass high-gain system, the next generation devices for higher performance and/or smaller and lower cost are under various stages of development. In the soft x-ray region, seeded FELs with high harmonic generated (HHG) laser input will produce coherent output in a shorter wavelength region. The x-ray FEL oscillator (XFELO) provides ultra-narrow spectral resolution. The XFELO employs optical cavity formed by Bragg reflectors, delivering temporally and spatially coherent hard x-rays, with meV spectral resolution. Its peak spectral brightness is similar to but the average spectral brightness is about five orders of magnitudes higher than LCLS.

5:42PM L17.00016 The effects of higher-harmonic mode coupling in quarter-wave SQUID parametric amplifiers, MINHYEA LEE, LAFE SPIETZ, JOSE AUMENTADO, National Institute of Standards and Technology — Recent interest in quarter-wave SQUID-based parametric amplifiers has motivated concerns regarding the coupling of higher harmonic modes to the operating frequency mode. We will present experiments in which the harmonic mode coupling is attempted to measure. We will also discuss the effect of higher mode coupling on noise performance and gain, focusing on whether this mode coupling limits practical amplifier performance.

5:54PM L17.00017 Nonlinear dissipative filters for measurement protection on superconducting qubits1, POL FORN-DIAZ, RAYMOND SCHOUTEN, KEES HARMANS, HANS MOOIJ, TU Delft. Kavli Institute of Nanoscience — Measurements on superconducting qubits require the system to be well isolated from noise sources if its quantum state is not being accessed. This ensures that decoherence induced by the measurement apparatus is minimized. The need to have slow (sub-GHz) and fast (GHz) lines to measure and control the state of the qubit is difficult to combine with the requirement to attenuate the noise over a broad spectral range. To overcome this problem, we have built a new type of non-linear coaxial copper powder filter with a Josephson junction in its inside. The junction in the filter acts as a shorting switch. For low frequencies, the junction acts as a shortcut to ground, and high frequencies are absorbed in the metallic powder. The Josephson junction critical current is taken such that when sending a pulse to probe the measurement device (a DC SQUID in our case), the junction in the filter switches to the voltage state, thus reaching the SQUID to perform the measurement. A minimum noise suppression of 40 dB is obtained, while allowing ns pulses to be transported.

6:06PM L17.00018 Development of a Microwave Resonator for Qubit Read-out1, ZAEILL KIM, V. ZARETSKEY, Department of Physics, University of Maryland, K. D. OSBORN, Laboratory for Physical Sciences, F. C. WELSTOOD, IQI, CNAM, Department of Physics, University of Maryland, B. S. PALMER, Laboratory for Physical Sciences — We have designed and fabricated a “lumped-element” thin-film superconducting Al microwave resonator on sapphire to be used to read out a Cooper-pair box. The resonator consists of a meandering inductor and an interdigitated capacitor coupled to a transmission line. At T=30 mK and on resonance at 5.578 GHz, the transmission through the transmission line decreases by 15 dB and the loaded quality factor is 60,000. We have studied the temperature dependence of our resonator at temperatures as high as 500 mK and compared it to the Mattis-Bardeen theory. Coupling of this resonator to a Cooper-pair box qubit will be discussed.

6:18PM L17.00019 Resolving Vacuum Fluctuations in an Electrical Circuit by Measuring the Lamb Shift, ANDREAS FRAGNER, MARTIN GOPPL, ETH Zurich, ALEXANDRE BLAIS, Universite de Sherbrooke, ANDREAS WALLRAFF, ETH Zurich, ETH QUANTUM DEVICE TEAM — Quantum theory predicts that empty space is not truly empty. Even in the absence of any particles or radiation, in pure vacuum, virtual particles are constantly created and annihilated. In an electromagnetic field, the presence of virtual photons manifests itself as a small renormalization of the energy of a quantum system, known as the Lamb shift. We present an experimental observation of the Lamb shift in a solid-state system. The strong dispersive coupling of a superconducting electronic circuit acting as a quantum bit (qubit) to the vacuum field in a transmission-line resonator leads to measurable Lamb shifts of up to 1.4% of the qubit transition frequency. The qubit is also observed to couple more strongly to the vacuum field than to a single photon inside the cavity, an effect that is explained by taking into account the limited anharmonicity of the higher excited qubit states.

Tuesday, March 17, 2009 2:30PM - 5:30PM – Session L18 DPB: Advanced Techniques in Acceleration and Coherent Radiation 319

2:30PM L18.00001 Recent Advances in X-Ray Free Electron Lasers1, KWANG-JE KIM, Argonne National Laboratory — X-ray free electron lasers(FELs) are undergoing an exciting development. They will soon become a reality with the commissioning of the LCLS in early next year, soon followed by Spring 8 X-FEL and the European XFEL at Hamburg. Intense, coherent pulses of x-rays from these machines will permit exploration of the atomic world with spatial and temporal precisions hitherto not feasible. After these first generation x-ray FELs based on self-amplified spontaneous emission (SASE) in a single pass high-gain system, the next generation devices for higher performance and/or smaller and lower cost are under various stages of development. In the soft x-ray region, seeded FELs with high harmonic generated (HHG) laser input will produce coherent output in a shorter system. Drastic improvement in hard x-ray region is possible with new types of electron injectors producing electron beams with an order of magnitude smaller emittance. Hard x-ray FELs can be built with an order of magnitude smaller electron energy and thus with a significant savings in the cost. The Spring-8 FEL is a first step in this direction. Novel types of FELs are possible; ultra-short SASE providing sub-fs time-resolution and x-ray FEL oscillator (XFELO) providing ultra-narrow spectral resolution. The XFELO employs optical cavity formed by Bragg reflectors, delivering temporally and spatially coherent hard x-rays, with meV spectral resolution. Its peak spectral brightness is similar to but the average spectral brightness is about five orders of magnitudes higher than LCLS.

3:06PM L18.00002 Novel Techniques for the Generation of Ultrashort Attosecond Pulses of Coherent Radiation1, ALEXANDER ZHOLENTS, Lawrence Berkeley National Laboratory — Revealing the laws of Nature often require developing unique experimental tools. In this talk I will discuss new tools that will enable probing of matter with attosecond time resolution and Angstrom spatial resolution. Their emergence is largely due to the spectacular progress in development of x-ray free electron lasers and similar progress in generation of the ultra-short light pulses in optics.
3:42PM L18.00003 Photonic Band-gap Materials for Particle Acceleration, GENNADY SHVETS, UT Austin — No abstract available.

4:18PM L18.00004 Emerging Long-Wavelength Coherent Light Sources—from the infrared to soft X-rays¹, JOSEPH BISOGNANO, SRC-University of Wisconsin — The theory and techniques of accelerator-based coherent light sources will be discussed. Application of these ideas to the design of user facilities from the IR to soft X-rays will be presented, including world-wide initiatives for next generation light source R&D and construction at these longer wavelengths.

Tuesday, March 17, 2009 2:30PM - 5:30PM — Session L19 DMP DPOLY: Focus Session: Ionically Gated and Conventional OFETs and Related Devices 320

2:30PM L19.00001 All-Printed Low Voltage Operation Polymer Transistors and Circuits Based on Ion Gel Gate Dielectrics, YU XIA, JEONG HO CHO, MINGJING HA, Department of Chemical Engineering and Materials Science, University of Minnesota, MICHAEL REENN, Optomec, Inc, C. FRISBIE, Department of Chemical Engineering and Materials Science, University of Minnesota, OPTOMEC, INC COLLABORATION — A key challenge in the development of organic electronics lies in the realization of high quality devices with low cost. In this presentation, we demonstrate high performance polymer transistors and circuits with all components fabricated by a commercial aerosol jet printing technique. Printing saves the device manufacturing cost through its simple procedure, fast speed, high throughput and low waste of materials. Furthermore, by employing a specially designed ion gel as the gate dielectric material, ultra-high density carrier accumulation (> 10¹⁴ cm⁻²) can be achieved in the transistor channel, which results in an exceptionally large transconductance of 10 µS/µm. Our typical transistors have mobility higher than 1cm²/Vs and frequency response up to 10 kHz. Inverters, NAND and NOR logic circuits and ring oscillators have been realized as well, with low operation voltage, fast speed and high gain. In addition, the high polarizability of the gate dielectric allows us to print the gate electrode of each single transistor along with its source and drain electrodes at the same time in a coplanar architecture, which significantly simplifies the fabrication procedure.

2:42PM L19.00002 Non-volatile Ferroelectric Poly(vinylidene fluoride-co-trifluoroethylene) Memory based on Single Crystalline Triisopropylisilyl ethynyl Pentacene Field Effect Transistor², SEOK JU KANG, INSUNG BAE, YOUN JUNG PARK, TAE HO PARK, JINWOO SUNG, CHEOLMIN PARK, Yonsei university — We develop a new type of non-volatile ferroelectric poly(vinylidene fluoride-co-trifluoroethylene) (P(VDF-TrFE)) memory based on Organic Thin Film Transistor (OTFT) with single crystal Triisopropylisilyl ethynyl pentacene (TIPS-PEN) active layer. A bottom gate OTFT was fabricated with thin P(VDF-TrFE) film gate insulator on which 1D ribbon type single crystal TIPS-PEN grown via solvent exchange method was positioned between Au source and drain electrode. As consequences a memory device exhibits substantially stable source-drain current modulation with the hysteresis ON/OFF ratio larger than 10³, superior to a ferroelectric P(VDF-TrFE) OTFT with vacuum evaporated pentacene layer. Data retention longer than 5x10⁶ seconds was achieved in ambient condition by incorporating an interlayer between gate electrode and P(VDF-TrFE) thin film. The device is environmentally stable for more than 40 days without additional passivation.

2:54PM L19.00003 Polymer Electrolyte Gated Inorganic Transistors, ANOOP SINGH DHOOIT, Cavendish Laboratory, University of Cambridge, CASEY ISRAEL, XAVIER MOYA, STUART WIMBUSH, Department of Materials Science and Metallurgy, University of Cambridge, TIM BENSEMAN, Cavendish Laboratory, University of Cambridge, JUDITH MACMANUS-DRISCOLL, Department of Materials Science and Metallurgy, University of Cambridge, JOHN COOPER, Cavendish Laboratory, University of Cambridge, NEIL MATHUR, Department of Materials Science and Metallurgy, University of Cambridge, RICHARD FRIEND, Cavendish Laboratory, University of Cambridge — Electric field-induced charge at the interface between gate dielectric and semiconductor is the basis of current semiconductor technology. We report that it is possible to use polymer electrolyte gate inorganic materials, and to achieve field-induced ‘doping’ equivalent to a full surface coverage of charged ions per unit cell area. Very high field-induced carrier densities, ~10¹⁵ cm⁻², in the transistor channel of La₉0₅Ca₁₅₀₇₋ₓMnO₃ devices enable modulation of the Curie temperature of over 30 K. We have also used electrolyte gating of the superconductor YBa₂Cu₃O₇₋ₓ to modulate the onset of superconductivity. This creates an exciting opportunity for use of the electrolyte as gate dielectric in a wide variety of inorganic materials to explore formerly inaccessible band-filling regimes without the need for chemical substitution and additional disorder.

3:06PM L19.00004 Employing ‘Liquid Gap’ Transistors to Examine the Mobility-Carrier Density Relation in Polymer and Single Crystal Organic Semiconductors¹, DANIEL FRISBIE, University of Minnesota — It is generally known that the carrier mobility in organic semiconductors can depend on carrier density, but the precise relationship hinges on the degree of structural order and the dielectric polarizability at the organic/dielectric interface. We have fabricated both single crystal and polymer transistors using the PDMS stamp approach pioneered by Podzorov and Rogers [1], where we have replaced the usual ‘air gap’ in these structures with liquids having different dielectric constants. This structure allows us to examine transport in single crystals and polymer semiconductors as a function of tunable dielectric constant and also charge density. We find striking differences in transport behavior for organic single crystals versus polymer semiconductor films using these liquid dielectric transistors. For organic single crystals such as rubrene, the carrier mobility does not seem to be a function of charge density but does strongly depend on the liquid dielectric constant, in keeping with previous results reported by Morpurgo [2] on the effects of dielectric polarizability. For polymer semiconductors, the effect of charge density is overwhelming; there is a strong increase in charge mobility with increasing carrier concentration, following a power law. These results are already largely known, but the ‘liquid gap’ transistors provide a convenient testbed for examining these effects side-by-side for different materials in the same device. We will describe the device fabrication and the nature of our results, as well as discuss the origins of the very different behavior for single crystals versus polymer semiconductor films. 1) Sundar, V.C., et al. Science 303 (2004) 1643. 2) Hulea, I. N., et al. Nature Mater. 5 (2006) 982.

properties of the semiconductor materials as well as their interfaces with contacts and substrates. These devices can be operated in aqueous environment as efficient ion-to-electron converters, thus providing an interface between the worlds of biology and electronics and also a unique platform for the study of organic/organic and organic/metal interfaces in liquids. Using photolithography, surface engineering and micro-fluidics we have developed several technique to fabricate OECTs having different geometries. This allows us to study the basic electronic properties and the sensing response of devices in order to understand their mechanism of operation. We studied how the dimensions of the transistors (in particular on the gate/channel area ratio) and the gate electrode material (metal or polymer) can be used to tune the device response for sensing of different species. The effect of the electrolyte on device response was evaluated studying transistors in aqueous electrolytes and ionic liquids. The detection limit of OECTs based sensors having different geometry, was analyzed for hydrogen peroxide, a species involved in glucose sensing.

3:42PM L19.00005 Organic electrochemical transistors for sensing applications. FABIO CICORA1,2, SANG YOON YANG, JOHNAH A. DEFRANCO, GEORGE G. MALLIARAS, MSE/Cornell University, ORGANIC ELECTRONICS LABORATORY CORNELL TEAM — The application of organic semiconductor devices to chemical and biological sensors seems to be a great fit. A promising approach towards organic-based sensors involves the use of organic electrochemical transistors (OECTs). These devices can be operated in aqueous environment as efficient ion-to-electron converters, thus providing an interface between the worlds of biology and electronics and also a unique platform for the study of organic/organic and organic/metal interfaces in liquids. Using photolithography, surface engineering and micro-fluidics we have developed several technique to fabricate OECTs having different geometries. This allows us to study the basic electronic properties and the sensing response of devices in order to understand their mechanism of operation. We studied how the dimensions of the transistors (in particular on the gate/channel area ratio) and the gate electrode material (metal or polymer) can be used to tune the device response for sensing of different species. The effect of the electrolyte on device response was evaluated studying transistors in aqueous electrolytes and ionic liquids. The detection limit of OECTs based sensors having different geometry, was analyzed for hydrogen peroxide, a species involved in glucose sensing.

3:54PM L19.00006 Contact resistance and lifetime of organic thin film transistors. GVIDO BRATINA, ANDRÁZ PETROVIC, University of Nova Gorica — We have used ed electric charge transport measurements coupled to Kelvin force probe microscopy of pentacene organic thin film transistors (OTFT’s) to monitor the evolution of contact resistance as a function of time of exposure to ambient air. Or results demonstrate that exposure of OTFTs to ambient air for extended periods of time, results in two competitive mechanisms that are responsible for observed variation in drain-current. Initially, relatively fast oxygen doping through electronegativity-related creation of holes increases the carrier concentration and therefore increases the drain current. Slower, and persistent mechanism of water diffusion in the pentacene layer induces dipole-charge carrier interactions through the creation of energetic disorder. This results in long-term irreversible reduction of drain current.

4:06PM L19.00007 Controlling charge carrier injection in solution processed pentacene transistors by molecular engineering of the electrodes, SANGAMESHWAR RAO SAUDARI, Department of Materials Engineering, University of Pennsylvania, CHERIE KAGAN, Department of Electrical and Systems Engineering, University of Pennsylvania — We present the device performance of pentacene transistors fabricated from a solution deposited precursor. The bottom-contact pentacene transistors are fabricated by spin-coating N-sulfinylacetamidopentacene precursor followed by thermal conversion of the precursor into pentacene. Hole mobilities >0.1 cm2/Vs and Ion/Ioff > 105 are repeatedly achieved by this process. The metal-semiconductor interface in organic transistors plays a very important role in charge carrier injection and the overall device performance. Here we have treated the metal surface with self-assembled monolayers having different head and tail chemistries prior to pentacene precursor deposition to tailor the interfacial electronic properties. We correlate monolayer chemistry with device contact resistance and threshold voltage. These studies are used to fabricate devices with high mobility, high Ion/Ioff and low subthreshold swing. Device hysteresis and stability issues will also be presented.

4:18PM L19.00008 Infrared and Electro-Optic Properties of TIPS-Pentacene1, E.G. BITTLE, J.W. BRILL, J.E. ANTHONY, University of Kentucky — We will discuss new measurements of the infrared and electro-optic properties of thin crystals of trisopropylsilylhexylpentacene (TIPS) pentacene. As with THz studies of this class of materials, crystalline films were grown from saturated tetrahydrofuran solutions on a gold electrode mask. Square wave voltages were applied to the electrical contacts on the sample as well as a gate electrode below the sample, through an oxide dielectric. Changes in phonon frequencies were studied as functions of voltage, position between contacts, and frequency of applied voltage. The results are interpreted in terms of charge diffusion through the TIPS-pentacene crystals.

4:30PM L19.00009 Crossover from recombination limited charge transport to mobility restricted charge transport in organic LED1, VLADIMIR PRIGODIN, ARTHUR EPSTEIN, Physics Department, Ohio State University, Columbus, OH 43210-1117 — The model of bipolar charge transport in organic semiconductors where the current solely is provided by e-h recombination (LEDs structures) is studied [1]. We have shown that depending on recombination rate there are two basic regimes of charge transport. For recombination rate above the critical value the current is space charge limited and the current as a function of recombination rate decreases with increasing the recombination rate. At recombination rate below the critical value the recombination takes place over the whole sample volume of sample and as a result the current is only contact limited. As a function of recombination rate the current increases with increasing recombination rate. Critical value for recombination rate depends on the thickness of sample, applied voltage and on both the hole and electron mobilities. [1] J.D. Bergeson et al., Phys. Rev. Lett. 100, 067201 (2008).

4:42PM L19.00010 Interface and bulk controlled charge transport in Pd/CuPc/Pd sandwich devices. CORNELIU COLESNICU, IVAN SCHULLER, University of California San Diego, La Jolla, CA 92093 — We present transport measurements in thin film devices of copper phthalocyanine sandwiched between palladium electrodes. The devices were grown in-situ using molecular beam deposition of phthalocyanine films with the thickness ranging between 30 and 600 nanometers. The I-V characteristics as a function of temperature and thickness exhibit two distinct regions - a low voltage Ohmic region with current proportional to the voltage and a high voltage region with a power law dependence. At low voltages the current shows an inverse power dependence on thickness, I ~ thickness^-n, with the exponent n > 2, suggesting that both the interfaces and the film control the transport mechanism. The temperature dependence of the current does not show a clear activated behavior, supporting the same conclusion. On the other hand, at high voltages the power-law exponent of the I-V decreases at lower thickness for constant temperature implying also that both the interfaces and the film may control the transport. Work supported by AFOSR.

4:54PM L19.00011 RC Transmission Line Characterization of Organic Semiconductors1, DANIEL LENSKI, ADRIAN SOUTHARD, MICHAEL S. FUHRER, Department of Physics and Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742, USA — We have characterized thin films of organic semiconductors (pentacene and poly-3-hexylthiophene) using a 3-contact transmission line configuration, in which an AC voltage is applied between the thin film and the gate, and the phase and magnitude of the current are measured. We compare the results with those obtained from simultaneous DC measurement, and find good agreement in the sheet resistance in the ON state measured using the DC and transmission line techniques, indicating that the transmission line technique is useful for obtaining sheet resistance and mobility in the ON state. Near threshold, or at high frequencies and electric fields, we observe systematic deviations of the AC impedance from the DC values. We discuss these deviations in terms of the of frequency-dependent length scale probed by the transmission line technique, and how these measurements can shed light on the properties of the semiconductor materials as well as their interfaces with contacts and substrates.

5:06PM L19.00012 Organic field effect transistors having single wall carbon nanotubes electrodes  
FABIO CICOIRA1, MSE/Cornell University, CARLA M. AGUIRRE, PATRICK DESJARDINS, Genie Physique /Polytechnique Montreal, RICHARD MARTEL, Chemie/Universite de Montreal — Single Wall Carbon Nanotubes (SWCNTs) are of great interest as electrode materials in Organic Field Effect Transistors (OFETs). Thanks to their field emission properties, SWCNTs electrodes, in principle, are able to inject both electrons and holes into organics with low injection barriers, promoting tunneling injection. We present well recent present result on the electrical properties of OFETs using hairy SWCNTs electrodes (see Figure 1), where the CNTs are attached on the substrate by means of metallic Ti contact pads. Devices with SWCNTs electrodes show improved injection characteristics compared with devices using conventional metallic electrodes.

1 Also at CNR/IFN, Trento (Italy)

5:18PM L19.00013 Electrospun tin oxide/poly(3-hexylthiophene) nanofiber p-n diodes  
NICHOLAS PINTO, University of Puerto Rico - Humacao — Electrospinning is a simple technique used to prepare nanofibers of various materials, organic and inorganic. Some advantages of this method is that the nanofibers are orders of magnitude longer than that obtained via conventional means and it is easy to isolate individual nanofibers. We have used this technique to make nanoribbons of n-doped tin oxide (SnO2) and to make nanofibers of p-doped region-regular poly(3hexylthiophene) (P3HT) in air and within seconds. Several p–n junction nanodiodes were fabricated by crossing individual nanofibers of P3HT with individual nanoribbons of SnO2 during the electrospinning process and electrically characterized them at room temperature. The SnO2 nanoribbons were fabricated first by electrospinning a precursor of SnO2 and then sintering them at 700 C to convert it to SnO2 before crossing them with P3HT nanofibers. The devices show clear evidence of rectification in air and in vacuum with a turn-on voltage of ~0.4 V and with rectification ratios ~10. Exposure of the diode to UV light increases the on-state current, while removing the light restores the device to its original state making it suitable as a reusable UV light sensor as well.

3:06PM L20.00002 Patterns on the iridescent beetle, Chrysina gloriosa  
JUNG OK PARK, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology, VIVEK SHARMA, Department of Mechanical Engineering, Massachusetts Institute of Technology, MATIJA CRNE, School of Chemistry and Biochemistry, Georgia Institute of Technology, MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology — The brilliant metallic color of a beetle Chrysina gloriosa has been known to occur due to selective reflectance from a cholesteric structure on the exoskeleton. The surface also appears to have hexagonally packed structures. Crystallographic concepts and Voronoï analysis were used to determine the degree of order in different regions of the beetle. Along the hexagons in the Voronoï diagram, many clustered pentagons and heptagons were observed due to the surface curvature, the number of pentagons was found to be higher than the number of heptagons. The cells appear yellow in the center surrounded by a green region with a yellow edge. Confocal microscopy was used to image the underlying structure, which was found to consist of concentric arcs on a surface of a shallow cone. The observed structures resemble the defects on a cholesteric phase with a free surface, and provide an interesting explanation of structural color development in beetles, along with inspiration for the design of chiral photonic structures.

3:18PM L20.00003 Frustrated self-assembly of dendron and dendrimer-based supramolecular liquid crystals  
RAFFAELE MEZZENGA, NADIA CANILHO, University of Fribourg, Switzerland, JANNE RUOKOLAINEN, Helsinki University of Technology, Finland, EDIS KASEMI, DIETER SCHLUETER, ETHZ, Switzerland, WON BO LEE, GLENN FREDRICKSON, UCSB, USA — A new inverted topological configuration is demonstrated both experimentally and theoretically for self-assembled dendron and dendrimer-based supramolecular liquid crystals in which the dendrons/dendrimers occupy the continuous domain and the ionically attached pendant chains are confined in discrete domains. All previous studies on dendrimer and dendron-based liquid crystals have reported normal liquid crystalle configurations in which the dendritic templates occupy discrete domains (in spherical or columnar phases) or continuous struts (in bicontinuous cubic phases), while the pendant chains occupy the continuous space-filling domain. These surprising results mandate a re-examination of the packing mechanisms for this important class of materials and open new routes to unique nanostructures of possible use in existing and emerging technologies. References: R. Mezzenga, J. Ruokolainen, N. Caniello, E. Kasemi, D.A. Schlüter, W.B. Lee, G. H. Fredrickson, Soft Matter, in press (DOI: 10.1039/b814972k)

3:30PM L20.00004 Hydrogen-Bonding Assisted Supramolecular Self-Assembly of Double Dis-otic Supermolecules  
JIANGJUN MIAO, LEI ZHU, Uconn — Symmetric double disotic supermolecules based on porphine (Py) and triphenylene (Tp), Py(Tp)4, have been successfully synthesized via PyBOP-catalyzed amidization reactions. The Tp moieties had either C5- or C12-arms, and the spacer linking between the central Py and peripheral Tp was either C8 or C10. Thermal properties of these supermolecules were studied by differential scanning calorimetry, and self-assembled crystalline and/or liquid crystalline textures were confirmed by polarized optical microscopy. For samples with C5-arms in Tp, only a crystal-melt transition was observed. X-ray diffraction (XRD) on shear-oriented samples showed that Py was crystalline and Tp formed columnar liquid crystal. For samples with C12-arms in Tp, sequential crystal-liquid crystal-isotropic melt transitions were observed. XRD results indicated that the crystalline unit cells were orthorhombic for all samples, and amide hydrogen-bonding was responsible for their supramolecular self-assembly.

3:42PM L20.00005 Glassy correlations in nematic elastomers  
BING LU, PAUL GOLDBART, University of Illinois at Urbana-Champaign, XIAOMING MAO, University of Pennsylvania — We address the physical properties of an isotropic melt or solution of nematogenic polymers that is then cross-linked beyond the vulcanization point. To do this, we construct a replica Landau theory involving a coupled pair of order—parameter fields: one describing vulcanization, the other describing local nematic order. Thermal nematic fluctuations, present at the time of cross-linking, are trapped by cross- linking into the vulcanized network. The resulting glassy nematic fluctuations are analyzed in the Gaussian approximation in two regimes. When the localization length is shorter than the thermal nematic correlation length, the nematic correlations are well captured as glassy correlations. In the opposite regime, fluctuations in the positions of the localized polymers partially wash out the glassy nematic correlations.
3:54PM L20.00006 Orientation distribution and process modeling of thermotropic liquid crystalline copolyester (TLCP) injection-moldings1, ROBERT BUBECK, Michigan Molecular Institute. JUN FANG, WESLEY BURGHARDT, Northwestern University, SUSAN BURGARD, Michigan Molecular Institute, DANIEL FISCHER, NIST — The influence of melt processing conditions upon mechanical properties and degrees of compound molecular orientation have been thoroughly studied for a series of well-defined injection molded samples fabricated from VECTRA (TM) A950 and 4,4'-dihydroxy-a-methylstilbene TLCPs. Fracture and tensile data were correlated with processing conditions, orientation, and molecular weight. Mechanical properties for both TLCPs were found to follow a “universal” Anisotropy Factor (AF) associated with the bimodal orientation states in the plaques determined from 2-D WAXS. Surface orientations were globally surveyed using Attenuated Total Reflectance – Fourier Transform Infrared (ATR-FTIR) spectroscopy and C K edge Near-Edge X-ray Absorption Fine Structure (NEXAFS). The results derived from the two spectroscopy techniques confirmed each other well. These results along with those from 2-D WAXS in transmission were compared with the results of process modeling using a commercial program, MOLDFLOW(TM). The agreement between model predictions and the measured orientation states was gratifyingly good.

1Research is supported by NSF Grant Nos. 0521771 and 0521823.

4:06PM L20.00007 In Situ X-ray Scattering Measurements and Polydomain Simulations of Molecular Orientation Development during Injection Molding of Liquid Crystalline Polymers. JUN FANG, WESLEY BURGHARDT, Northwestern University, ROBERT BUBECK, Michigan Molecular Institute — We report on a coordinated experimental/computational study of injection molding of commercial thermotropic LCPs. In situ synchrotron x-ray scattering, combined with a customized injection molding apparatus, is used to track development of molecular orientation during the mold filling process for a commercial LCP, Vectra A950, in two simple plaque mold geometries: square and T-shaped. Use of high brilliance undulator radiation at the Advanced Photon Source, coupled with a high speed CCD detector provides sufficient time resolution (~12 frames per second) to resolve the transient orientation dynamics during and following mold filling. In addition to in-situ scattering measurements, ex-situ 2-D wide angle X-ray scattering measurements are conducted on the same injection molded plaques. The experiments are complemented by process simulations performed using commercial mold filling software. A very close analogy between the Folgar-Tucker fiber orientation model and the Larson-Doi polydomain model for textured liquid crystalline polymers is exploited to allow for the first tests of Larson-Doi model predictions in injection molding processing.

4:18PM L20.00008 Dynamics and rheology of active polar liquid crystalline films, LUCA GIOMI, M. CRISTINA MARCHETTI, TANNIEMOLA B. LIVERPOOL — I will discuss the dynamical and rheological properties of active polar liquid crystalline films. Like active nematic films, active polar films undergo a dynamical transitions to spontaneously flowing steady states. Spontaneous flow in polar fluids is, however, always accompanied by strong concentration inhomogeneities or “banding” not seen in nematics. In addition, a spectacular property unique to polar active films is their ability to generate spontaneously oscillating and banded flows even at low activity. The oscillatory flows become increasingly complicated for strong polarity.

4:30PM L20.00009 Influence of nanorods on the properties of polymeric materials, GREGORY N. TOEPFERWEIN, ROBERT A. RIGGLEMAN, JUAN J. DE PABLO, University of Wisconsin — Nanoscopic additions, such as metallic nanoparticles or carbon nanotubes, can dramatically impact the mechanical properties of polymeric materials, such as the plateau modulus, which is intimately related to the entanglement length of the polymer. To explore the connection between nanocomposite configurations and the dynamic mechanical effects that are difficult to probe experimentally, due to challenges associated with sample preparation and particle dispersion, we have performed extensive Molecular Dynamics and Monte Carlo simulations of polymer nanocomposites with nanoparticles whose size, shape, and concentration have been varied systematically. Calculations of the entanglement network through primitive path analysis of these composites have enabled us to connect nanorod effects on the entanglement network structure and density to the system’s dynamic properties. The main outcome of our study is a better understanding of how inclusions alter entanglements and how those entanglements are magnified in macroscopic observables.

4:42PM L20.00010 Interactions between rod-like cellulose nanocrystals and xylan derivatives: A light scattering study, JAE HYUN SIM, Virginia Tech, KATRIN SCHWIKAL, THOMAS HEINZE, University of Jena, SHUPING DONG, MAREN ROMAN, ALAN ESKER, Virginia Tech — Interactions between rod-like cellulose nanocrystals and 2-hydroxypropyl-trimethylammonium (HPMA) xylan were investigated by polarized (DLS) and depolarized dynamic light scattering (DDLS). Cellulose nanocrystals were prepared by the controlled hydrolysis of black spruce pulp. Binary rod-like cellulose nanocrystal/water and ternary HPMA xylan/rod-like cellulose nanocrystal/water systems with different concentrations of cellulose nanocrystals were probed. Translational and rotational diffusion coefficients of cellulose nanocrystals in water are (4.8 ± 0.4) × 10−9 cm2/s and (526 ± 20) s−1, respectively, and calculated lengths and diameters for nanocrystals are comparable to those of cellulose whiskers from cotton. At high cellulose nanocrystal concentrations, DDLS studies in ternary systems provide translational and rotational diffusion coefficients. However, at low cellulose nanocrystal concentrations, DDLS studies of ternary systems do not yield rotational diffusion coefficients. This behavior is attributed to bridging between polymer chains that causes non-linear deviation on standard decay rate (Γ) versus scattering vector magnitude (q) plots.

4:54PM L20.00011 Polymerization-Enhanced Alignment Order in Carbon Nanotube Composites, HOWARD WANG, YAYONG LIU, NARANYAN DAS, Binghamton University, SUNY, KUNLUN HONG, GYULA ERES, DAVID URG, Oak Ridge National Laboratory — Polymer nanocomposites containing vertically aligned carbon nanotubes (VACNTs) have been synthesized via vacuum infiltration of monomers into confined VACNT arrays fabricated by in situ polymerization. The alignment order of VACNTs before and after polymerization has been quantitatively assessed using small angle neutron and x-ray scattering. The trend of continuous variation of alignment order along the height of VACNTs remains unaltered whereas the degree of order is enhanced upon polymerization. Polymerization-enhanced alignment order may assist preparing better carbon nanotube composites.

5:06PM L20.00012 Perylene diimide liquid crystals: A density functional study, JEVERSON ARANTES, Centro de Ciencias Naturais e Humanas, Universidade Federal do ABC, Santo Andre, SP, Brazil, MATHEUS LIMA, Institute of Fundamental Sciences, University of Auckland, New Zealand, GREGORY N. TOEPFERWEIN, ROBERT A. RIGGLEMAN, JUAN J. DE PABLO, University of Wisconsin, SUSAN BURGARD, Michigan Molecular Institute, DANIEL FISCHER, NIST — Perylene diimide PEBEE has been proposed, partially based on experimental observations. In this structural model, we’ve performed an ab initio calculations on the electronic structure of this material. Due to the strongly localized nature of the Oxygen atoms on the side chains, it is necessary to go beyond the standard LDA and GGA calculations. With the PBE0 approach, the electronic structure becomes in agreement with previous results. The tails of the molecular crystal not only is responsible for its structural conformation, but also can be used for tuning the electronic and optical properties of the material.

Tuesday, March 17, 2009 2:30PM - 5:30PM — Session L21 DCMP FIAP: Semiconductors: Atomic Structure and Lattices
2:30PM L21.00001 ABSTRACT HAS BEEN MOVED TO J23.00011

2:42PM L21.00002 Bonding states of Cu atoms in superionic α-Cul phase. HIROAKI OSHIHARA, KAZUO TSUMURAYA, Meiji University, Japan — The fast migration of cations in solids is used for solid state battery. Therefore the mechanism of the migration is of importance for the development of new material. The superionic conductor Cul is zinc blend-type structure at low temperature and fluorite-type at high temperature. So the bonding between Cu and I atoms has been considered to be a covalent bonding. The peak positions and the asymmetrical peaks in the pair distribution functions between the Cu-Cu and Cu-I components have been remained to be explained in an experiment and a computational studies. We investigate the electronic states of Cu using the plane-wave based density functional calculation. We evaluate the charge and bonding states with Bader decomposition method. The stability of the Cu-Cu pairs in the conductor will be discussed using their binding energies.

2:54PM L21.00003 Non-equilibrium Phonons in CaWO₄: Issues for Phonon Mediated Particle Detectors. MADELEINE MSALL, Bowdoin College, TIMOTHY HEAD, DANIEL JUMPER, Abilene Christian University — The CRESST experiment looks for evidence of dark matter particles colliding with nuclei in CaWO₄. Using cryogenic bolometers sensitive to energy deposition ~ 10 keV with a few percent accuracy, California, Los Angeles, K. BELASHCHENKO, Dep. of Physics and Astronomy, Univ. of Nebraska-Lincoln — We have computed the temperature-phase diagram of EuO alloys by combining density functional theory in the generalized-gradient approximation with Hubbard U correction on f-orbitals with the regular decomposition method. The stability of the Cu-Cu pairs in the conductor will be discussed using their binding energies.

3:06PM L21.00004 Ultrafast anisotropic strain in semiconductors measured by x-ray diffraction. D.A. WALKO, Argonne National Laboratory, SOOHEYONG LEE, Korea Research Institute of Standards and Science, E.C. LANDAHL, DePaul University, D.A. ARMS, Argonne National Laboratory — We have used time-resolved x-ray diffraction to probe the non-uniaxial properties of impulsive strains in ultrafast laser-excited III-V semiconductors. Transient shifts of x-ray rocking curves due to the strains are measured from three Bragg reflections whose scattering vectors range from perpendicular to the surface to nearly in plane. Time-dependent strain ellipsoids are then constructed, with a temporal resolution under ~150 ps. We find that the strain consists not only of a longitudinal expansion along the surface normal, but it also includes slight compression along the transverse direction. We compare measurements for GaAs and InSb; their significant differences in electron diffusion rates allow us to distinguish between lattice and electronic effects. Supported by the U.S. Department of Energy.

3:18PM L21.00005 Using DFT-based Cluster Expansions to Study Oxygen Adsorption on Platinum and Gold (111) Surfaces. SPENCER MILLER, Carnegie Mellon University — We have studied oxygen adsorption on Platinum and Gold (111) surfaces using Density Functional Theory. We have investigated the sensitization on the number of configurations we can consider through DFT through the use of two-dimensional cluster expansions on DFT data, allowing for high energy calculations for any arbitrary surface. We have used the cluster expansion to study adsorption properties and phase behavior on the surface including simulated TPD experiments and atomistic thermodynamics phase diagrams which we compare to experimental behavior.

3:30PM L21.00006 Can a re do of field theory numerically speaking help in I - E CDW curve data analysis? ANDREW BECKWITH — Density wave physics has a plethora of current versus electrical field data from experimental measurements. The author presented in his PhD dissertation a way of giving a false vacuum interpretation of how current can be measured against the magnitude of an applied electric field in laboratory conditions. This article purports to re examine the feasibility of such modeling taking into account Dr. Fred Cooper’s work on a time averaging scheme for phi to the fourth power field theory as could be applied to modified wash board potentials.

3:42PM L21.00007 Temperature-composition phase diagrams of Gd-doped EuO and EuS. JOONHEE AN, Dep. of Physics and Astronomy, Univ. of Nebraska-Lincoln, S. BARABASH, Dep. of Materials Science and Engineering, Univ. of California, Los Angeles, K. BELASHCHENKO, Dep. of Physics and Astronomy, Univ. of Nebraska-Lincoln. We have computed the temperature-phase diagram of EuO and GdO alloys by combining density functional theory in the generalized-gradient approximation with Hubbard U correction on f-orbitals with the regular cluster expansion and Monte-Carlo approach. The cluster expansion fit has been performed with varying numbers of distinct cluster types until the formal cross-validation score is minimized. Our results indicate that (i) pair interactions are relatively stronger than other cluster types, (ii) The pair terms are attractive for direct interactions between cations and repulsive for indirect interactions through anions, and (iv) the calculated convex hull is asymmetric about x=0.5, displaying more deep ground states in Eu-rich regions than in Gd-rich regions. The symmetry of the convex hull may relate relative instability of Gd-rich compounds, as was shown by previously-reported experimental difficulties to make Gd-rich compounds. A comparison with a similar binary system - sulfur replacing oxygen - is made, showing that both oxides and sulphides are dominated by deformation interaction.

3:54PM L21.00008 Low energy metastable states and immiscibility in (SiC)_{1-x}(AlN)_{x}. BENJAMIN BURTON, NIST, AXEL VAN DE WALLE, California Inst. of Technology, ALBERT DAVYDOV, NIST, VICTOR VINOGRAD, University of Frankfurt, Germany — A cluster expansion Hamiltonian was fit to VASP/PAW calculated supercell formation energies, \Delta E_I, and first principles based phase diagrams (miscibility gaps) were calculated for the wurzite-structure pseudobinary system SiC_{1-x}AlN_{x}. An unusually wide range of 3 \leq E_I \leq 125 \text{kJ/mole MX} (M= Al, Si; X = N, C) was calculated and all supercells with \Delta E_I \leq 8 \text{kJ/mole} exhibited characteristic (SiC)_{m}(AlN)_{n} crystallography, in which (SiC)_{m} indicates m SiC-double layers \perp to the hexagonal c-axis, and similarly for (AlN)_{n}. The prediction of (SiC)_{m}(AlN)_{n} low-energy metastable states, may explain why one can synthesize SiC_{1-x}AlN_{x} films, or single crystals of arbitrary bulk composition, in spite of the very strong tendency toward immiscibility. Specifically, one expects that metastable films or single crystals will be dominated by a disordered stacking of SiC- and AlN-double layers.

4:06PM L21.00009 Alloy Stabilized Wurtzite Ground State Structures of Zinc-Blende Semiconducting Compounds. HONGJUN XIAO, SUHUAI WEI, National Renewable Energy Laboratory, SHIYOU CHEN, XINGAO GONG, Surface Science Laboratory and Department of Physics, Fudan University, China — Although the ground state structures of zinc-blende (ZB) alloys have been extensively studied, the knowledge of the ground state structures of wurtzite (WZ) alloys remains incomplete. Here, the ground state structures of the A_B_{1-x}C WZ alloys with \( x = 0, 0.25, 0.5, \) and 0.75 are revealed by a ground state search using the valence-force field model and density-functional theory total energy calculations. It is shown that the ground state WZ alloy always has a lower strain energy and formation enthalpy than the corresponding ZB alloy. Therefore, we propose that the WZ phase can be stabilized through alloying. This novel idea is supported by the fact that the WZ AlP_{0.25}Sb_{0.5}, AlP_{0.75}Sb_{0.25}, ZnS_{0.5}Te_{0.5}, and ZnS_{0.75}Te_{0.25} alloys in the lowest energy structures are more stable than the corresponding ZB alloys. To our best knowledge, this is the first example where the alloy adopts a structure distinct from both parent phases.

Session L22 GMAG DMP FLAP: Focus Session: Spin-Orbit Effects in Semiconductors

2:30PM L22.00001 ABSTRACT WITHDRAWN –
4:06PM L22.00007 Spin-orbit control of magnetization and electrical detection of current-induced spin polarization. MASON OVERBY, ALEX CHERNYSHOV, LEONID ROKHINSON, Purdue University, XINYU LIU, JACEK FURDYNA, Notre Dame University — The success of future spintronic devices relies on the efficient control and detection of spin polarization. Extrinsicly polarized currents, injected from ferromagnetic materials, can interact with magnetic domains and initiate domain rotation. Alternatively, spin polarization can be generated intrinsically via relativistic coupling of spin to the momentum of charge carriers, known as spin-orbit interaction (SO). While the use of SO for electrostatic control of polarization forms the basis of various theoretical device concepts, SO control of magnetization has not been realized experimentally. Here we demonstrate that magnetization can be reversibly manipulated by intrinsically polarized currents in ferromagnetic semiconductors with strong SO coupling. The system under consideration is a two-dimensional electron gas (2DES) that is present at the interface of a heterostructure due to modulation doping. Within this approach, we study the coupling between spin and charge and we determine the charge (spin) profile induced by a non-uniform, periodic spin (charge) density in the presence of the external electric field. We determine the optimal range of parameters for observing the spin-charge coupling effects.

3:42PM L22.00005 Magneto-transport in high mobility n-InSb/InAlSb quantum wells1, W.R. BRANFORD, A.M. GILBERTSON, Imperial College, L.F. COHEN, M. FEARN, P.D. BUCKLE, L. BUCKLE, QinetiQ Malvern — The inherent large spin-orbit (SO) coupling InSb quantum wells (QWs) is expected to result in sensitive tunability of the Rashba effect with electric field. The strength of the SO coupling can be extracted from measurements of weak anti-localisation (WAL) and from the beating of Shubnikov-de Haas (SdH) oscillations [1]. We have investigated these phenomena and report magneto transport measurements from a range of InSb/InAlSb QWs with varying carrier density n and mobility μ. It is shown that the inherent large Zeeman splitting combined with inhomogeneous level broadening means that beating in the SdH oscillations in InSb QWs are rarely observed. However, her we show that in InSb/InAlSb QWs, n can be modulated using a gate electric field from 1.15 < n < 3.3x10^{11} cm^{-2} with 13 < μ < 38 mV−1 cm−1 and that under certain conditions weak beating effects can be observed which are attributable to the Rashba effect. Extracted values of the Rashba parameter from beating [2], WAL and k.p modelling [3] is discussed. 3:54PM L22.00006 Diffusive spin-charge dynamics in an external electric field, TUDOR-DAN STANESCU, BRANDON ANDERSON, VICTOR GALITSKI, University of Maryland — We study the dynamics of a spin density injected into a two-dimensional electron system with generic spin-orbit interactions. We generalize the spin-charge diffusion equation formalism by including the effects of a uniform electric field. Within this approximation, we study the coupling between spin and charge and we determine the charge (spin) profile induced by a non-uniform, periodic spin (charge) density in the presence of the external electric field. We determine the optimal range of parameters for observing the spin-charge coupling effects.

3:06PM L22.00002 Pure spin current pump in a quantum channel with both Rashba and Dresselhaus effects, CHIA-HUI LIN, RCAS, Academia Sinica, CHI-SHUNG TANG, National United University, Taiwan, YIA-CHUNG REN, RCAS, Academia Sinica, Taiwan — We demonstrate a spin pump to generate pure spin current of tunable intensity and polarization in the absence of charge current. The system under consideration is a two-dimensional electron gas (2DEG) that is present at the interface of a heterostructure due to modulation doping and has intrinsic static Rashba and Dresselhaus spin-orbit interactions. The pumping functionality is achieved by means of an ac gate voltage that modulates the Rashba constant dynamically in a local region of a quantum channel in which both the static Rashba and Dresselhaus spin-orbit interactions are taken into account. The spin-resolved Floquet scattering matrix formalism is applied to our system. Based on the Floquet theorem, this formalism provides an exact and nonperturbative solution to the time-periodic Schrodinger equation in the mesoscopic system. Because the time-dependent spin-orbit interaction couples two spin polarizations and all sidebands together, analytic expression for the sideband dispersion is not feasible. Thus, we determine the sideband dispersion relation numerically by solving the Schrodinger equation in a nearly complete basis with the spatial inhomogeneity handled by matching boundary conditions region by region. The Floquet scattering matrix gives a coherent solution that goes beyond the adiabatic regime.

3:18PM L22.00003 Mesoscopic fluctuations in the spin-electric susceptibility due to Rashba spin-orbit interaction, MATHIAS DUCKHEIM, DANIEL LOSS, Department of physics, University of Basel — Spin-orbit interaction enables the control of the spin with electric fields in non-magnetic semiconductors. The orbital transport processes generating the internal fields that are necessary for this control of spin are non-local and mesoscopic. We investigate mesoscopic fluctuations in the spin polarization generated by a static electric field and by Rashba spin-orbit interaction in a disordered 2D electron gas. In a diagrammatic approach we find that the out-of-plane polarization — while being zero for self-averaging systems — exhibits large sample-to-sample fluctuations which are shown to be within experimental reach. We evaluate the disorder-averaged variance of the susceptibility and find its dependence on magnetic field, spin-orbit interaction, dephasing, and chemical potential difference. [M. Duckheim and D. Loss, Phys. Rev. Lett. (in print), arXiv:0805.4145v1]

3:30PM L22.00004 Spin-orbit coupling effects and the angular dependence of the tunneling anisotropic magnetoresistance1, ALEX MATOS-ABIAGUE, MARTIN GMITRA, JAROSLAV FABIAN, University of Regensburg — We consider a tunnel junction in which one of the electrodes is ferromagnetic. Based on general properties and symmetry considerations, we develop a phenomenological model in which the anisotropy of the tunneling magnetoresistance with respect to the magnetization orientation of the ferromagnet originates from the spin-orbit interaction. The model reveals how the symmetry and angular dependence of the tunneling anisotropic magnetoresistance (TAMR) are determined by the form of the spin-orbit coupling field (SOCF), independently of the specific details of the system. We investigate the particularly important cases in which the SOCF is of Bychkov-Rashba and/or Dresselhaus type and obtain angular dependences which are in good agreement with available TAMR measurements. We also predict new forms of the angular dependence of the TAMR by exploring different geometric configurations.

3:24PM L22.00001 Spin-orbit interaction in low dimensional InSb/InAlSb systems, TUDOR-DAN STANESCU, RCAS, Academia Sinica, CHI-SHUNG TANG, National United University, Taiwan — Low temperature magnetotransport measurements were performed on high mobility InSb/InAlSb two dimensional electron systems (2DES) and quasi-1D wires fabricated from the 2DES. Anti-localization dominates the magnetoresistance in low applied magnetic fields; hence the spin-orbit interaction is sensitive to the electron spin and phase coherence lengths in the structures. Measurements of the low field magnetoresistance over temperature demonstrate that the antilocalization phenomena persists to temperatures above ~20 K in the quasi-1D wires, whereas antilocalization is not observed above ~15 K in the unpatterned 2DES. The extracted spin coherence lengths, obtained from fitting the magnetoresistance curves to localization theory, show only weak temperature dependence. Therefore, phase coherence appears to dominate the temperature dependence of antilocalization in the low dimensional InSb/InAlSb systems. (NSF DMR-0618235, DOE DE-FG02-08ER46532, NSF DMR-0520550)
4:30PM L22.00009 Full-zone spin-splitting for electrons and holes in bulk GaAs and GaSb
JUN-WEI LUO, GABRIEL BESTER, ALEX ZUNGER, National Renewable Energy Lab., Golden, CO 80401 — The spin-orbit interaction — a fundamental electronic force — is equivalent to an effective magnetic field intrinsic to crystals, leading to band spin-splitting for certain k-points in sufficiently low-symmetry structures. This (Dresselhaus) splitting has usually been calculated at restricted regions in the Brillouin-zone via small-wavevector approximations (e.g., k·p). We provide a full-zone description of the Dresselhaus splitting in zinc-blend semiconductors by using pseudopotentials, empirically corrected to rectify LDA errors by fitting GW results at a few frequencies. We find that (i) The largest spin-splitting occurs along the [110] direction, not the [110] direction as previously thought based on limited view of the Brillouin zone; (ii) the spin-splitting of the upper valence band VB1 is comparable to that of the next two valence bands VB2 and VB3. This has been previously overlooked due to the expectation that the largest spin-splitting will occur along the [110] direction; (iii) The spin-splitting pattern of each band is orthogonal to each other.

4:42PM L22.00010 Controlling the persistent spin helix with strain induced spin-orbit coupling
LUYI YANG, Lawrence Berkeley National Laboratory and University of California Berkeley, JAKE KORALEK, Lawrence Berkeley National Laboratory, JOE ORENSTEIN, Lawrence Berkeley National Laboratory and University of California Berkeley, ANDREI BERNEVIG, Princeton University, SHOUCHENG ZHANG, Stanford University, SHAWN MACK, DAVID ANSCHALOM, Center for Spintronics and Quantum Computation, University of California Santa Barbara — We use transient spin grating spectroscopy to study the persistent spin helix (PSH) state of the 2D electron gas. The PSH is a meta-stable helical spin density wave that emerges as a result of increased symmetry when the Rashba and Dresselhaus spin-orbit coupling terms are balanced, and which offers great promise as a means of controlling large ensembles of spins. We demonstrate that the spin-orbit symmetry, and the PSH dynamics, can be manipulated in-situ by the application of uniaxial strain. This strain induces spin-orbit coupling with precisely the same symmetry as the Rashba term, allowing us to effectively tune the Rashba/Dresselhaus ratio in a single sample. This work is supported by DMSE office of BES-DOE, NSF, MARCO, ASE and CNID.

5:45PM L22.00011 The precessing persistent spin helix in a magnetic field
RUNDONG LI, Stanford University, JING WANG, Stanford University, SHOUNG CHUNG ZHANG, Stanford University — While the spin-orbit interaction is useful for manipulating the electron spin, it could also cause spin decoherence. A Persistent Spin Helix (PSH) with infinite life time has been predicted [B. A. Bernevig et al., Phys. Rev. Lett. 97, 236601 (2006)], for 2D quantum wells with equal strength of Rashba and Dresselhaus spin-orbit coupling. This effect results from the spin SU(2) symmetry of electrons, which makes the spin density at a finite wave vector conserved. The PSH was later observed in the transient spin grating (TSG) experiment [C. P. Weber et al., Phys. Rev. Lett. 98, 076604 (2007)], where the spin density wave is pumped and its decay in the time domain is probed optically. In this work we propose measuring the PSH with an in-plane magnetic field and spin injection with alternating polarization. We derive and solve the drift-diffusion equation for the spin density and find that the persistence of the spin injection is the same as the Larmor frequency, a great enhancement of the diffusion length and the amplitude of the spin oscillation should be observed, giving rise to a precessing PSH.

5:06PM L22.00012 Theory of Electron Spin Relaxation in ZnO
NICHOLAS HARMON, WILLIAM PUTIKKA, Ohio State University, ROBERT JOYNT, University of Wisconsin — Doped ZnO is a promising material for spintronics applications. For such applications, it is important to understand the spin dynamics and particular the spin relaxation times of this II-VI semiconductor. The transverse spin lifetime $T_\perp$ has been measured by optical orientation experiments, and it shows a surprising non-monotonic behavior with temperature. We explain this behavior by invoking spin exchange between localized and extended states. Interestingly, the effects of spin-orbit coupling are by no means negligible, in spite of the relatively small valence band splitting. This is due to the wurtzite crystal structure of ZnO. Detailed analysis allows us to characterize the impurity binding energies and densities, showing for the first time that optical orientation experiments can actually be used as a characterization tool for semiconductor samples.

5:18PM L22.00013 Effect of Induced Spin-orbit Coupling in Cold Atomic Gas
XIANG-JUN LIU, MARIO F. BORUNDA, XIN LIU, JAIRO SINOVÁ, Department of Physics, Texas A&M University, College Station, Texas 77843-4242, USA, JAIRO SINOVÁ’S GROUP AT TAMU TEAM — Spin-orbit (SO) coupling effect in superfluids has emerged in the solid-state community as a very active field of research, fueled in part by the field of spintronics, e.g. spin current injection with spin Hall effect [1]. Recently, new schemes are developed to generate the SO interaction in cold atoms [2], which opens new possibilities in studying Spintronics in atomic systems. Here we shall report our recent proposal of SO coupling effects in Fermi atomic systems via optical method [3]. The induced SO coupling can be of the Dresselhaus and Rashba type with a Zeeman term. We show that the optically induced SO coupling can lead to a spin-dependent effective mass under proper condition, with one of them able to be tuned between positive and negative effective masses. As a direct observation we show that in the expansion dynamics of the atomic cloud the initial atomic cloud can split into two or four clouds depending on the effective mass regimes. Tuesday, March 17, 2009 2:30PM - 5:30PM – Session L23 DCMP FIAP: Fractional Quantum Hall Effect, Bilayers 325

2:30PM L23.00001 Different Signatures of the Total Filling Factor 1 State
LARS TIEMANN, YOUNGSOO YOON, STEFAN SCHMULT, MAIK HAUSER, WERNER DIETSCHE, KLAUS VON KLITZING, Max-Planck Institute for Solid State Research — Bringing two 2-dimensional electron systems in close proximity can yield a correlated state as the electrons will experience the presence of the neighboring system. At the individual filling factors of 1/2 this leads to a new double-layer ground state as positive and negative charges from opposite layers couple to excitons. Many remarkable properties were found such as vanishing Hall and longitudinal resistances in the counterflow configuration [1], a resonantly enhanced zero bias tunneling peak [2], and more recently, a critical DC tunneling current and vanishingly small interlayer resistances in DC measurements [3]. We will show how it is possible to combine the results of these three different measurements into a consistent picture. Under certain conditions it is possible to exceed the critical currents but still observe a minimum at total filling factor 1 in the counterflow configuration.

2:42PM L23.00002 Valley polarization and the polarization mass of composite fermions around $\nu = 3/2$, MEDINI PADMANABHAN, TAYFUN GOKMEN, MANSOUR SHAYEGAN, Dept. of Electrical Engineering, Princeton University, Princeton, NJ 08544 — In two-dimensional electron systems confined to AlAs quantum wells, composite fermions (CFs) around $\nu = 3/2$ are known to possess a valley degree of freedom [1]. The relative occupation of the valleys can be controlled via the application of uniaxial, in-plane strain. In this study, we measure the strain needed to completely valley-polarize the various fractional quantum Hall states around $\nu = 3/2$ as a function of density and compare our results to the theory explaining the complete spin-polarization of CFs in GaAs [2]. While the theory predicts it to be a constant, the energy needed for complete valley-polarization in units of the Coulomb energy is experimentally found to increase with increasing density. Translating this to the language of the 'polarization mass' for the CFs [2], we find an absence of the theoretically expected $\sqrt{B}$ dependence for the polarization mass. [1] N. C. Bishop et al., Phys. Rev. Lett. 98, 266404 (2007) [2] K. Park and J. K. Jain, Phys. Rev. Lett. 80, 4237 (1998)

2:54PM L23.00003 Clausius-Clayperon relation for onset of the coherent $\nu = 1$ phase in bilayer quantum Hall systems, YUE ZOU, GIL REFAEL, JAMES EISENSTEIN, Department of Physics, California Institute of Technology, Pasadena, CA 91125, USA, ADY STERN, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot, Israel 76100 — A bilayer system of two-dimensional electron gases in a perpendicular magnetic field exhibits extremely rich phenomena. At total filling factor $\nu = 1$, as one increases the layer separation, the bilayer system goes from an interlayer coherent exciton condensed state to an incoherent phase of two decoupled composite fermion Fermi liquids. Many question still remain as to the nature of the transition between these two phases. Recent experiments investigated the phase boundary as a function of both in plane magnetic field and density imbalance. We compare these experimental results, e.g., the curvature of the phase boundary, with respect to the interlayer density imbalance, with a theoretical calculation based on the assumption that there is a direct first order transition between the two phases.

3:06PM L23.00004 Quantum Hall Bilayer in a Periodic Potential, GANPATHY MURTHY, University of Kentucky, JIANMIN SUN, HERBERT FERTIG, Indiana University — Disorder is known to be central to the interlayer density imbalance, with a theoretical calculation based on the assumption that there is a direct first order transition between the two phases. We compare these experimental results, e.g., the curvature of the phase boundary, with respect to the interlayer density imbalance, with a theoretical calculation based on the assumption that there is a direct first order transition between the two phases.

3:18PM L23.00005 Piezoresistance and Metal Insulator Transition of Composite Fermions at $\nu = 3/2$, TAYFUN GOKMEN, MEDINI PADMANABHAN, MANSOUR SHAYEGAN, Dept. of Electrical Engineering, Princeton University, Princeton, NJ 08544 — In the composite fermion (CF) picture, at the Landau level filling factor $\nu = 3/2$ the particle-flux CF quasi-particles are analogous to electrons at zero perpendicular magnetic field. Here we report piezoresistance measurements of CFs at $\nu = 3/2$ in AlAs quantum wells. In this system, the electrons occupy two conduction band valleys with elliptical Fermi contours, and the valley occupation of electrons can be controlled via the application of uniaxial, in-plane strain. The system's response to strain at $\nu = 3/2$ is qualitatively very similar to that of the electrons at zero perpendicular magnetic field, and consistent with the picture of CFs with a valley degree of freedom. Temperature dependent studies also show that CFs, like their counterpart electrons, go through a metal-insulator transition as they become valley polarized.

3:30PM L23.00006 Composite Fermion signature in the single particle spectrum of the fractional quantum Hall system, RAY ASHOORI, OLIVER DIAL, MIT, LOREN PFIEFFER, KEN WEST, Bell Laboratories, Alcatel-Lucent — Using time domain capacitance spectroscopy we measure the single particle spectrum of the fractional quantum Hall system. The very high energy resolution of the technique (limited ultimately only by sample temperature) allows us to uncover the existence of new spectral features. Among these is a sharp line that crosses the Fermi level at filling factor $\nu = 1/2$. The structure is consistent with the composite Fermion Landau fan, allowing measurement of the composite Fermion mass. Observation of this feature allows us to study the composite Fermion mass as a function of magnetic field and filling fraction.

3:42PM L23.00007 Quasiparticles in the tunneling spectrum of the fractional quantum Hall system, OLIVER DIAL, RAYMOND ASHOORI, MIT, LOREN PFIEFFER, KEN WEST, Bell Laboratories, Alcatel-Lucent — Despite the central role that the tunneling (or single-particle) particle density of states (TDOS) plays in our theories of many-body systems, it has proven a difficult quantity to access experimentally in two dimensional electron systems. We have developed a technique, time domain capacitance spectroscopy, which allows measurement of the TDOS over a range of 30 meV centered about the Fermi surface, revealing the detailed and beautiful structure present in these systems far from the Fermi energy. With increased sample quality and higher magnetic fields, we see the emergence of the fractional quantum Hall effect in the TDOS along with negative compressibility and chemical potential jumps associated with several fractions. Most strikingly, we also observe a number of new, sharp quasiparticle lines far from the Fermi energy. The dependence of the quasiparticle energies on density allows us to identify different fractional quasiparticles as well as estimate emergent effective quasiparticle masses. These high energy spectral features shed new light on the highly correlated fractional ground state, as well as the nature of the state near $\nu = 1$.

3:54PM L23.00008 Quantum Hall States at filling $\nu = k + \frac{2}{2k+\nu}$, WAHEB BISHARA, GREGORY FIETE, California Institute of Technology, CHETAN NAYAK, UCSB, Microsoft Research Station Q — We study the $\nu = k/2 + 1/2k$ quantum Hall states which are particle-hole conjugates of the $\nu = k/2$ Read-Rezayi states. We find that equilibration between the different modes at the edge of such a state leads to an emergent SU(2)$_0$ algebra in the counter-propagating neutral sector. Heat flow along the edges of these states will be in the opposite direction of charge flow. In the $k = 3$ case, which may be relevant to $\nu = 2 + \frac{2}{3}$, the thermal Hall conductance and the exponents associated with quasiparticle and electron tunneling distinguish this state from competing states such as the hierarchy/Jain state.

4:06PM L23.00009 Phase diagram for bilayer quantum Hall effect at total filling $\nu_\perp = 5$, CHUNTAI SHI, SHIVAKUMAR JOLAD, Department of Physics, The Pennsylvania State University, NICOLAS REGNAULT, Laboratoire Pierre Aigrain, ENS, CNRS, France, JAINENDRA JAIN, Department of Physics, The Pennsylvania State University — There has been much interest in bilayer quantum Hall systems at total filling $\nu_\perp = 1$, which exhibit excitonic superfluidity at small separations and two uncoupled composite fermion Fermi seas at large separations. We evaluate the phase diagram of the bilayer quantum Hall effect at total filling $\nu_\perp = 5$, neglecting interlayer tunneling and spin fluctuations, which is expected to be a bilayer excitonic superfluid at small separations and two uncoupled 5/2 FQHE states at large separations. Based on a combination of variational and exact diagonalization (for up to 20 electrons) studies, we estimate that the transition between these states occurs at a layer separation of approximately one magnetic length, independent of the individual layer thickness. The composite fermion Fermi sea is not found to be relevant for any parameters.
4:18PM L23.00010 How universal is the fractional quantum Hall edge physics?, SHIVAKUMAR JOLAD, The Pennsylvania State University, DIPTIMAN SEN, Indian Institute of Science, JAINENDRA JAIN, The Pennsylvania State University — We report on study of edge excitations of fractional quantum Hall states at filling factors \( \nu = 1/3 \) and \( \nu = 2/5 \). By considering the restricted basis of composite fermion wave functions, which is very accurate for the low energy eigenstates, we are able to diagonalize systems with up to 54 particles which allows us to make extrapolations to the thermodynamic limit. In a model with neutralizing positive jellium background disk at a distance \( d \), we find that edge reconstruction is generic, occurring even when the electron and the background disks coincide. We also test the postulated form for the electron field operator of the effective field theory approach for the fractional edge and find it to be inconsistent with our microscopic calculations. Implications of our results for the observed non-universality of the edge exponent will be discussed.

4:30PM L23.00011 A universal molecular description for the spectra of bosons and fermions in the lowest Landau level 1. CONSTANTINE YANNOULEAS, UZI LANDMAN, Georgia Institute of Technology — We show that both the ground and excited states in the LLL spectra of small systems can be expressed as linear superpositions of appropriate rovibrational molecular trial functions, akin to the rotating-electron-molecule functions introduced earlier. Thus the nature of strong correlations in the lowest Landau level reflects the spontaneous emergence of intrinsic point-group symmetries associated with rotations and vibrations of molecules of localized particles arranged in concentric polygonal-ring configurations. The present molecular picture is valid for both bosons and fermions. We stress its validity and superiority for low (as well as high) angular momenta, where “quantum-fluid” trial functions of a markedly different nature (including Laughlin, composite-fermion, and Pfaffian ones) have been assumed to apply.

4:42PM L23.00012 Origin of chiral p-wave pairing in even-denominator fraction quantum Hall effect., YUAN-MING LU, Department of Physics, Boston College, YUE YU, Institute of Theoretical Physics, Chinese Academy of Sciences, ZIQIANG WANG, Department of Physics, Boston College — We show that gauge field fluctuations in the composite fermion field theory can be exactly integrated out using a non-unitary transformation. An instantaneous statistical interaction is induced which makes the Fermi sea unstable to chiral p-wave pairing. We show that the paired state is a Moore-Read Pfaffian and discuss the effects of Coulomb interaction in connection to even-denominator fractional quantum Hall effect.

4:54PM L23.00013 Pinning mode integer quantum Hall Wigner crystal of skyrmions, HAN ZHU, Princeton Physics; NHMFL, G. SAMBANDAMURTHY, Y.P. CHEN, P.-H. JIANG, NHMFL/FSU; Princeton EE, L.W. ENGEL, NHMFL/FSU, D.C. TSUI, Princeton EE, L.N. PFEIFFER, K.W. WEST, Bell Labs — Just away from integer Landau level (LL) filling factors \( \nu \), the dilute quasi-particles/holes at the partially filled LL form an integer-quantum-Hall Wigner crystal, which exhibits microwave pinning mode resonances [1]. Due to electron-electron interaction, it was predicted that the elementary excitation around \( \nu = 1 \) is not a single spin flip, but a larger-scale spin texture, known as a skyrmion [2]. We have compared the pinning mode resonances [1] of integer quantum Hall Wigner crystals formed in the partly filled LL just away from \( \nu = 1 \) and \( \nu = 2 \), in the presence of an in-plane magnetic field. As an in-plane field is applied, the peak frequencies of the resonances near \( \nu = 1 \) increase, while the peak frequencies below \( \nu = 2 \) show negligible dependence on in-plane field. We interpret this observation as due to a skyrmion crystal phase around \( \nu = 1 \) and a single-hole Wigner crystal phase below \( \nu = 2 \). The in-plane field increases the Zeeman gap and causes shrinking of the skyrmion size toward single spin flips. [1] Yong P. Chen et al., Phys. Rev. Lett. 91, 016801 (2003). [2] S. L. Sondhi et al., Phys. Rev. B 47, 16 419 (1993); L. Brey et al., Phys. Rev. Lett. 75, 2562 (1995).

5:06PM L23.00014 Observation of a Fractional Quantum Hall State at \( \nu = 1/4 \) in a Single Wide GaAs Quantum Well, DWIGHT R. LUHMAN, Department of Electrical Engineering Princeton University, W. PAN, Sandia National Laboratories, D.C. TSUI, Department of Electrical Engineering Princeton University, L.N. PFEIFFER, K.W. BALDWIN, K.W. WEST, Bell Laboratories — We have preformed low temperature (\( T = 35 \) mK) transport measurements using a 50 nm high-quality GaAs quantum well with an electron density of \( n_{e} = 2.55 \times 10^{11} \) cm\(^{-2} \) and a mobility of \( \mu \approx 10^7 \) cm\(^2\)/Vs. Magnetic fields up to \( B = 15 \) T were used to reach filling factor \( \nu = 1/4 \). With the sample situated perpendicular to the applied magnetic field, the diagonal resistance displays a kink at \( \nu = 1/4 \). When the sample is tilted to an angle of \( \theta = 30.3^\circ \), a clear minimum in the diagonal resistance and plateau in the Hall resistance are present at \( \nu = 1/4 \), indicating a fractional quantum Hall state at \( \nu = 1/4 \) in this sample. Several possibilities regarding the origin of this state will also be discussed.

5:18PM L23.00015 Charge-density wave formation in interacting two-dimensional electronic systems with Landau level mixing, PETER SMITH, MALCOLM KENNEDY, Simon Fraser University — Anisotropic transport in half-filled Landau levels has been explained in terms of charge-density wave (CDW) formation. We use the Hartree-Fock approximation to study the influence of electron-electron interactions and Landau level mixing on the formation of CDWs in two-dimensional electron and hole systems. For the situation of two nearly degenerate eigenstates, we construct a Landau free-energy theory appropriate for competing order parameters that allows for both striped and triangular CDW formation. We find the possibility of coexisting CDW ordering in the two states, along with possible hysteretic behaviour. This physics might be realized using an external parameter such as spin-orbit coupling to tune states into near degeneracy.

Tuesday, March 17, 2009 2:30PM - 5:30PM — Session L24 DMP: Focus Session: Electronic Properties of Nanotubes 326

2:30PM L24.00001 Strongly Correlated Electron Phenomena in Carbon Nanotubes, MARC BOCKRATH, California Institute of Technology — In this talk I will discuss our recent results demonstrating strongly correlated electron behavior in ultra-clean carbon nanotube quantum dots. Specifically, we have observed one-dimensional (1D) Wigner crystal behavior of dilute holes in semiconducting nanotubes, finding three distinct regimes of spin and valley quantum number ordering as the charge density and axial magnetic field are varied. The boundaries between the regimes in density and magnetic field are well-described by the theory of Levitov and Tsvelik for a narrow-gap Luttinger liquid. In the second part of the talk I will present results showing that the electrons in nominally metallic nanotubes comprise a 1D Mott insulator. This indicates that carbon nanotubes are never truly metallic, in agreement with theoretical predictions that account for Umklapp scattering at half-filling due to electron-electron interactions. Using inelastic cotunneling spectroscopy, we also observe neutral electronic excitations within the gap, yielding an additional signature of the Mott insulating state. Our results demonstrate nanotubes’ promise for studying a variety of tunable correlated electron phenomena in 1D.
3:06PM L24.00002 Relaxation and dephasing in a two-electron $^{13}$C nanotube double quantum dot , HUGH CHURCHILL, FERDINAND KUEMMETH, JENNIFER HARLOW, ANDREW BESTWICK, EMMANUEL RASHBA, Harvard University, KARSTEN FLENSBERG, University of Copenhagen, CAROLYN STWERTKA, THITI TAYCHATANAPAT, Harvard University, SUSAN WATSON, Harvard University and Middlebury College, CHARLES MARCUS, Harvard University — We use charge sensing of Pauli blockade (including spin and isospin) in a two-electron $^{13}$C nanotube double quantum dot to measure relaxation and dephasing times. The relaxation time, $T_1$, first decreases with parallel magnetic field and then goes through a minimum in a field of 1.4 T. We attribute both results to the spin-orbit-modified electronic spectrum of carbon nanotubes, which suppresses hyperfine mediated relaxation and enhances relaxation due to soft phonons. The inhomogeneous dephasing time, $T_2^*$, is consistent with previous data on hyperfine coupling strength in $^{13}$C nanotubes. This work was supported by the National Science Foundation under grant no. NIRT 0210736 and the GRFP, ARO/iARPA, the Department of Defense, and Harvard’s Center for Nanoscale Systems.

3:18PM L24.00003 Electrical evidence for the encapsulation of $^{14}$C$_{60}$ inside a carbon nanotube: Random telegraph signal and hysteretic current-voltage characteristics

3:30PM L24.00004 Breakdown of the Wigner-Mattis theorem in semiconductor carbon-nanotube quantum dots , MASSIMO RONTANI, INFN-CNR Research Center S3, Modena, Italy, ANDREA SECCHI, University of Modena, Italy, FRANCA MANGHI, INFN-CNR S3 and University of Modena, Italy — The Wigner-Mattis theorem states the ground state of two bound electrons, in the absence of the magnetic field, is always a spin-singlet. We predict the opposite result — a triplet — for two electrons in a quantum dot defined in a semiconductor carbon nanotube. The claim is supported by extensive many-body calculations based on the accurate configuration interaction code DONRO-DRIGO (www.s3.infm.it/donrodrigo). The crux of the matter is the peculiar two-valley structure of low-energy states, which encodes a pseudo-spin degree of freedom. The spin polarization of the ground state corresponds to a pseudo-spin singlet, which is selected by the inter-valley short-range Coulomb interaction. Single-electron excitation spectra and STM wave function images may validate this scenario, as shown by our numerical simulations.

3:42PM L24.00005 Casimir Interactions Between Scatterers on Carbon Nanotubes , DINA ZHABIN-SKAYA, University of Pennsylvania, JESSE KINDER, Cornell University, E. J. MELE, University of Pennsylvania — We study the interactions between two short-range scatterers in metallic carbon nanotubes as a Casimir problem. In the massless Dirac Hamiltonian for the electrons, a defect can be represented by a scattering potential with a pseudospin polarization. Sublattice-asymmetric and bond-centered potentials may lead to small momentum backscattering, depending on the chiral angle of the nanotube. Quasibound states formed between two defects determine the forces at the boundaries. We develop a force operator approach within the Dirac model to calculate the forces on two square well potentials of finite width, and take the limit of sharp and strong scatterers to study the Casimir force mediated by the fermions. For the special case of two identical scatterers we recover the conventional one-dimensional attractive Casimir force. For the general problem with inequivalent scatterers we find that the magnitude and sign of this force depends on the relative pseudospin polarizations of the two defect potentials. We will also discuss the effects intervalley scattering on the Casimir interactions between defects.

4:18PM L24.00008 Effect of spin-orbit interaction on the static polarizability of single-wall carbon nanotubes*, G. S. DINIZ, S. E. ULLOA, Ohio University — The electronic structure of carbon nanotubes (CNTs) is known to exhibit different metallic or insulating behavior as different chiral vectors are considered. Application of external electric fields and the presence of spin-orbit interaction (SOI) result in the Rashba effect modifying the level structure of CNTs, strongly coupling spin and orbital degrees of freedom, as demonstrated in recent experiments [1]. In this work we calculate the static long-wavelength limit of the dielectric response of different single-wall CNTs when subjected to uniform external electric fields both along and across the longitudinal direction (parallel to the nanotube axis). Our calculation uses a π-band tight-binding formalism, considers Rashba and intrinsic SOI, and utilizes the random phase approximation to evaluate $\epsilon(q \rightarrow 0, \omega = 0)$ [2]. We use parameters from the literature and find that the metallic-to-semiconductor transition induced by the intrinsic SOI is suppressed as the Rashba field is taken into account. We further show that this behavior has a clear signature on measurable quantities, such as the static polarizability. We discuss its dependence on nanotube size and chirality and propose possible nanoprobe experiments to study this phenomenon. [1] F. Kuemmeth et al., Nature 452, 448-452 (2008). [2] M. L. Cohen et al., Phys. Rev. B 52, 8541 (1995). *Supported by Fulbright, CAPES and NSF-DMR MWN.
4:30PM L24.00009 Low-Temperature Studies of Electrostatic Doping and Phonon Renormalization in Individual Single-Walled Carbon Nanotubes. GUGANG CHEN, Honda Research Institute USA Inc., Columbus, OH 43212, TEREZA PARONYAN, GAMIH SUMANASEKERA, Department of Physics, University of Louisville, Louisville, KY 40292, ELENA PIGOS, AVETIK HARUTYUNYAN, Honda Research Institute USA Inc., Columbus, OH 43212 — Electrostatic doping of carbon nanotubes (CNTs) induced by applied external gate voltage ($V_g$) in the field-effect transistor (FET) configuration allows controllable variation of charge density and the Fermi level in nanotubes. Raman scattering from a CNT is very sensitive to doping and its interaction with the surrounding environment. Recently, the peculiarities of G-mode as a function of gate induced carrier at room temperature have been reported in [1] (Nature Nanotechnology 2, 725 (2007)). In the present work, we used Raman scattering to study the p- and n-electrostatic doping of CNT as a function of $V_g$ in a wide range of temperature from 6.8 K to 300 K. Virtually symmetric blue-shifting of the G-mode for both p- and n-doping of CNTs has been observed. We found that the prehistory of the CNT measurement as well as environment interaction such as gas adsorption on CNT plays an important role on the observed phenomena. Explanation of our findings will be discussed based on phonon energy renormalization of carbon nanotubes [1] due to the carrier density variation during electrostatic doping.

4:42PM L24.00010 Field Enhancement inside Carbon Nanotubes. HONG ZHANG, Sichuan University, China, YOSHISHUKI MIYAMOTO, Nano Electronics Res. Labs., NEC, Japan — There are many investigations on photo-excitations with polarization vector parallel to tube axis (parallel-polarization), compared to it, few studies on those with polarization vector perpendicular to tube axis (cross-polarization) are reported because of early theoretical consideration on electric-field-depolarization effect of nanotubes with cross-polarization [1]. Using dynamical consideration and TDDFT analysis, we herein present the influence of external electric field perpendicular to the axis of semiconductor carbon nanotube (CNT). By adjusting frequency of applied E-field in corresponding wavelength of light from 800nm to 591 nm, the total E-field inside carbon nanotubes has been found to show slow change depending on the frequency; incomplete screening and strong enhancement even without including the excitonic effect [2]. The enhancement comes from increase of oscillating amplitude of electron cloud with resonant frequency given by the applied E-field. Also the numerical stability and the satisfaction of energy conservation rule with application of dynamical E-field were numerically checked [3]. This finding should be taken into account in interpreting a measurement of optical response of molecules being encapsulated in CNTs. [1]. H. Ajiki and T. Ando, Physica B 201, 349 (1994) [2]. S. Uryu and T. Ando, Phys. Rev. B 76, 115420 (2007) [3]. Y. Miyamoto and H. Zhang, Phys. Rev. B 77, 165123 (2008).

4:54PM L24.00011 Quasi-particle Energy Gap of Metal-coated Carbon Nanotubes. YU ZHOU, LI CHEN, YIMING ZHANG, SWASTIK KAR, PULICKEL AJAYAN, SARJU NAYAK, Rensselaer Polytechnic Institute — We have studied the electronic structures of metal-coated carbon nanotubes using density functional theory and many body corrections based on GW approximation (GWA). In particular, we will present energy band gap variation as a function of metal of metal atoms on the nanotube surface. Our results are compared with recent experiments.

5:06PM L24.00012 Microwave Rectification by Carbon Nanotube Schottky Diodes. ENRIQUE COBAS, STEVEN ANLAGE, MICHAEL FUHRER, Department of Physics and Center for Nanophysics and Advanced Materials, University of Maryland College Park — We report the fabrication and electrical characterization of carbon nanotube Schottky diodes (CNT-SDs) via photolithography on high-frequency-compatible substrates using dissimilar contacts of chromium and platinum. The diodes are well-described by the ideal diode equation ($n = 1.0$). DC and low-frequency behavior is compared to a model of a diode in series with a resistor. The diodes rectify microwave signals beyond 18GHz and produce dc currents of hundreds of nanoamperes. The frequency and voltage dependence is used to estimate the junction capacitance of 1aF and an intrinsic device cut-off frequency of 400GHz.

5:18PM L24.00013 Microwave Irradiation Induced Effects to Single-walled Carbon Nanotube Thin Films. LU WANG, University of Arizona, YAO XIONG, Ohio University, ZIRAN WU, University of Arizona, LIWEI CHEN, Ohio University, HAO XIN, University of Arizona — Carbon nanotubes have been considered as potential building blocks for nano-scale circuits in virtue of their unique mechanical and electrical properties. However, one of the biggest obstacles for massive production of nanotube circuits is the difficulty of separating semiconducting tubes from metallic tubes or vice versa. In this work, a convenient method which may be potentially employed to selectively remove metallic tubes using microwave induced breakdown is proposed and investigated. Carbon nanotube thin films deposited on glass and quartz substrates are placed in a commercial microwave oven and heated for up to several minutes. The radial breathing mode in Raman spectra on the nanotube samples before and after the microwave irradiation suggests that the metallic-to-semiconducting ratios are reduced by around 20%. Meanwhile, because in the thin film samples most of the nanotubes are entangled, smaller diameter nanotubes (both metallic and semiconducting) tend to be affected more. THz transmission measurements of these thin films are also performed before and after microwave irradiation. The significant increase of transmission after the microwave irradiation process confirms the loss of metallic tubes.

Tuesday, March 17, 2009 2:30PM - 5:30PM — Session L25 DMP: Focus Session: Probing and Modifying Materials with Lasers II 327

2:30PM L25.00001 Modeling of Laser Material Interactions. BARBARA GARRISON, Penn State University — Irradiation of a substrate by laser light initiates the complex chemical and physical process of ablation where large amounts of material are removed. Ablation has been successfully used in techniques such as nanolithography and LASIK surgery, however a fundamental understanding of the process is necessary in order to further optimize and develop applications. To accurately describe the ablation phenomenon, a model must take into account the multitude of events which occur when a laser irradiates a target including electronic excitation, bond cleavage, desorption of small molecules, ongoing chemical reactions, propagation of stress waves, and bulk ejection of material. A coarse grained molecular dynamics (MD) protocol with an embedded Monte Carlo (MC) scheme has been developed which effectively addresses each of these events during the simulation. Using the simulation technique, thermal and chemical excitation channels are investigated. The mechanism of ablation for thermal processes is governed by a critical number of bond breaks following the deposition of energy. For the case where an absorbed photon directly causes a bond scission, ablation occurs following the rapid chemical decomposition of material. The study provides insight of stress waves, and bulk ejection of material. A convenient method which may be potentially employed to selectively remove metallic tubes using microwave induced breakdown is proposed and investigated. Carbon nanotube thin films deposited on glass and quartz substrates are placed in a commercial microwave oven and heated for up to several minutes. The radial breathing mode in Raman spectra on the nanotube samples before and after the microwave irradiation suggests that the metallic-to-semiconducting ratios are reduced by around 20%. Meanwhile, because in the thin film samples most of the nanotubes are entangled, smaller diameter nanotubes (both metallic and semiconducting) tend to be affected more. THz transmission measurements of these thin films are also performed before and after microwave irradiation. The significant increase of transmission after the microwave irradiation process confirms the loss of metallic tubes.

3:06PM L25.00002 Molecular dynamics simulation study of the ejection and transport of polymer molecules in matrix-assisted pulsed laser evaporation. LEONID ZHIGILEI, ELODIE LEVEUGLE, University of Virginia — There are a number of applications that utilize the ability of laser ablation of a volatile matrix to entrain, eject and, if needed, deposit large macromolecules to a substrate with minimum chemical modification. In particular, the Matrix-Assisted Pulsed Laser Evaporation (MAPLE) technique is used in fabrication of ultra-thin organic films for optoelectronic, biomedical, and chemical sensor applications. In this presentation we report the results of a computational investigation of the mechanisms of molecule ejection in MAPLE. Coarse-grained molecular dynamics simulations are performed for polymer concentrations up to 6 wt.%. Contrary to the original picture of the ejection and transport of individual polymer molecules in MAPLE, the simulations indicate that polymer molecules are only ejected as parts of polymer-matrix clusters/droplets generated in the process of the explosive disintegration of the overheated matrix. An internal release of matrix vapor in the overheated droplets is shown to be capable of pushing polymer molecules to the outskirts of the droplets, forming “molecular balloons” in which polymer-rich surface layers enclose the volatile matrix material. The results of the simulations explain some of the complex morphologies observed in polymer films deposited in MAPLE and conventional polymer ablation/deposition experiments.

4:30PM L24.00009 Low-Temperature Studies of Electrostatic Doping and Phonon Renormalization in Individual Single-Walled Carbon Nanotubes. GUGANG CHEN, Honda Research Institute USA Inc., Columbus, OH 43212, TEREZA PARONYAN, GAMIH SUMANASEKERA, Department of Physics, University of Louisville, Louisville, KY 40292, ELENA PIGOS, AVETIK HARUTYUNYAN, Honda Research Institute USA Inc., Columbus, OH 43212 — Electrostatic doping of carbon nanotubes (CNTs) induced by applied external gate voltage ($V_g$) in the field-effect transistor (FET) configuration allows controllable variation of charge density and the Fermi level in nanotubes. Raman scattering from a CNT is very sensitive to doping and its interaction with the surrounding environment. Recently, the peculiarities of G-mode as a function of gate induced carrier at room temperature have been reported in [1] (Nature Nanotechnology 2, 725 (2007)). In the present work, we used Raman scattering to study the p- and n-electrostatic doping of CNT as a function of $V_g$ in a wide range of temperature from 6.8 K to 300 K. Virtually symmetric blue-shifting of the G-mode for both p- and n-doping of CNTs has been observed. We found that the prehistory of the CNT measurement as well as environment interaction such as gas adsorption on CNT plays an important role on the observed phenomena. Explanation of our findings will be discussed based on phonon energy renormalization of carbon nanotubes [1] due to the carrier density variation during electrostatic doping.
3:18PM L25.00003 Mechanism of Resonant Mid-Infrared Laser Ablation of Polystyrene, RICHARD HAGLUND, Vanderbilt University, STEPHEN JOHNSON, University of Kentucky, DANIEL BUBB, Rutgers University—Camden — We investigated the mechanism of resonant-infrared laser ablation of polymers using polystyrene as a model material. The ablation laser was a picosecond mid-infrared free-electron laser tuned to mid-IR laser wavelengths that are resonant with specific vibrational modes of the polystyrene target. Time-resolved plume imaging combined with etch-depth measurements and finite-element calculations indicate that a blowoff model fits the experimentally measured etch depths and plume images, provided one accounts for moderate shielding of the surface by the ablation plume. The finite-element model includes the temperature-dependent absorption coefficient and specific heat that dramatically change the material properties above the glass-transition temperature. Ablation begins after a thin surface layer of the material is superheated to temperatures exceeding 1000 C and undergoes spinodal decomposition. The majority of the ablated material is then expelled by way of recoil-induced ejection as the pressure of the expanding vapor plume compresses a laser-melted area at the target surface.

3:30PM L25.00004 The influence of thermal confinement and temperature-dependent absorption on resonant infrared ablation of frozen aqueous and alcohol targets, DANIEL BUBB, STEPHEN JOHNSON, RICHARD HAGLUND, Vanderbilt — We investigated the mechanism of matrix-assisted resonant infrared laser ablation in frozen aqueous and methanol solutions of polymer, by performing plume shadowgraphy and ablation yield measurements. A picosecond, tunable free-electron laser was used for ablation at two wavelengths, one (2960 nm) that was resonant with the –OH stretch in both water and methanol, and the other (3450 nm) that is resonant with the –CH stretch in methanol. The plume images showed gross similarities, differing only in the time required for the shockwave to appear and in the velocity of the shock front. Typically, 15-25 µs after the ablation laser pulse arrives the primary material ejection commences and lasts for hundreds of µs. In all three cases, the ablation plume appears to consist entirely of vapor with no droplets or solid particles. The ablation yield is either linear or quadratic in fluence. This dependence can be understood if we consider thermal diffusion in the targets and the temperature dependence of the absorption coefficient.

3:42PM L25.00005 VUV excimer laser-materials interactions with fluorocarbon polymers, TOM DICKINSON, SHARON GEORGE, STEVE LANGFORD, Washington State University — Particle emission from transparent wide bandgap materials at laser fluences below the threshold for optical breakdown can provide important insight on interactions at the higher fluences employed for surface modification, machining, and laser ablation deposition. We present recent studies of ion and neutral molecule emission from polytetrafluoroethylene [(C₂F₅)ₙ—PTFE—Teflon®] and polyvinylidene fluoride [(CH₂CF₂)n—PVDF] during nanosecond pulsed 157-nm excimer laser irradiation. The chemical and electrical properties of these materials play important roles in many technologies. In PTFE, the primary mechanism for material removal involves bond scission along the backbone of the polymer. In PVDF, HF emission is accompanied by carbonization of the irradiated region. High-energy positive and negative ions are observed from both materials under 157-nm irradiation. We describe critical measurements that reveal the physics and chemistry underlying these processes.

4:06PM L25.00007 Laser Interactions with Vertically-Aligned Carbon Nanotube Arrays, DAVID GEOHEGAN, Oak Ridge National Laboratory, CHRIS ROULEAU, ALEX PURETZKY, JEREMY JACKSON, NORBERT THONNARD, ILIA IVANOV, KARREN MORE, CNMS AND MSTD, OAK RIDGE NATIONAL LABORATORY TEAM — Femtosecond and nanosecond laser interactions with vertically aligned carbon nanotube arrays (VANTA)s have been studied in vacuum and background gases. As-grown VANTAks were synthesized by chemical vapor deposition onto Fe/Al-coated Si wafers to typical heights of 10-20 microns. The forests of aligned nanotubes grow from catalyst nanoparticles anchored to the substrate and typically have a disordered layer of nanotubes at their top surfaces. Laser interactions in vacuum, inert, and oxidizing atmospheres were compared. The nanotubes were found to form periodic surface structures in response to repeated laser pulses. Patterning of the nanotube arrays with scanning beams was studied. Damage to the nanotubes was studied by Raman spectroscopy and high-resolution TEM.

4:18PM L25.00008 Temperature-dependent energy-transfer between electrons and phonons in nickel around Curie temperature and its relation to ultra-fast demagnetization, XUAN WANG, Florida State University, SHOUHUA NIE, Carnegie Mellon University, JUNJIE LI, RICK CLINITE, JIM CAO, Florida State University, JIM CAO TEAM — We report on the use of Ultrafast Electron Diffraction (UED) to study the ultrafast dynamics of nickel induced by fs-laser excitation. Particularly, we have observed a significant increase of electron-phonon coupling time when the pre-set sample base-temperature is reduced across its Curie temperature. This implies a strong quenching of magnetic ordering (ultrafast demagnetization), which serves as an extra energy reservoir other than lattice to relax the electron energy. By modeling the energy transfer among these three systems, we conclude that ultrafast demagnetization happens in a time-scale even shorter than electron-phonon coupling and one temperature for both electron and magnetic ordering, as suggested by several former studies, works very well from energy point of view. Our results also support the former observed ultrafast demagnetization in itinerant ferromagnets, which happens in sub-ps time scale.

Tuesday, March 17, 2009 2:30PM - 5:30PM Session L26 DMP: Focus Sessions: Graphene VI: Phonons and Raman Spectroscopy 328

2:30PM L26.00001 Photovoltaic Hall Effect in Dirac systems – Application to Graphene. This work was supported by the Robert A. Welch Foundation.

2:42PM L26.00002 Thermal conductivity and thermal rectification in graphene nanoribbons: a molecular dynamics study. The project is supported by the Robert A. Welch Foundation.
2:54PM L26.00003 Raman scattering in bilayer graphene: probing phonons, electrons and electron-phonon interactions. LEANDRO M. MALARD, Departamento de Fisica, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil — The application of resonance Raman spectroscopy to study the electronic, vibrational and electron-phonon interaction properties in bilayer graphene will be presented. From the dependence of the second-order Raman bands on the laser excitation energy, we obtain experimental values for the Slonczewski-Weiss-McClure band parameters of bilayer graphene. We will discuss in detail the effect of each one of the tight band parameters on the electronic structure, showing that bilayer graphene has a larger electronic-phonon asymmetry compared to graphene. We will also present experimental results for the phonon dispersion relations near the K point, showing a strong Kohn anomaly for one of the phonon branches. In a gating experiment, the change in Fermi level of bilayer graphene gives rise to a symmetry breaking, allowing the observation of both the symmetric (S) and anti-symmetric (AS) phonon modes. The dependence of the energy and damping of these phonon modes on the Fermi level energy is explained in terms of distinct couplings of the S and AS phonons with intra- and inter-band electron-hole transitions.

3:30PM L26.00004 Phonon dispersion of graphene revisited. SILVIA VIOLA KUSMINSKY, DAVID CAMPBELL, ANTONIO CASTRO NETO, Boston University — We calculate the phonon spectrum for a graphene sheet resulting from the model proposed by T. Lenosky et al. (Nature 355, 333 (1992)) for the free energy of the lattice. This model takes into account not only the usual bond bending and stretching terms, but captures the possible misalignments of the p₆ orbitals. We compare our results with previous models used in the literature. We analyze the effect of anharmonic terms.

3:42PM L26.00005 Giant nonadiabatic effects in layer metals: Raman spectra of intercalated graphite and doped graphene explained. A. MARCO SAITTA, MICHELE LAZZERI, MATTEO CALANDRA, FRANCESCO MAURI, IMPMC, Paris, France — The occurrence of nonadiabatic effects in the vibrational properties of metals has been predicted since the 1960s [1], but hardly confirmed experimentally. We report the first fully ab initio calculations of nonadiabatic frequencies of a number of conventional (hcp Ti and Mg), layered metals (MgB₂, CaC₆, other intercalated graphites) [2] and doped graphene [3]. Nonadiabatic effects can be spectacularly large (up to 30% of the phonon frequencies), but they can only be experimentally observed in the Raman spectra of layered compounds. In layered metals nonadiabatic effects are crucial to explaining the observed Raman shifts and linewidths. Moreover, we show that those quantities can be used to extract the electron momentum-relaxation time. [1] S. Engelsberg and J.R. Schrieffer, Phys. Rev. 131, 993 (1962). [2] A.M. Saitta et al., Phys. Rev. Lett. 100, 226401 (2008). [3] M. Lazzeri and F. Mauri, Phys. Rev. Lett. 97 , 266407 (2006).

3:54PM L26.00006 Probing the Intrinsic Properties of Exfoliated Graphene: Raman Spectroscopy of Free-Standing Monolayers. STEPHANE BERCAUD, SUNMIN RYU, LOUIS BRUS, TONY HEINZ, Columbia University — The properties of pristine, free-standing graphene monolayers prepared by mechanical exfoliation of graphite are investigated. The graphene monolayers, which were suspended over open trenches, are examined by means of spatially resolved Raman spectroscopy of the G, D, and 2D phonon modes. The G-mode phonons exhibit low energies (1580 cm⁻¹) and broad widths (14 cm⁻¹) compared to the response for samples supported on the SiO₂-covered substrate. From analysis of the G-mode Raman spectra, we deduce that the free-standing graphene monolayers are essentially undoped, with an upper bound of 2×10¹⁴ cm⁻² for the residual carrier concentration. On the supported regions, significantly higher and spatially inhomogeneous doping is observed. The free-standing graphene monolayers show very little local disorder, based on the very low Raman D mode intensity.

4:06PM L26.00007 Micro Raman spectroscopy of graphene Hall Bars in the QHE regime. SEBASTIAN REMI, CONSTANZE METZGER, ANNA SWAN, BENNETT B. GOLDBERG, Boston University — One of the most intriguing aspects in the physics of graphene are new types of quantum Hall effects which differ significantly from observations on conventional 2DEG samples. Furthermore the Raman spectrum of graphene shows charge carrier dependent Kohn anomalies. So far transport and optical measurements on graphene haven’t been combined to explore the behavior of the Raman features dependent on the Landau levels. We present our latest measurements of Raman scattering on graphene single and bilayers in the Quantum Hall regime.

4:18PM L26.00008 ABSTRACT WITHDRAWN —

4:30PM L26.00009 Raman Scattering from Pt Island-Decorated Graphene. AWNISH GUPTA, HUMBERTO GUTIERREZ, Department of Physics, Pennsylvania State University, PETER EKLUND, Department of Physics, Department of Material Science and Engineering, Pennsylvania State University — We performed microRaman studies of decorated n–Graphene Layers (nGLs). Nano-islands (NI; dia~5-10 nm) of Pt were created by deposition on the nGL with gaps between the NI in the range of few nm. When the NI were present, we observed D and D’ Raman bands as well as splitting of the G-band into G⁺ and G⁻ (most pronounced for 1GL). The observations may be related to graphene “confined” in the interstitial spaces between NIs. The D and D’ bands show the following properties: (1) Intensity of D and D’ relative to G band decreases with increasing number of layers n between the nGL. (2) Peak frequencies, ωD increases linearly with 1/n while ωD’ remains constant. (3) Linewidth ΓD decreases linearly with 1/n, while ΓD’ increases linearly with 1/n. Our results will be discussed in terms of results theoretically predicted by zone folding (Jishi et al).

4:42PM L26.00010 Raman Spectroscopy of the 2D Mode in Free-Standing Graphene Multilayers. JANINA MAULTZSCH, T.U. Berlin, Germany, STEPHANE BERCAUD, LOUIS BRUS, TONY HEINZ, Columbia U., New York, NY 10027 — Raman spectroscopy of the 2D (or G') mode is a critical tool for the analysis of graphene mono- and multilayers. This symmetry-allowed overtone mode permits one to probe zone-edge phonons by Raman spectroscopy. Moreover, its doubly-resonant electronic character renders it readily observable and encodes in it information about the electronic structure of the graphene sample. In particular, the 2D mode provides a clear signature of the thickness of mono- and multilayer graphene films. In this paper, we present a detailed study of the properties of the 2D for a pristine, free-standing graphene monolayer prepared by mechanical exfoliation over a trench structure. In contrast to the behavior of monolayers of graphene on substrates, for this pristine graphene sample, we observe a positively skewed line shape. The linewidth is also somewhat reduced compared to that observed for graphene supported on a substrate. Further, the 2D mode in the free-standing graphene films exhibits a slightly stronger dispersion with energy of the pump photons than for supported monolayers. We discuss our findings within the framework of double resonance theory, taking into account the intrinsically undoped nature of the free-standing graphene samples. J. Maultzsch et al., Phys. Rev. B 70, 155403 (2004) A. Ferrari et al. Phys. Rev. Lett. 97, 187401 (2006)
4:54PM L26.00011 Seeing and counting graphene layers by elastic light scattering, C. CASIRAGHI, Cambridge University, UK, A. HARTSCHUH, LMU Munich, Germany, E. LIDORIKIS, Ioannina University, Greece, H. QIAN, H. HARUTYUNYAN, T. GOKUS, LMU Munich, Germany, K. S. NOVOSELOV, Manchester University, UK, A. C. FERRARI, Cambridge University, UK — Raman scattering has recently emerged as a viable and nondestructive technique for the identification of graphene, its doping, edges and amount of defects [1-3]. However, the Raman scattered photons are a minority compared to those elastically scattered. Here we show that large graphene layers can be mapped and identified in a few minutes by elastic scattering. We report an extensive investigation of graphene on silicon/silicon oxide substrate by monochromatic and white-light elastic scattering and the theoretical understanding of the experimental data [4]. Maps of the scattered light are obtained by raster scanning the sample with a piezo-electric stage. We show that the image contrast depends sensitively on the dielectric properties of the sample as well as the substrate geometry and can be described quantitatively using the complex refractive index of bulk graphite. [1] A. C. Ferrari et al., PRL 97, 187401 (2006) [2] S. Pisana et al., Nature Materials 6, 198 (2007) [3] C. Casiraghi et al., APL 91, 233108 (2007) [4] C. Casiraghi et al., Nano Letters 7, 2711 (2007)

5:06PM L26.00012 Polarized micro Raman spectroscopy of bilayer graphene, HYERIM MOON, DUHEE YOON, Department of Physics, Sogang University, Seoul 121-742, Korea, YOUNG-WOO SON, Korea Institute for Advanced Study, Seoul 130-722, Korea, HYEONSIK CHEONG, Department of Physics, Sogang University, Seoul 121-742, Korea — The frequency of Raman 2D band of the graphite depends on the excitation laser energy. This phenomenon is explained with double resonance Raman process. In polarized micro-Raman spectroscopy of single layer graphene, Raman G band (∼1586 cm⁻¹) is isotropic, and 2D band (∼2686 cm⁻¹) strongly depends on relative polarizations of the incident and scattered photons. This strong polarization dependence originates from inhomogeneous optical absorption and emission mediated by resonant electron-phonon interaction. In bi-layer graphene, Raman 2D band can be decomposed into four Lorentzian peaks which can be interpreted in terms of the four transition paths in the double resonance Raman process. We investigated the polarization dependence of each Lorentzian peak in the Raman 2D band of bi-layer graphene for different excitation laser energies. Strong polarization dependence of the polarized Raman scattering is analyzed in terms of the band structure of bi-layer graphene.

Tuesday, March 17, 2009 2:30PM - 4:42PM
Session L27 FLAP: Focus Session: Graphene Device and Applications II

2:30PM L27.00001 Graphene and chemically modified graphene sensors, JEREMY ROBINSON, Naval Research Laboratory — Molecular sensing via sp²-bonded carbon nanomaterials is a promising research area in both nanoscience and nanotechnology. In general these materials are thermally and chemically stable, come in a variety of different geometries (spheres, tubes, and sheets), and are process compatible with conventional micro-lithographic techniques. In this talk we focus on atomically thin sheets of sp²-bonded carbon, known as graphene, and discuss their sensing properties when exposed to chemical vapors. The remarkable physical properties of graphene—from near ballistic electron conduction to ultra high stiffness (≈5 times that of steel)—make it a unique system to study both electronic and mechanical transduction modes. Finally, we demonstrate the utility of graphene-based films is greatly expanded after chemical functionalization. In this regard, chemically modified graphene (CMG) is emerging as a material system whose properties are complementary to nominally pure graphene for sensing applications.

3:06PM L27.00002 Intrinsic Response of Graphene Vapor Sensors, YE LU, YAPING DAN, University of Pennsylvania, NICHOLAS KYBERT, University of Warwick, CHARLIE JOHNSON, University of Pennsylvania — Ye Lu, Yaping Dan, Nicholas J. Kybert, A. T. Charlie Johnson, 1 University of Pennsylvania, USA 2 University of Warwick, UK Graphene is a purely two-dimensional material that has extremely favorable chemical sensor properties. It is known, however, that conventional nanolithographic processing typically leaves a resist residue on the graphene surface, whose impact on the sensor characteristics of the system has not yet been determined. Here we show that the contamination layer both degrades the electronic properties of the graphene and masks graphene’s intrinsic sensor responses. The contamination layer chemically dopes the graphene, enhances carrier scattering, and acts as an absorbent layer that concentrates analyte molecules at the graphene surface, thereby enhancing the sensor response. We demonstrate a cleaning process that verifies the contamination on the device structure and allows the intrinsic chemical responses of graphene to be measured. Additionally, methods of functionalizing clean graphene device as high quality chemical vapor sensor are explored. Funding: JSTO DTRA and the Army Research Office Grant #W911NF-06-1-0462, NSF-NSEC/N Birck DMR-0425780, REU program of the Laboratory for Research on the Structure of Matter (N.I.K.).

3:18PM L27.00003 Single-layer graphene Motion and Mass Sensors with Electrical Readout, CHANGYAO CHEN, Columbia University, SAMI ROSENBLATT, KIRILL BOLOTIN, HORST STORMER, PHILIP KIM, TONY HEINZ, JAMES HONE — We report for the first time the implementation of graphene electromechanical resonators that can detect their own motion. Susspeed single-layer graphene field-effect transistors allow for electrical detection of the resonances while functioning as heterodyne mixers in a manner analogous to the operation of a radio receiver. Mechanical resonances occur in the 10-100 MHz range, can be lithographically-tailored, are tunable by tens of MHz, and have quality factors up to 200 while operated in vacuum at room temperature. Furthermore, by analyzing the frequency response of the resonators, we succeed in weighing both the pristine single-layer graphene and with a layer of organic material deposited on.
3:30PM L27.00004 Electronic and magnetic functions of nanographene-based host-guest system. TOSHIKAZU ENOKI, Tokyo Institute of Technology — The electronic structure of nanographene having open edges crucially depends on its edge shape. According to theoretical predictions, nanographene has nonbonding =-electron state (edge state) localized in zigzag edges. We investigated the electronic structure of graphene edges, the magnetism of the edge-state spins in nanographene and the effect of host-guest interaction on the magnetism. For magnetic investigations, we employed nanoporous activated carbon fiber (ACF) having a 3D disordered network of nanographite domains, each of which is a stack of 3-4 nanographene sheets. STM/STS investigations of hydrogen-terminated graphene edges confirm the presence of edge states around zigzag edges, in good agreement with theoretical works. The feature of the edge state depends on the detailed geometry of the edge structures. The magnetism of nanographene in ACF has a ferrimagnetic feature with a net magnetic moment, for which the cooperation of ferromagnetic intra-zigzag-edge and ferromagnetic/antiferromagnetic inter-zigzag-edge interactions is responsible. Heat-treatment, which induces an insulator-metal transition, brings about spin glass state of the edge-state spins in the vicinity of the transition. Physorption of guest species such as water, organic molecules, rare gas in the ACF nanopores generates a high-spin/low-spin magnetic switching phenomenon, in which a discontinuous reduction of the magnetic moment takes place. This is explained in terms of the strengthening of the inter-graphene-sheet antiferromagnetic interaction, which is induced by the mechanical compression of nanographite domains by the condensed guest molecules. The magnetic oxygen molecules physisorbed in the nanopores work seriously to decrease the magnetoresistance in ACF as a consequence of the interaction between the oxygen molecule spins and edge-state spins.

4:06PM L27.00005 Investigation of Molecular Functionalizing Agents for Graphene Device Optimization. DAMON FARMER, IBM, YU-MING LIN, ALI AFZALI-ARDAKANI, PHAEDON AVOURIS — Due to its linear dispersion relation and the predicted chiral nature of its quasiparticles, graphene has become a material of intense experimental and theoretical investigation. There has been rapid progress in the fabrication and understanding of graphene devices. However, many key issues still need to be addressed in order to fully exploit graphene for technological applications. Here, we identify stable molecular compounds that can be used as dopants and functionalizing agents on graphene. As dopants, these compounds are used to both modify the potential profile in the channel region of graphene devices, and reduce parasitic resistances in these devices. As functionalizing agents, these compounds serve as nucleation sites for the uniform growth of thin high-κ gate dielectrics, allowing for enhanced capacitive coupling with the graphene channel. The characteristics of graphene devices employing these molecular compounds will be presented, and problems associated with the implementation of these molecules in graphene devices will be discussed.

4:18PM L27.00006 Fabrication and Chemical Doping of Carbon-based Transparent Electrodes. GEORGE TULEVSKI, IBM T.J. Watson Research Center, ALI AFZALI — The use of carbon-based materials (carbon nanotubes and graphene) as transparent electrodes has attracted enormous interest due to their high transparencies, conductivity and potential as a lower cost alternative to traditional transparent electrode materials (i.e. Indium Tin Oxide). This talk will focus on using solution processes to suspend both carbon nanotubes and graphene flakes in solution and the fabrication of transparent electrodes from these solutions. Solutions were prepared using both surfactants and organic solvents, followed by purification to remove large aggregates and impurities. A variety of chemical dopants were then employed including metal salts and small organic molecules. The sheet resistance of the resultant films can be significantly reduced with chemical doping.

4:30PM L27.00007 Atomic Layer Deposition (ALD) methods for fabricating graphene devices - theory and experiments. Yvette Hancock, Department of Engineering Physics, Helsinki University of Technology, Finland, Saimiul Haque, Nokia Research Center, Helsinki, Finland, Maarit Karppinen, Laboratory of Inorganic Chemistry, Department of Chemistry, Helsinki University of Technology, Finland, Nasa Staralouet, Department of Physics, Helsinki University of Technology, Finland — ALD has the potential to be a well controlled method for coating and patterning graphene structures and making new generation devices. We have investigated the ALD of 5 nm thin coatings of high-κ dielectric Al2O3 onto graphene, and have determined the selectivity of the chemical specific deposition, for example, to the edges or starting from defect sites. Experimentally, we see an affinity for Al2O3 to coat the edges of graphene, which is also supported by our ab initio calculations. The affinity of the Al2O3 coating with the edges of graphene allows us to make a mask, which could then be used to fabricate graphene nanoribbons of widths less than 50 nm that are also gated.

Tuesday, March 17, 2009 2:30PM - 5:18PM —
Session L28 DMP FLAP: Focus Session: Thermoelectric Materials: Tellurides 330

2:30PM L28.00001 Enhancement of the thermoelectric figure of merit by distortions of the dispersion relation. Joseph P. Heremans, Department of Mechanical Engineering and Department of Physics, The Ohio State University — A doubling of the thermoelectric figure of merit (ZT) of p-type PbTe above 700 K has been recently demonstrated (1) in thallium-doped material. The effect comes about because of an electronic energy level of the Tl atoms resonates with the valence band of PbTe. This creates an excess density of states, g(E), at a specific energy about 60 meV below the valence band edge, which in turn gives a thermoelectric power at that carrier concentration about three times higher than that of similarly-doped p-type PbTe. In this talk, we will review the mechanisms by which this distortion of the g(E) function, from the normal E1/2 form valid for parabolic bands in three dimensions into a spike-like function, increases the thermoelectric power and thus ZT. We further derive a set of criteria for the excess g(E) to improve ZT. We will discuss the applicability of this approach to other electronic levels in PbTe first, and then describe the more general quest for such energy levels in other thermoelectric semiconductors. (1) J. P. Heremans et al., Science 321 554 (2008)

3:06PM L28.00002 Electronic Inhomogeneity in PbTe-based High Performance Thermoelectric Materials Observed by NMR. E.M. Levin, K. Schmidt-Rohr, B.A. Cook, Ames Laboratory DOE and Iowa State University, M.G. Kanatzidis, Northwestern University — Effects of composition and synthesis conditions on the local structure and charge carrier concentration in AgxSb2Pb1−xTe20 (LAST-18) thermoelectric (TE) materials have been studied by 125Te and 207Pb nuclear magnetic resonance (NMR) with magic-angel spinning. The high-resolution 125Te NMR spectra show that most Sb and Ag is not part of Sb2Te3, AgSbTe2, or Ag2Te inclusions. Biexponential NMR spin-lattice (T1) relaxation as well as Knight shifts of 125Te and 207Pb NMR signals show that many LAST-18 materials contain two phases of similar composition but with free electron concentrations that differ by more than an order of magnitude, i.e. these materials are electronically inhomogeneous. The NMR data were calibrated against Hall- and Seebeck-effect measurements to give the charge carrier concentrations in the two phases. This electronic inhomogeneity may result from the appearance of potential barriers inside TE materials, similar to those observed for semiconductor-semiconductor or metal-semiconductor junctions. Such barriers may affect thermopower, electrical, and thermal conductivity of TE materials.
3:18PM L28.00003 Thermodynamic Properties of Pb and Ag-Sb Based Chalcogenides: A First-Principles Study1, Yi ZHANG, University of Nevada, Las Vegas, XUEZHI KE, University of Nevada Las Vegas; East China Normal University, CHANGFENG CHEN, University of Nevada, Las Vegas, JIHUI YANG, General Motors, PAUL R. C. KENT, Oak Ridge National Lab — The Pb and Ag-Sb based chalcogenide compounds have received considerable interest for their potential applications in thermoelectric devices. Their low thermal conductivity plays a key role in producing the high figure of merit (ZT) that is critical for applications. We performed a series of first-principles calculations on several Pb and Ag-Sb based chalcogenide compounds to understand their lattice dynamics. The direct force method and density functional theory calculations were used to obtain the phonon dispersion and density of states. The phonon softening processes with the volume change were carefully evaluated. Moreover, we employed the quasiharmonic approximation to calculate the thermodynamic functions. The calculated results are in good agreement with available experimental data and provide insights for understanding the physical properties.

1Work supported by DOE grants DE-FG52-06NA20274, DE-FG-0604NT42278, DE-AC02-98CH10886. This research used resources of the National Center for Computational Sciences and the Center for Nanophase Materials Sciences at ORNL.

3:30PM L28.00004 Link between changes in ZT and microstructure in AgSbTe2. PETER SHARMA, JOSHUA SUGAR, DOUGLAS MEDLIN, Sandia National Laboratory — The best thermoelectric alloys have complex microstructures. For example, the LAST alloys, (AgSbTe2)x−y(PbTe)y, possess ZT~1.5–2 but have a great variety of inclusions with different chemistry at different length scales. How does microstructure affect thermoelectric efficiency? Since the phase diagram of this and most quaternary alloys is poorly known, transport properties have not been systematically connected to microstructure. We are attacking this problem by studying the simple ternary alloy AgSbTe2, a component of the LAST system, in order to show how thermoelectric properties change with a known, controlled microstructure. AgSbTe2 forms within the well-studied Ag2Te-Sb2Te3 pseudobinary phase diagam. We have found that Sb-rich AgSbTe2 is composed of Sb2Te5 precipitates embedded in a homogeneous rocksalt Ag10Sb30Te54 matrix. The precipitates are plate-like and crystallographically aligned along their close packed planes parallel to that of the matrix. The size of these Sb2Te5 plates can be tuned from the nanometer to micron scale. In this work, the formation and growth of precipitates over a wide length scale is linked to changes in thermoelectric properties for the first time. This study is useful for understanding the complexity of LAST, or any bulk thermoelectric where second phase precipitation occurs.

3:42PM L28.00005 Microstructure and Nucleation Mechanism for Nanoprecipitates in PbTe-Ag5Sb2Te2. XUEZHI KE, University of Nevada, Las Vegas; East China Normal University, CHANGFENG CHEN, University of Nevada, Las Vegas, JIHUI YANG, General Motors, LIJUN WU, JUAN ZHOU, QIAN LI, YIMEI ZHU, Brookhaven National Laboratory, PAUL R.C. KENT, Oak Ridge National Laboratory — Many recent advances in thermoelectric (TE) materials are attributed to their nanoscale constituents. Determination of the nanocomposite structures has represented a major experimental and theoretical challenge and eluded previous attempts. Here we present the first atomically resolved structures of high performance TE material PbTe-Ag5Sb2Te2 by transmission electron microscopy imaging and density functional theory calculations. The results establish an accurate structural characterization for PbTe-Ag5Sb2Te2 and identify the interplay of electric dipolar interactions and strain fields as the driving mechanism for nanoprecipitate nucleation and growth, which provides key insights for understanding a broad class of complex nanocomposite materials.

3:54PM L28.00006 Galvanomagnetic and Thermomagnetic Properties of Ag1−xNaSb2Te5 Alloys. MICHELE NIELSEN, VLADIMIR JOVOVIC, CHRISTOPHER JAWORSKI, Department of Mechanical Engineering, Ohio State University, Columbus, OH, JOSEPH HEREMANS, Department of Mechanical Engineering and Department of Physics, Ohio State University, Columbus, OH — Group I-V-VI alloys have intrinsically low thermal conductivity1 on the order of 0.65 W/mK due to Umklapp phonon-phonon scattering. Combined with the high valence band density of states in AbSb2Te3, this makes this material system ideal for thermoelectric applications up to 416 K, where AgSbTe2 undergoes a crystallographic phase transition. The partial substitution of Na for Ag is expected to address this problem. We synthesize bulk Ag1−xNaSb2Te5 alloys and measure the evolution of the phase transition as a function of Na concentration x. The thermoelectric and galvanomagnetic properties of the alloys are also studied; based on the measurement of resistivity, Seebeck, Nernst and Hall coefficients we calculate mobilities, Fermi energies and partial carrier concentrations of holes and electrons.

4:06PM L28.00007 Electronic and Thermal Properties of Cubic Ge-Sb-Te Compounds. DONALD MORELLI, KEVIN ZHOU, Michigan State University — The ternary rocksalt structure compound Ge4SbTe5 is unusual because most members of the Ge-Sb-Te family form along the tie-line of the binary compounds GeTe and Sb2Te3, and thus do not possess the 1:1 cation:anion ratio necessary to present themselves in a cubic structure. The TE properties of these (GeTe)2(Sb2Te3)x−y compounds, while interesting in their own right, are no better than those of commercially available materials. To understand the thermoelectric properties of these materials, we investigated the structural and thermal properties of the AlTe3 and Al2Te5 compounds and associated with TE properties a cubic compound is advantageous because there is no issue regarding anisotropy of the thermoelectric properties. We have fabricated bulk samples of Ge4SbTe5 and related compounds, characterized their crystal structure, and measured some of their thermal and electronic properties. Results of isoelectronic substitution of Se on the Te site and Sn on the Ge site will be reported.

4:18PM L28.00008 Thermoelectric Figure-of-merit in Bulk p-type PbTe. BO YU, HUI WANG, Boston College, BED POUMEL, GMZ Energy Inc., KENNETH MCENANEY, GANG CHEN, Mass. Institute of Technology, ZHIFENG REN, Boston College, BOSTON COLLEGE, DEPT. OF PHYSICS TEAM, MASS. INSTITUTE OF TECHNOLOGY, DEPT. OF MECHANICAL ENGINEERING COLLABORATION — Lead telluride and its relatives, with equal numbers of atoms on the cation and anion sites, form stably in the cubic rocksalt structure. For compounds, while interesting in their own right, are no better than those of commercially available materials. To understand the thermoelectric properties of these materials, we investigated the structural and thermal properties of the AlTe3 and Al2Te5 compounds and associated with TE properties a cubic compound is advantageous because there is no issue regarding anisotropy of the thermoelectric properties. We have fabricated bulk samples of Ge4SbTe5 and related compounds, characterized their crystal structure, and measured some of their thermal and electronic properties. Results of isoelectronic substitution of Se on the Te site and Sn on the Ge site will be reported.

4:30PM L28.00009 Modular assembly of binary nanocrystal composite solids for high-efficiency thermoelectric power generation. DONG-KYUN KO, University of Pennsylvania, Materials Sci. & Eng., CHRISTOPHER MURRAY, University of Pennsylvania, Materials Sci. & Eng. and Chemistry — Despite the numerous advantages of semiconductor nanostructures, doping nanometer size crystals show difficulties not found in conventional bulk systems. Especially for thermoelectric applications, it is critical to control the number of carriers that are available in semiconductors in order to maximize the figure of merit. Here, we report modular assembly of binary composite nanocrystals, as an effective bottom-up design tool, to create a new family of artificial solids with a prescribed set of doping levels. Silver telluride (Ag2Te) nanocrystals, which can act as dopants, are introduced in lead telluride (PbTe) nanocrystal assemblies in order to modify the carrier concentration until an optimum power factor is realized. This study focuses on electronic and thermoelectric characterization of these binary composite solids. Hall measurement and field effect transistor characteristics were investigated in order to identify the carrier type, mobility, and concentration. Temperature dependence of low-bias conductivity was also characterized to gain a better understanding of electronic conduction. Finally, Seebeck voltage was measured with varying PbTe to Ag2Te nanocrystal concentration ratios in order to investigate the Seebeck coefficient as a function of carrier concentration.
4:42PM L28.00010 Galvanomagnetic and thermomagnetic properties of thallium doped Pb-SnTe and PbSeTe1, VLADIMIR JOVOVIC, JOSEPH HEREMANS, The Ohio State University — Thallium acts as a resonant level in PbTe, so that PbTe:Tl shows a significant improvement of thermoelectric properties due to an increase in thermopower as compared to that of similarly Na-doped PbTe [2]. Further improvements in ZT are expected from a reduction of the thermal conductivity by alloy scattering in Pb1−x−y TlxSnxTe and Pb1−x−y TlxTe1−xSey alloys. However, the band structure of PbTe is sensitive to alloying with Sn and Se, and thus the location of the Tl level with respect to the valence band can change with x. In this study, we investigate the effects that band structure modifications have on the enhancement of thermopower. Thermoelectric properties of Pb1−x−y TlxSnxTe and Pb1−x−y TlxTe1−xSey alloys with y=0.01-0.04 and x=0-0.3 are measured in directions longitudinal and transverse to magnetic fields in the range of 0.5-1.5 T. We report zero field values of electrical resistivity, thermopower, Hall coefficient and adiabatic Nernst-Ettingshausen coefficient as measured in temperature range 80-420K. From these we calculate carrier density and mobility and the density of states effective masses and Fermi energies. [2] J.P. Heremans et al., Science 321, 554 (2008)

5:06PM L28.00012 Enhancement of Thermoelectric Figure-of-Merit by a Nanostructure Approach, ZHIFENG REN, Boston College, BED POUDEL, GMZ Energy, Inc., YI MA, YUCHENG LAN, XIAOWEI WANG, GIRI JOSHI, GAOHUA ZHU, JIAN YANG, BO YU, XIAO YAN, HUI WANG, DEZHI WANG, Boston College, QING HAO, HOHYUN LEE, AUSTIN MINNICH, ANDREW MUTO, DARYOOSH VASHAEE, MILDRED DRESSELHAUS, GANG CHEN, MIT COLLABORATION, MIT COLLABORATION — The dimensionless thermoelectric figure-of-merit (ZT) in bulk materials has remained about 1 for many years. Here we show that a significant ZT improvement can be achieved in nanocrystalline bulk materials. These nanocrystalline bulk materials were made by hot-pressing nanopowders that are ball-milled from either crystalline ingots or elements. Electrical transport measurements, coupled with microstructure studies and modeling, show that the ZT improvement is the result of low thermal conductivity caused by the increased phonon scattering by grain boundaries and defects. More importantly, the nanostructure approach has been successfully applied to a few thermoelectric material systems, proving its generality. The approach can be easily scaled up to multiple tons. Thermal stability studies have shown that the nanostructures are stable at the application temperature for an extended period of time. It is expected that such enhanced materials will make the existing cooling and power generation systems more efficient.

Tuesday, March 17, 2009 2:30PM - 5:30PM –
Session L29 FEd DCOMP: Focus Session: Incorporating Computational Physics into Teaching

2:30PM L29.00001 One Lattice Gauge Theorist’s Perspective on Important Skills and Concepts for Computational Physics Courses, STEVEN GOTTLIEB, Indiana University — Lattice Gauge Theory employs a number of numerical and statistical techniques including: sparse matrix inversion, Monte Carlo methods, higher order numerical integration schemes, resampling methods such as jackknife and bootstrap, and parameter estimation from correlated data. Many of these techniques can be taught to undergraduates in contexts more easily understood than a lattice gauge theory simulation.

3:06PM L29.00002 Tips and Tools for Teaching Quantum Mechanics, GUANGTIAN ZHU, CHANDRALEKHA SINGH, Department of Physics & Astronomy, University of Pittsburgh — Learning quantum mechanics is challenging – students usually struggle to master the basic concepts, even though they may perform well on solving quantitative problems. Our group is investigating the difficulties that upper-level students have in learning quantum mechanics. To help improve student understanding of quantum concepts, we are designing quantum interactive learning tutorials (QuILTs) and tools for peer-instruction. Many of the tutorials employ computer simulations to help students visualize and develop better intuition about quantum phenomena. We will discuss the common students’ difficulties, share the material we have developed and evaluated to make the quantum mechanics class engaging and useful, and show ways to bridge the gap between quantitative and conceptual aspects of quantum mechanics.

3:18PM L29.00003 Building a Digital Library: Theory, Computation, and Education1, WOLFGANG CHRISTIAN, Davidson College — Over the past dozen years the Open Source Physics (OSP) project has produced some of the most widely used interactive curricular materials for high teaching of introductory and advanced physics courses. These materials are based on Java applets called Phsylets and on new OSP programs and applications. In this talk we will outline the pedagogical and technical features of these programs and describe our current effort to create and distribute our material using the comPADRE National Science Digital Library. Open Source Physics collection is available on the comPADRE website at http://www.compadre.org/osp/

1Partial funding for this work was obtained through NSF grant DUE-0442581.
Introducing scientific computation from high school to college: the case of Modellus

BRYNDOL SONES, FRANK WATTENBERG, US Military Academy — DIYModeling (Do it Yourself Modeling) aims to improve both the quality of learning in the STEM disciplines and the extent to which the very best STEM learning reaches all students by leveraging the power of game-quality modeling and simulation. It builds on earlier work by many people using platforms like Java, Flash and game-quality simulations like the Federation of American Scientists' Immune Attack. DIYModeling adds a new element that enables students and faculty to build their own game-quality simulations by specifying the underlying scientific and mathematical models without getting into the details of programming. The DIYModeling team is a consortium of math and basic science faculty from six universities teamed up with the software development company Tietronix Software (an 8a certified company), which does contract work for NASA to build complex software systems including game-quality immersive simulations. The goal of the program is to enable curriculum developers and students to develop game-quality, three-dimensional immersive simulations with educational benefit. Current applications under development include a first-person shooter game environment for use in data collection and statistical analysis, orbital mechanics in executing the Hohman transfer, and solar power generation. Some pilot tests are planned for use in the spring semester.

3:30PM L29.00004 Introducing scientific computation from high school to college: the case of Modellus

3:42PM L29.00005 DIYModeling: a place for students and faculty to build their own game-quality simulations to enhance learning.

EJS enhances traditional learning in freshman mechanics

AMY BUG, JEN TRINH, Swarthmore College — Easy Java Simulations (EJS) is a freeware authoring tool (part of the Open Source Physics project) [1]. EJS allows not only physics teachers, but students as well, to produce nonproprietary, platform-independent simulations with both numerical and graphical output. We report on the use of EJS as a helpful tool in a physics course for majors. In particular, EJS allows a student to conceptualize tough introductory material such as kinematics in polar coordinates and conservation of momentum with mass-transfer. The construction of an EJS simulation gives the student an environment in which to surmount both conceptual and mathematical roadblocks to learning. [1] http://www.opensourcephysics.org/

3:54PM L29.00006 Computational Physics at Haverford College

Developing Computational Physics in Nigeria

GODFREY AKPOJOTOR, Max Planck Institute for Physics of Complex Systems, Dresden and Delta State University, Abakpa, EMMANUEL ENUKPERE, College of Education, Warri, FAMOUS AKPOJOTOR, Federal Government College, Sokoto, SUNNY OJOBOR, Delta State University, Abakpa — Computer based instruction is permeating the educational curricula of many countries owing to the realization that computational physics which involves computer modeling, enhances the teaching/learning process when combined with theory and experiment. For the students, it gives them more insight and understanding in the learning process and thereby equips them with scientific and computing skills to excel in the industrial and commercial environments as well as at the Masters and doctoral levels. And for the teachers, among others benefits, the availability of open access sites on both instructional and evaluation materials can improve their performances. With a growing population of students and new challenges to meet developmental goals, this paper examine the challenges and prospects of current drive to develop Computational physics as a university undergraduate programme or as a choice of specialized modules or laboratories within the mainstream physics programme in Nigeria institutions. In particular, the current effort of the Nigerian Computational Physics Working Group to design computational physics programmes to meet the developmental goals of the country is discussed.

4:06PM L29.00007 Developing Computational Physics in Nigeria

4:30PM L29.00009 Computational Labs Using VPython Complement Conventional Labs in Online and Regular Physics Classes

MARTINA E. BACHLECHNER, Fairmont State University — Fairmont State University has developed online physics classes for the high-school teaching certificate based on the text book Matter and Interaction by Chabay and Sherwood. This lead to using computational VPython labs also in the traditional class room setting to complement conventional labs. The computational modeling process has proven to provide an excellent basis for the subsequent classroom lab and allows for a concrete experience of the difference between behavior according to a model and realistic behavior. Observations in the regular class room setting feed back into the development of the online classes.

We thank the Howard Hughes Medical Institute for funding.

4:42PM L29.00010 A New Graduate Minor Program in Computational Science

LYLE LONG, The Pennsylvania State University — This talk will discuss the need for graduate educational programs in computational science. Due to the continued increase in computer power, algorithms, and software the need for students trained in computational science has increased dramatically. Theoretical and experimental methods are still important, but there is an enormous need for students who understand numerical methods, programming, parallel computing, and software engineering. A new Graduate Minor program has been developed at Penn State and is now available to all graduate students (http://www.csci.psu.edu) The Ph.D. students are required to take two core courses (out of three possible), attend two seminar series, and choose two additional courses (which are often in engineering, science and college curricula, where computers are mainly used for showing text, images and animations. Most curricula do not consider the use of computational scientific tools, particularly tools where students can manipulate and build mathematical models, as an integral part of the learning experiences all students must have. In this paper, we discuss how Modellus, a freely available software tool (created in Java and available for all operating systems) can be used to support curricula where students from the age of 12 to college years can be introduced to scientific computation. We will also show how such a wide range of learners and their teachers can use Modellus to implement simple numerical methods and interactive animations based on those methods to explore advanced mathematical and physical reasoning.
A compound with one-dimensional chains of irregular edge-shared CoO$_2$ has shown that a spontaneous electric polarization of the order of 1.5 $\mu$C m$^{-2}$ develops below the magnetic transition temperature. This phenomenon is unique in that it exhibits spontaneous magnetization as well as electric polarization. We have studied the detailed switching behavior of magnetoelectric behaviors and suggest possible quantum phase transitions.

We have discovered the appearance of ferroelectricity below the Neel temperature of 6.7 K in the square-lattice antiferromagnetic Ba$_2$CoGe$_2$O$_7$, grown by using a floating zone technique. The ferroelectric polarization aligns along the tetragonal $c$ axis, but is very small in magnitude. However, the magnitude of polarization increases remarkably and the polarization direction smoothly rotates away from the $c$ axis with increasing magnetic fields along the $c$ axis. This change of polarization and the associated change of dielectric constant with fields are monotonic without going through any phase transition.

Ferroelectric magnets: a Conical Spiral and an Ising Chain. YOUNG JAI CHOI, Rutgers University — We have discovered the appearance of ferroelectricity below the Neel temperature of 6.7 K in the square-lattice antiferromagnetic Ba$_2$CoGe$_2$O$_7$, grown by using a floating zone technique. The ferroelectric polarization aligns along the tetragonal $c$ axis, but is very small in magnitude. However, the magnitude of polarization increases remarkably and the polarization direction smoothly rotates away from the $c$ axis with increasing magnetic fields along the $c$ axis. This change of polarization and the associated change of dielectric constant with fields are monotonic without going through any phase transition.

3:18PM  L30.00003 Electric polarization reversal under high magnetic field in square lattice antiferromagnetic Ba$_2$CoGe$_2$O$_7$. JAE WOOK KIM, S.H. CHUN, S.H. KIM, KEE HOON KIM, Seoul National University, Y. JO, L. BALICAS, NHHFL, Y.J. CHOI, S.W. CHEONG, Rutgers University, F. BALAKIREV, N. HARRISON, LANL. — Recently, Ba$_2$CoGe$_2$O$_7$, was found to develop electric polarization ($P$) below $T_N$=6.7 K [1]. Interestingly, $P$ along the $a$-axis increases linearly, crossing zero at $H$=0 when magnetic field ($H$) is applied along the $a$-axis. To investigate the linear $H$-dependence of $P$ further, we measured $P$ electric constant ($\epsilon$), and magnetization ($M$) under high $H$ up to 45 T. On application of high $H$, $P$ increases linearly up to $H$~15 T but suddenly decreases to a constant negative value. A peak in $\epsilon$ is found at the $P$-reversal point which is suppressed with increasing $H$ to lower temperature with a concomitant sharpening up to $H$~36 T at $T$=0.6 K. Furthermore, $M$/$H$ curves below $T_N$ show saturation above the $P$-reversal magnetic field, indicating that the negative $P$ state is due to the fully ordered spin configuration. This phenomenon is similar to the case of multiferroic BiMn$_2$O$_5$, in which $P$ reversal is driven by a spin-flop crossover [2]. However, in Ba$_2$CoGe$_2$O$_7$, $P$-reversal does not accompany a $H$ induced magnetic phase transition. We discuss possible mechanisms for this unique magnetoelectric behavior and suggest possible quantum phase transition behavior. [1] H. Yi et al., Appl. Phys. Lett. 91, 212904 (2008). [2] Jae Wook Kim et al., arXiv:0810.1907.

3:30PM L30.00004 Magnetic Frustution and Magnetoelastic Coupling in CoSe$_2$O$_5$. BRENT MELOT, RAM SESHADRI, Materials Department, UC Santa Barbara, AMBESH DIXIT, GAVIN LAWES, Department of Physics and Astronomy, Wayne State University, EMMANUELLE SUJARD, Institute Laue Langevin, Grenoble, France — We present structural and magnetic measurements on CoSe$_2$O$_5$, a compound with one-dimensional chains of irregular edge-shared CoO$_2$ octahedra, separated by Se$_2$O$_5$ units. Below 8.5 K low-field magnetic susceptibility and heat capacity measurements show long range antiferromagnetic order develops. The magnetic structure of this ordered state has been determined by neutron diffraction to consist of moments aligned antiparallel along the length of the chain as well as antiparallel to neighboring chains. The magnetic ordering becomes more complex when the compound is exposed under strong fields, with highly non-linear $M$~$H$ behavior below the ordering temperature. Measurement of the magnetoelectric constant and pyrocurrent has also shown directed fields larger than 3 T results in spontaneous electric polarization of the order of 1.5 $\mu$C m$^{-2}$ which develops below the magnetic transition temperature.
3:42PM L30.00005 Ferroelectricity from magnetic order. MICHELE KENZELMANN, Paul Scherrer Institute—Magnetic insulators with competing exchange interactions can give rise to strong fluctuations and qualitatively new ground states. The proximity of such systems to quantum critical points can lead to strong cross-coupling between magnetic long-range order and the chemical lattice. Case in point is a new class of multiferroic materials in which the magnetic and ferroelectric order parameters are directly coupled, and a magnetic field can suppress or switch the electric polarization [1]. Our neutron measurements reveal that ferroelectricity is induced by magnetic order and emerges only if the magnetic structure creates a polar axis [2-5]. Our experiments prove that the onset of ferroelectricity is described by a magneto-electric Landau theory that seems to apply for a wide range of multiferroic materials [6]. The spin dynamics and the field-temperature phase diagram of the ordered phases provide evidence that competing ground states are essential for ferroelectricity. The magneto-electric coupling, however, arising from relatively small interactions that are currently under intense investigation.

4:18PM L30.00006 Q-domains in Multiferroic CoCr$_2$O$_4$. THOMAS A. KAPLAN, Michigan State University—In spinel CoCr$_2$O$_4$, the observed spin at low temperature is, approximately, a “ferrimagnetic spiral” given by $S_{\nu} = \sin \theta_{\nu} [2 \cos (Q \cdot R_{\nu} + \gamma_{\nu}) + \hat{y} \sin (Q \cdot R_{\nu} + \gamma_{\nu})]$; $\gamma_{\nu}$ is the phase of the 6 conical spirals, all with wave vector Q in the [110] direction. This yields magnetization $M$ and, via the Katsura et al mechanism, electric polarization $P$. Equivalent Q’s, e.g. $\pm Q$, with associated M’s and P’s, are expected to give degenerate states, “$Q - M - P$ domains”; poling in electric and magnetic fields selects a single such domain. Reversal of magnetic field then leads to P reversal and Q reversal. But Q $\rightarrow$ $-Q$ in the equation above does not appear to give a degenerate state. I show, via the Heisenberg model and the Generalized Luttinger-Tisza method used in the prediction of the spin state, that $\gamma_{\nu} \rightarrow -\gamma_{\nu}$ on Q reversal, making manifest the Q $\rightarrow$ $-Q$ degeneracy.

4:30PM L30.00007 Ginzburg-Landau theory for the conical cycloid state in multiferroics: Applications to CoCr$_2$O$_4$. CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University at Pullman, SUMANTA TEWARI, Department of Physics and Astronomy, Clemson University, JOHN TONER, Department of Physics and Institute of Theoretical Science, University of Oregon at Eugene, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland at College Park—We show that the cycloidal magnetic order of a multiferroic can arise in the absence of spin and lattice anisotropies, e.g., in a cubic material, and this explains the occurrence of such a state in CoCr$_2$O$_4$. We discuss the case when this order coexists with ferromagnetism in a so-called “conical cycloid” state and show that a direct transition to this state from the ferromagnet is necessarily first order. On quite general grounds, the reversal of the direction of the uniform magnetization in this state can lead to the reversal of the electric polarization as well without the need to invoke “toroidal moment” as the order parameter.

4:42PM L30.00008 Spin-driven ferroelectricity in triangular lattice antiferromagnets ACrO$_2$ ($A = Cu$, Ag, Li, or Na). SHINICHIRO SEKI, YOSHINORI ONOSE, YOSHINORI TOKURA, Department of Applied Physics, University of Tokyo — The correlation between the dielectric and magnetic properties is investigated on the triangular-lattice antiferromagnets ACrO$_2$ ($A = Cu$, Ag, Li, or Na) with the 120-degree spiral spin structure. For the $A = Cu$ and Ag compounds with defalosite structure, the ferroelectric polarization emerges with the spiral spin order, implying the strong coupling between the ferroelectricity and the spiral spin structure. For the $A = Li$ and Na compounds with ordered rock salt structure, on the other hand, no spontaneous polarization is discerned, while the clear anomaly in dielectric constant can be observed upon the transition to the spiral-spin ordered state. This feature can be ascribed to the possible antiferroelectric state induced by the alternate stacking of the Cr-spin chain with opposite vector spin chirality.

4:54PM L30.00009 Magnetoelectric coupling in a triangular lattice antiferromagnet CuCrO$_2$. KENTA KIMURA, HIROYUKI NAKAMURA, Osaka University, KEN'YA OHGUSHI, Institute for Solid State Physics, University of Tokyo, TSUYOSHI KIMURA, Osaka University—A triangular lattice antiferromagnet CuCrO$_2$ shows an out-of-plane 120° spin structure. Recently, ferroelectricity in the 120° phase has been reported for polycrystalline samples. However, no anisotropic information (e.g. direction of polarization) has been provided for lack of single-crystal measurement [1]. Therefore, we grew single crystals of CuCrO$_2$ and investigated their magnetic and ferroelectric properties [2]. We found that CuCrO$_2$ undergoes two successive magnetic phase transitions ($T_{N2}$ $\approx$ 24.2 K and $T_{N1}$ $\approx$ 23.6 K), probably into a collinear antiferromagnetic phase and then the out-of-plane 120° phase. Ferroelectric polarization within the triangular lattice plane appears only in the 120° phase. In the talk, we also discuss the magnetoelectric properties. [1] S. Seki et al., Phys. Rev. Lett. 101, 067204 (2008). [2] K. Kimura et al., Phys. Rev. B 78, 140401(R) (2008).

5:06PM L30.00010 Synthesis and properties of PbTi$_{1-x}$Ni$_x$O$_3$. LARRY BUROKER, SOMADITYA SEN, MARIJA GADJARDZISKA-JOSIFOVSKA, YING ZOU, SHISHIR RAY, MARK WILLIAMSEN, PRASENJIT GUPTASARMA, University of Wisconsin - Milwaukee, USA—Multiferroics are a class of multiferroic materials with magnetic and ferroelectric properties in the same phase. These have been a subject of intense investigation due to their fascinating physical properties, and the potential for new devices. We examine here the question of whether the successful substitution of a magnetic ion into a traditional ferroelectric lattice can result in a new magnetoelectric phase. Using a sol gel technique employing metal-ion chelate complexes, we have synthesized phase pure nanoparticulate samples of PbTi$_{1-x}$Ni$_x$O$_3$ for 0<x<0.3. We report our studies of crystal structure refinement, magnetic and dielectric properties 0.3<T<300 Kelvin, microstructure studies using High Resolution TEM, optical properties and vibrational spectroscopy in this new system.

5:18PM L30.00011 Impurity effects in multiferroic compounds, TRINANJAN DATTA, Augusta State University — We investigate the effect of impurities in multiferroic systems. Using an equation of motion approach for the spin dynamics of the host multiferroic compound, we find that the amplitude of the spin components of the material are affected by the impurities. We model the impurities as a two-level system and focus on the regime where the impurity spins relax slowly. When the impurity strength is weak the host spins oscillate with no decay and the electric polarization survives. However as the impurity strength is increased the host spin components get damped. This in turn causes the ferroelectricity to be destroyed. Since polarization in multiferroic materials is driven by magnetic ordering we conclude that the presence of impurities is detrimental to multiferroicity.

Session L31 GMAG DMP FLAP: Focus Session: Spin Transport and Exchange Bias in Nanostuctures 335

2:30PM L31.00001 Spin Injection and Accumulation in Metallic Lateral Spin Valves with Transparent Contacts1. FELIX CASANOVA, University of California San Diego — Creation and control of spin currents is a key ingredient in spintronics, which has as a goal the use of both the spin and charge of the electron. Ferromagnetic (FM)/non-magnetic (NM) lateral spin valves are powerful devices that decouple a pure spin current from an electrical current by using a non-local geometry. We will review previous works to show how the FM/NM interface and materials control in an essential way the generation and manipulation of a spin current in non-local spin valves (NLSV). For this reason, we have studied the electrical spin injection and spin accumulation in metallic NLSV with transparent interfaces as a function of important experimental parameters such as injection current direction and magnitude, temperature, materials, and thickness. Using injected DC currents we find that the spin injection is perfectly symmetric when injecting current from the FM or into the FM, causing exactly the opposite spin accumulation in the NM. This provides means for a pure electrical manipulation of the spin current polarity. The change in spin accumulation with increasing injected current is produced by a temperature raise of the device due to Joule heating and confirmed by independent spin accumulation measurements as a function of temperature. Comparing experimentally measured spin accumulation in NMs with a spin-diffusion model allows us to identify the effect of surfaces on the spin diffusion length and injection efficiency, and the effect of FM electrodes on spin accumulation. These experiments have important implications for the physics of NLSV and for the development of devices based on these phenomena.

3:06PM L31.00002 Large-Room-Temperature Resistive Switching Behavior in Spinel Structured Nanoparticle Compacts. TAE HEE KIM, EUN YOUNG JANG, NYUN JONG LEE, Ewha Womans University, JUNG-TAK JANG, Yonsei University, JIN-SIL CHO, JINWOO CHEON, Yonsei University, KYUNG-JIN LEE, Korea University, EWHA WOMANS UNIVERSITY TEAM, YONSEI UNIVERSITY COLLABORATION, KOREA UNIVERSITY COLLABORATION — Here we report an abrupt and large bipolar switching behavior in the form of nanoparticle assembly consisting of an infinite number of monodispersed magnetic oxide single-crystallins. In the assembly of magnetite nanoparticles with size below 10 nm, we observed a room temperature voltage-current hysteresis with an abrupt and large bipolar resistive switching (switching ratio of ∼ 2000 %). We also found that such switching behaviors can be general phenomena for nanoparticle assemblies: not limited to magnetites but also consistently observed for other kinds of spinel structured nanoparticles with different compositions. Such a huge switching phenomenon it has never been observed before in bulk powders, particularly at room temperature. Our results showed clearly that the new I-V hysteresis is dependent on the nanoparticle size, and arises from interparticle contacts. In an effort to understand and interpret the origin of the bipolar reversible switching behavior, a new theoretical model was suggested in this work.

3:18PM L31.00003 Self-Assembly and Tunneling Magneto Resistance of Magnetic Nanoparticle Superlattices1. CHAITANYA LEKSHMI INDIRA, CONCETTA NOBILE, RAFFAELLA BOUNSANTI, ELIANA D’AMONE, DAVIDE COZZOLI, GIUSEPPE MARUCCIO, National Nanotechnology Laboratory, 73100 Lecce — Template assisted self-assembly of magnetic oxide nanostructures into systematically ordered superlattices in presence of magnetic field can offer controlled interfaces and useful properties for the fabrication of magnetically engineered tunnel junctions with application in high performance magnetic random access memories. In our work we employ magnetite, an important class of half-metallic material showing super paramagnetic behavior close to room temperature and low coercivity at low temperatures, as nanoparticles. The self-assembly of nanoparticle superlattices on metallic non-magnetic substrates is demonstrated. Further, enhanced spin-dependent electron transport and tunneling magneto resistance in devices with crossbar geometry is discussed.

3:30PM L31.00004 Conductive atomic force microscopy measurements of nanopillar magnetic tunnel junctions. E. R. EVARTS, C. HOGG, Physics Dept, Carnegie Mellon University, J. A. BAIN, Electrical and Comp. Eng. Dept, Carnegie Mellon University, S. A. MAJETICH, Physics Dept, Carnegie Mellon University — Magnetic tunnel junctions have been studied extensively for their magnetoresistance and potential uses in magnetic logic and data storage devices, but little is known about how their performance will scale with size. Here we examined the electronic behavior of 12 nm diameter magnetic tunnel junctions fabricated by a novel nanomasking process. Scanning electron microscopy images indicated feature diameter of 12 nm, and atomic force microscopy showed a height of 5 nm suggesting that unmasked regions have been milled on average to the oxide barrier layer, and areas should have the remnants of the free layer exposed with no remaining nanoparticle. Electrical contact was made to individual nanopillars using a doped-diamond-coated atomic force microscopy probe with a 40 nm radius of curvature at the tip. Off pillar we observed a resistance of 8.1 x 106 Ω, while on pillar we found a resistance of 2.85 x 109 Ω. Based on the RA product for this film, 120 Ω - μm2, a 12 nm diameter cylinder with perfect contact would have a resistance of 1.06 x 109 Ω. The larger experimental value is consistent with a smaller contact area due to damaging the pillar during the ion milling process. The magnetoresistance characteristics of these magnetic tunnel junctions will be discussed.

3:42PM L31.00005 Spin filtering in transport through single-molecule magnet Mn12. KYUNGWHA PARK, Virginia Tech, Blacksburg, VA, SALVADOR BARRAZA-LOPEZ, Georgia Tech, Atlanta, GA, JAIME FERRER, Univ. of Oviedo, Spain, VICTOR GALVAÑA-SUÁREZ, U. de Oviedo, U. K. — We investigate electronic transport through a single-molecule magnet Mn12 in a two-terminal set up using the Green’s function method in conjunction with density-functional theory. Our transport calculation will provide crucial information on the effect of interfaces and molecular geometry on transport, and complement theoretical studies based on many-body model Hamiltonians. We consider a single-molecule magnet Mn12 bridged between Au electrodes via thiol group and alkane chains such that its magnetic easy axis is normal to the transport direction. The electrodes are treated semi-infinite and the transport calculation is performed self-consistently with density-functional theory. We present a spin-filtering effect through Mn12 and coupling strength of the Mn12 and electrodes. We also discuss the effect of additional electron correlations on the transport.
3:54PM L31.00006 Antiferromagnetic exchange coupling measurements on single Co clusters.
W. WERNSDORFER, CNRS, Institut Neel, Grenoble, D. LEROY, C. PORTEMONT, A. BRENAC, R. MOREL, L. NOTIN, CEA, INAC, Grenoble, D. MAILLY, LPN, CNRS, Marcoussis — We report on single-cluster measurements of the angular dependence of the low-temperature ferromagnetic core magnetization switching field in exchange-coupled Co/CoO core-shell clusters (4 nm) using a micro-bridge DC superconducting quantum interference device (µ-SQUID). It is observed that the coupling with the antiferromagnetic shell induces modification in the switching field for clusters with intrinsic uniaxial anisotropy depending on the direction of the magnetic field applied during the cooling. Using a modified Stoner-Wohlfarth model, it is shown that the core interacts with two weakly coupled and asymmetrical antiferromagnetic sublattices. Ref. : C. Portemont, R. Morel, W. Wernsdorfer, D. Mailly, A. Brenac, and L. Notin, Phys. Rev. B 78, 144415 (2008).

4:06PM L31.00007 The exchange bias effect in Ni/NiO and NiO nanoparticles1. ANGELA KOU, Harvard University, MIKHAIL FEYGENSON, LAUREN KRENO, Brookhaven National Laboratory. JONATHAN PATETE, AMANDA TIANO, FEN ZHANG, STANISLAUS WONG, SUNY at Stony Brook, MEIGAN ARONSON, Brookhaven National Laboratory — We used magnetic measurements, X-ray diffraction, and HRTEM to study the exchange bias field in Ni/NiO and NiO nanoparticles made by a modified wet chemistry method. We oxidized re-dispersed powders of bare Ni nanoparticles in air at 400°C and 900°C. HRTEM showed that annealing at 900°C of bare Ni nanoparticles led to the formation of exceptionally high quality NiO nanoparticles, resembling perfect bulk-like crystalline order. To our knowledge, there are no reports of NiO particles of such quality in the literature. The loop shift was 1000 Oe at 300K for the NiO nanoparticles, while it was only 120 Oe at 10K for the Ni/NiO nanoparticles. The difference is explained by the different origins of the loop shift in Ni/NiO and NiO nanoparticles. In Ni/NiO nanoparticles, the loop shift is associated with exchange interactions between ferromagnetic Ni and antiferromagnetic NiO. In NiO nanoparticles, however, the origin of the shift is an uneven number of ferromagnetic sublattices present in NiO nanoparticles, which interact differently with an applied magnetic field (Kodama, 1999).

4:18PM L31.00008 Correlation between bias fields and magnetoresistance in CoPt biased FeNi/Ta/FeNi GMR heterosystems, YI WANG, University of Nebraska-Lincoln, S. SAHOO, Seagate Technology. W. ECHTENKAMP, CH. BINEK, University of Nebraska-Lincoln — Exchange coupled magnetic hard layer (HL)/ soft layer (SL) thin films show SL biasing in close analogy to conventional exchange bias systems with antiferromagnetic pinning.1 Here we study CoPt(35nm)/FeNi450nm/Ta(d)/FeNi450nm heterostructures with d between 0.7 and 5nm. The CoPt films have in-plane magnetic anisotropy and pin the adjacent FeNi SL films. The latter are exchange coupled from top via Ta spacer layers with FeNi in a GMR-type architecture. We use AGFM and SQUID magnetometry to study the FeNi magnetization reversal with (CoPt) and without (vacuum) pinning layer proximity. The two minor FeNi hysteresis loops of the GMR trilayer reveal different biasing effects due to the distinct exchange interaction at the respective interfaces. The FeNi/CoPt coupling is systematically tuned via a series of set fields which allow partial demagnetization of the pinning layer. Moreover the comparison between the overall and minor magnetization reversals and the corresponding magnetoresistance effects for various temperature between T=20 and 400K.2 Ch. Binek, S. Poliysett, Xi He and A. Berger, Phys. Rev. Lett. 96, 067201 (2006). Financial support by NSF through Career DMR-0547887, MRSEC DMR-0820521 and the NRI.

4:30PM L31.00009 From Exchange Bias to Magnetic Memory, KARINE CHESNEL, BYU, Physics Dept, STEVE KEVAN, U Oregon, Physics Dept, ERIC FULLERTON, UCSD, MATT CAREY, Hitachi Global Storage, JEFF KORTRIGHT, LBNL, Material Sciences, BRIAN WILCKEN, JOSEPH NELSON, BYU — A better understanding and control of magnetic domain morphology and reversal processes in magnetic thin films is useful in the realm of perpendicular magnetic recording technology. We found the possibility to create magnetic domain memory in thin ferromagnetic films by inducing a spatially varying exchange coupling interactions. We evidenced this phenomenon in a perpendicular exchange bias film made of [Co/Pd] IrMn multilayers. Our coherent X-ray magnetic scattering speckle correlation study shows that the film exhibits no memory at room temperature but acquires a very high degree of magnetic memory, above 95% with subsequent field cycling when the sample is zero field cooled below the blocking temperature of the IrMn layers (Tc~275K).1 We present here the memory's dependency with magnetic field, temperature, and cooling conditions. We also discuss the spatial dependency by analyzing finely the local speckle correlation as a function of scattering angle, thus indicating variations of memory with different spatial scales in the domain pattern. [1] Chesnel et al, PRB, 78, 132409 (2008).

4:42PM L31.00010 Detection of Bottom Electrode Oxidation in Magnetic Tunnel Junctions via Exchange Bias Effect1. WEI CHEN, Department of Physics, University of Virginia, NAM DAO, KEVIN WEST, DAVID KIRKWOOD, JIWEI LU, STUART WOLF, Department of Materials Science and Engineering, University of Virginia, NANOSTAR TEAM — The oxidation of the bottom magnetic electrode (BE) in magnetic tunnel junctions (MTJs) is detrimental for high tunneling magnetoresistance (TMR). This has long been a tricky problem for the fabrication of MTJs. We propose a method to detect such oxidation by measuring the exchange bias effect from the CoO/ FM system if the BM surface is oxidized and CoO is formed. Along with the moderate exchange bias even more significant training effect and increased FM coercivity are observed at low temperature that depend on the oxidation level. All of these effects help in the detection of the FM surface oxidation. MTJs with MgO and vanadium oxide as tunnel barrier candidates are tested by this technique with the purpose of optimizing the barrier quality for best TMR performance.

Session L32 GMAG DMP: Focus Session: Nanostructured Manganites, Thin Films and Others

2:30PM L32.00001 Growth and characterization of the La0.67Sr0.33MnO3 nanowires. JUGDERSUREN BATTOGTOKH, 1, 2, SUNGMU KANG, 2, ROBERT S. DIPIETRO, DONALD HEIMAN, 3, ANDREW C. BUECHELE, 2, 1, 2, 3, 1DEPARTMENT OF PHYSICS, THE CATHOLIC UNIVERSITY OF AMERICA, WASHINGTON, DC 20064 TEAM. 2, VITREOUS STATE LABORATORY, THE CATHOLIC UNIVERSITY OF AMERICA TEAM. 3, DEPARTMENT OF PHYSICS, NORTHEASTERN UNIVERSITY, BOSTON, MA 02115. — Convolutional electrospinning method provides a simple approach to synthesis polymer nanowires. In this work, we report the growth, structural characterization, and magnetic properties of high-magnetic, ferromagnetic La0.67Sr0.33MnO3 (LSMO) alloy nanowires that are first time grown on Si/SiO2 substrates by the electrospinning method. Electrospun nanowires are annealed in an ultra-high purity argon-hydrogen gas mixture. Uniform, continuous, high aspect ratio LSMO nanowires with diameters in the range of 60–300 nm and lengths up to 500 µm are grown. The temperature dependent magnetization behavior of LSMO nanowires shows ferromagnetic behavior, and symmetric hysteresis loops are observed with magnetic fields applied to the substrate at 10 and 300 K. Finally, we will discuss the spin dependent electrical transport properties of the single LSMO nanowire.
2:42PM L32.00002 Resonant soft x-ray scattering from La$_{1-x}$Sr$_x$MnO$_3$ quantum wire arrays
SHUAI WANG, SERBAN SMADICI, JAMES LEE, MICHAEL ODLYZKO, XIAOFANG ZHAI, JAMES ECKSTEIN, AMISH SHAH, JIAN-MIN ZUO, PETER ABBAMONTE, Frederick Seitz Materials Research Laboratory, University of Illinois, ANAND BHATTACHARYA, Argonne National Laboratory — Any finite sized, patterned system with an energy gap is expected to have elementary excitations that are characteristic of its boundary. To test this idea we have fabricated large arrays (> 60000 elements) of colossal magnetoresistance - phase La$_{2/3}$Sr$_{1/3}$MnO$_3$ quantum wires. These wires are 80 nm in width so have properties that are dominated by edge effects. We used resonant soft x-ray scattering (RSXS) and SQUID magnetometry to study their magnetic properties. We found that patterning lowers the Curie temperature and suppresses the degree of magnetization. RSXS studies show diffusion maxima from the wire period, as well as temperature-dependent diffuse scattering. We will discuss these results in the context of combined structural and magnetic disorder. Funding #: DOE grants DE-FG02-07ER46453 and DE-FG02-06ER46285

2:54PM L32.00033 Structure driven collapse of charge ordering in La$_{0.5}$Ca$_{0.5}$MnO$_3$ nanoparticles
A.K. RAYCHAUDHURI, TAPATI SARKAR, S.N. Bose National Centre for Basic Sciences, E. BOZIN, Columbia University, T. PROFFEN, Los Alamos National Laboratory, T. CHATTERJII, Inst.Laue - Langevin, S. BILLINGE, Columbia University — High resolution X-Ray and neutron diffraction had been used to show that size reduction below a certain size ( < 150nm) can lead to a collapse of the charge and orbitally ordered as well as the Antiferromagnetic ground state of the half doped manganese La$_{0.5}$Ca$_{0.5}$MnO$_3$. This leads to a ferromagnetic ground state. We show that the phenomena is linked to the structural changes that accompany the size reduction. The low temperature (T~15K) structure of the nanocrystals is significantly different from that of the bulk. The structure of the nanoparticles shows a distortion albeit different from that seen in the bulk which is driven by the Jahn - Teller distortion. The Rietveld analysis along with analysis of the Pair Distribution Function data show that there are differences in the way the MnO$_6$ octahedra are distorted in the bulk and the nanocrystals. We find that in the nanocrystals the structural distortion sets in at room temperature and shows very little variation on cooling. The Bragg peak of the ferromagnetic order in the nanoparticles was found to have the same indexes and approximately same d – spacing as that seen in ferromagnetic La$_{0.67}$Ca$_{0.33}$MnO$_3$.

3:06PM L32.00004 Jahn-Teller contribution to the magneto-optical response of ferromagnetic manganite thin films
GERSAVI HERRANZ, DAVID HRABOVSKY, JOSE MANUEL CAICEDO, INGRID CANERO-INFANTE, FLORENCIO SANCHEZ, JOSEP FONTCUBERTA, Institut de Ciencia de Materials de Barcelona, (ICMAB-CSIC) Bellaterra, Spain — We report on the temperature dependence of the magneto-optical response in the visible spectrum of ferromagnetic manganite thin films measured in transverse Kerr geometry. We show that this response is dominated by the usual magneto-optical Kerr effects for all temperatures except for a narrow window around the Curie temperature (T$_C$). Remarkably, the magneto-optical response of these manganite films does not die out near the ferromagnetic transition, in spite of the vanishing Jahn effect at those temperatures. On the contrary, the transverse Kerr response is hugely enhanced near T$_C$ and follows the same temperature dependence as the colossal magnetoresistance. We attribute these remarkable phenomena to the magnetic field-induced suppression of Jahn-Teller dynamical charge localization around T$_C$. Thus, the peculiar optical response of manganite films comes from the intricate physics of these strongly correlated electronic systems. We argue that the methodology we use is demonstrated to be very useful to understand the nature of some structural and electronic transitions driven by magnetic/electric fields or by temperature in other complex oxides.

3:18PM L32.00005 Observation of Ferromagnetic Resonance in SrRuO$_3$ Using the Time-Resolved Magneto-Optical Kerr Effect
M.C. LANGNER, C.L.S. KANTNER, Dept. of Physics, UC Berkeley and Lawrence Berkeley National Lab, Y.H. CHU, L.W. MARTIN, Dept. of Materials Science, UC Berkeley, R. RAMESH, Dept. of Physics and Dept. of Materials Science, UC Berkeley, J. ORENSTEIN, Dept. of Physics, UC Berkeley and Lawrence Berkeley National Lab — We report the observation of ferromagnetic resonance (FMR) in strontium ruthenate using the time-resolved magneto-optical Kerr effect. The FMR oscillations in the time-domain appear in response to a sudden, optically induced magnetic field. The frequency of these oscillations shows a weak dependence on temperature and other parameters associated with the magnetization dynamics, have a non-monotonic temperature dependence, suggestive of a link to the anomalous Hall effect.

3:42PM L32.00007 ABSTRACT WITHDRAWN

3:54PM L32.00008 Switching Spectroscopy Piezoresponse Force Microscopy study of Domain Wall hysteresis at the nanoscale: Mapping lattice and defect pinning effects
VASUEVA RAO ARAVIND, Pennsylvania State University, SAMRAT CHOUDHURY, YULAN LI, KATYAYINI SEAL, STEPHEN JESSE, ANNA MOROZOVSKA, EUGENE ELISEEV, LONG-QING CHEN, SERGEI KALININ, VENKATRAMAN GOPALAN — In this work, using scanning probe microscopy with ~30 nanometer resolution along with theoretical modeling, we demonstrate the role of 180° ferroelectric domain wall as an intrinsic defect that lowers coercive fields in its vicinity by an order of magnitude. The interaction of ferroelectric 180° domain wall with a strongly inhomogeneous electric field of biased scanning probe microscope tip is analyzed within decoupling approximation allowing for the spatial redistribution of polarization caused by the biased probe using continuous Landau-Ginzburg-Devonshire theory. Theoretical calculations predict that equilibrium shape of the initially flat domain wall boundary bends, attracts or repels from the probe apex. The bending of the wall and its depolarization electric field facilitates tip induced domain nucleation. The experiments and theory are compared quantitatively, to show that lattice friction as well as lattice pinning play important role in the domain wall softening behavior. Acknowledgements: [1] National Science Foundation, [2] Center for Nanophase Materials Sciences, Oak Ridge National Laboratory.

4:06PM L32.00009 Controlling Orthorhombic Domain Orientations in Epitaxial LaPrCaMnO Thin Films
JOHN BUDAI, Oak Ridge National Laboratory, T. ZAC WARD, Univ. of Tennessee, JON TISCHLER, JIAN SHEN, Oak Ridge National Laboratory — Microstructural effects such as strain and domain formation are known to influence the physical properties of transition metal oxide materials. For epitaxial films, lattice mismatch with the substrate can be used to investigate the effects due to in-plane biaxial tensile or compressive strain. Using synchrotron x-ray diffraction at the Advanced Photon Source, we have investigated the temperature-dependent lattice parameters and orthorhombic domain orientations for distorted pervoskite LaPrCaMnO thin films grown on several different substrates (SrTiO$_3$, LaAlO$_3$, SrLaGaO$_3$, NdGaO$_3$). We find that structural phase transition in the substrate can have a large effect on the film. More generally, we find that tensile and compressive stresses generate different orthorhombic domain orientations and can be used to control the microstructure of the LPCMO films .

4:18PM L32.00010 Effect of the substrate on the orbital phase transition in a manganite thin film under magnetic field . Y. WAKABAYASHI, Osaka Univ., H. SAGAYAMA, T. ARIMA, Tohoku Univ., Y. NAKAMURA, Y. OGIMOTO, Tokyo Univ., K. MIYANO, Tokyo Univ., CREST, H. SAWA, Nagoya Univ. — Thin films of strongly correlated materials are studied intensively because of their potential of device application. Those materials in bulk form show various fascinating properties such as metal-insulator transition. However, clear phase transitions are often suppressed under the strain from the substrates. We have studied Nd$_{0.5}$Sr$_{0.5}$MnO$_3$ thin film on SrTiO$_3$ (011) substrate, which is a unique film that has clear orbital-ordering (OO) transition, by x-ray scattering under magnetic field up to 8T. As reported earlier [1], this system shows a net phase transition, paramagnetic (PM), ferromagnetic (F), A-type OO (A) to CE-type OO (CE) with cooling in zero field, and at F-A transition temperature (170K), the symmetry lowers and twin occurs. The phase sequence was changed to PM, F to CE above 4T, and above this field, considerable amount of the FM phase remains down to 10K. This field induced phase separation is attributable to the martensitic accommodation strain at the domain boundary. [1] Y.W. et al., Phys. Rev. Lett. 96 017202 (2006), J.Phys.Soc.Jpn. 77, 014712 (2008).

4:30PM L32.00011 Coherent Long Range Lateral Charge Ordering in strained Epitaxial Oxide Film Structures. JONG-WOO KIM, PHILIP, RYAN, Ames Laboratory, JAK, CHAKHALJAN, MIKHAIL, KAREEV, JIAN LIU, University of California, San Diego, STEVE MAY, ANAND BHATTACHARYA, JOHN FREELAND, Argonne National Laboratory, AMES LABORATORY COLLABORATION, UNIVERSITY OF ARKANSAS COLLABORATION — The quality of ordered oxide films has reached the level whereby epitaxial superlattice structures can now be achieved by both pulsed laser deposition (PLD) and ozon assisted molecular beam epitaxy (MBE) growth. Engineering each layer coupled with compressive and tensile strain with the explicit aim of controlling and or enhancing the macroscopic electrical and magnetic ordering is a considered aim of ordered oxide film growth. The question how highly strained films structurally respond to such stress is examined by synchrotron diffraction. Both LaSrMnO films grown on STO(001) by MBE and PLD grown LaNAlO films on both LAO(001) and STO(001) have revealed coherent lateral order dependent upon film disorder, substrate mismatch induced strain and even dislocations induced by the substrate step morphology.

4:42PM L32.00012 Dember effect induced photovoltage in perovskite p-n heterojunctions. KUI-JUAN JIN, KUN ZHAO, HUI-BIN LU, LENG LIAO, GUO-ZHEN YANG, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, CAS, Beijing 100080, China — An unusual and rather large transient lateral photovoltage (LPV) has been observed in La$_{0.9}$Sr$_{0.1}$MnO$_3$/SrNb$_{0.01}$Ti$_{0.99}$O$_3$ and La$_{0.7}$Sr$_{0.3}$MnO$_3$/Si heterojunctions under the nonuniform irradiation of pulsed laser. The irreversible LPVs on both sides of a p-n junction challenge the well established model for LPV in conventional semiconductor p-n junctions, which can be well explained by Dember effect. Much larger LPV is observed in La$_{0.7}$Sr$_{0.3}$MnO$_3$/Si than that in La$_{0.9}$Sr$_{0.1}$MnO$_3$/SrNb$_{0.01}$Ti$_{0.99}$O$_3$. Similar results measured from both substrates of SrNb$_{0.01}$Ti$_{0.99}$O$_3$ and Si also support such a Dember effect. Much larger LPVs in heterojunctions than those in simple samples (SrNb$_{0.01}$Ti$_{0.99}$O$_3$ or Si) suggest a potential application of Dember effect in heterostructures.

5:06PM L32.00014 Spins and Twins: Correlation between Crystallographic and Magnetic Domains at Co/NiO(001) Interfaces. HENDRIK OHLDAG, SSRL, Menlo Park CA, USA., ELKE ARENHOLZ, ALS, Berkeley CA, USA., GERRIT VAN DER LAAN, Diamond Light Source, Chilton UK — Using soft x-ray spectromicroscopy we show that NiO(001) exhibits a crystallographic and ordering dependent upon film disorder, substrate mismatch induced strain and even dislocations induced by the substrate step morphology.

5:06PM L32.00014 Spins and Twins: Correlation between Crystallographic and Magnetic Domains at Co/NiO(001) Interfaces. HENDRIK OHLDAG, SSRL, Menlo Park CA, USA., ELKE ARENHOLZ, ALS, Berkeley CA, USA., GERRIT VAN DER LAAN, Diamond Light Source, Chilton UK — Using soft x-ray spectromicroscopy we show that NiO(001) exhibits a crystallographic and ordering dependent upon film disorder, substrate mismatch induced strain and even dislocations induced by the substrate step morphology.

Session L33 DCMP: Superconductivity: Electronic Structure I 403

2:30PM L33.00001 IR Hall measurements in overdoped Pr$_{2-x}$Ce$_x$CuO$_4$: evidence for magnon induced current-vertex corrections . GREGORY S. JENKINS, DON C. SCHMADEL, R.L. GREENE, H.D. DREW, University of Maryland at College Park, P. FOURNIER, Universite de Sherbrooke, H. KONTANI, Nagoya University — In overdoped Pr$_{2-x}$Ce$_x$CuO$_4$, the dc Hall coefficient achieves its expected value $R_H \propto 1 + x$ consistent with the large hole-like Fermi surface observed in ARPES, but only at low temperatures. As temperature is raised, the dc Hall coefficient falls off and becomes negative at a temperature that increases with $x$. We have measured the IR Hall angle of two overdoped Pr$_{2-x}$Ce$_x$CuO$_4$ samples at sufficiently low optical excitation energies (below 10meV) to directly probe the Fermi-surface properties. The observed large deviations from the classical result correspond to the addition of electron-like contributions to $\sigma_{xy}$, even at $T=0$, due to the finite frequency. Results of a model developed by H. Kontani of the low frequency IR Hall response which incorporates current-vertex corrections induced by magnon scattering are directly compared to the data. The model fully captures the salient features of the measured Hall response as a function of doping, temperature, and frequency. These results demonstrate that the anomalous Hall effect in the cuprates is a consequence of current vertex corrections to $\sigma_{xy}$.

1We acknowledge the support of CNAM and NSF.
2:42PM L33.00002 Fermi surface reconstruction in e-doped cuprates: IR Hall measurements in underdoped \( Pr_{2-x}Ca_xCuO_4 \), D.C. SCHMADELE, G.S. JENKINS, H.D. DREW, R.L. GREENE, Center for Nanophysics and Advanced Materials, University of Maryland at College Park, P. FOURNIER, Universite de Sherbrooke — The complex IR Hall angle is measured in PCCO at doping levels ranging from 10% to 15% at low optical excitation energy (10 meV). A precipitous decrease in Hall mass with a decrease in doping level in the underdoped regime is strong evidence of Fermi surface reconstruction and pocket formation, an observation consistent with ARPES and optical spectroscopy measurements. The data over the entire underdoped region is consistent with the predicted IR Hall response based upon ARPES data and Boltzmann theory. The temperature dependence of the Hall mass indicate a gradual roll-over from small pockets to the large unreconstructed Fermi surface expected in overdoped PCCO.

1We acknowledge the support of CNAM and NSF.

2:54PM L33.00003 Evidence for Fermi surface reconstruction in h-doped cuprates: IR Hall measurements in underdoped \( La_{2−x}Sr_xCuO_4 \), H.D. DREW, G.S. JENKINS, D.C. SCHMADELE, R.L. GREENE, Center for Nanophysics and Advanced Materials, University of Maryland at College Park, ICHIRO TSUKADA, Central Research Institute of Electric Power Industry, Japan — We measure the IR Hall angle in \( La_{2−x}Sr_xCuO_4 \) as a function of doping ranging from 7% to 16.5%. The optimally doped sample is shown to be consistent with ARPES measurements of the Fermi arcs in ARPES experiments is observed. The rapid decrease in Hall mass with underdoping is a hallmark signature of Fermi surface reconstruction exhibited in systems which are well known to fractionalize into Fermi pockets (underdoped PCCO). Comparisons with Fermi surface models will be discussed.

We acknowledge the support of CNAM and NSF.

3:06PM L33.00004 Quantum Oscillations in the Specific Heat of Ultraclean YBCO in 45T magnetic fields, SCOTT RIGGS, NHMFL/FSU, JON BETTS, LANL, SUCHITRA SEBASTIAN, Cambridge, NEIL HARRISON, ALBERT MIGLIORE, LANL, GREG BOEBINGER, NHMFL/FSU, RUIXING LIANG, WALTER HARDY, DOUG BONN, Simon Fraser University — We report specific heat measurements of Ortho-II YBCO in a magnetic field as large as 45T to directly compare the superconducting state with the normal state at low temperatures. This thermodynamic measurement of the electronic density of states determines the total number of carrier pockets in the two-dimensional Fermi surface of Ortho-II YBCO. These measurements also reveal quantum oscillations in the specific heat that provide a bulk measurement of the quasiparticle density of states in the d-wave mixed state.

3:18PM L33.00005 De Haas-Van Alphen Experiments on BaNi_2P_2, TAICHI TERASHIMA, MOTOI KIMATA, HIDETAKA SATSUKAWA, ATSUSHI HARADA, KAORI HAZAMA, MOHORU IMAI, SHINYA UJI, National Institute for Materials Science, Japan, HIJIRI KITO, AKIRA IYO, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology (AIST), Japan, HISATOMO HARIMA, Kobe University, Japan — We have observed de Haas-van Alphen (dHvA) oscillations in BaNi_2P_2, which is isostruktrual with BaFe_2As_2 and becomes superconducting below \( T_c = 3 \) K without doping [T. Mine et al., Solid State Commun. 147, 111 (2008)]. It is a suitable compound to study how different electronic structures are between iron and nickel-based superconductors. The single crystals used in the study were obtained by high-pressure synthesis. dHvA frequencies up to 8 K were observed, and their size and angular dependences can be explained very well by a band-structure calculation. Effective masses are two to three times larger than the corresponding band masses, suggesting moderate mass enhancement due to electron-phonon-electron interactions.

3:30PM L33.00006 de Haas van Alphen Effect in Strongly Interacting Systems, LARA THOMPSON, University of British Columbia, P.C.E. STAMP, UBC, PITP — We present calculations of de Haas van Alphen (dHvA) oscillations for strongly interacting systems, for (1) systems near a quantum phase transition (QPT); and/or (2) 2D and quasi-2D systems. The standard Lifshitz-Kosevich (LK) results are then inapplicable. D Hva, the quantum interaction scale goes to zero, giving strong corrections to LK. In 2D, LK breaks down entirely in the presence of interactions. Recently, dHvA oscillations in high Tc systems have been measured, but their form does not yet rule out non-Fermi liquid behaviour. We calculate the expected magnetization response assuming various Fermi reconstruction scenarios. The response depends crucially on the inter-plane couplings, and we find deviations from LK if the reconstruction is interaction-driven.

3:42PM L33.00007 Interpreting the Gap Signatures in the Raman Spectra of Hg-1201, JAMES STOREY, University of Cambridge, JEFFERY TALLON, Industrial Research Limited — Recently, peaks in the B1g and B2g Raman spectra of the Hg-1201 high-Tc cuprate superconductor have been interpreted in terms of two gaps. These are i) a gap near the Brillouin zone boundary that decreases monotonically with doping, and ii) a gap near the zone diagonal that follows the dome-shaped doping dependence of the superconducting transition temperature. The former has come to be interpreted as the pseudogap and the latter the superconducting gap. However, this dome shaped superconducting gap contradicts ARPES evidence for the existence of Ca 3d derived states at \( E_F \), which probably play a crucial role for the unusually superconductivity. The electronic structure of CaC_6 is compared with the electronic structures of other graphite intercalation compounds, providing deeper understanding of the superconductivity of CaC_6.

1Supported by the Marsden Fund of New Zealand.

4:06PM L33.00009 The existence of substantial Ca 3d derived states at \( E_F \) in Ca-intercalated graphite superconductor CaC_6, HIROYUKI OKAZAKI, RIKIYA YOSHIDA, KEISUKE IWAI, KENGO NOAMI, Okayama University, TAKAYUKI MIRO, TETSUYA NAKAMURA, JASRI/SPring-8, TAKANORI WAKITA, YUJI MURAOKA, MASAKI HIROI, Okayama University, FUMIYAKI TOMIOKA, YOSHIKO TAKANO, NIMS, ASAMI TAKENAKA, MASASHI TOYODA, Oita University, TAMIO OGUCHI, Hiroshima University, TAKAYOSHI YOKOYA, Okayama University — We have performed soft x-ray photoemission studies of Ca-intercalated graphite superconductor CaC_6 (\( T_c = 11.2 \) K). The valence band spectrum shows six main structures that correspond to those of calculated DOS that predicts large Ca 3d contribution at the Fermi level (\( E_F \)). The Ca 2p core level spectrum has a very large asymmetric line shape, suggesting the existence of Ca 3d derived conduction electrons at Ca sites. These results provide spectroscopic evidence for the existence of Ca 3d derived conduction electrons at Ca sites. These results provide spectroscopic evidence for the existence of Ca 3d derived conduction electrons at Ca sites. These results provide spectroscopic evidence for the existence of Ca 3d derived conduction electrons at Ca sites. These results provide spectroscopic evidence for the existence of Ca 3d derived conduction electrons at Ca sites. These results provide spectroscopic evidence for the existence of Ca 3d derived conduction electrons at Ca sites. These results provide spectroscopic evidence for the existence of Ca 3d derived conduction electrons at Ca sites.

4:18PM L33.00010 Orbital excitation in Sr$_2$CuO$_2$Cl$_2$ resonant inelastic x-ray scattering at the Cu K pre-edge. JUNGHO KIM, D. S. ELLIS, T. GOG, D. CASA, YOUNG-JUNE KIM, CMC-CAT, APS. ARCONNE NATIONAL LAB. COLLABORATION, UNIVERSITY OF TORONTO COLLABORATION — d − d excitations has attracted much attention due to its fundamental importance in elucidating electronic structure. However, experimental study of these excitations is difficult, since direct optical transition is dipole forbidden. We show that the Cu 1s-3d intermediate state, which can be reached via electric quadrupole operator, provides an excellent high-resolution means for studying d − d excitations in cuprates, and complements other well established techniques. Since quadrupole operator is sensitive to the symmetry of the intermediate state, considerable information on the symmetry of d − d excitation can be gained by exploiting this resonance. We have carried out comprehensive angle resolved x-ray absorption spectroscopy experiment, which clearly demonstrates the quadrupole nature of the absorption. We find that our RIXS spectra at this quadrupole resonance exhibit a broad excitation centered at 2 eV. We suggest that the scattering angle dependence of the quadrupole resonance agrees well with the calculated polarization dependence of quadrupole matrix element and information on the symmetry of d − d excitation can be obtained. Our analysis show that the quadrupole resonance at 2eV is consistent with the excitation involving 3d$^9_{y^2-x^2}$ symmetry.

4:30PM L33.00011 Quantum oscillation experiments on YBa$_2$Cu$_3$O$_{6.60}$1. JOHN SINGLETON, ROSS MC DONALD, SUSAN COX, National High Magnetic Field Laboratory, SHILIANG LI, PENGCHENG DAI, Physics, University of Tennessee — Pulsed magnetic fields of up to 75 T and temperatures down to 0.40 K have been used to study single crystals of YBa$_2$Cu$_3$O$_{6.60}$. The samples are measured using a MHz technique that is sensitive to small changes in penetration depth in the superconducting state, and to changes in the skin depth in the normal state. Two series of magnetic quantum oscillations are observed, sensitive in periodic in inverse field; the frequencies are 590 ± 20 T and 1990 ± 40 T. This suggests that the predicted large Fermi surface is broken into smaller pockets due to nesting. These findings are discussed in the context of other recent observations of quantum oscillations in the cuprates, and a magnetically-mediated mechanism for superconductivity, driven by the topological mapping of the d-wave Cooper-pair wavefunction onto the antiferromagnetic fluctuations (due to Fermi-surface nesting) that are observed across the whole cuprate phase diagram (R.D. McDonald et al., J. Phys.: Condens. Matter, in press (2008)).

4:42PM L33.00012 Five Principles of Photoemission of High Temperature Superconducting Cuprates Deduced from the Diplon Theory. RAM SHARMA, University of Illinois at Chicago, IL. — In the process of the theoretical explanation of the observed photoemission result of high temperature superconducting cuprates we have been able to derive by means of the diplon theory [1,2] five principles of photoemission in various situations of doping, temperature and Fermi level crossing. These five principles interrelate the peak-dip-hump phenomenon, the kink structure (including the predicted high energy kinks [3]) in the quasiparticale energy dispersion and electron velocities at different energies with respect to the characteristic diplon excitations in the system. Details of the five principles will be presented. The theory contains Mott renormalization and all important and necessary electron-electron correlations.

5:06PM L33.00014 Using photoemission spectroscopy to probe a strongly interacting Fermi gas1. JOHN STEWART, JOHN GAEBLER, DEBORAH JIN, JILA-University of Colorado — We use photoemission spectroscopy to directly probe the elementary excitations and energy dispersion of a strongly interacting Fermi gas of atoms. In these photoemission experiments, an rf photon ejects an atom from our strongly interacting system via a spin-flip transition to a weakly interacting state. This new measurement technique for ultracold atom gases, like photoemission spectroscopy for electronic materials, directly probes low energy excitations and thus can reveal excitation gaps and/or pseudogaps. We observe a back-bending of the excitation spectrum consistent with a BCS-like dispersion curve.

1JILA, Quantum Physics Division, National Institute of Standards and Technology and Department of Physics, University of Colorado, Boulder, CO 80309-0440, USA.

5:18PM L33.00015 Ab initio calculation of core-valence-valence Auger spectra in closed shell systems. GIAN PAOLO BRIVIO, GUIDO FRATESI, MARIO ITALO TRIONI, Universita' di Milano-Bicocca, SIMONA UGENTI, ENRICO PERFETTO, MICHELE CINI, Universita' di Roma Tor-Vergata, MILANO-BICOCCA COLLABORATION, ROMA TOR-VERGATA COLLABORATION — We propose an ab initio method to evaluate the core-valence-valence Auger spectrum of systems with filled valence bands. The method is based on the Cini-Sawatzky theory, and aims at estimating the parameters by first-principles calculations in the framework of DFT. Photoemission energies and the interaction energy for the two holes in the final state are evaluated by performing DFT simulations for the system with varied population of electronic levels. Transition matrix elements are taken from atomic results. The approach takes into account the non spherical density of states of the emitting atom, spin-orbit interaction in core and valence, and non quadratic terms in the total energy expansion with respect to fractional occupation numbers. It is tested on two benchmark systems, Zn and Cu metals, leading in both cases to 2234/4514 Auger peaks within 2 eV from the experimental ones. Especially problematic is the evaluation of the hole-hole interaction for systems with broad valence bands: our method understimates its value in Cu, while we obtain excellent results for this quantity in Zn.
usual flux pinning effects and bistable superconductivity. We will firstly consider geometry hybrids exhibit a plethora of induced effects and novel physical properties, due to the interplay between the competing S and F orders. We will show a few examples of those, in a series of experiments on a simple hybrid system: a thin film with an array of F nanodots. Changing the array geometry, the nanodots size or their magnetic state allows to investigate a large variety of physical phenomena. We will focus on two of them: flux pinning effects and stray-magnetic-field induced manipulation of superconductivity. We will firstly consider geometry induced effects; in particular, we will compare the pinning properties of periodic, quasiperiodic, and fractal arrays. Secondly, we will discuss the effects induced by particular nanodot magnetic-states. We will show experiments on the interaction between flux quanta and nanodot magnetic vortices, which can be used to obtain switchable flux pinning potentials. Finally, we will describe an experiment in which the magnetic reversal events of the nanodot magnetic vortices are imprinted into the transport properties of a superconducting thin film. This yields a very unusual hysteretic magnetoresistance. This effect is induced by the stray magnetic fields from the nanodots, which drive the superconducting-to-normal transition of the hybrid depending on the magnetic history.

In collaboration with C. -P. Li, K. D. Smith, M. I. Montero, R. Morales, L. Huang, Y. Zhu and Ivan K. Schuller. Work supported by NSF and US-AFOSR.

3:06PM L34.00002 Vortex ratchet effect induced by different magnetic configurations in magnetic superconducting hybrids. D. PEREZ DE LARA, Universidad Complutense de Madrid(UCM), F.J. CASTANO, Massachusetts Institute of Technology(MIT), B.G. NG, MIT, R.K. DUMAS, University of California Davis(UC-Davis), E.M. GONZALEZ, UCM, KAI LIU, UC- Davis, C.A. ROSS, MIT, IVAN K. SCHULLER, University of California-San Diego, J.L. VICENT, UCM — We have used E-Beam Lithography to prepare hybrid systems consisting of arrays of nanometric Ni rings (elliptical and circular) covered by a superconducting Nb film. These nanometric rings were characterized by a First Order Reversal Curve method to realize the onion and vortex magnetic state at remanence. The transport properties of the superconducting Nb film were measured in the mixed state by applying a magnetic field perpendicular to the sample. Classical pinning matching effects of very high order were observed in resistance vs H, which vary with the magnetic state of Ni rings. Interestingly, a ratchet effect characterized by a dc output voltage produced by an applied ac current is found. Moreover, the ratchet effect is drastically modified by the remanent magnetic state of the Ni rings. The systematic and origin of the ratchet effect will be discussed.

3:18PM L34.00003 Antivortex complexes and intrinsic ratchet dynamics in superconductors with progressive magnetic topology. ANDRAS LIBAL, MILORAD MILOSEVIC, Departement Fysica, Universiteit Antwerpen, Belgium, FRANCOIS PEETERS, Departement Fysica, Universiteit Antwerpen, Belgium, W. GILLIJNS, A.V. SILHANEK, V.V. MOSCHALKOV, INPAC - Institute for Nanoscale Physics and Chemistry, Katholieke Universiteit Leuven, Belgium — Theoretically and experimentally, we analyze characteristic properties of a superconducting (Sc) film deposited on parallel arrays of ferromagnetic (Fm) dots with gradually increasing diameter in a periodic saw-tooth manner. Due to their perpendicular magnetization, dots induce vortex-antivortex molecules in the sample, with number of constituent (anti) vortices growing with magnet size. Resulting gradient of antivortex density between the dots predetermines local nucleation of superconductivity in the sample as a function of applied external field and temperature. In applied drive however, antivortices act collectively in an asymmetric potential of the dots and pinned vortices, and exhibit unique ratchet dynamics intrinsic to the Sc-Fm hybrids.

1. Work supported by the Flemish Science Foundation (FWO-VI), the Belgian Science Policy, the K.U.L. Research Fund GOA/2004/02, and the JSPS/ESF-ESF program. A.L., W.G., and A.V.S. acknowledge individual support from FWO-VI.

2:30PM L34.00004 Vortex dynamics and vortex lattice reconfiguration in superconducting-magnetic hybrids. JOSE L. VICENT, DAVID PEREZ DE LARA, Universidad Complutense, ALEJANDRO ALIJA, Universidad Oviedo, ELVIRA M. GONZALEZ, Universidad Complutense, JOSE I. MARTIN, MARIA VELEZ, Universidad Oviedo, JOSE V. ANGUITA, Instituto Microelectronica (CSIC) — Amorphous superconducting films (M02/Si) have been grown on top of array of nanometric magnets. These periodic magnetic centers have been fabricated on Si substrates by Electron Beam Lithography and sputtering techniques. In the mixed state the competition between the intrinsic and random pinning potential of the superconducting film and the artificial induced periodic pinning potential governs the vortex lattice behavior. Close to critical temperature, the periodic potentials could overcome the random potentials, then the vortex lattice dynamics shows effects which are related with the array dimension and symmetry. We will show in these hybrid systems enhancements of matching effects between the vortex lattice and the array unit cell, and different vortex lattice configurations.

3:00PM L34.00005 Scanning Tunneling Spectroscopy Study of Proximity Effect in Bilayer Manganese/Cuprate Thin Films. I. FRIDMAN, J.Y.T. WEI, University of Toronto, L. GUNAWAN, G.A. BOTTON, McMaster University — Recent work has suggested novel proximity and spin diffusion effects in ferromagnet/superconductor heterostructures composed of transition-metal perovskites. We have performed scanning tunneling spectroscopy (STS) on La0.75Ca0.25MnO3/YBa2Cu3O7−δ (LCMO/YBCO) bilayer thin films. Films were epitaxially grown on <001> SrTiO3 substrates using pulsed laser deposition with either the LCMO or YBCO layer on top. The STS data taken at 4.2 K were analyzed for spectral signatures of a pairing gap on the LCMO layer and spin diffusion in the YBCO layer, and to determine the length scale of the proximity effect and the role played by magnetic domain walls.

Work supported by NSERC, CFI/OIT and the Canadian Institute for Advanced Research.
Josephson junctions — We apply the scattering matrix approach to the triplet proximity effect in superconductor-half metal structures. We find that for junctions that do not mix different orbital modes, the zero bias Andreev conductance vanishes, while the zero bias Josephson current is nonzero. We illustrate this finding on a ballistic half-metal/superconductor (HS) and superconductor/half-metal/superconductor (SHS) junction with translation invariance along the interfaces, and on HS and SHS systems through the half-metallic region takes place through a single conducting channel. Our calculations for these physically single mode setups single mode point contacts and chaotic quantum dots with single mode contacts illustrate the main strength of the scattering matrix approach: it allows for studying systems in the quantum mechanical limit, which is inaccessible for quasiclassical Green’s function methods, the main theoretical tool in previous works on the triplet proximity effect.

4:06PM L34.00007 Reentrant resistance in mesoscopic superconductor-ferromagnet-superconductor structures1. MADALINA COLCI, MARTIN STEHNO, DALE VAN HARLINGEN, University of Illinois at Urbana-Champaign — We report measurements of the resistance as a function of temperature and magnetization alignment in hybrid structures consisting of superconducting electrodes connected by two ferromagnetic nanowires separated by less than a superconducting coherence length. It has been predicted that such structures could exhibit a supercurrent due to Cooper pair splitting and coherent transport through the ferromagnets. Although we have not observed a zero-voltage supercurrent, we find that as the temperature is lowered below the critical temperature of the superconductor, the resistance of the structure shows a minimum and then rises, suggestive of re-entrant behavior. The resistance of the superconducting array of ferromagnetic wires is found to be lower than in the parallel case just below Tc but becomes distinctly larger than in the parallel case at the lowest temperature. We discuss possible explanations and implications of this result.

1Work supported by NSF grant DMR06-05813

3:54PM L34.00006 Quantum limit of the triplet proximity effect in half-metal - superconductor junctions. JOERN K. KUPFERSCHMIDT, LASSP, Cornell University, B. BERI, C.W.J. BEENAKKER, Instituut-Lorentz, Universiteit Leiden, P.W. BROUWER, LASSP, Cornell University — We apply the scattering matrix approach to the triplet proximity effect in superconductor-half metal structures. We find that for junctions that do not mix different orbital modes, the zero bias Andreev conductance vanishes, while the zero bias Josephson current is nonzero. We illustrate this finding on a ballistic half-metal/superconductor (HS) and superconductor/half-metal/superconductor (SHS) junction with translation invariance along the interfaces, and on HS and SHS systems through the half-metallic region takes place through a single conducting channel. Our calculations for these physically single mode setups single mode point contacts and chaotic quantum dots with single mode contacts illustrate the main strength of the scattering matrix approach: it allows for studying systems in the quantum mechanical limit, which is inaccessible for quasiclassical Green’s function methods, the main theoretical tool in previous works on the triplet proximity effect.

4:18PM L34.00008 Ferromagnets without inversion symmetry - room for superconductivity?1. ANDRIY NEVIDOMSKY, Rutgers University, JACOB LINDER, ASLE SUDBø, Norwegian University of Science and Technology, Trondheim, Norway — Motivated by the recent discoveries of ferromagnetic and non-centrosymmetric superconductors, we present a mean-field theory [1] for a superconductor that both lacks inversion symmetry and displays ferromagnetism, a scenario which is believed to be realized in UIr under applied pressure [2]. We study the interplay between the order parameters to clarify how superconductivity is affected by the presence of ferromagnetism and spin-orbit coupling. We find that the spin-orbit coupling seems to enhance both ferromagnetism and superconductivity in both singlet and triplet channels. We discuss our results in the context of the heavy fermion superconductor UIr and analyze possible symmetries of the order parameter.

3:42PM L34.00010 Splitting of a Cooper pair by a pair of Majorana bound states. JOHAN NILSSON, Instituut-Lorentz, Leiden University — Majorana fermions are spatially localized superpositions of electron and hole excitations in the middle of a superconducting energy gap. These unusual particles have been predicted to occur at the interface between a magnetic and a superconducting electrode, in contact with a topological insulator (such as a BiSb crystal or a HgTe quantum well). A single qubit can be encoded nonlocally in a pair of spatially separated Majorana fermions. We have measured the critical current of Josephson junctions of the form Nb/Co/Ru/Co/Nb, where the two Co layers are exchange-coupled antiferromagnetically by an intrinsic flux cancellation. The junctions were fabricated by sputtering the S/F/N/F/S multilayer onto a Si substrate, followed by subtractive patterning by photolithography and ion milling into circular junctions ranging in diameter from 10-80 microns. The critical current density of the junctions decays exponentially along the interfaces, and on HS and SHS systems through the half-metallic region takes place through a single conducting channel. Our calculations for these physically single mode setups single mode point contacts and chaotic quantum dots with single mode contacts illustrate the main strength of the scattering matrix approach: it allows for studying systems in the quantum mechanical limit, which is inaccessible for quasiclassical Green’s function methods, the main theoretical tool in previous works on the triplet proximity effect.

4:42PM L34.00011 Sign reversal of ac Josephson current in a ferromagnetic Josephson junction. SHIN-ICHI HIKINO, MICHIOYUKI MORI, SAUBERO TAKAHASHI, SATAMICHI MAEKAWA, Institute for Materials Research, Tohoku University — It is known that in a superconductor/insulator/superconductor (SIS) junction, when a finite voltage is applied, the Josephson current shows a logarithmic divergence, i.e., the so-called Riedel peak (RP) at the gap voltage, V=2Δ/ε (Δ is a superconducting gap). This result is observed in a double barrier Josephson junction such as SXS junction, on the other hand, the voltage dependence of Ic has not been investigated so far, where X is a normal metal (N) or a ferromagnet (F). We study the voltage dependence of Josephson critical current (Ic) in a variety of SXN junctions. In a SNS junction, Ic shows the RP at the gap voltage similar to a Josephson junction. In the SXS junction, Ic shows the RP at the gap voltage similar to a Josephson junction. On the other hand, in a SFS junction, Ic shows a damped oscillation with the alternation of sign as a function of thickness (d) of F due to π transition. The RP exhibits a strong dependence on d, and changes its sign. It is predicted that the RP disappears at the 0-π transition in the SFS junction.

4:54PM L34.00011 Sign reversal of ac Josephson current in a ferromagnetic Josephson junction. MAZIN A. KHASAWNEH, WILLIAM P. PRATT JR., NORMAN O. BURGE, Dept. of Physics and Astronomy, Michigan State University, East Lansing, MI 48824 — We have measured the critical current of Josephson junctions of the form Nb/Co/Ru/Co/Nb, where the two Co layers are exchange-coupled antiferromagnetically by the thin (0.6 nm) Ru interlayer. The antiferromagnetic coupling causes nearly complete cancellation of the intrinsic magnetic flux produced by the Co domains, and allows us to study large-area junctions with total Co thicknesses ranging from 2 to 20 nm — four times thicker than in previous studies of Nb/Co/Nb Josephson junctions [1]. The dependence of the critical current on an in-plane external magnetic field results in a nearly perfect Fraunhofer pattern, due to the intrinsic flux cancellation. The junctions were fabricated by sputtering the S/F/N/F/S multilayer onto a Si substrate, followed by substracted patterning by photolithography and ion milling into circular junctions ranging in diameter from 10-80 microns. The critical current density of the decays exponentially with Co thickness, with a characteristic decay length of λF = 2.2 nm. There is no sign of a crossover to a slower decay at large Co thicknesses, which, if observed, might be a signature of the predicted long-range spin triplet state [2]. [1] Robinson et al., Phys. Rev. Lett. 68, 177003, 2006. [2] Bergeret et al., Rev. Mod. Phys. 77, 1321, 2005. [Work Supported by US DOE under grant DE-FG02-06ER4634]

5:06PM L34.00012 Josephson junctions with a synthetic antiferromagnetic interlayer. MAZIN A. KHASAWNEH, WILLIAM P. PRATT JR., NORMAN O. BURGE, Dept. of Physics and Astronomy, Michigan State University, East Lansing, MI 48824 — We have measured the critical current of Josephson junctions of the form Nb/Co/Ru/Co/Nb, where the two Co layers are exchange-coupled antiferromagnetically by the thin (0.6 nm) Ru interlayer. The antiferromagnetic coupling causes nearly complete cancellation of the intrinsic magnetic flux produced by the Co domains, and allows us to study large-area junctions with total Co thicknesses ranging from 2 to 20 nm — four times thicker than in previous studies of Nb/Co/Nb Josephson junctions [1]. The dependence of the critical current on an in-plane external magnetic field results in a nearly perfect Fraunhofer pattern, due to the intrinsic flux cancellation. The junctions were fabricated by sputtering the S/F/N/F/S multilayer onto a Si substrate, followed by substracted patterning by photolithography and ion milling into circular junctions ranging in diameter from 10-80 microns. The critical current density of the decays exponentially with Co thickness, with a characteristic decay length of λF = 2.2 nm. There is no sign of a crossover to a slower decay at large Co thicknesses, which, if observed, might be a signature of the predicted long-range spin triplet state [2]. [1] Robinson et al., Phys. Rev. Lett. 68, 177003, 2006. [2] Bergeret et al., Rev. Mod. Phys. 77, 1321, 2005. [Work Supported by US DOE under grant DE-FG02-06ER4634]
were performed for dF functional local pseudopotential Hamiltonian and non equilibrium quantum transport calculations, MAIA G. DE-AC02-05CH11231. The computational resources were provided by the Reseau quebecois de calcul haute perfomance (RQCHP).

This discrepancy hasn't been understood yet. Up to now, only calculations using the local density approximation for the exchange-correlation functional (LDA) for the electron-phonon coupling calculated within density functional theory do not agree with measured values, in contrast to others phonon related properties.

Once functionalized metallic nanotubes can become insulators if sp transitions in S/F/S junctions. We find the characteristic length of oscillation (ξF) to be 7.9 ± 0.4 nm. Earlier studies [1] using a similar PdNi alloy in S/F/S junctions found ξF ≈ ξP ≈ 2.8 nm, however, those measurements were performed for δF between 4.5 and 14 nm. In our experiment, ξF1 > ξF2, indicating that our samples are in the regime E<sub>ex</sub>-τ > h [2, 3], where E<sub>ex</sub> is the exchange energy and τ is the mean free time between electron collisions in the ferromagnet. In spite of covering this wide range, we see no evidence of a crossover to a slower decay, which, if present, would be indicative of long-range spin triplet correlations [4].

3:42PM L35.00007 Tackling localized d-states: a systematic investigation by GW@LDA+$U$, HONG JIANG, RICARDO I. GOMEZ-ABAL, FHI, Berlin, Germany, PATRICK RINKÉ, UC Santa Barbara, USA; MATTHIAS SCHEFFLER, FHI, Berlin, Germany — First-principles modeling of systems with localized d-states is currently a great challenge in condensed matter physics. Density-functional theory (DFT) in the standard local-density approximation (LDA) proves to be problematic. This can be partly overcome by including local Hubbard $U$ corrections (LDA+$U$), but itinerant states are still treated on the LDA level. Many-body perturbation theory in the GW approach offers both a quasiparticle perspective (appropriate for itinerant states) and an exact treatment of exchange (appropriate for localized states), and is therefore promising for these systems. Here we present a systematic investigation of the $G_0W_0$ method based on LDA+$U$ ($G_0W_0$@LDA+$U$) for a series of prototype systems: 1) ZnS with semicore 3s-states, 2) ScN and TiO$_2$ with empty 3d-states and 3) late transition metal oxides (MnO, FeO, CoO and NiO) with partially occupied d-states. We show that for ZnS, ScN and TiO$_2$, the $G_0W_0$ band gap only weakly depends on $U$, but for the other transition metal oxides the dependence on $U$ is as strong as in LDA+$U$. These different trends can be understood in terms of changes in the hybridization and screening. Our work demonstrates that $G_0W_0$@LDA+$U$ withphysivalvalues of $U$ provides a balanced and accurate description of both localized and itinerant states.

3:54PM L35.00008 LDA+DMFT Charge Self-consistency Applied to Yb Valence Transition, ERIK YLVISAKER, WARNER PICKETT, UC Davis, ANDREW MCMAHAN, LNL, JAN KUNYES, University of Augsburg — Elemental ytterbium metal is known to undergo a gradual transition from a divalent spd$^0f^{14}$ state to a trivalent spd$^0f^{13}$ state in a pressure range of 0 to 34 GPa. We present LDA+DMFT studies of this transition, comparing three impurity solvers (Hirsch-Fye QMC, continuous time QMC and Hubbard I) with each other and with experimental data. All Yb states of interest are kept; no downfolding to a minimum basis is done. This implementation of DMFT (especially the QMC solvers) to the correlated f-orbitals gives reasonable agreement with the experimental transition. However, the neglect charge self-consistency is questionable for a valence transition where the concentration of valence electrons changes. Therefore we generalize the procedure and compare and contrast LDA+DMFT results with and without charge self-consistency for Yb using the Hubbard I impurity solver.

4:06PM L35.00009 Computation of phonon spectra from density-functional perturbation theory in the projector augmented-wave approach, MARC TORRENT, FRANCOIS JOLLET, CEA, DAM, DIF, F-91297 Arpajon, France, CHRISTOPHE AUDOUZE, Laboratoire Math. Appliquées, Ecole Centrale de Paris, Grande Voie des Vignes F-92295 Châtenay-Malabry, France, XAVIER GONZE, Unité PCPM, Université Catholique de Louvain. B-1348 Louvain-la-Neuve, Belgium — The density-functional perturbation theory expressions have been derived within the projector augmented-wave formalism (PAW) and compared to those found in the ultrasoft pseudopotential framework [1]. They have been recently implemented in the ABINIT package [2] in the case of perturbations of the atomic-displacement type. We summarize the key points of this implementation. The variational and non-variational forms of the 2nd-order total energy changes are detailed. The resolution of the variational principle by a generalized Sternheimer equation is explained (the 1st-order wave-function change is found with a band-by-band conjugate gradient algorithm). We focus on some difficulties: metallic electronic occupations, response to incommensurate perturbations of periodic systems... Results on pure compounds are presented; a comparison with results from pseudopotentials approach is performed in order to highlight the effect of the PAW methodology and its accuracy. [1] Audouze, Jollet, Torrent and Gonze. Phys. Rev. B 73, 235101 (2006); 78, 035105 (2008) [2] http://www.abinit.org.

4:18PM L35.00010 eliminating the V-representability problem via coarse-graining, PAUL LAMMERT, Pennsylvania State University — The mathematical foundations of density functional theory remain in an incomplete state, with old nagging problems and questions. I propose a coarse-grained approach to eliminating the V-representability problem and present results on differentiability of the Lie functional.

4:30PM L35.00011 Density Functional Theory and Semiclassical Methods1, PETER ELLIOTT, DONGHYUNG LEE, ATTILA CANGI, KIERON BURKE, University of California, Irvine — In this work we explore the relationship between semiclassical methods and density functional theory. There is a rich history between the two, for example, the gradient expansion approximation (GEA), on top of which DFT methods and density functional theory. There is a rich history between the two, for example, the gradient expansion approximation (GEA), on top of which all common generalized gradient approximations (GGAs) are built, may be derived semiclassically. However methods like Thomas-Fermi and the GEA miss important contributions from quantum oscillations, such as shell structure. In Ref. [1] we showed why these are missing and how, for a simple system, one could derive them. This led to approximations to the density and kinetic energy density which were non-local functionals of just the external potential. Interpreting these in the context of DFT, allows us to understand current approximations and improve them. In fact the potential scaling (re-)introduced in Ref. [1] can be used to derive new exact conditions on the universal functional of DFT and its components. This talk will discuss both the development of potential functionals and how they can be used to understand DFT.

4:42PM L35.00012 Correlation-Kinetic Contributions in the Mapping to Model Noninteracting Fermion and Boson Systems, XIAOYIN PAN2, Ningbo University, VIRAJT SAHNI, The Graduate Center CUNY — In the mapping from a system of electrons in an external field $\mathcal{F}_{\text{ext}} = -V v(r)$ to one of noninteracting fermions or bosons in their ground state with equivalent density $n(r)$, electron correlations due to the Pauli principle, Coulomb repulsion, and Correlation-Kinetic effects must be accounted for. Via Quantal Density Functional Theory (QDFT), it is proved that the contributions due to the Pauli principle and Coulomb repulsion to either mapping are the same. The application to atoms of the QDFT mapping to the model fermion system shows the corresponding Correlation-Kinetic energy contribution to be a very small fraction of the electron-interaction energy. In contrast, the same application of the QDFT mapping to the model boson system shows the corresponding Correlation-Kinetic energy to be a substantial fraction of the electron-interaction energy. Thus, whereas Correlation-Kinetic effects are insignificant in the mapping to the fermionic system, they play a significant role in the mapping to the model system of bosons.

4:54PM L35.00013 DFT-MD simulations of shocked Xenon. RUDOLPH J. MAGYAR, THOMAS R. MATTSSON, Sandia National Laboratories — Xenon is not only a technologically important element used in laser technologies, jet propulsion and dental anesthesia, but it is also arguably the simplest material in which to study the metal-insulator transition at high pressure. Because of its closed shell electronic configuration, Xenon is often assumed to be chemically inert, interacting almost entirely through the van der Waals interaction, and at liquid density, is typically modeled well using Leonard–Jones potentials. However, such modeling has a limited range of validity as Xenon is known to form compounds at normal conditions and likely exhibits considerably more chemistry at higher densities when hybridization of occupied orbitals becomes significant. In this talk, we present DFT-MD simulations of shocked liquid Xenon with the goal of developing an improved equation of state. The relative importance of the van der Waals interaction compared to other Coulomb interactions is considered, and estimates of the relative accuracy of various density functionals are quantified. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

5:06PM L35.00014 Evaluation of Magnetic Moments using Bader Analysis. TOMOHARU SHIKAUCHI, KAZUO TSUMURAYA, Meiji University, Japan — Evaluation of the magnetic moments in solids is crucial in the computational physics. The moments have been calculated by an atomic sphere approximation or a Voronoi polyhedron approximation. There has been a method to partition the space with the minimum electron charge density surface, called zero flux planes, around each atom. The space is called Bader region. We apply the method to calculate the local magnetic moments of each atom depending on their circumstance using the first principle electronic structure calculation. We obtain the moments from the Bader charges using the up-spin charge and the down-spin charges. We apply the validity of this scheme to the analyses of the spin moments in Fe-N compounds, fcc Fe, and bcc Fe crystals and compare them with the experimental values. For Fe₃N, the difference of the moments between Fe(I) and Fe(II) atoms has been larger than that of the Voronoi method and is better agreement with the experimental values than the Voronoi method.

5:18PM L35.00015 Layered dilute magnetic semiconductors: A dynamical mean field study¹. MAJID NILI, UNJONG YU, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University — We study ferromagnetism of layered dilute magnetic semiconductors within the Dynamical Mean Field Approximation. Our approach includes the spin-orbit coupling in the host compound and the interaction between the magnetic ions and the itinerant carriers using a modified double-exchange coupling. We simulate heterostructures with different distributions of magnetic ions: uniform doping, delta-doping in one single layer and delta-doping in two layers. We investigate the magnetic properties by changing the hole filling as well as the magnetic doping and the position of the doped layers in the heterostructure. We also include the on-site attraction potential between the magnetic ions and charge carriers to show its effect on the formation of the impurity band. We find that the ferromagnetic transition temperature and other properties strongly depend on the distribution of magnetic ions.

Session L36 Panel Discussion: APS Publishing: Present and Future 408

2:30PM L36.00001 Panel Discussion: APS Publishing, Present and Future — This panel discussion will consist of a set of short presentations covering issues relevant to publication in the APS journals, including the concept of “significant” new physics, followed by questions and comments from the audience. The editors will comment on the identification of “significance” and its role in the editorial process, past, present, and future. There will be a brief “State of the Journals” address by APS Editor-in-Chief, Gene Sprouse, and statements of key issues facing the journals, by their editors. There will also be an introduction to the new APS publication Physics by its Editor, David Voss. The questions and comments section will be moderated by the Editor-in-Chief.

Session L37 DCP: Focus Session: Spectroscopic Probes of Biomolecular Structure and Function III 409

2:30PM L37.00001 UV Resonance Raman Discovery of Gibbs Free Energy Landscape for Protein Alpha Helix Folding. SANFORD ASHER, University of Pittsburgh — We developed a powerful method to follow the evolution of secondary structure in the amide peptide bonds of peptides and proteins. UV Raman excitation into these ~200 nm electronic transitions results in the enhancement of the amide vibrations of the peptide backbone. In our most recent studies we reassigned the amide III region and found a particular band (the amide III, band) which reports selectively on the Ramachandran Ψ angle and the state of peptide bond hydrogen bonding. We demonstrate that this band is Raman scattered independently by each peptide bond with insignificant coupling between peptide bonds. We also show that isotope editing of a peptide bond (by replacing the Cα–H with Cα–D) allows us to determine the frequency of an individual peptide bond within a peptide or protein which gives us its Ψ angle. Consideration of the Boltzmann equilibria allows us to determine the Ψ angle energy landscape which connects secondary structure conformations. The Ψ angle coordinate is the most important reaction coordinate required to enable the understanding of the mechanism(s) of protein folding.
3:42PM L37.0003 Inhibition of urinary calculi — a spectroscopic study¹ . FELICIA MANCIU, JAYESH GOVANI, WILLIAM DURRER, LAYRA REZA, LUIS PINALES, Physics Department, University of Texas at El Paso, El Paso, TX 79968 — We present multi-technique spectroscopic investigations by Raman, infrared absorption, X-ray photoelectron spectroscopy (XPS), and photoluminescence on the effects of the herb Rotula Aquatica Lour (RAL) on the growth of synthetically prepared Mg-based calculi of similar composition to common urinary calcui. Three samples were prepared; one MgPO₄-based standard and two others, separately incorporating 1 wt.% and 2 wt.% RAL herbal extract. Raman and infrared data show a newbeyrie structure for the crystals without and with inhibitor. XPS revealed the unexpected presence of Zn and a significant increase in Mg in the samples with RAL inhibitor. The presence of metallic Zn may contribute to the inhibition process by initiating rapid stone formation. XPS and Raman results also suggest another mechanism of inhibition by revealing evidence for Mg-O bonding between the plant extract and the phosphate units of urinary calculi. Similarity between our photoluminescence measurements and those of in vivo chlorophyll a provides additional evidence of Mg-related inhibition.

3:54PM L37.0004 Application of a Newly Built Chirped-Pulse Fourier Transform Microwave (CP-FTMW) Spectrometer to Study Biomolecules in the Gas Phase¹ . RYAN BIRD, DAVID PRATT, University of Pittsburgh, JUSTIN NEILL, BROOKS PATE, University of Virginia — Chirped-pulse Fourier Transform Microwave (CP-FTMW) spectroscopy is an exciting new technique that makes possible the recording of the complete microwave spectrum of a gas phase sample using a single 1 μs pulse. In this report, we will describe the recent introduction of a laser ablation nozzle for the study of small biomolecules using this technique.

¹Work supported by NSF (CHE-06 18740).

4:06PM L37.0005 Optical Conformational Transition Pathways of DsRed, Elucidated by Polarization-Modulated Fourier Imaging Correlation Spectroscopy . ANDREW MARCUS, ERIC SENNING, GEOFFREY LOTT, University of Oregon, MICHAEL FINK, Omega Optical, Inc — This work presents a novel ‘phase-selective’ approach to fluorescence fluctuation spectroscopy that simultaneously determines the joint probability distributions and two-dimensional spectral densities of protein conformational transitions, and nanometer center-of-mass displacements. Fourier imaging correlation spectroscopy (FICS) combines polarization- and intensity-modulated photo-excitation with phase-sensitive signal detection to monitor the collective coordinate fluctuations from a large population of fluorescent molecules (N ~ 10⁶). FICS is based on the principle that fluctuations of partially averaged molecular coordinates can be monitored through variations of an optical signal phase. Experiments are performed on DsRed, a tetrameric complex of fluorescent protein subunits, derived from a reef-building coral. Thermally induced conformational transitions of the DsRed complex lead to fluctuations in the optical dipolar coupling between adjacent chromophore sites. An analysis of polarization-resolved FICS fluctuation data, in terms of two-dimensional spectra and joint probability distributions, provides detailed information about cooperative ‘transition pathways’ between distinct dipole-coupled DsRed conformations.

4:18PM L37.0006 Insights on the Structural Details of Endonuclease EcoRI-DNA Complexes by Electron Spin Resonance . JESSICA SARVER, University of Pittsburgh — Pulsed electron spin resonance (ESR) was used to probe the binding specificity of EcoRI, a restriction endonuclease. Using site-directed spin labeling, a nitroxide side chain was incorporated into the protein, enabling the use of ESR to probe the structural details of EcoRI. Distance measurements were performed on EcoRI mutants when bound to varying sequences of DNA using the Double Electron-Electron Resonance experiment. These distances demonstrated that the average structure in the arm regions of EcoRI, thought to play a major role in binding specificity, is the same when the protein binds to different sequences of DNA. Also, it was determined that the arms exhibit higher flexibility when bound to sequences other than the specific sequence due to the larger distance distributions acquired from these spin labeled complexes. Molecular dynamics (MD) simulations were performed on the spin-label-modified specific EcoRI-DNA crystal structure to model the average nitroxide orientation. The distance distributions from MD were found to be narrower than experiment, indicating the need for a more rigorous sampling of the nitroxide conformers in silico.
4:30PM L37.00007 1D and 2D-IR spectroscopy of blended polymer-porphyrin thin films, AARON MASSARI, AUDREY EIGNER, PATRICK KONOLD, University of Minnesota, Twin Cities — One and two-dimensional IR spectroscopies are used to study the static and dynamic environments that form when ruthenium(tetraphenyl)porphyrin carbonyl is blended with regioregular poly(3-hexylthiophene). The 1D-IR spectra of the Ru-bound CO symmetric stretch indicate the development of several inhomogeneously broadened microenvironments as the concentration of porphyrin is increased. Transmission electron microscopy is used to characterize the blended films, which show evidence of phase-segregation. By correlating the degree of separation with the relative proportions of each component of the 1D-IR spectrum, we identify the IR spectra corresponding to the free and aggregated porphyrin-CO stretches. 2D-IR vibrational echo spectroscopy is then used to measure the ultrafast dynamics that are present in the polymer and porphyrin phases.

4:42PM L37.00008 Microtubule-associated-protein (MAP) Tau Regulates the Number of Protofilaments in Microtubules: A Synchrotron X-ray Scattering Study, MYUNG CHUL CHOI, UCSD, URI RAVIV, Univ. Jerusalem Israel, HERBERT MILLER, MICHELLE GAYLORD, ERKAN KIRIS, DONOVAN VENTIMIGLIA, UCSD, DANIEL NEEDLEMAN, Harvard Univ., MAHN WON KIM, KAIST, LESLIE WILSON, STUART FEINSTEIN, CYRUS SAFINYA, UCSD — Microtubules (MTs), 25 nm protein nanotubes, are a major filamentous element of the cytoskeleton involved in intracellular trafficking and cell division. MAP tau regulates tubulin assembly and MT stability. Dysfunction of tau has been correlated with numerous neurodegenerative diseases. We describe our recent findings about the effects of six naturally occurring central nervous system (CNS) tau isoforms on the assembly structure of taxol-stabilized MTs, using synchrotron small angle x-ray scattering (SAXS). Most significantly, we found that tau, at low binding density, regulates the distribution of protofilament numbers in MTs. DOE DE-FG02-06ER46314, NSF DMR-0803103, NIH RO1-NS35010 and NS13560.

Tuesday, March 17, 2009 2:30PM - 5:30PM — Session L38 DCP: Focus Session: Theory of Electron Transport Through Molecules III

2:30PM L38.00001 Statistical mechanics of non-equilibrium steady state systems, DANIEL KOSOV, University of Maryland — One of the important classes of non-equilibrium systems is the systems, which are maintained in non-equilibrium steady state by the contact with several external macroscopic reservoirs. These systems are ubiquitous and their theoretical description has been a challenging fundamental scientific problem for many years. They are also of significant practical interest for various nanotechnological and biological applications, such as quantum contacts, molecular motors, nanowires, and molecular junctions. There is no unique theoretical approach to wide variety of non-equilibrium steady state systems. General theoretical description of non-equilibrium steady states has not been developed yet and many fundamental theoretical questions are yet to be answered. For example, how to include many-particle correlation effects into theoretical treatment, is there exist a general variational principle for non-equilibrium steady state, do we enforce by the choice of a particular theoretical treatment a specific non-equilibrium steady state which is not the same as the real system would establish under the same boundary conditions, do we have a unique steady state in a system of non-equilibrium interacting particles for given boundary conditions? In my talk, I will review these questions and their relevance to electron transport through molecules. I will also give account of our recent computational and theoretical work on non-equilibrium quantum transport through molecular nanostructures.

3:06PM L38.00002 Vibronic effects in single molecule conductance1, MICHAEL THOSS, Department of Chemistry, Technical University of Munich — Recent experimental advances have allowed to study the conductance properties of single-molecule junctions and revealed a wealth of intriguing transport phenomena. An important aspect that distinguishes nanoscale molecular conductors from mesoscopic devices is the influence of the nuclear degrees of freedom of the molecular bridge. Due to the small size of molecules, the charging of the molecular bridge is often accompanied by significant changes of the nuclear geometry that indicate strong coupling between electronic and nuclear (in particular vibrational) degrees of freedom. In this contribution, the effect of electron-vibrational (vibronic) coupling on the transport properties of single molecule junctions is studied. The study is based on a combination of first-principles electronic structure calculations to characterize the system and different transport methods including inelastic scattering theory, master equations and nonequilibrium Green's function theory. The basic mechanisms of vibrationally coupled electron transport are analyzed for a generic model of a molecular junction as well as benzenealkanethiolates between gold electrodes. The results show that vibronic coupling can have a significant effect on the conductance of molecular junctions. It manifests itself in pronounced structures in the current-voltage characteristics. Moreover, the current-induced excitation of vibrational modes may result in a significant deviation of the vibrational degrees of freedom from their equilibrium distribution.

3:42PM L38.00003 Controlling Current Flow Through Molecules With Electric Fields Emerging From Nearby Molecules: Theory and Experiment2, G. KIRCZENOW, Simon Fraser U., P. G. PIVA, R. A. WOLKOW, NINT and U. of Alberta — We show that electrical conduction through molecules can be strongly modulated by electric fields of nearby polar molecules. We study 1D organic heterostructures consisting of contiguous lines of CF3-styrene and OCH3-styrene molecules on H-terminated Si(100). For suitable alignment of the OCH3 groups in the molecular chain, their combined electric fields are shown by density functional calculations to give rise to potential profiles along the OCH3-styrene chain that result in strongly enhanced conduction transverse to the CF3-styrene/OCH3-styrene heterojunction for moderately low negative substrate bias, as is observed by STM. Under similar bias, dipoles associated with CF3 groups are found in both theory and experiment to depress transport in the underlying Si. Under positive substrate bias, simulations suggest that the structural and electrostatic properties of CF3-styrene molecules may lead to more sharply localized conduction enhancement near the heterojunction. Thus choice of substituents, their attachment site on the host styrene molecules on Si and the orientations of the molecular dipoles and multipoles provide a means of differentially tuning transport on the molecular scale.

3:54PM L38.00004 Effects of Dephasing on DNA Sequencing via Transverse Electronic Transport1, MATT KREMS, University of California, San Diego, YURIY PEPSHIN, University of South Carolina, MICHAEL ZWOLAK, Los Alamos National Laboratory, MASSIMILIANO DI VENTRA, University of California, San Diego — We study theoretically the effects of dephasing on DNA sequencing in a nanopore via transverse electronic transport. To do this, we couple classical molecular dynamics simulations with transport calculations using scattering theory. Previous studies, which did not include dephasing, have shown that by measuring the transverse current of a particular base multiple times, one can get distributions of currents for each base that are distinguishable. We introduce a dephasing parameter into transport calculations to simulate the effects of the ions and other fluctuations which are not included in the Landauer approach. We find that the overall dephasing required for good contact transparency is broken by connecting through a six-member ring on the tube. Full dephasing is achieved by an all-carbon contact through a five-member ring leads to near perfect contact transparency for different conjugated molecular bridges. [Phys. Rev. Lett. 99, 146802 (2007)]

4:06PM L38.00005 Single-Electron Transistors made by chemical patterning of silicon dioxide substrates and selective deposition of gold nanoparticles. ULAS COSKUN, HENOK MEABRANTU, Physics Department Duke University, THOM LABEAN, Chemistry Department, Duke University, GLEB FINKELSTEIN, Physics Department Duke University — We describe a method to pattern SiO2 surfaces with colloidal gold nanoparticles by e-beam lithography and selective nanoparticle deposition. The method allows us to deposit nanoparticles in different shapes, including long continuous lines just one nanoparticle wide. We contact the pre-positioned nanoparticles with metal leads to form Single Electron Transistors. The Coulomb blockade pattern surprisingly does not show the parasitic “offset charges” at low temperatures, indicating relatively little surface contamination.

4:18PM L38.00006 Contact Transparency of Nanotube-Molecule-Nanotube Junctions, S. H. KE, H. U. BARANGER, WENTAO YANG, Duke University — The transparency of contacts between conjugated molecules and metallic single-walled carbon nanotubes is investigated using a single-particle Green’s function method which combines a Landauer approach with ab initio density functional theory. We find that the overall dephasing required for good contact transparency is broken by connecting through a six-member ring on the tube. Full dephasing is achieved by an all-carbon contact through a five-member ring leads to near perfect contact transparency for different conjugated molecular bridges. [Phys. Rev. Lett. 99, 146802 (2007)]

4:30PM L38.00007 Quantum many-body effects on the electric and thermoelectric response of molecular heterojunctions, JUSTIN BERGFIELD, CHARLES STAFFORD, University of Arizona — A semi-empirical e-electron Hamiltonian (extended Hubbard model) is used to model the electronic degrees of freedom most relevant for transport in a heterojunction consisting of a conjugated organic molecule coupled to two (or more) metallic electrodes. With an appropriate choice of parameters, the complete spectrum of electronic excitations of the molecule up to 8–10eV can be accurately described, which is essential to accurately model transport far from equilibrium. The electric and thermoelectric response of the junction is calculated within a many-body theory of transport based on nonequilibrium Green’s functions. For benzenedithiol-Au junctions, the parameters characterizing the lead-molecule coupling (tunneling width and chemical potential offset) are determined by comparison to linear-response measurements of conductance and thermopower. The nonlinear transport can then be predicted: the differential conductance as a function of gate and bias voltages exhibits clear signatures of charge quantization and resonant tunneling through excited states, with an irregular “molecular diamond” structure analogous to the regular Coulomb diamonds observed in quantum dot transport experiments. Several other small conjugated organic molecules are also investigated. [C. W. M. Castelon and W. Barford, J. Chem. Phys. 117, 3570 (2002)].

4:42PM L38.00008 Current induced local heating and heat transport in single molecular bridge junction, YOSHIHIRO ASAI, AIST, Umesono 1-1-1, Central 2, Tsukuba, Ibaraki 305-8568, Japan — Current induced local heating will be discussed theoretically. Both electronic and thermal conductance of electronic and phonon conduction are calculated in a microscopic way, including inelastic scattering effects due to electron-phonon coupling. [1] Based on the self-consistent solution of an alkanedithiol molecule bridging gold electrodes, we found that the effective temperature $T_{eff}$ due to the local heating is largely reduced by the heat conductance, which releases the Joule heat out of the molecule. All these calculations are made in a fully microscopic way without introduction of the phenomenological phonon diffusion effect used in literature. Theoretical voltage dependence of $T_{eff}$ agrees nicely with an experiment. [2 Ref.] [1] Y. Asai, Phys. Rev. B78, 045434 (2008). [2] Z.Huang et al, Nano Letters, 6, 1240 (2006).

5:06PM L38.00009 Fabrication and characterization of vertically aligned and interconnected nickel oxide Nanowalls1, LATHA KUMARI, WENZHI LI, Florida International University, CHARLES H. VANNOY, ROGER M. LEBLANC, University of Miami, DEZHI WANG, Boston College, DEPARTMENT OF PHYSICS, FLORIDA INTERNATIONAL UNIVERSITY, MIAMI, FL 33199, USA TEAM, DEPARTMENT OF CHEMISTRY, UNIVERSITY OF MIAMI, CORAL GABLES, FL 33124, USA COLLABORATION, DEPARTMENT OF PHYSICS, BOSTON COLLEGE, CHESTNUT HILL, MA 02467, USA COLLABORATION — Vertically aligned and well interconnected NiO nanowalls were fabricated on Ni foil by a two step hydrothermal route. The as-prepared nickel hydroxide was converted to NiO by further heat treatment. The NiO nanowalls are typically 15 nm thick and around 1-1.5 µm wide. The NiO nanowalls have cubic crystal structure with their growth plane along the [111] direction. The NiO nanowalls show an optical band gap of about 3.8 eV and exhibit broad photoluminescence emission band centered at around 390 nm. The present synthesis technique allows the growth of well aligned 2D nanostructures with large surface area for possible applications in nanoscale devices.

5:18PM L38.00011 ABSTRACT WITHDRAWN
2:30PM L39.00001 Biochemistry on a leash: Confinement as a regulatory mechanism for bimolecular reaction rates, DANIEL REEVES, KEITH CHEVERALLS, JANE KONDEV, Brandeis University — We describe two mechanisms by which confinement regulates diffusion-limited bimolecular reaction rates. The first mechanism, illustrated by the actin capping protein formin, uses a flexible polymer to tether ligand binding sites, which serve as intermediaries, to the reactive site. The second mechanism uses a potential (e.g. hard wall potential), to constrain the motion of a ligand receptor within a confining volume. We analyze both mechanisms theoretically, using a combination of analytic and numerical techniques, to obtain the steady state binding kinetics. We explore how the reaction rates are regulated by parameters of the model such as the length of the polymer tether, and use our findings to explain the key features of the formin system. Finally, we suggest other systems, both synthetic and biological, in which these mechanisms for regulating bimolecular reactions might be at play.

2:42PM L39.00002 Crowded, cell-like environment induces shape changes in aspherical protein, MARGARET CHEUNG, University of Houston — How the crowded environment inside cells affects the structures of proteins with aspherical shapes is a vital question because many proteins and protein–protein complexes in vivo adopt anisotropic shapes. Here we address this question by combining computational and experimental studies of a football-shaped protein (i.e. *Borreia burgdorferi* VlsE) under crowded, cell-like conditions. The results show that macromolecular crowding affects protein-folding dynamics as well as overall protein shape. In crowded milieus, distinct conformational changes in VlsE are accompanied by secondary structure alterations that lead to exposure of a hidden antigenic region. Our work demonstrates the malleability of “native” proteins and implies that crowding-induced shape changes may be important for protein function and malfunction in vivo.

3:18PM L39.00003 Molecular dynamics study of multimerization of the Mms6 protein from Magnetospirillum magnetism strain AMB-1, MONICA LAMM, RASTKO SKNEPNEK, LIJUN WANG, MARIT NILSEN-HAMILTON, Iowa State University and Ames Laboratory — In order to optimize their search for nutrients, magnetotactic bacteria have developed an ability to align themselves to Earth’s magnetic field. This is achieved by forming a chain of vesicles containing magnetite superparamagnetic nanoparticles with sizes of the order of 50nm. The presence of the small protein Mms6 plays an important role in the successful in vitro growth of magnetite nanoparticles, although the mechanism of this process is not understood. Preliminary experiments on Mms6 in solution indicate that the protein forms multimers of variable sizes, depending on the salt concentration. Using an intermediate level coarse grained model for Mms6 we investigated the formation of these multimers as a function of temperature and salt concentration.

3:30PM L39.00004 The Packing of Flexible Screws and the Self-Limited Assembly of Biopolymer Bundles, GREGORY GRASON, University of Massachusetts, Amherst — Living cells rely heavily on assemblies of filamentous proteins, such as F-actin and microtubules, to perform a variety of tasks, ranging from adhesion and locomotion to cell division and intracellular transport. In the dynamic cellular environment, the efficiency of these tasks is crucially dependent on the robust assembly and disassembly of rope-like bundles of filamentous molecules. Recent in vitro studies of F-actin assembly [Lai et al., Phys. Rev. Lett. (2007)] suggest that bundle formation may take place as an equilibrium process, with a thermodynamically-preferred bundle diameter. Within the context of a generalized elastic model of filament packings, we explore the possibility that limited-bundle growth is directly linked with the intrinsic chiral structure of biological filaments themselves. The hexagonal packing of biopolymers leads to the build up of chiral stress, or torque, that generically induces the formation of twisting filament bundles of finite size. We demonstrate that the underlying elasticity of the bundle—i.e. whether hexagonal-solid or hexagonal-columnar—plays a key role in dictating both the thermodynamics (i.e. disperse, bundled or bulk aggregation) and structure (i.e. size and twist) of “self-braiding” aggregates of helical filaments.

4:06PM L39.00005 Simulation of signal transduction in model multiprotein systems, JULIUS SU, Caltech — To simulate the dynamics of multiprotein machines, I have developed a method called multiconformer Brownian dynamics (mcBD). In this method, proteins rotate and translate via Brownian motion while their conformations are varied among a prestored set of structures on a simplified energy landscape. As an example, I build a simple model of a G-protein coupled receptor/G-protein complex, and show that ligand binding causes conformational shifts, which induce GDP to leave, GTP to bind, and the complex to dissociate. The two proteins couple their fast rotations and translations via Brownian motion while their conformations are varied among a prestored set of structures on a simplified energy landscape.

4:18PM L39.00006 Implicit solvent model for linear-scaling first-principles electronic structure calculations, HATEM H. HELAL, MIKE PAYNE, Theory of Condensed Matter, Cavendish Laboratory, University of Cambridge, ARASH A. MOSTOFI, Departments of Physics and Materials, Imperial College London — Density functional theory (DFT) enables first-principles calculations that exhibit cubic scaling of the computational time required with respect to the number of atoms in the system. This presents an unavoidable difficulty when first-principles accuracy is needed for the study of large-scale biological systems. The ONETEP program reformulates DFT so that the required computational effort scales only linearly with system size, recently demonstrated for up to 32,000 atoms on 64 cores. Further complicating DFT based studies of biomolecular systems is the need for an accurate representation of the electrostatic environment. Rather than introducing explicit solvent molecules into the system, which would be computationally prohibitive, we present our recent efforts to integrate an implicit solvent model with ONETEP in order to study systems in solution consisting of many thousands of atoms. We report preliminary results of our methodology with a study of the DNA nucleosome core particle.

---

4:30PM L39.00007 Using stochastic dynamics to validate runtimes of protein simulations1

STEPHEN D. HICKS, CHRISTOPHER L. HENLEY, Cornell University — We use short molecular dynamics simulations (~200 cpu-hr, using NAMD) of individual bonds between capsid proteins to microscopically determine coarse-grained elastic parameters of entire virus capsids. In particular, we treat each protein (or for larger proteins, each domain) as a rigid body described by a 6-vector of translational and orientational degrees of freedom, $\dot{\mathbf{x}}(t)$. We then model the evolution of the relative positions as an overdamped random walk, $\mathbf{x}(t) = -K_{ij} \dot{\mathbf{x}}(t) + \zeta(t)$, where $\zeta(t)$ are random variables satisfying $\langle \zeta(t) \rangle = 0$. Our goal is to determine the stiffness matrix $K_{ij}$, but this requires long-time data to measure accurately. We therefore measure the noise matrix $2\Gamma_{ij}$, which depends on much shorter timescales, and compute the relaxation times by diagonalizing $\Gamma = T \Delta \Gamma T$. Although we use biologically relevant configurations in each simulation, we have taken the domains out of their full context by simulating one pair at a time, and therefore external stresses are missing, which we measure from the drift and compensate for in subsequent simulations. Finally, we apply this technique to the HIV capsid protein.

4:42PM L39.00008 A symplectic integration method for elastic filaments

TAYLOR LADD, GAURAV MIRSA, University of Florida — Elastic rods are a ubiquitous coarse-grained model of semi-flexible biopolymers such as DNA, actin, and microtubules. The Worm-Like Chain (WLC) is the standard numerical model for semi-flexible polymers, but it is only a linearized approximation to the dynamics of an elastic rod, valid for small deflections; typically the torsional motion is neglected as well. In the standard finite-difference and finite-element formulations of an elastic rod, the continuum equations of motion are discretized in space and time, but it is then difficult to ensure that the Hamiltonian structure of the exact equations is preserved. Here we discretize the Hamiltonian itself, expressed as a line integral over the contour of the filament. This discrete representation of the continuum filament can then be integrated by one of the explicit symplectic integrators frequently used in molecular dynamics. The model systematically approximates the continuum partial differential equations, but has the same level of computational complexity as molecular dynamics and is constraint free. Numerical tests show that the algorithm is much more stable than a finite-difference formulation and can be used for high aspect ratio filaments, such as actin. We present numerical results for the deterministic and stochastic motion of single filaments.

5:06PM L39.00009 Biomolecular Structure Determination with Divide and Concur

YOAV KALLUS, VEIT ELSER, Cornell University — Divide and concur $D - C$ is a general computational approach, designed for the solution of highly frustrated problems. Recently applied to the problems of disk packing, the kissing number problem, and 3-SAT, it was competitive or outperformed special-purpose methods. We present a new method, adaptive anisotropic network model (aANM) for exploring functional transitions, based on the elastic network models which have been widely used to describe the collective dynamics of biomolecular systems. Application to bacterial chaperonin GroEL highlights the utility of the methodology. Comparisons with experimental data and results from action minimization algorithm support the utility of aANM as a computationally efficient, yet physically plausible, tool for unraveling potential transition pathways sampled by large complexes/ensembles and assessing the critical inter-structures formed/broken near the transition state(s), most of which involve conserved residues.

5:18PM L39.00011 Generic Coarse-Grained Model for Protein Folding and Aggregation

TRISTAN BEREAU, MARKUS DESERNO, Dept. of Physics, Carnegie Mellon University, Pittsburgh, PA 15213 — The complexity involved in protein structure is not only due to the rich variety of amino acids, but also the inherent weak interactions, comparable to thermal energy, and important cooperative phenomena. This presents a challenge in creating a unified model that captures the diversity of the sequence space. We developed a model that captures the diversity of the sequence space by using a coarse-grained approach. We tested our model on a variety of proteins and found that it accurately predicts the stability of the native state. We also found that the model is able to predict the aggregation of proteins, which is a key factor in the formation of amyloids.

5:30PM L39.00012 Computational Investigation of Conformational Changes in Proteins upon Adsorption

SUMIT SHARMA, Columbia University, GAURAV ANAND, GEORGES BELFORT, Rensselaer Polytechnic Institute, SANAT K. KUMAR, Columbia University — Amyloidogenic diseases, such as, Alzheimer’s, are caused by adsorption and aggregation of partially unfolded proteins. Protein adsorption is often accompanied by conformational rearrangements, which are thought to affect many properties such as their adhesion strength to the surface, biological activity, and aggregation tendency. Experiments have shown that many proteins, upon adsorption to hydrophobic surfaces, undergo a helix to sheet or random coil secondary structural rearrangement. To better understand the equilibrium structural complexities of this phenomenon, we have performed Monte Carlo (MC) simulations and Single Chain Mean Field calculations of adsorption of different proteins, modeled as lattice chains, to study the adsorption behavior and equilibrium protein conformations at different temperatures, protein concentration and surface hydrophobicity. Free energy and entropic effects on adsorption have been studied by determining density states using Weighted Histogram Analysis Method. Conformational transitions of proteins on surfaces will be discussed as a function of surface hydrophobicity.

5:42PM L39.00013 Role of van der Waals interactions for the intrinsic stability of polyalanine helices

ALEXANDRE TKATCHENKO, VOLKER BLUM, Fritz-Haber-Institut der MPG, Berlin, Germany, JOEL IRETA, Dep. Quimica, UAM-Iztapalapa, Mexico, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, Germany — The helical motif is an ubiquitous conformation adopted by amino acid residues in a protein structure and helix formation is the simplest example of the protein folding process. How stable is the folded peptide helix in comparison to a random coil structure? What are the interactions responsible for stabilizing the helical conformation? Answering these questions has thus a direct implication for understanding protein folding. In this work we use density functional theory (DFT) augmented with a non-empirical correction for van der Waals (vdW) forces to study the stability of alanine polypeptide helices in vacuo. We find a large stabilization of the native helical forms when vdW correction is used. It amounts to 121%, 157% and 83% on top of the Perdew-Burke-Ernzerhof (PBE) functional in the case of infinite $\alpha$, $\beta$ and $\pi$ helices, respectively. Thus, the experimentally observed $\alpha$ helix is significantly stabilized by vdW forces both over the fully extended and the $3_{10}$ conformations. Our findings also suggest an explanation to the remarkable stability of gas-phase alanine helices up to high temperatures [M. Kohtani et al. JACS 126, 7420 (2004)].
2:42PM L40.00002 Density fluctuations in confined and non-confined DNA

JUNHAN PAN, CHUNDA ZHOU, ROBERT RIEHN, North Carolina State University — DNA stretching in quasi one-dimensional nanochannels is an emerging technique for the analysis of genomic-sized DNA molecules. For formulating an optimal measurement strategy, the thermal fluctuations of confined molecules are of crucial importance. While previous measurements have concentrated only on the end-to-end length, we present here an experimental study of density fluctuations within the molecule, and find a good agreement with a model similar to a oscillator chain. We further discuss how such a model leads to a natural interpretation of the interesting intramolecular collapse of DNA that we recently under application of a.c. electric fields at frequencies of a few hundred Hertz.

2:54PM L40.00003 Direct Observation of Multiple Pathways of DNA Stacking Using Single-Molecule AFM

CHING-HWA KIANG, WEI-HUNG CHEN, Department of Physics and Astronomy, Rice University, Houston, TX 77005 — During DNA interactions, single-stranded DNA (ssDNA) is often stretched and stabilized by coupling with ssDNA binding proteins to serve as an intermediate state. The conformational and energetic changes of stretched DNA are of great interest because of their relevance in biological functions. Direct manipulation of DNA has yielded much of the information about the mechanical properties of DNA without the complication of interacting molecules. Stretching ssDNA has provided direct measurement of the base stacking mechanics and energetics. For example, polyA has been shown to have two transitions during overstretching. Here we showed direct observation of two overstretching pathways during the second transition. We have observed “hopping” between these two pathways during constant-force measurements. We will discuss the implications of such transition and its significance in biological functions.

3:06PM L40.00004 Stabilities of Constituent Hairpins Determine Whether RNA Folds via Ordered and/or Parallel Mechanisms

SAMUEL CHO, DEVARAJAN THIRUMALAI, University of Maryland — RNA molecules are increasing becoming seen as a set of critical players in numerous cellular processes, and a firm understanding of their folding energy landscapes is essential for understanding how they carry out their functions. While it might seem natural to assume that the simplicity of RNA molecules, with only four possible bases, dictate that they must fold via simple mechanisms, experiments continue to point to complex folding energy landscapes involving parallel mechanisms. In our present study, we address how even simple RNA molecules can give rise to very complex folding mechanisms. We begin by making the argument that the complexity observed for RNA folding are in fact fully expected because the lack of variability of the RNA subunits leads to a lack of specificity for folding to the native basin. To illustrate our point, we performed coarse-grained simulations of three RNA pseudoknots and a tRNA molecule, which each are all relatively simple RNA molecules that contain at least two hairpins. From our simulations, we find that the main determinant for how these RNA molecules fold is largely dependent on the relative stabilities of their constituent hairpins. Ordered mechanisms arise if the stabilities of the constituent hairpins are sufficiently dissimilar and parallel folding mechanisms occur if the stabilities of the hairpins are similar.

3:18PM L40.00005 Structural basis of pathway-dependent force profiles in DNA

DANIEL ROE, ANNE CHAKA, Physics Laboratory, National Institute of Standards and Technology — Since DNA must bend and/or stretch to perform many of its functions, it is important to understand the mechanical properties of DNA. Single molecule experiments have been able to study the response of DNA to applied forces. One interesting result of such studies is that at high loading rates a greater force is required to stretch DNA when pulling from the 3' ends as opposed to the 5' ends. While these experiments provide valuable insights into the stability of DNA, it is often difficult to relate the results to specific structural changes. We have used molecular dynamics simulation methods to study the structure and dynamics of DNA under a tensile load. Simulations were performed on a variety of fully solvated DNA sequences up to 30 base-pairs in length, and were conducted under both non-equilibrium and equilibrium conditions. Different stretched DNA structures are observed depending on whether pulling occurs from the 5' ends or 3' ends. Detailed analysis of these structures provides a direct structural explanation of the observed difference between 3' and 5' pulling.

3:30PM L40.00006 Folding Kinetics of Riboswitch Transcriptional Terminators

BENJAMIN SAUERWINE, MICHAEL WIDOM, Carnegie-Mellon University — Riboswitches control the expression of genes in bacteria by halting gene transcription or allowing it to proceed based on the presence of ligands in solution. A key feature of every riboswitch is a transcriptional terminator in which the messenger RNA folds into a secondary structure with the stem-loop structure of a hairpin. Through kinetic Monte Carlo simulation we show that terminators have been naturally selected to fold with high reliability on the time-scale of gene transcription. This efficient folding behavior is preserved among two classes of riboswitch and among two species of bacteria.

3:42PM L40.00007 First Principles Study of Nuclear Quadrupole Interactions in Single and Double Chain DNA and Solid Nucleobases

T.P. DAS, R.H. PINK, S.R. BADU, SUNY Albany, ARCHANA DUBEY, UCF Orlando, R.H. SCHEICHER, Uppsala University, Sweden, H.P. SAHA, LEE CHOW, UCF Orlando, M.B. HUANG, SUNY Albany — Nuclear Quadrupole Interactions (NQI) of \(^{17}O, ^{14}N\) and \(^{2}H\) nuclei have been studied for free nucleobases and nucleobases in single strand and double strand DNA and in solid state. Our first-principles investigations were carried out using the Gaussian 2003 set of programs to implement the Hartree-Fock procedure combined with many-body effects including using many-body perturbation theory. As expected for NQI in general, many-body effects are found to be small. Results will be presented for the quadrupole coupling constants \((e^2qQ)\) and asymmetry parameters \((\eta)\) for the nucleobases in various environments. Trends in \(e^2qQ\) and \(\eta\) in the different environments will be discussed. In the case of the solid nucleobases, comparisons will be made with available experimental data [1] for \(^{17}O\) nuclei.

3:54PM L40.00008 Optical control of DNA radio-sensitivity, RAMIN ABOLFATH, University of Texas, Southwestern Medical Center, Dallas — We explore the manipulation of the radio-sensitivity of the DNA molecules driven by the spin blockade mechanism of diffusive free radicals. We propose a mechanism which uses the simultaneous application of circularly polarized light and an external magnetic field to control the polarization of the free radicals and create an $S = 1$ electron-hole spin excitation (exciton) on DNA molecules. It allows us to manipulate and partially suppress the damage induced by ionizing radiation. We deploy an ab-initio molecular dynamics model to calculate the characteristic parameters of the light needed for optical transitions and investigate the effect of spin-injection on the formation of a free energy barrier in diffusion controlled chemical reaction pathways that controls radiation-induced DNA damage. As a specific example, we present the numerical results calculated for a nucleotide-base, e.g., Guanine, in the presence of an OH free radical.

4:06PM L40.00009 Acetylated histone H3 increases nucleosome dissociation1, MAREK SIMON, Department of Physics, The Ohio State University, MRIDULA MANOHAR, JENNIFER OTTESEN, Department of Biochemistry, The Ohio State University, MICHAEL POIRIER, Department of Physics, The Ohio State University — Chromatin’s basic unit structure is the nucleosome, i.e.: genomic DNA wrapped around a particular class of proteins – histones – which due to their physical hindrance, block vital biological processes, such as DNA repair, DNA replication, and RNA transcription. Histone post-translational modifications, which are known to exist in vivo, are hypothesized to regulate these biological processes by directly altering DNA-histone interactions and thus nucleosome structure and stability. Using magnetic tweezers technique we studied the acetylation of histone H3 in the dyad region, i.e. at K115 and K122, on reconstituted arrays of nucleosomes under constant external force. Based on the measured increase in the probability of dissociation of modified nucleosomes, we infer that this double modification could facilitate histone chaperone mediated nucleosome disassembly in vivo.

4:18PM L40.00010 First Principles Study of Muonium Trapping and Associated Magnetic Hyperfine Interactions in Nucleobases in Single and Double Chain DNA and Solid Nucleobases, S.R. BADU, R.H. PINK, SUNY Albany, ARCHANA DUBAY, UCF Orlando, R.H. SCHEICHER, Uppsala University, Sweden, H.P. SAHA, UCF Orlando, K. NAGAMINE, UC Riverside, E. TORIKAI, Yamanashi University, LEE CHOW, UCF Orlando, M.B. HUANG, T.P. DAS, SUNY Albany — The trapping of muonium (Mu) and muon hyperfine interactions (HFI) are studied for free nucleobases and nucleobases in single and double strand DNA and in solid nucleobases. For our investigations we have utilized the Hartree-Fock procedure with many-body effects included using many-body perturbation theory. Results for the muon magnetic contact and dipolar HFI will be presented for the various environments. The trends among the different environments is rather different from those for the nuclear quadrupole interactions in the corresponding systems because of the differences in geometry of the Mu trapping sites in the various systems. Quantitative comparison will be made between our theoretical results and experimentally measured$[^1]$muon HFI properties in the solid nucleobases.

4:30PM L40.00011 Modeling nucleic acid structure in the presence of single-stranded binding proteins1, ROBERT FORTIES, RALF BUNDSCUH, The Ohio State University — There are many important proteins which bind single-stranded nucleic acids, such as the nucleocapsid protein in HIV, the RecA DNA repair protein in bacteria, and all proteins involved in mRNA splicing and translation. We extend the Vienna Package for quantitatively modeling the secondary structure of nucleic acids to include proteins which bind to unpaired portions of the nucleic acid. All parameters needed to model nucleic acid secondary structures in the absence of proteins have been previously measured. This leaves the footprint and sequence dependent binding affinity of the protein as adjustable parameters of our model. Using this model we are able to predict the probability of the protein binding at any position in the nucleic acid sequence, the impact of the protein on nucleic acid base pairing, the end-to-end distance distribution for the nucleic acids, such as the nucleocapsid protein in HIV, the RecA DNA repair protein in bacteria, and all proteins involved in mRNA splicing and translation. We extend persistence length to dynamics on larger scales. [1] arXiv:0809.0667v1, Macromolecules in press (2008).

4:42PM L40.00012 A theoretical investigation of the interconversion between B and Z-DNA using the Adaptively Biased and Steered Molecular Dynamics methods, MAHMOUD MORADI, CHISTOPHER ROLAND, VOLODYMIR BABIN, CELESTE SAGUI, CHIPS and Department of Physics, North Carolina State University — The transition between right-handed B-DNA and left-handed Z-DNA in an implicit solvent environment was investigated via the free energy landscape of DNA as a function of the collective variables of handedness and radius of gyration, using the recently developed Adaptively Biased Molecular Dynamics (ABMD) method. The ABMD method, which belongs to the general category of umbrella sampling methods with a time-dependent potential, allows for an efficient and accurate estimation of the free energy barriers associated with the transition, especially when combined with multiple-walker and umbrella correction runs. The ABMD results are compared to those obtained using the Steered Molecular Dynamics (SMD) method. The implication of all these free energy results on the microscopics of the B to Z-DNA transition is to be discussed.

4:54PM L40.00013 End-monomer dynamics in semiflexible polymers, MICHAEL HINCEWSKI, XAVER SCHLAGBERGER, Physics Dept., Tech. Univ. of Munich, MICHAEL RUBINSTEIN, Dept. of Chemistry, Univ. of North Carolina, OLEG KRICHESKY, Physics Dept., Ben-Gurion Univ., ROLAND NETZ, Physics Dept., Tech. Univ. of Munich — Precise experimental observations over the last few years of end-monomer dynamics in the diffusion of double-stranded DNA have given conflicting results: one study indicated an unexpected Rouse-like scaling of the mean squared displacement (MSD) $\langle r^2(t) \rangle \sim t^{1/2}$ at intermediate times, corresponding to fluctuations at length scales larger than the persistence length but smaller than the coil size; another study claimed the more conventional Zimm scaling $\langle r^2(t) \rangle \sim t^{2/3}$ in the same time range. Spurred by this experimental controversy, we investigate the end-monomer dynamics of semiflexible polymers through Brownian hydrodynamic simulations, an improved dynamic mean-field theory, and a heuristic scaling argument [1]. Both theory and simulation point to a novel intermediate dynamical regime where the effective local exponent of the end-monomer MSD, $\alpha(t) = d \log \langle r^2(t) \rangle/d \log t$, drops below the Zimm value of 2/3 for sufficiently long chains. This deviation increases with chain length (though it does not reach the Rouse limit of 1/2), and is related to hydrodynamic effects in the slow crossover from dynamics on length scales smaller than the persistence length to dynamics on larger scales. [1] arXiv:0809.0667v1, Macromolecules in press (2008).
5:06PM L40.00014 Hydration effect on optical property of a DNA fiber: A first-principles study\textsuperscript{1}. TAKENORI YAMAMOTO, Faculty of Science, Toho University and IIS, The University of Tokyo, TSUYOSHI UDA, AdvanceSoft Corporation, TAKAHISA OHNO, National Institute for Materials Science (NIMS) and IIS, The University of Tokyo — We present a first-principles study for salvation effects on properties of a deoxyribonucleic acid (DNA) double helix fiber. The first-principles electronic structure and the molecular dynamics simulations reveal that the electronic structure of the DNA fiber is varied by the hydration amount and the deformation. The electrostatic interaction in the DNA fiber is screened by the hydration water. The screened electrostatic interaction determines the electronic structure of the DNA fiber, while the electronic structure of the water is determined by its polarized change as the result of the electrostatic response. We show that the optical conductivity is influenced by the hydration and the deformation, and that our findings agree with other theoretical results and experimental observations. In conclusion, we really stress that the solvation must be carefully taken account for simulating electronic structures and properties of DNA’s.

\textsuperscript{1}A part of this research was done in RISS project supported by RDINIT of MEXT.

5:18PM L40.00015 Supercoil Formation During DNA Melting\textsuperscript{1}. MEHMET SAYAR, BARIS AVSAROGLU, ALKAN KABAKCI OGLU, Koc University — Supercoil formation plays a key role in determining the structure-function relationship in DNA. Biological and technological processes, such as protein synthesis, polymerase chain reaction, and microarrays rely on separation of the two strands in DNA, which is coupled to the unwinding of the supercoiled structure. This problem has been studied theoretically via Peyrard-Bishop and Pollock-Scheraga type models, which include a simple representation of the DNA structural properties. In recent years, computational models, which provide a more realistic representation of DNA molecule, have been used to study the melting behavior of short DNA chains. Here, we will present a new coarse-grained model of DNA which is capable of simulating sufficiently long DNA chains for studying the supercoil formation during melting, without sacrificing the local structural properties. Our coarse-grained model successfully reproduces the local geometry of the DNA molecule, such as the 3'-5' directionality, major-minor groove structure, and the helical pitch. We will present our initial results on the dynamics of supercoiling during DNA melting.

Tuesday, March 17, 2009 2:30PM - 5:18PM — Session L41 DAMOP: Atom-Photon Interactions 413

2:30PM L41.00001 Few electron systems in a strong laser pulse. NICHOLAS VENCE, University of Tennessee, PREDRAG KRSTIC, Oak Ridge National Laboratory, ROBERT HARRISON, University of Tennessee / Oak Ridge National Laboratory — We propose a numerical procedure for investigating the dynamics of a one electron wave function in a strong, sub-femtosecond laser field. The non-perturbative time evolution method does not rely on an eigenfunction basis set but uses the multiresolution techniques for spatial discretization as described in [Harrison et. al., J. Chem. Phys. 121, 2866 (2004)]. The time propagation is done by the chin-chin time splitting method [Chin Chen, J. Chem. Phys. 114, 7338 (2001)]. The excitation and ionization cross-sections for the hydrogen atom, the oxygen ion and the hydrogen molecular ion could serve as a benchmark for future calculations and experiments due to the well controlled accuracy inherent in this numerical scheme.

2:42PM L41.00002 Theoretical study of electron momentum distribution in He tunneling ionization, LI GUO, SHENGSHENG HAN\textsuperscript{1}, JINGYUN FAN, Joint Quantum Institute, NIST and UMCP, JING CHEN, Institute of applied physics and computational mathematics — The electron scattering amplitude given by the S-matrix theory, up to the third order, can be written as

\[ S_{fi} = -i \int_{-\infty}^{\infty} dt \int_{-\infty}^{\infty} dt' \int_{-\infty}^{\infty} dt'' \left\langle \psi_{f}(p,t) \right| V_{A}(t) \left| \psi_{i}(p,t) \right\rangle - i \int_{-\infty}^{\infty} dt \int_{-\infty}^{\infty} dt' \left\langle \psi_{f}(p,t) \right| V_{G}(t,t') V_{A}(t') \left| \psi_{i}(p,t) \right\rangle, \]

with the first term describing the direct ATI process (that the initial state directly scatters to the final state), the second term describing that the electron initially scatters to the intermediate states via the laser-electron interaction (VA) and then scatters to the final state via the electron-ion interaction (V) (a rescattering ATI process), and the third term describing that the electron scatters to the final state via two cascaded ATI processes. All scattering processes are physically indistinguishable, so we assume that all divergence processes in scattering processes (corresponding to the forward scattering) can be absorbed into the first term and exclude them in the calculation, where the divergence is due to the long range Coulomb interaction (V = -1/r). We apply this method to study the He ionization and our theoretical results are qualitatively consistent with recent experimental observations.

2:54PM L41.00003 Modulation of molecular high harmonic generation by electron de Broglie wave interference. JING CHEN, Institute of Applied Physics and Computational Mathematics, P.O. Box 8009, 100088 Beijing, China, JING YUN FAN, Joint Quantum Institute, National Institute of Standards and Technology, and University of Maryland — In the intense laser field, the amplitude for the \( n \)-th-order high harmonic generation (HHG) of a two-center molecule using the modified Lewenstein model is written as

\[ S(n) \propto \sum_{J_{n}} \langle \psi_{f}(p,t) \rangle \langle \psi_{i}(p,t) \rangle^{*} \Phi_{l}(k) \right| J_{n}(\frac{k}{\omega}) \left| \Phi_{l}(k) \right\rangle, \]

where \( m \) and \( n \) are number of photons that the electron absorbs/emits at ionization/recombination and are restricted by the energy conservation, \( n = (m \pm 1) + \frac{1}{2} \). The electron’s kinetic energy is related to photon number \( m \) and molecular ionization potential \( I_{p} \) as \( E_{k}^{2} = (m \pm 1)\omega - I_{p} \). \( E_{k} \) is parallel to \( \overrightarrow{k} \) with \( k^{2} = 2 \omega^{2} + I_{p} \) due to the bound potential acceleration effect in the recapture. \( J_{n}(k) \) is \( n \)-th order Bessel function and \( \Phi_{l}(k) \) is the amplitude of electron momentum state (Fourier transformation of the atomic wavefunction \( \phi_{l} \) in the LCAO-MO approximation).

Clearly MMHG at each order \( (n) \) is contributed by a number of momentum states, being a summation of interferences \( \langle \psi_{f}(p,t) - \psi_{i}(p,t) \rangle \) weighted by state probabilities which is affected by laser parameters. We numerically evaluate the MMHG spectra for different laser intensities and various alignment angles, the results are consistent with recent experimental observations.

3:06PM L41.00004 ABSTRACT WITHDRAWN —

3:18PM L41.00005 ABSTRACT WITHDRAWN —
3:30PM L41.00006 Entangling photons by means of the nonlinear response of quantum wells to an ultrashort pulse. MIKHAIL EREMENCHOUK, MICHAEL LEUENBERGER, University of Central Florida — Polarization-entangled photons can be produced from semiconductor bulk crystals made of CuCl through resonant hyperparametric scattering off the bound biexciton state with a yield exceeding $10^{-5}$, much higher than yields $<10^{-9}$ achieved with bulk nonlinear crystals. Here we show a different method to produce pairs of entangled photons in the short time response of a quantum well excited by a short intense pulse. At the time scales, where the biexciton effect is not yet pronounced, the Pauli exclusion principle is responsible for many-body correlations among excitons, giving rise to the production of entangled photons with a yield of around $10^{-2}$. We make use of a quantum-field theoretical two-particle density matrix to calculate the entanglement for arbitrary emission angles of the entangled pairs of photons. At the time scales, where the heavy-light hole splitting is resolved, the resonances corresponding to different two-exciton states are developing, so that a simple kinematic theory can be presented, which relates the states of the outgoing photons with the respective two-exciton states. We study remarkably strong nontrivial dependence of entanglement on the emission angles of the entangled photons and on the ellipticity parameters of the incident photons. We show that the emitted entangled 2-photon states are always in a triplet state.

3:42PM L41.00007 Two and three dimensional study of the hydrogen molecular ion $H_2^+$ confined between double boxes of spherial and spherical geometries. MARTIN MOLINAR, GERMAN CAMPOY, Departamento de Investigacion en Fisica, Universidad de Sonara — Considering first a two-dimensional system, we study the hydrogen molecular ion confined in the space between two ellipses, and then we consider its confinement in the space between two prolate spheroids. In the Born – Oppenheimer approximation, we solve numerically the Schrodinger’s equation for the above mentioned cases, using an algorithm that allows us to calculate the energies for different given values of the confinement parameters. We also consider the confinement in the region limited by two concentric circumferences and in the two-dimensional case, in the region between two concentric spherical shells. In the last two cases we use the variational method in order to estimate the energy of the ground state. Some properties of the system as the pressure exerted by the confinement, the polarizability in the approximations of Kirkwood and Buckingham and the energies of the vibrational states are calculated. The behavior of the internuclear separation is analyzed for all the geometries considered.

3:54PM L41.00008 Dipole in a Magnetic Field, Work, and Quantum Spin. ROBERT J. DEISSLER, Physics Department, Cleveland State University, Cleveland, OH — Place an atom in a nonuniform static external magnetic field and, because of the interaction between the atom’s magnetic moment and the magnetic field gradient, the atom will accelerate. An important and fundamental question, which has been neglected in the literature, is whether or not the magnetic field is doing work on the atom. It is shown that, while the magnetic field does no work on the electron-orbital contribution to the magnetic moment (the source of translational kinetic energy being the atom’s internal energy), whether or not it does work on the electron-spin contribution to the magnetic moment depends on whether the electron has an intrinsic rotational kinetic energy associated with its spin. If the electron does have a rotational kinetic energy, which is shown to be consistent with the Dirac equation, the acceleration of a silver atom in a Stern-Gerlach experiment or the emission of a photon from an electron spin-flip can be explained without requiring the magnetic field to do work. A classical dipole (a spinning charged ball) is also studied. For details please refer to R.J. Deissler, Phys. Rev. E. 77, 036609 (2008). A link to this paper, as well as other information, may be found at http://deissler.us/.

4:06PM L41.00009 Casimir force measurements between a gold sphere and a rectangular corrugated Silicon plate. YILIANG BAO, JIE ZOU, H.B. CHAN, University of Florida — The Casimir force is the interaction that results from quantum fluctuations of electromagnetic fields in vacuum and strongly depends on the shape of the boundaries that confines the electromagnetic fields. Most previous experiments involve simple geometries such as plate-sphere, two parallel plates or two cylinders, where the pair-wise summation of two-body interactions is still valid. To demonstrate the strong shape dependence of the Casimir force, we choose one of the interacting surfaces to be an array of trenches with widths ranging from 200 nm to 500 nm. Both high-aspect-ratio trenches with depth of 1 um and shallow trenches with depth of 100 nm are fabricated. The force gradient on these structures is measured with a micromechanical torsional oscillator for the separations between 150 nm and 500 nm. We observe deviations from both the pair-wise additive approximation and the proximity force approximation. The observed deviation, however, is smaller than the calculated values for perfectly conducting surfaces, possibly due to the interplay between finite conductivity and geometry effects.

4:18PM L41.00010 Distance dependence of contact potential in cylindrical-plane Casimir force measurements. QUN WEI, KEVIN MILLER, Dartmouth College, DIEGO DALVIT, Los Alamos, ROBERTO ONOFRIO, Dartmouth College — We report on the status of an experiment aimed at measuring the Casimir force in cylinder-plane geometry. In order to characterize the apparatus, we have first performed small distance electrostatic calculations. This has allowed us to better identify various general issues on the measurement of the Casimir force, such as the determination of the way the distance dependence of the contact potential $V_{0}$ is particularly crucial since its distance dependence can affect the entire data analysis procedure. We also carried on the measurements of $V_{0}$ in sphere-plane and plane-plane geometries for comparison.

4:30PM L41.00011 Optical binding force acting on two optically trapped particles. H.D. OU-YANG, MING-TZO WEI, Lehigh University — In addition to common optical manipulation setups such as an optical tweezers, the radiation forces generated by a laser can also induce chain-like arrangements of $\mu$m-sized dielectric spheres through coherent multiple scattering, through a process known as optical binding (OB). Although the forces generated through OB are on the order of piconewtons, they are still sufficient to overcome other relevant interactions in the suspension such as Van Der Waals and gravitational forces and Brownian fluctuations. The OB force oscillates from attractive to repulsive as function of interparticle separation; as observed in theoretical models and optical fields found in systems such as counter propagating lasers in dual-beam optical-fibers. Using a dual optical tweezers setup, we have measured the inter-particle OB force from two 1.5 micron diameter polystyrene particles in suspension as a function of their separation by holding them in separate optical traps. Using a calibration scheme, we have isolated the OB force from the background of hydrodynamic and Brownian forces. Using experimental measurements and theoretical predictions, we also proved that by changing the respective polarizations between parallel and perpendicular orientations of the two traps, the OB force was the only force acting on the particles.

4:42PM L41.00012 Reflection of Various Types of Waves by Layered Media. SERGIY MOCHOV, BORIS ZELDOVICH, College of Optics and Photonics / CREOL, UCF — The one-dimensional wave equation describing propagation and reflection of waves in a layered medium is transformed into the notion of an exact first-order system for the amplitudes of coupled counter-propagating waves. Any choice of such amplitudes, out of continuous multitude of them, allows one to get an accurate numerical solution of the reflection problem. We discuss relative advantages of particular choices of amplitude. We also introduce the notion of reflection strength of a plane wave by a nonabsorbing layer, which is related to the reflection intensity $R$ by $R = \tan^{2}S$. We show that the total reflection strength by a sequence of elements is bounded above by the sum of the constituent strengths, and bounded below by their difference. Reflection strength is discussed for propagating acoustic waves and quantum mechanical waves. We show that the standard Fresnel reflection may be understood in terms of the variable $S$ as a sum or difference of two contributions, one due to a discontinuity in impedance and the other due to a speed discontinuity.
4:54PM L14.00013 Gravitational Redshift and Deflection of Slow Light, JUSTIN DRESSEL, S. RAJEV, JOHN HOWELL, ANDREW JORDAN, University of Rochester — We explore the nature of the classical propagation of light through media with strong frequency-dependent dispersion in the presence of a gravitational field. In the weak field limit, gravity causes a redshift of the optical frequency, which the slow-light medium converts into a spatially-varying index of refraction. This results in the bending of a light ray in the medium. We further propose experimental techniques to amplify and detect the phenomenon using weak value measurements. Independent heuristic and rigorous derivations of this effect are given.

5:06PM L14.00014 Control of a mechanical resonator mode by cavity-enhanced light scattering, AKO CHIJOKE, JOHN LAWALL, NIST — Reaching the quantum regime of a mechanical resonator is facilitated by using a resonator with a small mass and high frequency. On the other hand, optical interferometry fails if the dimensions of the resonator are not significantly larger than the optical wavelength. Here we discuss and demonstrate an alternative optical technique employing scattering losses within an optical cavity to sense the motion of a resonator that can have dimensions well below the optical wavelength. We place a wavelength-scale mechanical resonator at the waist of a high-finesse optical cavity, lock the cavity to a resonance, and monitor the transmission. As the resonator vibrates, it modulates the cavity loss and thereby the transmitted power. We calibrate the sensitivity to resonator position by means of a known static displacement. We then sense the thermal motion of the resonator, and employ active feedback to cool, heat, and stiffen the mechanical mode.

Wednesday, March 18, 2009 8:00AM - 11:00AM — Session P1 DCMP: Optoelectronic Manipulation and Control of Charges and Spins in Quantum Dots — Spirit of Pittsburgh Ballrom A

8:00AM P1.00001 Optical control of spin coherence in singly charged quantum dots, MANFRED BAYER, TU Dortmund University — The most promising candidate for implementation of quantum information technologies in semiconductors is the spin of an electron confined in a quantum dot because of its good coherence properties. Our approach is based on using an electron spin ensemble for defining a robust macroscopic quantum bit. Typically such an ensemble suffers from inhomogeneities. Using tailored pulsed laser excitation protocols this ensemble can be homogenized, such that the involved electrons appear to be identical when precessing about an external magnetic field. In this contribution problems and perspectives related to this approach will be discussed. In particular collective initialization and manipulation of the electron spin ensemble will be addressed. The use of all-optical techniques ensures that the manipulation can be performed on picosecond time scales.

8:36AM P1.00002 The quantum dot molecule from an optical point of view, DANIEL GAMMON, Naval Research Laboratory — For over ten years the techniques of single quantum dot optical spectroscopy has enabled rapid progress in the fundamental understanding of quantum dots and in the application of quantum information concepts [1]. We now apply these ever improving optical techniques to two self-assembled InAs/GaAs quantum dots that are coherently coupled through tunneling that is, a quantum dot molecule [2]. The optical spectrum of a quantum dot molecule is much richer than that of a single quantum dot. As one might expect, there is both new physics and enhanced opportunity for quantum information applications. We find that the optical spectrum of single QD molecules charged with 0, 1, or 2 electrons or holes show intriguing and unique patterns of anti-crossings and spin exchange splittings that are readily understood in terms of a few simple concepts. Closer inspection is revealing new information and opportunity, however. For example, on the fundamental side, we have recently discovered evidence that the ground state of the molecule can be an anti-bonding state when it is the hole that tunnels between the dots a new effect not found in atoms. On the quantum information side, we have engineered a quantum dot molecule in which we can simultaneously control and nondestructively measure the spin of a single electron. This solves a serious limitation in the optical control of single quantum dots. These studies are laying the groundwork necessary to enable optically controlled entanglement of two spins. Here I give an overview of our current understanding of this system from an optical point of view.

9:12AM P1.00003 Spectroscopy of Collective Modes in Few-electron Quantum Dots, SOKRATIS KALLIAKOS, Department of Materials Science and Technology, University of Crete — Quantum correlations among electrons confined in semiconductor quantum dots (QDs) are expected to lead to exotic states of matter, such as an electron molecule. In the limit of vanishing electron density, the distances between the confined electrons are rigidly fixed like those of nuclei in conventional molecules. The electronic excitations of such a molecule are quantized normal modes of roto-vibration, whose quanta have either a rigid-rotor or relative-motion character. Recent progress on the emergence of molecular roto-vibrational modes at experimentally attainable densities will be discussed. Signatures of the roto-vibrational spectrum are observed even if the localization in space of the electron wave functions is not yet fully achieved. I will present a joint experimental and theoretical investigation of the neutral electronic excitations of nanofabricated AlGaAs/GaAs QDs that contain four electrons. We use inelastic light scattering to probe electronic charge and spin excitations in an array of identical nanofabricated QDs. Spectra of low-lying excitations associated to changes of the relative-motion wave function -the analogues of the vibrational modes of a conventional molecule- do not depend on the rotational state represented by the angular momentum, which can be controlled by the application of a magnetic field. A theoretical model, based on full configuration-interaction method, offers an excellent quantitative agreement with the experimental findings. I will also demonstrate optical control of the number of electrons and lateral confining potential in our GaAs/AlGaAs QDs. This is achieved by illumination with a weak laser beam that is absorbed in the AlGaAs barrier. Precise tuning of the energy-level structure and number of electrons is manifested in the evolution of low-lying spin and charge excitations probed by inelastic light scattering. Our findings open a new venue towards the all-optical manipulation of single electrons in QDs.

10:24AM P1.00005 Ultrafast Coherent Control of a Single Electron Spin in a Quantum Dot

MAIKEN H. MIKKELSEN
Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — Quantum information processing schemes require fast single-qubit operations. For spin-based qubits, this involves performing arbitrary coherent rotations of the spin state on timescales much faster than the spin coherence time. While we recently demonstrated the ability to initialize and monitor the evolution of single spins in quantum dots (QDs) here we present an all-optical scheme for ultrafast manipulation of these states through arbitrary angles. The GaAs QDs are embedded in a diode structure to allow controllable charging of the QDs and positioned within a vertical optical cavity to enhance the small single spin signal. By applying off-resonant optical pulses, we coherently rotate a single electron spin in a QD up to 20 radians on picosecond timescales. We directly observe this spin manipulation using time-resolved Kerr rotation spectroscopy at T = 10K. Measurements of the spin rotation as a function of laser detuning and intensity confirm that the optical Stark effect is the operative mechanism and the results are well-described by a model including the electron-nuclear spin interaction. Using short tipping pulses, this technique enables one to perform a large number of operations within the coherence time. This ability to perform arbitrary single-qubit operations enables sequential all-optical initialization, ultrafast control and detection of a single electron spin for quantum information purposes.

Wednesday, March 18, 2009 8:00AM - 11:00AM –
Session P2 DCMP: Critical Spin Liquids in Strongly Correlated Systems

8:00AM P2.00001 Quantum spin liquid in the spin-1/2 triangular antiferromagnet EtMe_3Sb[Pd(dmit)_2]_2, REIZO KATO, RIKEN — EtMe_3Sb[Pd(dmit)_2]_2 (Et=C_2H_5-, Me=CH_3-, dmit=C_5H_5N^-) is one of molecular conductors derived from an anion radical of the Pd(dmit)_2 molecule and closed-shell monocations (EtMe_3Sb)^(2-)(Z=N, P, As, Sb; x=0, 1, 2) [1]. A common feature of these Pd(dmit)_2 salts is a conducting anion layer where the Pd(dmit)_2 anions form a dimer unit [Pd(dmit)_2]_2^2-. Electronic structure around the conduction band can be described by a simple tight-binding calculation based on the dimer unit. At ambient pressure, all the Pd (dmit)_2 salts behave as Mott insulators where one spin is localized on each dimer. Interdimer transfer integrals indicate that the dimers form a quasi (isosceles) triangular lattice. Interdimer transfer integrals can be tuned by the choice of the cation, which deeply affects the electronic state. The EtMe_3Sb salt has a nearly regular-triangular lattice. The EtMe_3Sb cations are located between conduction layers and exhibit orientational disorder. The temperature dependence of the magnetic susceptibility is described in terms of the Padé approximant expression based on the high temperature series expansion of the antiferromagnetic spin-1/2 Heisenberg model on the triangular lattice with an exchange interaction J=220-250 K. The 13C-NMR measurements show no indication of either spin ordering/freezing or an appreciable spin gap down to 1.37 K, which is lower than 1% of J [2]. The specific heat measurements indicate gapless spin excitation. These results strongly suggest that the ground state of the EtMe_3Sb salt is a gapless spin liquid state. On the other hand, the EtMe_3Sb salt, which has also a nearly regular-triangular lattice, shows a first-order transition toward a charge separation state (2Dimer^- \rightarrow Dimer^0 + Dimer^2+) at 70 K [3].

8:36AM P2.00002 Spin Liquid State of in the $S = 1/2$ Hyper-kagome Antiferromagnet Na$_2$Ir$_4$O$_8$, HIDENORI TAKAGI, University of Tokyo/RIKEN — A new Ir oxide, Na$_2$Ir$_4$O$_8$, with a cation-ordered (Ir and Na) spinel structure, was discovered [1]. This compound is an S=1/2 Mott insulator with d^3 (low spin state) Ir^4+. As a result of the ordering of Ir and Na within spinel B-sites, magnetic Ir^4+ ions form a three-dimensional network of corner-sharing triangles, called hyper-kagome lattice, which provides us with a novel playground for the physics of frustration in S=1/2 hyper-kagome A new Ir oxide, Na$_2$Ir$_4$O$_8$, with a cation-ordered (Ir and Na) spinel structure, was discovered [1]. This compound is an S = 1/2 Mott insulator with d^3 (low spin state) Ir^4+. As a result of the ordering of Ir and Na within spinel B-sites, magnetic Ir^4+ ions form a three-dimensional network of corner-sharing triangles, called hyper-kagome lattice, which provides us with a novel playground for the physics of frustration in S=1/2 hyper-kagome antiferromagnet. It may be interesting to infer that hyper-kagome lattice has a chirality. The result of magnetization measurements indicates the presence of strong antiferromagnetic coupling (Curie-Weiss temperature $\theta_{CW} \sim -650$ K) between $S = 1/2$ spins. Nevertheless, we find no evidence for long range magnetic ordering in this S=1/2 hyper-kagome antiferromagnet at least down to 2 K, apparently due to the presence of geometrical frustration. The absence of long range ordering was firmly established by the persistence of 23Na NMR lines down to 2 K without intensity change [2]. These results strongly suggest that the ground state of this system is a three dimensional S = 1/2 spin liquid. Unusual spin excitations of this S = 1/2 hyper kagome system will be discussed, based on the specific heat and the NMR data at low temperatures.

9:12AM P2.00003 Critical “metal”-like phases of frustrated spins and bosons in two dimensions, OLEXEI MOTRÜNICH, California Institute of Technology — I will review recent theoretical progress in understanding quantum phases of 2D correlated boson or spin systems which exhibit “Bose-metal” type phases with gapless excitations residing on surfaces in momentum space. A spin liquid phase with a Fermi surface of spinons is one example of interest, being potentially relevant to the organic spin liquid materials $\kappa$-(ET)$_2$Cu$_2$(CN)$_3$ and EtMe_3Sb[Pd(dmit)_2]_2. I will discuss frustrated spin and boson models with ring exchanges that may stabilize such phases, in particular in the vicinity of the Mott transition as is the case in the organic materials.

9:48AM P2.00004 Gapless spin liquids on the three dimensional hyper-kagome lattice of Na$_2$Ir$_4$O$_8$, YONG BAEK KIM, University of Toronto — Recent experiments indicate that Na$_2$Ir$_4$O$_8$, a material in which s=1/2 iridium local moments form a three dimensional network of corner-sharing triangles, may have a quantum spin liquid ground state with gapless spinon excitations. Using a combination of various theoretical approaches, we propose a quantum spin liquid with spinon Fermi surfaces as a favorable candidate for the ground state of the Heisenberg model on the hyper-kagome lattice of Na$_2$Ir$_4$O$_8$. We also present a theory of the bandwidth-controlled metal-insulator transition that may occur as a pressure-tuned transition in this material. We discuss our predictions in relation to the current and future experiments.
10:24AM P2.00005 Numerical Evidence of Gapless Spin Liquids on Ladders\textsuperscript{1}, DONNA SHENG, California State Univ. Northridge — I will present numerical evidence of strong-coupling phases for quasi-one-dimensional systems as ladder descendants of candidate models for 2D Bose metal and spin liquid states which possess surfaces of gapless excitations. I will discuss the phase diagrams for two concrete models (square lattice boson and triangular lattice spin models with ring-exchange) based on controlled numerical approaches (DMRG and ED), where such strong-coupling phases are realized in a wide regime of parameters. A close comparison between numerical results and slave-particle descriptions will allow us to characterize these phases in detail and identify signatures reflecting the parent 2D states.

\textsuperscript{1}Supported by NSF and DOE.

Wednesday, March 18, 2009 8:00AM - 10:24AM — Session P3 DCMP: Fe-based Superconductors: Correlation Effects 301/302

8:00AM P3.00001 ARPES studies of the electronic structure of Fe-based superconductors\textsuperscript{1}, DONGHUI LU, Stanford University — The recent discovery of superconductivity in Fe-based layered compounds has created renewed interest in high temperature superconductivity. With a superconducting transition temperature as high as 55 K, this discovery provides a new direction to understand the essential ingredients for achieving a high superconducting transition temperature. In this talk, I will present our recent angle-resolved photoemission spectroscopy (ARPES) studies on LaOFeP and (Ba,K)Fe\textsubscript{2}As\textsubscript{2} systems, with special emphasis on the basic electronic structure of the parent compounds. For LaOFeP, quantitative agreement can be found between our ARPES data and the LDA band structure calculations, suggesting that a weak coupling approach based on an itinerant ground state may be more appropriate for understanding this new superconducting compound [1]. On the other hand, the picture for (Ba,K)Fe\textsubscript{2}As\textsubscript{2} can be found between our ARPES data and the LDA band structure calculations, suggesting that a weak coupling approach based on an itinerant ground state may be more appropriate for understanding this new superconducting compound [1].

1The work is supported by DOE Office of Basic Energy Science.

8:36AM P3.00002 Charge dynamics in the normal state of the iron oxypnictide superconductor LaFePO\textsubscript{1}, M. M. QAZILBASH, University of California - San Diego — Many-body interactions in materials govern diverse and complex phenomena like high-T\textsubscript{c} superconductivity, density wave instabilities and metal-insulator transitions. Infrared spectroscopy is an ideal tool for identifying the fingerprints of the various interactions in a material. We present infrared and optical properties in the normal state of in-plane oriented single crystals of the iron oxypnictide superconductor LaFePO. Prominent Drude peaks and low scattering rates indicate the presence of coherent quasiparticles. We find that this metal has a relatively low carrier density compared to MgB\textsubscript{2}, for example. An important result is that the Drude spectral weight i.e. the kinetic energy of itinerant quasiparticles is reduced by correlation effects to 50% of the band theory value. Even though LaFePO is among the most conducting of the iron-pnictides, we find that electronic correlations cannot be ignored in any realistic physical description of this material. We classify LaFePO as a moderately correlated metal.

1This work was performed in collaboration with J. J. Hamlin, R.E. Baumbach, M. B. Maple, Lijun Zhang, D. J. Singh, and D. N. Basov. Support from the National Science Foundation via grant NSF-DMR0705171 is gratefully acknowledged.

9:12AM P3.00003 Electronic Correlations and Magnetic Frustration in the Iron Pnictides\textsuperscript{1}, QIMIAO SI, Rice University — An important question about the high T\textsubscript{c} iron pnictides is the extent to which they are strongly correlated. Based on the fact that they are “bad metals,” we propose that these materials are in proximity to a Mott insulator [1,2]. In other words, the degree of the electronic correlations here is closer to that of intermediate-coupled metallic systems like V2O3, which lies near the Mott transition, rather than that of simple antiferromagnetic metals such as Cr. Consequently, we model the incoherent electronic excitations in terms of localized moments, whose superexchange interaction contain the competing nearest-neighbor (J1) and next-nearest-neighbor (J2) components [1]. The magnetic frustration of the J1-J2 model in the relevant parameter range leads to a (pi,0) antiferromagnet and a reduced ordered moment. The model also features an Ising transition that naturally yields a structural phase transition. All these results are consistent with the neutron scattering results. With the coupling of the local moments to the coherent electronic excitations, the strength of the antiferromagnetic order is tuned, leading to a magnetic quantum critical point [2]. The ordered moment should therefore vary across the undoped iron arsenides. In addition, the magnetic quantum criticality can be probed by P doping for As in the parent iron pnictides, where the disruption to the quantum criticality caused by superconductivity is likely to be less compared to the electron or hole doped cases. Finally, the implications of the electronic correlations and magnetic frustration on the multi-band superconductivity will be briefly discussed.

\textsuperscript{1}In collaboration with E. Abrahams, J. Dai, P. Goswami, P. Nikolic and J.-X. Zhu. Supported by NSF and the Welch Foundation.

9:48AM P3.00004 Pairing symmetry and Antiferromagnetic Exchange Coupling in Fe-Based Superconductors\textsuperscript{1}, JIANGPING HU, Purdue University — I discuss the existence of strikingly identical paradigms applicable to both cuprates and iron-based superconductors in understanding magnetism, superconductivity and the interplay between the two. The magnetic states and transitions in iron-based superconductors are well described by a J\textsubscript{1} \(-\) J\textsubscript{2} \(-\) J\textsubscript{3} magnetic exchange model where J\textsubscript{1}, J\textsubscript{2} and J\textsubscript{3} are nearest neighbour, next nearest neighbour and inter-layer couplings respectively. Differing from the t-J model for cuprates where d-wave pairing symmetry is favored, the magnetic exchange in the iron based superconductors predicts an unconventional s-wave \(\cos k_x \cos k_y\) pairing. I will show that the predicted pairing symmetry is supported by many experimental results, and also discuss new predictions associated with the pairing symmetry.

reverse osmosis and nanofiltration membranes used for water purification are real-world examples of nanoscale functional materials: the active layer is only ~100 nm thick. Because the active layer is formed by a process of interfacial polymerization, the structure and composition of the membrane is highly inhomogeneous and even such basic physical and chemical properties as the atomic density, swelling in water, the distribution of charged species between water and membrane, and the mobility of water and ions, are poorly understood. We are using Rutherford backscattering spectrometry (RBS) to determine the composition, roughness, and thickness of the membrane; reveal the surprisingly high solubility of salt ions in the polymer active layer; analyze the acid-base chemistry of charged functional groups; and determine the degree of polymer cross-linking. Measurements of mass-uptake and adsorption-induced mechanical stress of membranes in humid air enable us to determine the water solubility, specific volume of water, and the mechanical strength of the membrane. Comparisons between these equilibrium data and the permeability of the membrane to water and salts show that the mobility of water molecules in the membrane approaches the mobility of bulk water, and that the rejection of salt ions is accomplished by low mobility, not low solubility. My collaborators in this work are Xijing Zhang, Orlando Coronell, and Prof. Benito Mariñas.

8:36AM P4.00002 High Flux Nanofibrous Membranes for Water Purification1, BENJAMIN HSIAO, Stony Brook University — Recently, nanofibrous materials have been made more readily available in large part due to advances in electro-spinning and related technologies, including the use of a combination of electrostatic and gas-blowing forces. The non-woven structure has unique features, including interconnected pores, very large surface-to-volume ratio, and ease of surface modifications which enable such scaffolds to have many biomedical and industrial applications. The chemical composition of electrosprun membranes can be adjusted by using different polymers, polymer blends or nanocomposites, made of organic or inorganic materials. In this talk, we demonstrate a breakthrough technology on the fabrication of high-flux water purification by carbon nanofibrous membranes. The breakthrough incorporates two new and unique concepts of the membrane design: (1) the replacement of the conventional flux-limited porous substrate with a highly porous nanofibrous scaffold, and (2) the creation of a very thin, strong and functional nanocomposite barrier layer, imbedded with interconnected and directed water channels. Preliminary experiments on the hierarchical design and assembly of this unique nanofibrous membrane have already revealed very promising potentials. By using a hydrophilic nanocomposite barrier layer, an asymmetric electrosprun nanofibrous mid-layer scaffold and a non-woven microfibrinous support, the flux rate of this not-yet-optimized membrane system is 3-10 times better than that of the best among all known conventional ultrafiltration/nanofiltration media without losing the high rejection and low fouling criteria.

1This is a joint collaboration with Ben Chu. The work is supported by ONR.

9:48AM P4.00004 Carbon Nanotube Membranes for Water Purification1, OLIGICA BAKAJIN, Biosciences and Biotechnology Division, PLS, Lawrence Livermore National Laboratory — Carbon nanotubes are an excellent platform for the fundamental studies of transport through channels commensurate with molecular size. Water transport through carbon nanotubes is also believed to be similar to transport in biological channels such as aquaporins. I will discuss the transport of gas, water and ions through microfabricated membranes with sub-2 nanometer aligned carbon nanotubes as ideal atomically-smooth pores. The measured gas flow through carbon nanotubes exceeded predictions of the Knudsen diffusion model by more than an order of magnitude. The measured water flow exceeded values calculated from continuum hydrodynamics models by more than three orders of magnitude and is comparable to flow rates extrapolated from molecular dynamics simulations and measured for aquaporins. More recent reverse osmosis experiments reveal ion rejection by our membranes. Based on our experimental findings, the current understanding of the fundamentals of water and gas transport and of ion rejection will be discussed. The potential application space that exploits these unique nanofluidic phenomena will be explored. The extremely high permeabilities of these membranes, combined with their small pore size will enable energy efficient filtration and eventually decrease the cost of water purification.

10:24AM P4.00005 Hierarchical Fiber Structures Made by Electrospinning Polymers, DARRELL H. RENEKER, The University of Akron — A filter for water purification that is very thin, with small interstices and high surface area per unit mass, can be made with nanofibers. The mechanical strength of a very thin sheet of nanofibers is not great enough to withstand the pressure drop of the fluid flowing through. If the sheet of nanofibers is made thicker, the strength will increase, but the flow will be reduced to an impractical level. An optimized filter can be made with nanometer scale structures supported on micron scale structures, which are in turn supported on millimeter scale structures. This leads to a durable hierarchical structure to optimize the filtration efficiency with a minimum amount of material. Buckling coils and pendulum coils spanning dimensions from a few microns to a few centimeters can be collected from a single jet by controlling the position and motion of a collector. Attractive routes to the design and construction of hierarchical structures for filtration are based on nanofibers supported on small coils that are in turn supported on larger coils, which are supported on even larger overlapping coils. "Such top-down" hierarchical structures are easy to make by electrospinning. In one example, a thin hierarchical structure was made, with a high surface area and small interstices, having an open area of over 50%, with the thinnest fibers supported at least by 10 microns.

8:00AM P5.00001 Inertial Particles in Turbulent Flows and the Clustering Instability of Interstellar Dust, PAOLO PADOAN, University of California, San Diego — The dynamics of dust grains in turbulent flows plays an important role in many astrophysical processes. I will review the problem of the formation of planetesimals (precursors of full-fledged planets) in turbulent circumstellar disks. I will then discuss some fundamental aspects of the physics of heavy particles in turbulent flows, and specifically the phenomenon of small scale clustering, an effect verified by laboratory experiments and in situ terrestrial cloud sampling. I will present results of large numerical simulations of particle-laden compressible turbulence, including statistics of clustering and of particle velocity differences.

8:36AM P5.00002 Multiscale modeling of the human arterial tree on the TeraGrid, GEORGE KARNAĐAKIS, Brown University — A multiscale model of the human arterial tree will be presented consisting of the macrovascular network (MaN, arteries above 1-2 mm), the mesovascular network (MeN, arterioles above 10 micro-m) and the microvascular network (MiN, capillaries). Coupling conditions between the MaN-MeN-MiN will be discussed and three different methods in modeling each network will be presented. Specific examples will be shown for the intracranial arterial tree for healthy subjects but also for patients with hydrocephalus.

9:12AM P5.00003 Terascale Direct Numerical Simulations of Turbulent Combustion, JACQUELINE CHEN, Sandia National Laboratories — The rapid growth in computational power in the past decade has presented both opportunities and challenges for high-fidelity simulations of turbulent reacting flows. The advent of terascale computing power has made it possible to glean fundamental physical insight into fine-grained “turbulence-chemistry” interactions in simple laboratory-scale turbulent flames from direct numerical simulation at moderate Reynolds numbers with detailed chemistry. Recent DNS results are presented to elucidate the role of autoignition and large-eddy mixing on the stabilization of a lifted ethylene-air jet flame in a heated coflow. The role of scalar dissipation rate on modulating ignition delays or lift-off heights is discussed. The simulations were performed at a jet Reynolds number of 10,000 and required 1.3 billion grid points to resolve the turbulence and flame structure. In a second related topic, the morphology of the scalar dissipation rate field in a turbulent jet flame is examined using topological methods, in particular the Morse-Smale Complex, which provides a natural segmentation of dissipation rate elements or “features.” These features are tracked in time, and conditional feature statistics are presented.

9:48AM P5.00004 Prediction and predictability of hurricanes with high-performance computers and cloud-resolving ensembles, FUQING ZHANG, Penn State University — This talk will be primarily devoted to the use of high-performance computing facilities to perform ensemble-based state estimation of hurricanes with cloud-resolving numerical weather prediction models. I will be sharing our recent experience in using approximately 30,000 cluster cores simultaneously at the Texas Advanced Computing Center which successfully assimilates high-resolution airborne Doppler radar observations in realtime and subsequently delivers 2 deterministic and 60-member ensemble forecasts running at 4.5/1.5-km effective horizontal grid spacings in a timely fashion. Since the predictability of hurricanes may be fundamentally limited by chaotic moist convection and subsequent upscale error growth, I would advocate that besides the need of continuously improving the hurricane forecast models and ingesting high-resolution observations into the models to better initialize the storm, the hurricane state estimation is fundamentally probabilistic that demands cloud-solving ensemble-based data assimilation and forecasting. Improvements of forecast models may come from ever increasing computer power to better resolve the storms numerically and from improved fundamental understanding of the dynamics and impact of subgrid-scale turbulence in hurricanes. Improvements of better state estimation may also come from development of new theories that are applicable for high-dimensional, non-linear, non-Gaussian dynamic systems such as in hurricanes.

1Supported by the Division of Chemical Sciences, Geosciences, and Biosciences, Office of Basic Energy Sciences and the Office of Advanced Scientific Computing Research of the Department of Energy.

10:24AM P5.00005 On the two-way interactions between dispersed particles and turbulent flows, SAID ELGHOBASHI, Mechan. and Aerospace Engineering Department, University of California, Irvine — Particle-laden turbulent flows are ubiquitous in nature (e.g., dust storms on Earth and Mars) and in industrial applications (e.g., liquid fuel and pulverized coal sprays in combustion chambers). Experimental and numerical studies of these flows are quite challenging due to the wide spectra of length- and time-scales of the dispersed particles in addition to the spectra of scales intrinsic to the carrier fluid turbulence. The two-way nonlinear interactions between the dispersed particles and the turbulence result in complex multi-scale physical phenomena. The lecture focuses on the physical mechanisms of the two-way interactions between dispersed spherical particles and simple turbulent flows using Direct Numerical Simulation (DNS). Particles whose diameter is smaller than the Kolmogorov length scale of turbulence are simulated as point particles. Results of particle-laden isotropic and homogeneous shear turbulent flows are presented. Particles with diameter larger than the Kolmogorov length scale are fully resolved using the Immersed Boundary method. Results of fully resolved particle-laden isotropic turbulence are presented.

Wednesday, March 18, 2009 8:00AM - 11:00AM — Session P6 DAMOP: Ultracold Gases with Dipolar Interactions

8:00AM P6.00001 Ultracold polar molecules, SILKE OSPELKAUS, JILA, NIST and University of Colorado — Polar molecules — molecules exhibiting a permanent electric dipole moment — have bright perspectives as systems with long-range and anisotropic interaction. These interactions have been the basis for numerous exciting theoretical proposals ranging from ultra-cold chemistry, precision measurements, quantum phase transitions to novel systems for quantum information processing and quantum control with external magnetic and electric fields. We will present our recent work on the creation and manipulation of polar molecules exhibiting a permanent electric dipole moment, which we measure with Stark spectroscopy to be 0.566(17) Debye.

8:36AM P6.00002 Effects of magnetic dipolar interactions on collective modes and instabilities of alkali BECs, EUGENE DEMLER, Harvard University — In this talk I will review the phenomenon of roton softening in systems with dipolar interactions. Special emphasis will be on magnetic dipolar interactions in Bose condensates of alkali atoms, when fast Larmor precession and spin dynamics strongly modify the character of unstable modes. I will also discuss the enhancement of roton softening in multilayer stacks of two dimensional condensates. Implications of these theoretical results for recent experiments with Rb-87 and K-39 atoms will be discussed.
Dynamics and coherence in a collapsing dipolar BEC

Axel Griesmaier, University of Stuttgart — Chromium atoms in a Bose-Einstein condensate (BEC) interact – in addition to s-wave scattering – via magnetic dipole-dipole interaction. Although the magnetic forces between the atoms which carry a large magnetic moment of 6 Bohr magnetons are still rather weak, they can become the dominant interaction when a Feshbach resonance is used to reduce the contact interaction to zero [1]. In this regime, the stability of a chromium Bose-Einstein condensate depends on the geometry of the trap. This is an intrinsic and unique effect of an anisotropic interaction. We have measured the stability diagram of such a dipolar BEC by exploring the border between stable and unstable regions [2]. When we cross this border with an initially stable condensate by a sudden change of the scattering length into the unstable regime, we observe the collapse and subsequent explosion due to dipole-dipole interaction [3].

The anisotropy of the underlying interaction reveals in the formation of a non-trivial structure during the collapse. I will discuss the dynamics of the collapse depending on variable distance. The coexistence of translational symmetry breaking, characteristic of a solid, and long-range phase coherence, characteristic of a superfluid, are hallmarks of the sought-after supersolid phase.

Condensed Matter Physics and Quantum Simulations with Cold Polar Molecules and Rydberg Atoms

Peter Zoller, University of Innsbruck — Polar molecules prepared in their electronic and vibrational ground state are characterized by large dipole moments associated with rotational excitations. This gives rise to large dipole-dipole interactions between molecules, which can be manipulated with external DC and AC microwave fields. The possibility to tune these strong, long-range and anisotropic interactions, combined with the trapping in reduced dimensions, raises interesting prospects for cold ensembles of polar molecules as strongly correlated condensed matter system, i.e. provides analog quantum simulation of strongly interacting systems and quantum phases. Specific examples to be discussed include the engineering of various spin and Hubbard models for polar molecules in optical lattices, e.g. the Kitaev model and three body interactions, and the tailoring effective molecular interaction potentials based on “blue-shields” with microwave fields. Furthermore, dipolar gases in 1D and 2D trapping geometries can form self-assembled lattice structures in single layer and bilayer systems. In addition, a mixture of cold atoms and polar molecules forming a self-assembled lattice gives rise to a new realization of Hubbard models with widely tunable lattice parameters and small lattice spacing, which represents a systems with both strong correlation and phonon dynamics. Extremely strong dipolar or Van der Waals interactions can also be obtained in cold atomic gases excited to Rydberg states. We will briefly discuss new ideas of developing a digital quantum simulator for spin models. It is based on performing a stroboscopic sequence of many particle quantum gates based on manipulating dipolar interactions between groups of Rydberg atoms in large spacing optical lattices.

Wednesday, March 18, 2009 8:00AM - 10:24AM –
Session P7 FEd FPS: Forging Effective Partnerships with Your Local Science Center: Outcomes from the Workshop on University/Science Center Collaborations

Lessons Learned from the APS/TFI Workshop on University/Science Center Collaborations: Outreach Targets for Potential Partners from Other Local Science Centers

David Statman, Allegheny College — On May 31 – June 1, 2008, The Franklin Institute (TFI) hosted the American Physical Society/Franklin Institute Workshop on University/Science Center Collaborations. This Workshop brought together forty leaders from science centers, universities, and federal funding agencies to explore what works and what doesn’t work in university-science center collaborations. The goal was to explore the outreach motivations of academic institutions, their scientists and students, the characteristics and needs of small vs. large science centers, and the goals for and outcomes expected from reaching out to the general public from the perspectives of universities and science centers. The result was a convergence of viewpoints on how a good collaboration is established, built upon, sustained, and evaluated.

University Perspectives on Science Center/University Interactions

Leo Kadonoff, University of Chicago — A program bringing graduate students into science museums is described. Practical, nuts and bolts, methods for making the program work are outlined. Questions are asked about the somewhat uncomfortable relation between graduate education, research, and informal education.
9:12 AM P7.00003 University/Science Center Collaborations (A Science Center Perspective): Developing an Infrastructure of Partnerships with Science Centers to Support the Engagement of Scientists and Engineers in Education and Outreach for Broad Impact, ERIC MARSHALL, Vice President, Strategic Partnerships and Innovation, Director, TryScience.org and VoITS (Volunteers TryScience) — Science centers, professional associations, corporations and university research centers share the same mission of education and outreach, yet come from “different worlds.” This gap may be bridged by working together to leverage unique strengths in partnership. Front-end evaluation results for the development of new resources to support these (mostly volunteer-based) partnerships elucidate the factors which lead to a successful relationship. Maintaining a science museum-scientific community partnership requires that all partners devote adequate resources (time, money, etc.). In general, scientists/engineers and science museum professionals often approach relationships with different assumptions and expectations. The culture of science centers is distinctly different from the culture of science. Scientists/engineers prefer to select how they will ultimately share their expertise from an array of choices. Successful partnerships stem from clearly defined roles and responsibilities. Scientists/engineers are somewhat resistant to the idea of traditional, formal training. Instead of developing new expertise, many prefer to offer their existing strengths and expertise. Maintaining a healthy relationship requires the routine recognition of the contributions of scientists/engineers. As professional societies, university research centers and corporations increasingly engage in education and outreach, a need for a supportive infrastructure becomes evident. Work of TryScience.org/VoITS (Volunteers TryScience), the MRS NISE Net (Nanoscale Informal Science Education Network) subcommittee, NRCEN (NSF Research Center Education Network), the IBM On Demand Community, and IEEE Educational Activities exemplify some of the pieces of this evolving infrastructure.

9:48 AM P7.00004 Perspective of NSF-MPS Program Directors on Educational Outreach, DANIELE FINOTELLO, National Science Foundation — The National Science Foundation Broader Impacts review criterion (often known as Criterion 2) has been subject to much discussion since first implemented by NSF. The broader impact of different proposals can vary widely, based on different factors such as the particular research activities proposed, the interests of the PI(s), the type of institution involved in the proposal, and the different opportunities available on the local area, to name just a few. In this talk the Broader Impacts review criterion will be discussed from the viewpoint of the NSF Program Officers and will include different examples of potential Broader Impact activities. In Collaboration with Uma Venkateswaran, and Kathleen V. McCcloud.

Wednesday, March 18, 2009 8:00 AM - 11:00 AM –

Session P8 FHP: Centenary of Lev Landau 414/415

8:00 AM P8.00001 Lev Landau: A View from the West, PIERRE HOHENBERG, New York University — The tragic accident which ended Landau’s scientific career at an early age meant that Lev Landau was known personally to only a small number of western scientists. His remarkable influence on twentieth century physics thus came from his published work and indirectly from the members of the famed Landau school, who are so well represented at this Symposium. Regarding the published work, I would distinguish three distinct ways in which Landau’s influence has been felt. The most obvious is the set of seminal papers on a broad set of topics ranging from Landau diamagnetism, to the phonon-roton theory and two-fluid hydrodynamics of He, Fermi-liquid theory and zero sound, the theory of second-order phase transitions, the Landau-Hopf theory of fluid turbulence and many more. The second class of contributions consists of the famed Landau-Lifshitz Course of Theoretical Physics, which first appeared in the West in the late fifties and early sixties. In many ways the third aspect of Landau’s influence, although more difficult to define, is probably even more significant. This is Landau’s pervasive presence in a large number of the major theoretical advances in condensed matter and statistical physics throughout the second half of the twentieth century. So many major developments can be viewed as elaborations, advances and - yes - corrections to the foundational theories and points of view laid down by Landau. One example is the theory of superfluidity in Bose liquids, for which one may ask why Landau resisted London’s explanation in terms of Bose condensation, which has turned out to be important after all. A second example is the Fermi liquid theory and important later developments stemming from superfluid transitions or effects of strong correlations. A third example is the theory of second-order phase transitions which lays the foundations for the study of critical phenomena using the renormalization group. In each case one marvels at the important foundational role played by Landau’s work and one may ask to what extent he anticipated the later developments. It is hoped that the subsequent speakers might address some of these questions.

8:36 AM P8.00002 Landau and theory of quantum liquids, LEV PITAEVSKII, CNR INFN-HEC, University of Trento, Trento, Italy and Kapitza Institute for Physical Problems, Moscow, Russia — General conceptions and history of the Landau Theory of superfluidity and the Theory of Fermi liquid will be discussed.

9:12 AM P8.00003 Landau and Theory of Phase Transitions, VALERY POKROVSKY, Texas A&M University — Landau’s theory of phase transitions is probably his most general and most influential work. I describe history of its creation, its basic ideas and their developments and extensions and its deep influence on modern science.

The DOE support through the grant DE-FG02-06ER46278 is acknowledged.

9:48 AM P8.00004 Landau and Feynman diagrams, IGOR DZYALOSHINSKII, University of California, Irvine — Landau considered the Feynman diagrams and the Dyson concept of their visual summation as a breakthrough in the physics of particles. This visual perception in his opinion activated the person intuition. In this intuitive way Landau introduced the concept of partial summation which led to major results in the particle physics and the condensed matter theory. Some of his and of the members of his school results will be presented in a pure visual way.

10:24 AM P8.00005 Landau’s Contributions to Applied Physics, ROAUL SAGDEEV, University of Maryland — No abstract available.

Wednesday, March 18, 2009 8:00 AM - 10:48 AM –

Session P9 GSNP: Jamming: Theory and Experiment I 303

8:00 AM P9.00001 Cooperative Particle Dynamics in the Manhattan Model, PRASANTA PAL, Department of Applied Physics, Yale University, COREY O’HERN, JERZY BLAWZDZIEWICZ, Department of Mechanical Engineering, Yale University, O’HERN GROUP TEAM, BLAWZDZIEWICZ GROUP TEAM — We study Brownian dynamics of hard rods in a Manhattan-like traffic grid, in which a series of narrow one-dimensional horizontal and vertical channels intersect at right angles, and particles are forbidden from turning at the intersections. We measure the intermediate scattering function (ISF) and mean-square displacement (msd) as a function of packing fraction φ and determine φg at which dynamical arrest occurs as a function of the system size, number of intersections, and topology of the grid. As a particular example, we explicitly characterize the cooperative particle dynamics required for structural relaxation for symmetric systems in which all lobes between junctions contain the same number of particles. In these systems, we predict the scaling behavior of the structural relaxation time and self-diffusion coefficient versus φg — φ. We will also quantify the extent to which these systems age and determine whether there is a characteristic number of junctions above which glassy dynamics occurs.
8:12AM P9.00002 Universal Scaling Relation Near Point J. THOMAS HAXTON, ANDREA LIU, Department of Physics and Astronomy, University of Pennsylvania — Recently, several studies (P. Olsson and S. Teitel. Phys. Rev. Lett. 99, 178001 (2007); T. Hatano, arXiv:0803.2296; L. Berthier and T. A. Witten. arXiv:0810.4405) have indicated the existence of a dynamical phase transition at or near Point J, the point at zero temperature, zero shear stress, and a critical density where repulsive amorphous sphere packings lose rigidity. However, a universal scaling relation connecting the rheology of the jammed solid to that of the viscous liquid has been lacking. We control the temperature, strain rate, and pressure in molecular dynamics simulations to show that the steady-state rheology is described by a universal scaling relation near Point J.

1Supported by NSF-DMR-0605044.

8:24AM P9.00003 Scaling of Rheology Near the Colloidal Jamming Transition. ZEXIN ZHANG, ANINDITA BASU, THOMAS HAXTON, ANDREA LIU, ARJUN YODH, University of Pennsylvania — Recent simulations have proposed that the zero-temperature, zero-shear-stress jamming transition can be understood in the framework of critical phenomena, and thus can be described by various asymptotic scaling laws. We carry out rheology experiments in the vicinity of the jamming transition to study the scaling of flow properties of a bidisperse colloidal soft sphere system. We find, both below and above the jamming transition, a scaling collapse of the rheological data when the shear stress and shear rate are rescaled by proximity to the jamming transition. We extract critical scaling exponents and compared with simulations. C. S. O’Hern et al. Phys. Rev. E 68, 011306 (2003). P. Olsson, S. Teitel, Phys. Rev. Lett., 99, 178001 (2007). T. Hatano, arXiv:0803.2296v4 (2008), arXiv:0804.0477v2 (2008)

8:36AM P9.00004 Quenched Disorder as a Fourth Axis to the Jamming Phase Diagram. CYNTHIA OLSON REICHHARDT, Los Alamos National Laboratory, EVAN GROOPMAN, ZOHAR NUSSINOV, Washington University - St. Louis, CHARLES REICHHARDT, Los Alamos National Laboratory — We propose that the general jamming phase diagram proposed by Liu and Nagel [Nature 396, 21, 1998] as a function of shear, density and temperature could also have a fourth axis which is the density of quenched disorder. This could represent jamming in porous media. Using numerical simulations we show that the density at which jamming occurs in a two-dimensional system of disordered disks decreases as the amount of quenched disorder in the sample increases. We argue that when the jamming correlation length is on the same length scale as the average distance between disorder sites, the system will jam.

8:48AM P9.00005 Critical behavior from geometric confinement in shear thickening suspensions. ERIC BROWN, University of Chicago, HEINRICH JAEGER, University of Chicago — We performed rheometry measurements on shear thickening suspensions. The viscosity is measured as a shear stress over shear rate in the shear thickening region to have divergent scalings of both the magnitude and slope at a critical packing fraction $\phi_c$. The yield stress also has a divergent scaling at $\phi_c$. This is qualitatively different from jamming models in which the yield stress grows gradually from an onset packing fraction. The value of $\phi_c$ depends only on particle shape and equals 0.56 for hard spheres, corresponding to random loose packing and the onset of dilation.

9:00AM P9.00006 Stress Fluctuations and Nonlinear Dynamical Modes Near Jamming. DAVID A. EGOLF, Department of Physics; Georgetown University, EDWARD J. BANIGAN, Dept of Physics and Astronomy; Univ of Pennsylvania — The jamming transition is often considered a dynamical transition, but how to properly and quantitatively characterize the changes in dynamical behavior is an open question. We perform numerical simulations of a two-dimensional sheared granular layer over a range of packing fractions spanning the transition. Within these simulations, we calculate a partial spectrum of Lyapunov exponents and vectors, which (at least in one sense) is an optimal decomposition of the dynamics of the system. We find that the Lyapunov exponents and vectors corresponding to the most important dynamical modes of the system tend to localize in space and time near important physical events, such as cooperative rearrangements or redistributions of stresses. In addition, we find that the magnitudes of Lyapunov exponents are directly linked to the size of relative stress fluctuations of the system. At high densities, the system changes from chaotic to non-chaotic, and we measure dynamical time and length scales that diverge as the system jams.

9:12AM P9.00007 From Spheres to Ellipsoids: The Story of the Density of States1. ZORANA ZERAVCIC, Institute Lorentz, University of Leiden and The James Frank Institute, University of Chicago, NING XU, Department of Physics and Astronomy, University of Pennsylvania and The James Frank Institute, University of Chicago, SIDNEY R. NAGEL, The James Frank Institute, University of Chicago, ANDREA J. LIU, Department of Physics and Astronomy, University of Pennsylvania — Packings of frictionless ellipsoids have not only captured the imagination of the public, but also bring up a number of fundamental issues regarding the properties of jammed media. For instance, the average contact number $Z$ is turned on. Here we study the vibrational spectra of soft ellipsoids both as a function of density and $\epsilon$. Our spectra show a two-band structure. For small aspect ratios there is first a rotational band, then a gap and then a second band of translational character. As we increase the aspect ratio, the gap closes and there is first a rotational band, then a gap and then a second band of translational character. In addition, we find that the magnitudes of Lyapunov exponents depend only on particle shape and equals 0.56 for hard spheres, corresponding to random loose packing and the onset of dilation.

1We acknowledge support from Chicago MRSEC and Dutch physics foundation FOM.

9:24AM P9.00008 Growing length scale in gravity-driven dense granular flows. SHUBHA TEWARI, University of Massachusetts, Amherst, MELANIE FINN, Mount Holyoke College, ALLISON FERGUSON, University of Toronto, BULBUL CHAKRAVARTY, Brandeis University — We report on simulations of a two-dimensional, dense, bidisperse system of inelastic hard disks falling down a vertical tube under the influence of gravity. We examine the approach to jamming as the average flow of particles down the tube is slowed by making the outlet narrower. Defining coarse- grained velocity and stress fields, we find a length scale and a time scale can be extracted from two-point spatial and temporal correlations of these fields. Both length and time scales are found to grow as jamming is approached in an ongoing effort to understand the origin of the growing length and time scales, we have been investigating velocity profiles and distributions, and we will report on these results.

1 S. Tewari, B. Tithi, A. Ferguson and B. Chakrabortty, arXiv:0806.2413
9:36AM P9.00009 Experimental Study of the 2D Jamming Transition, XIANG CHENG, The University of Chicago — We can study a jammed system of particles by following a loosely-packed configuration as the individual particles increase their size until all the particles are constrained by their neighbors. Because tapioca pearls swell to over twice their initial diameter when submerged in water, they offer an ideal medium with which to study properties of the jamming transition in the presence of frictional interactions. Using an array of ~10,000 tapioca pearls, we study several static and dynamic signatures of the two-dimensional jamming transition. The amplitude of the first peak of the pair-correlation function changes non-monotonically as the packing fraction of the system increases. This is consistent with recent experiments in a colloidal system of NIPA particles at finite temperatures [1]. This signature is a vestige of the divergence of this peak in the frictionless-sphere limit [2]. A length scale, defined by the spatial velocity correlation function, and the number hexagons in the Voronoi tessellation have pronounced maxima at the transition. [1] Z. Zhang, D. T. N. Chen, A. G. Yodh, K. B. Aptowicz and P. Habdas, Bull. Am. Phys. Soc. Volume 53, Number 2 (2008). [2] C. S. O’Hern, L. E. Silbert, A. J. Liu and S. R. Nagel, Phys. Rev. E 68, 011306 1-19 (2003).

9:48AM P9.00010 Influence of Confinement on the Structure of Random Close Packing, KENNETH DESMOND, ERIC R. WEEKS, Emory University — We study the structure of many simulated random close packings confined between two walls. Each packing consists of a binary mixture in equal number with a radius ratio of 1.4. Our aim is to quantify how a confining boundary and the thickness between the boundaries alters the structure of randomly close packed disks in 2D and spheres in 3D. We find that confinement lowers the packing fraction, and induces heterogeneity in particle density where particles show strong layering near the wall. Both the particle density and the structure of the local packing show oscillations that decay outward from the wall. The decay in the oscillations is rapid, with a characteristic length scale less than the largest particle diameter. We have also developed a simple model for describing the decrease in packing fraction with confinement.

10:00AM P9.00011 Influence of Confinement on Dynamical Heterogeneities in Dense Colloidal Samples, KAZED EDMOND, ERIC R. WEEKS, Department of Physics, Emory University — We study a colloidal suspension confined between two parallel walls as a model system for glass transitions in confined geometries. The suspension is a mixture of two particle sizes to prevent wall-induced crystallization. We use confocal microscopy to directly observe the motion of the colloidal particles. This motion is slower in confinement, thus producing glassy behavior in a sample which is a liquid in an unconfinned geometry. Like in particles in an unconfined near-glassy system, groups of particles in our confined system move together cooperatively. Normally these groups would be spatially isotropic. However, the confining boundaries induce a layering of the particles. We show that the layering modifies the shapes of the mobile groups within the sample so that they are planar. We investigate how the planar restriction of the shapes of the mobile groups may be the cause of the sample’s glassy behavior.

10:12AM P9.00012 Influence of Boundary Mobility on the Dynamics of Confined Colloidal Suspensions, GARY L. HUNTER, KAZED V. EDMOND, ERIC R. WEEKS, Emory University — We use fast confocal microscopy to study the influence of interfacial mobility and confinement on the dynamics of dense colloidal suspensions. Experiments on confined molecular super-cooled liquids have shown that hard/immobile boundaries result in an increase in relaxation times relative to bulk measurements, whereas soft/mobile boundaries lead to a decrease in relaxation times. We confine suspensions of PMMA microspheres within emulsion droplets of different sizes, thereby probing the consequences of confinement. By changing the viscosity of the external, continuous phase, we also control the interfacial mobility of our samples. In this way, we separate the two effects and draw comparisons between mobility within colloidal suspensions and molecular liquids.

10:24AM P9.00013 Jamming of Foams, GIJS KATGERT, MARTIN VAN HECKE, Kamerlingh Onnes Laboratorium, Universiteit Leiden — We experimentally investigate jamming of soft frictionless spheres at zero stress and zero temperature, using static two-dimensional packings of foam bubbles. As a function of the distance to the jamming point, we obtain the distribution of interparticle forces, the scaling of the contact number and the distribution of free Voronoi area per bubble. Our results compare favorably to earlier predictions for soft discs and grains from theory and numerics.

10:36AM P9.00014 Controlled jamming of particle-laden interfaces using a spinning drop tensiometer, HSIN-LING CHENG, SACHIN VELANKAR, Chemical Engineering, University of Pittsburgh — Partially-wettable particles often adsorb nearly irreversibly at liquid/liquid interfaces. Under conditions when the interface is crowded with a particle monolayer, “2D jamming” can occur, i.e. the interface loses mobility and displays solid-like characteristics. We studied the jamming of iron oxyhydroxide (FeOOH) particles adsorbed at the interface between ethylene glycol and mineral oil using a spinning drop tensiometer (SDT). With decreasing rotational rate, the cylindrical drop retracted due to interfacial tension, and the interface loses mobility and displays solid-like characteristics. We investigated the jamming of iron oxyhydroxide (FeOOH) particles adsorbed at the interface between ethylene glycol and mineral oil using a spinning drop tensiometer (SDT). With decreasing rotational rate, the cylindrical drop retracted due to interfacial tension, and the interface loses mobility and displays solid-like characteristics.

Wednesday, March 18, 2009 8:00AM - 10:48AM – Session P10 FIAP: Focus Session: Multiferroics II

8:00AM P10.00001 Exchange interactions between soft ferromagnetic thin films and multiferroic BiFeO₃, DELPHINE LEBEUGLE, Laboratoire de Physique des Solides, CNRS, Université Paris Sud, 91404 Orsay — Controlling the magnetization of a thin ferromagnetic (FM) film using an electric field is a Holy Grail of nowadays spintronics as it would revolutionize the addressing of magnetic memory elements. One strategy is to combine the magnetoelectric coupling of multiferroic materials like BiFeO₃ (BFO) [1] with the exchange coupling (EC) observed in FM / antiferromagnetic (AFM) systems such as in BFO/CofeB bilayers [2]. BFO is a material of choice as it is one of the very few room-temperature AFM multiferroics. The two types of studied structures consist in FM layers of CoFeB deposited on BFO/STO films as well as thick permalloy layers sputtered onto BFO single crystals. They have been investigated by MagnetOptic Kerr Effect (MOKE) measurements. A macroscopic shift H₀ of the FM loops is a signature of exchange-bias (EB) in bilayers where the FM spins are coupled to the uncompensated AFM ones. We will show that the complex angular dependences of H₀ and Hₑₑ result from the competition between the anisotropies of the FM and AFM layers and the strength of the EC. We will also compare the magnetic properties of the FM layers in relation with the ferroelectric structure of the underlying BFO. In their virgin state, the crystals are in a single ferroelectric and AFM domain with a cycloidal magnetic structure whereas thin films, in which the cyloid is suppressed, are in a highly multidomain state. This comparative study allows us to determine the nature and location of the spins involved in the mechanism of EC. Finally, we present the electric field effect on H₀ and Hₑₑ of these systems. Our previous work on BFO crystals demonstrated that during electrical poling, any change of the polarization direction induces a spin flop of the AFM moments. We will show here that a 90° rotation of the anisotropy axes can be obtained in domains where the polarisation is electrically flipped.

10:00AM P10.00009 Ideal Nanocheckerboard BiFeO$_3$ – BiMnO$_3$ from First Principles , LUCIA PALOVA, KARIN RABE, PREMALA CHANDRA, Rutgers University — Motivated by recent nanocheckerboard patternings of oxide materials, we use first principles calculations to characterize a prototypical atomic-scale checkerboard of BiFeO$_3$ – BiMnO$_3$ and to compare its properties to those of its bulk constituents. We find this checkerboard has a multiferroic ground state with nonzero ferroelectric polarization and a nonzero magnetic moment, thereby combining desirable features of bulk BiFeO$_3$ and BiMnO$_3$. Unlike either of its parent compounds, structural distortion of the checkerboard stabilizes different magnetic states; this magnetostuctural effect can be used to switch between states with zero and nonzero magnetization. The role of oxygen-octahedron rotations and strain in the magnetic ordering of the nanocheckerboard will be examined in detail.

10:12AM P10.00010 Mechanism of Spontaneous Electric Polarization Flop in TbMnO$_3$ , HAJIME SAGAYAMA, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, NOBUYUKI ABE, Department of Physics, Tohoku University, TAKA-HISA ARIMA, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, KAZUAKI IWASA, Department of Physics, Tohoku University — Orthorhombic perovskite TbMnO$_3$ is one of the typical multiferroic systems. Spontaneous electric polarization (P) along the c-axis which originates from the spiral configuration of Mn$^{3+}$ spins rotating in the bc-plane appears below $T_C$ ($\sim 27$K). P/c is turned to the direction along the a-axis by applying a magnetic field along the a-axis. Magnetic structure analysis and a spin-polarized neutron diffraction study of $^{151}$Gd$_{0.02}$Tb$_{0.98}$MnO$_3$ strongly suggest that P/a in TbMnO$_3$ in high magnetic fields also originates from spin spiral rotating in the ab-plane as in the case of P/c. It has been pointed out that anisotropic Tb f-electron magnetic moments play an important role for the complicated electric polarization flop. In this study, we have confirmed the change of spin basal plane of TbMnO$_3$ from the bc- to ab-plane by applying a magnetic field along the b-axis using spin-polarized neutron diffraction technique. We observed that a magnetic fields induce a C-type antiferromagnetic structure caused by the local anisotropy of Tb magnetic moments. We have succeeded in explaining the electric polarization flop of TbMnO$_3$ in terms of a coupling between Mn$^{3+}$ spins and anisotropic Tb magnetic moments.

10:24AM P10.00011 Non-\(d^0\) Mn-driven ferroelectricity in antiferromagnetic BaMnO$_3$ , JAMES RONDINELLI, NICOLA SPALDIN, UC Santa Barbara — Using first-principles density functional theory calculations we predict a ferroelectric ground state structure – driven by off-centering of the magnetic Mn ion – for perovskite-structure BaMnO$_3$. Our finding is surprising, since the competition between energy-lowering covalent bond formation, and energy-raising Coulombic repulsions (the 2nd order Jahn-Teller effect) usually only favors off-centering for non-magnetic $d^0$ ions. It is consistent, however, with the recent observation [S. Bhattacharjee, E. Bousquet and P. Ghosez, Arxiv e-prints 811, 0811.2344 (2008)], that large lattice constants can stabilize polar off-centering of magnetic ions, by lowering the short-range Coulomb repulsions that favor the centrosymmetric phase. We calculate the Born effective charges for the compound, and find anomalously large values for Mn and O, consistent with the large calculated ferroelectric polarization of 30 $\mu$C/cm$^2$. We also describe the changes that occur in the electronic structure when the system transitions from a centrosymmetric to polar state. Finally, we suggest possible routes by which the cubic perovskite phase can be stabilized over the usual hexagonal phase.

10:36AM P10.00012 Antiferromagnetic Resonance in Multiferroic YMnO$_3$ and LuMnO$_3$\(^1\) , SERGEI ZVYAGIN, Dresden High Magnetic Field Laboratory — Multiferroic rare-earth manganeseates have attracted much attention because of the coexistence of ferroelectric and magnetic orders. Combining conventional far-infrared Fourier-transform and THz-range free electron laser electron spin resonance (ESR) spectroscopy techniques, magnetic excitations in hexagonal multiferroic YMnO$_3$ and LuMnO$_3$ in the antiferromagnetically (AFM) ordered phase have been studied. The gap in the excitation spectrum ($\sim 42$ and $\sim 48$ cm$^{-1}$ for YMnO$_3$ and LuMnO$_3$, respectively) was observed directly. Similar slope of the frequency-field dependences of AFM resonance modes, $\sim 0.5$ cm$^{-1}$/T, was revealed for both compounds. A fine structure of AFM resonance absorption has been revealed by means of high-resolution ESR techniques, which can be explained taking into account a finite interaction between the neighboring Mn$^{3+}$ layers. The work was done in collaboration with M. Ozerov, D. Kamensky, E. Čižmár, J. Wosnitza, A.K. Kolezhuk, D. Smirnov, H.D. Zhou, and C.R. Wiebe.

Wednesday, March 18, 2009 8:00AM - 11:00AM —
Session P11 DCMP: Focus Session: Transport Properties of Nanostructures IV: Correlation Effects

8:00AM P11.00001 Incorporating Exchange-Correlation Effects in Quantum Transport through Nano-scale Junctions , KRISTIAN THYGESEN, Center for Atomic-scale Materials Design (CAMD), Department of Physics, Technical University of Denmark — State-of-the-art computational methods for modelling electron transport in nano-scale junctions are based on effective single-particle approximations such as the Kohn-Sham theory of density functional theory. This methodology has been successfully applied to junctions with strong coupling to the metallic electrodes, but has proved insufficient for less homogeneous junctions where the distinction between the nano-device and the electrodes is more pronounced. In order to obtain a more accurate and rigorous description of exchange-correlation effects in weakly correlated molecular junctions, we have implemented the many-body GW approximation within a transport framework suitable to treat non-periodic systems consisting of an interacting region coupled to infinite non-interacting leads with different chemical potentials. Fundamental trends in the properties of metal-molecule-metal junctions are identified on the basis of simple model calculations. These include renormalization of molecular QP levels due to dynamical polarization effects both in- and out of equilibrium as well as the reduction of QP lifetimes due to enhanced QP scattering under finite bias conditions. As will be shown, these genuine many-body effects can have a large influence on the junction IV characteristics even for weakly correlated systems. The importance of using a fully self-consistent GW self-energy for quantum transport calculations will be demonstrated. Finally (preliminary) results for more realistic molecular junctions will be discussed. References: K. S. Thygesen and A. Rubio, PRB 77, 115333 (2008); K. S. Thygesen, PRL 100, 166804 (2008); K. S. Thygesen and A. Rubio, arXiv:0810.5214.

8:36AM P11.00002 ABSTRACT WITHDRAWN —
8:48AM P11.00003 Two-channel Kondo effect and phonon-assisted transport in single-molecular junctions1, LUIS DIAS DA SILVA, ELBIO DAGOTTO, Oak Ridge Natl. Laboratory, Oak Ridge TN, and University of Tennessee, Knoxville TN — The interplay between vibrational modes and Kondo physics is a fundamental aspect of transport properties of correlated molecular conductors. In this theoretical work, we study such interplay in a system consisting of a single molecule in a metallic break junction tuned (by gate voltages) to be in an “odd-N” Coulomb blockade state (Kondo-probe). The connection to left and right metallic leads creates the usual coupling to a conduction channel with left-right symmetry (the “even”-parity channel). A center-of-mass vibrational mode introduces an additional, phonon-assisted tunneling through the asymmetric (“odd”-parity channel). Our numerical renormalization-group calculations reveal that the phonon-mediated coupling to the odd channel leads to the appearance of a two-channel Kondo (2chK) effect, characterized by a non-Fermi-liquid (NFL) fixed point. The ground-state has NFL properties for a critical value of the phonon-mediated coupling strength and critical lines are present for wide range of parameters, including the regime away from particle-hole symmetry. Signatures of this 2chK non-Fermi-liquid behavior are prominent in the thermodynamic properties as well as in the linear conductance.

9:00AM P11.00004 Universal Scaling of Zero-Bias Conductance Peaks in Single-Molecule Transistors Incorporating Tetra[2,3-thiénylene] , ZACHARY KEANE, GAVIN SCOTT, DOUGLAS NATELSON, Rice University — There is significant interest in exploring universal scaling laws as they apply to the Kondo effect in diverse physical systems. One such system is GaAs quantum dots, in which Grobini et al. have demonstrated that the conductance follows a universal scaling function in temperature and source-drain bias. More recently, Scott et al. have demonstrated that the same scaling law applies to single molecule transistors incorporating both C60 and bis(2,5-di-[2]pyridyl-3,4-dithiocyanato-pyrrolate)Cu(II), despite the fact that the relevant energy scales in these systems can differ by 3 orders of magnitude. We will report measurements and universal scaling analysis of the Kondo conductance as a function of temperature and source-drain bias in a fourth system, single molecule transistors incorporating tetra[2,3-thiénylene].

9:12AM P11.00005 Tunneling spectra of individual magnetic endofullerenes molecules , E. S. TAM, J. E. GROSE, J. J. PARKS, B. ULGUT, H. D. ABRUNA, D. C. RALPH, Cornell University, C. TIMM, University of Kansas, M. SCHELOSKE, W. HARNEIT, Freie Universität Berlin — We report measurements of electron tunneling spectra for individual NbC60 molecules, a spin-3/2 endohedral fullerene. The molecules were measured at low temperature in electromigrated break-junctions in the single-electron transistor configuration. We observe that the NbC60 devices exhibit a spin-state transition as a function of applied magnetic field which was not observed in C60 control devices. The nature of this transition enables us to identify the charge and spin states of the molecule. The spectra of NbC60 devices also exhibit low-energy excited states and signatures of non-equilibrium spin excitations predicted for this molecule. The experimental spectra can be reproduced theoretically by accounting for the exchange interaction between the nitrogen spin and electron(s) on the C60 cage.

9:24AM P11.00006 Spin-dependent effects in transport through individual molecules and nanoparticles , J. J. PARKS, E. S. TAM, S. FLORES-TORRES, H. D. ABRUNA, D. C. RALPH, Cornell University — We report measurements of electron transport through individual molecules and nanoparticles incorporated into electromigrated break junction devices. In low-temperature studies of a thiol-terminated organometallic complex using a mechanically controllable break junction, we have studied the effects of molecular distortions. We find that as a function of stretching the molecule, a zero-bias Kondo peak can split into two finite-bias peaks, reminiscent of singlet-triplet transitions in other types of quantum dots. We discuss possible mechanisms in terms of coupling between broken spatial symmetries and the spin state of the molecule. We also measure devices in which molecules and nanoparticles are contacted by ferromagnetic electrodes, so as to study the interplay of spin polarization with single-electron charging effects.

9:36AM P11.00007 Universal Scaling of Nonequilibrium Transport in the Kondo Regime of Single Molecule Devices , GAVIN SCOTT, ZACHARY KEANE, Rice University, Dept of Physics & Astronomy, JACOB CISZEK1, JAMES TOUR, Rice University, Dept of Chemistry, DOUGLAS NATELSON, Rice University, Dept of Physics & Astronomy, Dept of Electrical & Computer Engineering — Scaling laws and universality are often associated with systems exhibiting emergent phenomena possessing a characteristic energy scale. We report nonequilibrium transport measurements on two different types of single-molecule transistor (SMT) devices in the Kondo regime. The conductance at low bias and temperature adheres to a scaling function characterized by two parameters. This result, analogous to that reported recently in semiconductor dots with Kondo temperatures two orders of magnitude lower, demonstrates the universality of this scaling form. We compare the extracted values of the scaling coefficients to previous experimental and theoretical results.

9:48AM P11.00008 Spatial range of the Kondo effect1, C.A. BÜSSE, G. B. MARTINS, Oakland University, MI, USA, L. COSTA RIBEIRO, E. V. ANDA, PUC-Rio, RJ, Brazil, E. DAGOTTO, University of Tennessee and ORNL, TN, USA — The objective of this work is to discuss the spatial range of the effect caused by the Coulomb interaction localized at an impurity center. The numerical method we use, the embedded cluster approximation (ECA) and the finite U slave boson mean field (FU-SBHF), are developed to treat localized impurity systems. It is important to note that, contrary to other techniques, ECA and FUSB work in real space. Instead of using the spin-spin correlation to determine the length of the Kondo cloud, we will use the local density of states (LDOS) on the lead, far from the impurity. The presence of the impurity produce a disturbance in the LDOS of sites away from it. In this work, we propose to use this distortion to evaluate the spatial range of the Kondo effect. We observe that the effect of the distortion decays exponentially as a function of the distance from the impurity. With that in mind, a characteristic length $L_K$ can be easily defined. When the coupling between the impurity and the metal is increased, we verify that $L_K \sim 1/T_K$. We will also discuss how the magnetic field and temperature affect the length $L_K$.

10:00AM P11.00009 1/N expansion of the nonequilibrium single-impurity Anderson Model1, ZURAB RATIANI, ADITI MITRA, New York University — Results are presented for the nonequilibrium single-impurity Anderson model using a large-N approach, where N is the degeneracy of the impurity level. Using the Keldysh formalism, we extend the slave-boson functional integral method of Read and Nussinov to the out of equilibrium current carrying case. The correlation function for the slave boson is shown to exhibit a long time power law behavior along with an exponential decay whose origin is current induced decoherence, a result consistent with nonequilibrium X-ray edge physics. Expressions for the impurity susceptibility and the conductance through the device are presented to $O(1/N)$ and for an applied voltage less than the Kondo temperature.

1Supported by NSF-DMR 0705584
demonstrated the expected suppression of shot noise when junction conductance is near an integer multiple of the conductance quantum, $G$. Previous experiments at low temperatures in metal and semiconductor point contacts have approach is illustrated on several two-terminal nanostructures. I will also discuss the relationship between the present approach and the Landauer-Büttiker model that averages over transmission coefficients. Full understanding of RSOI on the Kondo regime is fundamental, as it studies the competition of different coherent phenomena and has potential applications in devices such as spin-filters. A study of this geometry included the role of RSOI perturbatively [1]. However, the full features of Kondo physics are subtle and not captured in perturbation theory. In this work, we present a numerical renormalization group study that addresses charge and spin transport properties in the zero-bias regime, and allows comparisons with perturbation results. We find that the presence of both AB fields and RSOI results in an intrinsic polarization field that breaks the spin degeneracy. This allows a delicate control of spin polarization of the conductance in the system, while strong RSOI suppresses the Kondo effect. [1] R. J. Heany et al., PRB 77, 155132 (2008)

Decoherence due to contacts in ballistic nanostructures[1]. I. KNEZEVIC, University of Wisconsin - Madison — In quasiballistic nanoscale electronic structures, the process of relaxation towards a steady state cannot be attributed to carrier scattering. Rather, the active region of a nanostructure is an open quantum-mechanical system, whose nonunitary evolution (decoherence) toward a nonequilibrium steady state is determined by carrier injection from the rapidly dephasing contacts. I will present a technique for the treatment of contact-induced decoherence in ballistic nanostructures, which is established within the framework of the open system theory. Efficient electron-electron scattering in the contacts enables one to consider them nearly “memoryless” and derive a Markovian kinetic equation for the active region’s statistical operator through coarse graining over the contacts’ short memory-retention time. By incorporating a first-principles model interaction between the active region and the contacts into the Markovian dynamics derived, nonequilibrium steady-state distribution functions of the forward- and backward-propagating states in the active region are derived analytically. The approach is illustrated on several two-terminal nanostructures. I will also discuss the relationship between the present approach and the Landauer-Büttiker formalism, as well as the inclusion of scattering.

Supported by the NSF, award ECCS-0547415.

High frequency measurements of shot noise suppression in atomic-scale metal contacts[1]. PATRICK J. WHEELER, Department of Physics and Astronomy, Rice University, KENNETH EVANS, Applied Physics Program, Rice University, JEFFREY RUSSOM, Department of Physics and Astronomy, Rice University, NICHOLAS KING, Department of Physics and Astronomy, DOUGLAS NATelson, Department of Physics and Astronomy, Rice University — Shot noise provides a means of assessing the number and transmission coefficients of transmitting channels in atomic- and molecular-scale junctions. Previous experiments at low temperatures in metal and semiconductor point contacts have demonstrated the expected suppression of shot noise when junction conductance is near an integer multiple of the conductance quantum, $G_0 \equiv 2e^2/h$. Using high frequency techniques, we demonstrate the high speed acquisition of such data at room temperature in mechanical break junctions. In clean Au contacts conductance histograms with clear peaks at $G_0$, 2$G_0$, and 3$G_0$ are acquired within hours, and histograms of simultaneous measurements of the shot noise show clear suppression at those conductance values. We describe the dependence of the noise on bias voltage and analyze the noise vs. conductance histograms in terms of a model that averages over transmission coefficients.

The authors acknowledge support of the Robert A. Welch Foundation grant C-1636 and NSF DMR-0347253.

Wednesday, March 18, 2009 8:00AM - 11:00AM – Session P12 DMP DCMP: Focus Session: Characterization and Modeling of Complex Surfaces and Interfaces 308

Atomistic Structure and Energy of Solid-Liquid Interfaces, WAYNE KAPLAN, Technion - Israel Institute of Technology — As microstructural length-scales are reduced, the role of interfaces in determining the properties of materials becomes more dominant. The importance of the correlation between interface structure and chemistry with interface (and bulk) properties is evident in a range of material systems, and is a topic of intense experimental and theoretical work for solid-solid interfaces. While detailed thermodynamic analysis of solid-liquid interfaces is routinely conducted, knowledge of the local structure at solid-liquid interfaces is still incomplete. To be more specific, the correlation between the structure of the solid, and the structure in the liquid near the interface, has not been fully addressed. In this presentation, in-situ (~750 °C) high resolution transmission electron microscopy (HRTEM) of liquid Al in contact with sapphire ($\alpha$-Al$_2$O$_3$) will be presented. Contrast perturbations in the liquid Al adjacent to the crystalline substrate were determined to be due to ordering of the liquid, via detailed multi-slice dynamic electron scattering simulations. Details on the type of ordering were interpreted by molecular dynamics simulations of liquid Al in contact with crystalline substrates, and compared to sessile drop studies of liquid Al on sapphire. These results are compared with recent HRTEM investigations of equilibrium amorphous films at metal-Al$_2$O$_3$ interfaces, where partial ordering of the film plays an important entropic role in reaching stable nanometer-thick films. This will then be extended to equilibrium segregation, and the concept of extremely small volumes of liquids confined by crystals.
8:36AM P12.00002 Calculation of excess interfacial entropy, stress and energy for solid-liquid interfaces

BRIAN B. LAIRD, Dept. of Chemistry, Univ. of Kansas, RUSLAN L. DAVIDCHACK, Dept. of Mathematics, Univ. of Leicester, UK, MARK ASTA, YANG YANG, Dept. of Chem. Eng. and Materials Sci., UC Davis — The solid-liquid interfacial free energy, \( \gamma_{\text{sl}} \), governs a number of important phenomena, e.g., crystal nucleation and growth, and wetting. For an equilibrium crystal-melt interface, \( \gamma_{\text{sl}} \) can be calculated via simulation using thermodynamic integration or capillary fluctuations [Phys. Chem. B 109, 17802 (2005)]. The calculation of \( \gamma_{\text{sl}} \) away from coexistence requires the temperature and strain dependence of \( \gamma_{\text{sl}} \), which can be determined from the excess interfacial entropy, \( \eta_{\text{sl}} \), and stress tensor, \( \tau_{\text{sl}} \). We determine \( \eta_{\text{sl}} \) and \( \tau_{\text{sl}} \) for a system of Lennard-Jones particles and for particles with an inverse-power interaction \( [\phi(r) = \epsilon / r^n] \) for \( n = 6, 8 \) (fcc and bcc) and 12, 20 (fcc). We determine \( \eta_{\text{sl}} \) and \( \tau_{\text{sl}} \) for the (100), (110) and (111) orientations. We calculate \( \eta_{\text{sl}} \) using two methods, both using the Gibbs dividing surface defined so that the excess interfacial particle number is zero. In the first, we calculate \( \eta_{\text{sl}} \) from the temperature dependence of \( \gamma_{\text{sl}} \), \( \tau_{\text{sl}} \) and the number density, \( \rho \), along the coexistence curve. In the second, we calculate the excess interfacial energy, \( \eta_{\text{sl}} \), and use the equation \( \gamma_{\text{sl}} = \epsilon_{\text{sl}} - T \eta_{\text{sl}} \). The results agree within estimated errors. One surprising observation is that \( \eta_{\text{sl}}, \epsilon_{\text{sl}} \) and \( \tau_{\text{sl}} \) are significantly more anisotropic than \( \gamma_{\text{sl}} \).

8:48AM P12.00003 Spin Order in Magnetic Organic Semiconductor V[TCNE]∼2

HAILEMARIAM AMBAYE, VALERIA LAUTER, STEPHEN NAGLER, CHRISTINA HOFFMANN, Ornlé, HAL LÉE, ANDREW PÄZNT, Ornlé, ARTHUR ÉPSTEIN, CHEN CHI-YI, Ohio state university, RICHARD GÓYETTE, Ornlé — These Organic-based magnets are new area of materials research. The discovery of V[TCNE]∼2 with its high Tc ∼ 400 K and semiconducting behavior similar to silicon, as well as its photonic response unique for magnetic materials, opens up many issues of fundamental physics and chemistry as well as the potential opportunities for use of these and related materials in technologies ranging from spintronics to sensing. To understand the magnetic state and the evolution of the magnetic at and near interfaces with other magnetic and non magnetic materials we have performed a polarized neutron measurement at the SNS magnetism reflectometer instrument. The measurements show the presence of magnetic resonances at 5K temperature. The room temperature measurements show no magnetic responses. The systems considered are magnetic and non magnetic materials we have performed a polarized neutron measurement at the SNS magnetism reflectometer instrument. The measurements show the presence of magnetic resonances at 5K temperature. The room temperature measurements show no magnetic responses. The systems considered are V[TCNE]∼2(1500A) and 6000A on Si substrate. Work supported by DOE.

9:00AM P12.00004 Stabilization of a ferromagnetic insulating phase with colloidal magnetore sistance at the interface of manganese bilayers

JONATHAN LAVERDIÈRE, SERGE JANDL, PATRICK FOURNIER, Université de Sherbrooke — The charge ordered phase observed in colloidal magnetoresistive mangetites motivated many theoretical and experimental efforts. Charge order is an insulating electronic phase that becomes metallic in sufficiently high magnetic field. This high “milling” field hinders any applications for magnetic storage devices. Here, we present the study of the proximity effect in Nd$_{0.57}$Sr$_{0.13}$MnO$_3$ (NSMO) / Nd$_{0.55}$Ca$_{0.15}$MnO$_3$ (NCMO) bilayers. NSMO is dominated by ferromagnetic double exchange, producing a ferromagnetic metallic phase, while NCMO is strongly influenced by the Jahn-Teller lattice distortion, localization charges on the Mn$^{3+}$ sites. Our study addresses the following question: Which one will dominate at the NSMO/NCMO interface? We will present Raman scattering and magnetotransport measurements on NCMO/NSMO bilayers grown on SrTiO$_3$ substrate. A ferromagnetic insulating phase has been observed for very thin NSMO films. This phase becomes metallic and gives rise to colossal magnetoresistance at a low field compared to the usual melting field.

9:12AM P12.00005 Effects of surfactant on the physical properties of single-walled carbon nanotube buckypaper.

JIN GYU PARK, CHARLIE LIN, JESSE SMITHYMAN, ADAM COOKE, SHU LI, RICHARD LIANG, CHUCK ZHANG, BEN WANG, High-Performance Materials Institute, Florida State University, ADE KIYARAHARJDJA, JAMES BROOKS, Department of Physics, Florida State University, HIGH-PERFORMANCE MATERIALS INSTITUTE, FLORIDA STATE UNIVERSITY COLLABORATION, DEPARTMENT OF PHYSICS, FLORIDA STATE UNIVERSITY COLLABORATION, BANDGAP ENGINEERING INC. COLLABORATION, DEPARTMENT OF PHYSICS AND DEPARTMENT OF ELECTRICAL ENGINEERING, MIT COLLABORATION — Bulk bismuth has a small band overlap between the conduction and valence bands and a highly anisotropic electron effective-mass tensor. Previously, we have shown evidence for strong quantum confinement in Bi nanorods with diameters ~10 nm which undergo a transition from a semimetal with a small band overlap to a semiconductor with a small indirect band gap. These quantum confinement effects can be potentially useful in optical and electro-optical devices. Here, we report the low temperature (77 K) optical absorption properties of ~10 nm diameter Bi nanorods using Fourier Transform Infrared spectroscopy. The Bi nanorods exhibit a strong absorption peak (~1000 – 1400 cm$^{-1}$, depending on the diameter) in the mid-IR that is not present in bulk bismuth. The full width at half maximum intensity of the IR absorption peaks decrease from 26 cm$^{-1}$ at 300 K to 15 cm$^{-1}$ at 77 K. No significant blue-shift in energy was observed, and these changes will be discussed in terms of the temperature dependence of the L-point and T-point electron energies.

9:24AM P12.00006 Low-Temperature Absorption Studies in Bismuth Nanowires

JASON REPPERT, Clemson University, MALCOLM SKOVE, MARCIE BLACK, MILDRED DRESSELHAUS, APPARAO RAO, SCHOOL OF MATERIALS SCIENCE AND ENGINEERING, CLEMSON UNIVERSITY COLLABORATION, DEPARTMENT OF PHYSICS AND ASTRONOMY, COMSET, CLEMSON UNIVERSITY COLLABORATION, BANDGAP ENGINEERING INC. COLLABORATION, DEPARTMENT OF PHYSICS AND DEPARTMENT OF ELECTRICAL ENGINEERING, MIT COLLABORATION — Bulk bismuth has a small band overlap between the conduction and valence bands and a highly anisotropic electron effective-mass tensor. Previously, we have shown evidence for strong quantum confinement in Bi nanorods with diameters ~10 nm which undergo a transition from a semimetal with a small band overlap to a semiconductor with a small indirect band gap. These quantum confinement effects can be potentially useful in optical and electro-optical devices. Here, we report the low temperature (77 K) optical absorption properties of ~10 nm diameter Bi nanorods using Fourier Transform Infrared spectroscopy. The Bi nanorods exhibit a strong absorption peak (~1000 – 1400 cm$^{-1}$, depending on the diameter) in the mid-IR that is not present in bulk bismuth. The full width at half maximum intensity of the IR absorption peaks decrease from 26 cm$^{-1}$ at 300 K to 15 cm$^{-1}$ at 77 K. No significant blue-shift in energy was observed, and these changes will be discussed in terms of the temperature dependence of the L-point and T-point electron energies.

9:36AM P12.00007 Nanopatterned Biomimetic Surfaces to Promote the Role of Cytoskeletal Proteins in Cell Adhesion

JUSTIN ABRAMSON, MATTEO PALMA, Department of Mechanical Engineering, Columbia University, MARK SCHWARTZMAN, Department of Chemical Engineering, Columbia University, SHALOM WIND, Department of Applied Physics and Applied Mathematics, Columbia University, MICHAEL SHEETZ, Department of Biological Sciences, Columbia university, JAMES HONE, Department of Mechanical Engineering, Columbia University — Nanometer level spatial organization has been shown to play a crucial role in cell mechanics, in particular in cell adhesion to the extracellular matrix. Combining nanolithography and biomolecular self-assembly strategies, we report on the fabrication of nanopatterned biomimetic surfaces to probe the importance of both the spatial ordering of transmembrane proteins as well as the role played by peptide sequences as cell binding domains in the formation of cell focal adhesions. We have fabricated arrays of Au/Pd nano-dots using electron-beam and nanoimprint lithography. Different chemical strategies have been pursued to biofunctionalize such nanostructures, both through the formation of mixed Self Assembled Monolayers as well as via chemical reactions at surfaces. Fluorescence microscopy allowed us to monitor single-molecule chemisorption of cell-adhesion proteins in vitro, as well as to follow cell spreading on the nanopatterned bio-arrays, in order to investigate cytoskeletal protein binding interactions in vivo.

9:48AM P12.00008 Molecular Dynamics Simulations of Interfaces in Complex Materials. TAHIR CAGIN, Texas A&M University — Molecular details of structure and chemistry play an important role in the properties and engineering performance of composites and complex materials. Experimental investigation of the interfaces most often presents itself as a major challenge. This, in turn, becomes an opportunity in disguise for the molecular level simulation approaches. However, in order to convincingly address to the problem of elucidating the structure and chemistry at the interfaces, one must employ reliable and accurate and transferable interaction potentials for dissimilar materials - this is the case for composites and complex materials. In this talk, we will present examples of molecular dynamics studies on the structure and properties of silicon nano-crystals in a silica matrix, piezoelectric CNT-polyimide nano-composites, and on the role of super lattice structures for enhancing mechano-electric coupling in ferro-electric ceramic alloys.

10:24AM P12.00009 Evaluation of dispersion interactions in general geometries. ANTHONY MAGGS, CNRS-ESPCI, PASQUALI SAMUELA, IBPC-Paris 7 — Dispersion interactions are very often approximated by pairwise van der Waals interactions between molecules. In dense media, however, there are important corrections due to the many-body nature of fluctuations. These many-body forms can be calculated in closed form in the simplest of geometries using the methods of Casimir and Lifshitz. Here we study dispersion interactions between bodies in general geometries. We map the calculation of the partition function onto a determinant which we discretize and evaluate with the help of Cholesky factorization. We study the efficiency of the factorization in two and in three dimensions and conclude that accuracies of the order of one per cent are readily achieved in the total interaction energy. We compare the approximations of pairwise additivity and proximity force with our numerical methods.

10:36AM P12.00010 Phase-field Simulation of Phase Coarsening at Ultra-high Volume Fractions. KE-GANG WANG, XUERU DING, Department of Physics and Space Sciences, Florida Institute of Technology, Melbourne, FL 32901 — The study of phase coarsening kinetics during microstructure evolution is critical to a variety of industrial applications involving two-phase systems in which the dispersed phase controls the properties of the material. Liquid-phase sintering, casting and spray deposition are just a few examples of processes in which the coarsening process has important technological implications. In this talk, the dynamics of phase coarsening at ultra-high volume fractions (V_c > 0.9) will be presented based on 2-D phase-field simulations. Kinetics of phase coarsening and spatial correlations in microstructures will be revealed. Pair distribution functions in microstructures will be shown. The scaled particle-size distribution as functions of the dispersed volume fraction will be demonstrated. Finally, computational results are compared with experimental observations.

10:48AM P12.00011 The impact of self-healing on the life-time of materials. JOHN GADDY, WOUTER MONTFROOIJ, University of Missouri, ALEXANDER SCHMETS, Delft University of Technology — Structural materials that are attributed with the (new) property of "self-healing" will obviously lead to safer, longer lasting and more reliable structures. The property of "self-healing" can be defined as the ability of a material to mitigate autonomously early stages of damage such as micro cracks, and many examples of materials with this properties have been reported in recent years [1]. In this contribution we investigate the effect of healing on the expected service life time of a model material. We apply a statistical mechanics' inspired computational approach to model the process of damage accumulation and on-site healing of a material under well defined loading conditions. We define a material as being at the end of its service life when a percolative path of damaged cells has passed a prescribed length. The variation of service life for various scenarios, such as healing times and distribution of healing centers is investigated. Finally we show how this type of models may be useful for the design of optimized self-healing materials.

Session P13 DCOMP GSCCM: Focus Session: Extreme Conditions and High Pressure I: Chemistry

8:00AM P13.00001 Shock-induced Reactions in Pentaerythritol Tetranitrate Studied by Molecular Dynamics Simulation 1. JOANNE BUDZIEN, AIDAN P. THOMPSON, Sandia National Laboratories, SERGEY V. ZYBIN, California Institute of Technology — Molecular dynamics simulations were performed using the reactive force field, ReaxFF, as implemented in the General Reactive Atomistic Simulation Program code for systems consisting of a single crystal of PETN with not fewer than 237000 atoms. The crystals were shocked along the [100] direction using two different piston velocities. The resulting chemical reactions were tracked in an attempt to elucidate short-time initiation mechanisms. Here, we present the primary, secondary, and intermediate products as a function of time and position behind the shock front.

1Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under Contract DE-AC04-94AL85000.

8:12AM P13.00002 Molecular dynamics simulations of uniaxial shock compression of RDX crystals. DMITRY BEDROV, JUSTIN HOOKER, GRANT SMITH, University of Utah — Using the Hugoniot method atomistic molecular dynamics simulations of uniaxial shock compressions along [001], [100], and [010] directions of RDX crystal have been conducted over a wide range of shock pressures. The Hugoniot simulations allow modeling of shocked material without the necessity to have extremely large simulation cell required to explicitly resolve the shock wave propagation. Hugoniot simulations on systems containing only few thousand molecules allowed us to determine Hugoniot elastic limit and to investigate shock-induced shear banding and phase transition in RDX crystal.

8:24AM P13.00003 A molecular dynamics study of the role of pressure on the response of reactive materials to thermal initiation. N. SCOTT WEINGARTEN, WILLIAM D. MATTSON, BETSY M. RICE, U. S. Army Research Laboratory, ANTHONY D. YAU, High Performance Technologies, Inc., TIMOTHY P. WEIHS, Johns Hopkins University — Reactive materials have the potential for implementation into a wide variety of commercial and military applications. However, the fundamental physical and chemical processes that control the energy release are not well understood. To elucidate the mechanisms of energy release, we simulated the exothermic alloying reactions of a Ni/Al bilayer with initial temperatures of 1100 K and 1500 K using both microcanonical (NVE) and isoentropic (NPH) molecular dynamics simulations with an embedded atom method (EAM) potential. The mechanism of the mixing is the same for all simulations: as mixing and reaction occurs at the interface, the heat generated first melts the Al layer, and subsequent mixing leads to further heat generation after which the Ni layer melts, leading to additional mixing until the alloying reactions are completed. The results indicate that pressure has a significant influence on the rates of atomic mixing and alloying reactions. In addition, two-phase coexistence simulations were used to determine the melting temperatures of pure Al and pure Ni at various pressures using this potential, and these values are discussed within the context of the Ni/Al bilayer results.
8:36AM P13.00004 Mbar Chemistry: Novel States of Matter in Extreme Conditions

SHIK YOO, Department of Chemistry and Institute for Shock Physics, Washington State University, Pullman, Washington 99164-2816 USA — Compression energy at 100 GPa often exceed several eV/atom, rivaling the energy of strong chemical bonds. Therefore, the application of such a high pressure significantly alters the chemical, electronic/optical, thermomechanical properties of solids and, in turn, provides a way to test condensed matter theory and to exploit novel materials with advanced properties. Furthermore, recent advances in diamond-anvil cell high-pressure technologies coupled with advanced third-generation synchrotron x-ray offer unprecedented opportunities to discover exotic states of matter at high pressure-temperature conditions of the Earth and planetary interiors. In this paper, I will discuss several recent results of high-pressure chemistries that occur in simple low Z molecular solids to novel nonmolecular extended solids. Broadly speaking, these molecular-to-nonmolecular transitions occur as a result of the pressure-induced electron delocalization arising from a rapid increase in electron kinetic energy at high density. Yet, the details are substantially more complicated because of the phase metastability, large lattice strain, and governing kinetics. As a result, there are many outstanding questions regarding the exact nature of chemical bonding, phase stability, and transition mechanisms. Also, presented are several future directions of high pressure materials research in an complementary phase and time scales of dynamic and static high pressures.

9:12AM P13.00005 Novel Catalytic Behavior of Dense Hot Water in PETN Decomposition Reactions

CHRISTINE WU, LAURENCE FRIED, LIN YANG, NIR GOLDMAN, SORIN BASTEA, Lawrence Livermore National Lab — Under extreme conditions, water is known to exhibit fascinating physical behaviors. Its remarkable structural and phase complexity strongly suggests that its chemical properties may be unusual as well, which have remained largely unrevealed. Using ab initio molecular dynamics simulations, we have recently discovered that water plays a non-trivial role in catalyzing complex reactions of a high explosive pentaerythritol tetranitrate (PETN). This finding is in contrary to the current view of water as a stable final product of high explosive reactions, and has possible implications in geochemistry, such as reactions in planetary interiors.

This work preformed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

9:24AM P13.00006 The formation of carbon nitride clusters in shocked insensitive explosives

LAURENCE FRIED, RIAD MANAA, EVAN REED, NIR GOLDMAN, Lawrence Livermore National Laboratory — Many high explosives are organic molecular crystals that contain both oxidizing and reducing functional groups. These solids rapidly release their energy in supersonic detonation waves. It has been observed that explosives rich in carbon tend to have much longer reaction zones than those that do not. These explosives form graphitic or diamond-like carbon particles during detonation. The slow diffusion-limited process of forming the solid carbon from bulk explosives is believed to a play a central role in determining the reaction zone length of a given explosive. In this work, we identify an altogether new mechanism for the slow reactvity of carbon rich explosives. Quantum-based multi-scale simulations of shocked 1,3,5-triamino-2,4,6-trinitrobenzene (TATB) provide the first evidence for the formation of nitrogen-rich heterocyclic clusters that impede the formation of fluid nitrogen and solid carbon.

This work was performed by the Lawrence Livermore National Laboratory under contract number W-7405-Eng-48.

9:36AM P13.00007 Ab initio molecular dynamics of hypervelocity chemistry

IGOR SCHWEIGERT, BRETT DUNLAP, Theoretical Chemistry Section, US Naval Research Laboratory, 4555 Overlook Ave SW, Washington, DC 20375 — Resolving chemical dynamics of decomposition of energetic molecules is crucial for understanding detonation initiation in energetic materials and predicting their sensitivity to shock and impact stimuli. We employ Born-Oppenheimer molecular dynamics driven by density-functional methods to identify possible decomposition pathways in nitric esters (including pentaerythritol tetranitrate) and to understand the effect of collision orientation and velocity. Studies of the potential energy surface in the bond-breaking region, unimolecular decomposition, and binary hypervelocity collisions of model nitric esters (methyl and ethyl nitrates) will be reported. Methodological challenges in describing extensive changes in the electronic structure that accompany decomposition will be discussed.

This work was supported by the Naval Research Laboratory via the National Research Council of the National Academy of Science and by the Office of Naval Research, both directly and through the Naval Research Laboratory.

9:48AM P13.00008 Boron carbides from first principles

EMMANUEL BETRANHANDY, JELENA SJAKSTE, NATHALIE VAST, Laboratoire des solides irride d’École polytechnique-CEA-CNRS — In this work, we focus on the understanding gained from the investigation of the physical properties of boron-carbides with theoretical methods based on density functional theory (DFT). Comparison of computed and experimental vibrational or NMR spectra has shown that the atomic structure of B$_4$C consists in C-B-C chains linking mostly B$_3$Cicosahedra, and a few percent of B$_2$C$_2$icosahedra. In particular, C-C-C chains are excluded and can not be responsible for B$_4$C amorphization under shockwaves. In this work we find that at lower carbon concentration all models are metastable with respect to B$_3$C plus α-boron. This could explain actual difficulties in the synthesis of clean samples. Furthermore we discuss effects of temperature and/or pressure on stabilities and properties. Finally, the idea of combining high hardness and superconductivity in the same material by doping boron-rich solids has emerged. We show results on the strength of the electron-phonon coupling constant obtained with DFT-based methods in B$_3$C$_2$.

Support from DGA through a grant is gratefully acknowledged. Results have been obtained in part with the espresso package and computer time granted by CEA DSM on the NEC SX8.

10:00AM P13.00009 Dynamical stability of the cubic metallic phase of AlH$_3$ at ambient pressure

DUCK YOUNG KIM, RALPH H. SCHEICHER, Condensed Matter Theory Group, Department of Physics and Materials Science, Uppsala University, Box 530, SE-751 21, Uppsala Sweden, RAJEEV AHUJA, CMT Group, Uppsala; Applied Materials Physics, Dept. of Materials and Engineering, Royal Institute of Technology (KTH), Stockholm — We have characterized the high-pressure cubic phase of AlH$_3$ using density functional theory to determine mechanical as well as electronic properties and lattice dynamics from the response function method [1]. Metallization in AlH$_3$ under pressure has been studied, which is of great interest not only from a fundamental physics point of view for the study of phenomena related to metallic hydrogen, but also, because metallic AlH$_3$ possesses weaker Al-H bonds than other insulating phases [2]. Our phonon calculations show the softening of a particular mode with decreasing pressure, indicating the onset of a dynamical instability that continues to persist at ambient conditions. We find from analyzing the atomic and electronic interactions using theoretical calculations that finite-temperature effects lead to the desired stabilization of metallic AlH$_3$ at ambient conditions.

The simulations are performed using the Multi-Scale Shock Method (MSST) which we have extended to maintain thermodynamic equilibrium between electrons and ions to correctly treat electronic heat capacity.

This work was performed in part under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
9:00AM P14.00006 Colloidal Hydrodynamics with Arbitrary Boundary Conditions. JONATHAN K. WHITMER, ERIK LUIJTEN, University of Illinois at Urbana-Champaign — Hydrodynamic interactions are essential to the understanding of colloidal dynamics. Due to their complexity and computational cost, they are often ignored in simulations. Over the past decade, coarse-grained methods such as Stochastic Rotation Dynamics (an example of the larger family of Multi-Particle Collision (MPC) methods) have been developed to include these interactions efficiently in simulation. To use these methods for the study of self-assembly dynamics of particles with anisotropic surface chemistry, we extend previously implemented methods for stick boundary conditions to arbitrarily slipping surfaces on the curved surfaces of spherical colloids. We present a mapping from an easily tunable simulation parameter onto the slip length as defined by Navier, and discuss the dynamics of anisotropic particles simulated using this method.

9:12AM P14.00007 Reversible Rayleigh-to-Mie Scattering Transition in a Core-Shell Colloidal System. GUANGNAN MENG, Harvard University, ADELINE PERRO, VINOTHAN MANOHARAN — We present a study of light scattering from colloidal particles with small polystyrene cores and large shells of poly(N-isopropylacrylamide-co-acrylic acid). When swollen in deionize water at room temperature, the shell is nearly index-matched to pure water, and the scattering is dominated by Rayleigh scattering from the polystyrene cores. As we change the solvent condition by increasing temperature or salt concentration, the shell starts to shrink and scatter light. Both the scattering cross section and the forward scattering of the particles increase, characteristic of Mie scatterers. We use optical microscopy, static light scattering and turbidimetry to study this optical transition. Such core-shell particles might be used as aqueous index-matched tracer colloids, as model scatterers for self-assembly studies, or as optical filters with tunable opacity.

9:24AM P14.00008 Pressure driven foam flow rheology. C.D. JONES, K. NORDSTROM, D.J. DURIAN, University of Pennsylvania — We probe the complex rheology of 3d foams by flowing them through a narrow column. The foam flows upward through one of two vertical rectangular columns with a 41 cross-sectional aspect ratio, by bubbling gas through a soapy solution at the base of our apparatus. One column is clear acrylic sheet on all sides, which is slippery to the foam, and results in plug flow. The other column has the narrow surfaces covered with sandpaper, giving them a sticky surface, which creates shear due to the zero velocity boundary condition. As expected, the flow profile between the slippery broad faces is flat, however the profile between the narrow, sticky faces exhibits a curved velocity profile that is strongly dependent on flow rate. We are able to analyze a 2d velocity profile from a 3d bulk system, whereas other recent foam rheology work has been constrained to the 2d system. We employ particle image velocimetry to measure the strain rate, and compute the stress from the pressure drop along the channel, to investigate the local stress-strain relationships in a flowing foam.

1Supported by DOE Office of Basic Energy Sciences, grant DE-FG02-06ER46298

9:36AM P14.00009 Effective temperature of a sheared foam. DANIEL VALDEZ-BALDERAS, University of Rochester, PETER OLSSON, Umea University, STEPHEN TEITEL, University of Rochester — We perform computer simulations of a model for an overdamped, sheared foam in two dimensions at zero temperature. We measure an effective temperature with the use of an embedded oscillator, in manner analogous to experiments done by Abate and Durian on a different system [arXiv:0806.0765v2]. Our oscillator is one of the bubbles in the foam, which, in addition to its interaction with other bubbles, is also subject to a harmonic potential. We define an effective temperature based on the fluctuations in the position of the oscillator. We compare our results to the effective temperatures computed with the use of measurements of the fluctuations of the shear stress and fluctuations of the energy, respectively.

9:48AM P14.00010 Realization spaces of bubble clusters and coarsening trajectories. BRYAN CHEN, RANDALL KAMIEN, University of Pennsylvania — In the search for a more unified description of the geometry of equilibrium foams, we study the space of all realizations of equilibrium bubble clusters of fixed topology. The geometry of foam is highly constrained due to the area minimization property - in two dimensions, this means that all interfaces must be portions of circles and interfaces intersect in threes at angles of 120°. This results in a finite dimensional space of bubble clusters, and the dynamics of coarsening via gas diffusion induces a vector flow on it. The boundaries and singularities of the realization space may be identified with topological transitions and instabilities in coarsening.

10:00AM P14.00011 Experimental studies of low-density fluid phases in tunable dipolar colloids. ANAND YETHIRAJ, NING LI, HUGH NEWMAN, MANUEL VALERA, IVAN SAIKA-VOIVOD, Memorial University — Experiments of low-density colloidal fluid phases in the presence of an external electric field are presented. We obtain angular order parameters as a function of the applied electric field. When plotted against a dimensionless dipole strength parameter, the order parameters for different particle sizes fall on a single curve, suggesting that colloids in a fluid phase in the presence of electric fields do indeed interact by an effective point dipolar interaction. We then explore the statistics of particle packings at low-density and extract the experimental compressibilities and equation of state for these dipolar colloids.

Wednesday, March 18, 2009 8:00AM - 11:00AM – Session P15 DFD: Biologically Inspired Physics: Swimming, Propulsion, Bio-fluids 316

8:00AM P15.00001 Swimming in a vortex street. SILAS ALBEN, Georgia Tech — Recent studies showed that a trout swimming in a cylinder wake can save energy by “slaloming” through a vortex street. We present a simple model using a flexible body with vortex sheets, and find swimming shapes which maximize output power and efficiency. We find analytic solutions and compare the optimal swimming phase between the body and vortices with previous experiments and numerics.

1NSF-DMS support is acknowledged.

8:24AM P15.00003 Collective locomotion of non-swimmers, ERIC LAUGA, University of California, San Diego (USA), DENIS BARTOLO, ESPCI (France) — To achieve propulsion at low Reynolds numbers, a swimmer (e.g. a biological cell such as a bacterium, or a spermatozoon) must deform its shape in time in a way that is not invariant under time-reversal symmetry (non-reciprocal); this is Purcell’s scallop theorem. We show here explicitly that there is no many-scallop theorem. Two active bodies undergoing reciprocal deformations - and therefore incapable of swimming when considered separately - can exploit hydrodynamic interaction to swim. If the bodies are polar, we also show that they experience effective long-range interactions. We derive our results analytically for a minimal dimers model, and generalize them to more complex geometries on the basis of symmetry and scaling arguments. Furthermore, we explain how such cooperative locomotion can be realized experimentally by shaking a collection of soft particles with a homogeneous external field, thereby making non-swimmers swim.

8:36AM P15.00004 Self-Assembled Magnetic Surface Swimmers: Theoretical Model†, IGOR ARANSON, MAXIM BELKIN, ALEXEY SNEZHKO, Argonne National Laboratory — The mechanisms of self-propulsion of living microorganisms are a fascinating phenomenon attracting enormous attention in the physics community. A new type of self-assembled micro-swimmers, magnetic snakes, is an excellent tool to model locomotion in a simple table-top experiment. The snakes self-assemble from a dispersion of magnetic microparticles suspended on the liquid-air interface and subjected to an alternating magnetic field. Formation and dynamics of these swimmers are captured in the framework of theoretical model coupling paradigm equation for the amplitude of surface waves, conservation law for the density of particles, and the Navier-Stokes equation for hydrodynamic flows. The results of continuum modeling are supported by hybrid molecular dynamics simulations of magnetic particles floating on the surface of fluid.

8:48AM P15.00005 Accumulation of microswimmers near surface due to steric confinement and rotational Brownian motion, GUANGLAI LI, JAY TANG, Brown University — Microscopic swimmers display some intriguing features dictated by Brownian motion, low Reynolds number fluid mechanics, and boundary confinement. We re-examine the reported accumulation of swimming bacteria or bull spermatozoa near the boundaries of a fluid chamber, and propose a kinetic model to explain how collision with surface, confinement and rotational Brownian motion give rise to the accumulation of micro-swimmers near a surface. In this model, an elongated microswimmer invariably travels parallel to the surface after hitting it from any incident angle. It then takes off and swims away from the surface after some time due to rotational Brownian motion. Based on this analysis, we obtain through computer simulation steady state density distributions that reproduce the ones measured for the small bacteria E coli and Caulobacter crescentus as well as for the much larger bull spermatozoa swimming near surfaces. These results suggest strongly that Brownian dynamics and surface confinement are the dominant factors for the accumulation of microswimmers near a surface.

9:00AM P15.00006 Modeling the Behavior of Self-Propelled Microcapsules, AMITABH BHATTACHARYA, Dept of Chemical Engg, University of Pittsburgh, O. BERK USTA, ANNA C. BALAZS, Dept of Chemical Engg, Univ Pittsburgh — Biological cells can perform complex tasks by signaling and moving autonomously in their environment. We study a system of self-propelled microcapsules, first proposed by Usta et al (2008), that mimics this process. It consists of a signaling and target microcapsule placed close to an adhesive substrate and immersed in fluid. The signaling microcapsule encases nanoparticles, which, when released, modifies the adhesive strength of the substrate. The adhesion gradients in the substrate, along with hydrodynamic interactions among the capsules, gives rise to a sustained motion of the microcapsules. In this work, we perform simulations (based on lattice Boltzmann method for the fluid and random walk simulation for nanoparticles) of several signal-target configurations, consisting of two or more rigid capsules. In particular, we examine a configuration consisting of a single signaling capsule pushing multiple target capsules in a single file. For a constant release rate of nanoparticles, the velocity of the train of capsules asymptotes to a constant value at large times. Using a low-order analytical model for this system, we find that there is a simple relationship between this asymptotic velocity and the parameters in the system (e.g. number of capsules, release rate of nanoparticles, viscosity of fluid, adhesive strength of substrate etc.).

9:12AM P15.00007 Mixing fluid by self-propelled objects, MAXIM BELKIN, Illinois Institute of Technology / Argonne National Lab, ALEXEY SNEZHKO, IGOR ARANSON, WAI-KWONG KWOK, Argonne National Lab — Magnetic microparticles suspended at the water-air interface and subjected to an ac external driving self-assemble into dynamic structures (magnetic snakes). The snakes are accompanied by four large hydrodynamic vortices. At high enough frequencies and amplitudes of driving the snakes transform into self-propelled swimmers. Moving erratically, these swimmers mix the surface of fluid at a very high rate. We performed detailed experimental studies of these self-organized mixing. We studied space and time correlation and diffusion process in such systems.

9:24AM P15.00008 Enskog-theory for stochastic models with self-propelled and passive particles, ALEMAYEHU GEBREMIHARI, THOMAS IHLE, Department of Physics, North Dakota State University — Macroscopic evolution equations for interacting many-body systems do not just “emerge”; they follow from microscopic laws. However, it is often difficult to quantitatively establish this link, especially for systems which cannot be described by a Hamiltonian and which do not have pairwise additive interactions. Therefore, the general form of the macroscopic equations is usually obtained by symmetry arguments. Here, using a particle-based model with discrete time evolution steps for fluid flow I show how the macroscopic transport equations can be rigorously derived from microscopic collision rules. The approach starts with the full N-particle Liouville equation and leads to a multi-particle Enskog-equation which is treated by a Chapman-Enskog expansion. No linearization or single-relaxation time approximation of the collision operator are needed. The obtained thermo-hydrodynamic equations show excellent agreement with previous numerical results. The same approach is used to study a simple model of self-propelled, swimming birds. This model was proposed by T. Vicsek et al. [Phys. Rev. Lett. 75 (1995) 1226]; it has “multi-particle collisions” where birds within some interaction range align their flying directions. I analytically analyze the collision-operator for small and large bird density, and derive the hydrodynamic equations for the density and velocity fields.

9:36AM P15.00009 The “caterpillar” simulation model for a biological filament1, AIMIE BAILEY, Imperial College London, CHRISTOPHER LOWE, Universiteit van Amsterdam, ADRIAN SUTTON, Imperial College London — We present a simulation model for an elastic filament in a viscous fluid, relevant for systems ranging from suspensions of paper pulp to micro-organism motility. It incorporates the Stokeslet treatment of the hydrodynamic force. We show that a non-arbitrary choice of the hydrodynamic radius is necessary to recover known dynamic behavior of a fiber with a finite cross-section. Our simulations explore configurations inaccessible by theory. We illustrate the utility of the model by considering the simple scenario of a charged filament in an electric field. Results suggest a circularly polarized electric field is a viable means for aligning microtubules in solution.

1 A.G.B. thanks the Thouron Award and the NSF Graduate Research Fellowship Program for support.

9:48AM P15.00010 Flow and nutrient transport through porous scaffolds used for the culture of bone cells in perfusion bioreactors1, 2, 3, DIMITRIOS PAPAVASSILIOU, The University of Oklahoma, ROMAN VORONO, VASSILIOS SIKAVITAS, The University of Oklahoma, SAMUEL VANGORDON — The goal is to understand via computation the behavior of the flow inside porous scaffolds that are used for bone tissue engineering. Fluid shear is an important stimulatory factor in preosteoblastic cells seeded in scaffolds and cultured under flow perfusion. A Lattice Boltzmann method has been employed to simulate the flow field within porous scaffolds obtained with high resolution micro-CT. Lagrangian methods have also been used to determine the nutrient dispersion inside the scaffolds. The shear stresses calculated inside the scaffold architecture indicate that the shear stresses experienced by cells inside the scaffold can vary by orders of magnitude. This is important when designing scaffolds for bone tissue engineering as it could effect the behavior of the scaffold. Moreover, cell detachment can occur when the fluid shear is too high, thus placing a limit on the stresses that a particular scaffold design should allow. The talk will address the methodology, the validation and the correlation of scaffold structure characteristics with the shear stresses and with the rate of mass transfer.

1 NSF (CBET-0700813) and TeraGrid support (TS080042)

10:00AM P15.00011 Instabilities and waves in thin films of living fluids, SUMITHRA SANKARARAMAN, SRIRAM RAMASWAMY — We formulate the thin-film hydrodynamics of a suspension of polar self-driven particles and show that it is prone to several instabilities through the interplay of activity, polarity and the existence of a free surface. Our approach extends, to self-propelling systems, the work of Ben Amar and Combettes [Phys Fluids 13 (2001) 1160] on thin-film nematics. Based on our estimates the instabilities should be seen in bacterial suspensions and the lamellipodium, and are potentially relevant to the morphology of biofilms. We suggest several experimental tests of our theory.

10:12AM P15.00012 Tuning inter-virus interactions in natural aquatic environments, NATHAN W. SCHMIDT, Department of Physics, University of Illinois, Urbana-Champaign, ANDREW K. UDIT, Department of Chemistry, Scripps Research Institute, LEONARDO GUTIERREZ, THANH H. (HELEN) NGUYEN, Civil and Bioengineering, University of Illinois, Urbana-Champaign, M.G. FINN, Department of Chemistry, Scripps Research Institute, GERARD C.L. VONG, Department of Materials Science and Engineering, University of Illinois, Urbana-Champaign — Polymeric natural organic matter (NOM) originating from plants and animals is ubiquitous in natural aquatic environments. Many water-borne pathogens, including viruses, readily associate with NOM, which has a statistic distribution of charged and hydrophobic groups. Virus-NOM association influences the transport of viruses in groundwater environments, but little is known about this interaction, or how NOM can induce new inter-virus interactions. To better understand the interaction between NOM and aqueous contaminants, we use the MS2 and Qbeta viruses (diameters ~ 27nm) as surrogate water-borne pathogens. Smal Angle X-Ray Scattering is used to characterize the inter-particle interaction between viruses over a range of NOM concentrations and different salt types and concentrations.

10:24AM P15.00013 Computational studies on characteristic fluid behavior in the stented cerebral aneurysm, MIKI HIRABAYASHI1, University of Geneva, MAKOTO OHTA2, DANIEL A. RÜFENACHT3, Hospital University of Geneva, BASTIEN CHOPARD, University of Geneva — We present a computational analysis of the fluid behavior in the stented aneurysm. It is important to reveal the complex mechanism of the velocity reduction of the flow in the stented aneurysm in order to design the effective stent, which is a tubular mesh of wires placed for the treatment of the cerebral aneurysm. To understand the effect of a stent we already proposed a qualitative analysis of the flow pattern in the stented aneurysm. Here we present a quantitative analysis of the transition of the pressure and the shear stress caused by the changes of the flow pattern to verify the velocity reduction mechanism of the stent. We expect that our study will lead to a new suggestion for the effective treatment of the cerebral aneurysm by the stent.

10:36AM P15.00014 Run length is the dimension that characterizes path integrals useful for designing passive bacterial pumps1, DAVID LIAO, GUILLAUME LAMBERT, Department of Physics, Princeton University, Princeton, NJ 08544, PETER GILADAJA, Delft University of Technology, C.J. Delft, The Netherlands, ROBERT AUSTIN, Department of Physics, Princeton University, Princeton, NJ 08544 — Asymmetric funnels have been used as passive pumps to concentrate E. coli in nanofabricated devices (Austin 2007). Funnel geometry changes pump efficiency, which could be important when driving cell sorters (Whitesides 2008). The large set of funnel geometries that could be considered when designing pumps motivated us to derive a path-integral-like formula to predict the flux produced by arbitrary funnel geometries. We applied this equation to a two-dimensional wedge-shaped funnel. Model and experiment agree that the steady-state ratio between concentrations on two sides of a funnel open to 60° is 3 when the aperture is one fifth the bacterial run length and 1 when the aperture is 16 times the run length, an example of how the run length here has a role loosely analogous to the wavelength in quantum mechanical path integrals.

10:48AM P15.00015 Selective transport through nano-channels: do we understand it?, ANTON ZILMAN, Los Alamos National Laboratory, T. JOVANOVIC-TALISMAN, B. CHAIT, M. ROUT, S. DI TALIA, M. MAGNASCO, Rockefeller University — Functioning of living cells requires selective molecular transport, which is provided by transport channels that are able to selectively transport certain molecular species while filtering others, even similar ones. Such channels can selectively transport their specific molecules in the presence of vast amounts of non-specific competition. In many cases, efficient and selective transport occurs without direct input of metabolic energy and without transitions from an ‘open’ to a ‘closed’ state during the transport event. Examples include selective permeability of porins and transport through the nuclear pore complex. Mechanisms of selectivity of such channels have inspired design of artificial selective nano-channels, which mimic the function of selective biological channels. Mechanisms of selectivity of such nano-channels are still unknown. I present a theoretical model to explain the selectivity of transport through nano-channels, which contains only the essentials of stochastic kinetics inside the channel. The theory provides a mechanism for selectivity based on the differences in the kinetics of transport through the channel between different molecules. The theory explains how the specific molecules are able to filter out the non-specific competitors - and proposes a mechanism for sharp molecular discrimination. The theoretical predictions account for previous experimental results and have been verified in ongoing experiments.
Wednesday, March 18, 2009 8:00AM - 10:00AM –
Session P16 DAMOP: Solid Helium: Theory 317

8:00AM P16.00001 Simulating the Melting Transition of Helium in Two Dimensions , KEOLA WIERSCHEN, MARTECH & Department of Physics, Florida State University, EFSTRATIOS MANOUSAKIS, MARTECH & Department of Physics, Florida State University and Department of Physics, University of Athens, Greece — We study the melting behavior of helium in two dimensions with the path integral Monte Carlo method. Two dimensional melting theory predicts two melting transitions: solid to hexatic and hexatic to isotropic liquid, described by a loss of translational and orientational order, respectively. We calculate the translational and orientational order parameters, and use finite size scaling to determine the two melting transitions in the thermodynamic limit. We also study the superfluid/normal phase boundary of 2D helium relative to the above mentioned two stage melting boundaries.

8:12AM P16.00002 Superfluid networks with mesoscopic structure as models of supersolid 4He , BURCU YUCESOY, JON MACHTA, NIKOLAI PROKOF’EV, BORIS SVISTUNOV, U. Massachusetts Amherst — One proposal for understanding supersolidity is that grain boundaries and/or defect lines in solid 4He may support superfluidity. To understand the consequences of this proposal, we carry out simulations of the XY model with mesoscale structure corresponding to grain boundaries and/or defect lines. In the absence of disorder, we find a sharp phase transition unlike the gradual transition seen in experiments on supersolids. However, with disorder we find results that are qualitatively similar to the experiments.

8:24AM P16.00003 Absence of Dislocation Quantum Roughening in Solid 4He , DARYA ALENIKAVA, EUGENE DZEDZITS, ANATOLY KUKLOV, CSI, CUNY, DAVID SCHMELTZER, CCNY, CUNY — Dislocations in quantum crystals are shown to be smooth at zero temperature because of the effective Coulomb-type interaction between kinks induced by exchange of bulk phonons. We provide heuristic Kosterlitz-Thouless and Renormalization Group arguments against quantum roughening and confirm them by Monte Carlo simulations of the effective model of edge dislocation moving in its gliding plane - a quantum string (or classical membrane in d = 2) subjected to periodic Peierls potential and Coulomb-type interaction. Simulations of such Sine-Gordon type action have been conducted in the Villain approximation in terms of the J-current formulation. Renormalized stiffness as a function of the long-range interaction strength C and dislocation length L is shown to be described by a master curve $F(C/L, x)$, where $F(x) \to 0$, as $x \to \infty$. We also discuss a mechanism of suppression of superfluidity along the dislocation core by thermal kinks and show that it leads to locking in of the mechanical and superfluid responses at finite temperature, which is consistent with the recent experiment of Day and Beamish (Nature 450, 853 (2007)).

8:36AM P16.00004 Classical roughening of dislocations and the effect of shear modulus softening in solid 4He , EUGENE DZEDZITS, DARYA ALENIKAVA, ANATOLY KUKLOV, CSI, CUNY, DAVID SCHMELTZER, CCNY, CUNY — We propose that shear modulus $\mu(T)$ softening with increasing temperature $T$ observed by Day and Beamish [1] is due to a crossover experienced by dislocations from quantum smooth to classically rough state in the Peierls potential. Quantum dislocation is described by the Sine-Gordon model in dimensions $d = 1 + 1$ with long-range interactions between kinks (induced by exchanging bulk phonons). Monte Carlo simulations of this model show that finite $T$ response on external stress can fit well the data $\mu(T)$ [1] for the parameters typical for 4He. We compare this model with the one proposed in Ref. [1]: the 4He impurities boiling off from the dislocations. Good fit of $\mu(T)$ cannot be achieved within this model for realistic values of the dislocation densities and relative fractions of 4He atoms. [1] J. Day and J. Beamish, Nature 450, 853(2007)

8:48AM P16.00005 Quantum Glass in Solid He71 , ALEXANDER BALATSKY, MATTHIAS GRAF, LANL — Recent discovery of a possible supersolid state by Kim and Chan has stimulated an active debate about true nature of a low temperature state of solid 4He. We will discuss possible glassy component that could be present in solid 4He. We will focus on i) the role of tunneling systems (TS) as a component that freezes out at lowest temperatures and ii) interactions between TS. We will address possible quantum effects and the role of TS statistics in solid 4He vs solid 3He-4He mixtures. Implications for the torsional oscillator and for thermodynamics will be discussed as well.

2 Work Supported by US DOE

9:00AM P16.00006 The glassy response of torsion oscillators of solid 4He , MATTHIAS J. GRAF, LANL, ZOHAR NUSSINOV, WUSTL, ALEXANDER V. BALATSKY, LANL — We have calculated the glassy response of a torsional oscillator filled with solid 4He assuming a phenomenological glass model. Making only a few assumptions about the distribution of glassy relaxation times in a small subsystem of otherwise rigid solid 4He, we can account for the bulk of the magnitude of the observed period shift and dissipation peak as reported in several torsion oscillator experiments. The glass model places stringent constraints on dynamic and thermodynamic responses of solid 4He and the magnitude of a possible supersolid phase. We also discuss the implications for a superglass state proposed recently by the Cornell group.

3 Supported by parts by LDRD of LANL and CMI of WUSTL.

9:12AM P16.00007 A ‘Superglass’ State in Solid 4He , BENJAMIN HUNT, ETHAN PRATT, VIKRAM GADAGKAR, Cornell University, MINORU YAMASHITA, Kyoto University, ALEXANDER V. BALATSKY, T-Division, Center for Integrated Nanotechnologies, Los Alamos National Lab, J. C. DAVIS, Cornell University, Brookhaven National Laboratory, University of St Andrews — We study the relaxation dynamics of both the resonance frequency $f(T)$ and the dissipation rate $D(T) = Q^{-1}(T)$ of a torsional oscillator (TO) containing solid 4He. Abruptly at the temperature $T^*$ characteristic of the proposed supersolid phase, the relaxation times within $f(T)$ and $D(T)$ begin to increase precipitously together. Moreover, for all $T < T^*$, relaxation processes in both $D(T)$ and a component of $f(T)$ exhibit a synchronized ultra-slow evolution towards equilibrium and strong thermal hysteresis. We demonstrate that, while reminiscent of glassy dynamics, these phenomena are quantitatively inconsistent with a simple freeze-out transition because the variation in $f$ is far too large. We conclude that, if solid 4He exhibits a superfluid component, this system represents a new form of quantum matter – a complex supersolid in which a crystalline excitation exhibiting glassy dynamics controls the superfluid phase stiffness.

We model the torsional oscillator experiments by using the Kelvin-Voigt model of viscoelasticity for solid $^3$He [1]. Recent heat capacity experiments on solid $^4$He [2] show a peak in the specific heat which is interpreted as the signature of the supersolid transition. We pursue an alternative explanation for the heat capacity feature in which $^3$He impurities desorb from dislocations in solid $^4$He; the peak temperature scales with the binding energy of $^3$He to dislocations in $^4$He. Within a continuum elastic model for solid $^4$He, we make quantum mechanical estimates for the binding energy, using a combination of variational and numerical methods. We find for a short distance cut-off of one lattice constant of $^4$He, the binding energy is about 70 mK for edge and 60 mK for a screw dislocation. [1] X. Lin, A. C. Clark, and M. H. W. Chan, Nature 449, 1025 (2007).

8:36AM P17.00004 Quantum multiobservable control . RAJ CHAKRABARTI, Princeton University, REBINDING WU, Tsinghua University, HERSHEYEL RABITZ, Princeton University — We present deterministic algorithms for the simultaneous control of an arbitrary number of quantum observables. Unlike optimal control approaches based on cost function optimization, quantum multiobservable tracking control (MOTC) is capable of tracking predetermined homotopic trajectories to target expectation values in the space of multiobservables. The convergence of these algorithms is facilitated by the favorable critical topology of quantum control landscapes. Fundamental properties of quantum multiobservable control landscapes that underlie the efficiency of MOTC, including the multiobservable controllability Gramian, are introduced. The effects of multiple control objectives on the structure and complexity of optimal fields are examined. With minor modifications, the techniques described herein can be applied to general quantum multiobjective control problems.

8:48AM P17.00005 Quantum speed limit and optimal control . TOMMASO CANEVA, International School for Advanced Studies (SISSA), Via Beirut 2-4, I-34014 Trieste, Italy, MICHAEL MURPHY, TOMMASO CALARCO, Institut für Quanteninformationsverarbeitung, Universität Ulm, D-89069 Ulm, Germany, ROSARIO FAZIO, NEST-CNR-INFN & Scuola Normale Superiore, Piazza dei Cavalieri 7, I-56126 Pisa, Italy, SIMONE MONTANGER, Institut für Quanteninformationsverarbeitung, Universität Ulm, D-89069 Ulm, Germany, VITTORIO GIOVANETTI, NEST-CNR-INFN & Scuola Normale Superiore, Piazza dei Cavalieri 7, I-56126 Pisa, Italy, GIUSEPPE E. SANTORO, International School for Advanced Studies (SISSA), Via Beirut 2-4, I-34014 Trieste, Italy — The Heisenberg uncertainty principle, $\Delta E \Delta t \geq \hbar$, implies that a system cannot pass through distinguishable, i.e. orthogonal, states within arbitrarily short time. In the case of a time-independent Hamiltonian, the presence of this ultimate bound has been well established and summarized in the concept of a maximum allowed velocity, called quantum speed limit (QSL). On other hand for a time-dependent Hamiltonian the problem started to be addressed only very recently and is still open. Optimal control theory offers a valuable tool to explore this issue: we test its performance in two paradigmatic cases, Landau-Zener model and transfer of information along a chain of coupled spins, and show that the results are compatible with the ultimate limits enabled by quantum mechanics.

9:00AM P17.00006 Performance Gains for Superconducting Qubits by Means of Optimal Control Theory1. ROBERT ROLOFF, WALTER POETZ, Karl-Franzens-Universitaet Graz — Superconducting circuits are promising candidates for the successful implementation of qubit-arrays and qubit-gates within solid-state systems. However, despite recent progress within coherent control of charge, phase and flux qubits, considerable improvement in gate fidelities is needed to build large-scale quantum information processing devices. We present an optimal control scheme based on process tomography, capable of taking into account relaxation, dephasing and unwanted state-leakage within the qubit (array). We apply this theory to explore the performance limits of Josephson charge qubits within current experimental means. Environmental effects, as well as state-leakage, are modeled microscopically, using a fully quantum mechanical description and taking into account $1/f$ and Ohmic fluctuations based on experimental noise spectra. Within time-optimal control theory, we show that under typical conditions gate fidelities of $F = 1 - 10^{-3}$ should be possible for a Josephson charge qubit. 1The authors wish to acknowledge financial support of this work by FWF Project P18829.

9:12AM P17.00007 Towards non-adiabatic quantum control of a superconducting qubit . JONAS BYLANDER2, MARK S. RUDNER1, ANDREY V. SHYTOV2, SERGIO O. VALENZUELA1, DAVID M. BURNS1, KARL K. BERGGREN1, LEONID S. LEVITOV1, WILLIAM D. OLIVER1. 1Massachusetts Institute of Technology, 2University of Utah — Transitions in a qubit driven through an energy-level avoided crossing can be controlled by carefully engineering the driving protocol. With the driving rate chosen to optimize the coupling strength, an arbitrary rotation of a qubit’s quantum state on the Bloch sphere can be performed. This regime, if realized experimentally, may lead to fast quantum-logic gates with times of operation much shorter than those achieved by using Rabi transition-based protocols. We have performed an experiment with a superconducting persistent-current qubit in the non-adiabatic regime, driven by a large-amplitude radio-frequency field. By applying a waveform consisting of two harmonic components generated by a digital source, we demonstrate a mapping between the amplitude and phase of the harmonics produced at the source and those received by the device. This mapping allows us to image the actual waveform at the device and accurately determine the desired time dependence. Our method constitutes a step towards non-adiabatic control with arbitrary waveforms.

9:24AM P17.00008 Universal quantum control of two electron spin qubits via dynamic nuclear polarization . HENDRIK BLOHM, SANDRA FOLETTI, Harvard University, DIANA MAHALU, VLADIMIR UMANSKY, Weizmann Institute of Science, AMIR YACOBY, Harvard University — Encoding a single logical qubit in the collective spin states of two electrons in a double quantum dot can provide sub-nanosecond electrically controlled gates that are fast enough to refocus dephasing due to slow fluctuations of the hyperfine field from the nuclei of the host material [1]. In this work, we experimentally demonstrate full quantum control of a GaAs two electron logical spin qubit. One fast electrical control axis resulting from coherently exchanging the two electrons has already been demonstrated [2]. We achieve coherent evolution around a second axis caused by a difference in the nuclear hyperfine fields felt by the two electrons. This field difference is obtained by dynamically polarizing the Ga and As nuclei by transferring spin from the electrons to the nuclei. It can reach up to several hundred mT and can be maintained in a steady state. We demonstrate rotations around this axis with a programmable frequency that can exceed 1 GHz. Using quantum state tomography enabled by both control axes, we characterize the evolution of the qubit state around a fixed but tunable combined axis. Our results establish full electrical quantum control at the single qubit level with gate times of a few nanoseconds. [1] Taylor et al., Nature Physics 1, 177 (2005). [2] Petta et al. Science 309, 2180 (2005).

9:36AM P17.00009 Control of exchange coupling in Si double quantum dots1. DAMITRIE CULCER, L. CYWINSKI, QIUZI LI, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park MD 20742 — We determine the exchange coupling in a Si double quantum dot in the Heitler-London approximation. Qubit manipulation in bulk Si is hindered by the sixfold valley degeneracy of conduction band electrons which causes the exchange interaction between qubits to oscillate as a function of their separation. We demonstrate that in quantum dots these oscillations are suppressed by quantum confinement. We determine the dependence of the exchange coupling on the barrier potential between the dots and examine the role of charge fluctuations. Our results suggest that together with long Si spin lifetimes Si quantum dots could lead to improved control of spin qubits. Within the Heitler-London approximation the work presented is completely general and the results are valid for any ground state. 1Work supported by LPS-NSA.
9:48AM P17.00010 Optimal experiment design for parameter estimation as applied to dipole- and exchange-coupled qubits\textsuperscript{1}, KEVIN YOUNG, MOHAN SAROVAR, BIRGITTA WHALEY, University of California - Berkeley, ROBERT KOSUT, SC Solutions — We consider the problem of quantum parameter estimation with the constraint that all measurements and initial states are separable. Two qubits are presumed coupled through the dipole and exchange interactions. The resulting Hamiltonian generates a unitary evolution which, when combined with arbitrary single-qubit operations, contributes to a universal set of quantum gates. However, while the functional form of the Hamiltonian is known, a particular experimental realization depends on several free parameters - in this case, the position vector relating the two qubits and the magnitude of the exchange interaction. We use the Cramer-Rao bound on the variance of a point estimator to construct the optimal series of experiments to estimate these free parameters. Our method of transforming the constrained optimal estimation problem into a convex optimization is powerful and widely applicable to other systems.

\textsuperscript{1}Supported by NSF Grant No. MOD713106A

10:00AM P17.00011 Measurement of the nonadiabatically-induced coherent time evolution of a single-electron wavefunction in a surface acoustic wave dynamic quantum dot , ADAM THORN, MASAYA KATAOKA, MICHAEL ASTLEY, University of Cambridge, UK, DANIEL OI, University of Strathclyde, UK, CRISPIN BARNES, CHRIS FORD, DAVE ANDERSON, GEB JONES, IAN FARRER, DAVE RITCHIE, MICHAEL PEPPER, University of Cambridge, UK — Observation of coherent single-electron dynamics is severely limited by experimental bandwidth. We present a method to overcome this using moving quantum dots defined by surface acoustic waves. Each dot holds a single electron, and travels through a static potential landscape. When the dot moves abruptly between regions of different confinement, the electron is excited into a superposition of states, and oscillates unitarily from side to side. These oscillations are measured almost non-invasively, by allowing a small amount of tunnelling out of the dot each time the wavefunction approaches a tunnel barrier. We have modelled this in detail by solving the single-particle time-dependent Schrödinger equation for a realistic potential, and find good agreement between the measurements and the simulations.

10:12AM P17.00012 Weak measurement of a solid-state qubit revealed in low-frequency noise\textsuperscript{2}, ALEXANDER KOROTKOV, University of California, Riverside — Weak quantum measurement becomes a subject of experimental study with solid-state qubits. Partial collapse, quantum uncollapsing, and persistent Rabi oscillations have been already demonstrated with superconducting qubits by the UCSB and Saclay groups. Now we propose an experiment, in which the features of a weak quantum measurement are revealed in the low-frequency noise of the detector signal. (Here we mean a frequency much lower than the Rabi frequency, though sufficiently high to avoid 1/f noise.) The idea is to use two detectors measuring the same qubit, so that one detector collapses the qubit, while the other detector senses the result of the collapse. Then the cross-correlation of low-frequency noises in outputs of the two detectors carries information about the collapse process. The experiment can be realized with superconducting or semiconductor qubits.

\textsuperscript{2}Supported by NSA/IARPA/ARO grant

10:24AM P17.00013 Error Accounting in Electron Counting Experiments\textsuperscript{1}, MICHAEL WULF, ALEXANDER B. ZORIN, Physikalisch Technische Bundesanstalt — Electron counting experiments attempt to provide a current of a known number of electrons per unit time. We propose architectures utilizing a few readily available electron-pumps or turnstiles with error rates of 1 part in 10\textsuperscript{8} with common sensitive electrometers to achieve the desirable accuracy of 1 part in 10\textsuperscript{4}. This is achieved not by counting electrons but by counting the errors of individual devices; these are less frequent and therefore readily recognized and then accounted for. We thereby ease the route towards quantum based standards of current and capacitance.

\textsuperscript{1}Supported in part by the EU under projects EuroSQIP and REUNIAM.

10:36AM P17.00014 High-fidelity universal quantum gates through quantum interference , FRANK GAITAN, Southern Illinois University, RAN LI — Numerical simulation results are presented which suggest that a class of non-adiabatic rapid passage sweeps first realized experimentally in 1991, and which give rise to controllable quantum interference effects observed in 2003 using NMR, should be capable of implementing a universal set of quantum gates $g$ that operate with high-fidelity. $g$ consists of the Hadamard and NOT gates, together with variants of the phase, $\pi/8$, and controlled-phase gates. Sweep parameter values are provided which simulations indicate will produce the different gates in $g$, and for each gate, yield an error probability $P_e < 10^{-4}$. These simulations suggest that the universal gate set produced by these rapid passage sweeps show promise as possible elements of a fault-tolerant scheme for quantum computing. We discuss current challenges facing experimental implementation of this approach to universal quantum computing.

10:48AM P17.00015 Dynamics of Quantum Control for Bosons in Optical Lattices\textsuperscript{1}, ANALABHA ROY, Graduate Student, University of Texas at Austin, LINDA REICHL, Director, CQS University of Texas at Austin — We investigate the possibility of quantum control in an ultracold atom Bose gas in an optical lattice by looking at numerical simulations of the dynamics of controlled excitations in these systems. These excitations are mediated by pulsed signals that cause Stimulated Raman Adiabatic passage (STIRAP) from the ground state to excited states. The transition to chaos affects the quantum dynamics of such systems as has been demonstrated for single-particle and mesoscopic-systems in optical potentials. We determine the influence of Bose statistics on this dynamics, as well as the effects of controlling quantum phase transitions in this manner for interacting cold atom systems.

\textsuperscript{1}The authors thank the Texas Advanced Computing Center (T.A.C.C.) at the University of Texas at Austin for the use of their high-performance distributed computing grid.

Wednesday, March 18, 2009 8:00AM - 11:00AM – Session P18 DPOLY: Bulk Block Copolymers II 319

8:00AM P18.00001 Directed Self-Assembly of Cadmium Selenide Nanocrystals in Conjugated Rod-Coil Block Copolymers , B. L. MCCULLOCH, Dept of Chemical Engineering, University of California-Berkeley, J. URBAN, Molecular Foundry, Lawrence Berkeley National Laboratory, R. A. SEGALMAN, Dept of Chemical Engineering, University of California-Berkeley — Semiconducting polymer/nanocrystal composites are attractive for many applications; however their performance relies crucially on nanoscale morphology. We demonstrate that a conjugated rod-coil diblock copolymer can be used both to absorb light and template the location of CdSe nanocrystals. A combination of the liquid crystallinity of the conjugated rod block and the interactions of the nanocrystal ligand coat with the block copolymer control self-assembly. For example, incorporation of the nanocrystal in the rod nanodomain disrupts liquid crystallinity. In the case of a poly(alkoxy-phenylene vinylene-b-2-vinyl pyridine) (PPV-b- P2VP) block copolymer and CdSe nanocrystals, self-assembly leads to a bulk lamellar structure on the 10nm length scale. Small angle X-ray scattering confirms the addition of nanocrystals swells the domain size. We demonstrate via transmission electron microscopy the nanocrystals reside preferentially in the P2VP domain, presumably due to the strong nanocrystal surface interactions with polar P2VP and exclusion effects of the crystalline PPV phase.
8:24AM P18.00003 Nano-porous Poly(3-hexylthiophene) films: A novel route to prepare bulk heterojunction photovoltaic devices, TIRTHA CHATTERJEE, KULANDAIVELU SIVANANDAN, CRAIG J. HAWKER, EDWARD J. KRAMER, Mitsubishi Chemicals-Center for Advanced Materials, Materials Research Laboratory, University of California, Santa Barbara, CA 93106 — Conjugated polymers are excellent candidates for use in low-cost electronics and photovoltaic applications. Bulk heterojunction (BHJ) morphologies are promising device architecture as the close proximity of the electron donor and acceptor micro-domains (with domain size comparable with the exciton diffusion length) facilitates the charge transport process. In order to achieve a well ordered BHJ architecture, poly(3-hexylthiophene) (P3HT) based rod-coil copolymers are synthesized where coil blocks are grafted to the P3HT chain through a cleavable linker. The linker and the attached sacrificial coil block can easily be cleaved and removed by chemical treatment leaving a rough nano-porous P3HT film. Scanning force microscopy and grazing incidence small angle X-ray scattering convincingly show the nano-pore formation. Further, depth profiling using dynamic secondary ion mass spectroscopy indicates that nano-pores probably penetrate the entire depth of the film (device thickness). Subsequently refilling of the nano-pores by electron transporting component (fullerene derivatives) provides the required device morphology.

8:36AM P18.00004 The Influence of Electric Fields on the Order-Disorder Transition Temperature of Block Copolymer Systems, HEIKO SCHOBERTH, Lehrstuhl fuer Physischale Chemie II, Universitaet Bayreuth, D-95440 Bayreuth, Germany, KRISTIN SCHMIDT, Materials Research Laboratory, University of California, Santa Barbara, CA 93106, USA, KERSTIN SCHMIDLER, ALEXANDER BÖKER, Lehrstuhl fuer Physischale Chemie II, Universitaet Bayreuth, D-95440 Bayreuth, Germany — We investigate the influence of electric fields on the phase behavior of diblock copolymers in concentrated solutions using synchrotron small-angle X-ray scattering (synchrotron SAXS). When heating the solutions through the order-disorder transition temperature $T_{ODT}$, we find a significant decrease in $T_{ODT}$ with increasing electric-field strength. In addition we found a temperature regime in which it is possible to switch between the mixed and phase separated state at constant temperature upon application of a moderate electric field.

3This work was carried out in the framework of the SFB 481 (TP A2) funded by the German Science Foundation (DFG). AB acknowledges financial support by the Lichtenberg-Program of the VolkswagenStiftung.

8:48AM P18.00005 Phase Behavior of Polystyrene-block-Poly(n-alkyl-ran-n’alkyl methacrylate) Copolymers, HONG CHUL MOON, JUNHAN CHO, Dankook University, JIN KON KIM, Pohang University of Science and Technology — The phase behavior of polystyrene-block-poly(n-butyl-ran-n’-hexyl) methacrylate copolymers and polystyrene-block-poly(n’-octyl-ran-methyl) methacrylate copolymers were investigated by using small angle X-ray scattering, birefringence and rheometry. When the total molecular weight and the composition of the random copolymers were judiciously controlled, the closed-loop phase behavior with both a lower disorder-to-order transition and an upper order-to-disorder transition was observed. These block copolymers exhibited excellent baroplasticity. The observed phase behavior was explained by a compressible mean field approach.

3This work was supported by Creative Research Initiative Program supported by KOSEF.

9:00AM P18.00006 Gas Pressure Effect on Phase Behavior of Deuterated Polystyrene-block-poly(n-pentyl methacrylate) Copolymers, HYE JEONG KIM, JIN KON KIM, Pohang University of Science and Technology, DU YEOL RYU, Yonsei University — The pressure effect of various gases on the phase transitions of deuterated polystyrene-block-poly(n-pentyl methacrylate) copolymer was investigated by small angle neutron scattering (SANS) and birefringence. With increasing helium gas pressure, the size of closed-loop consisting of both the lower disordered-to-ordered transition and the upper ordered-to-disordered transition was decreased, which is similar to the hydrostatic pressure effect. On the other hand, when nitrogen gas was used, the size of the closed-loop became larger with increasing pressure. These interesting results are explained by the binding energy calculation.

3This work was supported by Creative Research Initiative Program supported by KOSEF.

9:12AM P18.00007 Pressure Jump Studies of Block Copolymer Phase Transition in Selective Solvent, YONGSHENG LIU, RAMA BANSIL, Boston University, MILOS STEINHART, Institute of Macromolecular Chemistry, CZ Republic — Synchrotron based time-resolved small angle x-ray scattering (SAXS) was used to study the kinetics of the order-disorder transition (ODT) in a 39% (w/v) solution of a diblock copolymer of poly(styrene – isoprene) (SI 18-12) in diethylphthalate (DEP), a selective solvent for the PS block using pressure jump methods. The results show that the ODT temperature increases at about 20°/kbar with pressure. Time resolved pressure jump SAXS experiments were done to study the kinetics of disorder to BCC phase transition and the reverse transition. Pressure jump from 100 bar to 800 bar at 108 C from disordered state displayed a BCC structure at 30 seconds. Results of experiments with solvent viscosity increased by adding low molecular weight polystyrene will also be presented.

3Supported by NSF DMR. RB acknowledges IR/D support of NSF.

9:24AM P18.00008 Self-assembled Oniontype Multiferroic Nanostructures, SHENQIANG REN, ROBERT M. BRIBER, MANFRED WUTTIG, Dept. of Mater. Sci. & Engi. University of Maryland, College Park — Spontaneously self-assembled oniontype multiferroic nanostructures based on block copolymers as templating materials are reported. Diblock copolymer containing two different magnetoelectric precursors separately segregated to the two microdomains have been shown to form well-ordered templated lamellar structures. Onion-type multilamellar ordered multiferroic (PZT/CeFe$_2$O$_4$) nanostructures have been induced by room temperature solvent annealing in a magnetic field oriented perpendicular to the plane of the film. The evolution of the onion-like microstructure has been characterized by AFM, MFM, and TEM. The structure retains lamellar periodicity observed at zero field. The onion structure is superparamagnetic above and antiferromagnetic below the blocking temperature. This templating process opens a route for the development of materials that will contribute to novel future technologies. Polymers can act as hosts for metallic and dielectric nanoparticles as well as organic molecules, resulting in nanocomposites with combinations of properties not available by other means. Periodic structural assemblies are of particular interest, due to their interesting interactions with waves: especially light and mechanical waves. Progress in this exciting area requires excellent control of structure formation. A top-down, bottom-up approach, using interference lithography and self assembly is demonstrating good success in fabricating the requisite structures and desired properties for photonics and phononics.

9:36AM P18.00009 Periodic Polymers for PhoXonics, EDWIN THOMAS, Department of Materials Science and Engineering, Massachusetts Institute of Technology — Exploiting the size and shape dependence of material properties and accessing multi-functionality holds great promise for the development of materials that will contribute to novel future technologies. Polymers can act as hosts for metallic and dielectric nanoparticles as well as organic molecules, resulting in nanocomposites with combinations of properties not available by other means. Periodic structural assemblies of particular interest, due to their interesting interactions with waves: especially light and mechanical waves. Progress in this exciting area requires excellent control of structure formation. A top-down, bottom-up approach, using interference lithography and self assembly is demonstrating good success in fabricating the requisite structures and desired properties for photonics and phononics.
9:48AM P18.00010 Hydration and phase separation of polyethylene glycol in copolymers of tyrosine derived carbonates, N. SANJEEVA MURTHY, Rutgers University, WENJIE WANG, University of Vermont, JOACHIM KOHN, Rutgers University — Effect of PEG fraction and its block size on the temperature-induced phase transitions and the hydration-induced phase separation were investigated in a copolymer of desaminotyrosyl tyrosine ethyl ester (DTE) and PEG using simultaneous SAXS/WAXS/DSC. The PEG segments crystallized when the block size was at least 2000 Daltons and present at ~ 40 wt%, and raised the Tg of the polymer by ~ 15 °C. The PEG blocks in dry polymers with up to 50 wt% PEG, even when crystalline, were found to be uniformly distributed without evidence of phase separation at 10 nm length scales. The non-iodinated PEG-rich sample with 30 mole% PEG20k showed the lower critical solution temperature (LCST) behavior with PEG blocks forming a separate phase above ~21 °C. In the iodinated version of this polymer, the PEG20k blocks were phase separated in the solid phase. In all samples, whether PEG was crystalline or not, hydration induced PEG to separate into 15 nm hydrated domains. Phase behavior was dependent on whether poly(DTE) or the PEG was the major (matrix) phase. Changes in the mobility of the chains brought about by water-mediated hydrogen-bonding, and modulated by heat, appear to be the common underlying explanation for the range of observed phase behavior.

10:00AM P18.00011 Robustness of Pluronic Block Copolymer Nanostructure to Structural Changes in Dispersed Nanoparticles, THERESA A. LAFOLLETTE, LYNN M. WALKER, Carnegie Mellon University — Thermoreversible block copolymers [(PEO)n-(PPO)m-(PEO)n; trade name Pluronic] self assemble into ordered micelle gels. Nanoparticles (3-10nm) are templated in the interstitial spaces of Pluronic micelle gels to form nanocomposite systems. Globular hydrophilic proteins have served as model monodisperse nanoparticles in this work. We have shown that these proteins are templated in the interstitial sites of the cubic packed micelle gels at room temperature. By raising the temperature, the proteins are denatured to study the robustness of the micelle gel to structural changes due to the unfolded protein. Nanoscale structure is determined from small angle neutron scattering (SANS). It was expected that any change in the nanoparticle size would cause a change in the packing of the Pluronic micelle gel. However in SANS experiments, the FCC and BCC Pluronic templates show no nanoscale structural differences between a room temperature sample and a sample that has been heated to denature the protein and then cooled back to room temperature. There is a change in the template at longer length scales as evidenced by a low q upturn in the scattered intensity. The robustness of the micelle gel at different length scales will be discussed.

10:12AM P18.00012 Phase behavior of block copolymer nanocomposites, GEORGE PAPAKONSTANTOPOULOS, Arkema Inc., ANALYTICAL AND SYSTEMS, ARKEMA INC. TEAM — Incorporating nanoparticles in block copolymers can allow the creation of a material with modified properties. In addition, the control of the nanoparticle location in a nanometer scale, can lead to novel applications for these materials. Although, the phase behavior of block copolymers in the bulk is well established, the effects of nanoparticles on their phase behavior, especially under confinement, are not well understood. We carried out a systematic study to investigate the self-assembly of block copolymer-nanoparticle composites using a coarse grain model. These systems are studied in the bulk and under confinement. The dependence of the location and distribution of the nanoparticles within the block copolymer as a function of particle-polymer interaction, size and shape were examined.

10:24AM P18.00013 Effect of Chain Architecture on Nanoparticle Miscibility in Block Copolymer Nanocomposites, JESSICA LISKAT, HYUNG JU RYU, ILHEM F. HAKEM, Carnegie Mellon University, RANGOU SOFIA, POLITAKOS NIKOLAOS, MISICRONIS KONSTANTINOS, APOSTOLOS NGERPOULOS, University of Ioannina — This contribution will present a combined experimental and theoretical analysis of the effect of block copolymer chain architecture on the miscibility and morphology of enthalpically neutralized particle additives. The chain architecture is found to be a critical parameter in facilitating particle dispersion imposing both direct as well as indirect constraints on the particle distribution. Continuous block configurations (such as the bridged midblocks in triblock copolymers) are found to inhibit particle compatibilization. Interestingly, the particle miscibility is found to be strongly affected by the configuration of the block adjacent to particle-filled domains (indirect constraint). In particular, incompatibility is observed for high branching densities in the adjacent domains (such as miktoarm chain architectures). A mean-field model will be presented to rationalize this observation as a consequence of segmental crowding that counteracts changes in the layer dimensions induced by particle sequestration.

10:36AM P18.00014 Rheological and Mechanical Properties of Crosslinked Block Copolymer Nanofiber and Polystyrene Blends, SUNGWON MA, YONATHAN THIO, Georgia Institute of Technology — The mechanical and rheological properties of blends of crosslinked and uncrosslinked poly(styrene)-b-poly(isoprene) copolymer with commercially available polystyrene were studied. Cylindrical morphology of PS-b-PI copolymer was employed for generating nanofiber morphology. Cold vulcanization process using sulfur monochloride (S2Cl2) was used to preserve the morphology. Blends of uncrosslinked PS-b-PI copolymer with neat polystyrene were also prepared. Both blend samples were prepared by solvent casting method with the filler contents varying between 0.5 and 10 wt%. The mechanical and rheological properties were characterized and the microstructures of the fiber and the systems were imaged. The dynamic moduli (G' and G") of the crosslinked system increased with increasing the fiber content compared to the uncrosslinked system. The results were compared to the rheological model by fitting to Cross-Williamson. This blend study indicated critical volume concentration of nanofiber between 5 and 10 wt% of nanofiber content.

10:48AM P18.00015 Well Ordered Polymer Melts with Sub 5-Nanometer Domains upon Blending Surfactants with Selectively Associating Additives, VIKRAM DAGA, University of Massachusetts Amherst, VIJAY TIRUMALA, Polymers Division, NIST, JAMES WATKINS, University of Massachusetts Amherst — Applications employing block copolymers such as templating mesoporous inorganic structures and patterning would benefit from reduction in domain size formed in well-ordered block copolymer templates. The extent to which the domain size can be reduced is limited by the minimum required segregation strength, χN, where N denotes the size of block copolymer chains and the domain size. We have shown that disordered block copolymer surfactants with molar mass less than 15 kg/mol, can be made to undergo disorder-to-order transition by blending selectively associating homopolymers as well as small molecule additives with multi-point, non-ionic interactions. Blending with selectively associating additives result in an increase in segregation strength χN through an increase in apparent χ. The resulting domain sizes were found to be as low as 5 nm which is significantly lower than that seen for a typical block copolymer template.

Wednesday, March 18, 2009 8:00AM - 11:00AM — Session P19 DPOLY: The Physics of Polymer Nanocomposites: Properties 320

8:00AM P19.00001 Tuning optical properties of gold nanorods in polymer films through thermal reshaping, RUSSELL COMPOSTO, ERIC MILLS, YU LIU, University of Pennsylvania — The thermal reshaping of gold nanorods (NRs) in a poly(methyl methacrylate) (PMMA) nanocomposite film is controlled by UV-vis and TEM. To ensure dispersion, the NRs are modified with PEG brushes, and then dispersed in PMMA. Thermal annealing of the PMMA:NR film results in a blue shift of the longitudinal plasmon resonance, caused by a decrease in the length of the NR. The rate of the blue shift increases as temperature increases from 100 °C to 200 °C, and the longitudinal absorption peak approaches a constant value that scales linearly with temperature. We demonstrate a potential application by fabricating a device with a gradient in optical properties.

1 NSF/DMR and MRSEC Programs
8:12AM P19.00002 Quenching Photoluminescence in Single-Walled Carbon Nanotube/Copolymer Composite Materials, ANDREW SCHOCH, Material Science and Engineering Dept. Northwestern University, L. CATHERINE BRINSON, Mechanical Engineering Dept. Northwestern University, KENNETH R. SHULL, Material Science and Engineering Dept. Northwestern University — Single-walled carbon nanotubes (SWNTs) stabilized by A-B diblock and A-B-A triblock copolymers are excellent model systems for studying the relationship between nanotube dispersion and mechanical response. The SWNTs cannot be dispersed in the alcoholic solvent used here without the addition of copolymer. However, the B blocks are in good solvent conditions for all temperatures and the A blocks solvent quality decreases with decreasing temperature. This solvate quality difference drives the formation of micelles with A block cores at low temperatures. As verified by AFM, the micelles form homogeneous micelles in solutions by incorporating the SWNTs. The dispersion has also been verified with near-IR photoluminescence spectroscopy (NIR-PLS) and the mechanical properties of these materials have been examined with rheological methods. The elastic contribution to the shear modulus increases while at high temperatures which we attribute to an increase in the number of NT-NT contacts. We have attempted to verify this observation by simulating the high temperature environment in the NIR-PLS measurements and looking for quenching.

8:24AM P19.00003 Temperature measurements of inverse micelles coated in gold nanoparticles using fluorescence, CHAD DALEY, JAMES A. FORREST, RYAN SPELLER, TOEWS WILLIAM, PATRICK MCVEIGH, Dept. of Physics and Astronomy, University of Waterloo, TODD EMRICK, Dept. of Polymer Sciene and Engineering, UMass Amherst — When nanoparticles are subject to laser radiation they have the ability to efficiently absorb energy from the beam and transform this energy into heat. Photothermal therapy uses this phenomenon to irreparably damage tissue surrounding nanoparticle conjugates. Despite the promise of this technique, there is no consensus on the damage mechanism or even the local heating. Here we present an experiment designed to measure local temperatures achieved in such processes. Ligand covered Gold nanoparticles are used to stabilize inverse micelles containing fluorescence dye in the water component. The fluorescence intensity being temperature dependent provides us with a means of measuring the temperature of the micelles as a function of time immediately following a laser pulse.

8:36AM P19.00004 Magnetic and Optical anisotropy thiol-capped Au NPs embedded into a polymer, JOSE DE LA VENTA, MIGUEL ANGEL GARCIA, VIRGINIA BOUZAS, Materials Physics Dept. University Complutense, ANDREA PUCCI, GIACOMO RUGGERI, Chemistry and Industrial Chemistry Departmen. University of Pisa — The anisotropy at the nanoscale is achieved when the shape of the objects is not spherical such as in the case of nanorods, nanotubes or nanowires. However, when they are embedded in a macroscopic matrix, the random distribution destroys the anisotropy. In this work we study the possibility of induce optical and magnetic anisotropy in a system consisting of spherical thiol capped Au NPs embedded in a polymeric matrix. The ferromagnetic-like behavior arises from the bond between the Au-S atoms and the optical response is also highly dependent on these bonds. So, modifications in the environment and in these bonds could alter the behavior of the whole system. When the NPs are embedded in a polymeric matrix, which is stretched even 40 times in one direction, SQUID and UV/Vis measurements show that a macroscopic anisotropy in spite of the spherical shape of the NPs. EXAFS measurements confirm that there are modifications in the Au-S bonds along the stretched direction that are responsible of the induced macroscopic anisotropy.

8:48AM P19.00005 Stability of the double gyroid phase to nanoparticle polydispersity in polymer tethered nanosphere systems, CAROLYN PHILLIPS, CHRISTOPHER IACOVELLA, SHARON GLOTZER, University of Michigan — Recent simulations have shown that aggregating nanospheres functionalized with polymer “tethers” can self-assemble to form the double gyroid phase also seen in block copolymer and surfactant systems. Within the gyroid domain, the nanoparticles pack in icosahedral motifs, stabilizing the gyroid phase in a small region of the phase diagram[1]. We study the impact of nanoparticle polydispersity on the properties of the double gyroid phase [2]. Here we show that a low amount of polydispersity lowers the energy of the phase. A large amount of polydispersity raises the potential energy of the system, disrupts the icosahedral packing, and eventually, destabilizes the gyroid. A study of binary gyroids indicates that the inclusion of a small population of either smaller or larger nanospheres encourages low-energy icosahedral clusters. Using a new measure for determining the volume of a component in a microphase-separated system based on the Voronoi-tessellation, we show that polydispersity compacts the gyroid domain and lowers the average coordination of the nanospheres. [1] Iacovella, et al., PRE, 2007 [2] Phillips, et al., “Stability of the double gyroid phase to nanoparticle polydispersity in polymer tethered nanosphere systems, preprint.

9:00AM P19.00006 Experimental and computational investigation of percolation in complex polymer nanocomposites, DERRICK STEVENS, LORI DOWNEN, NCSU Dept. of Physics, RUSSELL GORG, NCSU Dept. of Textile Engineering, LAURA CLARKE, NCSU Dept. of Physics — The continuing development of polymer nanocomposites has led to increasingly complex morphology, such as the mats of composite nanofibers formed from electrospinning. The formation of particle networks within the composite volume that leads to enhanced properties, such as electrical conductivity, may be influenced by this complex sample geometry. In this work, experimental and computational efforts are utilized to understand and predict the percolation threshold (critical volume fraction) for two cases: single ultra-high aspect ratio fibers (where fiber diameter can be similar to the particle dimensions) and these same fibers arranged in a random mat with up to 80% porosity. 2D and 3D Monte Carlo simulations, modeled on the actual parameters of our experimental system [1], are utilized and the results are compared with our experimental findings. In particular, confinement to fibers increases the percolation threshold; however the multi-fiber pathways available in mats partially reduce this constraint [2]. [1] S.S. Ojha, D.R. Stevens, K. Stano, T. Hoffman, L.I. Clarke, R.E. Gorga, Macromolecules 41, 2509 (2008). [2] D.R. Stevens, L.I. Downen, L.I. Clarke, Phys. Rev. B in press (2008).

9:12AM P19.00007 Influence on Thermal Diffusivity through a Transformation of Nanotube-like Clay Platelets in Polymer Blends, SEONGCHAN PACK, TAKASHI KASHIWAGI, TADANORI KOGA, JONATHAN SOKOLOV, MIRIAM RAFAILOVICH, Department of Materials Science and Engineering, Stony Brook University — We have previously demonstrated that large aspect ratio nanoparticles such as clays or nanotubes can form in-situ grafts which become universal compatibilizing agents for polymer blends. Here we show how the same mechanism could be applied to producing flame retardant materials in the polymer matrix. In particular, the large aspect nanoclays prevent thermally induced phase segregation and disperse the flame retardants, which greatly decrease flammability and increase efficiency of the flame retardants during combustion due to a formation of ribbons-like structures. These structures could produce a larger thermal differential gradient between the two polymer phases, which could change a heat specific of the system during combustion. Therefore, a small addition of the nanoclays affects the huge reduction on heat release rate and the mass loss rates. Furthermore, using a small angle X-ray scattering (SAXS), a transmission electron microscopy (TEM), and a scanning electron microscopy (SEM) shows that the clay platelets could be transformed into tubular-like rods during combustion, which would increase of the thermal diffusivity in the polymer blend.
of Pennsylvania — The study of rod percolation behavior has resurfaced in recent years, because it explains electrical conductivity in polymer nanocomposites containing carbon nanotubes and metal nanowires. Common processing techniques result in fillers with L/D < 50, so traditional models, which are only strictly correct in the limit of L/D ~ ∞, are ineffective at predicting percolation in these systems. We present a simulation that constructs percolated networks of finite-aspect ratio rods and calculates their electrical conductivity. We will compare our simulation results with polymer composites containing silver nanowires with aspect ratios of ~10 and ~30. Finally, we will present the temperature-dependent electrical conductivity of these composites and interpret the results using the thermal expansion coefficients of polyethylene and silver. These materials act as “thermal switches,” wherein electrical conductivity of certain composites can be manipulated by several orders of magnitude over the temperature range from 80K-425 K.

Polymer Nanocomposites Made with Unmodified Graphite or Carbon Nanotubes: Role of Dispersion in Optimizing Mechanical and Thermal Properties and Electrical Conductivity

JUNICHI MASUDA, KATSUYUKI WAKABAYASHI, PHILIP BRUNNER, CYNTHIA PIERRE, JOHN TORKELSON, Northwestern University — Polymer nanocomposites made with carbon-based nanofiller have the potential to achieve unprecedented, multifunctional property enhancements in comparison with other nanocomposite systems. Here, we describe research in which we prepare nanocomposites with polymers that are not amenable to solution-based processing, such as polypyrrole and poly(ethylene terephthalate). Solid-state shear pulverization is used singly or in conjunction with melt processing to obtain well-dispersed polymer/graphite and polymer/carbon nanotube nanocomposites. We report record improvements in properties of unoriented films of polypyrrole nanocomposites, including Young’s modulus, crystallization rate, and thermal degradation temperature. We also characterize electrical conductivity of such nanocomposites and note that the dispersion characteristics necessary to achieve maximum mechanical and thermal properties differ from those needed to maximize electrical conductivity. The potential of and challenges with using unmodified graphite as a filler in polymer nanocomposites will be discussed.

Conductive Paper by LBL Assembly of PSS and ITO onto Wood Fibers and its Electrical Properties through Impedance Spectroscopy and I-AFM

CHUNQING PENG, YONATHAN THIO, ROSARIO GERHARDT, Georgia Institute of Technology — Conductive paper has been fabricated by layer-by-layer (LBL) assembly of polyelectrolytes and indium tin oxide (ITO) nanoparticles onto wood fibers, followed by traditional paper making method. The wood fibers were first coated with polyelectrolymeinime (PEI) and then LBL assembled with poly(sodium 4-styrenesulfonate) (PSS) and ITO for several bilayers. The AC electrical properties, measured for frequencies ranging from 0.01 Hz to 1 MHz, will be reported for the in-plane (IP) and through-the-thickness (TT) directions. With 10 bilayers of PSS/ITO assembly on wood fibers, the conductivity of as-prepared paper was improved by more than six orders of magnitude and reach to 5.2×10⁻⁸ S cm⁻¹ in IP direction and 1.9×10⁻⁸ S cm⁻¹ in TT direction. The percolation phenomenon of ITO nanoparticles through the handsheet in both directions was observed through current atomic force microscopy (I-AFM). By applying a bias voltage, either on one end of the paper stripes or on one side of the paper handsheet, the current can be detected on the other end of the paper stripes or on the other side of the paper handsheet. PEI can be used to modify the ITO suspension and significantly improve the LBL procedure. The mechanism of PEI modifying ITO colloidal suspension will be discussed.

Placement Control of Nanomaterial Arrays on Surface-Reconstructed Block Copolymer Thin Films

JEONG GON SON, WAN KI BAE, Seoul National University, HUIMAN KANG, PAUL F. NEALEY, University of Wisconsin-Madison, KOOKHEON CHAR, Seoul National University — Nanomaterials such as nanoparticles, quantum dots and nanorods/wires have recently attracted considerable attention not only because of their unique electronic, optical, and magnetic properties depending on their size and chemical structure but also due to their possible applications to optoelectronic devices, next-generation memory devices, and biological sensors. In order to take full advantage of these useful properties for highly integrated fabrication, precise control of such nanomaterials on patterned substrates is inevitably required. In this presentation, we demonstrate a straightforward and reproducible method for the placement of nanomaterials such as nanoparticles and nanorods on patterned PS-b-PMM block copolymer (BCP) thin films. This concept is based on the properties of surface-reconstructed BCP thin films, which could induce topographical nanopatterns induced by selective solvent vapor treatment without any etching process. The deposition conditions for high density nanomaterial patterns in the grooves of BCP nanopatterns were optimized. By treating the surface under electron beam irradiation, the pattern inversion of nanomaterial-containing BCP nanopatterns was also observed, which can be further processed to realize the dual nanomaterial patterning.

Confinement and Ordering of Au Nanorods in Polymer Films

MICHAEL J. A. HORE, ERIC MILLS, YU LIU, RUSSELL J. COMPOSTO, Department of Materials Science and Engineering, University of Pennsylvania — Ordered arrays of gold nanorods (Au NRs) possess interesting optical properties that might be utilized in future devices. Au NRs functionalized with a poly(ethylene glycol)-thiol brush are incorporated into homopolymer or block copolymer (BCP) films. NR distribution and orientational correlations are studied as a function of nanorod concentration and spacial confinement via Rutherford backscattering spectrometry (RBS) and transmission electron microscopy, respectively. In particular, differences in the degree of nanorod ordering are presented for PMMA homopolymer films (d ~ 45 nm) versus PS-b-PMM block copolymer films (L/2 ~ 40 nm), where higher ordering is seen in the case of BCP films. At moderate volume fractions of NRs, φ = 1% to 10%, the degree of ordering is moderate, and increases with increasing φ. However, coexistence between regions of higher ordering and isotropic orientations is observed. In addition to the planar confinement considered above, orientation of Au NRs confined to cylindrical P2VP domains is studied in PS-b-P2VP BCP films.

Carbon nanotubes nucleate the growth of graphitic layers during carbonization.of electrospun poly(acrylonitrile) nanofibers.

SABINA PRILUTSKY, YACHIN COHEN, EYAL ZUSSMAN, Technion, Israel — Hybrid nanofibers with varying concentration of multwall carbon nanotubes (MWCNTs) in polyacrylonitrile (PAN) were fabricated using the electrospinning technique and subsequently carbonized. The morphology of the fabricated carbon nanofibers (CNFs) at different stages of the carbonization process was characterized by high-resolution transmission electron microscopy (HRTEM) and Raman spectroscopy. In-situ morphological changes during heating were followed by HRTEM using a heated stage. The polycrystalline nature of the CNFs was shown, with increasing content of ordered crystalline regions having enhanced orientation with increasing content of MWCNTs. The results indicate that MWCNTs embedded within the PAN nanofibers nucleate the growth of graphitic layers during PAN carbonization.
10:36AM P19.00014 Crystallization and melting behavior of isatoic polypropylene and carbon nanotube nanocomposites1, GEORGI GEORGIEV, Assumption College/Tufts University, YANIEL CABRERA, LAUREN WIELGUS, Tufts University, ZARNAB IFTIKHAR, MICHAEL MATTERA, PETER GATI, AUSTIN POTTER, Assumption College, PEGGY CEBE, Tufts University, TUFTS/ASSUMPTION COLLABORATION — Polymer nanocomposites(PNCs) are the most recent development in the field of polymer science and technology. Geared toward creating novel polymer based materials, PNCs are the largest commercial application for nanotubes. Spherulitic polymer crystal growth was changed by using new fibrillar crystals on the surface of carbon nanotubes. Upon isothermal melt crystallization at 135°C, CNTs lead to monocrystalline crystal growth perpendicularly to the long axis of the nanotubes, explained by the multiple nucleation centers formed at the interface of the carbon nanotube and the polymer chains. Using Microscopic Transmission Ellipsometry (MTE), the sign of the alpha crystallographic phase was determined as positive. Using Differential Scanning Calorimetry (DSC), a decrease in the Avrami exponent was measured with increase of concentration of nanotubes.

10:48AM P19.00015 Crystallization kinetics in poly(ethylene oxide) / layered silicates nanocomposites, ELENI PAVLOPOULOU, SAPFO FOTIADOU1, ELENI PAPANANOU1, KIIRARI CHRISSOPOLOU, SPIROS H. ANASTASIADIS, Foundation for Research and Technology-Hellas and University of Crete, Heraklion Crete, Greece, GIUSEPPE PORTALE, WIFI BRAS, ESRF-DUBBLE, Grenoble, France — We investigate the effect of inorganic clay on the crystalline characteristics and the crystallization kinetics of PEO in its intercalated nanocomposites with natural montmorillonite (Na+ + MMT). The structure of the hybrids was investigated over multiple length scales by X-ray diffraction, small-angle X-ray scattering (SAXS) and polarizing optical microscopy (POM) as well as by DSC. The PEO within the galleries is completely amorphous whereas only the excess polymer outside the completely full galleries can crystallize at high PEO concentrations. The time resolved measurements reveal the effect of clay on crystallization. Even very small amount of the inorganic can cause a significant decrease of the spherulite size. The crystallization mechanism varies from sporadic nucleation for pure PEO to two-dimensional growth with predetermined nuclei at 10wt% clay with a higher activation barrier for low clay concentration. Sponsored by NATO’s Scientific Affairs Division, by the Greek GSRT and by the EU.

Wednesday, March 18, 2009 8:00AM - 10:48AM
Session P20 DPOLY: Melts and Solutions 321

8:00AM P20.00001 Dynamics and rheology of high molar mass polyethylene oxide solutions, ABHISHEK SHETTY, MICHAEL SOLOMON, University of Michigan — We report dynamic light scattering (DLS), bulk rheology and turbulent drag reduction (TDR) measurements that investigate the structure and dynamics of high molar mass PEO solutions. Steady shear rheology of high molar mass PEO solutions, when modeled by the FENE-P constitutive equation, was consistent with viscoelastic relaxation times much larger than predicted by single polymer, dilute solution theory. DLS of conjugate PEO solutions showed a single relaxation mode in the decay time distribution, which scales as q−2 rather than the q−4 scaling expected of diffusive dynamics. We interpret this result as consistent with the internal dynamics of large multichain domains, clusters or aggregates in the high molar mass PEO solutions. By means of DLS, we also show that the aggregation state of dilute solutions of high molar mass PEO can be manipulated by addition of the chaotropic salt guanidine sulfate or the divalent salt magnesium sulfate. Addition of these salts shifts the power law scaling of the relaxation time from q−4 to q−2. This shift of relaxation time scaling from one indicative of aggregate dynamics (q−4) to one characteristic of polymer center-of-mass diffusion (q−2) shows that these salts are effective de-aggregation agents for PEO. We discuss the results in light of the potential connection between aggregation behavior and polymer TDR of high molar mass PEO.

8:12AM P20.00002 Diffusive Properties of Dilute HPC Solutions: Comparative Study with DLS and FPR, RYAN MCDONOUGH, KIRIL STRELETZKY, Cleveland State University, PAUL RUSSO, Louisiana State University — The dynamics of HPC (Hydroxy-propyl-cellulose) solutions were studied by two fundamentally different methods: FPR (Fluorescence Photo-bleaching and Recovery) and DLS (Dynamic Light Scattering). FPR captures diffusive processes by establishing a photo-bleached boundary and “seeing” only tagged particles diffusing back into bleached area, which yields a contrast function. DLS auto-correlates scattered light intensity from particles in order to determine a statistical decay function. (Dynamic Light Scattering). FPR captures diffusive processes by establishing a photo-bleached boundary and “seeing” only tagged particles diffusing back into bleached area, which yields a contrast function. DLS auto-correlates scattered light intensity from particles in order to determine a statistical decay function. Inverse Laplace transform (CONTIN) and stretch exponential line shape analysis (LSA) serve to quantitatively decompose decay data into different diffusion processes or modes. The first finding is that the CONTIN and LSA results on the same sample are fairly consistent. The second finding is that the modal distributions for FPR and DLS spectra on the same sample show consistent dissimilarities. This indicates a comparative limitation or sensitivity in range of detectable diffusive processes between FPR and DLS in a complex system. The third finding is that the fluorescent tag and tagging process seem to alter the diffusion processes seen by DLS in a way that is consistent; there is a slower mode apparent in non-tagged sample which does not appear in the tagged sample.

8:24AM P20.00003 Helix formation via kinetic assembly of charged block copolymer cylinders in solution, SHENG ZHONG, Department of Materials Science and Engineering and Delaware Biotechnology Institute, University of Delaware, KE ZHANG, KAREN WOOLEY, Center for Materials Innovation, Department of Chemistry and Department of Radiology, Washington University in Saint Louis, DARRIN POCHAN, Department of Materials Science and Engineering and Delaware Biotechnology Institute, University of Delaware — A multi-micrometer-long, cylinder with helical superstructure is created from coassembly of polyanion (poly(acrylic acid))-block- poly(methyl acrylate)-block-poly(styrene) (PAA-b-PMA-b-PS) triblock copolymers with excessive triethylentetramine or diethylenetriamine in the mixture of 67% volume ratio of water in tetrahydrofuran (THF). The stable pitch distance of the formed helices is due to the balance of long range electrostatic association and uniaxial tension along the cylinder, which can be efficiently tuned by varying the type and amount of the multivalent amine molecules. Double and triple helices are also formed with characteristic interhelical cylinder distances similar to what is observed as the pitch in single helices. A kinetic study shows that the formation of a helix undergoes a complex, but reproducible, nanostructure evolution, including a starting stacked structure, a transition state of very short helices with the length of tens of nanometers and a final multi-micrometer-long mature helix by connecting those short helices.

8:36AM P20.00004 Enhancing Polymer-Fullerene Miscibility Through Enthalpic Interactions, KATIE CAMPBELL, DAVID BUCKNALL, YONATHAN THIO, HASKELL BECKHAM, UWE BUNZ, ADAM HANNON, ANDREW ZAPPAS, BILGE HATLIOGLU, Georgia Institute of Technology, MICHAEL KEMPF, Universität Karlsruhe — Using both theoretical and experimental methods, the use of functional groups in controlling the miscibility between various polymers and fullerenes has been investigated. Molecular dynamics simulations with unmodified C60 and C60 dimers indicated that the number and connectivity of phenyl rings as functional groups, polymer backbone spacing, and aromaticity are all factors in fullerene miscibility. To distinguish between entropic and enthalpic factors, UV-visible spectroscopy was used to determine fullerene solubility with a variety of solvents and also observed changes in solvation concentrations with solvents and polymers. A distinct time dependency for complex formation with many of the fullerene-organic materials investigated was observed as evidenced by a change in solution color with time. Stern-Volmer approximations and fluorescence quenching were used to examine the association of C60 with a series of poly(para-phenylene ethynylene), cyclic polystyrene (PS), and linear PS. The fluorescence quenching of these materials by C60 indicates an association between C60 and the polymer. WAXS studies have shown the formation of C60 aggregates in PS at concentrations of C60 as low as 1 wt%.
8:48AM P20.00005 Modeling Thermodynamic Behavior of Nonionic Surfactants in Water
VALERIY GINZBURG, PIERRE VARINEAU, Dow Chemical Company — Aqueous solutions of nonionic surfactants exhibit a non-trivial phase behavior known as lower critical solution temperature (UCST), where solutions are homogeneous at lower temperatures but become cloudy (two-phase) at higher temperatures. Conventional Flory-Huggins theory of polymer solutions fails to describe such phase behavior. We utilize the approach suggested by Dormidontova and modify Flory-Huggins theory by explicitly accounting for water-water and water-alkylene oxide hydrogen bonding. While the Dormidontova model was restricted to aqueous solutions of polyethylene oxide (PEO), we extend it to include other monomers and their copolymers. With the new approach, we can semi-quantitatively predict cloud points of various nonionic surfactants (TergitolTM and EcosurfTM series) as functions of their molecular structures. We also discuss extensions of this model to calculate micellar phase behavior and oil/water/surfactant interfacial tensions. TM Trademark of The Dow Chemical Company

9:00AM P20.00006 Role of surfactants on the assembly of amphiphilic copolymers through instabilities of organic/water interfaces , JINTAO ZHU, RYAN C. HAYWARD, Department of Polymer Science & Engineering, University of Massachusetts Amherst — We have studied the influence of aqueous surfactants on the assembly of amphiphilic copolymers through hydrodynamic instabilities of organic/water interfaces. Micropipette aspiration measurements on evaporating chloroform droplets containing polystyrene-poly(ethylene oxide) (PS-PEO) diblock copolymers revealed that the onset of interfacial instability and subsequent growth in surface area corresponded to a near vanishing of the interfacial tension. By adding another surfactant, such as sodium dodecyl sulfate (SDS), to the aqueous phase, the chloroform/water interfacial tension was reduced and the onset of instability shifted to lower concentration of PS-PEO. Varying amounts of SDS also led to qualitatively different mechanisms of growth in interfacial area and correspondingly different morphologies of the resulting copolymer assemblies.

9:12AM P20.00007 Influence of Intermolecular Interactions on Fragility of Polymers , KUMAR KUNAL, ALEXEI SOKOLOV, The University of Akron — Glass transition in polymers is a result of slowing down of segmental relaxation. Steepness of the temperature-dependence of segmental relaxation times close to the glass transition temperature, Tg, is expressed in terms of fragility parameter. A strongly non-Arrhenius temperature dependence of segmental relaxation times with steep variations close to Tg is called a ‘fragile’ behavior, and a nearly Arrhenius behavior is called ‘strong’. The existing theoretical models and experimental investigations on polymers with weak van der Waals interactions suggest that fragile behavior of polymers may be linked to their poor packing ability. However, the effect of strong intermolecular interactions on fragility such as polar interactions and hydrogen bonds remains unexplored. It has been predicted that polymers composed of polar monomers are likely to be highly fragile. We have studied polymers with strongly polar interactions and hydrogen bonds and found that although polar polymers do seem to have a higher Tg than their non-polar counterparts, no such conclusion can be drawn about their fragility. The different effects of polar interactions on different classes of polymers may be attributed to the difference in their Tgs.

9:24AM P20.00008 Random Walk of Chain Molecules Along Pore Axis , GUIDUK YU, School of Chem. and Bio. Eng., Seoul National University, SERGEI OBUKHOV, Dpt. of Physics, University of Florida, JIUN-TAI CHEN, Dpt. of Polym. Sci. and Eng., University of Massachusetts Amherst, JUNE HUH, School of Mater. Sci. and Eng., Seoul National University, YOONTAE HWANG, SOONCHUN MOK, School of Chem. and Bio. Eng., Seoul National University, PRIYANKA DOBRIYAL, Dpt. of Polym. Sci. and Eng., University of Massachusetts Amherst, PAPPANNAN THIYAGARAJAN, Intense Pulsed Neutron Source Division, Argonne National Laboratory, THOMAS P. RUSSELL*, Dpt. of Polym. Sci. and Eng., University of Massachusetts Amherst, KYU.SOON SHIN*, School of Chem. and Bio. Eng., Seoul National University — We investigated the overall conformation of polymer chain in cylindrical nanopores using small-angle neutron scattering. The mixture of hydrogenous PS and deuterated PS is confined in nanopores. Surprisingly, the overall conformation of polymer chains along the pore axis is observed to be the same as that in bulk. Even though the chain dimension is larger than the radius of the pores, the chains along the pore axis are not stretched, but sustain to be in unperturbed state. The SANS results implicate that the interpenetration of polymer chains decreases as polymer enters nanopores. We expect the reduction of intermolecular entanglement possibly alters other physical properties of polymer under nanoconfinement.

9:36AM P20.00009 Dynamics of Cyclic Molecules Threaded into a Linear Polymer Chain, KOICHI MAYUMI, HITOSHI ENDO, The University of Tokyo, MICHlHIRO NAGAO, Indiana University and National Institute of Standards and Technology, NOBORU OSAKA, HIDEAKI YOKOYAMA, MITSUHIRO SHIBAYAMA, KOHZO ITO, The University of Tokyo — Dynamics of polynotaxane (PR), in which cyclic molecules, cyclodextrins (CDs), are threaded on an axis linear polymer chain, poly(ethylene glycol) (PEG), are first studied by contrast variation neutron spin echo (CV-NSE). By comparing PRs of hydrogenated and deuterated PEG with different scattering contrasts, we successfully extract two diffusive modes of CDs, corresponding to self diffusion and relative motion to the axis PEG in PR. The self-diffusion constant of CD in PR is determined to be about one-third of the free one in the absence of the axis polymer, which would reflect the space dimension of diffusion with the topological restriction on the axis chain path.

9:48AM P20.00010 Diffusion of Water through Methyl- and Hydroxyl-Terminated Poly(Dimethyldisiloxane)1 , AHMED E. ISMAIL, GARY S. GREST, DAVID R. HEINE2, MARK J. STEVENS, Sandia National Laboratories, MESFIN TSIGE, Southern Illinois University — Both experimental and numerical reports of the diffusion constant of water through poly(dimethylsiloxane) (PDMS) show variances of nearly an order of magnitude. We use molecular dynamics simulations to calculate the diffusion constant for both methyl- and hydroxyl-terminated PDMS chains. We examine the effects of both concentration and chain length. For a single water molecule, we find that diffusion depends strongly on the initial location of the molecule, as the “caging” phenomenon reported by Miller-Plattee can occur. At intermediate concentrations, we observe the formation of dimer and trimer water clusters, leading to lower diffusion rates; at concentrations above the reported aggregation limit of 0.1 wt %, we observe the onset of phase segregation.

10:00AM P20.00011 Effect of Stereochemistry and Polydispersity on Diffusion in Polypropylene\textsuperscript{1}. ERNST VON MEERWALL, NUMAN WAHED, WAYNE MATTICE, Univ. Akron — We have performed dynamic Monte-Carlo (MC) simulations and pulsed-gradient diffusion (D) experiments to study the effect of stereochemical composition in linear polypropylene (PP) melts. The coarse-grained simulations were based on the rotational isomeric state model and Lennard-Jones potentials. For the proton NMR diffusion measurements we obtained three PP specimens of differing molecular weight M and dispersity, with the probability of a meso diad Pm = 0.02 (syndiotactic), 0.23 (atactic), and 0.89 (nearly isotactic). The experiment supplied the fixed conversion between MC steps and real time; no dependence on Pm is expected. Both simulation and M-scaled experiment found D at high Pm several times faster than at low Pm. The constant-M simulation also showed a maximum near Pm = 0.8 due to quenched randomness. To find the source of the remaining disagreement with experiment, new simulations tracked the samples’ Pm, mean M, and polydispersity, producing modest improvement. We suspect that the GPC determination of M and its distribution, based on linear polyethylene calibration, is somewhat dependent on PP stereochemistry (via D), generating misleading results.

10:12AM P20.00012 On chain statistics and entanglement of flexible linear polymer melts. SHI-QING WANG, University of Akron — In this work the chain statistics of most linear flexible polymers have been found to be rather universal, allowing chain entanglement to be depicted with few parameters. We first show, to our surprise, based on the literature data of most familiar linear polymers that (a) at the same number of backbone bonds most linear polymers have comparable coil size and are similarly flexible in spite of widely varying chain thickness and (b) the Kuhn length involves a similar number of backbone bonds. The packing model is found to describe the onset molecular weight Mc obtained from the elastic plateau modulus whereas all other models in the literature fail to provide good correlation. It is chain thickness not stiffness that correlates with Mc for over one hundred flexible linear polymers. On the other hand, other models such as percolation model appear to provide some crude correlation for Mc, to which the packing model does not apply well, where Mc denotes the point of departure in the molecular weight scaling from Rouse like to reptation like. Thus, our analysis clarified the apparent contradiction among the various models.

10:24AM P20.00013 Translational Diffusion in a Confined Polymer Melt. JANET WONG, Department of Mechanical Engineering, Imperial College London, LIANG HONG, Dow Chemical Company, SUNG CHUL BAE, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — At the University of Illinois, a new experimental platform has been developed that combines the surface forces apparatus with spatially-resolved fluorescence recovery after photobleaching, giving direct measurements of translational diffusion when polymer melts are confined between mica sheets to controlled thicknesses comparable to the size of the molecules themselves. Applying this platform to polydimethylsiloxane (PDMS), we find not only the anticipated dependence on film thickness but also a dependence on the local pressure: when mica sheets are pressed together so that they flatten, the diffusion of chains confined between them depends on the local pressure, being slowest near the center of the contact. The confined chains split into two populations: those that are immobile on the scale of hours, and those whose mobility is close to that of the unperturbed polymer melt.

10:36AM P20.00014 Entangled Polymer Melt Dynamics Studied By Low-Field NMR. FABIAN VACA CHAVEZ, PATRICK HUEBSCH, RONALD ZIRBS, WOLFGANG BINDER, KAY SAULWAECHTER, Martin-Luther-University Halle-Wittenberg — Proton Multiple-Quantum (MQ) NMR is a powerful technique to investigate polymer dynamics due to its sensitivity to molecular motions on very different timescales. Entangled melts exhibit dynamic processes that cover a wide range of timescales, starting from fast ps-scale segmental reorientation up to diffusive and cooperative motions on the ms-scale. In this work, we apply MQ NMR to linear poly(cis-1,4-isoprene) and poly(isobutylene) of different molecular weight to establish the dynamic regimes predicted by the tube model, and, for the first time, to extract actual time scale information. This directly complements many neutron scattering studies, which are restricted to the sub-\(\mu\)s-timescale. Measurements on PIB-grafted silica particles with different molecular weights and different chain densities on the surface of the particle are also shown. The data is analyzed by establishing scaling laws which can be directly associated with different dynamic regimes predicted by the tube/reptation model. Full analytical analyses based on a correlation function which explicitly includes segmental, Rouse, and reptation dynamics are discussed.

Wednesday, March 18, 2009 8:00AM - 11:00AM –
Session P21 FLAP DCMP: Computational Study of Semiconductor Band Structures 323

8:00AM P21.00001 First-Principles determination of deformation potentials in nitrides. QIMIN YAN, PATRICK RINKE, MATTHIAS SCHEFFLER, CHRIS G. VAN DE WALLE, University of California at Santa Barbara — Group-III nitrides and their alloys are now commonly used in optoelectronic devices such as light emitting diodes (LEDs) and laser diodes (LDs). In these devices strain plays a crucial role since it affects the band structure near the valence- and conduction-band edge and thus the optical properties and the device characteristics. The deformation potentials that describe the change in band structure under strain have not yet been reliably determined, either experimentally and theoretically. Here we present a systematic study of the strain effects in AIN, GaN and InN in the zinc-blende and wurtzite phase. Besides density functional theory (DFT) in the most commonly applied local- and gradient corrected density approximation (LDA/GGA) we also apply the Heyd-Scuseria-Ernzerhof (HSE) hybrid functional \cite{1} and \(G_0W_0\) quasiparticle corrections to address the band gap problem. We present a complete set of deformation potentials that allows us to predict the band positions under realistic strain conditions. For the wurtzite phase we observe non-linearities in the strain dependence that may, in parts, explain the appreciable scatter in previous theoretical work on deformation potentials of group-III-nitrides. \cite{1} J. Heyd, G. E. Scuseria, and M. Ernzerhof, J. Chem. Phys. 118, 8207 (2003) Work supported by the UCSB Solid State Lighting and Energy Center.

8:12AM P21.00002 Band-gap bowing, band offsets, and electron affinity for InGaN alloys: A DFT study.\textsuperscript{1}. POUL MOSES, CHRIS VAN DE WALLE, UCSC — InGaN alloys are successfully being used in optical, electronic, and photovoltaic devices; a novel application is for photochemical water splitting. Because the InGaN alloys using density functional theory. The HSE exchange correlation functional has been used in order to accurately calculate the electronic band structure \cite{1}. Detailed surface calculations have been performed that, combined with bulk calculations for alloys, yield information about the positions of valence and conduction bands on an absolute energy scale. We will discuss bowing effects, band offsets, and electron affinities in light of the application of InGaN alloys for photochemical hydrogen production. \cite{1} J. Heyd, G. E. Scuseria, and M. Ernzerhof, J. Chem. Phys. 118, 8207 (2003)

8:24AM P21.00003 A Hybrid Look at Band Offsets in AlN/GaN Heterostructures, JEREMY NICKLAS, JOHN WILKINS — Hybrid functionals have been gaining traction for their better estimation of band gaps in semiconductors. Recently, a screened hybrid functional, HSE, has been introduced that improves upon the hybrid functionals by essentially screening out the Fock exchange after a given radius. This study compares how well the HSE functional does with the technologically important band offsets in the AlN and GaN wide bandgap heterostructures compared to experiment and other previous theoretical calculations. Both the strained polar hexagonal and the nonpolar cubic phases of these III-V semiconductors are taken into consideration. Due to the large induced electric field in the polar hexagonal structure, a multipole decomposition will be discussed as well.

8:36AM P21.00004 Reassessing the Description of the Electronic Structure of a Semiconductor Alloy1, YONG ZHANG, A. MASCARENHAS, National Renewable Energy Laboratory, L.-W. WANG, Lawrence Berkeley National Laboratory — Although an electronic state in an alloy like Ga1-xInxP is not a Bloch state, it is generally considered to be reasonably close to a Bloch state in the sense of a virtual crystal approximation (VCA), and it is often referred to as Γ-like, L-like, or X-like. We have find that within certain context one could call a band edge state as Γ-like, if the dominant component of its wavefunction is indeed the Γ state of the VCA, but globally the alloy states are in general very different from those of the VCA in two important aspects: (1) a Γ-like state, for instance, could in fact have a very small Γ component of the VCA state, and (2) if the corresponding VCA states are degenerate, for instance, a Χ-like band edge alloy state, there will be strong coupling among the degenerate valleys. These new insights have major impacts on our understanding of the optical and electronic properties[1], and the ordering effects [2] in a semiconductor alloy.

8:48AM P21.00005 Ab initio study of the optical properties of Si-XII, BRAD MALONE, JAY SAU, MARVIN COHEN, Department of Physics, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — We present a first-principles calculation of the optical excitation spectrum of Si-XII, a high-pressure, metastable phase of silicon in the R8 structure. Recent calculations of the quasiparticle spectrum have shown Si-XII to be semiconducting with a small, indirect band gap. In this paper we solve the Bethe-Salpeter equation (BSE) to obtain the optical spectrum of this material. We then compare our calculated optical spectrum with experimental data for other forms of silicon commonly used in photovoltaic devices. These include cubic, polycrystalline, and amorphous forms of silicon. We find that the calculated values of the optical functions relevant to photovoltaic absorption in Si-XII show great overlap with the incident solar spectrum than those found in these other silicon phases.

9:00AM P21.00006 First-Principles Hartree-Fock Study of Locations and Hyperfine Interactions of Transition Metal Impurities in Silicon, R.H. PINK, S.R. BADU, SUNY Albany, ARCHANA DUBEY, UCF Orlando, R.H. SCHEICHER, Uppsala University, Sweden, LEE CHOW, UCF Orlando, M.B. HUANG, T.P. GAS, SUNY Albany — The study of the magnetic properties of transition metal ions in silicon is currently of great interest because of their potential applications in spintronics. An understanding of the ferromagnetism associated with the interactions between these impurities requires a knowledge of their locations in the lattice. Three possible locations of Mn2+, V2+, and Cr3+ ions have been investigated, namely, the interstitial hexagonal (H) and tetrahedral (T) and substitutional (S) sites. Both binding energies and hyperfine interactions are being studied using the Hartree-Fock Cluster procedure with many-body effects included by the many-body perturbation theory (MBPT) procedure. For Mn2+ ion, the Hi site is found to be unstable while the Ti and S sites have positive binding energies. Our calculated 55Mn hyperfine constant favors the Ti site which is also supported by channeling measurements.

2J. LalRose and M.B. Huang (to be published).

9:12AM P21.00007 Theoretical analysis of the effect of tip-induced band bending on scanning tunneling spectroscopy measurements on H-terminated Si(100) surface, HIDEOMI TOTSUKA, totsuka.hideomi@nihon-u.ac.jp, SATOSHI WATANABE, watanabe@cello.t.u-tokyo.ac.jp — Scanning tunneling spectroscopy (STS) is widely used experimental technique. However, theoretical study on STS is not sufficient yet, in the sense that the effects of important factors such as the tip-induced band bending (TIBB) in measurements on semiconductor surfaces have not been examined yet. In this study, we have analyzed the STS spectra on a H-terminated Si(100) surface theoretically using a method [1] which can calculate the electron states under applied bias voltages self-consistently. We found that the band gap in the STS spectra is larger than that in the density of states calculation. Furthermore, we found that this cannot be understood from TIBB, while the bias voltage dependence of TIBB in our calculation corresponds well with experimental result [2]. [1] Y. Gohda et al., Phys. Rev. Lett. 85, 1750 (2000). [2] M. McEllistrem, et al., Phys. Rev. Lett. 70, 2471 (1993)

9:24AM P21.00008 Band gaps and band offsets in the SiO2/Si interface calculated by including the self-energy of electrons and holes, LUIZ FERREIRA, Universidade de São Paulo, Brazil, LEONARDO FONSECA, MAURO RIBEIRO, Jr., Center Werner von Braun for Advanced Research, Brazil — Density Functional theory, as formulated by Kohn and Sham (Phys. Rev. 140, A1133 (1965)), is insufficient when it comes to the calculation of one-particle excitations (electrons and holes). In this case, one has to include the self-energy of the particle (see for instance R. Gómez- Abal. et al Phys. Rev. Lett. 101, 106404 (2008)). This self-energy is mostly the classical electrostatic self-energy of the particle charge density but has an important contribution from exchange and correlation. In a recent paper (L. G. Ferreira et al, Phys. Rev. B 78, 125116 (2008)), it is shown that the self-energy can be calculated with the help of a “self-energy potential”, wholly derived from pure atomic calculations. The band gaps calculated with those self-energies are precise, in no way worse than the GW band gaps, and yet the calculation is very simple and fast. Next challenge we faced was the calculation of the band-offsets of the all important Si/SiO2 system. Notice that the “self-energy potential” is centered between two covalent bonded atoms in the Si side and centered at the O in the SiO2 side. Then the question is whether these self-energy potential perturbations create a wrong charge density at the interface. The answer is that both gaps and band offsets were calculated with outstanding quality.
9:36AM P21.00009 The influence of pressure on defects in amorphous silicon1. JEFFREY GROSSMAN, LUCAS WAGNER, University of California, Berkeley — Amorphous silicon(a-Si) thin-film solar cells are promising materials for solar cells, but they suffer from the Staebler-Wronski effect (SWE), in which the efficiency degrades over the course of a few hours of light exposure. While there has been progress in mitigating this effect through sample preparation, there is still no clear microscopic explanation for the degradation. We have used first principles density functional theory and highly accurate quantum Monte Carlo calculations to investigate the effect of pressure on different types of defects present in a-Si. Our calculations show that the effect of pressure on a-Si is strongly dependent on the particular type of defect, and they further may provide new ways to experimentally determine the dominant defect type. We also report on the effect of pressure on the simplest reaction in a-Si: a bond switch between two neighboring Si atoms, which could be an important element in the understanding of the SWE [1]. [1] L. K. Wagner and J. C. Grossman. PRL (in press)

9:48AM P21.00010 Ab initio calculations of the dielectric functions of semiconductors and alloys including excitonic effect via LASTO method. HYEJUNG KIM, YIA-CHUNG CHANG, Department of Physics, University of Illinois at Urbana-Champaign, Urbana IL and Research center for Applied Sciences, Academia Sinica, Taipei, Taiwan — We calculate dielectric functions of semiconductors and alloys including the electron-hole interactions within the ab initio framework. The Bethe-Salpeter equation is constructed using a full-potential linear augmented-Slater-type orbital (LASTO) method. The electron-hole interaction is computed with a sufficiently dense k-point mesh, which shows good convergence. Point group symmetry has been utilized to speed up the computation significantly. Dielectric functions of alloys are calculated by the configurational average of special quasirandom structures. The inclusion of the electron-hole interaction both shifts the peak positions and changes peak heights of the imaginary part of the dielectric functions, resulting in better agreement with ellipsometry data than the spectra obtained without including the electron-hole interactions.

10:00AM P21.00011 The Electronic and Optical Properties of Manganese-doped Wurtzite ZnO. YIMING MI, XINXIN ZHAO, School of Fundamental Studies, Shanghai University of Engineering Science, SHUICHI IWATA, Graduate School of Frontier Sciences, The University of Tokyo — The electronic and optical properties of Manganese-doped Wurtzite ZnO were studied by the first principles pseudopotential plane wave method within density functional theory formalism. The electronic structures, density of states, and optical absorption spectra were investigated for different doping concentration. The acquired results reveal that the energy gap of the Mn-doped ZnO increases with the increase of Mn-doping concentration, and the UV absorption of the system gets stronger with the Mn-doping concentration augmented, which are consistent with others’ calculation and experimental results fairly well.

10:24AM P21.00013 Dielectric Function and Critical Point of GeSbTe Pseudo-binary Compound Thin Films. HOSUNG LEE, JUN-WOO PARK, Kyung Hee University, YOUN-SEON KANG, TAE-YON LEE, DONG-SEOK SUH, KI-JOON KIM, CHEOL KYU KIM, YOON HO KANG, Samsung Electronics, JUAREZ L. F. DA SILVA, NREL — We measure the dielectric functions of GeSbTe pseudo-binary thin films by using spectroscopic ellipsometry. We anneal the thin films at various temperatures. According to x-ray diffraction, the as-grown thin films are amorphous and the annealed films have metastable and stable crystalline phases. By using standard critical point model, we obtain the accurate values of the energy gap of the amorphous phase as well as the critical point energies of the crystalline thin films. The critical point energies are compared to the band gap energies determined by the method of linear extrapolation of the optical absorption. As the Sb to Ge atomic ratio increases, the optical (band) gap energy of amorphous (crystalline) phase decreases. Standard critical point fitting show several higher band gaps. The electronic structures and the dielectric functions of the thin films are calculated by using density functional theory and are compared to the measured ones. The band structure calculations show in stable phase that GeTe, GeSbTe3, and Ge3Sb2Te7 have indirect gap whereas Ge5Sb1Te17 and Sb2Te3 have direct gap. The measured indirect band gap energies match well with the electronic band structure calculations.

10:36AM P21.00014 Origin of the unusually large band gap bowing and the breakdown of the band-edge distribution rule in the SnxGe1-x alloys. WAN-JIAN YIN, XIN-GAO GONG, Fudan University, Shanghai, China, SU-HUAI WEI, National Renewable Energy Laboratory, Golden, Colorado, USA — Most semiconductor alloy AxB1-x has a non-linear dependence of its band-edge distribution rule in the SnxGe1-x alloys. The bowing parameter is the band-gap difference between the direct interband transition of a system and the so-called bowing parameter, which is the average of two valence band edge states and find that the bowing of the conduction band edge is much larger than the bowing of the valence band edge, although the natural valence band offset between Ge and Sn is larger than the natural conduction band offset. The breakdown of the band-edge distribution rule is explained by the large lattice mismatch between Ge and Sn and the large deformation potential of the band edge states.

10:48AM P21.00015 Accurate electronic structure calculations of lead chalcogenides by QSGW method. SERGEY FALEEV, OLEG MYRASOV, Seagate Technology — Enhancement of the energy conversion efficiency of thermoelectric materials has been a long goal of materials physics. Recent experiments show that distortion of the electronic structure of PbTe by adding small amount of impurities results in enhancement of the Seebeck coefficient and doubling of the ZT factor [Heremans et al., Science 321, 554 (2008)]. This enhancement is thought to be due to the impurity-induced increase of the energy dependence of density of states near the Fermi level. The reliable theoretical prediction of the energy states of impurities in host matrix (which often very difficult to measure experimentally) are required in order to explain the experiments and predict and optimize properties of new materials. Accurate calculations for bulk system is a first necessary step required for further study of systems with impurities. Here we report results for bulk lead chalcogenides obtained with recently developed QSGW method [Faleev et al., PRL 93, 126406 (2004)]. We found that electronic structure of lead chalcogenides and, in particular, the band gaps and effective masses are predicted with much higher accuracy within the QSGW approach than within most commonly used DFT theory. This result opens way for predictive search of novel thermoelectric materials.
8:00AM P22.00001 Beller Lectureship Talk: Spin Hall Effect  . MICHEL I. DYAKONOV, University of Montpellier II, CNRS, France — The Spin Hall Effect (SHE) and related transport phenomena originating from the coupling of the charge and spin currents due to spin-orbit interaction were predicted [1] in 1971. Following the suggestion in [2], the first experiments in this domain were done at Joffe Institute in Saint Petersburg [3], providing the first observation of what is now called the Inverse Spin Hall Effect. As to the SHE itself, it had to wait for 33 years before it was experimentally discovered by two groups [4] in Santa Barbara (US) and in Cambridge (UK). The phenomenon consists in spin accumulation at the lateral boundaries of a current-carrying non-magnetic conductor, the spin directions being opposite at the opposing boundaries. The boundary spin polarization is proportional to the current and changes sign when the direction of the current is reversed. It exists in relatively wide spin layers determined by the spin diffusion length, typically on the order of 1 µm. I will discuss the phenomenology of spin-charge coupling, the underlying microscopic mechanisms, and the existing experimental results obtained in semiconductors and metals at cryogenic, as well as at room temperatures. I will also address a related, but as yet unknown phenomenon, the "swapping" of spin currents, which is due to the correlation between spin rotation during a scattering event and the direction of scattering. [1] M.I. Dyakonov and V.I. Perel, JETP Lett. 13, 467 (1971); Phys. Lett. A35, 459 (1971) [2] N.S. Averkiev and M.I. Dyakonov, JETP Lett. 35, 196 (1983) [3] A.A. Bukun et al., JETP Lett. 40, 1293 (1984) [4] Y.K. Kato et al., Science 306, 1910 (2004); J. Wunderlich et al., Phys. Rev. Lett. 94, 047204 (2005)  

8:36AM P22.00002 Spin Hall frequency doubling and spin memristive effects1 . YURI V. PERSHIN, Department of Physics and Astronomy and USC Nanocenter, University of South Carolina, Columbia, South Carolina 29208, USA; MASSIMILIANO DI VENTRA, Department of Physics, University of California, San Diego, La Jolla, California 92093-0319, USA — It is shown that when a time dependent voltage is applied to a system with inhomogeneous electron density in the direction perpendicular to main current flow, the spin Hall effect results in a transverse voltage containing a double frequency component. We demonstrate that there is a phase shift between applied and transverse voltage oscillations, related to memristive behavior of semiconductor spintronics systems. It is interesting that spin memristive effects in this system are manifested directly in the voltage response. A different method to achieve the second harmonic generation, based on the inverse spin Hall effect, is also discussed.  

1This work was partially supported by the National Science Foundation and Department of Energy.  

8:48AM P22.00003 Enhanced Spin Hall Effect by Single Antidot Potential . MIKIO ETO, TOMOHIRO YOKOYAMA, Faculty of Science and Technology, Keio University — We theoretically investigate an extrinsic spin Hall effect in semiconductor heterostructures due to the scattering by an artificial potential created by a single antidot, STM tip, etc. The strength of the potential is electrically tunable. First, we formulate the spin Hall effect in terms of phase shifts in the partial wave expansion for two-dimensional electron gas. For scattered electrons in θ direction, we obtain a spin polarization P(θ) perpendicular to the two-dimensional plane [P(_−θ) = −P(θ)]. The spin polarization P(θ) is significantly enhanced by an attractive potential when the resonant condition of a partial wave is satisfied by tuning the potential strength. Second, we study the spin Hall effect in a three-terminal device with an antidot at the junction. The conductance and spin polarization are evaluated numerically [1]. We obtain a spin polarization of more than 50% due to the resonant scattering when the attractive potential is properly tuned.  

9:00AM P22.00004 Competing interplay between Rashba and cubic-k Dresselhaus spin-orbit interaction in spin Hall effect1 . C.S. CHU, R.S. CHANG, Dept. of Electrophysics, National Chiao Tung University, Taiwan, ROC, A.G. MAL’SHUKOV, Institute of Spectroscopy, Russian Academy of Science, Russia — We study the interplay between the Rashba and cubic-k Dresselhaus spin-orbit interactions (SOI) in a diffusive two-dimensional electron gas (2DEG). Within the spin Hall configuration, we perform a systematic calculation of the spin accumulation S_i and the spin polarizations S_{ij} at the lateral edges and in the bulk of the 2DEG, respectively. Both the relative coupling strength of the Rashba and the Dresselhaus SOI, and the electron densities are varied. The spin accumulation exhibits strong competing features, including in the Dresselhaus-dominant regime the sign change in S_z when electron density is large enough, and in the Rashba-dominant regime the complete suppression of S_z. Most surprisingly is our finding that the Rashba-dominant regime occurs as early as α ≈ β, where α, β are the Rashba and the effective linear-k Dresselhaus SOI coupling constant, respectively. Similar Rashba-dominant regime is found in the spin polarizations, when α ≥ β. Our results point out that decreasing |α| leads to the restoration of the spin accumulation.  

1Work supported by Taiwan NSC No. 96-2112-M-009-0038-MY3  

9:12AM P22.00005 Monte Carlo Simulation of Spin-Injection Hall Effect . LIVIU P. ZÁRBO, JAIRO SINOVA, Department of Physics, Texas A&M University, USA; JÖRG WUNDERLICH, Hitachi Cambridge Laboratory, United Kingdom; TOMAS JUNGWIRTH, Institute of Physics, ASCR, Czech Republic; SHOU-CHENG ZHANG, Department of Physics, Stanford University, USA — The spin-injection Hall effect, which is the newest addition to the spintronic Hall effect family, consists in the transversal deflection of a charge spin-polarized current injected in a spin-orbit coupled semiconductor channel which results in transverse Hall voltage whose magnitude varies along the channel direction. Just as in the case of spin Hall effect, the phenomenon is due to both intrinsic and extrinsic (impurity driven) spin-orbit scattering. We develop a semiclassical spin-dependent Monte Carlo simulation technique which enables us to quantitatively explain the mechanisms of spin-injection Hall effect in experimentally relevant systems. This is achieved by incorporating both intrinsic and extrinsic contributions to anomalous Hall effect (AHE) which are rigorously derived within the recently developed gauge invariant semiclassical theory of AHE. The advantage of this approach over a fully quantum mechanical treatment is that it enables us to investigate the spin-injection Hall effect in micrometer-size devices while still retaining the essential physics.  

9:24AM P22.00006 Calculations of Spin-orbit Splittings in Two-Dimensional Heterostructures1 . MARTA PRADA, MARK FRIESEN, ROBERT JOYNT, University of Wisconsin-Madison, QUANTUM COMPUTING GROUP TEAM — We present calculations of spin-orbit level splittings in GaAs/InGaAs and Si/SiGe quantum wells. We use both an effective mass approach and a numerical tight-binding approach (NEMO-3D) that includes the effects of the interfaces on atomic scales. We are able to separate the Rashba and Dresselhaus contributions. The calculations are done as a function of applied electric field and well width. We find good agreement of theory and experiment for the measurements of L. Meier et al., (Nature Physics 3, 650 (2007)) on GaAs/InGaAs. In Si/SiGe wells, we find significant valley- spin-orbit mixing and also that the Dresselhaus term is substantial, and can even be larger than the Rashba term for realistic parameters.

9:36AM P22.00007 Coherent ultrafast spin flip in a 2D electron gas\textsuperscript{1}. CAREY PHEILPS, TIMOTHY SWEENEY, HAILIN WANG. Department of Physics and Oregon Center for Optics, University of Oregon, Eugene, OR 97405 — We report the experimental demonstration of ultrafast electron spin flip in a modulation doped CdTe quantum well. Complete spin flip is realized with an off-resonant laser pulse of 2 ps in duration. The effective pi-pulse flips the electron spins with respect to an axis that is orthogonal to both the external magnetic field (Voigt geometry) and the sample growth axis. The realization of the ultrafast pi-pulse opens up a new avenue for protecting electron spins from decoherence with dynamical decoupling.

9:48AM P22.00008 Analysis of Electron Spin Relaxation Momentum Time in Narrow Gap Semiconductor Quantum Well and Dots: Including Rashba and Dresselhaus Effects. YUNG-SHENG HUANG, JUNG-SHENG HUANG, College of EECS, Semiconductors Research Laboratory, I-Shou Univ., 840 Kaoshuing, Taiwan — A model of GaAs quantum dots embedded in a quantum wire is studied. We want to investigate how the electron spin relaxation momentum time (SRT) is varying with some physical parameters. We find that SRT decreases while the four parameters, external magnetic field, surrounding temperatures, both quantum wire width and thickness increase. The reason is caused by more and more phonons resulted in a higher scattering probability between electrons and phonons. Thus the SRT is reduced. Besides, Lommer and Silva showed that in narrow gap semiconductor bulk materials, the Rashba effect is larger than Dresselhaus effect. Our results show that Dresshaus effect is larger than Rashba effect for the quantum well under electric field, especially when the quantum well width is small. The authors are interested in studying whether the same characteristics exist in quantum dots. We are working on this line.

10:00AM P22.00009 Spin accumulation in a Rashba-type two-dimensional electron gas due to a nonuniform driving electric field\textsuperscript{1}. LU-YAO WANG, CHON-SAAR CHU, Department of Electrophysics, National Chiao Tung University, MAL SHUKOV ANATOLY, Institute of Spectroscopy, Russian Academy of Science — It is well understood that a Rashba-type two-dimensional electron gas (2DEG) does not support spin accumulation, or spin Hall effect, in the diffusive regime when the driving electric field is uniform. In this work we address the issue about a possible restoration of the spin Hall effect when the driving field is nonuniform. Toward this end, we consider the spin accumulation in the vicinity of a circular hole, with radius $R \sim l_{so}$, where the driving field becomes nonuniform. Here $l_{so}$ is the spin relaxation length, and $l_{so} \gg l_{c}$, the mean free path. Our result shows that the nonuniform driving field gives rise to nonuniform in-plane spin densities $S_x$ and $S_y$, which in turn contribute to a finite spin current via the combined processes of spin diffusion and spin-precession. The spin accumulation thus obtained is proportional to the Rashba coupling constant $\alpha$, and its spatial pattern is one of spin-dipole form, aligned perpendicular to the driving field.

10:12AM P22.00010 Scattering approach in calculating Rashba Spin-orbit coupling in asymmetric\textsuperscript{1}. CHIH-PIAO CHUU, QIAN NIU — The Rashba Spin-orbit coupling plays a crucial role in spin manipulation in semiconductor heterostructures. We study the underlying physics through scattering approach with the Kane model. Several physical parameters are considered, including potential barrier asymmetries, quantum well inclination, as well as band structure parameters. This may provide a better understanding in designing spintronic devices.

10:24AM P22.00011 2D Holstein polarons in the presence of spin-orbit interactions. LUCIAN COVACI, MONA BERCIU, University of British Columbia, Vancouver, Canada — The electron-phonon interaction in the presence of spin-orbit interactions (of either Rashba or Dresselhaus type) must be taken in account for GaAs quantum dots or for spintronic devices. The possibility of tuning the electron-phonon interaction by coupling to a substrate (e.g. in organic transistors) requires an accurate treatment of this problem in all coupling regimes. We apply a recently developed approximation (the Momentum Average Approximation) to this specific theoretical question. We have shown that this method is exact in various asymptotic regimes while being accurate for all coupling strengths. We calculate the self-energy at the MA(2) level of the approximation. From ground state properties (energy and effective mass) we conclude that in the presence of spin-orbit interactions, the polaron is harder to trap – the crossover from large to small polarons is shifted to higher couplings. From the spectral function, we show that there are two distinct regimes, depending on relation between the phonon frequency and the strength of the spin-orbit interaction. When the latter is larger we find that the polaron character is dominated by only one band (the '-' band). We also show that the off-diagonal part of the self-energy plays an essential role in obtaining the polaron + one phonon continuum correctly.

10:36AM P22.00012 Full spin control in 2DEGs with no magnetic fields. B.J. MOEHLMANN, M. E. FLATTÉ, OSTC and Department of Physics and Astronomy, University of Iowa — A properly chosen closed spin transport path in the plane of a III-V semiconductor quantum well suffices for arbitrary spin manipulation of conduction electrons about any desired axis. This feature of spin transport relies on the non-commutativity of the precession matrices associated with non-colinear path segments. The electron spin rotation depends solely on the path geometry, not the speed of the spin along the path. Simple closed paths have been found which will perform arbitrary spin rotations along arbitrary axes with no net spatial displacement of the spins. The paths differ depending on the form of the internal effective magnetic fields induced by crystal asymmetry, growth asymmetry, and strain and electric fields. This work was supported by an ONR MURI.

10:48AM P22.00013 Many-body effects on $\rho_{xx}$. Ringlike Structures via SDFT\textsuperscript{1}. GERSON J. FERREIRA, HENRIQUE J. P. FREIRE, J. CARLOS EGUES, University of Sao Paulo — In the quantum Hall regime, the longitudinal resistivity $\rho_{xx}$ plotted in a density-magnetic-field diagram displays ringlike structures due to the crossings of spin split Landau levels of distinct subbands. We theoretically investigated the dependence of the magnetoresistance on the magnetic field tilt angle and on the temperature using Spin Density Functional Theory (SDFT). Assuming a temperature dependence of the Landau levels broadening, we show that the ringlike structures are broken at sufficiently low temperatures due to a ferromagnetic quantum phase transition. Additionally, for tilt magnetic field, the momentum in the growth direction (z) also couples to the magnetic field $z P_{\perp}$ coupling, thus giving rise to anticrossings between consecutive Landau levels and subbands, collapsing the ring with increasing tilt angle. We find that the interplay of these anticrossings and many-body interactions (via SDFT) leads to a reduced $z P_{\perp}$ coupling, increasing the collapsing angle at which the ring fully disappears. Our results explain some of the physical mechanisms behind ring formation and collapse which have been experimentally observed.

8:00AM P23.00001 Temperature dependence of the phonon density of states in FeSi and CoSi, OLIVIER DELAIRE, Oak Ridge National Laboratory, MATTHEW LUCAS, MATTHEW STONE, DOUGLAS ABERNATHY — The phonon density of states (DOS) of the B20 compounds Fe(1-x)Co(x)-Si (x=0.0, 0.03, 0.5, 1.0) was measured as a function of temperature from 10K to 773K using inelastic neutron scattering. The phonon DOS of FeSi exhibits an excess softening compared to the predictions of the quasiharmonic model, in agreement with previous measurements of elastic constants as function of temperature [1]. The phonon DOS of CoSi softens less, on the other hand, and appears in better agreement with the pure volume effect of the quasiharmonic model. These trends are compared to previous measurements of the temperature dependence of the phonon DOS in the A15 compounds V5Si3 and V3Ge [2]. Using first-principles electronic structure calculations, the observed anomalies are related to the details of the band structure in these compounds. It is shown that sharp features in proximity to the Fermi level lead to anomalous phonons through a sensitivity to thermal disorder, or adiabatic electron-phonon coupling. [1] D. Mandrus et al., Phys. Rev. B 51, 4763 (1994) [2] O. Delaire et al., Phys. Rev. Lett. 101, 105504 (2008)

8:12AM P23.00002 Effects of temperature and chemical order on phonons in Fe-V alloys, MATTHEW LUCAS, Oak Ridge National Lab, JORGE MUNOZ, California Institute of Technology, OLIVIER DELAIRE, Oak Ridge National Lab, BRENT Fultz, California Institute of Technology, DOUGLAS ABERNATHY, MATTHEW STONE, MARK LOGUILLIO, Oak Ridge National Lab — Inelastic neutron-scattering spectra were measured on body-centered-cubic Fe-V alloys as a function of temperature and composition. These data were reduced from time-of-flight histograms to spectra that resemble the phonon density of states (DOS), but were distorted by differences in efficiencies of the atom species for phonon scattering. Nuclear resonant inelastic x-ray scattering spectra were measured for the 57-Fe isotope in a similar set of alloys at room temperature to compliment the neutron spectra. With temperature the 50-50 alloy undergoes an ordering transition from A2 to B2, as evidenced by increasing intensity in the superlattice peaks from the elastic regime of the neutron spectra. This ordering is accompanied by a change in the phonon DOS. The Connolly-Williams cluster inversion method is performed on the DOS of the disordered Fe-V alloys in order to correlate changes in the chemical order with changes in the DOS for the 50-50 alloy. The temperature dependence of the DOS of the disordered alloys is used to determine the anharmonic phonon entropy, and the chemical dependence to determine the phonon entropy of mixing.

8:24AM P23.00003 Ambipolar diffusion and recombination of photoexcited carriers in bismuth films, YU-MIIN SHEU, YI-JIUNN CHIEN, CITRAD UHER, STEPHEN FAHY, DAVID REIS, FOCUS Center and Department of Physics, University of Michigan, Ann Arbor, Michigan 48109-1040, USA — Recent experimental and theoretical studies on bismuth show that intense ultrafast photoexcitation leads to a large−amplitude, softened coherent Alg phonon. Thus, the subsequent dynamics of the photoexcited carriers will strongly influence the dynamics of the phonon. However, little is known about the nonequilibrium carrier dynamics due to difficulty in separating carrier relaxation and other processes. Here we report ultrafast counter propagating pump-probe experiments, measuring photoexcited carrier transport across optically thick single crystal bismuth films at room temperature. The films are grown on transparent sapphire substrates with thicknesses varying between 185 and 385 nm, sufficient to separate the carriers from the effects of lattice heating and strain, when pumped and probed on opposite faces. The measured recombination time is about 14-30 ps and the carrier recombination time is much longer than the Alg phonon period, supporting a two chemical potential model for the photoexcited electronic system and phonon dynamics, in which carrier diffusion (rather than electron-hole plasma cooling or recombination substantially reduces the carrier density over the lifetime of the phonon, leading to a chirped mode.

8:36AM P23.00004 Magnetotransport in ultra quantum Bismuth and related alloys, DORON BERGMAN, KARYN LE HUR, Yale University — Recent studies of elementary Bismuth and related alloys in strong magnetic fields, have uncovered peculiar electric and thermal transport behavior (Bhnia et al. Science 317, 1729 (2007), Banerjee PRB 78, 161103 (2008)). In particular, the Hall resistivity resembles that of the fractional quantum Hall effect, in exhibiting quasi-plateaux, corresponding to fractional filling factors. At the same time anomalous features appear in the Nernst and Seebeck coefficients. Recent efforts to address possible interaction effects (Burnell et al., Aicel et al. preprints 2008), while suggesting interesting electronic states of Bismuth in this ultra quantum regime, have not explained the unusual transport phenomena. We investigate the transport phenomena in more detail, by using a microscopic model of the Bismuth band structure. We first explore Landau level physics in this model, and then go on to develop a theory of the anomalous transport phenomena, using Boltzmann kinetic theory.

8:48AM P23.00005 Angular dependent Nernst effect in Bi,Sb, across the quantum limit, KAMRAN BEHNIA, ZENGWEI ZHU, BENJOUT FAQUÉ, ARITRA BANERJEE, ESPCL, BERTRAND LENOIR, Ecole des Mines — The Fermi surface of bismuth occupies a tiny (10−5) fraction of the Brillouin zone. Therefore, a field of 9 T oriented along the trigonal axis pushes the electrons to their lowest Landau level. Allowing bismuth with antimony reduces the carrier density and lowers this threshold field known as the quantum limit. Approaching this limit, the Nernst-Ettingshausen effect was found to control the macroscopic quantities whose magnitude is yet to be understood. The Nernst response presents sharp peaks each time a Landau level of hole-like quasi-particles meets the chemical potential. In addition to these peaks, a number of anomalies of unidentified origin were detected. Here, we present the first study of Nernst effect as a function of a rotating magnetic field in Bi,Sb, up to 12 T. The results highlight the role played by the Dirac quasi-particles of the electron pockets in the generation of the unidentified anomalies.

9:00AM P23.00006 Thermal transport properties of two-dimensional Dirac fermion, YOUSSEF ROMIAH, Department of Physics and Texas Center for Superconductivity, University of Houston, XIN-ZHONG YAN, Chinese Academy of Science, CHIN-SEN TING, Department of Physics and Texas Center for Superconductivity, University of Houston — The self consistent Born approximation is utilized to obtain the electronic density of states of the disordered alloys is used to determine the anharmonic phonon entropy, and the chemical dependence to determine the phonon entropy of mixing.

9:12AM P23.00007 Grain coarsening in crystals from evolution of dislocation densities: Results from a continuum theory of dislocation dynamics, WOOSONG CHOI, YONG CHEN, STEFANOS PAPANIKOLOAU, JAMES SETHNA, Cornell University, SURACHATE LINKUMNERD, Chulalongkorn University — Continuum theories of grain growth and coalescence dynamics are used to incorporate dislocation line tension energy, and explore the resulting coarsening mechanisms in two dimensions. We report initial results both on scaling behavior, coarsening and coalescence phenomena in more detail, by using a microscopic model of the Bismuth band structure. We first explore Landau level physics in this model, and then go on to develop a theory of the anomalous transport phenomena, using Boltzmann kinetic theory.

9:24AM P23.00008 Smooth versus jerky motion of packets of dislocations across fields of obstacles. CATALIN PICU, RENGE LI, Rensselaer Polytechnic Institute — We report on the transition from smooth (“unzipping”) to jerky motion of multiple interacting dislocations (elastic manifolds) moving across a field of randomly located obstacles under constant applied stress. The transition is controlled by the stress, the obstacle strength and distribution. The system exhibits spatial and temporal correlations ( intermittency) similar to those observed experimentally at much larger scale in dislocation avalanches. Power law distributions of jump amplitudes and separation times emerge. Comparison of the simulation results with experimental data indicates that the jerky motion is more relevant for plastic deformation of real crystals than unzipping. The strain rate sensitivity parameter, m, decreases sharply when the system enters the jerky mode and becomes independent of the obstacle strength, presence of obstacles of various strengths and the way those are mixed, and of temperature.

9:36AM P23.00009 Molecular-dynamics analysis of the mechanical behavior of face-centered cubic metallic ultrathin films. KEDARNATH KOLLURI, M. RAUF GUNGOR, DIMITRIOS MAROUDAS, Department of Chemical Engineering, University of Massachusetts, Amherst, MA 01003-3110 — We report results of large-scale molecular-dynamics simulations for the dynamic deformation under biaxial tensile strain of nanometer-scale-thick films of various face-centered cubic metals. Our results indicate that films of metals with moderate to high propensity for formation of stacking faults (e.g., Ni and Cu) exhibit an extended easy glide regime followed by a sharp increase in the material stress, whereas those with low propensity for stacking-fault formation (such as Al) exhibit a monotonic increase in the stress during dynamic loading. We find that the plastic strain rate in Cu and Ni thin films is far greater than that in Al thin films, leading to stress dissipation and an extended easy glide regime. Analysis of defect interaction mechanisms during dynamic deformation reveals dislocation annihilation, which is due to stacking-fault-mediated cross-slip mechanisms in Ni and Cu films and due to collinear interactions between dislocations in Al films.

9:48AM P23.00010 Composition dependence of the elastic constants of β and (α + βp)-phase PdHx. DOUGLAS SAFARIK, RICARDO SCHWARZ, STEPHEN PAGLIERI, DALE TUGGLE, ROBERT QUINTANA, Los Alamos National Laboratory — Previously [1], we measured the room-temperature elastic constants of PdHx for 0 < x < 0.75. These measurements were done on single crystals of α-phase Pd(H) solid solution (x < 0.01), of β-phase Pd-H hydride (x > 0.62), and of coherent two-phase mixtures of α + β phases (0.01 < x < 0.62). We found [1] that for all x the shear modulus C14 decreases linearly with x (Vegard law), whereas for 0 < x < 0.62 the shear modulus C' = (C11 + C12)/2 shows a parabolic dependence on x. We attributed [1] this unusual composition dependence of C' to thermally activated anelastic relaxations of the coherent lenticular-shaped precipitates. If this explanation is correct, then the unusual behavior of C' should disappear on cooling to low temperature. In the present work we have measured the three independent elastic constants and internal friction for both the β-phase and the coherent (α + βp)-two-phase mixture in the temperature range 1.4 < T < 296 K. We find that C14 for the (α + βp) single crystal follows a Vegard law irrespective of temperature. In contrast, C' shows deviations from the Vegard law, and these deviations grow with temperature. We discuss our results in terms of anelastic relaxations of the precipitates, and the elastic properties of two-phase composites. [1] Acta Mat. 53, 569 (2005).

10:00AM P23.00011 Adhesion Enhancement by Interfacial Microcrack Toughening. YUE QI, GM &D Center, HAIIBO GUO, University of South Carolina, XINGCHENG XIAO, GM &D Center, ZHIHUI LI, University of South Carolina — In this study, we reported a novel approach to enhance the adhesion of diamond coatings on titanium substrate by interfacial toughening. An array of oriented and confined micro-cracks around the interface was found to have the ability of opening and self-healing to release strain energy, by which to enhance macro-adhesion. Density functional theory calculations explained that cracks are energetically preferred to initiate and propagate along the (100) plane in titanium carbide interlayer. Thus by controlling the orientation of the interlayer for the failure associated with the delamination can be avoided for the coating/interlayer/substrate system.

10:12AM P23.00012 Oxide-Dispersion Strengthened Nanoparticulate Composites with Application to Magnetic Materials. ROBERT CAMMARATA, STEPHEN FARIAS, Johns Hopkins University, CHAI-LING CHIEN, Johns Hopkins University — Metal matrix nanocomposites have been fabricated by a novel electrochemical deposition method in order to produce enhanced yield strength and creep resistant materials. Metals have been synthesized from an electrolytic solution containing a suspension of oxide nanoparticles. Using a rotating disk electrode, metal samples with a uniform dispersion of oxide nanoparticles are obtained. By controlling the concentration of particles in the solution, the electrode rotation rate, and deposition current density, the volume fraction of oxide in the nanocomposite can be sensitively controlled. Low load indentation testing reveals a substantial increase in room temperature yield strength compared to single phase metals that is close to that predicted from classical hardening models. Particular attention has given to magnetic materials such as Ni and FeCo with the aim of producing materials with improved mechanical behavior without significant degradation of the magnetic properties.

10:24AM P23.00013 High pressure thermoelectricity of vanadium. DANIEL ORLIKOWSKI, LLNL — To support a larger effort for a multi-phase constitutive strength model for vanadium, we discuss the calculations performed to determine the anharmonic thermoelectricity for bcc and rhombohedral phases of vanadium. In this investigation, we have performed extensive calculations of the elastic moduli over broad ranges of temperature (<10,000 K) and pressure (<3 Mbar), accounting for both the electron-thermal and ion-thermal contributions. Using density functional theory (DFT) with the projector augmented-wave (PAW) methodology to calculate the electron-thermal component, we have combined this with the ion-thermal component, which is calculated from Monte Carlo (MC) canonical distribution averages of the strain derivatives on a multi-ion potential itself. The ion-potential is described through a many-body, quantum-based interatomic potential—the model generalized pseudopotential theory (MGPT). We suggest regions of stability for the phase diagram. The resulting elastic moduli are compared to available experimental results and to sound speeds measured along the Hugoniot.

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

10:36AM P23.00014 Shock-wave dispersion and attenuation in discrete media, effect on source localization. HASSON TAVOSSI, Valdosta State University, Department of Physics, Astronomy & Geosciences, 1500 N. Patterson St. Valdosta, GA 31698 — Shock wave speed and attenuation in a non-linear discrete media are investigated. The goal of the study is to identify parameters that control shock wave or impulsive wave speed and energy dissipation in the discrete non homogeneous binary media. Material properties of solid constituents and the elastic behavior of contact points are shown to depend on the wave frequency. The behavior at both high frequency and low frequency limits are analyzed. The effects of depth on wave velocity profile, wave spectral content and attenuation are also considered. Among applications are: accurate near ground shock wave source localization by microseism waves.

Wednesday, March 18, 2009 8:00AM - 10:48AM – Session P24 DMP: Focus Session: Electron Transport in Nanotubes 326
8:00AM P24.00001 Coupling of spin and orbital motion of electrons in carbon nanotubes

Paul Mceuen, Cornell University — Electrons in atoms possess both spin and orbital degrees of freedom. In non-relativistic quantum mechanics, these are independent, resulting in large degeneracies in atomic spectra. However, relativistic effects couple the spin and orbital motion, leading to the well-known fine structure in atomic spectra. The electronic states in defect-free carbon nanotubes are widely believed to be four-fold degenerate, owing to independent spin and orbital symmetries, and also to possess electron–hole symmetry. Here we report measurements demonstrating that the spin and orbital motion of electrons are coupled, thereby breaking all of these symmetries. This spin–orbit coupling is directly observed as a splitting of the four-fold degeneracy of a single electron in ultra-clean quantum dots. The coupling favors parallel alignment of the orbital and spin magnetic moments for electrons and antiparallel alignment for holes. Our measurements are consistent with recent theories that predict the existence of spin–orbit coupling in curved graphene and describe it as a spin-dependent topological phase in nanotubes. Work done in collaboration with F. Kuemmeth, S. Ilani, and D. C. Ralph

8:36AM P24.00002 Sensitivity of carbon nanotube and graphene transistors to local atomic structure

Iddo Heller, Sohail Chatoor, Jaan Mannik, Marcel A. G. Zevenbergen, Cees Dekker, Serge G. Lemay, Delft University of Technology — Transistors based on single-walled carbon nanotubes (SWNTs) and graphene can be operated in aqueous solution where the electrolyte acts as a highly efficient gate. We show that the composition and spatial distribution of ions in the electrolyte intrinsically affect the conductance of SWNT and graphene transistors. Changes in the ionic strength, pH, and surprisingly, the type of ions affect the electronic transport through the electrostatic gating effect. In addition, changing pH leads to Schottky-barrier modification, while changing ionic strength affects the gate capacitance. Interestingly, the observed electrostatic gating effect for graphene is larger than for SWNTs. Most of our data is explained by a model that considers ionizable groups on both the underlying substrate and on the carbon surfaces. Our findings have significant implications for optimizing sensing experiments with nanocarbon transistors.

8:48AM P24.00003 Boosting electronic transport in carbon nanotubes by isotopic disorder

9:00AM P24.00004 Electrical Transport in Long Bundles of Carbon Nanotube-Metal Hybrids

Saikat Talapatra, Rakesh Shah, Clayton Schenk, Xianfeng Zhang, Department of Physics, Southern Illinois University Carbondale, Carbondale, Illinois, 62901, Swastik Kar, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, Troy, NY 12180 — Although a number of works have proposed that bundles of carbon nanotubes can withstand high current densities at low resistances for high-performance applications, such structures have been demonstrated to fall short of proposed expectations. This is chiefly due to limited access to all nanotubes in a bundle in conventional two-terminal device configurations, with low number of effective conducting channels. By depositing a small quantity of high-conductance metal alloys that wet the nanotube surface, our CNT-Au/Pd alloy hybrid conductors show improved performance in terms of failure current density and resistivity. Low temperature transport measurements show that the nanotube bundles with metal coating and especially after the high-bias treatment show more and more metallic nature, with decreased negative temperature coefficient of resistance. The results will be discussed in the framework of transport theories of quasi-one dimensional systems.

9:12AM P24.00005 Phonon populations in a biased carbon nanotube transistor

Mathias Steiner, Marcus Freitag, Vasili Perebeinos, James Tsang, Joshua Small, Megumi Kinoshita, IBM T.J. Watson Research Center, Dongning Yuan, Jie Liu, Dept. of Chemistry, Duke University, Phaedon Avouris, IBM T.J. Watson Research Center — We present a comprehensive picture of the phonon populations in an electrically-driven carbon nanotube transistor, including the Raman-active G and radial breathing modes (RBM), and also the Raman-inactive zone boundary mode (K), and intermediate-frequency mode (IFP), populated by anharmonic decay. The effective temperature of the RBM is considerably lower than the intermediate- and high-frequency mode temperatures, which we explain by a phonon-decay bottleneck. We include substrate polar phonon scattering to fully account for the device electronic characteristics.

Nicola Bonini, Nicola Marzari, Department of Materials Science and Engineering, Massachusetts Institute of Technology — Low-frequency phonon modes play an important role in the electronic and thermal transport properties of carbon nanotubes and ultrathin graphitic films. Not only they determine the very high thermal conductivity of these materials, but they also affect the electrical transport: at low bias they weakly scatter electrons, while at high bias they concur to determine the population of those optical phonon modes that most strongly limit the electrical conductivity. Quite interestingly, these low frequency phonons are also expected to couple to the vibrational modes of a surrounding material, thereby breaking all of these symmetries. This spin–orbit coupling is directly observed as a splitting of the four-fold degeneracy of a single electron in a topological phase in nanotubes. Work done in collaboration with F. Kuemmeth, S. Ilani, and D. C. Ralph

9:36AM P24.00007 Temperature-dependant current saturation in double-wall carbon nanotubes

Delphine Bouilly, Department of physics, Universite de Montreal, Canada, Matthieu Paillet, Richard Martel, Department of Chemistry, Universite de Montreal, Canada, REGROUPEMENT QUEBECOIS SUR LES MATERIAUX DE POINTE (ROMP) COLLABORATION — Current saturation is known to occur at high voltage bias in carbon nanotubes, for single-wall as well as multi-wall configurations. This saturation is generally attributed to the backscattering of carriers by optical phonons. Here we report transport measurements performed on single double-walled carbon nanotubes as a function of temperature between 77K and 400K. The good quality of the contacts between the nanotubes and the electrodes allows to observe a temperature dependence of the I-V curves. At high temperature, the saturation current shows a value around 25nA, as expected from the energy of optical phonons, but then increases non-linearly with decreasing temperature. The low-bias conductance is also measured to increase with decreasing temperature. Phenomenological models are investigated in order to explain the observed trends.

1Financial support from NSERC and FQRNT is acknowledged.
9:48AM P24.00008 Conductance Switching in Gated Graphene Nanoribbons, JESSE M. KINDER, JONATHON J. DORANDO, GARNET K.L. CHAN, Cornell University — We have investigated transport through locally gated metallic graphene nanoribbons using a numerical tight-binding method. We consider a device in which the orientation of the gate with respect to the axis of the ribbon is variable. We find that the conductance, as calculated within the nonequilibrium Green function formalism, depends strongly on the gate voltage and the orientation of the gate.

In particular, we identify specific angles at which a small change in gate voltage results in a large change in the probability of transmission. This response occurs in ribbons with zigzag or armchair edges and could provide a mechanism for a nanometer-scale electronic switch. Using the effective Dirac Hamiltonian for electrons in graphene, we provide a qualitative explanation for the ON-OFF response at particular angles and characterize its dependence on the geometry of the ribbon.

10:00AM P24.00009 Variable Range Hopping Conductivity in Carbon Nanotube Threads, CHAMINDA JAYASHINGHE, DAVID MAST, MARK SCHULZ, VESSELIN SHANOV, University of Cincinnati — We have measured the low temperature, dc electrical transport in threads spun from long multi-wall carbon nanotubes (MWCNT). The electrical transport in these threads shows variable range hopping (VRH) behavior at low temperatures, as well as non-linear IV characteristics at high applied electric fields. The MWCNT used to make the threads have an outer diameter from about 6 nm to 30 nm; these MWCNT’s have been grown in lengths up to 18 mm. The diameter of the CNT threads in this study have diameters of 15 and 25 microns; the threads were spun using 2 mm long MWCNT’s. The room temperature (RT) resistivity of the threads is on the order of 5 Ohm cm and can be changed by post-spinning treatment strategies such as high temperature annealing. From 300 K down to 4.2 K, the resistivities show an exponential dependence with temperature consistent with VRH conduction. As the RT resistivity decreases, the low temperature transport shifts from being dominated, at low temperatures, by Coulomb Gap VRH described by Efros and Shklovskii [1] to 3D-VRH as first formulated by Mott [2]. Analysis will be given of how the VRH behavior changes with intrinsic and post-treatment thread resistivity. [1] A.L. Efros and B.I. Shklovskii, J. Phys. C: Solid State Physics. 8, L49 (1975). [2] N.F. Mott, J. Non-Crist. Solids 1, 1 (1968).

10:12AM P24.00010 Experimental and computational study of 1/f noise scaling in single-walled carbon nanotube percolation films, ASHKAN BEHNAM, GIJS BOSMAN, ANT URAL, University of Florida — We study the scaling of 1/f noise in single-walled carbon nanotube percolation films as a function of device parameters and film resistivity both experimentally and computationally. Our experiments were performed on single-walled carbon nanotube arrays grown on indium tin oxide (ITO) substrates. The nanotube length distribution was characterized by a mean length of 20 μm and a standard deviation of 10 μm. The geometrical characteristics of these nanotube arrays were captured by scanning electron microscopy (SEM). We measured the 1/f noise in several p-n junctions in the percolation regime at room temperature using current fluctuations at 100 mV applied bias. We also computed the 1/f noise in this regime using a percolation theory framework. In this study, we measured the magnitude of the 1/f noise and its scaling exponent for a range of device parameters such as area, thickness, and resistivity. We observed a scaling exponent of approximately 1.2 for a large range of resistivities and found that the noise amplitude depends strongly on device dimensions, nanotube degree of alignment, and the film resistivity, following a power-law relationship with resistivity near the percolation threshold after properly removing the effect of device dimensions. We also find that the critical exponents associated with the noise-resistivity and noise-device dimension relationships are not universal invariants, but rather depend on the specific parameter that causes the change in the resistivity and 1/f noise, and the value of the other device parameters. Since 1/f noise is a more sensitive measure of percolation than resistivity, these results not only provide important fundamental physical insights into the complex interdependencies associated with percolation transport in nanotube films, but also help understand and improve the performance of these nanomaterials in potential device applications, such as nanoscale sensors, where noise is an important figure of merit.

10:24AM P24.00011 Anisotropic Terahertz Response of Highly Aligned Single-Walled Carbon Nanotubes, L. REN, X. WANG, L. BOOSHEHRI, D. HILTON, J. KONO, I. KAWAYAMA, M. TONOUCHI, Inst. of Laser Eng., Osaka University — Dynamic conductivities of degenerate 1-D electrons are expected to provide a wealth of information on quantum confinement, electron interactions, and disorder. Here, we use terahertz time-domain spectroscopy (THz-TDS) to determine the complex dielectric function of a thin film of highly aligned single-walled carbon nanotubes (SWNTs) on sapphire. The THz electromagnetic wave used was linearly polarized, and the measured dielectric function was very anisotropic. As the angle between the nanotube axis and the THz electric field changed, anisotropy was clearly observed for both the real and imaginary parts of the dielectric function. The absorption of the THz wave decreased monotonically with increasing angle from 0 to 90 degrees, with maximum and minimum absorption at 0 and 90 degrees, respectively. Through a proper model, the complex dynamic conductivity was extracted and showed a non-Drude-like frequency dependence, with the real part increasing monotonically with increasing frequency between 0.2 and 1.8 THz.

10:36AM P24.00012 Carbon nanotube diode performance and photovoltaic response, DANER ABDULA, MOONSUB SHIM, University of Illinois Urbana-Champaign — Due to their unique electronic properties, carbon nanotubes have been at the forefront in the development of next generation electronic devices. The p-n diode is arguably the most pivotal electronic and photovoltaic device. Up to now, nanotube diodes have had significant drawbacks including complex quad-terminal device geometries to achieve electrostatic doping, large series resistances from the inclusion of an intrinsic region at the junction, unstable n-type doping, and Zener breakdown. We have developed a method to create two terminal abrupt junction diodes from single semiconducting carbon nanotubes with simple photo-patterned polymer layers defining air-stable p- and n-regions. These intratube diodes show nearly ideal behavior with relatively low series resistance and no sign of Zener breakdown at room temperature. Spatial doping profiles measured by micro-Raman spectroscopy and selective electrochemical gating of the n-region indicate that diode performance depends strongly on relative doping levels. A short circuit current of 1.4 nA with an open circuit voltage of 205 mV are measured when illuminated to saturation.

Wednesday, March 18, 2009 8:00AM — 11:00AM Session P25 DMP: Focus Session: Graphene VII: Electronic Properties

8:00AM P25.00001 Cyclotron Resonance at the Dirac Point, PAUL CADDEN-ZIMANSKY, Columbia University/NHMF, ERIK HENRIKSEN, Columbia University, ZHIGANG JIANG, Georgia Tech University, LI-CHUN TUNG, NHMF, MOLLIE SCHWARTZ, Columbia University, YONG-JIE WANG, NHMF, PHILIP KIM, Columbia University, HORST STORMER, Columbia University/Bell Labs — We present high field infrared spectroscopy data on the n = -1 and n = 0 graphene quantum dots. Our results indicate that the bare Zeeman splitting naively expected for a spin-split state. We compare the field dependence of the shifts with proposed degeneracy-breaking mechanisms.

8:12AM P25.00002 Hydrodynamic approach to transport in graphene, RAFI BISTRITZER, ALLAN MACDONALD, University of Texas at Austin — Exploiting the strong electron-electron interactions in graphene we construct a hydrodynamic theory in which the carrier dynamics is described by three parameters: the electronic temperature, the chemical potential and the drift velocity. We use this theory to describe both linear and non linear transport in graphene.

9:00AM P25.00004 Energy Relaxation of Hot Dirac Fermions in Graphene1, WANG-KONG TSE, University of Texas, Austin; University of Maryland, College Park, SANKAR DAS SARMA, University of Maryland, College Park — We develop a theory for the energy relaxation of hot Dirac fermions in graphene. We obtain a generic expression for the energy relaxation rate of hot Dirac fermions in graphene due to electron-phonon interaction and calculate the power loss due to both optical and acoustic phonon emission as a function of electron temperature $T_e$ and density $n$. We find an intrinsic power loss weakly dependent on carrier density and non-vanishing at $n = 0$, originating from interband electron-optical phonon scattering from the intrinsic electrons in the Dirac valence band. We also obtain the total power loss per carrier to be $\sim 10^{-12}$ and $10^{-11}$ for within the range of electron temperatures $\sim 20 - 1000 K$, finding that the temperature for the optical phonon emission to overtake acoustic phonon emission as the dominant energy loss mechanism ranges $\sim 200 - 300 K$ for $n = 10^{11} - 10^{13} cm^{-2}$.

9:12AM P25.00005 Electron and hole puddles in monolayer graphene on SiO$_2$, B.J. LEROY, A. DESHPANDE, University of Arizona, W. BAO, F. MIAO, C.N. LAU, University of California at Riverside — We have performed spatially resolved scanning tunneling spectroscopy measurements on single layer graphene. The graphene was prepared on SiO$_2$ by the mechanical exfoliation technique and an electrode was attached by electron beam lithography. Atomically resolved topography images over 40 nm areas show that the graphene conforms to the SiO$_2$ surface as well as having intrinsic ripples. In addition to the topography measurements, we have mapped the local density of states as a function of position and energy. We observe a spatially varying Dirac point which leads to electron and hole puddles at low energy. These puddles have a characteristic size scale of about 5 nm. The puddles arise due to curvature in the graphene film which induces shifts in the chemical potential as well as long range scattering from charged impurities.

9:24AM P25.00006 Ripples on graphene and their effect on lattice and electronic properties, MIKHAIL KATSNELSON, Radboud University Nijmegen — A discovery of graphene, a new allotrope of carbon [1], representing the simplest, one-atom thick, membrane, opens exciting perspectives in statistical physics of two-dimensional systems in general. As expected from theory of flexible membranes [2], free suspended graphene is corrugated (rippled) due to thermal bending fluctuations, which was confirmed by experiment [3] and atomistic simulations [4]. This makes graphene strongly anharmonic crystal leading to anomalous temperature dependences of its thermal expansion, elastic moduli and other thermodynamic and mechanical properties. The ripples are also a source of pseudomagnetic gauge field [5] acting on Dirac fermions which leads to important consequences for the electronic structure such as a formation of midgap states [6,7]. Quenched ripples can be also important sources of electron scattering limiting charge-carrier mobility in graphene [8]. Possible mechanisms of this quenching are discussed.

10:00AM P25.00007 Rippling of Graphene1, MARIA MOURA, UT Austin Physics Department, REbecca THOMPson-FLAGG, APS PhysicsCentral, MICHAEL MARDER, UT Austin Physics Department — Experiments found that free standing single-layer graphene sheets display ripples (see ref. Meyer et al. Nature 446, 60 2007). Here we show that these ripples can be a consequence of adsorbed molecules sitting on random sites. The adsorbates cause the bonds between the carbon atom to lengthen slightly. Static buckles caused by roughly 20 % coverage of adsorbates are consistent with experimental observations. We explain why this mechanism is more likely to explain ripples than are thermal fluctuations or the Mermin-Wagner theorem (previously invoked).

1National Science Foundation DMR 0701373.

10:12AM P25.00008 Spectroscopy and Reflection Properties of Massive Graphene[1], KEVIN KNOX, MEHMET YILMAZ, Columbia University, SHANCAI WANG, Renmin University of China, ALBERTO MORGANTE, University of Padua, DEAN Cvetko, University of Ljubljana, ANDREAS KLOSE, TU Berlin, ANDREAS LOOS, University of Munich, MARIA MOURA, UT Austin Physics Department, REBECCA THOMPSON-FLAGG, APS PhysicsCentral, MICHAEL MARDER, UT Austin Physics Department — We develop a theory for the energy relaxation of massive Dirac fermions due to phonon scattering in graphene. We obtain an analytic expression for the energy relaxation rate of massive Dirac fermions in graphene due to electron-phonon interaction and calculate the power loss as a function of electron temperature $T_e$ and density $n$. We find that the energy relaxation rate is weakly dependent on carrier density and non-vanishing at $n = 0$, originating from interband electron-optical phonon scattering from the intrinsic electrons in the Dirac valence band. We also obtain the total power loss per carrier to be $\sim 10^{-12}$ and $10^{-11}$ within the range of electron temperatures $\sim 20 - 1000 K$, finding that the temperature for the optical phonon emission to overtake acoustic phonon emission as the dominant energy loss mechanism ranges $\sim 200 - 300 K$ for $n = 10^{11} - 10^{13} cm^{-2}$.

10:24AM P25.00009 Kohn-Luttinger superconductivity in graphene, JOSE GONZALEZ, Universidad de de la Materia, CSIC, Madrid (Spain) — We address the development of superconductivity in graphene when the Fermi level becomes close to one of the Van Hove singularities of the electron spectrum. The different segments of the Fermi line show then an approximate nesting, which enhances unconventional superconducting and magnetic correlations for a dominant repulsive interaction. The origin of the pairing instability lies in the strong anisotropy of the e-e scattering along the Fermi line, leading to a channel with attractive coupling when making the projection of the BCS vertex on the symmetry modes with nontrivial angular dependence. We show that the superconducting instability is particularly strong at the Van Hove singularity in the valence band of graphene, where the critical scale may be pushed up to temperatures larger than 1 K, depending on the ability to tune the Fermi level to the proximity of the singularity.

10:36AM P25.00010 Polarization and Spectral Properties of Massive Graphene, VALERI KOTOV, VITOR PEREIRA, Boston University, BRUNO UCHOA, Boston University and UIUC, ANTONIO CASTRO NETO, Boston University — We discuss the situation when a finite gap exists in the Dirac fermion spectrum, due to either external factors (substrate-induced), or the mesoscopic (finite size) nature of the sample. The gap could also be generated dynamically via chiral symmetry breaking. We will overview: (1.) The behavior of the polarization charge, induced by an external Coulomb source. The charge density exhibits an unconventional distribution is space, which we present in detail. The density variation could be observable in real experiments when an external ion is placed on the graphene sheet. (2.) The modification of the fermion self-energy, in particular, the large-$N$ limit of the theory. We find that in this limit, which could be relevant for Graphene, the electronic dispersion is strongly renormalized at small energies. We discuss possible consequences of this behavior.
10:48AM P25.00011 High-Mobility Dual-gated Graphene Field-Effect Transistors with Al2O3,Dielectric1 SEYOUNG KIM, JUNCHYO NAH, INSUN JO, DAVID SHAHRIRDI, The University of Texas at Austin, LUIGI COLOMBO, Texas Instruments, ZHEN YAO, EMANUEL TUTUC, SANJAY BANERJEE, The University of Texas at Austin — The carrier mobility in graphene field-effect transistors (GFETs) is primarily dominated by the extrinsic impurity scattering, such as charged impurities in the dielectric. Therefore, the impact of a top-gate dielectric stack on the transport characteristics of graphene represents a key issue for high-performance GFETs. Here, we present the fabrication and characterization of dual-gated graphene FETs and dual-gated graphene devices with Hall bar geometry using Al2O3 as top-gate dielectric. We use a thin Al film as a nucleation layer to enable the atomic layer deposition of Al2O3. Our FETs show mobility values of over 6,000 cm2/Vs at room temperature, a finding which indicates that the top-gate stack does not significantly increase the carrier scattering, and consequently degrade the device characteristics. We propose a device model to fit the experimental data with a single mobility value.

Wednesday, March 18, 2009 8:00AM - 11:00AM
Session P26 DMP: Focus Session: Graphene VIII: Electronic Properties 328

8:00AM P26.00001 Experimental studies of the transport in graphene in a parallel magnetic field at low temperatures1 LIUYAN ZHANG, JORGE CAMACHO, Brookhaven National Laboratory, HELIN CAO, ISAAC CHILDRES, YONG CHEN, Purdue University, ALEXEI TSVELIK, DMITRI KHARZEEV, MAXIM KHODAS, MYRON STRONGIN, TONICA VALLA, IGOR ZALIZNYAK, Brookhaven National Laboratory, BROOKHAVEN NATIONAL LABORATORY COLLABORATION, PURDUE UNIVERSITY COLLABORATION — Graphene has remarkable electronic properties, and it is also a very promising material for spintronic applications. Most previous experiments, however, were focused on studying graphene devices in perpendicular magnetic field, which quantizes the real-space motion of Dirac electrons in graphene and leads to an unusual quantum Hall effect. Here we present the results of experimental studies of electric transport in single- and few-layer graphene devices in parallel magnetic field and at low temperatures. The Dirac-point resistance of our graphene devices was studied as a function of magnetic field and temperature. The effect of tuning the chemical potential under different magnetic fields was also investigated and will be discussed.

1This work was supported by the US Department of Energy, and Purdue University.

8:12AM P26.00002 The Image Potential for Graphene with an Electrostatic Grating1 GODFREY GUMBS, Hunter College/CUNY, DANHONG HUANG, USAF Research Lab, PEDRO ECHENIQUE, DIPC, Donastia, San Sebastian — We calculate the surface response function and the image potential of a layered structure of two-dimensional (2D) electron systems (ES). A point charge is placed at a distance away from the surface which is in the xy-plane. These 2D layers are coupled through the Coulomb interaction and there is no interlayer electron hopping. The separation between adjacent layers can be adjusted to investigate the role which layer separation and the number of layers play on both the surface response function and the image potential. Specifically, we consider the system composed of graphene layers or the layered 2D electron gas (EG) formed at the interface of a semiconductor heterostructure such as GaAs/AlGaAs. We show that the image potential for graphene is qualitatively the same as for the 2DEG. We examine the way in which the image potential is modified by applying a one-dimensional periodic electrostatic potential (through a gated grating for modulation). These results indicate that the charge screening for graphene is not much different from the 2DEG.

1Supported by contract FA 9535-07-C-0207 of AFRL.

8:24AM P26.00003 Adsorption of Ammonia on Graphene1 PRASOON JOSHI, Electrical Engineering Department, Pennsylvania State University, HUGO ROMERO, AWNIL GUPTA, HUMBERTO GUTIERREZ, MILTON COLE, Physics Department, Pennsylvania State University, SRINIVAS TADIGADAPA, Electrical Engineering Department, Pennsylvania State University, PETER EKLUND, Physics Department, Material Science & Engineering Department — We report on experimental studies of NH3 adsorption/desorption kinetics on graphene surfaces. The study employs bottom-gated graphene field effect transistors (FETs) supported on Si/SiO2 substrates. Detection of NH3 occurs through the shift of the source-drain resistance maximum (“Dirac peak”) with gate voltage. The observed shift of the Dirac peak toward negative gate voltages in response to NH3 exposure is attributed to the charge transfer from adsorbed NH3, with the amount of charge estimated to be ∼0.06 electrons per molecule. The sorption kinetics of our FET devices is well described by the sum of two exponential terms corresponding to a fast and a much slower process, whose time constants differ by a factor of ∼9. The two-time constant sorption kinetics is consistent with Fickian-type diffusion of NH3 from the interstitial pockets formed at the interface between the graphene and the supporting SiO2 gate dielectric.

1NSF NIRT # ECS 06-09243

8:36AM P26.00004 Resistive-free method for contacting graphene and few-layer graphene CATERINA SOLDANO, CEMES - Centre d Elaboration de Mateiaux et d Etudes Structurales Toulouse, France, JORGE CAMACHO, Brookhaven National Laboratory, HELIN CAO, ISAAC CHILDRES, JEREMIE GRISOLIA, Department of Genie Physique, INSA, Toulouse, France — We report on experimental studies of NH3 adsorption/desorption kinetics on graphene surfaces. The study employs bottom-gated graphene field effect transistors (FETs) supported on Si/SiO2 substrates. Detection of NH3 occurs through the shift of the source-drain resistance maximum (“Dirac peak”) with gate voltage. The observed shift of the Dirac peak toward negative gate voltages in response to NH3 exposure is attributed to the charge transfer from adsorbed NH3, with the amount of charge estimated to be ∼0.06 electrons per molecule. The sorption kinetics of our FET devices is well described by the sum of two exponential terms corresponding to a fast and a much slower process, whose time constants differ by a factor of ∼9. The two-time constant sorption kinetics is consistent with Fickian-type diffusion of NH3 from the interstitial pockets formed at the interface between the graphene and the supporting SiO2 gate dielectric.

8:48AM P26.00005 Transport studies of highly oriented pyrolytic graphite ARUNA N. RAMANAYAKA, BHASKAR KAVIRAJ, RAMESH G. MANI, Department of Physics & Astronomy, Georgia State University — Highly Oriented Pyrolytic Graphite (HOPG) consists of stacked sheets of single layers of carbon with weak interlayer interactions, which gives rise to anisotropic transport with striking differences between in-plane and perpendicular transport. Transport studies of single layers of carbon, known as Graphene, have shown striking new features in two dimensional transport, arising from the linear dispersion relation and analogies to quantum electrodynamics. A question of interest for our experiments is to examine the crossover from Graphite to Graphene and trace the three-dimensional to two-dimensional evolution in the transport properties of the layered carbon system. Hence, we report here on our efforts to fabricate specimens starting from commercially available HOPG, and present measurements in magnetic fields up to 12 Tesla, down to 1.5 K.

9:00AM P26.00006 ABSTRACT WITHDRAWN
9:12AM P26.00007 Semiclassical model for the magnetoresistance and Hall coefficient of inhomogeneous graphene$^1$, RAKESH TIWARI, DAVID STROUD, The Ohio State University — We show that when bulk graphene breaks into n-type and p-type puddles, the in-plane resistivity becomes strongly field dependent in the presence of a perpendicular magnetic field, even if homogeneous graphene has a field-independent resistivity. We calculate the longitudinal resistivity $\rho_{xx}$ and Hall resistivity $\rho_{xy}$ as a function of field for such a system, using the effective-medium approximation. The conductivity tensors of the individual puddles are calculated using a standard Boltzmann approach suitable for the band structure of graphene near the Dirac points. The resulting resistivity saturates, provided that the area fractions $f_n$ and $1 - f_p$ of n and p type puddles are slightly unequal, and agrees with experiments if the relaxation time is weakly field-dependent. The Hall resistivity $\rho_{xy}$ found to change sign at $f_n = 1/2$.

9:24AM P26.00008 Anomalous Quantum Oscillations in Graphene Hybrid Structures, CONOR PULS, NEAL STALEY, YING LIU, The Pennsylvania State University, Department of Physics — It is well recognized that the edge states of graphene are interesting and important for both fundamental inquiry and potential practical applications of graphene. However, states associated with a step found in a continuous sheet of graphene with two different thicknesses have not been explored to date. We report a study of graphene hybrid structures featuring such a step. In a bulk hybrid featuring two large-area one- and two-layer graphene, two sets of Landau levels and features related to the interface were found. In edge hybrids featuring a large two-layer graphene with narrow one-layer graphene edges, we observed an anomalous suppression in quantum oscillation amplitude due to the locking of one- and two-layer graphene Fermi energies by charge transfer across the interface. These findings demonstrate the existence of unique interface states and related phenomena deserving of further studies. We will also report relevant studies on epitaxially-grown graphene films.

9:36AM P26.00009 Graphene mediated exchange bias$^1$, YURIY SEMENOV, JOHN ZAVADA, KI WOOK KIM, NCSU, DEPARTMENT OF ECE TEAM — We have theoretically investigated the role of graphene in mediating the indirect exchange interaction when it is placed between two ferromagnetic dielectric materials. The calculation based on a tight-binding model illustrates that the magnetic interactions at the interfaces affect not only the graphene band structure but also the thermodynamic potential of the system. This induces an indirect exchange interaction between the magnetic layers that can be considered in terms of an effective exchange bias field. The analysis clearly indicates a strong dependence of the effective exchange bias on the properties of the mediating layer. Through the dependence on the graphene electro-chemical potential, the effective exchange bias can be modulated electrically over a wide range even at room temperature. This dependence also results in qualitatively different characteristics for the cases involving monolayer and bilayer graphene. The numerical estimate indicates the potential significance of the proposed phenomenon in practical applications.

9:48AM P26.00010 Conductivity engineering of graphene by defect formation, BIPLAB SANYAL, Uppsala University — Graphene exhibits exotic electronic properties revealed in transport measurements. The possibility to influence the electronic structure and hence control the conductivity by physisorption or doping with adatoms is crucial in view of electronics applications. Here we show that in contrast to expectation, the conductivity of graphene increases with increasing concentration of vacancy defects, with an amount of over one order of magnitude. We obtain a pronounced enhancement of the conductivity after insertion of defects by ab-initio electronic structure calculations. The theoretical results are supported by the experimental studies on carbon nano-sheets. Our finding is attributed to defect induced mid-gap states, which create a region exhibiting metallic behavior around the vacancy defects. The modification of the conductivity of graphene by implementation of stable defects is crucial for the creation of electronic junctions in graphene-based electronics.

10:00AM P26.00011 A computational study of electrical transport in graphene-based films and composites, JEREMY HICKS, ASHKAN BEHNAM, ANT URAL, Electrical and Computer Engineering, University of Florida — We study the electrical behavior of films and composites composed of a mesh of graphene sheets using Monte Carlo simulations. We take into account the sheet-sheet junctions with different areas as well individual graphene sheets in calculating the film/composite transport properties. We find that the resistivity of composites varies by many more orders of magnitude than films approaching the percolation threshold due to tunneling-percolation through the sheet network, but otherwise the two exhibit many of the same scaling trends. Furthermore, we find that resistivity in both cases is a strong function of graphene sheet aspect ratio, density, volume fraction, and device dimensions. We extract important parameters such as the critical exponents near the percolation threshold and compare them with the available experimental data. These results, explained through physical and geometrical arguments, give valuable insights into the factors influencing the electrical transport in graphene sheet films and nanocomposites. Such graphene-based nanomaterials might find applications in many fields such as photovoltaics, sensors, and multifunctional nanocomposites.

10:12AM P26.00012 Investigating the quantum behavior of a graphene-based Josephson Junction, JOSEPH LAMBERT, ZECHARIAH THRALLKILL, ROBERTO RAMOS, Drexel University — Recent experiments have demonstrated the Josephson effect in superconducting mesoscopic graphene devices consisting of two superconducting leads separated by a few hundred nanometers, contacted by single and multiple layers of graphene [1]. We report on the progress of low temperature experiments that study the temperature dependence of switching currents in this device. The motivation is to explore the presence of macroscopic quantum metastable states similar to those found in current-biased Josephson junctions. These states are interesting and have been used as basis states for superconducting qubits. [1] H.B. Heersche, P.D. Jarillo-Herrero, J.B. Oostinga, L.M.K. Vandersypen, and A.F. Morpurgo, Induced superconductivity in graphene, Solid state communications, 143(1-2), 72-76 (2007)

10:24AM P26.00013 Study on the Electronic Band Structures of Doped Graphene, C.G. HWANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, KEVIN T. CHAN, D. SIEGEL, Department of Physics, University of California, Berkeley, CA, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, A.V. FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA, MARVIN L. COHEN, Department of Physics, University of California, Berkeley, CA, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, J.B. NEATON, The Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, CA, A. LANZARA, Department of Physics, University of California, Berkeley, CA, Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA — A carbon sheet self-assembled on a SiC substrate, has been found to undergo changes in an electronic property as a function of doping concentration. Depending on the species of dopants, charge carrier density is gradually modified with increasing dopant coverage. By using angle resolved photoemission spectroscopy, we study how the graphene pi bands are modified by changing doping concentration and we discuss the effect of doping on many-body interaction such as electron-phonon coupling. These results provide new information on the role of electron-phonon coupling for superconductivity in the graphite intercalated compounds.
10:36AM P26.00014 Anomalous thermoelectric transport of Dirac particles in graphene. PENG WEI, WENZHONG BAO, YONG PU, CHUN NING (JEANIE) LAI, JING SHI, Department of Physics, University of California at Riverside — We report a thermoelectric transport property study of single layer graphene devices in both classical and quantum Hall regimes. In zero magnetic field, by sweeping the gate voltage $V_g$ to vary the carrier density $n_{2D}$, we demonstrate a diverging behavior in the Seebeck coefficient $S_{xx}$, i.e. $S_{xx} \sim 1/\sqrt{n_{2D}}$, which is a direct consequence of the linear energy dispersion of the massless particles. At low temperatures and high carrier densities, the Seebeck coefficient depends linearly on temperature, indicating the validity of the Mott relation. In the applied magnetic fields, we observe an anomalously large Nernst signal ($\sim 6 \mu V/K\mu T$) at the Dirac point. This is another unusual property expected for massless particles. At low temperatures where the quantum Hall effect is observed, both the Seebeck and Nernst signals show oscillations corresponding to the Landau levels manifested in the quantum Hall plateaus.

Wednesday, March 18, 2009 8:00AM - 11:00AM
Session P27 GIMS: Focus Session: Advances in Scanned Probe Microscopy III: High Frequency and Optical Techniques 329

8:00AM P27.00001 Nanoscale Spectroscopy with Optical Antennas, LUKAS NOVOTNY, University of Rochester — Antennas are devices that efficiently convert localized energy to free propagating radiation, and vice versa. They are a key enabling technology in the microwave and radio-wave regime but their optical analogue is greatly unexplored. In order to understand antenna-coupled light emission and absorption we use a single molecule as an elementary light emitting device. With an optical antenna in the form of a simple gold particle we are able to increase the emission efficiency by more than a factor of 10. However, for very short distances between particle and molecule the fluorescence yield drops drastically because of nonradiative energy transfer. A simple gold particle is not an efficient optical antenna and it can be expected that favorably designed nanoplasmic structures will yield much higher enhancement. Optical antennas can be employed as light sources for high-resolution optical microscopy and spectroscopy. We demonstrate vibrational (Raman scattering) and nonlinear imaging with spatial resolutions down to 10nm.

8:36AM P27.00002 Nano-Prism Probe for Nano-Optical Applications, TAEKYEONG KIM, BYUNG YANG LEE, SEUNGHUN HONG, Department of Physics and Astronomy, Seoul National University, DEOK-SOO KIM, ZEE HWAN KIM, Department of Chemistry, Korea University — Recently, a nano-prism structure has drawn attention as an optical nano-antenna due to its exotic optical properties, while it has been extremely difficult to prepare a probe terminated with a nano-prism for nano-optical applications. Herein, we report a method to mass-produce pristine nano-prism probes. Our fabrication process resulted in nano-prism with sharp edge at the end of the probe, which significantly enhanced the electric field around it and made nano-prism probes ideal for nano-optical applications. We performed the apertureless near-field scanning optical microscopy on gold nanoparticles using a nano-prism probe, revealing the field localization at the vertices of the nano-prism. We also demonstrated the fabrication of multiple nano-prism probes in a parallel fashion. This method could be a major breakthrough and provide tremendous flexibility for SPM optical applications such as nano-TERS (tip enhanced Raman scattering) or FRET (fluorescent resonance energy transfer) because it allows one to mass-produce nano-probes terminated virtually general nanostructures. (Advanced Materials, in press)

8:48AM P27.00003 Optical Response of Absorbates in the STM Environment; The Influence of the STM Tip and Plasmonic Effects, PING CHU, D.L. MILLS, University of California, Irvine — STM is widely used to explore the excited states and related optical properties of adsorbates on metal surfaces. The adsorbate may be placed on a thin oxide layer that is grown on the metallic substrate. One may ignore the direct hybridization between the adsorbate electrons and those in the substrate. We have developed the theory of the optical response of adsorbates in such an environment. Electrons in the adsorbate may interact with the electronic degrees of freedom of the tip/substrate complex through the fluctuating electric fields generated by the zero point motions of electrons in the substrate and the tip. The coupled plasmons of the tip/substrate complex contribute to these fluctuating fields. We have developed a formalism which allows us to describe energy level shifts of the adsorbate orbitals and the non radiative decay rate of excited states from coupling to the electronic degrees of freedom in the tip and substrate. We have also developed a theory of plasmon enhanced radiation emission under the tip, where the coupled plasmons of the tip/substrate complex are responsible for the enhancement of the emission.

1Research supported by the U. S. DOE, Grant No. DE-FG03-84ER-45083.

9:00AM P27.00004 Ultrafast Stroboscopic Optical Interferometry of Nanoelectromechanical Devices in Damping Pressurized Gas Environment, O. SVITSELSKIY, V. SAUER, N. LIU, K.M. CHENG, M.R. FREEMAN, W.K. HIEBERT, University of Alberta Physics Dept and National Institute for Nanotechnology, Edmonton AB Canada — A broad range of prospective applications of nanoelectromechanical devices necessitates understanding their performance under varying external conditions. We report a comprehensive gas damping study of a series of Si nanoribbons and nanocantilevers with thickness of 0.147 µm, widths ranging from 0.1 to 1 µm, and lengths from 0.5 to 12 µm. Free ring-down oscillations of the resonators, capacitively excited by 1 ns 50 V electric pulses, were measured via instantaneous optical interference pictures snapped by a femtosecond laser. The decay response to a range of damping environments was studied, including response to different gases (He, N₂, CO₂) in widely ranging pressures from deep vacuum up to 200 bar, all done in a specially designed scanning optical microscopy chamber [1]. The resonator parameters demonstrate three distinct regions of pressure behavior: high vacuum, free molecular flow, and viscous. For each region a qualitative model is presented. [1] O.Svitsel'skiy et al, Rev.Sci.Instr.79 093701, 2008

9:12AM P27.00005 An Ultra High Vacuum Radio Frequency Scanning Tunneling Microscope, UTKU KEMIKTARAK, Dept. of Physics, Boston University, Boston, MA 02215, KEITH SCHWAB, Dept. of Physics, Cornell University, Ithaca NY 14853, KAMIL EKINCI, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD 20899 and Dept. of Mechanical Eng., Boston University, Boston, MA 02215 — Radio frequency scanning tunneling microscope (RF-STM) utilizes a LC resonant circuit to achieve impedance matching between the STM tunnel junction and 50-Ω high frequency electronics. This technique allows measurement bandwidths up to 10 MHz. We have built an ultra high vacuum (UHV) RF-STM system with in-situ tip and surface treatment as well as sample, tip and matching circuit exchange. In this talk, we will describe the basic operation of this system and discuss the application of UHV RF-STM to high frequency displacement detection. We will argue that UHV RF-STM is a suitable tool to measure back-action forces of tunneling electrons and other tip-sample interactions.
9:24AM P27.00006 Development of a scanning probe microscope for localized ferromagnetic resonance measurements. CHRISTIAN LONG, NAOYUKI TAKETOSHI, University of Maryland, HAITAO YANG, Intumatic Corporation, ICHIRO TAKEUCHI, University of Maryland — We present an update on our research into the development of a scanning probe microscope capable of performing localized ferromagnetic resonance measurements. The system is based on near-field microwave microscopy using a resonant microwave cavity. Using near-field microwave microscopy allows us to produce a GHz frequency magnetic field which is confined to the region around the probe tip. By recording the change in the transmission coefficient of the resonator (S12) as a function of applied DC magnetic field, we measure the absorption of RF energy by the sample. The resulting ferromagnetic resonance spectrum allows us to map the magnetic properties of the material under the probe tip. The possibility to perform localized ferromagnetic resonance measurements using a scanning probe geometry promises to yield new insight into the properties of magnetic thin films.

9:36AM P27.00007 Scanning magnetic resonance microscopy: Spatially resolved imaging of ferromagnetic resonance on yttrium iron garnet disk. TOSHU AN1, TOYOAKI EGUCHI, YUKIO HASEGAWA, The Institute for Solid State Physics, The University of Tokyo — We developed a radio frequency (RF) probe which can be implemented into scanning probe microscopy aiming for its spatially resolved imaging. The probe is composed of a sharp tip attached at the end of a semi-rigid coaxial cable which transmits RF over 10 GHz. To measure ferromagnetic resonance (FMR) of a sample, the probe is set close to the sample, and the S11 parameter was measured by using a network analyzer. As a test magnetic sample, a 10 mm-diameter and 1 mm-thickness polycrystalline YIG (yttrium iron garnet) disk was used. By locating the RF probe at the center of the YIG disk, FMR signal was detected as an absorption dip at 2.8 GHz in the S11 measurements under in-plane static magnetic field of 458 Oe. The detected FMR signal has a sharper dip compared with that obtained in the coplanar wave guide method, and by moving the RF probe to the edge of the YIG disk, two different frequencies of FMR signal appears depending on the moving direction parallel or perpendicular to the applied magnetic field. The detected spatially dependent FMR signals are well explained by the magnetostatic waves.

9:48AM P27.00008 Design and Fabrication of a Nanoscale Force Sensor for High-Speed Atomic Force Microscopy. J. M. CAMPBELL, B. LUCHT, R. G. KNOBEL, Queens University — The atomic force microscope (AFM) has become an important tool in many fields ranging from materials science to biology. Conventional microfabricated AFM cantilevers have resonance frequencies of 10–300 kHz; some specialized cantilevers are available with frequencies up to 2 MHz. However, this represents the practical limit of the resonance frequency of microcantilevers. Three modeling methods were used to design a 200 MHz silicon nitride cantilever suitable for integration into an atomic resolution, frequency-modulation AFM. A process was developed to fabricate the cantilever coupled to an atomic point contact (APC) displacement detector, a device first demonstrated by Flowers-Jacobs et al. (2007). The cantilever mask and APC electrodes were defined through electron-beam lithography and triple-angle evaporation. The cantilever pattern was transferred to the nitride layer through focused ion beam milling and a subsequent wet etch into the underlying Si substrate suspended the structure. Then, using an active feedback system similar to that developed by Strachan et al. (2005), electromigration was used to form the APC at 77 K and 10−6 Torr. Progress toward measuring cantilever motion with the APC displacement detector through microwave reflectometry will be discussed.

10:00AM P27.00009 Interferometric and Synthetic Aperture Real-Time Terahertz Imaging 1. KE SU, ZHINWEI LII, DAME E. GARY, JOHN F. FEDERICI, Department of Physics, New Jersey Institute of Technology, ROBERT B. BARAT, Otto York Department of Chemical Engineering, New Jersey Institute of Technology, ZOI-HELENI MICHALOPOULOUL, Department of Mathematical Sciences, New Jersey Institute of Technology — Over the past several years, several methods of real-time THz imaging have been developed. In this presentation, we describe a synthetic aperture imaging method of THz imaging. A 4-element THz detector array is used to reconstruct 2-D images of a point source through the interferometric synthetic aperture imaging method. A capture rate up to 63 frames/s can be achieved. The recorded video showing the movement of the terahertz source in real time can be viewed at http://www.njit.edu/~ks265/imagingvideo.html after baseline and phase correction. Furthermore, a high power THz source will be integrated in this CW THz system for longer stand-off imaging distances.

10:12AM P27.00010 Fabrication of MEMS Bimaterial Sensors for Uncooled THz Imaging. DRAGOSLAV GROBOVIC, GAMANI KARUNASIRI, Naval Postgraduate School — Recently, there has been a significant interest in Terahertz (THz) technology, primarily its applications in concealed object detection and medical imaging. THz region of the spectrum has been underutilized due to lack of compact and efficient sources and detectors. THz imaging has recently been achieved using uncooled, microbolometer infrared (IR) camera and quantum cascade laser (QCL) operating as a THz illuminator. However, bolometer IR cameras are not optimized for the THz band and fabrication of their focal plane arrays (FPAs) is complex due to required monolithic integration of detectors and readout electronics. Recent developments in bi-material based IR FPAs with optical readout, substantially simplify the fabrication process by decoupling readout from sensing. This presentation describes the design and fabrication of THz-optimized bi-material FPAs, as well as integration of the real-time imaging system. The detection scheme involves detector deformation to minute temperature changes due to absorption of THz radiation. Individual detector deformations are simultaneously probed by shining visible light on entire FPA and reflecting it into a CCD camera. Optical readout eliminates the self-heating effects, enabling longer integration times and, better signal-to-noise ratio.

10:24AM P27.00011 Detection of terahertz radiation from 410 GHz CMOS circuit and other high-frequency oscillators using a Fourier Transform Interferometer 1. EUNYOUNG SEOK2. Department of Electrical and Computer Engineering, University of Florida, DANIEL J. ARENAS, Department of Physics, University of Florida, DONGHA SHIM, KENNETH K. O, Department of Electrical and Computer Engineering, University of Florida, DAVID B. TANNER, Department of Physics, University of Florida — Recently, a record-setting operating frequency of 410 GHz was reported for a CMOS circuit, fabricated using 45 nm technology. To measure the emission from this and related devices, we employed a Bruker 113v fourier transform interferometer. The radiation from an on-chip patch antenna attached to the 410 GHz push-push oscillator circuit was measured by placing the chip in the lamp housing of the interferometer. Emission was detected in the first and second harmonics of the oscillator fundamental. Power was estimated by comparison to that from quasi-blackbody sources (globar and mercury lamp). Possible applications will be discussed.

10:36AM P27.00012 Measuring Spin-Lattice and Spin-Spin Relaxation Times Using a Continuous Wave Electron Paramagnetic Resonance Spectrometer, MICHAEL R. PAGE, M.R. HERMAN, K.C. FONG, D.V. PELEKHOV, P.C. HAMMEL, The Ohio State University — The spin-spin and spin-lattice relaxation times, known as $T_1$ and $T_2$, respectively, provide information about the spins in a material. This information can be used as an imaging technique in Magnetic Resonance methods. $T_1$ and $T_2$ can be measured by a Continuous Wave Electron Paramagnetic Resonance Spectrometer, provided the relationship between the input power and oscillating magnetic field is known. The advantage to this is that Continuous Wave Electron Paramagnetic Resonance Spectrometers are much cheaper than Pulse Electron Paramagnetic Resonance Spectrometers. The relationship between the input power and the oscillating magnetic field is determined by using a sample with known $T_1$ and $T_2$, measuring the absorption at different power levels, and fitting the distribution of absorptions to a curve. We show the results of this measurement with a Bruker EMX 2.7 Continuous Wave Electron Paramagnetic Resonance Spectrometer. This work was supported by The U.S. Army Research Office MURI under contract W911NF-05-1-0414 and by The U.S. Army Research Office DURIP under contract W911NF-07-1-0305.

10:48AM P27.00013 Terahertz Near-Field Nanoscopy of Mobile Carriers in Single Semiconductor Nanodevices, ANDREAS J. HUBER, Max-Planck-Institut für Biochemie, Munich, Germany and CIC nanoGUNE, San Sebastian, Spain, FRITZ KEILMANN, Max-Planck-Institut für Biochemie, Munich, Germany, J. WITTBORN, Infineon Technologies AG, Munich, Germany, JAVIER AIZPURUA, CSIC-UPV/EHU and DIPC, San Sebastian, Spain, RAINER HILLENBRAND, Max-Planck-Institut für Biochemie, Munich, Germany and CIC nanoGUNE, San Sebastian, Spain — We introduce ultraresolving Terahertz (THz) near-field microscopy based on THz scattering at atomic force microscope tips. Nanoscope resolution is achieved by THz field confinement at the very tip apex to within 30 nm, which is in good agreement with full electro-dynamic calculations. Imaging semiconductor transistors, we provide first evidence of 40 nm ($\lambda/3000$) spatial resolution at 2.54 THz (wavelength $\approx 118 \mu m$) and demonstrate the simultaneous THz recognition of materials and mobile carriers in a single nanodevice. We find that the mobile carrier contrast can be directly related to near-field excitation of THz-plasmons in the doped semiconductor regions. This opens the door to quantitative studies of local carrier concentration and mobility at the nanometer scale. The THz near-field response is extraordinary sensitive, providing contrast from less than 100 mobile electrons in the probed volume. Future improvements could allow for THz characterization of even single electrons or biomolecules.

Wednesday, March 18, 2009 8:00AM - 11:00AM
Session P28 FLAP: Focus Session: Thermoelectricity in Si-containing Materials 330

8:00AM P28.00001 Atomistic Simulations of Heat Transport in Silicon Nanowires, DAVIDE DONADIO, University of California Davis — Silicon is one of the best known materials of our age, cheap and readily available, being the basic constituent of semiconductor electronics. It would therefore be highly desirable to broaden its utilization for, e.g., renewable energy applications. Recently, it has been proposed that Silicon may be engineered to be an efficient thermoelectric material for use in solid state devices. Although a rather inefficient thermoelectric in its bulk form, at the nanoscale Si may become a poor heat conductor, while retaining good electronic conduction properties, and thus exhibit high efficiency in converting heat into electric current. However the fundamental reasons for the reported low heat conduction in Si nanowires (NW) are not yet understood, and different interpretations has so far appeared in the literature. Here we present atomistic simulations of heat conduction in Si NW of 1 to 3 nm diameter. Our results show that, depending on their surface structure, these wires may exhibit values of the thermal conductivity varying by two orders of magnitude, and as high as those of bulk Si. This clearly indicates that the increased surface to bulk ratio at the nanoscale may be only partially responsible for the decreased thermal conductivity observed experimentally. We also find that diffusive, yet extended, vibrational modes present in the case of wires with amorphous surfaces, are responsible for the dramatic decrease in thermal conductivity. Our findings suggest ways of engineering wires with even lower thermal conductivity, by increasing surface disorder, in particular by alloying Si with, e.g. Ge at the crystalline-amorphous interface.

8:36AM P28.00002 Ultralow thermal conductivity in Electrolessly Etched (EE) Silicon Nanowires, KEDAR HIPPALGAONKAR, RENKUN CHEN, BAIR BUDAEV, Dept of Mech Eng, UC Berkeley, JINYAO TANG, SEAN ANDREWS, Dept of Chem, UC Berkeley, PADRAIG MURPHY, SUBROTO MUKERJEE, JOEL MOORE, Dept of Phys, UC Berkeley, PEIDONG YANG, Dept of Chem, UC Berkeley, ARUN MAJUMDAR, Dept of Mech Eng, UC Berkeley — EE process produces single-crystalline Silicon nanowires with rough walls. We use suspended structures to directly compute the heat transfer through single nanowires. Nanowires with diameters less than the mean free path of phonons impede transport by boundary scattering. The roughness acts as a secondary scattering mechanism to further reduce phonon transport. By controlling the amount of roughness it is possible to push limits to the extent that nanowire conductance close to quanta of thermal conductance, $hT/\pi k_B^2$ is observed. Traditionally, the lower limit of conductivity is amorphous Silicon at 1 W/mK at room temperature. The measured conductivity of our nanostructures challenges even this amorphous limit pointing towards previously unstudied mechanisms of thermal resistance. We measure thermal conductivity of ~150nm diameter EE wires to be ~1 W/mK.

8:48AM P28.00003 Thermoelectric Power of Silicon Nanowires, HYUK JU RYU, DEBORAH PASKIEWICZ, SHELLEY SCOTT, MAX LGALLY, MARK ERIKSSON, UNIVERSITY OF WISCONSIN-MADISON TEAM — Thermoelectric nanomaterials have been attracting considerable interest for the cooling of hotspots and the conversion of waste thermal energy into useful electrical energy. There is special interest in silicon thermoelectrics because of potential monolithic integration on microchips as well as opportunities in nanofabrication and bandstructure engineering. We present measurements of the thermoelectric power of silicon nanowires with different doping concentrations and the gate field effect. Because silicon heterostructures can have modulation in charge density and mobility along the charge path, we have fabricated and measured silicon/silicide, silicon/silicon-germanium, and hybrid orientation silicon heterostructures in the form of nanowires. Measurements of the thermoelectric power of these structures and the effects of the internal interfaces will be presented and compared with theoretical calculations. This work is supported by DOE, AFOSR, NZ-FRST, NDSEG, NSF, and SOITECH.

9:00AM P28.00004 Thermoelectric Properties of Higher Manganese Silicide Nanowires, ARDEN MOORE, THE UNIVERSITY OF TEXAS AT AUSTIN, JEREMY HIGGINS, University of Wisconsin-Madison, FENG ZHOU, THE UNIVERSITY OF TEXAS AT AUSTIN, SONG JIN, University of Wisconsin-Madison, LI SHI, THE UNIVERSITY OF TEXAS AT AUSTIN — Higher manganese silicides (HMS) have a relatively high thermoelectric figure of merit (ZT) of about 0.7. HMS nanowires have been synthesized using a chemical vapor deposition method. In this work, the thermoelectric properties of individual HMS nanowires are measured and determined to rule the role of size effects on electron and phonon transport as well as potential ZT enhancement. Measurements of Seebeck coefficient, electrical conductivity, and thermal conductivity were performed using both suspended and substrate-based microdevices. Results show that the Seebeck coefficient of two as-synthesized 60 nm diameter nanowires between 300-400K is about 25-50% lower than that of single crystal bulk parallel to the c-axis, while the electrical conductivity values are about 25% lower than bulk single crystal in the same direction. The thermal conductivity of one 60 nm diameter nanowire at room temperature was found to be four times smaller than the bulk value along the c-axis. The large reduction in thermal conductivity and small to moderate impact on electrical transport may lead to HMS nanowires with enhanced ZT.
The enhancement of power factor is mainly due to increase in mobility of carriers without much affecting the Seebeck coefficient. We have improved onboard electrical power to several US space vehicles. Since their performance is related to dimensionless figure-of-merit (ZT), material scientists have focused on possible improvements in ZT of SiGe alloys through an increase in power factor and decrease in thermal conductivity. We have improved their attention on possible improvements in ZT of SiGe alloys through an increase in power factor and decrease in thermal conductivity. We have improved the total Seebeck coefficient in agreement with experiment. Boundary roughness scattering indeed proves to have a significant effect on both electronic and thermal transport, and we discuss a novel method to account for the phonon boundary scattering, which supplants the use of the phenomenological specular parameter. We demonstrate that indeed the room-temperature figure of merit in thin wires reaches values close to 1, and discuss options for its further enhancement.

9:48AM P28.00008 Lattice thermal conductivity of nanostructured semiconductors from atomistic simulations

We present an atomistic analysis of the thermal conductivity (k) of nanoporous silicon (np-Si) [1, 2], and we compare our results with those obtained for bulk crystalline (c-Si) and amorphous Si. We computed k using equilibrium molecular dynamics and Green Kubo relations; we then analyzed our results by solving the Boltzmann Transport Equation in the single mode relaxation time approximation, and by using an approach devised [3] to describe thermal transport in disordered semiconductors. We observe that in np-Si the phonon mean free path is reduced by up to a factor of 10 with respect to c-Si, yielding a reduction of the k of about 2 orders of magnitude. The predominant phonon scattering processes contributing to k can be modeled by the same non-perturbative [3] approach that describes thermal transport in a-Si.

10:00AM P28.00009 Direct Measurements of Figure-of-Merit in Amorphous Silicon-based Thermoelectric thin films

The primary challenge is to search for materials with optimized electrical transport while minimizing the thermal conductivity. Amorphous materials and their alloys are relatively new functionally important materials that demonstrate superior properties in wide range of applications such as in thermoelectricity because of their low thermal conductivity due the higher degree of disorder. Previously, we reported in plane thermal conductivity of amorphous Silicon Nitride (a-Si-N) membranes. In this talk we present our measurement technique and recent results of thermoelectric properties of thin film amorphous Si and its alloys by direct measurement of in plane thermal conductivity, thermopower and electrical conductivity on one platform and discuss the thermoelectric figure of merit.

10:12AM P28.00010 Enhancement in power factor in p-type bulk SiGe alloys

We have measured the thermal conductivity - e.g. in alloys it is lower than the binary endpoints due to increased scattering induced by strain and disorder. Understanding the thermal conductivity of complex materials is also important in other applications - from reducing hot-spot temperatures in electronic chips to better thermal-insulation materials. Here, we have calculated the thermal conductivity of silicon-germanium alloys using ab-initio density functional perturbation theory. The electronic structure of the alloy is studied with the virtual crystal approximation and the single mode relaxation time approximation; perturbation theory up to the third order provides phonon lifetimes, and disorder effects are taken into account by ensemble averages over configurations with random mass disorder. The contribution of acoustic and optical phonons to the thermal conductivity is also presented, together with the phonon mean free paths. These calculations could be used to estimate the size of the nanostructures that could reduce the thermal conductivity below bulk values through increased scattering of phonons.

9:12AM P28.00005 Thermal conductivity of silicon-germanium alloys from first-principles

We have calculated the thermal conductivity of silicon-germanium alloys using ab-initio density functional perturbation theory. The electronic structure of the alloy is studied with the virtual crystal approximation and the single mode relaxation time approximation; perturbation theory up to the third order provides phonon lifetimes, and disorder effects are taken into account by ensemble averages over configurations with random mass disorder. The contribution of acoustic and optical phonons to the thermal conductivity is also presented, together with the phonon mean free paths. These calculations could be used to estimate the size of the nanostructures that could reduce the thermal conductivity below bulk values through increased scattering of phonons.

9:24AM P28.00006 ABSTRACT HAS BEEN MOVED TO S1.00260 —
10:36AM P28.00012 High Temperature Elastic Moduli Measurements and Phase Transition Studies of Novel Thermoelectric Materials. GUANCYAN LI, RESHEED ADEBISSI, JOSH GLADDEN. University of Mississippi — Thermoelectric (TE) materials can be used to convert heat including waste heat to electrical power. They are one component to energy savings and independence. Silicon germanium (SiGe) and Zintl phase compounds are excellent candidates for high temperature applications. The mechanical properties of these materials need to be known before their actual applications in high temperature (1000°C) environments. The temperature dependent elastic moduli of five different SiGe alloys were successfully measured using a high temperature resonant ultrasound spectroscopy (RUS) technique. A linear trend is generally observed up to 600°C, a downward curvature especially in two n-type samples is noticeable at higher temperatures. Hysteresis is only observed in one of the n-type SiGe samples. Phase transitions, indicated by shifts in the natural frequencies of a Zintl sample, were observed near 792, 892, 931°C. The nature of these transitions will be discussed.

10:48AM P28.00013 Preparation and thermoelectric properties of Magnesium compounds. XI-UNU LIN, Eastern Kentucky University, GEORGE NOLAS, University of South Florida, DONGLI WANG. Semiconductor Manufacture International Corporation, Shanghai, China — We report on the synthesis and low temperature transport properties measurements of environmental-friendly thermoelectric materials Mg$_2$B$_n$Ge$_{2(n-1)}$ (B=Si, Ge, Sn) and their alloys. These semiconductors are prepared through solid-state reaction of constituent elements. The effect of electrons doping and structure vacancies on thermoelectric properties are studied by substituting trivalent Sb for tetravalent Ge or Si on Mg$_2$Si and Mg$_2$Ge compounds. For Mg$_2$B$_n$Si, both the Seebeck coefficient and electrical resistivity first decrease and then increase with increasing Sb content, whereas the thermal conductivity decrease monotonically. The Mg$_2$Si system displays similar tendency in seebeck coefficient, resistivity, and thermal conductivity but shows smaller magnitudes. Our Hall measurement at room temperature indicates that the modulation in these thermoelectric properties can be accounted for by the variance of electron concentration. The Mg$_2$Si$_{1-x}$Sn$_x$ solid solutions were prepared and investigated to study the dependence of thermoelectric properties on carrier types and carrier concentrations.

Wednesday, March 18, 2009 8:00AM - 11:00AM – Session P29 DMP GMAG: Focus Session: Manganites

8:00AM P29.00001 Recent studies of models for manganites in the bulk and in superlattices$^1$. SHUAI DONG. 1. University of Tennessee, Knoxville; 2. Oak Ridge National Laboratory; 3. Nanjing University — In this talk, we will review our recent double-exchange model studies for manganites and some related experimental discoveries. First, we will briefly address the existence of a clear CMR effect in numerical simulations, and the short-range spin and charge correlations and local density of states in this CMR regime [1, 2]. Second, we will analyze manganite superlattices (LaMnO$_{3(n+1)}$/SrMnO$_3$)$_n$. The reconstruction of charge density, spin order, and orbital order at the interfaces and the relation with a novel experimentally observed metal-insulator transition (MIT) at $n = 3$ will be discussed [3]. Finally, the multiiferroic spin order in the undoped manganite $\text{RMnO}_3$ ($R = \text{Tb}, \text{Dy}$) will be also briefly studied under the double-exchange framework [4].

$^1$Work was supported by the NSF DMR-0706020 and the Division of Materials Science and Engineering, U.S. DOE, under contract with UT-Battelle, LLC. S.D. was also supported by the China Scholarship Council.

8:36AM P29.00002 Small dissimilarity in lattice distortion triggers anomalously large anisotropic magnetoresistance in manganite perovskites$^1$. R. LI, Ningbo Institute of Materials Technology and Engineering, CAS, China; H. WANG, X.Z. WANG, Y. MATSUI. National Institute for Materials Science, Tsukuba, Japan; X. WANG. Florida International University, Miami, FL 33199, Z. CHENG, B. SHEN. Institute of Physics, CAS, Beijing 100080, China; E.W. PLUMMER, JIANDI ZHANG. Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803 — Anisotropic magnetoresistance (AMR) effects are of fundamental importance not only for providing information on spin-orbital coupling and magneto-crystalline anisotropy, but also for enabling technological applications. Here, we report an anomalous AMR effect in a prototype manganite single crystal—$\text{La}_{0.59}\text{Ca}_{0.41}\text{MnO}_3$. We demonstrate that the broken symmetry, through cubic to orthorhombic structural distortion in the crystal, leads to profound anisotropic magneto-transport behavior. The measured AMR behavior shows a direct correlation with the anisotropic field-tuned metal-insulator transition (MIT) in the system and can be understood via a phenomenological uniaxial anisotropy model. It is revealed that a small crystalline anisotropy can trigger a large AMR near the MIT phase boundary of the system.

$^1$Supported by MEXT of Japan and the U.S. NSF DMR-0346826.

8:48AM P29.00003 Doping dependent evolution of the polaron metal. N. MANNELLA, K. TANAKA, S.-K. MO, W. YANG, H. ZHENG, J. MITCHELL, J. ZAÄÑEN, T.P. DEVERAUX, N. NAGAOSA, Z. HUSSAIN, Z.-X. SHEN. University of Tennessee-Knoxville — Experimental and theoretical evidence has already suggested that the ferromagnetic metallic (FM) phase in colossal magnetoresistive manganites is not a conventional metal but rather a polaronic conductor. In the bilayer manganites $\text{La}_{2-x}\text{Sr}_x\text{Si}_{1+2x}\text{Mn}_2\text{O}_7$ (LSMO), Angle Resolved Photoemission (ARPES) experiment revealed that the FM phase is a polaronic metal with a strong anisotropic character of the electronic excitations [1, 2]. A small but well-defined quasiparticle (QP) with heavy mass along the [110] or “nodal” direction is found to account for the metallic properties and their temperature dependent evolution [2]. In this talk, we will discuss recent ARPES results on the $x = 0.60$ composition and contrast them to the $x = 0.40$ results. Recent work has shown that the region in proximity of $x = 0.60$ constitute the most metallic bilayer manganite with DC conductivity about one order of magnitude higher than that corresponding to the region $0.30 < x < 0.40$. Much as in the $x = 0.40$ composition, for $x = 0.60$ along the nodal direction we observe a peak-dip-hump structure with QP of heavy effective mass. Quantitative differences in the electron-phonon coupling constant $\lambda$, the QP spectral weight and the hump energy are fully consistent with the doping evolution of the transport properties. [1] Nature 438, 474 (2005), [2] Phys. Rev. B 76, 233102 (2007).

9:00AM P29.00004 Metal-insulator transition in $\text{La}_{2-x}\text{Sr}_{1+2x}\text{Mn}_2\text{O}_7$ ($x=0.59$) revealed by ARPES. ZHE SUN, J. F. DOUGLAS, Q. WANG. University of Colorado at Boulder, A. FEDOROV, Y. -D. CHUANG. Advanced Light Source, Lawrence Berkeley National Laboratory, H. ZHENG, J. F. MITCHELL. Argonne National Laboratory, D. S. DESSAU. University of Colorado at Boulder — Using angle-resolved photoemission spectroscopy (ARPES), we studied the metal-insulator transition of $\text{La}_{2-x}\text{Sr}_{1+2x}\text{Mn}_2\text{O}_7$ ($x=0.59$). Below $T_c$, there is significant metallic weight at the Fermi level, while a gap opens above $T_c$, in excellent agreement with resistivity measurements. We also found that in this compound the metal-insulator transition is associated with a remarkable coherent-incoherent weight transfer from the dispersive band to a non-dispersive feature over a large energy scale. The band dispersion also shows an unusual change with increasing temperature, suggesting complicated interactions in this material.
9:12AM P29.00005 Role of Oxygen Electrons in the Metal-Insulator Transition in the Manganosite Oxide La$_{2-x}$Sr$_1{+x}$Mn$_7$O$_{21}$, W. AL-SAWAI, B. BARBIELLINI, Northeastern U., (NU), A. KOIZUMI, U. Hyogo, P.E. M. JNARENDRA, Delft U. of Tech, & NU, T. NAGAO, U. Hyogo, K. HIROTA, Osaka U., M. ITOU, JASRI (SPRING-8), Y. SAKURAI, SPRING-8, A. BANSIL, NU. We have studied the [100]-[110] anisotropy of the Compton profile in the bilayer manganite. Quantitative agreement is found between theory and experiment with respect to the anisotropy in the two metallic phases (i.e. the low temperature ferromagnetic and the colossal magnetoresistant phase under a magnetic field of 7T). Robust signatures of the metal-insulator transition are identified in the momentum density for the paramagnetic phase above the Curie temperature. We interpret our results as providing direct evidence for the transition from the metallic-like to the admixed ionic-covalent bonding accompanying the magnetic transition. The number of electrons involved in this phase transition is estimated from the area enclosed by the Compton profile anisotropy differences. Our work demonstrates the sensitivity of the Compton scattering technique for identifying the number of electrons involved in the metal-insulator transition. Work supported in part by the USDOE.

9:24AM P29.00006 Charge/Orbital Ordered Phases of La$_2-2x$Sr$_1+2x$Mn$_7$O$_{21-\delta}$, KENNETH GRAY, HONG ZHENG, QING’AN LI, JOHN MITCHELL, Argonne National Laboratory — Our studies have significantly modified the conventionally-held view of the phase diagram of La$_{2-2x}$Sr$_{1+2x}$Mn$_7$O$_{21-\delta}$ for four compositions exhibiting charge (and orbital) order (CO), i.e., at hole doping levels, h=\pm 0.5 and \pm 0.6. These CO phases are stable over very narrow doping ranges (\Delta h \sim 0.005) at the lowest temperatures, but those ranges increase at higher temperatures (\Delta h \sim 0.02) in a manner consistent with simple entropy considerations. Such narrow ranges dictate the crucial need for crystal homogeneity. Attesting to such homogeneity is a conductivity ratio of \sim 10$^3$ upon crossing the first-order phase boundary from CO at h=0.60 to AAFM at h=0.59 or h=0.61 plus two findings that were missed in the existing literature: that these CO phases are the ground state at the lowest temperatures and, for h=0.5, that coexistence of the CO and AAFM phase is absent at any temperature.

9:36AM P29.00007 Resonant Inelastic X-ray Scattering in CE-ordered bilayer manganite, FRANK WEBER, STEPHAN ROSENKRANZ, JOHN-PAUL CASTELLAN, JOHN MITCHELL, HONG ZHENG, Materials Science Division, Argonne National Laboratory, DIEGO CASA, THOMAS GOG, X-ray Science Division, Argonne National Laboratory — Resonant Inelastic X-ray Scattering (RIXS) has recently emerged as valuable tool in the study of orbital excitations in transition metal oxides. Stephan We have performed RIXS measurements at the Mn K-edge in the half doped bilayer manganite La$_2$Sr$_2$Mn$_2$O$_7$. Our sample was a non-reentrant single crystal with long range CE order down to lowest temperatures. We made wave vector dependent energy loss scans with \Delta E=15eV in the (110) direction at three different temperatures, i.e. T=75K (AFM CE ordered), 175K (FM CE ordered), and 250K (FM and no orbital order). In particular, we compare the temperature dependence of the 2eV peak with previous results on manganite perovskites [1]. Work supported by US DOE-BES-DE-AC02-06CH11357.

9:48AM P29.00008 Time-resolved Optical Study of Charge-ordered Manganites, 1 TAKAHAJI TAKAMA, JUDY CHERIAN, RYAN DEROSA, PAULA SAHANGGAMU, SANHITA GHOSH, STEPHEN MCGILL, National High Magnetic Field Laboratory, Florida State University, TAI-TOI WANG, X-ray Science Division, Argonne National Laboratory — Charge and orbital order effects in La$_2$Sr$_2$Mn$_2$O$_7$, a complex Mott insulator with a large magnetic response, have been extensively studied since the magnetic-field induced melting of charge and orbital order (CO-OO) results in colossal magnetoresistance phenomena. However, there remain two points to be clarified, concerning the CO-OO states. First issue is the degree of charge disproportionation (CD); Full CD between Mn$^{3+}$ and Mn$^{4+}$ ions has been widely believed while charge density wave ordering with less distinct CD has also been recently proposed. Another issue is the orbital shape at critical doping levels (\sim 0.59 or h=0.61) plus two findings that were missed in the existing literature: that these CO phases are the ground state at the lowest temperatures and, for h=0.5, that coexistence of the CO and AAFM phase is absent at any temperature.

1This work was supported by the NSF-DMR-0706610 and at ANL by the U.S. DOE under contract No. DE-AC02-06CH11357.

10:00AM P29.00009 Lattice-form dependent charge- and orbital- ordered states in perovskite-related mangananites, DAISUKE OKUYAMA, CMGR-RIKEN, YUSUKE TOKUNAGA, ERATO-JST, REJI KUMAI, AIST, YASUJIRO TAGUCHI, CMGR-RIKEN, TAKA-HISA ARIMA, Tohoku Univ., YOSHINORI TOKURA, Univ. of Tokyo — Charge and orbital order in half-doped manganites has been extensively studied since the magnetic-field induced melting of charge and orbital order (CO-OO) results in colossal magnetoresistance phenomena. However, there remain two points to be clarified, concerning the CO-OO states. First issue is the degree of charge disproportionation (CD); Full CD between Mn$^{3+}$ and Mn$^{4+}$ ions has been widely believed while charge density wave ordering with less distinct CD has also been recently proposed. Another issue is the orbital shape (OS) at Mn$^{3+}$ ion in the CO-OO phase. The reason why the OSs of (La,Ca)MnO$_x$ at hole doping levels, h=x-0.5 (PCMO) and La$_{(1-x)}$Ca$_x$MnO$_3$ (x=0.18) (LCMO) using time-resolved techniques. Our measurements are performed down to 4 K and in dc magnetic fields up to 31 T. The conductivity of the low-temperature strong charge/orbital order in PCMO is altered by the application of an electric field and a magnetic field. We demonstrate that this time-resolved optical observation is capable of capturing these mixed electronic and magnetic effects to gain further insight into the change of the ordering.

10:12AM P29.00010 Charge and orbital order effects in La$_2$Sr$_{1-x}$Mn$_{1+y}$O$_6$, B. DABROWSKI, Physics Department, Northern Illinois University, DeKalb, IL 60115, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, L. SUESCUN, Facultad de Quimica, Universidad de la Republica, Montevideo, Uruguay, S. KOLESNIK, S. REMSEN, J. MAIS, Physics Department, Northern Illinois University, DeKalb, IL 60115 — Low temperature annealing in hydrogen have been used to obtain oxygen vacancy ordered manganites Sr$_4$Mn$_{1+y}$O$_{10+3x}$ (n=0, 1, 3) displaying charge and orbital ordering. For the La-substituted n=1 phase four Mn$^{3+}$ cations exhibit elongated pyramidal coordination while the fifth one in octahedral coordination shows decreasing formal valence Mn$^{4-(5-\delta)}$. This selective doping produces structural strain resulting in unusual apically compressed coordination leading to complex magnetic interactions and frustration. These structures have been previously observed for the (La,Ba)CuO$_3$-$\delta$ cuprates revealing common vacancy ordering relationships in perovskites for which highly distorted Mn$^{3+}$ (Cu$^{2+}$) and symmetric Mn$^{4+}$ (Cu$^{2+}$) ions are present simultaneously. Work at NU was supported by the NSF-DMR-0706610 and at ANL by the U.S. DOE under contract No. DE-AC02-06CH11357.

10:24AM P29.00011 Phase separations in La$_{1-x}$Ca$_x$MnO$_3$ at critical doping levels, J. TAO, Q. JIE, Q. LI, Y. ZHU, Condensed Matter Physics & Materials Science Department, Brookhaven National Lab, D. NIEBIESKIKWIAT, Colegio de Ciencias e Ingenieria, Universidad San Francisco de Quito, Ecuador, M.B. SALAMON, Department of Physics, University of Texas at Dallas, S.J. PENNYCOOK, Materials Science & Technology Division, Oak Ridge National Lab — La$_{1-x}$Ca$_x$MnO$_3$ specimens have been widely studied for their rich and complex physics. There is a boundary in the phase diagram at x = 0.50. At low temperatures, the system is ferromagnetic for x less than 0.5 while charge ordering phase is favored for x equal to or greater than 0.5. The mechanisms for this drastic change over the continuous doping still remains unclear. Here we report our electron diffraction study on bulk La$_{1-x}$Ca$_x$MnO$_3$ at the critical doping x = 0.48 and 0.50. Lorentz microscopy is also employed in the study to obtain the magnetic domain information during the phase transitions in these two specimens. The observed structure is integrated with the measured properties and it shows novel phenomena of the materials at nanoscale. This work is funded by U.S. DOE/BES under Contract No. DE-AC02-98CH10886.
300K up to 5 layers, but revealed strong half-order spots with weak intensity at quarter-order by 20 layers. STM images show the surfaces of thick films to have

We have measured electrical conductivity and structure of in-situ grown SRO films using scanning probe microscopy, low energy electron diffraction (LEED)
