12:39PM T17.00008 Enhanced hydrogen storage from nanostructured graphene and nickel hybrids based on spiller mechanism, LIN WEI, YUANBING MAO, The University of Texas-Pan American — As a fascinating 2-dimensional carbon material, graphene has been decorated with metal nanoparticles to enhance its hydrogen storage performance based on the spiller mechanism. In this work, Ni and Ni alloys have been used to decorate the surface of graphene. Graphene oxide was fabricated from graphite by improved Hummer method. To form Ni/graphene and Ni/Pd/graphene hybrids, the graphene oxide water dispersion was mixed with nickel chloride (and palladium chloride). Ni(OH)₂/graphene and Ni(OH)₂/Pd(OH)₂/graphene hybrids were synthesized through hydrothermal treatment, using water as a solvent and HMT as a capping agent. After heat treatment and in situ reduction with hydrogen flow, the nanostructured Ni/graphene and Ni/Pd graphene hybrids were obtained. The nanostructured Ni/Pd/Ag/graphene hybrid was synthesized from graphene oxide in the ethylene glycol solution and metal nitrates using similar reactions. XRD, Raman, SEM, AFM were used to characterize these products. ASAP 2020 was used to test the hydrogen adsorption and desorption capacities.

12:51PM T17.00009 Tailored crumpling and unfolding of spray-dried pristine graphene and graphene oxide nanosheets, DORSA PARVIZ, Texas A&M Univ, SRiya DAS, FAHMIDA IRIN, Texas Tech Univ, MICAH GREEN, Texas A&M Univ — 3D Crumpled graphene was directly obtained from aqueous dispersions of pristine graphene using an industrially scalable spray drying technique. Capillary forces during the water evaporation induced the crumpling of nanosheets to multi-faced dimpled morphology. For the first time, the transition of 2D graphene nanosheets to a 3D crumpled morphology was directly observed inside the spray dryer. Graphene oxide (GO) was spray dried using the same procedure; however, their highly wrinkled final morphology was different than the crumpled pristine graphene nanosheets. The degree of crumpling of the nanosheets was controlled by changing the dimensionless ratio of evaporation rate to diffusion rate. Crumpled particles were dispersed into various solvents to evaluate their morphological changes as a response to rewetting. Crumpled GO nanosheets remained crumpled as a response to hydration, while the pristine graphene nanosheets unfolding behavior was solvent-dependent. This study holds significance for both fundamental understanding of the origins of nanosheets crumpling and also for the use of crumpled nanosheets for further material processing.

1:03PM T17.00010 Local field enhanced photoluminescence and Raman effect in Reduced Graphene Oxide Nanoclusters, SANJAY KARNA, TAE-YOUL CHOI, RAKESH SHAH, MEG MAHAT, ARUP NEOGI, Univ of North Texas — The increase in local field due to metal nanoparticles can influence the radiative emission and phonon interaction in semiconductors. Graphene oxide can be reduced to modify its bandgap and tune its emission energy from the red to the ultraviolet wavelength range. Reduced graphene oxide (rGO) with Ag nanoparticles has been synthesized and studied to enhance the effect of resonant surface plasmon interaction on the light emission from rGO. Comparative study of sp² cluster size, defect density and electrical conductivity has been performed. Preliminary results show that the maximum decrease in the defects density in rGO structure as treated with Ag NPs and also in the same way the inter-defect distance increase as density of defects decrease and sp² cluster size increase rapidly. The increase in size of sp² cluster and decrease in defect density due to localized electric field due to Ag NPs is responsible for the increase in electrical conductivity and in PL emission. The localized electric field increases the electrical conductivity due to the decrease in sp² clusters compared to an (defects oxides functional in GO)? increase in sp² in the rGO clusters. The increase in electric field due to localized plasmon due to Ag NP resonant to the emission from rGO results in an increase in enhancement from emission from rGO. By controlling the localized surface plasmon density, the enhancement efficiency from rGO can be enhanced.

1:15PM T17.00011 Gas Barrier and Separation Behavior of Graphene Oxide Nanobrick Wall Thin Films, JAIME GRUNLAN, Texas A&M University — In many cases, electronics packaging requires electrical conductivity and barrier to oxygen, even under humid conditions. These two properties have simultaneously been realized through the use of surfactant-free aqueous layer-by-layer (LbL) processing, in the form of a polymeric composite nanocoating. By layering graphene oxide (GO) with polyethyleneimine (PEI), a “nano brick wall” structure has been created, imparting gas barrier properties to the film. Reducing the graphene oxide with a thermal treatment further produces high oxygen barrier in humid conditions (≥ 1750 S/m). These thin films (<400 nm) are flexible relative traditional conductive thin films (e.g. ITO), and processing occurs under ambient conditions with water as the only solvent. Additionally, these PEI/GO thick films exhibit H₂/CO₂ selectivity (>300), making them interesting for gas purification membranes. The flexible nature of the aforementioned thin films, along with their excellent combination of transport properties, make them ideal candidates for use in a broad range of electronics and other packaging applications.

1:27PM T17.00012 Near-Field Radiation Between Graphene-Covered Carbon Nanotube Arrays, RICHARD ZHANG, XIANGLIE LIU, ZHUOMIN ZHANG, Georgia Institute of Technology, NANOSCALE THERMAL RADIATION LABORATORY TEAM — It has been shown that at nanometer gap distances, or the near-field, thermal radiation is enhanced over blackbody by hyperbolic metamaterials. It was shown that vertically aligned carbon nanotube (VACNT) arrays in the near-field demonstrate exceptional enhancement. In this study, graphene is covered on the surfaces of two semi-infinite VACNT arrays separated by a sub-micron vacuum gap. Doped graphene (μ ≥ 0.3 eV) is found to improve photon tunneling in a broad hyperbolic frequency range, due to the interaction with graphene grapheme surface plasmons. Increasing doping that shifts the peak spectral heat flux toward higher frequencies attests to the tunable bandgap of graphene. Although graphene covering of VACNT does not offer many magnitudes of near-field heat flux enhancement over uncovered VACNT, this study identifies conditions (i.e. gap distance and doping) that best augments heat transfer to that of VACNT arrays. In addition, this study demonstrates the near-field Poynting vector to determine the energy absorption due to graphene. It is found that graphene, in low frequencies and high chemical potentials, attenuates large penetration depths of hyperbolic modes, thereby increasing the contribution of graphene-graphene surface plasmons. This study has an impact toward designing carbon-based emitters and thermal junctions.
Electronic and Optical Properties of Atomically Precise Graphene Nanoribbons and Heterojunctions. CARLO ANTONIO PIGNEDOLI, Empa, Swiss Federal Laboratories for Materials Science and Technology, 8600 Dübendorf, Switzerland — Among graphene related materials, nanoribbons (GNRs) — narrow stripes of graphene — have emerged as promising building blocks for nanoelectronic devices. The lateral confinement in GNRs opens a bandgap that sensitively depends on the ribbon width, allowing in principle for the design of GNR-based structures with tunable properties. However, structuring with atomic precision is required to avoid detrimental effects induced by edge defects. Recently, we have introduced a versatile route for the bottom-up fabrication of GNRs [1], allowing for the atomically precise synthesis of ribbons with different shapes as well as heterojunctions between doped and undoped ribbon segments [2,3]. Here, we report on detailed experimental and computational investigations of the structural, electronic and optical properties of selected GNRs and heterojunctions [1-3]. For the case of armchair GNRs of width \( N = 7 \), the electronic band gap and band dispersions have been determined with high precision [4,5]. Optical characterization has revealed important excitonic effects [6], which are in good agreement with ab initio calculations including many-body effects. For the case of heterojunctions, consisting of seamlessly assembled segments of pristine (undoped) graphene nanoribbons and deterministically nitrogen-doped graphene nanoribbons, we find a behavior similar to traditional p–n junctions. With a band shift of 0.5 eV and an electric field of \( 2 \times 10^8 \) V m\(^{-1} \) at the heterojunction, these materials bear a high potential for applications in photovoltaics and electronics. Finally, we will discuss the potential of the bottom-up approach with regard to the fabrication of GNRs exhibiting zigzag edges, which are predicted to exhibit spin-polarized edge states.

Session T19 FIAP: Invited Session: FIAP Prize Session and the Forum on Entrepreneurship in Physics  Mission Room 103B - John Rumble, R&R Data Services

11:15AM T19.00001 Prize for Industrial Applications of Physics: Materials science, microelectronics scaling, and beyond the silicon transistor, SUPRATIK GUHA, IBM — Conventional density and performance scaling of the silicon microprocessor will reach an end within about a decade. In anticipation of this, there has been extensive interest in examining materials and devices that will replace silicon transistors. There is also the far reaching interest in going beyond conventional computing and exploring non-Boolean forms of logic, and the devices and materials that will go with it. I will describe some of the research at IBM in these areas, including our work in developing carbon nanotube transistors as a drop in replacement for the silicon MOSFET.

11:51AM T19.00002 George E. Pake Prize Lecture: Physical Sciences Research at IBM: Still at the Cutting Edge, THOMAS THEIS1, IBM Research — The information technology revolution is in its “build out” phase. The foundational scientific insights and hardware advances are now many decades old. The microelectronics industry is maturing. An increasing fraction of the total research investment is in software and services. As applications of information technology transform every business and every sector of the public and private economy. Yet IBM Research continues to make substantial investments in hardware technology and the underlying physical sciences. While some of this investment is aimed at extending the established transistor technology, an increasing fraction is aimed at longer-term and possibly disruptive research — new devices for computing, such as tunneling field-effect transistors and nanophotonic circuits, and new architectures, such as neurosynaptic systems and quantum computing. This research investment is a bet that the old foundations of information technology are ripe for reinvention. After all, today’s information technology devices and systems operate far from any fundamental limits on speed and energy efficiency. But how can IBM make risky long-term research investments in an era of global competition, with financial markets focused on the short term? One important answer is partnerships. Since its early days, IBM Research has pursued innovation in information technology and innovation in the ways it conducts the business of research. By continuously evolving new models for research and development partnerships, it has extended its global reach, increased its impact on IBM’s customers, and expanded the breadth and depth of its research project portfolio. Research in the physical sciences has often led the way.

1 currently on assignment to the Semiconductor Research Corporation

12:27PM T19.00003 Distinguished Lectureship Award on the Applications of Physics: Illuminating My Career From Flash Gordon to Laser Surgery, JAMES WYNE, IBM T J Watson Res Ctr — As a child, I was fascinated by television programs about Flash Gordon. His partner in conquering the universe was Dr. Alexis Zarkov, a physicist, who had invented, among other things, a death ray gun. My personal “death ray” was a magnifying glass, focusing sunlight on unsuspecting insects, like crawling ants. I also practiced sneaking up on resting, flying, stinging insects and burning their wings before they could take off and attack me. So I understood something about the power of sunlight. In my senior year of high school, I had a fabulous physics teacher, Lewis E. Love, and I knew after one week that I wanted to be a physicist, not a medical doctor, which is the career my parents wanted me to pursue. It turns out that the first laser functioned on May 16, 1960, just one month before I graduated from high school, and it was inevitable that I would pursue a career working with lasers. My first job as a physicist, during the summer of 1963, was working with lasers at TRG, Inc. a small company whose guru was Gordon Gould, now recognized as the inventor of the laser. After three summers at TRG, I spent three years working on nonlinear optics for my PhD thesis, under the guidance of Prof. Nicolaas Bloembergen, who later won the Nobel Prize in Physics for his pioneering work in nonlinear optics. Following completion of my PhD research in 1969, I joined IBM Research, where I have worked ever since. Upon joining the Quantum Electronics group in the Physical Sciences Dept. of the T.J. Watson Research Center, my management told me to “do something great” with lasers. After working on atomic spectroscopy with dye lasers through the 1970s, I had the inspiration to acquire an excimer laser for the Laser Physics and Chemistry group. Using this laser, my colleagues and I discovered excimer laser surgery, capable of removing human and animal tissue with great precision, while leaving the undermined and adjacent tissue free of collateral damage. This discovery laid the foundation for the laser refractive surgical procedures of PRK and LASIK, which have been used to improve the visual acuity of nearly 30 million people. Today, I am working on validating my concept that the argon fluoride excimer laser can serve as a “smart scalpel,” capable of debriding necrotic lesions of the skin without damaging the underlying and adjacent viable tissue, leading to faster healing, reduced pain, reduced probability of infection, and minimal scarring. To quote Louis Pasteur, “Chance favors the prepared mind!”

1:03PM T19.00004 FIAP Forum on Entrepreneurship in Physics — With the changes in science as globalization has taken root, the future role of physicists becoming a part of the industrial physics community is more imperative. When 80% of graduating physicists will not be employed in academic positions, and 50% of all jobs for these physicists will be industrial sector, the importance of bringing our next generation of scientists up to speed on industrial applications is becoming much more important with the rapid, world-wide development of technology. FIAP is initiating a forum on entrepreneurship as a major role for the next generation of scientists. As physicists are problem solvers and the entrepreneurial experience is all about problem solving: whether involving technology, building a team, or financing a business. This forum seeks to link successful entrepreneurial physicists with the upcoming generation, through the dissemination of their global expertise and experience. Speakers will include Dr. Leo Showalter (Crystal IS), Dr. Cha Mei Tang (MicroTech), Mr. Aaron Weiss (Google), Dr. Sefan Murry (Applied Optoelectronics), Mr. Blaine Johns (Film-Sense), and Dr. Maximilian Biberger (SDC Materials).
Thursday, March 5, 2015 11:15AM - 2:15PM
Session T20 GQI DAMOP: Invited Session: Recent Frontiers of Quantum Thermodynamics: From Theory to Experiment  Ballroom B - Akimasa Miyake, University of New Mexico

11:15AM T20.00001 Quantum Quantum-Thermodynamics, TERENCE RUDOLPH, Imperial College London — The thermodynamic implications of quantization of energy were realized before the full quantum theory was developed, and today its effects are very well (though perhaps not completely) understood. By contrast the thermodynamic implications of quantum coherence, in the myriad guises it can arise, are still encountered in a somewhat piecemeal fashion and are lacking a (coherent!) unified and completely general framework. I will discuss some attempts to provide such a framework using tools of quantum information theory and to explain how thermodynamical constraints on the manipulation of quantum coherence arise.

11:51AM T20.00002 Quantum thermalization and the dynamics of entanglement, DAVID HUSE, Princeton University — I will address some aspects of how conventional thermodynamics emerges from quantum many-body physics, and also discuss one generic example where it fails to emerge, namely many-body Anderson localization. One aspect of this is the Eigenstate Thermalization Hypothesis (ETH), which suggests alternative statistical-mechanical ensembles that consist of only a single eigenstate of the many-body Hamiltonian. These ensembles, unlike the standard statistical mechanical ensembles, can detect many-body localization and the dynamical phases and quantum phase transitions within the localized phase. I will also discuss the dynamics of many-body quantum entanglement.

12:27PM T20.00003 Single ion heat engine, KILIAN SINGER, University of Mainz — An experimental realization of a heat engine with a single ion is presented, which will allow for work extraction even with non-classical thermal reservoirs. To this goal a custom designed linear Paul trap with a single ion performing an Otto cycle is presented. The radial state of the ion is used as the working gas analogous to the gas in a conventional heat engine. The conventional piston is realized by the axial degrees of freedom and the axial motional excitation stores the generated work, just like a conventional fly-wheel. The heat baths can be realized by tailored laser radiation. Alternatively electrical noise can be used to control the state of the ion. The presented system possesses advantageous properties, as the working parameters can be tuned over a broad range and the motional degrees of freedom of the ion can be accurately determined. Dark resonances allow for fast stroboscopic thermometry during the entire working cycle. Monte Carlo simulations are performed to predict the efficiency and the gained work of the working cycle [1]. We have also shown how the equations for the Carnot limit have to be modified if a squeezed thermal reservoir is employed [2]. Furthermore structural phase transitions with laser cooled linear ion crystals are induced verifying the Kibble-Zurek mechanism [3].

1:03PM T20.00004 Cavity Cooling for Ensemble Spin Systems, DAVID CORY, University of Waterloo — Recently there has been a surge of interest in exploring thermodynamics in quantum systems where dissipative effects can be exploited to perform useful work. One such example is quantum state engineering where a quantum state of high purity may be prepared by dissipative coupling through a cold thermal bath. This has been used to great effect in many quantum systems where cavity cooling has been used to cool mechanical modes to their quantum ground state through coupling to the resolved sidebands of a high-Q resonator. In this talk we explore how these techniques may be applied to an ensemble spin system. This is an attractive process as it potentially allows for parallel remove of entropy from a large number of quantum systems, enabling an ensemble to achieve a polarization greater than thermal equilibrium, and potentially on a time scale much shorter than thermal relaxation processes. This is achieved by the coupled angular momentum subspaces of the ensemble behaving as larger effective spins, overcoming the weak individual coupling of individual spins to a microwave resonator. Cavity cooling is shown to cool each of these subspaces to their respective ground state, however an additional algorithmic step or dissipative process is required to couple between these subspaces and enable cooling to the full ground state of the system.

1:39PM T20.00005 Experimental investigation of Demon-like Algorithmic Quantum Cooling and its Applications1, CHUAN-FENG LI, University of Science and Tech of China — Simulation of the low-temperature properties of many-body systems remains one of the major challenges in theoretical and experimental quantum information science. Firstly we demonstrate experimentally a Demon-like algorithmic cooling method that is applicable to any physical system that can be simulated by a quantum computer. This method allows us to distill and eliminate hot components of quantum states like a quantum Maxwell’s demon. The experimental implementation is realized with a quantum optical network, and the results are in full agreement with theoretical predictions (with fidelity higher than 0.978). Secondly, we use the demon-like algorithmic cooling method to experimentally investigate Majorana zero modes exhibiting a fundamental property of non-Abelian statistics.

Thursday, March 5, 2015 11:15AM - 1:51PM
Session T21 DCMP: Numerical Methods for Correlated Electrons 201 - Emmanuele Gull, University of Michigan

11:15AM T21.00001 Quantum quenches in 2D via arrays of coupled chains, ANDREW JAMES, London Center Nanotechnology, ROBERT KONIK, Brookhaven National Laboratory — Matrix product state (MPS) methods are extremely powerful when applied to strongly correlated systems in 1D. However they are less efficacious in 2D due to the ‘area law’ growth of entanglement, limiting the system sizes that can be studied. We combine MPS methods with analytical results for integrable chains to build an algorithm that can study large (anisotropic) 2D many body quantum systems, because it reduces the need for a large ‘area’. As an example we describe the application of our method to quantum quenches of the 2+1 dimensional quantum Ising model.

11:27AM T21.00002 Exact transient dynamics of the Anderson impurity, ANDREY ANTIPOV, DONG QIAOYUAN, EMANUEL GULL, Univ of Michigan - Ann Arbor — We study dynamics of a single Anderson impurity model subject to voltage and thermal quenches. We develop a hybridization expansion diagrammatic Monte Carlo algorithm to describe the exact dynamics of the problem. By including the initial correlations into the problem we describe the destruction of the Kondo state and infer the characteristic time scales of the problem. An interplay between different time scales of spin and charge excitations of the strongly correlated setup as visible in the ultra-fast response is in the focus of our study. We compare our results with frequently employed non-crossing and one-crossing approximations.
11:39AM T21.00003 Time Evolution of a Quantum Impurity System following a Sudden Quench and General Pulse at Finite Temperatures - a td-NRG Study. HOA NGHIE, THEODOULOS COSTI, Forschungszentrum Juelich — To study the time evolution of an observable of a quantum impurity system after a sudden quench at an arbitrary temperature, we apply the recently developed time-dependent numerical renormalization group approach (td-NRG) to the Anderson model and resonant level model. In the application to the Anderson model, we quantify the results in the short and long time limits by comparing them to the thermodynamic values in the initial and final states. In the case of the resonant level model, we compare the time evolution of the local occupancy calculated by td-NRG to the exact analytic result. We also present the time evolution in response to general continuous pulses, acting in a finite time interval, and in response to periodic driving fields. The study is accomplished by a generalization of the single-quench formalism to multiple quenches and by approximating smooth pulses (or periodic trains of pulses) by a sufficient number of smaller quenches.

11:51AM T21.00004 Non-equilibrium Hybridization Expansion Impurity-solver1, QIAOYUAN DONG2, Univ of Michigan - Ann Arbor — The study of non-equilibrium phenomena in strongly correlated systems has developed into one of the most active and exciting branches of condensed matter physics. Meanwhile, quantum impurity models play a prominent role as mathematical representations of quantum dots, single-molecule devices, and effective models for the dynamical mean field theory. We show results for a generalization of the hybridization expansion diagrammatic Monte Carlo technique for the Anderson impurity model. And we perform non-equilibrium calculations on the full Keldysh contour, where a dynamical sign problem vastly increases the complexity of real-time simulation. By further combining this method with a non-crossing approximation, our "bold-line" Monte Carlo can reach substantially longer times out of equilibrium than previously accessible, and provides an accurate description of quench and driven dynamics of correlated systems.

12:03PM T21.00005 Electric-field-driven resistive switching in dissipative Hubbard model1. JIAJUN LI, State Univ of NY - Buffalo, CAMILLE ARON, Princeton University, GABRIEL KOTLIAR, Rutgers University, JONG HAN, State Univ of NY - Buffalo — Understanding of solids driven out of equilibrium by external fields has been one of the central goals in condensed matter physics for the past century and is relevant to nanotechnology applications such as resistive transitions. We study how strongly correlated electrons on a dissipative lattice evolve from equilibrium when driven by a constant electric field, focusing on the extent of the linear regime and hysteretic non-linear effects at higher fields. We access the non-equilibrium steady state non-perturbatively in both the field and the electronic interactions, by means of a non-equilibrium dynamical mean-field theory in the Coulomb gauge. The linear response regime is limited by Joule heating effects and breaks down at fields orders of magnitude smaller than the quasi-particle energy scale. For large electronic interactions, strong but experimentally accessible electric fields can induce a resistive switching by driving the strongly correlated metal into a Mott insulator. Hysteretic I-V curves suggest that the non-equilibrium current is carried through a spatially inhomogeneous metal-insulator mixed state.

12:15PM T21.00006 The Actinide Transition Revisited by Gutzwiller Approximation. WENHUI XU, Brookhaven Natl Lab, NICOLA LANATA, Rutgers University, YONGXIN YAO, Ames Laboratory, GABRIEL KOTLIAR, Rutgers University — We revisit the problem of the actinide transition using the Gutzwiller approximation (GA) in combination with the local density approximation (LDA). In particular, we compute the equilibrium volumes of the actinide series and reproduce the abrupt change of density found experimentally near plutonium as a function of the atomic number. We discuss how this behavior relates with the electron correlations in the 5f states, the lattice structure, and the spin-orbit interaction. Our results are in good agreement with the experiments.

12:27PM T21.00007 Magnetic formfactor and dynamic magnetic susceptibility within DMFT for α − γ transition in Cerium and δ-Plutonium . BISMAYAN CHAKRABARTI, Rutgers University, MARIA PEZZOLI, None, GIOVANNI SORDI, Royal Holloway, University of London, KRISTJAN HAULE, GABRIEL KOTLIAR, Rutgers University — Using LDA+DMFT we study the magnetic properties of the isostuctural volume collapse transition between α and γ Cerium. We compute the magnetic formfactor F(q,ω) and show that it is very close to free ion behavior in both the local moment γ phase as well as the more itinerant α phase, in excellent agreement with neutron scattering experiments. In sharp contrast, the dynamic local magnetic susceptibility χloc(ω) of the two phases is strikingly different. In the γ phase, the spectra is dominated by the sharp low energy peak due to local moment formation, whereas in the α phase we see two broad peaks, the first due to Kondo screening and the second due to Hund’s coupling. We also calculate the magnetic spectral function S(q,ω) where we achieve excellent agreement with experiment. This shows that hybridization plays a central role in the α − γ transition in cerium, and that the 4f electrons are strongly correlated in both phases. We also study the magnetic properties of δ-Plutonium where our results give us important clues about the magnetic excitations of the system.

12:39PM T21.00008 Geometry Dependence of the Sign Problem. VLADIMIR IGLOVIKOV, Physics Department, University of California, Davis, California 95616, USA, EHSAN KHATAMI, Department of Physics and Astronomy, San Jose State University, San Jose, CA 95192, USA, RICHARD FYE, RICHARD SCALETTR, Physics Department, University of California, Davis, California 95616, USA — The sign problem is a fundamental limitation to Quantum Monte Carlo (QMC) simulations of the statistical mechanics of interacting fermions and frustrated quantum spins. We produced a comprehensive dataset on the geometry dependence of the sign problem for different densities, interaction strengths, inverse temperatures and spatial lattice sizes. We supplement this data with several observations concerning general patterns/trends in the data, including the dependence on spatial volume and how this can be probed by examining decoupled clusters, the scaling of the sign in the vicinity of a particle-hole symmetric point, and the correlation between the total sign and the signs of the individual spin up and spin down components.

12:51PM T21.00009 ABSTRACT WITHDRAWN
β-enhanced impurity solver for single-site DMFT [1]. The novel algorithm is based on a multigrid version of BSS-QMC [2,3], which yields Green functions free of significant Trotter errors, and scales linearly with the inverse temperature $\beta = 1/T$ and cubically in the cluster size $N$. We use the superior scaling to explore ultra-low temperature regimes at moderate cluster sizes, not reachable with state-of-the-art continuous time QMC impurity solvers that scale cubically in $\beta$. Benchmark results for the two-dimensional (2d) Hubbard model, compared with complementary methods (unbiased lattice QMC, dynamical vertex approximation (DVA) [4]), are presented as well as a study of the 2d doped Kondo lattice model.

1:15PM T21.00011 The density matrix renormalization group as a solver for cluster perturbation theory, CHUN YANG, ADRIAN FEIGUIN, Northeastern Univ — Cluster Perturbation Theory (CPT) provides an approximation for the single particle Green’s function of strongly correlated models in the thermodynamic limit by coupling clusters of small size using a variation of strong coupling perturbation theory. The method itself cannot account for the effects of symmetry breaking, such as in the presence of antiferromagnetic long range order, since it relies on the exact solution of clusters that are too small. The DMRG method provides a path toward a more reliable application of the CPT in the presence of long range order since it is able to calculate the single particle Green’s function of an infinite (very large) one dimensional chain, or ladder. By coupling these chains and ladders in the perpendicular direction using CPT we recover the spectral functions of the 2D lattice in the thermodynamic limit. A remarkable advantage of this approach is that unlike small clusters, the one-dimensional systems are already “(it) infinite”. We can study the effects of the onset of long range order and its spectral signatures by extending our study to multi-leg ladders.

1:27PM T21.00012 Typical medium dynamical cluster approximation applied to Migdal-Eliashberg theory 1, ZHOU LI, Department of Physics & Astronomy and Center for Computation and Technology, Louisiana State University, HANNA TERLETSKA, Department of Physics & Astronomy and Center for Computation and Technology, Louisiana State University, currently at Ames lab, ELISHA SIDDIQI, JUANA MORENO, MARK JARRELL, Department of Physics & Astronomy and Center for Computation and Technology, Louisiana State University — We use the recently developed typical medium dynamical cluster approximation (TMDCA) to study Anderson localization and the superconductor-insulator transition. In our analysis both phonons and disorder are treated on equal footing. For phonons we use the Holstein model Hamiltonian and perform analysis for different types of disorder distributions, i.e. binary or box distribution. It is of interest to see how phonons and disorder compete in fine-tuning of this phase transition by re-normalizing the gap parameter. For weak disorder we find that the size of the gap depends on the phonon frequency. Since for large phonon frequencies the Holstein model maps onto an attractive Hubbard model, we focus on the region where the phonon frequency is small and intermediate for both weak and strong disorders.

1:30PM T21.00013 Correlations in lacunar spinels: dynamical mean-field study with configuration interaction based impurity solver1, ARA GO, Department of Physics, Columbia University, HEUNG-SIK KIM, Department of Physics, University of Toronto, HOSUB JIN, Center for Correlated Electron Systems, Institute for Basic Science / Department of Physics and Astronomy, Seoul National University, ANDREW MILLIS, Department of Physics, Columbia University — Density functional plus dynamical mean field methods are used to study the role of correlations in lacunar spinel compounds GaM$_4$X$_8$ ($M$=Nb, Mo, Ta and and $X$=S, Se and Te) to investigate the interplay of correlations and topology in materials with strong spin-orbit coupling. A novel configuration-interaction exact diagonalization solver enables inclusion of more bath orbitals, enabling a better treatment of spectral functions and more accurate computations of phase boundaries. Focussing on GaTa$_4$Se$_8$, we discuss how the correlation induces metal-insulator transition in presence of the spin-orbit coupling, based on spectral functions and optical conductivities.

11:15AM T22.00001 Many-body localization as percolation in $d>1$, ANUSHYA CHANDRAN, Perimeter Institute, CHRISS LAUMAN, University of Washington, DANIEL GOTTESMAN, Perimeter Institute — Statistical mechanics is the framework that connects thermodynamics to the microscopic world. It hinges on the assumption of equilibration. Isolated quantum systems need not equilibrate; this is the phenomenon of many-body localization (MBL). While a detailed understanding of MBL and the associated delocalization transition is beginning to emerge in one dimension, relatively little is known about higher dimensions. In this work, we present a minimal tractable model for MBL in all spatial dimensions. Specifically, we analyze a disordered Floquet circuit composed of Clifford gates. In one dimension, the system is always localized, while in higher dimensions, it exhibits both delocalized and localized phases. The localized phase consists of well-defined metallic puddles embedded in an insulating matrix. When the puddles percolate, the system delocalizes; this maps the dynamical transition to critical percolation. We also comment on the stability of the phases to generic perturbations away from the Clifford class.

11:27AM T22.00002 Quasi Many-Body Localization in Translation Invariant Systems, NORMAN YAO, University of California Berkeley, CHRISS LAUMANN, University of Washington, J. IGNACIO CIRAC, Max Planck Institute for Quantum Optics, MIKHAIL LUKIN, Harvard University, JOEL MOORE, University of California Berkeley — We examine localization phenomena associated with generic, high entropy, states of a translation invariant, one-dimensional spin ladder. At intermediate time scales, we find slow growth of entanglement entropy consistent with the known phenomenology of many-body localization in disordered, interacting systems. At longer times, however, anomalous diffusion sets in, leading to full spin polarization decay on a time-scale exponential in system size. We identify a single length scale which parametrically controls both the eventual spin transport times and the divergence of the susceptibility to spin glass ordering. We dub this pre-thermal dynamical behavior, quasi many-body localization.
we introduce a parameter \( V \)

Physics — We propose the statistics of matrix elements of local operators as a new probe of the many-body localized (MBL) phase. Matrix elements of a given localized systems.

provides a quantitative, experimentally observable alternative to entanglement growth as a measure of the "non-ergodic but dephasing" nature of many-body

of dephasing. In contrast, the ergodic phase acts as a bath for the qubit, with no revivals visible on the time scales studied. The suppression of quantum revivals

localization, the magnetization exhibits periodic revivals, whose rate is strongly suppressed upon adding interactions after a time scale corresponding to the onset

dynamics of a single "qubit" spin weakly coupled to an otherwise isolated disordered spin chain and first demonstrate that in the localized regime the spin

chain is unable to act as a source of dissipation for the qubit, which therefore retains an imprint of its initial magnetization at infinite time. For Anderson

localization, the magnetization exhibits periodic revivals, whose rate is strongly suppressed upon adding interactions after a time scale corresponding to the onset of dephasing. In contrast, the ergodic phase acts as a bath for the qubit, with no revivals visible on the time scales studied. The suppression of quantum revivals provides a quantitative, experimentally observable alternative to entanglement growth as a measure of the "non-ergodic but dephasing" nature of many-body localized systems.

and dynamics of the system. The distribution of matrix elements of a local operator between system's eigenstates exhibits qualitatively different behavior in the

and ergodic phases, allowing for an accurate determination of the two phases. To characterize this distribution, for a given system size \( L \), we introduce a parameter \( g(L) = (\log \frac{\langle \Delta \rangle}{\Delta}) \), which is a disorder-averaged ratio of the matrix element of operator \( Y' \) between adjacent eigenstates, and \( \Delta \) is the level spacing. We find that \( g(L) \) decreases with \( L \) in the MBL phase, and grows in the ergodic phase. We propose that at the MBL-delocalization transition \( g(L) \) is independent of system size, \( g(L) = g_\infty \sim 1 \), and use this criterion to map out the phase diagram of a disordered 1D XXZ spin-1/2 chain. By studying the scaling of \( g(L) \) as a function of energy density, we locate the many-body mobility edge. We discuss implications for delocalization phase transition.

Strong-randomness phenomena in quantum Ashkin-Teller models. THOMAS VOJTA, HATEM BARGHATHI, FAWAZ HRAHSHEH, Missouri Univ of Sci & Tech, JOSE HOYOS, Instituto de Fisica de Sao Carlos, Universidade de Sao Paulo, RAJ NARAYANAN, Indian Institute of Technology Madras \( \longrightarrow \) N-color quantum Ashkin-Teller spin chain is a prototypical model for the study of strong-randomness phenomena at first-order and continuous quantum phase transitions. This talk discusses strong-disorder renormalization group approaches to this system in the weak-coupling as well as the strong-coupling regimes. Specifically, we introduce a novel general variable transformation that unifies the treatment of the strong-coupling regime. This allows us to determine the phase diagram for all color numbers \( N \), and the critical behavior for all \( N \neq 4 \). In the case of two colors, \( N = 2 \), a partially ordered product phase separates the paramagnetic and ferromagnetic phases in the strong-coupling regime. This phase is absent for all \( N > 2 \), i.e., there is a direct phase boundary between the paramagnetic and ferromagnetic phases. In agreement with the quantum version of the Aizenman-Wehr theorem, all phase transitions are continuous, even if their clean counterparts are of first order. We also discuss the various critical and multicritical points. They are all of infinite-randomness type, but depending on the coupling strength, they belong to different universality classes.

Electronic glasses, regardless of disorder.

Our study suggests universal characteristics of all electron glasses, regardless of disorder.
**12:51PM T22.00009 Many-body mobility edge due to symmetry-constrained dynamics and strong interactions**, JAN MONDRAGON-SHEM, Univ of Illinois - Urbana, ARUJEET PAL, Harvard University, CHRIS LAUMANN, University of Washington, TAYLOR HUGHES, Univ of Illinois - Urbana — Many-body localization at a finite energy density inhibits thermalization and opens the possibility to study macroscopic quantum phenomena in highly excited states. The system transitions from an ergodic to a nonergodic phase at a critical energy density defined to be the many-body mobility edge. We present a mechanism for the formation of a many-body mobility edge in disordered systems with strong interactions, that satisfy conservation laws. The strong interaction spectrally differentiates eigenstates at positive temperature from those at negative temperature based on correlations, whose quantum dynamics differ dramatically due to the conservation laws. Upon introducing disorder, this difference in the dynamics can lead to an energy-dependent onset of many-body localization, thus leading to the formation of a many-body mobility edge. We exemplify this mechanism in the strongly anisotropic spin-1/2 XXZ model in a random field, whose dynamics is constrained by the conservation of total spin projection. We compute a set of diagnostic quantities that verify the presence of a mobility edge in this model. Furthermore, we discuss how introducing correlated disorder in the model can enhance this effect and stabilize the mobility edge itself.

**1:03PM T22.00010 Lattice aspect ratio effects on transport in two-dimensional quantum percolation**, BRIANNA DILLON, HISAO NAKANISHI, Purdue Univ — In a previous work [Dillon and Nakanishi, E.Phys.J.B, to be published (2014)], we calculated the transmission coefficient of the two-dimensional quantum percolation problem and concluded that there are three regimes, namely, exponentially localized, power-law localized, and delocalized. However, this remains a controversial problem and works by many others fall either in a group claiming that quantum percolation in 2D is always exponentially localized (as one-parameter scaling would suggest) or in one claiming that there is a transition to a less localized (perhaps power-law localized or delocalized) state. Among the many different types of calculations, it stood out that most works based on two-dimensional strips of highly anisotropic aspect ratios fall in the first group, whereas our previous calculations and most others in the second group were based on isotropic square geometry. In order to understand the deviations between our results and those based on strip geometry, we applied our direct calculation of the transmission coefficient to strips of a wide range of aspect ratios, and report on how aspect ratio influences transmission and localization length.

**1:15PM T22.00011 Heat diffusion in the disordered Fermi and electron liquids: the role of inelastic processes**, GEORG SCHWIETE, Johannes Gutenberg University Mainz, ALEXANDER FINKEL’SSTEIN, Texas A&M University — We study transport thermal in the disordered Fermi and electron liquids at low temperatures. Gravitational potentials are used as sources for finding the heat density and its correlation function. For a comprehensive study, we extend the renormalization group (RG) analysis developed for electric transport by including the gravitational potentials into the RG scheme. The analysis reveals that for the disordered Fermi liquid the Wiedemann-Franz law remains valid even in the presence of quantum corrections caused by the interplay of diffusion modes and the electron-electron interaction. In the present scheme this fundamental relation is closely connected with a fixed point in the multi-parametric RG flow of the gravitational potentials. While the disordered electron liquid we additionally analyze inelastic processes induced by the Coulomb interaction at sub-temperature energies. While the general form of the correlation function has to be compatible with energy conservation, these inelastic processes are at the origin of logarithmic corrections violating the Wiedemann-Franz law. The interplay of various terms in the heat density-heat density correlation function therefore differs from that for densities of other conserved quantities, such as total number of particles or spin.

**1:27PM T22.00012 Effect of impurities on strongly-correlated superconductivity with inhomogeneous cluster dynamical mean field theory**, ALEXANDRE FOLEY, SIMON VERRET, Université de Sherbrooke and RQMP, Sherbrooke, Canada, JYOTIRMROY ROY, TIFR, Mumbai, India, ANDRÉ-MARIE TREMBLAY, DAVID SÉNECHAL, Université de Sherbrooke and RQMP, Sherbrooke, Canada — We study the problem of an out-of-plane impurity in the square-lattice Hubbard model using inhomogeneous cluster dynamical mean field theory (1-CDMFT). This problem simulates the effect of impurities in superconducting cuprates. The impurity is located at the center of a 2x2 quasiparticle, surrounded by 8 or 24 other plaquettes without impurities. This system constitutes the repeated unit treated with cluster dynamical mean field theory. We find that the impurity shifts the onset of superconductivity towards higher doping. We study the effect of the impurity on the pseudogap as it appears in the local density of states. We also discuss its effect on the extent of the antiferromagnetic phase.

**1:39PM T22.00013 Disorder Driven Quantum Criticality in Three Dimensional Dirac Semimetals**, JEDEDIAH PIXLEY, PALLAB GOSWAMI, Condensed Matter Theory Center, University of Maryland, College Park — We study the nature of the quantum phase transition between a three dimensional Dirac semi-metal and a disorder controlled diffusive metal. We analyze a lattice model using numerical and field theoretical methods to explore the phase diagram and quantum critical behavior. We determine the scaling properties of the density of states and various thermodynamic observables for sufficiently large system sizes and extract the relevant critical exponents. As a result, we show the scaling functions obey energy over temperature scaling and the quantum critical point is an interacting fixed point.

**1:51PM T22.00014 Microscopic driving force in electronic smectic-nematic transition in La1/3Ca2/3MnO3**, JING TAO, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, K. SUN, Department of Physics, University of Michigan, W.G. YIN, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, S.J. PENNYCOOK, Department of Materials Science and Engineering, University of Tennessee, J.M. TRANQUADA, Y. ZHU, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory — Electronic liquid crystal (ELC) phases provide unique descriptions to characterize the electronic structures and elucidate the underlying physics in correlated materials from symmetry perspective. Although ELC phases have been proposed to play a key role in interpreting the structure-property relationship in a wide range of correlated materials, the experimental manifestations of the nature of the transition between such phases have been waiting to be explored. Using transmission electron microscopic tools with recently developed techniques, we studied the electronic smectic-nematic phase transition in La1/3Ca2/3MnO3 by monitoring the evolution of charge ordering and orbital ordering superstructures as a function of temperature. We observed that the transition is driven by the formation of defects and electronic phase separation. In addition, we found that charge inhomogeneity is responsible for the electronic smectic-nematic phase transition in this material.

**Thursday, March 5, 2015 11:15AM - 2:15PM – Session T23 DCOMP DMP: Multiscale Modeling**

202B - Richard Lombardini, St. Mary’s University
11:15AM T23.00001 Time Domain Propagation of Quantum and Classical Systems using a Wavelet Basis Set Method, RICHARD LOMBARDINI, EWAN NOWARA, St. Mary's University (San Antonio, TX), BRUCE JOHNSON, Rice University — The use of an orthogonal wavelet basis set (Optimized Maximum-N Generalized Colleffts) to effectively model physical systems in the time domain, in particular the electromagnetic (EM) pulse and quantum mechanical (QM) wavefunction, is examined in this work. Although past research has demonstrated the benefits of wavelet basis sets to handle computationally expensive problems due to their multisresolution properties, the overlapping supports of neighboring wavelet basis functions poses problems when dealing with boundary conditions, especially with material interfaces in the EM case. Specifically, this talk addresses this issue using the idea of derivative matching creating fictitious grid points (T.A. Driscoll and B. Fornberg), but replaces the latter element with fictitious source functions in conjunction with wavelet reconstruction filters. Two-dimensional (2D) systems are analyzed, EM pulse incident on silver cylinders and the QM electron wave packet circling the proton in a hydrogen atom system (reduced to 2D, and the new wavelet method is compared to the popular finite-difference time-domain technique.

11:27AM T23.00002 A Hamiltonian theory of adaptive resolution simulations of classical and quantum models of nuclei, KARSTEN KREIS, DAVIDE DONADIO, KURT KREMER, RAFFAELLO POTESTIO, Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany — Quantum delocalization of atomic nuclei strongly affects the physical properties of low temperature systems, such as superfluid helium. However, also at room temperature nuclear quantum effects can play an important role for molecules composed by light atoms. An accurate modeling of these effects is possible making use of the Path Integral formulation of Quantum Mechanics. In simulations, this numerically expensive description can be restricted to a small region of space, while modeling the remaining atoms as classical particles. In this way the computational resources required can be significantly reduced. In the present talk we demonstrate the derivation of a Hamiltonian formulation for a bottom-up, theoretically solid coupling between a classical model and a Path Integral description of the same system. The coupling between the two models is established with the so-called Hamiltonian Adaptive Resolution Scheme, resulting in a fully adaptive setup in which molecules can freely diffuse across the classical and the Path Integral regions by smoothly switching their description on the fly. Finally, we show the validation of the approach by means of adaptive resolution simulations of low temperature parahydrogen.

11:39AM T23.00003 Simulating long time behavior of materials: a case study of sintering of nanoparticles, AMIT SAMANTA, SELIM ELHADJ, JEFF BUDE, TAMMY OLSON, JON LEE, JAE HYUCK YOO, Lawrence Livermore National Laboratory — Physical processes in nature exhibit disparate time-scales, for example time scales associated with processes like phase transitions, various manifestations of creep, sintering of particles etc. are often much higher than time the system spends in the metastable states. The transition times associated with such events are also orders of magnitude higher than time scales associated with vibration of atoms. Thus, atomistic simulations of such transition events is a challenging task. In this talk, I will present a method to overcome the time-scale problem and efficiently explore the free energy surface of a complex system. I will discuss how this method can be used to gain quantitative atomic-scale insights into the sintering of nanoparticles. The simulations suggest that processes like interfacial and bulk diffusion along with grain rotation play an important role during sintering. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract DE-AC52-07NA27344. LLNL-ABS-664253.

11:51AM T23.00004 Time-dependent potential-functional embedding theory, CHEN HUANG, Department of Scientific Computing, Florida State University, USA, FLORIAN LIBISCH, Institute for Theoretical Physics, Vienna University of Technology, Austria, QING PENG, Department of Mechanical, Aerospace and Nuclear Engineering, Rensselaer Polytechnic Institute, USA, EMILY CARTER, Department of Mechanical and Aerospace Engineering, Princeton University, USA — We introduce a time-dependent potential-functional embedding theory (TD-PFET), in which atoms are grouped into subsystems. In TD-PFET, subsystems can be propagated by different suitable time-dependent quantum mechanical methods and their interactions can be treated in a seamless, first-principles manner. TD-PFET is formulated based on the time-dependent quantum mechanics variational principle. The action of the total quantum system is written as a functional of the time-dependent embedding potential, i.e., a potential-functional formulation. We derive the integral equation that such an embedding potential needs to satisfy. As proof-of-principle, we demonstrate TD-PFET for a Na4 cluster, in which each Na atom is treated as one subsystem and propagated by time-dependent Kohn-Sham density functional theory (TDDFT) using the adiabatic local density approximation (ALDA). Our results agree well with a direct TDDFT calculation on the whole Na4 cluster using ALDA. We envision that TD-PFET will ultimately be useful for studying ultrafast quantum dynamics in condensed matter, where key regions are solved by highly accurate time-dependent quantum mechanics methods, and unimportant regions are solved by faster, less accurate methods.

12:03PM T23.00005 Coupled molecular-dynamics and first-principle transport calculations of metal/oxyde/metal heterostructures, PETER ZAPOL, Argonne Natl Lab, DMITRY KARPEYEV, University of Chicago, KETAN MAHESHWARI, XIANGLIANG ZHONG, BADRI NARAYANAN, SUBRAMANIAN SANKARANARAYANAN, MICHAEL WILDE, OLLE HEINONEN, Argonne Natl Lab, IVAN RUNDGER, Trinity College — The electronic conduction in Hf-oxygen heterostructures for use in, e.g., resistive switching devices, depends sensitively on local oxygen stoichiometry and interactions at interfaces with metal electrodes. In order to model the electronic structure of different disordered configurations near interfaces, we have combined molecular dynamics (MD) simulations with first-principle based non-equilibrium Green’s functions (NEGF) methods, including self-interaction corrections. We have developed an approach to generating automated workflows that combine MD and NEGF computations over many parameter values using the Swift parallel scripting language. A sequence of software tools transforms the result of one calculation into the input of the next allowing for a high-throughput concurrent parameter sweep. MD simulations generate systems with quenched disorder, which are then directly fed to NEGF and on to postprocessing. Different computations can be run on different computer platforms matching the computational load to the hardware resources. We will demonstrate results for metal-HfO2-metal heterostructures obtained using this workflow.

12:15PM T23.00006 Quasi-continuum multiscale theory for confined Lennard-Jones fluid mixture, MOHAMMAD H. MOTEVASSELIAN, SIKANDAR Y. MASHAYKH, NARAYANA R. ALURI, Univ of Illinois - Urbana — A continuum-based approach is developed to predict the structure of confined multicomponent Lennard-Jones fluids at multiple length-scales, ranging from few angstroms to microns. The continuum approach is based on the empirical potential-based quasi-continuum theory (EQT) that incorporates atomistic detail into a continuum framework such as the Nernst-Planck equation. It can also be used to construct a grand potential functional for classical density functional theories (cDFT). EQT and cDFT combination, provide a simple and fast approach to predict the inhomogeneous density, potential profiles and thermodynamic properties of confined fluids. In this work, we demonstrate EQT-cDFT approach by simulating a mixture of methane and hydrogen inside slit-like channels of graphene. We show that the structure of the confined mixture compares well with MD simulation results.
12:27PM T23.00007 Multiscale Investigations of the Oxidation of Stepped Cu Surfaces, QING ZHU, Chemical Engineering, University of Pittsburgh, WISSAM SAIDI, Materials Science, University of Pittsburgh, JUDITH YANG, Chemical Engineering, University of Pittsburgh — Defects on metal surfaces can induce non-canonical oxidation channels that may lead to the formation of novel nanostructures. Cu surfaces have been actively researched in the surface science community due to their wide range of applications in many fields. Recently, in situ TEM experiments showed that the oxidation of stepped surfaces promotes the formation of a flat metal-oxide interface through the Cu adatoms detachment from steps and diffusion across the terraces. In order to better understand these results, and to provide a tight bridge between the experiment and theory, we have investigated the Cu(100) oxidation using a multiscale computational approach that employs density functional theory and reactive force field. Our results demonstrate that the step-edge defects induce markedly different oxidation dynamical behavior compared to the flat surface. Additionally, on the stepped-surfaces, we find that the oxidation of the upper-terrace are more favored than the lower-terrace. We show that this behavior is due to a negative Ehrlich-Schwoebel diffusion barrier for oxygen in the ascending direction. The favoring of the oxidation of the top terrace drives Cu diffusion flux from the upper-terrace to the lower-terrace that explains the recent TEM experiments.

We acknowledge support from the NSF, Alfred P. Sloan Foundation, and KITP.

12:39PM T23.00008 A systematically improvable second-principles method including electron and lattice degrees of freedom, PABLO GARCIA-FERNANDEZ, Departamento CITIMAC, Universidad de Cantabria, Avenida de los Castros s/n, 39005 Santander, Spain, JACEK WOJDELA, JORGE IÑIGUEZ, Institut de Ciencia de Materiales de Barcelona (ICMAB-CSIC), Campus UAB, E-08193 Bellaterra, Spain, JAVIER JUNQUIERA, Departamento CITIMAC, Universidad de Cantabria, Avenida de los Castros s/n, 39005 Santander, Spain — One of the most difficult tasks when trying to expand Density Functional Theory (DFT) calculations to large systems is the scaling of computational time with the number of electrons in the simulation box. However, not all electrons play a relevant role in the determination of the physical magnitude under scrutiny. In this work we present a systematic approach to DFT based on a rigorous separation of these active electrons and holes from those of a reference state. Using a similar expansion to that found in Tight-binding DFT methods we obtain a large term containing the energy of the reference system, and a second, much smaller one, associated to the active part of the electron density. We associate the energy of the reference system to the lattice degrees of freedom and use a well-tested model Hamiltonian to represent them, on the other hand, the active electrons are described using a small but accurate Wannier function basis-set. Combined with an efficient Lanczos-based diagonalization, our method provides a systematically improvable scheme to simulate systems including tens of thousands of atoms under experimental conditions. We provide several examples of its application in the field of transition-metal oxides.

1:03PM T23.00010 The impact of resolution upon the complexity, information, thermodynamics, and transferability of coarse-grained models, THOMAS FOLEY, Pennsylvania State University. M. SCOTT SHELL, University of California, Santa Barbara, WILLIAM NOIID, Pennsylvania State University, NOIID/SHELL TEAM — By eliminating atomic degrees of freedom, coarse-grained (CG) models allow highly efficient simulations of complex phenomena. However, as a consequence of changing the model resolution, the coarse-graining procedure alters the apparent thermodynamic properties and model transferability. The present work analyzes the effects of model resolution upon the exact many-body potential of mean force (PMF), W, and, in particular, its entropic component, S_T. We demonstrate that S_T quantifies the loss of information from the atomistic model and impacts the complexity, thermodynamics, and transferability of the CG model. In order to investigate these formal results, we analytically calculate the exact PMF for the popular Gaussian Network Model of proteins and quantify both the energy-entropy balance as well as the entropic contribution to intramolecular interactions as a function of resolution. Interestingly, seven diverse proteins demonstrate strikingly similar shifts in energy-entropy balance with decreasing model resolution. We expect that these results may provide general insight into both the thermodynamic properties and model transferability. The present work analyzes the effects of model resolution upon the complexity, information, thermodynamics, and transferability of coarse-grained models for soft materials.

1:15PM T23.00011 Calculation of energy relaxation rates of fast particles by phonons in crystals, MICAH PRANGE, LUKE CAMPBELL, DANGXIN WU, SEBASTIEN KERISIT, Pacific Northwest National Laboratory — We present ab initio calculations of the temperature-dependent exchange of energy between a classical charged point-particle and the phonons of a crystalline material. The phonons, which are computed using density functional perturbation theory (DFPT) methods, interact with the moving particle via the Coulomb interaction between the density induced in the material by phonon excitation and the charge of the classical particle. Energy relaxation rates are computed using time-dependent perturbation theory. The method, which is applicable wherever DFPT is, is illustrated with results for several important scintillators whose performance is affected by electron thermalization. We discuss the influence of the form assumed for quasiparticle dispersion on theoretical estimates of electron cooling rates.

We acknowledge support from the NSF, Alfred P. Sloan Foundation, and KITP.

12:51PM T23.00009 Mesoscale modeling of functional properties in core-shell nanoparticles, JOHN MANGERI, Department of Physics, University of Connecticut, Storrs, CT, United States, OLLE HEINONEN, Material Science Division, Argonne National Laboratory, Lemont, IL, United States, DMITRY KARPEEV, University of Chicago, Chicago, IL, United States, SERGE NAKHMANSON, Institute of Materials Science, University of Connecticut, Storrs, CT, United States — Core-shell nanoparticle systems of Zn-ZnO and ZrO-TiO_2 are studied computationally using the highly scalable MOOSE finite-element framework, developed at Idaho National Lab. The elastic anisotropic mismatch of the core and shell create an imprinting effect within the shell that produces a wide variation of strains. Due to this diversity of strains, the sharp band gap edges of the bulk semiconductor are observed to be “thinned-out” much like amorphous silicon. We show that a variety of factors, such as particle size, core-to-shell volume ratio, applied hydrostatic pressure, shell microstructure, as well as the effect of surface elasticity, can influence the distribution of optical band-gap values within the particle, which may prove useful within the field of photovoltaics.

1Part of the work by O.H. was supported by award 70NANB14H012 from U.S. Department of Commerce, National Institute of Standards and Technology as part of the Center for Hierarchical Material Design.

2Northwestern-Argonne Institute of Science and Engineering, Northwestern University, Evanston, IL, United States
The limitations and possible modifications of the stress theorem are discussed. Strained orbitals minimize the non-interacting kinetic energy. The first assumption is correct. I find that the second assumption applies only in special cases.

The non-interacting kinetic energy depends on two assumptions: 1) the modulus squared of the strained orbitals equals the strained electron density, and 2) the density at zero strain; it does. The algebraic derivatives of the Hartree and exchange energies are straightforward. The derivative with respect to strain of the lattice of ions can be obtained by evaluating the algebraic derivative of the DFT energy (in practice a local or other approximation) of an electron density.

Within the scheme, non-equilibrium situation and quantum transport within the open-boundary condition are described by the region-dependent ∆ of Science and Technology — We report on the development of a novel first-principles method for the calculation of non-equilibrium quantum transport process. Within the scheme, the non-equilibrium situation and quantum transport within the open-boundary condition are described by the region-dependent. ∆ self-consistent field method and matrix Green’s function theory, respectively. We will discuss our solutions to the technical difficulties in describing bias-dependent electron transport at complicated nanointerfaces and present several application examples.

1:27PM T23.00012 Using the IRC n-Tiered model to generate exact numeric solutions for possible leptons. ARAN STUBBBS, Inframatter Research Center — Our model has 3 tiers below leptons and quarks: proto-matter, mezzo-matter, and infra-matter. Each has characteristic tachyons binding together the lower level structures to produce the higher level. Each class of tachyon generates its own granularity constant. The proto-matter is bound by gravitons to form the leptons and quarks. The mezzo-matter is bound by mezzo-tachyons to form the proto-matter. The infra-matter is bound by infra-tachyons to form the mezzo-matter. 2 types of mezzo tachyons bind the mezzo-matter structures: a charge tachyon binding s mezzo-matter (with l =0), and a color tachyon binding structures with l>0. The s structure has 1 infra-tachyon and 1 infra-photon, in 1s orbits. The p structure has 7 of each: among 4 s sub-shells and 1 p. The d structure has 11 s sub-shells, 3 p, and 1 d. Etc. Based on the first 2 leptons, a solution for the energy of the s (charge) structure, and the p (color) structure were deduced, from which the other mezzo structures energies were generated. From the mezzo matter energy content, and a pattern of orbits at the proto-matter level, energies for the next few leptons were found (to 3 sig figs): 140 MeV, 827 MeV, 1780 MeV, and 4690 MeV.

1:39PM T23.00013 A variational free-energy functional approach to the Schrödinger-Poisson theory. FRANCISCO J. SOLIS, School of Mathematical and Natural Sciences, Arizona State University, VIKRAM JADHAO, Department of Physics and Astronomy, Johns Hopkins University, KAUSHIK MITRA, None, MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University — In the numerical simulation of model electronic device systems, where electrons are typically under confinement, a key obstacle is the need to iteratively solve the coupled Schrödinger-Poisson equation in order to obtain the electronic potential. We show that it is possible to bypass this obstacle by adopting a variational approach and obtaining the solution of the SP equation by minimizing a functional. We construct the required functional and establish some of its properties. We apply this formulation to the case of narrow channel quantum wells where the local density approximation yields accurate results.

1:51PM T23.00014 Ab initio quantum transport in atomic carbon chains. ANDRÉS R. BOTELLO-MÉNDEZ, JEAN-CHRISTOPHE CHARLIER, University of Louvain, Institute of Condensed Matter and Nanosciences (Belgium), FLORIAN BANHART, Université de Strasbourg, Institut de Physique et Chimie des Matériaux (France), NAPS TEAM, CARBYNE COLLABORATION — Carbyne, the sp-hybridized phase of carbon, is still a missing link in the family of carbon allotropes. Recently, detailed electrical measurements and first-principles electronic transport calculations have been performed on monoatomic carbon chains [1]. When the 1D system is under strain, the current-voltage curves exhibit a semiconducting behavior, which corresponds to the polyyne structure of the atomic chain with alternating single and triple bonds. Conversely, when the chain is unstrained, the ohmic behavior is observed in agreement with the metallic cumulene structure with double bonds, confirming recent theoretical predictions, namely that a metal-insulator transition can be induced by adjusting the strain. The key role of the contacting leads is also scrutinized by ab initio quantum conductance calculations [2], explaining the rectifying behavior measured in monoatomic carbon chains in a non-symmetric contact configuration.

2:03PM T23.00015 Development of a non-equilibrium quantum transport calculation method based on constrained density functional1. HAN SEUL KIM, YONG-HOON KIM, Graduate School of EEWS, Korea Advanced Institute of Science and Technology — We report on the development of a novel first-principles method for the calculation of non-equilibrium quantum transport process. Within the scheme, the non-equilibrium situation and quantum transport within the open-boundary condition are described by the region-dependent ∆ self-consistent field method and matrix Green’s function theory, respectively. We will discuss our solutions to the technical difficulties in describing bias-dependent electron transport at complicated nanointerfaces and present several application examples.

2:17PM T24.00002 A problem with the stress theorem commonly used in DFT codes1. DONALD NICHOLSON, Department of Physics, University of North Carolina Asheville — The change in energy when an affine transformation (strain) is applied to a lattice of ions can be obtained by evaluating the algebraic derivative of the DFT energy (in practice a local or other approximation) of an electron density that has been similarly strained [1]. Because the DFT energy is stationary in the density, it is only required that the strained density reduces to the exact density at zero strain; it does. The algebraic derivatives of the Hartree and exchange energies are straightforward. The derivative with respect to strain of the non-interacting kinetic energy depends on two assumptions: 1) the modulus squared of the strained orbitals equals the strained electron density, and 2) the strained orbitals minimize the non-interacting kinetic energy. The first assumption is correct. I find that the second assumption applies only in special cases. The limitations and possible applications of the stress theorem are discussed.

1Work at the University of North Carolina Asheville and Oak Ridge National Laboratory was supported by the U. S. Department of Energy, Office of Basic Energy Sciences, Materials Science and Engineering Division.
GREGORY MANN, Dept. of Chemistry, UC Berkeley; KIYUHO LEE, Department of Chemical & Biomolecular Engineering, UC Berkeley; MOLECULAR FOUNDRY, Lawrence Berkeley National Lab; MATTEO COCCIONI, Institute of Materials, École polytechnique fédérale de Lausanne, BEREND SMIT, Departments of Chemistry and Chemical & Biomolecular Engineering, UC Berkeley; JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Lab; Dept. of Physics, UC Berkeley — In order to use density functional theory (DFT) to reliably treat small molecule binding at open metal sites in metal-organic frameworks (MOFs), electron correlation effects associated with the localized d-states present at the metal centers must be accounted for. Incorporation of a Hubbard U-like term can be an approximate but computationally efficient means, yielding excellent agreement with experiment provided an appropriate value for the parameter U is chosen. To predict adsorption energetics for as-yet unsynthesized MOFs, we would need to select U using a systematic, physically motivated approach rather than the ad hoc methods typically employed. Here, we use an ab initio linear response approach to calculate U. We show that U values determined with this method reproduce previous results for the binding of carbon dioxide in Co-MOF-74 and Cu-MOF-74, and we discuss the method’s application to other 3d metals in the MOF-74 framework. Our preliminary results suggest that a wide range of U above a critical value will produce accurate binding energies. Finally, we present U values calculated for Co2+ ions in other systems, probing the environment dependence of this parameter. This work supported by DOE, and computational resources provided by NERSC.

11:51AM T24.00004 Density versus spin-density functional in DFT+U and DFT+DMFT
HYOWON PARK, University of Illinois at Chicago; ANDREW MILLIS, CHRIS MARIANETTI, Columbia University — The construction of multi-variable effective action theories such as DFT+U and DFT+DMFT requires the choice of a local subspace of correlated orbitals and an additional variable being either the charge density or spin density. This talk examines the differences between using charge-only and spin-dependent exchange-correlation functionals with the aim of providing guidance for constructing more sophisticated beyond-density functional theories. The widely used spin-dependent approximations to the exchange-correlation functional are found to lead to a large and in some cases unphysical effective exchange coupling within the correlated subspace. Additionally, the differences between Wannier and Projector based definitions of the correlated orbitals are examined, and only small differences are found provided that the orbitals are orthonormal and strongly localized. These results are documented in the context of the rare earth nickelates.

12:03PM T24.00005 The Hubbard Dimer: A Complete DFT Solution to a Many-Body Problem
JUSTIN SMITH, Univ of California - Irvine; DIEGO CARRASCAL, JAIME FERRER, Universidad de Oviedo; KIERON BURKE, Univ of California - Irvine — In this work we explain the relationship between density functional theory and strongly correlated models using the simplest possible example, the two-site asymmetric Hubbard model. We discuss the connection between the lattice and real-space and how this is a simple model for stretched H2. We can solve this elementary example analytically, and with that we can illuminate the underlying logic and aims of DFT. While the many-body solution is analytic, the density functional is given only implicitly. We overcome this difficulty by creating a highly accurate parameterization of the exact function. We use this parameterization to perform benchmark calculations of correlation kinetic energy, the adiabatic connection, etc. We also test Hartree-Fock and the Bethe Ansatz Local Density Approximation. We also discuss and illustrate the derivative discontinuity in the exchange-correlation energy and the infamous gap problem in DFT.

12:15PM T24.00006 Development of a DFT+DMFT method using multi-orbital impurity solver
MANCHEON HAN, HYUNJU OH, CHOONG-KI LEE, HYOUNG JOON CHOI, Department of Physics, IPAP, and Center for Computational Studies of Advanced Electronic Material Properties, Yonsei University — The density functional theory (DFT), often performed with the local density approximation or the generalized gradient approximation, is very successful for ab initio calculations of various materials. However, it has limited accuracy for strongly correlated materials. The dynamical mean field theory (DMFT), which maps a correlated lattice system to an interacting impurity site in a non-interacting bath, may describe local correlation effects. Combination of above methods, DFT+DMFT, can be an adequate approach for investigation of strongly correlated materials. We develop a multi-orbital DFT+DMFT method based on the ab-initio pseudopotential method of the SIESTA code, where electronic wavefunctions are expanded with pseudo-atomic orbitals. An exact diagonalization method is used in our DFT+DMFT method to obtain the local Green function of the impurity site with multiple orbitals. We apply our DFT+DMFT method to the electronic structure of LaFeAsO and compare the results with those from DFT and experiments. This work is supported by the NRF of Korea (Grant No.2011-0018306). Computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2013-C3-062).

12:27PM T24.00007 Nonorthogonal generalized hybrid Wannier functions for linear scaling DFT simulations of surfaces and interfaces
ANDREA GRECO, ARASH MOSTOFI, Imperial College London; JOHN FREELAND, Argonne National Laboratory — Semiconductor-based thin-films have applications in microelectronics, where transistors to nano-capacitors. Many of their properties depend on phenomena at multiple length scales, but their complexity makes it difficult to obtain a detailed understanding of their behavior from experiment alone. First-principles simulations based on density-functional theory (DFT) are invaluable for providing insight into materials’ properties including for the study of thin films. In particular, hybrid Wannier functions (WFs), fully extended in the surface plane, but localized along the direction normal to the surface, have been successfully used to explore the properties of systems layered along a given direction. The large length scales associated with structures and processes in more realistic surfaces, however, are beyond the scope of such calculations, because they rely on first performing a traditional cubic-scaling DFT calculation. To overcome this limitation, we extend the concept of hybrid WFs to nonorthogonal orbitals that are directly optimized in situ in the electronic structure calculation. We show that this method, implemented in the ONETEP linear scaling DFT code, enables the study of large-scale surfaces and interfaces with plane-wave accuracy but at reduced computational expense.

12:39PM T24.00008 Performance and Accuracy of Recursive Subspace Bisection for Hybrid DFT Calculations
WILLIAM DAWSON, FRANCOIS GYGI, Univ of California - Davis — The high cost of computing the Hartree-Fock exchange has resulted in limited use of Hybrid Functionals in DFT calculations. Approximations based on transformation to localized orbitals provide one way to reduce this cost. One such method is the recursive subspace bisection method (RSB)[1]. Such localization methods involve truncation of localized orbitals, which introduces an additional approximation. We take advantage of our ability to systematically reduce the error in RSB calculations through a single parameter to study this approximation. We present the errors in ground state energy, forces, and relative energy differences between configurations for a variety of systems, including tungsten oxide, a silicon-water interface, and liquid water including the calculation of empty states.

12:51PM T24.00009 Speeding up DFT: A faster method for integrating band energy in SCF cycles

MATTHEW M. BURBIDGE, JEREMY J. JORGENSEN, CONRAD W. ROSENBROCK, Brigham Young University, DEREK C. THOMAS, University of Texas at Austin, BRENT C. HESS, ROYDIE W. FORCADE, Brigham Young University, STEFANO CURTAROLO, Duke University, Center for Materials Genomics, GUS L. W. HART, Brigham Young University — Typically in SCF cycles, a “rectangle rule” is used on uniformly spaced points (Monk Pack meshes) to integrate the band energy. The use of rectangles is motivated by their fast convergence when used on the fully occupied bands of semiconductors. Unfortunately integration with rectangles is extremely inefficient for metals. This motivates the use of gauss quadrature (or other higher order methods) for integrating the band energy. As we show, however, even in the case of semiconductors where the rectangle convergence is extremely efficient, higher order methods are still more efficient. The savings in semiconductors alone are sufficient to motivate the implementation of a higher order method in current DFT codes. Even though higher order quadrature methods were discussed immediately following the original Monkhorst and Pack paper, we revisit the issue in light of modern DFT calculations. [1] H. J. Monkhorst and J. D. Pack, Phys. Rev. B 13, 5188 (1976).

1:03PM T24.00010 Efficient parameter-free calculation of absorption spectra for insulators, semiconductors and metals from time-dependent current DFT

ARJAN BERGER, LCPQ - IRSAMC, Université de Toulouse III - Paul Sabatier, CNRS, Toulouse, France and European Theoretical Spectroscopy Facility — In this work we show that with a simple dynamical kernel we can obtain good absorption spectra from time-dependent current-density functional theory (TDDCFT) for insulators, semiconductors and metals. Our approach is fully parameter free since no artificial broadening parameter is used to match calculated and measured spectra. The cost of a calculation is equal to an RPA calculation. Moreover, our TDDCFT approach scales better with system size than standard TD-DFT implementations.

1:15PM T24.00011 Gauge invariant calculation of magnetic properties from time-dependent current DFT

NATHANIEL RAIMBAULT, Laboratoire de Chimie et Physique Quantiques, IRSAMC, Université Toulouse III - Paul Sabatier, CNRS & European Theoretical Spectroscopy Facility, PAUL L. DE BOEIJ, Scientific Computing & Modeling NV, Vrije Universiteit, Theoretical Chemistry, PINA ROMANIENLO, Laboratoire de Physique Théorique, CNRS, IRSAMC, Université Toulouse III - Paul Sabatier & European Theoretical Spectroscopy Facility, ARJAN BERGER, Laboratoire de Chimie et Physique Quantiques, IRSAMC, Université Toulouse III - Paul Sabatier, CNRS & European Theoretical Spectroscopy Facility — We present a method to calculate magnetic properties from the current density that does not depend on the gauge choice for the vector potential when a finite basis set is used [1]. To obtain this we put paramagnetic and diamagnetic contributions to the current on equal footing by making use of a sum rule [1]. Our method is general. Here we use it to calculate static and dynamical magnetizabilities of molecules within Time-Dependent Current-Density-Functional Theory.

1:27PM T24.00012 Accurate Energies and Orbital Description in Semi-Local Kohn-Sham DFT

ALEXANDER LINDMAA, Linkoping University, STEPHAN KUEMMEL, University of Bayreuth, RICKARD ARMIENTO, Linkoping University — We present our progress on a scheme in semi-local Kohn-Sham density-functional theory (KS-DFT) for improving the orbital description while still retaining the level of accuracy of the usual semi-local exchange-correlation (xc) functionals. DFT is a widely used tool for first-principles calculations of properties of materials. A given task normally requires a balance of accuracy and computational cost, which is well achieved with semi-local DFT. However, commonly used semi-local xc functionals have important shortcomings which often can be attributed to features of the corresponding xc potential. One shortcoming is an overly delocalized representation of localized orbitals. Recently a semi-local GGA-type xc functional was constructed to address these issues [1], however, it has the trade-off of lower accuracy of the total energy. We discuss the source of this error in terms of a surplus energy contribution in the functional that needs to be accounted for, and offer a remedy for this issue which formally stays within KS-DFT, and, which does not harshly increase the computational effort. The end result is a scheme that combines accurate total energies (e.g., relaxed geometries) with an improved orbital description (e.g., improved band structure). [1] PRL 111, 036402 (2013)

1:39PM T24.00013 Understanding Density Functional Theory (DFT) and Completing it in Practice

DIOLA BAGAYOKO, Southern Univ & A&M Coll — A brief review of the seminal article by Hohenberg and Kohn leads to two conditions that have to be met by electronic structure calculations in order for their results to represent the physics content of DFT. One of these conditions is often the verifiable attainment of the absolute minima of the occupied energies. Using the second Hohenberg Kohn theorem, we show that results of calculations that do not meet this condition, when they applies, do not necessarily represent DFT findings. We illustrate this fact with over 100 calculated band gaps that are much smaller than corresponding, measured ones; in contrast, we list calculations that strictly adhered to the aforementioned conditions and whose results are in excellent agreement with experiment. We describe two crucial steps in the latter calculations that add to or complete DFT in practice. Some implications of our findings for academia, industry, and program package developers will be discussed. Acknowledgments: This work was funded in part by the National Science Foundation (NSF) and the Louisiana Board of Regents, through LASIGMA [Award Nos. EPS-1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award Nos. DE-NA0001861 and DE-NA0002630), LaSPACE, and LONI-SUBR.

1:51PM T24.00014 Elimination of the fractional dissociation problem in Kohn-Sham DFT using the ensemble-generalization approach

ELI KRAISLER, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science, Israel — Many approximations within density-functional theory (DFT) spuriously predict that a many-electron system can dissociate into fractionally charged fragments. Here, we revisit the case of infinitely separated diatomic molecules, known to exhibit this problem when studied within standard approximations, including the local spin-density approximation (LSDA). We apply the recently suggested ensemble-generalization to LSDA (elSDA) [1,2] and find that fractional dissociation is eliminated in all systems examined. The elSDA Kohn-Sham potential develops a spatial step, associated with the emergence of the derivative discontinuity in the exchange-correlation energy functional. This step, predicted in the past for the exact Kohn-Sham potential and observed in some of its more advanced approximate forms, is a desired feature that prevents any fractional charge transfer between the system’s fragments. Our findings show that, if appropriately generalized for fractional electron densities, even the most simple approximate functionals correctly predict integer dissociation [3].

2:03PM T24.00015 Representability of Bloch states on Projector-augmented-wave (PAW) basis sets
LUIS AGAPITO, Univ of North Texas and Duke Univ, ANDREA FERRETTI, CNR-NANO S3 Center, Istituto Nanoscienze, I-41125, Modena, Italy, STEFANO CURTAROLO, Duke University, MARCO BUONGIORNO NARDELLI, Univ of North Texas — Design of small, yet 'complete', localized basis sets is necessary for an efficient dual representation of Bloch states on both plane-wave and localized basis sets. Such simultaneous dual representation permits the development of faster more accurate (beyond DFT) electronic-structure methods for atomistic materials (e.g. the ACBN0 method) by benefiting from algorithms (real and reciprocal space) and hardware acceleration (e.g. GPUs) used in the quantum-chemistry and solid-state communities. Finding a 'complete' atomic-orbital basis (partial waves) is also a requirement in the generation of robust and transferable PAW pseudopotentials. We have employed the atomic-orbital basis from available PAW data sets, which extends through most of the periodic table, and tested the representability of Bloch states on such basis. Our results show that PAW data sets allow systematic and accurate representability of the PAW Bloch states, better than with traditional quantum-chemistry double-zeta- and double-zeta-polarized-quality basis sets.

Thursday, March 5, 2015 11:15AM - 1:51PM — Session T25 DMP: Focus Session: Search for New Superconductors II
203B - Jiaqing Yan, University of Tennessee at Knoxville

11:15AM T25.00001 Superconductivity in the vicinity of antiferromagnetic order in CrAs and related materials.
JIANLIN LUO, Institute of Physics, Chinese academy of Sciences, Beijing 100190, China — Transition-metal oxides or pnictides are in rich of novel and intriguing electronic behaviors due to multiple quantum orders and competing phenomena. Among the different electronic states, the emergence of superconductivity in the vicinity of other quantum orders is at the heart of the rich physics. Superconductivity has been observed in a majority of 3d transition-metal compounds except for the Cr- and Mn- based compounds. It is thus of high interest in exploring possible superconductivity in those systems. In this talk, I will present the discovery of superconductivity on the verge of antiferromagnetic order in CrAs via the application of external high pressure. Bulk superconductivity with Tc ≈ 2 K emerges at the critical pressure Pc ≈ 8 kbar, where the first-order antiferromagnetic transition at TN ≈ 265 K under ambient pressure is completely suppressed. In addition, quantum criticality and non-Fermi liquid behavior are observed near Ppc, which we interpret as originating from a second- order magnetic quantum phase transition that is concomitant with a first-order structural transition. The present finding opens a new avenue for searching novel superconductors in the Cr and other 3d transitional-metal based systems. In collaboration with Wei Wu, Jinguang Cheng, Kazuyuki Matsubayashi, Panpan Kong, Fukun Lin, Changqing Jin, Nanlin Wang, Yoshiya Uwatoko, Rong Yi, and Qinmiao Si.

11:51AM T25.00002 Nodal and multi-gap superconductivity in Ta4Pd3Te16 with weakly ferromagnetic normal state
GUANG-HAN CAO, WEN-HE JIAO, CHUN-MU FENG, ZHU-AN XU, Department of Physics, Zhejiang University, INSTITUTE OF CONDENSED MATTER PHYSICS TEAM — We recently discovered bulk superconductivity at Tc ≈ 4.6 K in a transition metal telluride Ta4Pd3Te16 [W. H. Jiao et al., J. Am. Chem. Soc. 136, 1284 (2014)]. This material has a layered structure with one-dimensional PdTe2 chains. Significant electron correlations are indicated by the enhanced Sommerfeld coefficient. Here we report the measurements of magnetoresistance, Hall effect, magnetization and specific heat using high-quality crystals. Our results show that Ta4Pd3Te16 is an anisotropic type-II superconductor. The anisotropy of upper critical fields Hc2(T) is strongly T-dependent, resulted from the multi-band effect. The zero-field electronic specific heat C0(T) far below the Tc is found to be proportional to T3, suggestive of presence of point nodes in at least one of the superconducting gaps, which is further supported by a nonlinear (∝ H1/2) field dependence of Sommerfeld coefficient in the mixed state. Notably, the material shows anisotropic weak-ferromagnetism above Tc, implying that spin-triplet superconductivity is likely in this material.

12:03PM T25.00003 Search for superconductivity in ternary chalcogenides Bi2Rh1S2
UDHARA KALUIRACHCHI, WEIWEI XIE, QISHENG LIN, VALENTIN TAUFOUR, SERGEY BUD'KO, GORDON MILLER, PAUL CANFIELD, Ames Laboratory/ Iowa State University — Recently Sakamoto and co-workers reported[1] that parkerite-type Bi2Rh1S2 is a new superconducting (~0.7 K) compound with the charge density wave (250 K) behavior. In this work we present the physical properties of iso-structural compound[2] Bi2Rh1S2. For the first time we have been able to grow single crystals of Bi2Rh1S2 and separate them from excess melt via high temperature decanting. We will present the detailed characterization of Bi2Rh1S2 and a new, closely related phase by mean of resistivity, magnetization, specific heat and single crystals diffraction measurements.

12:15PM T25.00004 Superconductivity in non-centrosymmetric BiPd
ANA MALDONADO, University of St Andrews, ZHI-XIANG SUN, MOSTAFA ENAYAT, Max-Planck-Institut fuer Festkoerperforschung, CALUM LITHGOW, University of Edinburgh, ED YELAND, University of St Andrews, DARREN PEETS, Seoul National University, ALEXANDER YARESKO, ANDREAS SCHNYDER, Max-Planck-Institut fuer Festkoerperforschung, PETER WAHL, University of St Andrews — In non-magnetic bulk materials, inversion symmetry protects the spin degeneracy. If the bulk crystal structure lacks a center of inversion, however, Rashba-type spin-orbit interactions lift the spin-degeneracy, leading to a Rashba metal whose Fermi surfaces exhibit a intricate spin texture. In superconducting Rashba metals a pairing wavefunction constructed from these complex spin structures will generally contain both singlet and triplet character. We examine possible triplet components of the order parameter in non-centrosymmetric BiPd, combining macroscopic characterization, atomic-scale ultra-low temperature scanning tunneling spectroscopy and relativistic first-principles calculations. The superconducting state of BiPd appears topologically trivial, consistent with Bardeen-Cooper-Schrieffer theory with an order parameter governed by a single isotropic s-wave gap.
12:27PM T25.00005 Evidence for a superconducting surface state in the half-heusler alloy LuPtBi1, ABHIMANYU BANERJEE, ALAN FANG, CAROLINA ADAMO, PHIL WU, ELI LEVENSEN-FALK, AHARON KAPITULNIK, Stanford University, SHEKHAR CHANDRA, BINGHAI YAN, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids — The half-Heusler alloy LuPtBi is predicted by band structure calculations to be a potential candidate for topological superconductivity. We present experimental evidence for a superconducting surface state at much higher temperatures than the bulk $T_c$ of 0.9K (seen from transport). STM measurements of the 111 surface show a well developed superconducting gap at temperatures below 2.4K, with an IV curve consistent with d-wave superconductivity. The ratio of $\Delta$ to $T_c$ is about 12.0 as opposed to the BCS value of 1.76, implying that the true $T_c$ is about ~7 K. This result is supported by SQUID magnetization measurements as well as theoretical predictions for enhanced surface superconductivity due to a Van-Hove singularity in a Bi-terminated [111] surface. We discuss implications of our measurements and possible future experiments.

12:39PM T25.00006 Beyond annealing: A revealing story of electron doped cuprate superconductors, YOSHIHARU KROCKENBERGER, MASAFUMI HORIO, HIROSHI IRIE, HIDEKI YAMAMOTO, NTT Basic Research Labs — High superconducting transition temperatures are a unique feature of cuprate superconductors. The standard phase diagram randomly combines cuprates with various Cu coordinations, e.g., octahedral vs. square-planar, thus violates electron-hole symmetry arguments. In contrast to hole-doped cuprates, the concept of doping dependency is disordered on the electron-doped side. Doping alone fails to induce superconductivity and a process commonly referred to as “annealing” is required. We have shown that an elaborate annealing process, i.e. 2-step annealing process, is capable to induce superconductivity into $Pr_{2-x}Ce_xCu_3O_7$ with $x$ as low as $x = 0.00$. Here we show that appropriate synthesis conditions allow for the growth of as-grown superconducting $Pr_{2-x}Ce_xCu_3O_7$ thin films by molecular beam epitaxy. We observe a hole-like Hall coefficient being linear up to high magnetic fields. Hence, high quality thin films of electron doped cuprate superconductors still show a positive Hall coefficient even at optimal doping level. Finally, the transition from a Mott insulator in $T_{La_2Cu_3O_4}$ to a superconducting metal in $T_{La_2Cu_3O_4}$ at $x = 0.00$ is solely associated to the coordination of Cu.

12:51PM T25.00007 Superconductivity in the Tungsten Bronzes, PHILLIP WU, Department of Applied Physics, Stanford University, Stanford, California 94305, USA and Geballe Laboratory for Advanced Materials, Stanford University, SATOSHI ISHII, KENJI TANABE, Department of Applied Electronics, Tokyo University of Science, Katsushika-ku, Tokyo 125-8585, Japan, KO MUNAKATA, ROBERT H. HAMMOND, Department of Applied Physics, Stanford University, Stanford, California 94305, USA and Geballe Laboratory for Advanced Materials, Stanford University, KAZUYASU TOKIWA, Department of Applied Electronics, Tokyo University of Science, Katsushika-ku, Tokyo 125-8585, Japan, THEODORE H. GEBALLE, MALCOLM R. BEASLEY, Department of Applied Physics, Stanford University, Stanford, California 94305, USA and Geballe Laboratory for Advanced Materials, Stanford University — Via pulsed laser deposition and post-annealing, high quality K-doped $WO_3_{-\nu}$ films with reproducible transport properties are obtained. A home built two-coil mutual inductance setup is used to probe the behavior of the films in the superconducting and normal state. The inverse penetration depths and dissipation peaks are measured as a function of temperature and field. Separately, via thin film deposition techniques, we report for the first time stable $Pr_{2-x}Ce_xCu_3O_7$ films by molecular beam epitaxy. We observe a hole-like Hall coefficient being linear up to high magnetic fields. Hence, high quality thin films of electron doped cuprate superconductors still show a positive Hall coefficient even at optimal doping level. Finally, the transition from a Mott insulator in $T_{La_2Cu_3O_4}$ to a superconducting metal in $T_{La_2Cu_3O_4}$ at $x = 0.00$ is solely associated to the coordination of Cu.

1:03PM T25.00008 Prediction of Superconductivity in Potassium-Doped Benzene, HAI-QING LIN, Beijing Computational Science Research Center, GUOHUA ZHONG, Center for Photovoltaics and Solar Energy, Shenzhen Institutes of, CHRISTOPHER TIMMS, Univ of Texas - Dallas, ALAN G. MACDIARMID NANOTECH INSTITUTE AT THE UNIVERSITY OF TEXAS AT DALLAS TEAM — To explore underline mechanism for the superconducting phase in recent discovered aromatic hydrocarbons, we carry out the first-principles calculations on benzene, the basic and the simplest unit of the series and examine the structural and phase stability when doped by potassium, K$_2$C$_6$H$_6$, $x = 1.25$. We found that K$_2$C$_6$H$_6$ with the space group of $Pbca$ is the most stable phase with superconducting transition temperature $T_c$ around 6.2K. Moreover, we argue that all existing hydrocarbons should have superconducting phase in the same range, 5K < $T_c$ < 7K, when doped by potassium atoms.

1:27PM T25.00010 Detection of pairing in a new high-$T_c$ system: Density of states in nanoclusters, AVIK HALDER, VITALY KRESIN, University of Southern California — A unique property of metal nanocluster particles is the “superatom”-like shell structure of the delocalized electrons. The electronic shell levels are highly degenerate, i.e., present sharp peaks in the density of states, which can enable exceptionally strong electron pairing in certain clusters composed of just tens of hundreds of atoms. This offers the potential of using them as blocking layers in high-$T_c$ materials. But how can one verify the onset of a superconducting transition in a free nanocluster? To answer this question we demonstrate the production of an intense flux of size-resolved nanoclusters with an adjustable internal temperature, and show that an accurate spectroscopic measurement of their photoelectron yield curves reveals the density of states near the Fermi level and strong changes which can occur upon reaching $T_c$. This has enabled our observation of a new family of high-temperature superconductors.

1Research supported by NSF . DMR-1206334
1:39PM T25.00011 High-Tc superconducting state of metal nanoclusters: Experimental observation

VITALY KRESIN, AVIK HALDER, University of Southern California — A spectroscopic investigation of size-resolved aluminum nanoclusters, Aln, has revealed a novel phenomenon: a rapid rise in the near-threshold density of states of several specific clusters with decreasing temperature. The effect is especially prominent in the closed-shell “magic” cluster Al66. The characteristics of this behavior are fully consistent with a pairing transition, implying a high-temperature superconducting state with Tc >∼ 100 K. This value exceeds that of bulk aluminum by two orders of magnitude. This is the first experimental observation of high temperature superconductivity in nanocluster particles. Our results highlight the promise of metal nanoclusters as high-Tc building blocks for materials and networks.

11:15AM T26.00001 Attenuated second order Møller-Plesset perturbation theory: correcting finite basis set errors and infinite basis set inaccuracies
MATTHEW GOLDEY, Institute for Molecular Engineering, the University of Chicago, MARTIN HEAD-GORDON, Department of Chemistry, University of California, Berkeley — Second order Møller-Plesset perturbation theory (MP2) in finite basis sets describes several classes of noncovalent interactions poorly due to basis set superposition error (BSSE) and underlying inaccurate physics for dispersion interactions. Attenuation of the Coulomb operator provides a direct path toward improving MP2 for noncovalent interactions. In limited basis sets, we demonstrate improvements in accuracy for intermolecular interactions with a three to five-fold reduction in RMS errors. For a range of inter- and intramolecular test cases, attenuated MP2 even outperforms complete basis set estimates of MP2. Finite basis attenuated MP2 is useful for inter- and intramolecular interactions where higher cost approaches are intractable. Extending this approach, recent research pairs attenuated MP2 with long-range correction to describe potential energy landscapes, and further results for large systems with noncovalent interactions are shown.

11:27AM T26.00002 Vapor liquid equilibria of hydrofluorocarbons via first principles Monte Carlo simulations
NEERAJ RAJ, HIMANSHU GOEL, Mississippi State Univ — The Kohn-Sham density functional theory (DFT) is a popular approach to compute condensed phase properties. In Kohn-Sham DFT, the local or semi local density functionals do not capture van der Waals interactions accurately. An accurate description of van der Waals interactions is essential in determining thermodynamic properties of molecules. The development of fully non local van der Waals density functional adequately describe dispersion interactions. In this work, we present first principles Monte Carlo simulations to obtain vapor liquid coexistence curves for hydrofluorocarbons by using Becke-Lee-Yang-Parr (BLYP) functional, dispersion corrected functionals, and with rVV10 nonlocal van der Waals density functional.

11:39AM T26.00003 Optical spectra and quasiparticle energies of molecules using a local basis set
MATHIAS LJUNGBERG, PETER KOVAL, FRANCESCO FERRARI, Donostia International Physics Center, Paseo Manuel de Lardizabal, 4. E-20018 Donostia-San Sebastián, DIETRICH FOERSTER, CPMOH/LOMA, Université de Bordeaux 1, 351 Cours de la Liberation, 33405 Talence, France, DANIEL SÁNCHEZ-PORTAL, Donostia International Physics Center, Paseo Manuel de Lardizabal, 4. E-20018 Donostia-San Sebastián — The Bethe-Salpeter equation (BSE) is the state of the art for computing optical spectra for solids and molecular clusters. Here we present an implementation of BSE for clusters that scales asymptotically like O(N^3) with the number of atoms, achieved by exploiting the locality of the problem in the local basis set representation and by using the Haydock recursion method to compute the spectrum. Using a pseudo-Hermitian Lanczos algorithm we can go beyond the Tamm-Dancoff approximation within our iterative scheme. As a starting point for the BSE we compute quasiparticle energies with our low-scaling GW implementation [1], retaining the frequency dependence of all quantities and thus avoiding the plasmon-pole model or similar schemes. The initial wave functions are taken from a preceding SIESTA calculation. We discuss the influence of self-consistency on the quasiparticle energies [2] and its effect on the BSE spectra. We also investigate the satellite peaks that are present in the GW density of states. Computed GW/BSE spectra are shown for some organic molecules of medium size that are relevant for photovoltaic applications.

11:51AM T26.00004 Computational XPS from Koopmans compliant Functionals
NICOLAS POILVERT, NATHAN KEILBART, ISMAILA DABO, The Pennsylvania State University — X-Ray Photo-emission Spectroscopy (XPS) is one of the most accurate experimental probe when it comes to deciphering the chemical composition of materials like Transition-Metals and Transition-Metal Oxides. Because of the sensitivity of electron binding energies to the local chemistry surrounding an atom, XPS can also help identify atomic oxidation states. Nevertheless, the complexity of XPS signals makes it a challenging task to go from the spectra to a list of chemical species and their respective oxidation states. Electronic structure methods such as Density Functional Theory fall short when it comes to predicting electron binding energies because of large self-interaction errors. The recent introduction of Koopmans-compliant functionals[1] on the other hand has led to the conclusion that UPS spectra can be accurately predicted at the level of Many-Body Perturbation Theory and beyond, while retaining most of the conceptual and computational simplicity of DFT. In this talk, we will more particularly focus our attention on assessing the accuracy of predicted Transition-Metal XPS spectra.

12:03PM T26.00005 Computational studies of the acid catalysts and solvent effects on Diels-Alder cycloaddition and dehydration reactions: Maleic anhydride and 2,5 dimethylfuran, TAHA SALAVATI-FARD, STAVROS CARATZOULAS, DOUGLAS DOREN, University of Delaware — Using DFT calculations, we present a detailed gas-phase mechanism for the conversion of DMF and maleic anhydride to 3,6 dimethyl phthalic anhydride. The conversion includes Diels-Alder cycloaddition followed by dehydration of cycloadduct. In addition, we consider the effects of solvent by making use of the PCM. We provide free energies of uncatalyzed, Lewis acid and Brønsted acid catalyzed reactions in vacuum and in a broad range of solvents. Our calculations show that a Lewis acid catalyzes the reaction through decreasing HOMO-LUMO gap of the addends. Also, a Brønsted acid changes the mechanism of reaction and is able to lower the activation free energy of cycloaddition, effectively. Furthermore, we show that as Lewis acids lower the activation barrier of dehydration reaction which is originally too high, a Brønsted acid changes the mechanism and is extremely effective in catalyzing the dehydration. Also, increasing dielectric constant of solvent decreases the activation barrier of uncatalyzed and Lewis acid catalyzed Diels-Alder reaction. For both the Lewis and Brønsted acid catalyzed Diels-Alder reaction, the dependency of activation free energy to increasing dielectric constant is much stronger when the acid is coordinated to DMF.

12:15PM T26.00006 First-principles Study of the Removal of Boron by Co-precipitation with Hydroxyapatite Using Dolomite as a Starting Material, CHENYANG LI, LAZARO CALDERIN, Pennsylvania State University, KEIKO SASAKI, Kyushu University, ISMAILA DABO, Pennsylvania State University, PENNSYLVANIA STATE UNIVERSITY COLLABORATION, KYUSHU UNIVERSITY COLLABORATION — Boron is a toxic chemical in drinking water and a major health concern worldwide. One method to reduce boron concentration in water consists of co-precipitating boron with hydrated minerals. Nevertheless, little is known about the chemical mechanisms underlying boron reactions with complex minerals. In this work, we have applied first-principles calculations based on density-functional theory (DFT) to characterize boron-bearing hydroxyapatite (HAp) resulting from co-precipitation with hydrated dolomite. DFT calculations have been performed to interpret X-ray diffraction (XRD) and nuclear magnetic resonance (NMR) experiments and to characterize solid residues after boron removal with a focus on determining the absorption sites of B(OH)₃ and B(OH)₄ in the formed minerals. The computed results indicate that the absorption takes place at phosphate (PO₄)3 sites. In addition, changes in the lattice parameters of the co-precipitate of HAp as a function of boron concentration have been calculated and compared with experimental results. Good agreement of the decreasing trend in a-direction and the increasing trend in c-direction has been observed by our calculations. Raman and infrared (IR) spectra have been studied as well to achieve a better understanding the B-HAp structures.

12:27PM T26.00007 Effective Many-Body Interactions in Dipolar Fluids and their Effect on Structure: Can the Dipole-Dipole Interaction be Modelled as a Short-Ranged 3-Body Interaction?, JULIEN SINDT, PHILIP CAMP, University of Edinburgh — In the 1970s, Stell et al. showed that it is possible to map the partition function of a system of particles interacting via anisotropic dipolar pairwise interactions to that of a hypothetical system with isotropic many-body interactions. It follows that “polar and nonpolar fluids have the same critical exponents” irrespective of long-ranged Coulombic interactions. We have calculated the structural properties of a system of soft spheres with the leading-order 2- and 3-body terms of the isotropic many-body potential. We have compared radial distribution functions and structure factors obtained from molecular dynamics simulations of dipolar soft spheres (DSSs) under the same physical conditions. We find that the many-body potential overemphasises chaining when compared to the equivalent DSS system. The chain-inducing component is the three-body Axilrod-Teller potential, and by adjusting its contribution, it is possible to match the structure with that of the DSS fluid, showing that the many-body potential can be used as a proxy for the dipolar potential. We conclude by studying the gas-liquid phase transition, finding that the phase transition disappears beyond a threshold degree of chaining.

12:39PM T26.00008 A new lattice Monte-Carlo simulation for the dielectric inhomogeneity of ion-containing liquids, XIAOZHENG DUAN, ISSEI NAKAMURA, State Key Laboratory of Polymer Physics and Chemistry, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences — We develop a novel lattice Monte-Carlo method to capture the effects of the reorientation of solvent dipoles under external electrostatic fields. Our simulation accounts for the effects of saturated dipoles near ions on the angstrom scale and hence spatial variations in the dielectric function. We will discuss the substantial disparity in the dielectric functions between like and unlike charges. Importantly, a contacting cation-anion pair cannot be literally taken as “charge-neutral species” in terms of the solvation energy. On the other hand, even when the two charges are separated by 1 nm, a significant correlation in the dielectric function may arise. Our simulation also provides the dependence of the bulk dielectric value on the ionic strength, which is consistent with experimental data.

12:51PM T26.00009 Energy levels of a particle confined in an ellipsoidal potential well, ROMAN KEZERASHVILII, New York City College of Technology, CUNY, USA, TAMAZ KERESELIDZE, TAMAR TCHELIDZE, Tbilisi State University, Georgia — The Schrodinger equation is solved for a particle confined within the ellipsoidal potential well using the perturbation theory and the Hamiltonian diagonalization method. The explicit expressions are obtained for the energy levels that are size and shape dependent and appropriate wave functions. The calculated energy levels are in a good qualitative and quantitative agreement with the result obtained by numerical solution of the Schrodinger equation. It is revealed that for the lowest states of a given symmetry the region of validity of the perturbation approximation is much larger than it follows from the usual condition of applicability of the perturbation theory. The optical properties of nanoparticles of a prolate and oblate ellipsoidal shape are discussed.

1:03PM T26.00010 Potential and kinetic energetic analysis of phonon modes in varied molecular solids, BRENT KRACZEK, US Army Research Laboratory — We calculate partitioned kinetic and potential energies of the phonon modes in molecular solids to illuminate the dynamical behavior of the constituent molecules. This enables analysis of the relationship between the characteristics of sets of phonon modes, molecular structure and chemical reactivity by partitioning the kinetic energy into the translational, rotational and vibrational motions of groups of atoms (including molecules), and the potential energy into the energy contained within interatomic interactions[1]. We consider three solids of differing size and rigidity: naphthalene (C₁₀H₈), nitromethane (CH₃NO₂) and α-HMX (C₇H₆N₃O₉). Naphthalene and nitromethane mostly act in the semi-rigid manner often expected in molecular solids. HMX exhibits behavior that is significantly less-rigid. While there are definite correlations between the kinetic and potential energetic analyses, there are also differences, particularly in the excitation of chemical bonds by low-frequency lattice modes. This suggests that in many cases computational and experimental methods depend on atomic displacements may not identify phonon modes active in chemical reactivity. 1. Kraczek, Chung, J. Chem. Phys. 138:074505 (2013).
1:15PM T26.00011 Switching mechanisms and role of entropy in chemically controlled hydrazone-based switches. RENE DERIAN, IVAN STICH, Inst. of Physics, Slovak Academy of Sciences — Chemically controlled synthetic rotary switches are important as they resemble rotary motors found in nature. In order to elucidate the recent experiments [1], using hybrid QM/MM methods we have studied chemically controlled hydrazone-based switches in a strongly polar solvent. The experiments indicate a controlled E→Z+H switching by addition of acid and thermal backward isomerization. We have studied the Z→E switching mechanisms and the role of entropy. We find use of explicit MM solvent crucial for understanding the huge dipole moments (>10D) in the Z conformation and significantly smaller (∼5D) in the E conformation and at the transition state, pointing toward very different ordering in those states. Furthermore, the internal and free energy surfaces from thermodynamic integration are qualitatively very different with the free energy surface exhibiting much smaller energy differences between E and Z. In addition, the solvent causes a pronounced shift (∼30°) in the position of the Z states from internal and free energies. Both finding highlight the role of the entropy in the switching process and help a quantitative understanding of the switching in the solvent.

1:27PM T26.00012 Determination of the Torsional Potential Energy Surfaces of the Ortho-, Meta- and Para-Isomers of Dinitrobenzene. PAUL SMITH, MARIO BORUNDA, Oklahoma State Univ — The three unique isomers of dinitrobenzene, the ortho-, meta-, and para-isomers, have widely varying steric hindrances and bond hybridizations. The steric effects and the hybridized bonds cause the molecular energy to be dependent on the rotation of the nitro groups. We have calculated the torsional potential energy surfaces of each of the three dinitrobenzene isomers using density functional theory, obtaining a 33x33 plot of the energy of each molecule as a function of the torsional angles of the C-N bonds. The accuracy of the method used is determined by comparison with previous theoretical and experimental results. The potential energy surfaces provide valuable insight into the mechanics of conjugated molecules, and the method we present can be extended even to proteins, which have very complicated conformations and many conjugated bonds. This method makes the determination of the lowest energy conformations of complex molecules far more computationally accessible.

1:39PM T26.00013 Density Functional Plus Dynamical Mean Field Study of Spin Crossover Molecule. JIA CHEN, Departemtn of Applied Physics and Applied Math, Columbia University, ANDREW MILLIS, Departmentn of Physics, Columbia University, CHRIS MARIANETTI, Departmentn of Applied Physics and Applied Math, Columbia University — We report a density functional plus dynamical mean field study of spin crossover molecule Fe(phen)2(NCS)2. The temperature dependent magnetic susceptibility, Fe-d spectral and total energy were calculated and compared with experimental magnetization, metal L-edge x-ray adsorption spectroscopy. The importance of dynamic effect on energetics is demonstrated by comparison with density functional plus U method, and the role of full charge self-consistency is identified. Moreover, the local spin density plus U (LSDA+U) method with exchange interaction explicitly included is shown to dramatically overemphasize magnetic interaction.

2:03PM T26.00015 Machine learning of single molecule free energy surfaces and the impact of chemistry and environment upon structure and dynamics. RACHAEL MANSBACH, ANDREW FERGUSON, Univ of Illinois - Urbana — The conformational states explored by proteins and polymers can be controlled by environmental conditions (e.g., temperature, pressure, solvent) or molecular chemistry (e.g., chain length, side chains). It is of fundamental interest to quantify the impact upon molecular structure and function, and a prerequisite to the rational engineering of proteins and polymers with desired properties. Using the diffusion map nonlinear manifold learning algorithm, we have developed an approach to: (i) extract from molecular simulations the single molecule free energy surface governing the microscopic molecular behavior, (ii) quantify changes in its topography as a function of environmental conditions and molecular chemistry, and (iii) relate these perturbations to changes in molecular structure and dynamics. In a first application to an n-icosane chain, we have quantified the thermally accessible chain configurations as a function of temperature and solvent conditions. In a second application to a family of polyglutamate-derivative decameric homopeptides, we quantify the stability of the helical state relative to the random coil as a function of side chain length and expose the molecular mechanism underpinning side chain-mediated helix stability.

Thursday, March 5, 2015 11:15AM - 2:15PM
Session T27 DCP: Focus Session: Solvation of Ions and Electrons III 204B - Etienne Garand, University of Wisconsin, Madison

11:15AM T27.00001 Solvation and Organization of Ions at the Air-Water Interface. HEATHER ALLEN, Ohio State University — The air-water interface has been the focus of research in the Allen Lab at Ohio State for more than a decade. We utilize nonlinear and linear optical spectroscopic methods to understand the local intermolecular interactions and organization of water itself with various solutes and monolayers. Motivated by atmospheric aerosol chemistry of marine and urban regions, and biophysical applications related to lung lining and biomembranes, monovalent and divalent cations and anions continue to be investigated by our group using conventional and heterodyne-detection vibrational sum frequency generation (VSFG) spectroscopy. Interest is in the surface propensity and availability for reaction at water surfaces. Ion valency, polarizability, size, shape, and identity of the counterion are critical factors in considering ion organization and subsequent changes in interfacial electric field at the air-water interface. The hydrating water molecules play a key role in the interfacial organization of other species in the solution, and is studied directly as it reveals the details of ion interfacial distributions. Phospholipids and fatty acids are also investigated using both VSFG and Brewster angle microscopy (BAM). Head group differences, especially with regard to hydrogen bonding capability and extent, are discerning factors for surface organization and shape distinction at the water surface.

In collaboration with Wei Hua and Dominique Verreault, Ohio State University.
11:51 AM T27.00002 Sensitivity of ultrafast vibrational dynamics of interfacial water to cations at silica/water interfaces, SHALAKA DEWAN, AASHISH TULADHAR, ERIC BORGUET, Temple Univ — Interfacial water structure is a key player in the chemistry of environmentally relevant processes, e.g., the dissolution of mineral surfaces. Since the properties of water are dominated by its hydrogen-bonding network, understanding the local changes in this structure at the mineral/water interface is important. Vibrational sum-frequency generation (vSFG) spectroscopy is a tool that can probe the hydrogen bonding environment at buried interfaces. Time-resolved vSFG of the OH stretch is further sensitive to the changes in hydrogen bonding at surfaces. vSFG has demonstrated that interfacial water structure at silica is most sensitive to cations at near water pH 6-8. Further, at this pH, increasing the ionic strength slows the vibrational relaxation of O-H stretch of water from ~200 to ~600 fs. Here, we show that the slowing down of O-H dynamics on addition of cations is more pronounced at pH 6 than at pH 12, even though the surface is negatively charged in both cases. This suggests that, in addition to the ion screening the surface charge, the cations actually change the local H-bonding environment of water differently at distinct bulk pH. Our results shed light on the ongoing debate on the role of ions in altering the structure of water at an interface.

12:03 PM T27.00003 Vibrational Spectroscopy of Hydrated MOH Clusters, BRETT MARSH, JONATHAN VOSS, JIA ZHOU, ETIENNE GARAND, Univ of Wisconsin, Madison — Hydrated metal ions have importance in a number of fields of chemistry including environmental chemistry, biochemical chemistry, and catalysis. Although the aqua complexes of transition metals are well studied there is a dearth of information on hydroxide containing metal clusters which have been implicated in catalytic mechanisms of water oxidation. In this work we use cryogenic ion vibrational spectroscopy (CIVS) to interrogate clusters of the form MOH(H2O)n (M = Fe, Co, Ni, Cu, Zn) in the hydride stretching region (2400-3800 cm⁻¹). Comparison of the spectral data to density functional theory calculations allows for unambiguous assignment of the observed spectral features. The resulting spectra show both a metal dependent and size dependent shift of the hydroxide stretching frequency in all clusters. The spectra also reveal that the first solvation shells of Fe, Co, Cu, and Zn containing clusters are composed of 4 ligands while the first solvation shell in Ni clusters is at least 6 ligands. This is markedly different from previous work on Ni(H2O)6+, Cu(H2O)4+, and Zn(H2O)6+ cluster in which the first solvation shells are 4 ligands, 2 ligands, and 3 ligands respectively. Aspects of hydration in the second solvation shell of these clusters will also be discussed.

12:15 PM T27.00004 Exploring Specific Ion Effects on Ion Hydration at Aqueous Interfaces, PAUL CREMER, Penn State University — We used sum frequency generation vibrational spectroscopy to probe the interactions of ions with self-assembled monolayers and proteins at aqueous interfaces. I will discuss the behavior of cations and anions as they relate to the Hofmeister series, which is a rank ordering of the efficacy of these species to influence the physical behavior of colloidal and interfacial systems in solution. Ion specific effects at these interfaces were found to be determined by several factors. These include the sign and magnitude of the surface potential, ion pairing effects in the double layer, as well as the presence of polar and nonpolar interfacial moieties. At negatively charged, hydrophilic surfaces, we found that Na⁺ adsorption and double layer formation were modulated by the type of the counterion in solution. The same ordering was observed for the anions whether this interface was relatively hydrophilic or hydrophobic. Changing the sign of the charge at the interface also led to a similar Hofmeister ordering. Moreover, at negatively charged hydrophilic surfaces, the smallest and best hydrated cations were mostly favored over more poorly hydrated cations. By contrast, well hydrated cations were expelled from more apolar surfaces.

12:15PM T27.00005 Structural properties of simple aqueous solutions from ab initio simulations, ALEX P. GAIDUK, Institute for Molecular Engineering, University of Chicago, FRANCOIS GYGI, Department of Computer Science, University of California, Davis, GIULIA GALLI, Department of Molecular Engineering, University of Chicago — Although water and salt solutions have been studied for many decades, several aspects of their microscopic and electronic properties remain uncertain. One of the open questions is whether simple ions have long-range effects on the structure of liquid water. We performed extensive first-principles molecular dynamics simulations [1] of solutions of a simple salt (NaCl) and found that what Na⁺ does not significantly change the structure of water beyond the first solvation shell. This has far reaching hydrogen-bond-breaking effect. We present an analysis of the structural modifications in terms of molecular polarizabilities and dipole angular correlations. Our results are in agreement with the traditional classification of Cl⁻ as a structure-breaker, but at variance with several theoretical and experimental studies which did not observe significant modifications of the structure of water outside the first solvation shell of ions [2]. We also present an analysis of the electronic properties of the solutions [3].

1:03PM T27.00006 Ultrafast vibrational spectroscopy (2D-IR) of anions in ionic liquids, SEAN GARRETT-ROE, University of Pittsburgh — Ionic liquids hold promise for applications in energy storage as the electrolyte in electric double-layer capacitors and other devices. Further optimizing device performance through their physical and chemical properties requires an improved understanding of the detailed interactions between cation and anion and how they reorganize in the presence of charge. Here we probe the dynamics of thiocyanate ions in several bulk imidazolium bis(trifluoromethylsulfonyl)amide ionic liquids from femtoseconds to 100 ps using ultrafast vibrational spectroscopy. Two-dimensional infrared (2D-IR) spectroscopy of thiocyanate ions detect both inertial motion (on the hundreds of femtosecond timescales) as well as slower, diffusive motions (on the tens of picosecond timescales). The 2D-IR experiments show that the rate of fluctuation of the electrostatic environment around the thiocyanate is sensitive to hydrogen bonding at the 2-position of the imidazolium ring. The correspondence of time-scales with molecular dynamics simulations suggests that the slowest motions we observe are fluctuations around a local free-energy minimum while the faster timescales correspond to the rearrangement of those local intermolecular arrangements. Our measurements implicate the break-up of local ion cages as the activating event for the onset of translational motions which are responsible for viscosity and conductivity. We additionally test our hypothesis that the SCN anion is sensitive to the local environment by introducing co-solutes - counter-cations such as K⁺ and water. We observe contact-ion pairs, i.e., SCN- anions with a K⁺ counter charge in the first solvation shell through a static component in the frequency correlation function. We observe water-bound SCN- through changes in linewidth, population relaxation rates, and dynamics. The SCN- is an eloquent reporter of local structure and dynamics in these complex fluids.

1:39PM T27.00007 Structural dynamics of solvated OH⁻ and H₃O⁺ in liquid water: an ab initio molecular dynamics study using PBE0 hybrid functional with van der Waals’ interaction, LIXIN ZHENG, XIFAN WU, Temple Univ — The nature of solvation structure of hydroxide (OH⁻) and hydronium (H₃O⁺) solvated in liquid water is of fundamental interest, as it is the prerequisite to understand the autoprotolysis process, which is often a crucial step in chemical and biological activities. It has been revealed that the proton transfer (PT) process, especially in hydroxide case, is of great controversy and complexity compared to traditional textbook description. One major source of inaccuracy originates from the delocalization error and lack of dispersion force in the conventional adopted electron exchange correlation function in GGA functional leading to an over-structured H-bond (HB) structure. Now with state-of-the-art PBE0 hybrid density functional, and the inclusion of long-range van der Waals dispersion force, we are able to perform ab initio molecular dynamics with higher accuracy. Through the analysis of mean square displacement of ion, HB geometrical distribution and lifetime, and the strength change of HB, we are presenting a quantitatively accurate picture of proton transfer structural mechanism.

---

Work supported by DOE BES DE-SC0008938. Computer time provided by the Argonne Leadership Computing Facility through the INCITE program.
1:51PM T27.00008 Solvation of a Ruthenium Water Oxidation Catalyst, [Ru(tpy)(bpy)(H₂O)]²⁺. ERIN DUFFY, BRETT MARSH, JONATHAN VOSS, ETIENNE GARAND, University of Wisconsin-Madison — The splitting of H₂O into H₂ and O₂ is an important reaction for alternative energy sources, but it is hindered by the water oxidation step due to its unfavorable thermodynamics. Production of a suitable water oxidation catalyst (WOC) has posed a challenge to researchers for decades, and the reaction mechanism is not well understood. One of the most well-known and extensively studied WOCs is [Ru(tpy)(bpy)(H₂O)]²⁺ (tpy = 2,2'-bipyridine and bpy = 2,2'-bipyridine) and its derivatives. In this talk, infrared spectral data (2400-3800 cm⁻¹) obtained by Cryogenic Ion Vibrational Spectroscopy (CIVS) of [Ru(tpy)(bpy)(H₂O)]²⁺ and its water clusters, [Ru(tpy)(bpy)(H₂O)]²⁺·nH₂O, are presented. In particular, the OH stretches are used as a probe of solvation strength, and trends in their spectral shifts are examined as a function of cluster size. Determination of water binding geometries are facilitated with comparison with density functional theory (DFT) calculations. Additionally, IR and mass spectral data of electrochemically-produced intermediates of the water oxidation cycle are shown, which provide evidence of proton-coupled electron transfer (PCET) events, in agreement with proposed mechanisms.

2:03PM T27.00009 Ion Induced Hydrophilicity at Hexane Vapor Water Interface. SHANSHAN YANG, YUDAN SU, CHUANSHAN TIAN, Fudan University, STATE KEY LABORATORY OF SURFACE PHYSICS, DEPARTMENT OF PHYSICS, FUDAN UNIVERSITY TEAM — How ions occupy themselves at hydrophobic interface plays a key role in physical, chemical, atmospheric, and biological processes. However, hydrophobic molecules often gather together on water surface, thus few experiment taking on the adsorption of hydrophobic molecules on aqueous solutions from vapor phase. In this work, we report unexpected mutually promoted adsorption of hydrophobic molecules and ions through unification of contact angle method and sum frequency vibrational spectroscopy (SFVS). We observe oil tends to spread on solutions with higher pH, implying interaction exists between hydrophobic molecules and ions. SFVS suggests that this phenomenon stems from relatively strong Coulomb interaction between hydrophobic molecule and hydroxide ions, the initial hydroxide ion adsorption free energy is calculated. The surface charge density induced at the interface is plotted to show the variation of surface charge density with both hydroxide ion molar fraction and hexane vapor pressure. In addition, we propose a new perspective on explanation of intensity decay of icelike band at high pH (>10) aqueous solution, hydrophobic interfaces, in which the relative relation between Debye length and coherence length plays an essential role.

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T28 GMAG DMP FIAP: Focus Session: Spin-Hall Effect II

11:15AM T28.00001 Spin Hall Effect in Spin Glass Systems, YASUHIRO NIIMI, Univ of Tokyo-Kashiwanaga — The spin Hall effect (SHE) and its inverse play important roles in spintronics devices as they enable interconversions between charge and spin currents. The conversion efficiency, i.e., the spin Hall angle, strongly depends on detailed material properties, such as the electronic band structure and the nature of impurities. While most of the work has focused on the mechanism of the SHE and the magnitude of the spin Hall angle, there are only a few examples to utilize the SHE such as current generated by the SHE is much more sensitive to magnetization measurements.

11:51AM T28.00002 Scaling of the Anomalous Hall Effect in the Low Conductivity Regime³. FRANCES HELLMAN, UC Berkeley Physics Department, JULIE KAREL², UC Berkeley Materials Science and Engineering Department, CATHERINE BORDEL, SIMCA BOUMA, HYEON-JUN LEE, UC Berkeley Physics Department, MATERIALS SCIENCE DIVISION, LAWRENCE BERKELEY NATIONAL LAB TEAM — Temperature-dependent resistivity, magnetization, magnetoresistance and Hall effect were measured in amorphous and epitaxial Fe₇₀Si₃₀ thin films. The resistivity increases as x is decreased, and changes in the temperature coefficient of resistivity (α) are observed with variation in both structure and composition. All films are ferromagnetic and display an anomalous Hall effect (AHE). AHE of the amorphous films is 10 times larger than crystalline films of the same composition. The epitaxial films display a scaling behavior consistent with the intrinsic AHE mechanism. The AHE in the low conductivity regime (amorphous films) shows a scaling with conductivity similar to that seen in low conductivity GaMnAs films despite much larger disorder and carrier concentration in the amorphous films. Amorphous FeₓSi₁₋ₓ in this range of x however is notably not in the insulating hopping regime but is instead a strongly disordered metal, a regime that lacks theoretical understanding of AHE.

12:03PM T28.00003 Anomalous Hall effect and persistent current due to spin chirality in a diffusive regime. KAZUKI NAKAZAWA, HIROSHI KOHNO, Department of Physics, Nagoya University, CONDENSED-MATTER THEORY TEAM — It is known that a non-coplanar spin configuration having spin chirality gives a Berry phase to electrons through the exchange interaction, leading to anomalous Hall effect (AHE). Tatara and Kawamura showed that AHE can result without the concept of Berry phase by treating the exchange coupling perturbatively in a model with discretely distributed spins [1]. Recently, we reexamined the AHE in the same model by considering vertex corrections due to normal impurities [2]. This amounts to electron’s diffusive motion and spin conservation at the scattering from normal impurities, and leads to the expression of AHE conductivity which satisfies spin conservation. We also investigated a persistent current around the spin chirality as a physical origin of the AHE response, and we found that the “typical” value of the persistent current reproduces the AHE conductivity in the diffusive regime.

12:15PM T28.00004 Planar Hall effect (PHE), anisotropy magnetoresistance (AMR), and anomalous Hall effect (AHE) in perpendicularly magnetized synthetic ferromagnets, SEE-HUN YANG, IBM Almaden Research Center, PRISCILA BARBA, AURELIEN MANCHON, KAUST, STUART PARKIN, IBM Almaden Research Center — Chiral spin torque driven domain wall motion (CIDW/M) faster than 300 m/s along the current direction has been reported in perpendicularly magnetized atomically thin Co/Ni bilayers deposited on Pt underlayers [1], making these materials promising for DW-based memory and logic devices. Moreover, most recently even more efficiently domain motion (~ 750 m/s) has been observed from synthetic antiferromagnetic (SAF) racetracks with almost compensated magnetization [2]. In this talk we will present Hall measurement results from SAF Hall bars that exhibit characteristic planar Hall effect and anomalous Hall effect. We discuss the origin of these behaviors.

12:27PM T28.00005 Phase-Sensitive Detection Of The AC Inverse Spin Hall Effect, MATHIAS WEILER, National Institute of Standards and Technology — Spin pumping [1] is a significant source of damping in ultrathin ferromagnet/normal metal bilayers. In these structures, the magnetization relaxation is enhanced via the diffusion of spin currents across the bilayer interface. The pumped spin currents have both a small dc and dominant ac contributions. The nonlinear dc spin current contribution that arises in ferromagnetic resonance (FMR) has been extensively studied in electrical dc measurements that are enabled by means of the inverse spin Hall effect (ISHE) in the normal metal [2]. The ac charge voltage generated in FMR due to the ac ISHE should be linear in the magnetization precession and thus much larger than the corresponding dc voltage for small precession cone angles [3]. However, any measurement of the ac iSHE voltage needs to take the linear inductive voltages due to Faraday’s law into account, as magnetization dynamics in ferromagnet/normal metal bilayers result in both, inductive and possible ac iSHE voltages. These voltage signals are always superimposed and cannot be separated in a measurement scheme that is only sensitive to the magnitude of the signal [4-7]. Moreover, inductive and ac ISHE voltages are estimated to be of the same order of magnitude for typical nm-thick ferromagnetic layers in contact with Pt and share identical symmetry with respect to magnetization orientation. The only qualitative difference between inductive and ac ISHE voltages is their expected phase difference of π/2. We thus use a phase-sensitive, quantitative technique to separate inductive and ac ISHE signals in a variety of Ni$_81$Fe$_{19}$/normal metal thin film bilayers at room temperature. All samples show the expected behavior in terms of damping and dc iSHE voltages from which we find a dc spin Hall angle Θ$_{SH}$=0.1 for Pt [8]. Our ac iSHE experiments [9] are carried out using Ni$_81$Fe$_{19}$/normal metal bilayers deposited simultaneously with the dc structures. Using Ta, W, Pd, Cu or Nb as the normal metal, we find that the inductive contribution dominates over any ac iSHE signal, in agreement with simple estimates based on the extracted dc spin Hall angles for these materials. However, for Pt, we find a surprisingly large ac iSHE contribution that has a significantly different phase than expected. Similar results are also found in Ni$_81$Fe$_{19}$/Cu/Pt trilayers, excluding the possibility of an interfacial origin of the large ac iSHE signal. Modeling of our experimental results in the context of the ac iSHE requires a complex-valued spin Hall angle Ψ$_{SH}$ of Pt with Θ$_{SH}$≈ 1 and arg (Θ$_{SH}$)≈ 110° in the investigated frequency range of 7 to 20 GHz.

1:03PM T28.00006 Skew-scattering contribution to anomalous and spin Hall effects in dilute ferromagnetic alloys, BERND ZIMMERMANN, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — The spin Hall effect (SHE) possesses great potential for the generation of pure spin currents, but it is difficult to measure directly. The closely related anomalous Hall effect (AHE) is much easier to access in experiment via a finite Hall voltage. Phenomenologically, the only difference between the two effects is the ferromagnetic order needed for the AHE. In this work [1], we investigate the skew-scattering contribution to the AHE in dilute ferromagnetic alloys from first principles. We compare three state-of-the-art methods and analyze chemical trends by considering 3d impurities in bcc-Fe, as well as magnetic 3d impurities in fcc Pd, Pt and Au. We arrive at general rules to obtain a large anomalous Hall angle, which represents an efficiency for the conversion of a longitudinal into a transverse current. Moreover, we reveal a clear correlation between the AHE and SHE in the alloy s which are based on a nonmagnetic host material.

1:15PM T28.00007 Epitaxial IrMn3 on MgO(111) by sputter deposition, ALEJANDRO JARA, IGOR BARSUKOV, YU-JIN CHEN, BRIAN YOUNGBLOOD, Univ of California - Irvine, JOHN READ, PATRICK BRAGANCA, HGST, San Jose CA, USA, ILYA KRIVOROTOV, Univ of California - Irvine — Antiferromagnets are promising systems for spintronic applications due to the absence of stray fields and high spin wave group velocity. Coupling between the charge and spin degrees of freedom in metallic antiferromagnets is a topic of high interest. The chemically ordered compensated antiferromagnet IrMn3 has recently been predicted to show anomalous Hall effect (AHE) arising from its noncollinear spin configuration. The AHE would provide a unique opportunity to probe the order parameter of an antiferromagnet via direct electrical measurements, which should be of tremendous utility for antiferromagnetic spintronics. To quantify and further exploit AHE, IrMn3 must be grown in the L12 phase, which supports ordering of the Mn spins on stacked sheets of Kagome spin lattices. Here we present an experimental study of IrMn3 thin films grown on MgO(111) by sputter deposition. We carry out XRD measurements and identify two quasi-epitaxial phases rotated by 60 deg to each other in the film plane. The IrMn3 is strongly (111)-textured with the (111) axis deviating by less than 2 degrees from the film normal due to oblique deposition of the material. The grain size in our films is determined to be 15 nm, while the dimensionless chemical order parameter of the L12 phase is found to be 0.4.

1:27PM T28.00008 Spin Hall effects in CuAu-I-type metallic antiferromagnets, WEI ZHANG, BENJAMIN JUNGFLEISCH, WANJUN JIANG, JOHN PEARSON, AXEL HOFFMANN, Argonne National Laboratory, FRANK FREimuth, YURIY MOKROUSOV, Forschungszentrum Jülich — We investigated the spin Hall effect of CuAu-I-type metallic antiferromagnets by using spin pumping — inverse spin Hall effect via a coplanar waveguide ferromagnetic resonance broadband technique. By studying the ratio of the two voltage components (anisotropic magnetoresistance and inverse spin Hall effect) with the metal layer thickness, the spin diffusion lengths of the materials are directly extracted, which further allows the determination of the spin Hall angle. We performed such analysis for polycrystalline FeMn, PdMn, IrMn, and PtMn. In particular, PtMn showed large spin Hall effect that is comparable to Pt. First principle calculations of the intrinsic spin Hall effect reproduce these results. We also demonstrate the epitaxial growth of these metallic crystals and its influence to the spin Hall effects due to different crystalline orientation. This work highlights the importance of both spin-orbit coupling and the magnetic ordering to the spin Hall effects of metals. W. Zhang, et al., Phys. Rev. Lett. 113, 196602 (2014)

1:39PM T28.00009 Probing the Inverse Spin Hall Effect and Spin-Orbit Coupling in a Broad Range of Transition Metals by $Y_3Fe_5O_{12}$-Based Spin Pumping. HAILONG WANG, CHUNHUI DU, P. CHRIS HAMMEL, FENGYOU YANG, The Ohio State University — Spin-orbit coupling (SOC) is the underlying mechanism for spin Hall physics and it is generally believed that SOC follows $Z^2$ (atomic number) dependence and becomes significant only in heavy elements. We report FMR spin pumping from 20-nm $Y_3Fe_5O_{12}$ (YIG) films into a series of 3d, 4d, and 5d transition metals. We observe surprising large mV-level inverse spin Hall effect (ISHE) voltages in Pt, Ta, W, and Cr and robust ISHE signals in other metals. Using the ISHE voltages and damping enhancement, we determine the spin Hall angles and interfacial spin mixing conductances for these metals. Both 3d and 5d metals exhibit systematic behavior of the spin Hall angle, which reveals the critical role of $d$-electrons in SOC. Our result enriches the understanding of ISHE and broadens the scope of materials available for exploring the rich phenomena enabled by SOC as well as presenting a guidepost for testing theoretical models of SOC in transition metals.

1:51PM T28.00010 Inverse spin Hall effect in Cr metal. DANRU QU, Johns Hopkins University, SSU-YEN HUANG, National Taiwan University, CHIA-LING CHIEN, Johns Hopkins University — Spin Hall angle, which measures the conversion efficiency between spin current and charge current, is the most important quantity in spin current phenomena. Sizable spin Hall angles have thus far been reported exclusively in non-magnetic materials of heavy elements, such as Pt and Au, and recently in ferromagnetic metals, such as Py. In this work, we use the thermal spin injection method to inject a spin current from ferromagnetic insulator YIG into a 3d metal Cr, which is a well-known antiferromagnet (AF) with spin density ordering. We report the observation of inverse spin Hall effect (ISHE) in Cr with a large spin Hall angle, comparable to that of Ta. Through measurements above and below the Neél temperature of the AF ordering, we show that the origin of the large ISHE in Cr is not due to its spin density wave AF ordering. Moreover, there is no magnetic proximity effect that plagued Pt and Ta. These features show that Cr can be a superior spin current generator/detector in pure spin current phenomena and devices. [1] D. Qu, S. Y. Huang, B. F. Miao, S. X. Huang, and C. L. Chien, Phys. Rev. B 89, 140407(R) (2014). [2] B. F. Miao, S. Y. Huang, D. Qu and C. L. Chien, Phys. Rev. Lett. 111, 066602 (2013)

2:03PM T28.00011 Towards the terahertz frequency measurement of the Inverse Spin Hall Effect. EVAN V. JASPER, M. T. WARREN, T. T. MAI, J. BRANCHAM, H. WANG, J. GALLAGHER, F. YANG, R. VALDÉS AGUILAR, Center for Emergent Materials, Department of Physics. The Ohio State University. Columbus, OH 43210 — The Inverse Spin Hall Effect (ISHE) has become an important tool in the spintronics field as a promising route for generation and detection of spin currents via charge currents. In particular, when the magnetization of a ferromagnet is resonantly excited by a radio-frequency field, angular momentum can be transferred to a non-magnetic metal to produce a pure spin current (spin-pumping), and the ISHE provides a way to measure the generated spin current in the metal and extract essential spin pumping parameters. Very recently, theoretical predictions of spin pumping from an antiferromagnetic (AF) insulator to a normal metal have attracted significant interest. We will report results of experiments where terahertz pulses of electromagnetic radiation resonantly excite the AF resonance on the AF insulator NiO coupled with a thin film of Pt, and attempt to measure the ISHE voltage at terahertz frequencies.

Thursday, March 5, 2015 11:15AM - 2:15PM – Session T29 GMAG: Correlated Electron Magnetism II

11:15AM T29.00001 Onset of ferromagnetism in EuB$_6$. NICHOLAS BUTCH, NIST - Natl Inst of Stds & Tech, I-LIN LIU, XIAOHANG ZHANG, University of Maryland, College Park, KATHRYN KRYCKA, JEFFREY LYNN, DANIEL PARSHALL, WILLIAM RATCLIFF, YANG ZHAO, NIST - Natl Inst of Stds & Tech, PRISCILLA ROSA, ZACHARY FISK, UC Irvine — We assess the magnetic experimental signatures of precursor magnetic polarons and characterize the ferromagnetic ordering transition in EuB$_6$. The results of bulk magnetometry and neutron scattering measurements will be discussed.

11:27AM T29.00002 High-pressure magnetotransport measurements of the semimetallic ferromagnet EuB$_6$. DANIELLE SIMMONS, LIUQI YU, STEPHAN VON MOLNAR, PENG XIONG, Florida State University, JUN ZHU, CONG REN, Institute of Physics, Chinese Academy of Sciences, ZACHARY FISK, University of California, Irvine — Hall effect measurements on EuB$_6$ have revealed manifestations of the microscopic electronic phase separation and resulting percolative phase transition in a macroscopic magnetotransport property of this semimetallic ferromagnet: the Hall resistivity as a function of applied field in the paramagnetic phase exhibits two distinct linear regions with a transition point at a single critical magnetization in a broad temperature range, which was interpreted as the percolation point for the more conducting phase. To further understand this phenomenon, magnetotransport measurements were performed on EuB$_6$ under high pressure. Hydrostatic pressure is known to substantially modify the magnetic state of EuB$_6$. EuB$_6$ single crystals were inserted in a high-pressure cell filled with silicone oil and measurements were taken at different pressures up to 1.8 GPa. Increasing hydrostatic pressure caused a decrease in resistivity and an increase in $T_H$, while the ferromagnetic ordering temperature stayed approximately constant. The Hall resistivity in the paramagnetic phase developed an intermediate region between the two previously observed regions. The transition fields between the low-field and intermediate regions depend linearly on temperature and their intercepts increase with pressure similar to the variation of $T_H$ indicated by the resistivity peak. [1] X. H. Zhang et al, Phys. Rev. Lett. 103, 106602 (2009). [2] J.C. Cooley et al, Phys. Rev. B 56, 14541 (1997).

1:39AM T29.00003 Interplay of many-body and single-particle interactions in iridates and rhodates. YURIY SIZYUK, NATALIA PERKINS, Univ of Minn - Minneapolis, PETER WOLFLE, Institute for Condensed Matter Theory and Institute for Nanotechnology, Karlsruhe Institute of Technology — Motivated by recent experiments exploring the spin-orbit-coupled magnetism in 4d- and 5d-band transition metal oxides, we study magnetic interactions in Ir- and Rh-based compounds. In these systems, the comparable strength of spin-orbit coupling (SOC), crystal field splitting (CF) and Coulomb and Hund’s coupling leads to a rich variety of magnetic exchange interactions, leading to new types of ground states. Using a strong coupling approach, we derive effective low-energy super-exchange Hamiltonians from the multi-orbital Hubbard model by taking full account of the Coulomb and Hund’s interactions in the intermediate states. We find that in the presence of strong SOC and lattice distortions the super-exchange Hamiltonian contains various kinds of magnetic anisotropies. Here we are primarily interested in the magnetic properties of Sr$_2$IrO$_4$ and Sr$_2$Ir$_{1-x}$Rh$_x$O$_4$ compounds. We perform a systematic study of how magnetic interactions in these systems depend on the microscopic parameters and provide a thorough analysis of the resulting magnetic phase diagram. Comparison of our results with experimental data shows good agreement. [1] J.C. Cooley et al, Phys. Rev. B 56, 14541 (1997).
11:51AM T29.00004 Impact of spin-orbit coupling on the magnetism of Sr$_3$MIrO$_6$ (M = Ni, Co) , XUEDONG OU, HUA WU, Fudan University, LABORATORY FOR COMPUTATIONAL PHYSICAL SCIENCES TEAM — Recently, Iridates have recently drawn considerable attention due to their significant spin-orbit coupling (SOC) effect and possibly exotic properties [1]. In this work, we demonstrate, using density functional calculations, that the SOC of Ir$^{4+}$ ions plays an essential role in determining the antiferromagnetism of hexagonal spin-chain materials Sr$_3$MgIrO$_6$ (M=Ni, Co) by tuning the crystal-field level sequence and altering the Ir-M inter-orbital interactions. Owing to the SOC effect, the single t$_{2g}$ hole of the Ir$^{4+}$ ion resides on the e$_g$ upper branch and gives rise to the Ir$^{4+}$-M$^{2+}$ antiferromagnetic coupling. In absence of the SOC, however, the single t$_{2g}$ hole would occupy the crystal-field a$_{1g}$ singlet instead, which would mediate an unreal ferromagnetic exchange This work clarifies the nature and the origin of the intra-chain Ising antiferromagnetism of Sr$_3$MgIrO$_6$ (M = Ni, Co) [2].

12:03PM T29.00005 LDA+DMFT Approach to Magnetocrystalline Anisotropy of Strong Magnets , JIAN-XIN ZHU, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, MARC JANOSCHEK, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, RICHARD ROSENBERG, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, FILIP RONNING, J.D. THOMPSON, MICHAEL A. TORREZ, ERIC D. BAUER, CRISTIAN D. BATISTA, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — The new challenges posed by the need of finding strong rare-earth-free magnets demand methods that can predict magnetization and magnetocrystalline anisotropy energy (MAE). We argue that correlated electron effects, which are normally underestimated in band structure calculations, play a crucial role in the development of the orbital component of the magnetic moments. Because magnetic anisotropy arises from this orbital component, the ability to include correlation effects has profound consequences on our predictive power of the MAE of strong magnets. Here we show [1] that incorporating the local effects of electronic correlations with dynamical mean-field theory provides reliable estimates of the orbital moment, the mass enhancement and the MAE of YCo$_5$.

12:15PM T29.00006 Quantum Indian Rope Tricks: Fluctuation driven magnetic hard-axis ordering in metallic ferromagnets , FRANK KRUGER, CHRIS PEDDER, ANDREW GREEN, London Centre for Nanotechnology, UCL — We demonstrate that the interplay between soft electronic particle-hole fluctuations and magnetic anisotropies can drive ferromagnetic moments to point along a magnetic hard axis. As a proof of concept, we show this behavior explicitly for a generic two-band model with local Coulomb and Hund’s interactions, and a spin-orbit-induced easy plane anisotropy. The phase diagram is calculated within the fermionic quantum order-by-disorder approach, which is based on a self consistent free-energy expansion around a magnetically ordered state with unspecified orientation. Quantum fluctuations render the transition of the easy-plane ferromagnet first-order below a tricritical point. At even lower temperatures, directionally dependent transverse fluctuations dominate the magnetic anisotropy and the moments flip to lie along the magnetic hard axis. We discuss our findings in the context of recent experiments that show this unusual ordering along the magnetic hard direction.

12:27PM T29.00007 New mechanism of kinetic exchange interaction induced by strong magnetic anisotropy , NAOYA IWAHARA, LIVIU CHIBOTARU, Theory of Nanomaterials Group, Katholieke Universiteit Leuven — It is well known that the kinetic exchange interaction between single-occupied magnetic orbitals (s-s) is always antiferromagnetic, of the order $-t^2/U$, where $t$ is the transfer parameter and $U$ is the electron promotion energy. At the same time the exchange interaction between single- and double-occupied orbitals, s-d, is always ferromagnetic, of the order $t^2U/JU$, where $J$ is the Hund’s rule coupling parameter ($|J/U| \approx 0.1$). Here we show that the exchange interaction between ground doublet states of lanthanide or actinide ions is characterized by equal in magnitude s-s and s-d kinetic exchange interactions, both scaling as $\sim t^2/U$ [1]. Moreover, the s-d kinetic mechanism prevails in many situations, contributing to antiferromagnetic coupling in the case of collinear magnetic ions. In the non-collinear case the s-d kinetic mechanism can cause an overall ferromagnetic exchange interaction of the order of $t^2/U$, already for the angle $\sim \pi/2$ between the main magnetic axes on sites, which appears quite counter-intuitive. This new s-d kinetic mechanism is not operative in the case of exchange interaction between strongly anisotropic magnetic doublets and an isotropic spin.

12:39PM T29.00008 ABSTRACT WITHDRAWN —

12:51PM T29.00009 First-Order Magnetostuctural Phase Transition in AlFe$_2$B$_2$ , BRIAN LEJEUNE, RADHIKA BARUA, Department of Chemical Engineering, Northeastern University, Boston, MA 02115, ENRIC STERN-TAULATS, LLUIS MANOSA, ANTONI PLANES, Departament d’Estructura i Constituents de la Matèria, Facultat de Física, Universitat de Barcelona, 08028 Barcelona, Catalonia, POL LLOVERAS, Departament de Física i Enginyeria Nuclear, ETSEIB, Universitat Politècnica de Catalunya, 08028 Barcelona, Catalonia, L.H. LEWIS, Departament d’Estructura i Constituents de la Matèria, Facultat de Física, Universitat de Barcelona, 08028 Barcelona, Catalonia — Understanding correlations between composition and crystal structure is key to tailoring the response of functional magnetic materials. In particular, the ferromagnetic AlFe$_2$B$_2$ compound with the layered AlMn$_2$B$_2$-type structure is reported to exhibit a magnetic transition of relevance for magnetocaloric cooling, with a reported entropy change $\Delta S \sim 4J/\text{kg} \cdot K$ at an applied magnetic field of 2 T [1].[2] New results derived from magnetic, structural and calorimetric probes confirm a thermodynamically first-order magnetic phase change in AlFe$_2$B$_2$ in the vicinity of the Curie temperature of $\sim 300$ K. The transformation from the ferromagnetic to the paramagnetic state is accompanied by a non-uniform 1% unit cell volume expansion upon heating, signifying that application of magnetic field is anticipated to have a similar effect (stabilizing the ferromagnetic phase) as the application of chemical or hydrostatic pressure. Relevant barocoralic effects are expected in this compound.

[2] 12:03PM T29.00010 Pressure tuning of itinerant magnetism in Mo$_5$Sb$_7$ , YISHU WANG, Univ of Chicago, JINGJUN CHENG, Chinese Academy of Sciences, ALEXANDER PALMER, DANIEL SILEVITCH, THOMAS ROSENBAUM, Univ of Chicago, JIAQIANG YAN, BRIAN SALES, Oak Ridge National Laboratory, YOSHIYA UWATOKO, University of Tokyo, YEJUN FENG, Argonne National Laboratory — Mo$_5$Sb$_7$ is a recently discovered itinerant antiferromagnet with a magnetic phase formed by spin dimerization at 53 K and ambient pressure, followed by a 2.3 K superconducting phase. In concert with the dimer pairing of S=1/2 Mo ions, a contraction of the crystalline lattice breaks the cubic symmetry. Here we use both high pressure x-ray single crystal diffraction and electrical transport techniques to investigate the magnetic behavior and map out the Pe-T phase diagram of Mo$_5$Sb$_7$. Our results demonstrate that the magnetic phase is eventually suppressed by high pressure, where the lattice structure returns to cubic. The disappearance of the antiferromagnetic phase in Mo$_5$Sb$_7$ could influence the evolution of the superconducting state.
Au faster than the superexchange interaction, favoring a spin-spiral state. For realistic values of double exchange. We find that, contrary to earlier reports, the ground state in standard density functional theory is ferromagnetic, induced by a competition between the short-range antiferromagnetic exchange and a long-range interaction induced by the polarization of Au bands, similar to double exchange. We find that, contrary to earlier reports, the ground state in standard density functional theory is ferromagnetic, whereas the other compounds order antiferromagnetically. Preliminary studies on single crystals of SmCuGa indicate that the spiral state is still not clear. The spiral cannot be explained via relativistic effects due to the short pitch of the spiral and the weakness of the spin-orbit interaction in LnCuGa, with the largest being 16% in Ce at only 0.7 GPa but 6% in Dy at 73 GPa, possibly a sign that the magnetic state has become unstable. Recent electrical resistivity measurements on Dy reveal a highly non-monotonic dependence of $T_c$ on pressure. Immediately above $P_{cr}, T_c(P)$ in Dy shows a dramatic increase, extrapolating to values near 400 K at 160 GPa (1.6 Mbar). Interestingly, the pressure dependence of the magnetic spin-disorder resistivity $\rho_{sd}(P)$ tracks that of $T_c(P)$.

2:17PM T29.00013 CF excitations of CeCu$_2$Si$_2$: Revisited employing a single crystal and triple-axis spectrometers, MICHAEL LOEVENHAPPT, Tech Univ Dresden, SERGEY DANILKIN, GUOCHU DENG, ANSTO, KLAUDIA HRADIL, TU Wien, OLIVER STOCKERT, MPI-CPS, ASTRID SCHNEIDEWIND, JCNS-MLZ — CeCu$_2$Si$_2$ is the famous heavy-fermion system showing unconventional superconductivity mediated by low-energy magnetic excitations of the CF ground-state doublet. From the point symmetry of the Ce$^{3+}$ ions in the tetragonal crystal lattice a CF splitting into 3 doublets is expected for the (J=5/2) multiplet. First INS measurements on polycrystalline samples of CeCu$_2$Si$_2$ employing a time-of-flight technique revealed a CF level scheme of 0-12-30 meV but were disputed by more advanced INS data in subsequent years. Finally it was accepted that the CF excitations of CeCu$_2$Si$_2$ consist of only one very broad transition with 30 meV from the ground-state doublet to both of the more or less degenerated excited CF states, the so-called “quasi-quartet.” Employing a large single crystal of CeCu$_2$Si$_2$ and the thermal neutron triple-axis spectrometers PUMA at FRM II and TAIPIAN at OPAL we revisited the CF-transitions to verify or falsify this interpretation. We performed TAS measurements for different crystallographic directions. From our results we infer that the quasi-quartet actually consists of two doublets situated at 30 and 35 meV exhibiting a strong directional dependence of their transition matrix elements to the ground state doublet.

1:51PM T29.00014 Magnetism and magnetic ordering in LnCuGa$_3$ ($\text{Ln} =$ lanthanide), MICHAEL GRAF, RYAN POLISCHUK, MARKIAN BOJKO, STEPHEN TRUDEAU, ELENI HUGHES, REBECCA DALLY, Boston College, UDUMULA SUBBARAO, SEBASTIAN PETER, Jawaharlal Nehru Centre for Advanced Scientific Research — We report structural characterization and magnetization and transport measurements on LnCuGa$_3$ ($\text{Ln} =$ La, Ce, Pr, Nd, Sm, Eu, and Gd) intermetallics. Magnetization in fixed field was measured for high quality polycrystalline samples at temperatures between 1.8 and 300 K, along with the isothermal variation of magnetization with field, while the temperature dependent resistivity was measured down to $T = 0.3$ K. All members of this family, except for the PrCuGa$_3$ and non-magnetic LaCuGa$_3$ compounds, exhibit magnetic ordering above 1.8 K at temperatures ranging from 2 K (CeCuGa$_3$) to 75 K (EuCuGa$_3$). The Eu and Sm based compounds exhibit multiple magnetic transitions. SmCuGa$_3$ appears to be ferromagnetic, whereas the other compounds order antiferromagnetically. Preliminary studies on single crystals of SmCuGa$_3$ indicate that the ordered moments lie parallel to the $c$-axis in the low temperature magnetically ordered phase of this tetragonal system.

1:39PM T29.00011 Possible Correlation-Enhanced Magnetic Ordering at Anomalously High Temperatures in Dy under Extreme Compression, JINHYUK LIM, Washington University in St. Louis, GILBERTO FABBRIX, Argonne National Lab/Washington University in St. Louis, DANIEL HASKEL, Argonne National Lab, JAMES SCHILLING, Washington University in St. Louis — Most lanthanides order magnetically at temperatures $T_c$, well below ambient, the highest being 292 K for Gd. The highly localized magnetic state of the heavy lanthanoids should become unstable at sufficiently high pressure, leading to a competition between the RKKY interaction and Kondo physics. Most lanthanoids undergo a volume collapse at a critical pressure $P_{cr}$, the largest being 16% in Ce at only 0.7 GPa but 6% in Dy at 73 GPa, possibly a sign that the magnetic state has become unstable. Recent electrical resistivity measurements on Dy reveal a highly non-monotonic dependence of $T_c$ on pressure. Immediately above $P_{cr}, T_c(P)$ in Dy shows a dramatic increase, extrapolating to values near 400 K at 160 GPa (1.6 Mbar). Interestingly, the pressure dependence of the magnetic spin-disorder resistivity $\rho_{sd}(P)$ tracks that of $T_c(P)$. The results of parallel experiments on Gd and further heavy lanthanoids will also be presented.

2:03PM T29.00015 Magnetic spiral induced by strong correlations in MnAu$_3$, JAMES GLASBRENNER, NRC/NRL, KONRAD BUSSMANN, IGOR MAZIN, NRL — The compound MnAu$_3$ is one of the oldest known spin-spiral materials, yet the nature of the spiral state is still not clear. The spiral cannot be explained via relativistic effects due to the short pitch of the spiral and the weakness of the spin-orbit interaction in Mn, and another common mechanism, nesting, is ruled out as direct calculations show no features at the relevant wave vector. We propose that the spiral state is induced by a competition between the short-range antiferromagnetic exchange and a long-range interaction induced by the polarization of Au bands, similar to double exchange. We find that, contrary to earlier reports, the ground state in standard density functional theory is ferromagnetic, i.e., the latter interaction dominates. However, an accounting for Coulomb correlations via a Hubbard $U$ suppresses the Schrieffer-Wolff type $s-d$ magnetic interaction between Mn and Au faster than the superexchange interaction, favoring a spin-spiral state. For realistic values of $U$ the resulting spiral wave vector is in close agreement with experiment.

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T30:GMAG DMP: Focus Session: Exchange Spring Magnets and Multilayers
11:15AM T30.00001 Depth dependent magnetization profiles of hybrid exchange springs , R. KNUT, Uppsala University - Sweden, T-N. ANH NGUYEN, S. CHUNG, Q. TUAN LE, S.M. MOHSEN, Royal Institute of Technology - Sweden, V. FALLAH, Amirkabir University of Technology - Iran, S. PERDEKOV, Lund University - Sweden, O. KARIS, Uppsala University - Sweden, R.K. DUMAS, University of Gothenburg - Sweden, C.W. MILLER, Rochester Institute of Technology - USA, J. AKERMAN, Royal Institute of Technology - Sweden — We report on the magnetization depth profile of a hybrid exchange spring system in which a Co/Pd multilayer with perpendicular anisotropy is coupled to a CoFeB thin film with in-plane anisotropy. Such materials allow for additional control of the magnetization dynamics in magnetic nanostructures, and suggest the possibility of improved spin transfer torque-MRAM switching behavior and thermal stability. The competition between these two orthogonal anisotropies promotes a strong depth dependence of the magnetization orientation. The angle of the magnetization vector is sensitive both to the strength of the individual anisotropies and to the local exchange constant, and is thus tunable by changing the thickness of the CoFeB layer and by substituting Ni for Pd in one layer of the Co/Pd stack. The resulting magnetic depth profiles are directly probed by element-specific x-ray magnetic circular dichroism of the Fe and Ni layers located at different average depths. The experimental results are corroborated by micromagnetic simulations.

11:27AM T30.00002 Quadratic magneto-optical Kerr effect and chirality of magnetization reversal in Py/SmFe/Py exchange spring magnet thin films , JIYEONG GU, HANNING YUAN, California State University, Long Beach — Magnetic switching behavior of the exchange spring magnet, Py(Permalloy)/SmFe/Py thin films, was investigated by magneto-optical Kerr effect (MOKE). Exchange spring magnet shows a unique magnetic hysteresis loop due to the non-collinear magnetization developed by magnetic coupling of the soft and hard magnetic layers. Py/SmFe/Py thin films were deposited on silicon substrate by DC magnetron sputtering. Experimental Kerr rotation measurement showed asymmetric hysteresis loops as a result of superimposed quadratic MOKE (QMOKE) contribution to linear MOKE (LMOKE). Overall MOKE signal was separated into LMOKE and QMOKE signals using loop symmetrization and antisymmetrization operation. The longitudinal ($M_z$) and transverse ($M_T$) magnetization components with respect to the plane of light incidence were extracted and QMOKE signal was simulated from the two mixed terms, $M_z$ and $M_T$. QMOKE signal not only showed the nature of magnetization reversal in exchange spring magnet system from the information of $M_T$ at switching field but also determined the direction of magnetization rotation from the positions of the peaks. Our work demonstrated that the chirality of magnetization reversal can be determined from analysis of QMOKE signal.

11:39AM T30.00003 Nanoscale Engineering Toward Bulk Exchange-Spring Permanent Magnetic Fe/MnAl Nanocomposites , LUK G. MARSHALL, IAN J. MCDONALD, LAURA H. LEWIS, Department of Chemical Engineering, Northeastern University, Boston, MA 02115, USA — The ability to amplify the performance of exchange-spring nanocomposites through correlation and tailoring of chemical order, microstructural scale and magnetic response is necessary for the development of novel high-performance permanent magnets. To this end, rapid solidification of near-equiatomic MnAl for incorporation into the model exchange-spring Fe/MnAl system has produced alloys containing 20-30% ferromagnetic Fe/MnAl with the high-temperature parent hexagonal $\alpha$-MnAl phase composing the balance. While typically formed by briefly annealing the quenched $\alpha$-phase, this work has confirmed direct attainment of nanoscale $\tau$-MnAl via cryogenic milling. Magnetic and structural data indicate a significantly decreased chemical order accompanied by increased lattice strain with increased milling time. Control of the chemical order and nanostructure of near-equiatomic MnAl will favor metastable configurations to foster robust exchange coupling between $\tau$-MnAl and $\alpha$-Fe to create high performance magnetic nanocomposites.

1This work is supported by the U.S. Office of Naval Research and the U.S. Army Research Office.

11:51AM T30.00004 Micromagnetic Modeling of Reversal Nucleation in Core/Shell Exchange-Spring Structures , J.S. JIANG, SAM BADER, Argonne National Laboratory — Nanocomposite exchange-spring permanent magnet materials promise superior performance and are a potential solution to the supply criticality of rare earth elements [1]. The nucleation of magnetization reversal in cylindrical and spherical soft core/hard shell exchange-spring structures has been investigated by solving the linearized Brown’s equation perturbatively, and has been verified with numerical simulations [2]. Accounting for the magnetostatic self-interaction field leads to a modification to the proposed quasi-coherent “bulging” mode of nucleation for small core sizes. The modified curling mode, where the magnetization configuration is vortex-like and flux-closed, becomes favored at large core sizes. The mode crossover occurs at a core diameter of approximately twice the exchange length for the cylindrical geometry. Since flux-closure allows magnetic elements to be densely packed without affecting the nucleation field, a potential direction for improving permanent magnet materials is to induce the modified curling mode by creating a soft-cylinder-in-hard-matrix exchange-spring microstructure.

12:03PM T30.00005 Fabrication and Characterization of MnBi/Co and MnBi/FeCo Nanocomposite Bulk Magnets , NARAYAN POUYDAL, KINJAL GANDHA, WEI WANG, XIAOTONG LIU, ZHAOGUO QIU, KEVIN ELKINS, JING LIU, Department of Physics, the University of Texas at Arlington, Texas 76019, USA; JUN CUI, Energy and Environment Directorate, Pacific Northwest National Laboratory, Richland, Washington 99352, USA, DEPARTMENT OF PHYSICS, THE UNIVERSITY OF TEXAS AT ARLINGTON, TEXAS 76019, USA TEAM, ENERGY AND ENVIRONMENT DIRECTORATE, PACIFIC NORTHWEST NATIONAL LABORATORY, RICHLAND, WASHINGTON USA COLLABORATION — We report the fabrication of MnBi/Co and MnBi/FeCo nanocomposite bulk magnets by consolidating the hard and the soft phase powder particles under a magnetic field followed by subsequent sintering process. The anisotropic micro and submicron hard magnetic MnBi particles were first prepared by low energy cryo ball milling at liquid nitrogen temperature. MnBi/Co and MnBi/FeCo nanocomposite powders were then prepared by using different fraction of chemically synthesized Co nanowires and FeCo nanoparticles as the soft magnetic phase. The saturation magnetization ($M_s$) of the composite magnets increases with addition of the soft phase while the coercivity first increases and then decreases. The MnBi/Co and MnBi/FeCo nanocomposite bulk magnets have reached an enhanced magnetization value ($M_s = 78$ and 80.6 emu/g) with 30 wt. % of Co nanowires and FeCo nanoparticles, respectively compared to the single phase MnBi bulk magnet ($M_s = 52$ emu/g).

12:15PM T30.00006 ABSTRACT WITHDRAWN —
12:27PM T30.00007 Direct measurement of interlayer interaction in Permalloy/Gd nanodots\(^1\). PAVEL LAPA, Argonne National Laboratory, Texas A&M University, JUNJIA DING, VALENTINE NOVOSAD, AXEL HOFFMANN, Argonne National Laboratory — Antiferromagnetic interaction at the interfaces of ferromagnetic transition metals (TM) and Gd is well known phenomenon. However, quantitative description of this interaction still lack understanding. The main reason is that most experimental data were obtained by inspecting the hysteresis loops of TM/Gd multilayers. First, in plane domain structures of TM and Gd films complicates the description of the magnetization reversal process. Second, experimentally measured parameters are averaged over the domains obfuscating the microscopical picture. We make an effort to overcome these limitations by studying the magnetization reversal process of Permalloy/Gd nanodots. The dots were prepared by combination of optical lithography and magnetron sputtering. Experimentally it is observed that in these dots the antiferromagnetic interlayer interaction tunes magnetic vortex nucleation/annihilation fields. Rise of Gd magnetization at low temperature provides unusual temperature behavior of hysteresis loop. Micromagnetic models in which interlayer interaction energy acts as a fitting parameter is applied to simulate experimental hysteresis curves. The effect of nonmagnetic spacer between Permalloy and Gd is also considered and will be presented.

12:39PM T30.00008 Detection of Magneto-Crystalline Anisotropy in YIG Films Formed by Aerosol Deposition. SCOOTER JOHNSON, E.R. GLASER, KONRAD BUSSMANN, FREDERICK RACHFORD, FRITZ KUB, CHARLES EDDY, JR., Naval Research Lab — We have employed aerosol deposition (AD) to form dense polycrystalline films of yttrium iron garnet (YIG) at room temperature in thicknesses of 0.3–11 \(\mu\)m onto \(\alpha\)-plane sapphire substrates. AD is a room-temperature process that accelerates a precursor of dry sub-micron-sized crystallites to impact and form a thick dense nano-crystalline film that is well-bonded to the substrate. We present results of ferromagnetic resonance (FMR) taken on the as-deposited films. In addition to the main resonance at 2815 G (in-plane) and 4650 G (out-of-plane) we find a distinct resonance mode \(H'_r\), that depends on film thickness. It appears in the 0.3-\(\mu\)m-thick film, becomes most intense in the 1-\(\mu\)m-thick film, and saturates for thicker films. \(H'_r\) moves with field orientation in the applied field from 4085 G (in-plane) to 3010 G (out-of-plane). FMR performed by rotating the applied field in the film plane shows that \(H'_r\) exhibits an anisotropy that reflects the crystallographic orientation of the substrate. These results suggest that during the early stages of growth a magneto-crystalline anisotropy is created in the interface region of the film that may be oriented to the crystallographic axis of the sapphire possibly caused by local heating that may facilitate recrystallization.

12:51PM T30.00009 The magnetism of TiN. BARBARA JONES, IBM Almaden Res Ctr, CHIUNG-YUAN LIN, SZU-WEN YANG, National Chiao Tung University, Taiwan, PUSHPA RAGHANI, Boise State University, SHRUBA GANGOPADHYYA, University of California Davis — Titanium Nitride is a well-known technological material, used typically in thin 3 micron coatings, in which form it is an extremely hard ceramic. It is the most common PVD coating used today. It shows no evidence of magnetism. We have studied isolated atoms of Ti on a Cu/N/Cu surface, layers of TiN on a Cu surface, and isolated monolayers of TiN, using first-principles density functional theory (DFT). In all of these geometries, TiN is magnetic, its interactions mainly governed by superexchange, resulting in striped magnetic structures. The question of how this dramatic magnetism disappears as more layers are added and TiN approaches bulk is one we have studied using DFT. We discuss the process by which the magnetism of TiN makes the transition between nanoscale and bulk.

1:03PM T30.00010 Role of Cu in exchange bias in FeMn revealed with neutron scattering\(^1\). IGOR V. ROSCHIN, PAVEL N. LAPA, Texas A&M Univ., ARTUR GLAVIC, HAILE AMBAYE, VALERIA LAUTER, Oak Ridge National Lab., SUNGYUN PARK, Pusan National U., TATIANA EGGERS, U. South Florida, CASEY W. MILLER, U. South Florida, Rochester Inst. of Technology — We observed an unusual behavior: a non-magnetic material, copper, modifies magnetic properties of antiferromagnetic FeMn in close proximity. Copper is responsible for the “intrinsic” exchange bias (EB) observed in a multilayered system without a distinct, separate ferromagnetic (FM) layer: Ta(5 nm)/\(\text{FeMn}(5-45\text{ nm})/\text{Cu}(5 \text{ nm})\)/\(\text{Ta}(5 \text{ nm})\) [1]. This EB occurs between pinned and unpinned uncompensated magnetization (UM) in the FeMn layers. The analysis of the remanent magnetization (\(M_r\)) shows that the unpinned (ferromagnet-like) UM is distributed individually throughout FeMn [1]. Since the magnitude of the EB loop shift (\(H_\theta\)) scales with the inverse thickness of the FeMn layer, this EB is clearly an interfacial phenomena. This behavior is similar to that described by Malozemoff’s model for the bilayer (antiferromagnet-ferromagnet) EB systems [2]. Thus, the pinned UM should be located near the FeMn interface. Results of polarized neutron reflectometry experiment show the explanation of how the Cu in the unusual magnetism in these FeMn/Cu multilayers will be presented.

1:15PM T30.00011 Multilayers of Co and Pt: the ultrathin limit. MICHALIS CHARILAOU, ETH Zurich, CATHERINE BORDEL, UC Berkeley, PIERRE-EMMANUEL BERCHE, Université de Rouen, BRIAN MARANVILLE, NIST, FRANCES HELLMAN, UC Berkeley — Magnetic properties of ultrathin (Co/Pt) multilayers, with overall composition 1Co:3Pt, has been investigated in to provide deeper understanding of magnetism in the ultrathin limit and to better understand the alloy. A comparison between a sub-monolayer multilayer and an fcc CoPt\(_2\) alloy film with perpendicular magnetic anisotropy (PMA) attributed to growth-induced Co clustering reveals significant differences in magnetization, despite the presence of thin Co platelets in both cases. Two regimes of the ferromagnetic phase transition, Brillouin and non-Brillouin-like, are seen in the experimental \(M(T)\) data and have been reproduced in Monte Carlo simulations, associated with different distributions of Co-Co nearest neighbors. Both the average number of Co-Co pairs and the width of the distribution are higher for the alloy than the sub-monolayer, leading to surprisingly higher Curie temperature and a nearly linear temperature-dependence of the magnetization of the alloy film, in contrast to the Brillouin-like behavior of the multilayer.

1:27PM T30.00012 Direct surface charging and alkali-metal doping for tuning the interlayer exchange coupling and magnetic anisotropy. TAMENE DASA, VALERI STEPANYUK, Max Planck Institute of Microstructure Physics — Manipulation of surface or interface charges allows one to control the magnetic orders in nanostructures. In this contribution we show two main surface charge alteration techniques for tuning the interlayer exchange coupling and magnetic anisotropy of ferromagnetic layers interspaced with non-magnetic ones. Our ab-initio study reveals that a modest amount of extra charge could switch the mutual alignment of the magnetic layers from anti-ferromagnetic to ferromagnetic or vice versa, taking Fe/NxCu(Pt)/Fe trilayer as model system. We also propose adsorption of alkali metals as a natural way of surface charging mechanism. Clear evidence is found that the interlayer magnetic order can be tuned only by adsorbing alkali metals on the magnetic layer. A combined effect of non-magnetic overlayers and interlayer magnetic order leads to a high perpendicular magnetic anisotropy in FePt thin films. These findings suggest that the interplay of interlayer magnetic coupling with magnetic anisotropy could play a crucial role for magnetic hardening and controlling the spin states.

1:39PM T30.00013 Antiferromagnetic interaction at the interfaces of ferromagnetic transition metals (TM) and Gd is well known phenomenon. However, quantitative description of this interaction still lack understanding. The main reason is that most experimental data were obtained by inspecting the hysteresis loops of TM/Gd multilayers. First, in plane domain structures of TM and Gd films complicates the description of the magnetization reversal process. Second, experimentally measured parameters are averaged over the domains obfuscating the microscopical picture. We make an effort to overcome these limitations by studying the magnetization reversal process of Permalloy/Gd nanodots. The dots were prepared by combination of optical lithography and magnetron sputtering. Experimentally it is observed that in these dots the antiferromagnetic interlayer interaction tunes magnetic vortex nucleation/annihilation fields. Rise of Gd magnetization at low temperature provides unusual temperature behavior of hysteresis loop. Micromagnetic models in which interlayer interaction energy acts as a fitting parameter is applied to simulate experimental hysteresis curves. The effect of nonmagnetic spacer between Permalloy and Gd is also considered and will be presented.
1:39PM T30.00013 Maximization of surface-enhanced transversal magneto-optic Kerr effect in Au/Co/Au thin films¹, EDGAR PATIÑO, CESAR HERREÑO, Universidad de los Andes — In order to maximize the transversal magneto optic Kerr effect (T-MOKE) of a Au/Co/Au structure we propose a method to obtain the optimum thickness values. A criteria based on preserving good plasmonic properties has been included as part of this method. Using the theoretical prediction we grew Au/Co/Au trilayers and perform optical and MO characterization using the Kretschmann configuration. The results admit very easy interpretation in terms of the interaction between the magneto-optical and plasmonic proper-ties dictating the optimal thicknesses of the structure. Moreover we have grown and characterized the optimized structure finding good agreement with theory reaching, for a 532 nm green laser, a maximal surface magneto-optic (MO) signal enhancement of close to nine folds with respect to the signal without plasmonic excitation.

1:51PM T30.00014 Investigation of Boundary Magnetization and Exchange Bias of B-doped Chromia, MICHAEL STREET, WILL ECHTENKAMP, CHRISTIAN BINEK, University of Nebraska-Lincoln — This work is devoted to utilize the magnetoelectric material Cr2O3 (chromia) for spintronics. We exploit the electric switchable boundary magnetization (BM) of chromia to manipulate an adjacent exchange-coupled ferromagnetic material. Using a ferromagnetic Co/Pd multilayer deposited on chromia, reversible, room-temperature isothermal switching of the exchange bias (EB) field has been achieved by reversing the electric field in the presence of a constant magnetic field. To use voltage-controlled BM in chromia as a key component in a spintronic device, the Néel temperature must be increased above the bulk value of TN = 307 K. First principle calculations show that boron doping of chromia can increase TN by roughly 10% per 1% O site substitution by B. We have grown B-doped chromia samples in a gaseous decaborane background atmosphere. We diagram structural and magnetic characterizations of pure and B-doped chromia. SQUID measurements of the BM of B-doped chromia samples indicate an enhancement of TN from the bulk value. This finding has been corroborated by spin dependent inverse photoemission spectroscopy [Ref]. Further, we investigate EB systems using a Co/Pd multilayer deposited on B-doped chromia for independent proof of TN increase in the experimental context most relevant for voltage-controlled spintronics. [Ref] M. Street, et al., Appl. Phys. Lett. 104, 222402 (2014). This work was supported in part by C-SPIN, a center of STARnet, a SRC program, sponsored by MARCO and DARPA.

2:03PM T30.00015 Theoretical analysis of magnetic structures in the fcc-Fe/Cu(001) system¹, YASUTOMI TATETSU, The University of Tokyo, SHINJI TSUNEYUKI, The University of Tokyo, Institute for Solid State Physics, YOSHIHIRO GOHDA, The University of Tokyo, Tokyo Institute of Technology — Magnetic thin films have been studied due to its peculiar magnetic behaviors compared to their bulk systems. Fe/Cu magnetic thin films have been studied for the past decades, because of their uncertain magnetic structures. As is well known, the ground state of Fe has the bcc structure, but the fcc-Fe, which is stable above 1184 K, can epitaxially grow on a Cu(001) substrate even below room temperature, since the lattice parameters of Cu (3.62Å) and fcc Fe (3.58Å) are quite close to each other. Many kinds of studies for the systems have been reported, but its ground state is controversial. We applied first-principles calculations to the fcc-Fe/Cu(001) system using a computational code OpenMX for understanding of its electronic and magnetic structures. Our structural model is a slab model consisting of seven Cu layers and several Fe layers capped by a 10-Å vacuum layer. According to our collinear-spin calculations, an antiferromagnetic structure is stable in the 4 to 7-ML systems and a ferromagnetic coupling at the top of its electronic and magnetic structures. Our structural model is a slab model consisting of seven Cu layers and several Fe layers capped by a 10-Å vacuum layer. 207A - Dennis Meier, ETH Zuerich

11:15AM T31.00001 Field-induced antiferromagnetic order in Sr3Ru2O7 - CHRISTOPHER LESTER, STEPHEN HAYDEN, University of Bristol, UK, SILVIA RAMOS, University of Kent, UK, ROBIN PERRY, UCL, UK, THOMAS CROFT, University of Bristol, UK, ROBERT BEWLEY, TATIANA GUIDI, PASCAL MANUEL, DMITRY KHALYAVIN, ISIS Neutron Source, UK — Many novel electronic ground states form in close proximity to quantum critical points, that is, the point where a continuous phase transition occurs at zero temperature. By suppressing the metamagnetic transition in Sr3Ru2O7 to low temperatures via the application of a magnetic field, the system is driven into a ‘nematic’ phase. This phase occurs at temperatures below approximately 1 K and at fields μ0Hc2 ≈ 8 T. The phase is often described as nematic since transport properties display pronounced anisotropic tendencies which are not present in the underlying crystal lattice. Using elastic neutron scattering we have found evidence for two adjacent magnetically ordered phases near μ0Hc1 in this material. The period of the order in both phases is incommensurate with the underlying lattice and most likely determined by the electronic band structure. The presence of static antiferromagnetic order provides a very natural explanation for the anisotropic transport properties that have been observed in this system. Our observation of field-induced antiferromagnetic order in a clean metal provides valuable insights into the physics of novel phase formation near quantum critical points.

11:27AM T31.00002 Possible spin-momentum locking and band-dependent coherence in Sr3Ru2O7 revealed by angle-dependent magneto thermolectric measurements, CHENYI SHEN, HUI XING, Department of Physics, Zhejiang University, XINXIN CAI, Department of Physics and Materials Research Institute, Pennsylvania State University, DAVID FOBES, Department of Physics, Tulane University, MINGLIANG TIAN, High Magnetic Field Laboratory, Chinese Academy of Science, ZHIQIANG MAO, Department of Physics, Tulane University, ZHUAN XU, Department of Physics, Zhejiang University, YING LIU, Department of Physics and Materials Research Institute, Pennsylvania State University — The bilayer member of the Roddedson-Popper(R-P) series, Sr3Ru2O7, with its complex phenomena such as a magnetic field orientation dependent metamagnetic transition and the possible existence of a nematic phase, has attracted much attention. Both INS and NMR studies suggested that the metamagnetic transition is band dependent and some bands of Sr3Ru2O7 are heavily renormalized according to the ARPES experiment. However, the underlying electronic and magnetic properties of these bands are yet to be clarified. We explored band dependent electronic and magnetic properties in Sr3Ru2O7 by using angle-dependent magnetoresistance and magneto thermolectric measurements on crystals cut along two specific crystalline directions and a magnetic field rotating in the ab plane. We found evidence supporting the presence of spin-momentum locking and the emergence of a coherent state with unconventional magnetism phase formed in a two-dimensional band in Sr3Ru2O7.
11:39AM T31.00003 Soft magnetic excitations and quantum critically in Sr$_3$Ru$_2$O$_7$ . STEPHEN HAYDEN, C. LESTER, University of Bristol, R. RAMOS, University of Kent, R. PERRY, University College London, T. CROFT, University of Bristol, R. BEWLEY, T. GUIDI, Rutherford Appleton Laboratory, E. FORGAN, University of Birmingham — The application of a magnetic field of approximately $B_H = 8$ T induces quantum critical behavior in Sr$_3$Ru$_2$O$_7$. Near $B_c$, the resistivity shows an anomalous power law temperature dependence and the linear specific heat becomes large. In addition, new ordered phases with strong nematic tendencies appear below 1 K near $B_c$. These phases have recently been identified as spin density wave order. Here we report an inelastic neutron scattering study of the low-energy magnetic excitations. We find a dramatic field-induced softening of the collective magnetic excitations in the region surrounding $B_c$. This suggests that the quantum critically observed in Sr$_3$Ru$_2$O$_7$ is magnetic in origin. The presence of additional magnetic excitations can also explain the increase in entropy and specific heat present near $B_c$.

11:51AM T31.00004 Double metamagnetic transition in Sr$_3$Ru$_2$O$_{10}$ investigated by low temperature magnetization measurements1 . DAGMAR FRANZISKA WEICKERT, LEONARDO CIVALE, MARCELO JAIME, BORIS MAIOROV, ROMAN MOVSHOVICH, Los Alamos National Laboratory, R. FITTIPALDI, V. GRANATA, A. VECCHIONE, University of Salerno, Via Giovanni Paolo II, I-84084 Fisciano, Italy, TENG TAN, Temple University, Philadelphia, Pennsylvania 19122, USA, MYRON SALAMON, University of Texas at Dallas, Richardson, TX 75080, Dallas, USA — We report a study of the magnetization of the n = 3 member of the Sr$_{n+1}$Ru$_2$O$_{3n+1}$ Ruddlesden-Popper series down to 1 K temperatures. Sr$_3$Ru$_2$O$_{10}$ exhibits ferromagnetism below 105 K with magnetic moments aligned along the crystallographic c-direction in the tetragonal crystal structure. Metamagnetism is observed at about 2 T below 50 K when a magnetic field is applied in the ab-plane. A recent study on high quality samples revealed that the magnetization has a substructure [1]. We extend the studies to very low temperatures and found i) a clear double peak in δM/dH, ii) that the metamagnetism is accompanied by a reduction of the magnetic moment and iii) no further splitting of the metamagnetic anomalies to the lowest temperatures of 0.46 K. Furthermore, the measurements indicate a shift of both metamagnetic signatures to higher fields by rotating from $H//ab$ to $H//c$. We will discuss the phase diagram and possible ordered states.

12:03PM T31.00005 Optical Response of Sr$_2$RuO$_4$ Reveals Universal Fermi-liquid Scaling and Quasiparticles Beyond Landau Theory1 . DAMIEN STRICKER, University of Geneva, JERNEJ MRAVLJE, Ecole Polytechnique CNRS, CHRISTOPHE BERTHOD, University of Geneva, ROSALBA FITTIPALDI, ANTONIO VecCHIONE, Università di Salerno, ANTOINE GEORGES, Ecole Polytechnique CNRS, DIRK VAN DER MAREL, University de Geneva — We report optical measurements demonstrating that the low-energy relaxation rate $1/\tau$ of the conduction electrons in Sr$_2$RuO$_4$ obeys scaling relations for its frequency ($\omega$) and temperature (T) dependence in accordance with Fermi-liquid theory. In the thermal relaxation regime, $1/\tau \propto (h\omega^2 + p(T^2))^{2}$ with $p = 2$, and $\omega/T$ scaling applies. Many-body electronic structure calculations using dynamical mean-field theory confirm the low-energy Fermi-liquid scaling, and provide quantitative understanding of the deviations from Fermi-liquid behavior at higher energy and temperature. In this regime, evidence for electron-like “resilient” quasiparticle excitations with a scattering rate deviating from Landau’s theory. In the thermal relaxation regime, $1/\tau \propto (h\omega^2 + p(T^2))^{2}$ with $p = 2$, and $\omega/T$ scaling applies. Many-body electronic structure calculations using dynamical mean-field theory confirm the low-energy Fermi-liquid scaling, and provide quantitative understanding of the deviations from Fermi-liquid behavior at higher energy and temperature. In this regime, evidence for electron-like “resilient” quasiparticle excitations with a scattering rate deviating from Landau’s theory.

12:15PM T31.00006 Commensurate-incommensurate magnetic phase transition in the Fedoped ruthenate bilayer Ca$_3$Ru$_2$O$_7$ . XIANGLIN KE, M. ZHU, Michigan State University, W. TIAN, T. HONG, Oak Ridge National Laboratory, J. PENG, Z.Q. MAO, Tulane University — Neutron diffraction studies have revealed an uncommon commensurate-incommensurate magnetic phase transition with decreasing temperature in the (~ 5%) Fe-doped bilayer ruthenate Ca$_3$(Ru,Fe)$_2$O$_7$. An incommensurate phase formed of a cycloidal spiral spin structure coexists with a commensurate one below the phase transition at 42 K and persists down to the lowest temperature, accompanied by higher-order magnetic satellite peaks which indicate the formation of a magnetic soliton lattice. We ascribe these findings to the competing magnetic interactions in Ca$_3$Ru$_2$O$_7$. This study demonstrates an effective approach to tune novel magnetic and electronic properties of this complex system via 3d magnetic transition-metal substitution.

12:27PM T31.00007 ARPES and spin ARPES measurements of nonmagnetic centrosymmetric crystal LaBiO$_2$. JUSTIN VAUGH, XIAOQING ZOU, HAOXING LI, THOMAS NUMMY, STEPHEN PARHAM, QIHANG LIU, XIUWEN ZHANG, Univ of Colorado - Boulder, JASMINKA ZURIC, University of Kentucky, XIANGDE ZHU, Chinese Academy of Sciences, GANG CAO, University of Kentucky, ALEX ZUNGER, DANIEL DESSAU, Univ of Colorado - Boulder — Spin polarized bands are traditionally expected to exist only under global bulk symmetry breaking. LaBiO$_2$ has a centrosymmetric structure thus expected to have no spin polarization. However, it is predicted to have local inversion-asymmetric structure, leading to spin polarization localized on the individual Bi$_2$O$_2$ sublayers. This spin polarization theoretically presents itself in energetically doubly degenerate bands that are spatially separated on different Bi$_2$O$_2$ layers. We measured ARPES and spin ARPES on the inversion-symmetric bulk crystal LaBiO$_2$ in search of such a hidden spin polarization. Our measurements show band structure to have qualitative agreement with DFT calculations. We additionally observe spin polarization in the valence band and will discuss its spin orientation in this talk. This work is supported by NSF DMREF project 1334170.

12:39PM T31.00008 Anisotropic Magnetocaloric Effect in Single Crystalline CoSb$_2$O$_6$. AARON B. CHRISTIAN, JOHN J. NEUMEIER, Montana State Univ., YI-KUO YU, National Center for Biotechnology Information — The quasi one-dimensional spin chains of CoSb$_2$O$_6$ are oriented along [110] at $z = 0$ and [100] at $z = 1/2$. Application of magnetic field $H$ parallel to [110] is therefore parallel to one set of chains and perpendicular to the other. $H > 2$ tesla, applied parallel to [110], lowers the Néel temperature ($T_N = 13.4$ K) for one set of chains, leaving the other set unaffected. This gives rise to two peaks in the heat capacity $C_p$, which are separated by 3.8 K when $H = 8$ tesla. Integrating $C_p(T,H)/T$ with respect to temperature yields a change in entropy $\Delta S_T$, from which the change in magnetic entropy $\Delta S_M$, determined. Near 12 K we find that $\Delta S_M$(8 T) = 2.97 J/kg K for measurements with $H // 110$ or $100$ and $\Delta S_M$(8 T) = 0.44 J/kg K for $H // [001]$. This anisotropy implies that rotation of the sample in constant magnetic field could induce a change in sample temperature.

12:15PM T31.00009 Hall effect of triplons in a dimerized quantum magnet. JUDIT ROMHANYI, Max Planck Institute for Solid State Research, Stuttgart, Germany, KARŁO PENC, Institute for Solid State Physics and Optics, Wigner Research Centre for Physics, RAMACHANDRAN GANESH, The Institute of Mathematical Sciences, Chennai, India — SrCu$_2$(BO$_3$)$_2$ is the archetypal quantum magnet with a gapped dimer-singlet ground state and triplon excitations. It serves as a realisation of the Shastry Sutherland model, up to small anisotropies arising from Dzyaloshinskii-Moriya (DM) interactions. We demonstrate that the DM couplings give rise to topological character in the triplon band structure. The triplons form a new kind of a Dirac cone with three bands touching at a single point, a spin-1 generalization of graphene. An applied magnetic field opens band gaps and as a result topological bands with Chern numbers $\pm 2$ develop. Thus SrCu$_2$(BO$_3$)$_2$ is a magnetic analogue of the integer quantum Hall effect and supports topologically protected edge modes. At a critical value of the magnetic field set by the strength of DM interactions, the three triplon bands touch again in a spin-1 Dirac cone, and lose their topological character. We predict thermal Hall signature in the topological regime.

1:03PM T31.00010 Spin induced ferroelectric-like structural transition in a metal. YANFENG GUO, Department of Physics, University of Oxford, HAI FENG, National Institute for Materials Science, PRINCEP ANDREW, Department of Physics, University of Oxford, PASCAL MANUEL, ISIS Facility, Rutherford Appleton Laboratory, KAZUNARI YAMAURA, National Institute for Materials Science, BOOTHROYD ANDREW, Department of Physics, University of Oxford — LiOsO$_3$ represents a previously only known example of “ferroelectric metal,” a concept presented by Anderson and Blount in 1965, with the properties being promoted by electron lattice coupling involving Li$^+$ ions displacement in the crystal structure [Y. Shi et al., Nat. Mater. 12, 1024(2013)]. We report that in Pb$_2$CoO$_4$, a new ordered double-perovskite with a centrosymmetric monoclinic space group of $P2_1/n$, a ferroelectric-like structural transition occurs at $\sim$ 38 K in the metallic state, i.e. a continuous second order transition to a noncentrosymmetric structure (space group: P1) associated by appearance of a nominal unique polar axis along the c-axis. The phase transition is coincident with a magnetic transition at the same temperature which corresponds to a long-range antiferromagnetic order. The magnetic structure analysis and theoretical calculations prove that the antiferromagnetic ordering is the driven force for the structural transition in Pb$_2$CoO$_4$ and it ordering involving a magnetic ordering.

1:15PM T31.00011 Anisotropic Magnetocaloric Effect in Single Crystalline NiTa$_2$O$_6$. AARON T. SCHYE, SUELI H. MASUNAGA, AARON B. CHRISTIAN, JOHN J. NEUMEIER, Montana State University, YI-KUO YU, National Center for Biotechnology Information — Magnetic susceptibility and heat capacity measurements were made on the low-dimensional antiferromagnet NiTa$_2$O$_6$. The antiferromagnetic structure most consistent with our measurements is the two sub-lattice model proposed by Law et al.[2] in which magnetic moments in the $z = 0$ plane are aligned parallel to [110] and those in the $z = 1/2$ plane are aligned parallel to [10]. Applying a magnetic field along [110] causes the peak in the heat capacity to split into two with one remaining at $T_N$ and the other shifting to lower temperatures as the field is increased with a maximum $\Delta T \sim 3$ K at 8 T. This splitting indicates that each sub-lattice orders at different Néel temperatures. Calculation of the magnetic entropy change associated with an increase in magnetic field($\Delta S_m(T, \Delta H)$) reveals $\Delta S_m(T, \Delta H) \sim 0.7$ J/kg K for $H \parallel$ [110] and $\Delta S_m(T, \Delta H) \sim 0$ J/kg K for $H \parallel$ [001] if $\Delta H = 8$ T. This anisotropy in the magnetocaloric effect suggests that rotating the sample in constant magnetic field will result in a change in sample temperature.

1:27PM T31.00012 Transport properties of novel molybdenum bronze oxide materials. JOSEPH HAGMANN, SON LE, National Institute of Standards and Technology, LYNN SCHNEEMEYER, PATTI OLSEN, Montclair State University, THEO SIEGRIST, Florida State University, CURT RICHTER, DAVID SEILER, National Institute of Standards and Technology — Reduced ternary molybdenum oxides, or bronzes, offer an attractive materials platform to study a wide variety of remarkable physical phenomena, including charge density waves [1] and superconductivity [2], in a system with highly varied structural chemistry. Interesting electronic behaviors in these materials arise from the strong hybridization of the 4d states of high-valent Mo with O p orbitals (conditions amenable to itinerancy) and reduced dimensionality arising from ordered O vacancies. This study aims to demonstrate the transport phenomena in a series of novel molybdenum bronze materials, including the new electrochemically-grown molybdenum bronzes, K3LiMo15O47, and the rare earth molybdenum bronze, HoMo16O44, and relate these behaviors to their experimentally-characterized structures. Dependence of the transport behavior on numerous experimental parameters, including temperature, magnetic field and drive current, and gate voltage, is presented to fully reveal charge carrier transport in these materials.

1:39PM T31.00013 Properties of the low dimensional Sr$_2$Cu(W$_{1-x}$Mo$_x$)$_6$O$_{17}$ spin system. OMAR CHMAISSEM, Northern Illinois University, DeKalb IL and Argonne National Laboratory, Argonne IL, MAXIM AVDEEV, SERGEY DANILKIN, Australian Nuclear Science and Technology Organisation, Bragg Institute, Austria, SAMI VASALA, HISAO YAMAUCHI, MAARTEN GARPNEN, Department of Chemistry, Aalto University, Finland — Low-dimensional spin systems have gained much attention in solid state physics. Such systems could have a ground state with no long-range magnetic order and an energy gap in the spin excitation spectrum, offering the possibility of a quantum spin-liquid phase. Quantum fluctuations causing the spin-liquid state are particularly strong in systems with reduced dimensionality and a low spin value, and magnetic frustration can further enhance the fluctuations. Among various low-dimensional spin systems, the S = 1/2 Heisenberg frustrated square lattice model is especially interesting due to its relevance to high-T$_C$ superconducting cuprates, whose undoped parent materials are S = 1/2 square-lattice antiferromagnets. Sr$_2$CuWO$_6$ and Sr$_2$CuMoO$_6$ have been found to be quasi-two-dimensional S = 1/2 magnetic systems with a square lattice of Cu-ions. These compounds show low-dimensional magnetic properties, with no clear indication of long-range order in magnetic susceptibility. I will discuss the materials properties and the observation of long range magnetism by neutron diffraction and other techniques.

1:51PM T31.00014 NMR studies of the internal electric field in a single crystal of the quasi-one-dimensional conductor Li$_{0.8}$Mn$_{0.2}$O$_2$. GUOQING WU, Yangzhou University, BING WU, Fayetteville State University — The quasi-one-dimensional (Q1D) conductor Li$_{0.8}$Mn$_{0.2}$O$_2$ is of considerable interest because it has a highly conducting phase with properties likely associated with a Luttinger liquid, a poorly understood “metal-insulator” crossover at temperature $T_{MI} = 24$ K, and a 3D superconducting phase that may involve triplet Cooper pairs at $T_c = 2.2$ K, while the mechanism for many of its properties has been a long mystery and it presents tremendous experimental challenges. We report the $^7$Li-NMR measurements of the internal electric field with an externally applied magnetic field $B_0 = 9 - 12$ T, and we also show our theoretically calculated result of the electric field based on the structure of the crystal lattice. We find that the $^7$Li-NMR frequency ($\nu_{Q}$) has a value of $\sim$ 45 kHz and the electric field gradient (EFG) at the Li site due to the charges of the surrounding Mo conduction electrons has an axial symmetry with the principle axis ($p_z$) to be along the lattice a-axis. There is no temperature or field dependence for the value of $\nu_{Q}$ or EFG, indicating that the “metal-insulator” crossover has a magnetic origin, rather than the charge density wave (CDW) as one of the possible mechanisms previously thought in literature.
2:03PM T31.00015 ARPES and NMTO of Li$_{0.5}$Mo$_{0.5}$O$_2$: Implications for Unusually Robust Quasi-One Dimensional Behavior$^1$, J.W. ALLEN, U. Michigan, L.M. DUDY, Uni Wuerzburg. J.D. DENLINGER, Lawrence Berkeley Nat’l Lab. J. HE, Clemens U., M. GREENBLATT, Rutgers U., M.W. HAVENKORT, MPI Chem. Phys. Dresden, O.K. ANDERSEN, Y. NOHARA, MPI Stuttgart — Li$_{0.5}$Mo$_{0.5}$O$_2$: displays theoretically interesting $^1$ metallic quasi-one dimensional (1D) behavior that is unusually robust $^2$ against 3D crossover before superconductivity at $\approx 1.9$K, and has large anomalous Luttinger liquid density-of-states exponent $\alpha \approx 0.6$. We present very high resolution, low temperature ($T \approx 6$K-26K) angle resolved photoemission spectroscopy (ARPES) data analyzed with non-linear muffin tin orbital (NOMTO) Wannier function band theory. We confirm a previous conclusion $^3$ that the LDA agrees unusually well with ARPES, implying small Hubbard U, and find in ARPES the dispersion and Fermi surface warping and splitting expected for predicted small but long range inter-chain hoppings ($t_c \approx 10$-15 meV). These various findings imply the likely importance of long range Coulomb interactions for the large $\alpha$ value $^4$ and reaffirm the great puzzle $^2$ of quasi-1D behavior well below the 3D crossover $T$ implied by $t_c$.

12:03PM T32.00003 Photoinduced phase transitions in vanadium dioxide revealed by ultrafast electron diffraction and mid-infrared spectroscopy$^1$. KUNAL TIWARI, VANCE MORRISON, ROBERT CHATELAIN, McGill University Department of Physics, ALI HENDAOUI, Institut National de la Recherche Scientifique, ANDREW BRUHACS, McGill University Department of Chemistry, MOHAMED CHAKER, Institut National de la Recherche Scientifique, BRADLEY SIWICK, McGill University Departments of Physics and Chemistry — The complex interplay between strong electron-electron correlations and structural distortions is thought to determine the electronic properties of many oxides, but the respective role of these two contributions is often difficult to determine. We report combined radio-frequency compressed ultrafast electron diffraction (RF-UED) and infrared transmissivity experiments in which we directly monitor and separate the lattice and charge density reorganizations associated with the optically induced semiconductor-to-metal phase transition in vanadium dioxide. These studies have uncovered a previously unreported photoinduced transition to a metastable phase retaining the periodic lattice distortion characteristic of the insulating phase, but differing by a reorganization of charge density along the vanadium dimer chains and a transition to metal-like mid IR optical properties. These results demonstrate that UED is able to follow details of both lattice and electronic structural dynamics on the ultrafast timescale.

12:15PM T32.00004 Elucidating the Band Gap of Niobium Dioxide . ANDREW O'HARA, The University of Texas at Austin, DEREK VIGIL-FOWERLER, STEVEN G. LOUIE, University of California - Berkeley and Lawrence Berkeley National Lab, ALEXANDER A. DEMKOV, The University of Texas at Austin — Like VO$_2$, niobium dioxide (NbO$_2$) belongs to the family of transition metal oxides with a temperature-driven metal-to-insulator transition. However, NbO$_2$ has received considerably less attention, and several open questions about the material remain. One such question, of both practical and fundamental importance, is the nature and size of the band gap in the low-temperature, distorted rutile phase with a range reported for the gap of $1$–$1.5$ eV. In this talk, we investigate the band structure utilizing several electronic correlations to extract the electronic energy bands with the standard local density approximation (LDA). LDA+U, hybrid functional, and the GW approximation, to better understand the physics of the band gap in NbO$_2$. Comparisons of the calculations are made to recent experimental work on NbO$_2$ utilizing photoemission spectroscopy and ellipsometry. This work is supported by DOE under the SciDAC program, the NSF, and SRC.

12:27PM T32.00005 Orbital and magnetic states in BaV$_{11}$O$_{15}$ . SACHITH DISSANAYAKE, TIANRAN CHEN, Univ of Virginia, JOOSEOP LEE, MATTHEW STONE, MASAKI MATSUDA, Oak Ridge National Laboratory, TOMOMASA KAZITA, TAKURO KATSUFUJI, Waseda University, SEUNGHUN LEE, Univ of Virginia — BaV$_{11}$O$_{15}$ is a new type of frustrated magnet that exhibits interesting physics due to its charge and orbital ordering which has an average V valance of $2.8^+$. The V ions form a lattice with V “boats,” each of which is made of five V atoms and connected along ab plane. The system undergoes a structural phase transition at $T_s$ = 130 K and shows an antiferromagnetic long range ordering below $T_N$ = 43 K. Although there have been several studies about this complex V spin system, nature of the orbital and magnetic correlations is still unclear. In this talk I will discuss about our elastic and inelastic neutron scattering results obtained from a powder sample and a single crystal of BaV$_{11}$O$_{15}$. We investigated the magnetic ground states of BaV$_{11}$O$_{15}$ by neutron diffraction refinements and observed magnetic excitations below 15 meV were analyzed by performing linear spinwave calculations. Another broad high energy excitation around 33 meV was observed at temperatures below the structural transition $T_s$ = 130 K. Possible orbital and magnetic states for this complex V spin system will be discussed.

12:39PM T32.00006 Pressure-dependent Raman scattering study of CoV$_2$O$_4$ . TAYLOR BYRUM, SAMUEL GLEASON, Univ of Illinois - Urbana, HAIDONG ZHOU, Univ of Tennessee - Knoxville, S. LANCE COOPER, Univ of Illinois - Urbana — The Co$_x$V$_{1-x}$O$_4$ ($A$ = Cd, Mn, Mg, Zn, Co) spinel family provides a fertile ground to explore the crossover between electron localization and itinerancy, which can be tuned with chemical ($A$-site substitution) and/or physical pressure. CoV$_2$O$_4$ resides closest to the predicted itinerant electron limit for the vanadium spinel family. Recent experiments have shown the existence of a critical V-V separation by inducing a metallic transition in CoV$_2$O$_4$ with a pressure of ~6 GPa. While the structure of CoV$_2$O$_4$ has been theoretically suggested to remain cubic through the metallic transition, no structural measurements under pressure have been performed. Raman spectroscopy is well suited to address this issue, as it is sensitive to even subtle structural changes. In this presentation, I present a pressure-dependent Raman scattering study of CoV$_2$O$_4$ to elucidate the role the structure plays in the metallic transition.

12:51PM T32.00007 Spin-glass insulating ground state in Y$_2$Os$_3$O$_7$ . ZHIYING ZHAO, Department of Physics and Astronomy, University of Tennessee, Knoxville, Tennessee 37996, USA, STUART CALDER, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, MICHAEL MCGUIRE, BRIAN SALES, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, HAIDONG ZHOU, Department of Physics and Astronomy, University of Tennessee, Knoxville, Tennessee 37996, USA, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA — 4d/5d transition-metal oxides can display many exotic physical properties due to the interplay between spin-orbit coupling (SOC), Coulomb interaction, crystal field effect, Hund’s coupling, and lattice distortion. The magnetic ground state of systems with $d^4$ electronic configuration is under hot debate since the consensus between experiments and theories has not been achieved. A non-magnetic ground state has been predicted under the $J_{eff}$ scenario in the presence of SOC. However, various ground states are observed in some $d^4$ systems (such as InO$_2$, Os$_2$S, and RuO$_2$). In this talk, I will present our study of Y$_2$Os$_3$O$_7$ with nonmagnetic $Y^{3+}$ at A site which allows us to study the magnetism of Os$^{5+}$ ($d^5$) sublattice. Polycrystalline Y$_2$Os$_3$O$_7$ was synthesized by solid state reaction and was studied by measuring electrical resistivity, magnetic susceptibility, specific heat, and neutron powder diffraction. A spin-glass insulating state is observed in contrast to the long-range magnetic ordered state in Y$_2$Ru$_2$O$_7$.

1:03PM T32.00008 First-principles evidence of Slater-type metal-to-insulator transition in NaOsO$_3$ . BONGJAE KIM, ZEYNEP ERGONENC, CESARE FRANCHINI, Faculty of Physics and Center for Computational Materials Science, University of Vienna — NaOsO$_3$ is thought to be the first example of a three-dimensional Slater insulator where the metal-to-insulator transition (MIT) is driven by the emergence of the (antiferro)magnetism in the system. This picture is fundamentally different from the most widely known Mott-Hubbard (MH) insulators for which the opening of the gap is due to electron correlation. However, there are still experimental evidences for the Slater-type state in NaOsO$_3$ such as the continuous character of the transition and the simultaneous onset of the magnetic and insulating regime at the same temperature ($T_{MIT}=T_N$), both directly and unambiguously indicated by results presented in the theory. Based on ab initio band structure methods, we have studied the origin of the MIT in NaOsO$_3$ and found that the MIT is predominantly driven by magnetic, and only marginally dependent on electronic correlation. A direct comparison between NaOsO$_3$ and other typical MH oxides allows us to analyze and interpret the distinct role of magnetism and the electronic correlation in favoring Slater- or MH-type states. Finally, fingerprints of the Slater behaviour are found in the optical response, that we have computed within a model Bethe-Salpeter scheme.

1:15PM T32.00009 Unconventional electronic state in half-frustrated Ca$_2$Os$_2$O$_7$ . MAREIN RAHN, ROGER JOHNSON, University of Oxford, JAMES VALE, CHRISTIAN DONNERER, University College London, PASCAL MANUEL, DMITRY KHALYAVIN, ISIS Facility, GARETH NISBET, DIAMOND Light Source, DESMOND MCMORROW, University College London, ANDREW BOOTHROYD, University of Oxford — In 5d transition metal oxides ($5d$ TMOS), the combination of strong spin-orbit coupling and electronic correlation can lead to unusual ground states. Orthorhombic calcium osmate is a “half-frustrated” compound with a strange phase transition at $327$ K, enhancing its resistivity by an order of magnitude. We have investigated the concomitant magnetic ordering process by neutron powder diffraction and single crystal resonant x-ray diffraction. Our results reveal a complex reordering process, likely induced by magnetic frustration. Similar coupling of magnetic order and electronic transport has been observed in other families of 5d TMOS. Given the itinerant character of these materials, one cannot explained such behaviour in a Mott-Hubbard scenario. We hope that Ca$_2$Os$_2$O$_7$ will serve as a model system to help understand this peculiar interplay of spin-orbit coupling, correlation and frustration.
1:27PM T32.00010 Magnetic properties of the double perovskite Sr₃FeOsO₉: microscopic insights from ab-initio density-functional theory study. SUDIPTA KANUNGO, BINGHAI YAN, Max Planck Institute for Chemical Physics of Solids, MARTIN JANSEN, Max Plack Institute for Solid State Research, CLAUDIA FELSER, Max Plack Institute for Chemical Physics of Solids — Using density-functional theory calculations, we investigated the electronic and magnetic properties of the ordered 3d-5d double perovskite Sr₃FeOsO₉, which has recently drawn attention for interesting antiferromagnetic (AFM) phase transitions in low temperature observed in experiments. The calculated effective magnetic exchange interactions reveal the importance of long-range super-superexchange interactions in this compound. The competition between the ferromagnetic (FM) Os-O-Fe short-range interaction and AFM Os-O-Fe-O-Os long-range interaction induces strong magnetic frustration along the crystallographic c axis. This strong magnetic frustration is proposed to drive the magnetic phase transition between two AFM phases (AFM1 to AFM2) and related lattice distortion, which were also observed in the experiment. [Ref: Sudipta Kanungo, Binghai Yan, Martin Jansen, and Claudia Felser; Phys. Rev. B 89, 214414 (2014)]

1:39PM T32.00011 Structure and physical properties of R₂Os₂O₇ Pyrochlores ¹ , RYAN RAWL, Univ of Tennessee, Knoxville, STUART CALDER, Oak Ridge National Laboratory, ZHIYING ZHAO, HAIDONG ZHOU, DAVID MANDRUS, JIAQIANG YAN, Univ of Tennessee, Knoxville — The spin-orbit coupling (SOC) in 4d/5d transition metal oxides is enhanced to such a degree, relative to 3d oxides, that it can alter the electronic structure and have a dramatic effect on materials properties. A good example of this is the SOC assisted metal-insulator transition in Sr₂IrO₄, which has been extensively studied in the last few years. In a strong SOC scenario, a nonmagnetic ground state is expected for systems with d⁴ electronic configuration. R₂Os₂O₇ pyrochlores, in which Os⁴⁺ has d⁴ electron count, provides a material playground to study the magnetism of d⁴ and effect of R³⁺-Os⁴⁺ interplay on the ground states. This series has only undergone limited studies, with the only published data investigating the lattice parameters and electrical resistivity at room temperature. In this talk, I will report our study on the magnetic, transport, thermodynamic, and structural properties of R₂Os₂O₇ pyrochlores.

¹Part of the work was supported by the CEM, and NSF MRSEC, under grant DMR-1420451

1:51PM T32.00012 Evolution of symmetry-broken states in the pseudogap regime of cuprates - the atomic structure footprints ¹, EMIL BOZIN, R. Zhong, K.R. Knox, Brookhaven National Laboratory, B.L. Winn, Oak Ridge National Laboratory, G.D. Gu, J.P. Hill, J.M. Tranquada, S.J.L. Billinge, Brookhaven National Laboratory — Revealing the nature of the symmetry broken states in strongly correlated electron systems in general, and in the pseudo-gap (PG) phase of cuprates in particular, is instrumental in understanding the underlying properties. To that effect the knowledge of the local atomic structure may reveal relevant details important for more comprehensive understanding of the character of symmetry broken states in strongly correlated electron systems. Atomic pair distribution function (PDF) is one of the few experimental methods that can speak to this problem. Mounting experimental evidence suggests that the pseudogap phase may represent an electronic state in which the four-fold rotational symmetry of the Cu₂O₂ planes is broken, pointing to stripe or nematic character. Systematic approach has been taken in charting both long and short range structural orders, on an equal footing, across the (x, T) phase diagrams of cuprates. For example, in La₂₋ₓBaₓCuO₄, by combining inelastic neutron scattering and neutron PDF approaches, we find evidence consistent with there being a dynamic symmetry breaking well above the charge ordering temperature and within the pseudogap regime. The response has non-monotonic doping dependence that peaks at 1/8 composition.

2:03PM T32.00013 Prediction of novel perovskite-type oxyhydride KTi(O₂H) with two-dimensional electronic states ¹, NOBUYA SATO, SHINJI TSUNEYUKI, Dept. of Phys., The Univ. of Tokyo — Perovskite-type oxides ABO₃ have been widely studied for their dielectricity. The properties of these materials significantly change by substituting A or B cations, while compositions of A and B cations are limited to (A²⁺, B⁴⁺) for charge neutrality. Recently, it has been demonstrated that oxygen anions in BaTiO₃ can be partially substituted with hydride ions (H⁻) suggesting that more varieties of compositions might be realized (e.g., (A¹⁺, B³⁺)) combined with oxygen substitution. In this work, using first-principles calculations, we investigate an unsynthesized model composition with the oxygen substitution, KTi(O₂H). This compound is expected to crystallize into the perovskite-type structure from its tolerance factor. We confirm its stability with the crystal structure optimization. The electronic properties reveal the two-dimensional low-energy electronic states within Ti–O–H planes. For its unconventional composition and the peculiar two-dimensional property, this material may realize novel electronic properties.

11:27AM T33.00002 Conformations of double stranded DNA: the effect of breathing bubbles
AIQUIN HUANG, ANIKET BHATTACHARYA, University of Central Florida — A double stranded DNA (dsDNA) is a natural semi-flexible biopolymer with persistence length \( \approx 50 \) nm, while a single stranded (ss) DNA is very flexible whose persistence length is one order of magnitude smaller (3-5 nm). Depending on the size of a polymer, the sequence and the end groups, the two strands in a dsDNA can locally denature into two single strands and form bubbles along the polymer chain, i.e. dsDNA exists in the form of a combination of double strands and single strands, exhibiting a heterogeneity of bending rigidity. In our study, we adopt a coarse grained model of dsDNA developed by Kim et al. [J. Y. Kim, J. H. Jeon, and W. Sung, J. Chem. Phys. 128, 055101 (2008)] and further improve it by incorporating excluded volume effect and sequence heterogeneity. In this model, a dsDNA is described as two semi-flexible chains paired with each other by hydrogen bonding. The stacking interaction is designed such that the persistence length of the paired chains interpalates 3 nm and 50 nm depending on the fraction of the melted pair base pairs. By performing Langevin dynamics simulation we study the bubble statistics as a function of temperature and sequence and how the bubbles affect local bending rigidity and the chain conformations. We compare our results with those from WLC model.

11:39AM T33.00003 Knots along DNA Confined in Nanochannels
C. BENJAMIN RENNER, MIT, LIANG DAI, SMART, PATRICK DOYLE, MIT — We study the size distribution of spontaneous knots on semiflexible chains confined in square channels using Monte Carlo simulations. The most probable knot size is shown to vary non-monotonically with the channel size. For knotted polymers confined in channels larger than the size of a knot in bulk, our analysis reveals that the metastable knot size in weak confinement is larger than the knot size in absence of confinement because the confinement free energy gained by shrinking the knot is lessened when the chain experiences the confinement of a channel. In the case of strong confinement, the metastable knot size is smaller than the knot size in the absence of confinement because the segments in the core of the knot experience more confinement free energy, and the channels pushes the segments outside of the core of the knot. We demonstrate that a simple theory can capture this non-monotonic behavior and quantitatively explain the metastable knot size as a function of the channel size. These results may have implications for tuning the channel size to either generate or screen knots.

11:51AM T33.00004 Protein dynamics from structural ensembles: Diffusive and activated contributions in a linear mode description
JEREMY COPPERMAN, MARINA GUENZA, University of Oregon — We have developed a coarse-grained linear Langevin equation for protein dynamics, which describes proteins as semiflexible objects collapsed into the free energy well representing the folded state of the protein. Fundamental to this approach is the inclusion of internal dissipation, absent in any rigid-body hydrodynamical modeling scheme. The normal mode analytical solution naturally separates into global modes describing the anisotropic tumbling of the object, and internal modes which contain both diffusive and activated glass-like contributions. We show how cooperativity in the dynamical modes is related to the energy barriers to mode diffusion. While molecular dynamics simulations generate the most accurate structural ensembles, we show how sets of NMR conformers can be used to generate the structural ensemble needed as input to the theory, making the approach truly predictive in nature. Results are in good agreement when compared with both nuclear magnetic resonance relaxation, and time correlation functions calculated from molecular dynamic simulations.

12:03PM T33.00005 Driven Polymer Translocation into a Crosslinked Gel, DAVID SEAN, GARY W. SLATER, University of Ottawa — In a typical polymer translocation setup, a thin membrane is used to separate two chambers and a polyelectrolyte is driven by an electric field to translocate from one side of the membrane to the other via a small nanopore. However, the high translocation rate that results from the forces required to drive this process makes optical and/or electrical analysis of the translocating polymer challenging. Using coarse-grained Langevin Dynamics simulations we investigate how the translocation process can be slowed down by placing a crosslinked gel on the trans-side of the membrane. Since the driving electric field is localized in the neighborhood of the nanopore, electrophoretic migration is only achieved by a “pushing” action from the polymer segment residing in the nanopore. For the case of a flexible polymer we find that the polymer fills the gel pores via multiple “herniation” processes, whereas for a semi-flexible chain in a tight gel there are no hernias and the polymer follows a smooth curvilinear path. Moreover, for the case of a semi-flexible polymer the gel makes the translocation process more uniform by reducing the acceleration at the end of the process.

12:15PM T33.00006 Backfolded Odijk regime for semiflexible polymers confined in nanochannels
ABHIRAM MURALIDHAR, University of Minnesota, DOUGLAS TREE, University of California Santa Barbara, KEVIN DORFMAN, University of Minnesota — The description of properties of DNA confined in a nanochannel with size close to its persistence length represents a major challenge to current theories. Accurate description of DNA in a nanochannel is essential for understanding many applications ranging from DNA translocation to genome mapping technology. We study the effect of channel confinement on DNA conformations using coarse-grained Langevin dynamics. Capturing the electrostatically-driven structural dependence is important for understanding many biological systems. Here, we use single molecule manipulation experiments to collect force-extension behavior on hyaluronic acid (HA), a polysaccharide which is a major component of the extracellular matrix in all vertebrates. By measuring HA elasticity in a variety of salt conditions, we are able to directly assess the contribution of electrostatics to the chain’s self-avoidance and local stiffness. Similar to recent results from a group on single-stranded nucleic acids, our data indicate that HA behaves as a swollen chain of electrostatic blobs, with blob size proportional to the solution Debye length. Our data indicate that the chain structure within the blob is not worm-like, likely due to long-range electrostatic interactions. We discuss potential models of this effect.

12:27PM T33.00007 Electrophoresis of a polyelectrolyte attached to a solid object: A strong influence of the attachment point
MYKKYA V. CHUBYSKYY, GARY W. SLATER, University of Ottawa — In some applications of electrophoresis, a polyelectrolyte (such as the DNA) is attached to an electrically neutral object of an irregular shape (e.g., a globular protein). Because of the hydrodynamic interactions (HI) between the polymer and the object, the amount by which the polymer is slowed down should depend on the shape of the object, especially near the attachment point, and not only on its drag coefficient. To study this effect, we compute the electrophoretic mobility of a short neutral tube closed at one end with a charged polymer attached to the closed end, either inside or outside the tube. Both the polymer and the tube are represented as sets of beads and the HI are pre-averaged. For a short polymer that would occupy only a small part of the tube, the mobility is much lower when the polymer is inside than when it is outside. The mobility ratio depends exponentially on the tube length and exceeds an order of magnitude already when the length of the tube equals its width. As the polymer size is increased and the coil size approaches the tube length, the mobility in the case of inside attachment starts to grow rapidly and then quickly approaches that in the case of outside attachment.

12:39PM T33.00008 Electrostatic effects on hyaluronic acid configuration
JOHN BEREZNEY, OMAR SALEH, University of California, Santa Barbara — In systems of polyelectrolytes, such as solutions of charged biopolymers, the electrostatic repulsion between charged monomers plays a dominant role in determining the molecular conformation. Altering the ionic strength of the solvent thus affects the structure of such a polymer. Capturing this electrostatically-driven structural dependence is important for understanding many biological systems. Here, we use single molecule manipulation experiments to collect force-extension behavior on hyaluronic acid (HA), a polyanion which is a major component of the extracellular matrix in all vertebrates. By measuring HA elasticity in a variety of salt conditions, we are able to directly assess the contribution of electrostatics to the chain’s self-avoidance and local stiffness. Similar to recent results from our group on single-stranded nucleic acids, our data indicate that HA behaves as a swollen chain of electrostatic blobs, with blob size proportional to the solution Debye length. Our data indicate that the chain structure within the blob is not worm-like, likely due to long-range electrostatic interactions. We discuss potential models of this effect.
1:15PM T33.00011 Molecular Dynamics study on the Micellization of Rhamnolipids. ELANGO MUNUSAMY, STEVEN D. SCHWARTZ, Department of Chemistry and Biochemistry, University of Arizona, Tucson, AZ 85721 — Oil spills have become one of the most serious environmental and ecological problems owing to the growth of oil exploitation, production and transportation. Millions of gallons of crude oil are released into the environment each year. Large volumes of surfactants are applied to the ocean as a remediation strategy. Environmental and toxicity issues arise when such a voluminous amounts of chemical surfactants are applied. One prospective solution to this problem is to use greener surfactants that possess excellent biodegradation and toxicity characteristics relative to existing classes of commonly used surfactants. In this context, we are interested in designing and developing greener surfactants that are patterned after naturally occurring glycolipids. In the present work, we concentrate on one of the more commonly studied glycolipid, rhamnolipid (Rha2C10). Despite the available experimental data, the molecular structure, shape and geometry of micelles formed by rhamnolipid is unknown. Molecular Dynamics (MD) simulations were performed to understand the aggregation behavior of rhamnolipids in aqueous solution and at air-water interface. All calculations were performed in NPT ensembles at 300 K using NAMD 2.8, a parallel code designed for high-performance simulation of large biological macromolecules where we use the CHARMM force field. The results obtained from MD simulations on the aggregation of rhamnolipids in water and at air-water interface will be presented.

1:27PM T33.00012 Combining Protein Dynamics and Aggregation Measurements, CURTIS MEUSE, NIST - Natl Inst of Stds & Tech — Infrared spectroscopy has long been used to deduce concentration and structural descriptions of proteins in a variety of static and time resolved experiments. We have developed an infrared order parameter to describe protein conformation variations around the average molecular value. Here we compare our parameter to other techniques including small angle scattering and atomic force microscopy measurements to clarify the characterization of protein structure and aggregation. By combining the information from our suite of methods, we explore the relationship between protein stability, dynamics and aggregation. Our focus is on developing new methods to compare the structure, dynamics and function of nearly identical biopharmaceutical protein ensembles. Examples include lysozyme, albumin cytchrome c and the characterization of amylod beta during aggregation.

1:39PM T33.00013 Wide Field Spectroscopy of Diffusing and Interacting DNA Using Tunable Nanoscale Geometries1, SHANE SCOTT, JASON LEITH, HUGO BRANDAO, SIMON SEHAYEK, ALEXANDER HOFKIRCHNER, JILL LAURIN, DANIEL BERAUD, ALEXANDER VERGE, PAUL WISEMAN, SABRINA LESLIE, McGill University — It remains an outstanding challenge to directly image interacting and diffusing biomolecules under physiological conditions. Many biochemical questions can be posed in the form: Does A interact with B? What are the energetics, kinetics, stoichiometry, and cooperativity of this interaction? To tackle this challenge, we use tunable nanoscale confinement to perform wide-field imaging of interacting DNA molecules in free solution, under an extended range of reagent concentrations and interaction rates. We present the integration of “Convex Lens-induced Confinement (CLIC)” microscopy with image correlation analysis, simultaneously suppressing background fluorescence and extending imaging times. The measured DNA-DNA interactions would be inaccessible to standard techniques but are important for developing a mechanistic understanding of life-preserving processes such as DNA transcription.

1 NSERC

1:51PM T33.00014 Observation of DNA dynamics near silicon nanopores by controlling the ultraviolet light spot, HIROHITO YAMAZAKI, SHINTARO ITO, KEIKO ESASHIKA, TOSHIHARU SAIKI, Keio University — Biopolymer translocation through a nanopore is an attractive phenomenon in the field of biophysics. When the voltage is applied through a nanopore, DNA coils thread into a nanopore by deforming its coil structure and recoil after translocation through a nanopore. Because DNA coil structure is relative with DNA translation, DNA dynamics near a nanopore have a correlation with DNA translocation. To investigate DNA dynamics, we developed the optical nanopore detection system, which has a capability to observe DNA dynamics near nanopore at sub-100-nm and sub-millisecond resolutions. Here, we report our experimental results of DNA dynamics near nanopores by controlling position of light spots. Because silica has high refractive index and extinction coefficient at ultraviolet light, the ultraviolet light creates z- and x-polarized light spot, which locate on nanopores and 50 nm apart from nanopores, respectively. By controlling light polarization, we observed different fluorescence intensity traces between z- and x-polarized light spot. The experimental results showed that fluorescence intensity trance of z-polarized light spot decayed faster than that of x-polarized light spot, which explain DNA dynamics near nanopores change by position from nanopores.

2:03PM T33.00015 Tension-induced binding of semiflexible biopolymers1, PANAYOTIS BENETATOS, Dept. of Physics, Kyungpook National University, Rep. of Korea, ALICE VON DER HEYDT, Inst. for Theoretical Physics, University of Gottingen, Germany, ANNETTE ZIPPELIUS, Inst. for Theoretical Physics at University of Gottingen and Max-Planck Inst. for Dynamics and Self-Organization, Germany — We investigate theoretically the effect of polymer tension on the collective behaviour of reversible cross-links. We use a model of two parallel-aligned, weakly-bending wormlike chains with a regularly spaced sequence of binding sites subjected to a tensile force. Reversible cross-links attach and detach at the binding sites with an affinity controlled by a chemical potential. In a mean-field approach, we calculate the free energy of the system and we show the emergence of a free energy barrier which controls the reversible (un)binding. The tension affects the conformational entropy of the chains which competes with the binding energy of the cross-links. This competition gives rise to a sudden increase in the fraction of bound sites as the polymer tension increases. The force-induced first-order transition in the number of cross-links implies a sudden force-induced stiffening of the effective stretching modulus of the polymers. This mechanism may be relevant to the formation and stress-induced strengthening of stress fibers in the cytoskeleton.

1 We acknowledge support by the Deutsche Forschungsgemeinschaft (DFG) via grant SFB-937/A1.

12:51PM T33.00009 Nuclear Pore Complex Protein Sequences Determine Overall Copolymer Brush Structure and Function?, DAVID ANDO, University of California, Merced, YONGWOOON KIM, KAIST, South Korea, ROYA ZANDI, University of California, Riverside, MICHAEL COLVIN, MICHAEL REXACH, AJAY GOPINATHAN, University of California, Merced — Disordered proteins are an interesting class of unfolded protein biopolymers which are functionally versatile. Their sequences are unconstrained by a structure-sequence relationship, and allow for a wide range of chemical and physical polymer properties. The Nuclear Pore Complex (NPC) contains over one hundred of such proteins (FG nups), which collectively function to regulate the exchange of all materials between the nucleus and cytoplasm. We perform coarse grained simulations of both individual FG nups and grafted rings of nups mimicking the in vivo geometry of the NPC, complemented with polymer brush modeling. Our results indicate that different regions or “blocks” of an individual FG nup can have distinctly different forms of disorder and that this property appears to be a conserved feature across eukarya. Furthermore, this block structure at the individual protein level is critical to the formation of a unique higher-order polymer brush architecture. The interactions between FG nups may be modulated by certain forms of transport factors, our results indicate that transitions between brush morphologies could play an important role in regulating transport across the NPC, suggesting novel forms of gated transport across membrane pores with wide biomimetic applicability.

Session T34 GERA DMP FIAP: Materials for Electrochemical Energy Storage I 210A -

11:15AM T34.00001 Vortex Stabilized Compressed Fusion Grade Plasma1. ADY HERSHCOVITCH, Brookhaven National Laboratory — Inertial confinement fusion schemes comprise of highly compressed dense plasmas. Some involve short pulses of powerful beams (lasers, particles) applied to solid pellets, while others utilize plasma focus to obtain dense pinch plasmas. Although compression factor >1000 has been achieved for starting pressures in the Torr range, the latter is limited by instabilities for initial gas density above 10 Torr. One alternative approach could be shooting electron beams through very dense, atmospheric pressure, vortex stabilized plasma. Large azimuthal magnetic generated by an electron beam can compress and heat the plasma to fusion viable parameters. This configuration is stable against sausage, kink, or beam – plasma instabilities. Based on experimental evidence beam propagation through the plasma is not be an issue. A second possibility is to tangentially squeeze a quasi-neutral plasma focus flow by a surrounding gas vortex. Based on currently available electron beams, the first scheme viability as an electrical power generating reactor does not seem to be promising. But using a plasma cathode electron beam that was developed a while ago, for which DOE has a patent U.S. Patent 4,942,339, could result in net generation of electricity. Calculations will be presented.

11:27AM T34.00002 High Thermal Conducting Boron Arsenide: Crystal Growth and Characterization2, BING LV, YUCHENG LAN, TcSUH and Department of Physics, Univ. of Houston, XIQU WANG, TcSUH and Department of Chemistry, Univ. of Houston, QIAN ZHANG, TcSUH and Department of Physics, Univ. of Houston, YONGJIE HU, Dept. of Mechanical Engineering, Massachusetts Institute of Technology, ALLAN J. JACOBSON, TcSUH and Department of Chemistry, Univ. of Houston, DAVID BROIDO, Department of Physics, Boston College, GANG CHEN, Dept. of Mechanical Engineering, Massachusetts Institute of Technology, ZHIFENG REN, CHING-WU CHU1, TcSUH and Department of Physics, Univ. of Houston — Intrigued by recent calculations [Phys. Rev. Lett. 111, 025901(2013)] which predict a remarkably high thermal conductivity of \( \sim 2,000 \text{ Wm}^{-1}\text{K}^{-1} \), comparable to that of diamond, in cubic boron arsenide (BAs) crystals, we have succeeded in synthesizing single crystals of BAs with a zinc blende structure and lattice parameters of \( a = 4.7830(7) \text{ Å} \) characterized by X-ray single crystal diffraction and transmission electron microscopy (TEM). A relatively high thermal conductivity is obtained but still smaller than the predicted value. We attribute the difference of thermal conductivity value to the defect scattering associated with crystal twinning and As vacancies, verified both from experimental evidence and theoretical calculations. The predicted super-thermal-conductivity may be achieved in BAs single crystals with further improvement of crystal growth by removing the defects.

11:51AM T34.00004 Evidence for Critical Energy for Ion Confinement in Magnetic Fusion Reactors, BOGDAN MAGLICH, TIM HESTER, DAN SCOTT, California Science & Engineering Corporation (CALSEC), CALSEC COLLABORATION — It is shown here that fusion test reactors could not ignite for half-a-century because trials were conducted at thermonuclear ion energies 10-30 KeV, an order of magnitude lower than critical energy [1-2], \( E_c \sim 200 \text{ KeV} \). At subcritical energies, plasma is destroyed by neutralization of ions via lookedover atomic (non-nuclear) charge transfer collisions with giant cross-section, \( 10^9 \text{ barns} \), 100 times greater than that for ionization collisions that counters neutralization. Neutral injection sets limit on ion magnetic confinement time \( <10^{-15} \text{ s vs. } >1 \text{ s} \) required for ignition. In contrast, at energies above \( E_c \), ionization prevails; near \( >1 \text{ MeV} \), stable confinement of 20 s was routinely observed [3] with charged injection. - To render ITER viable, ion energy must be increased to \( >1 \text{ MeV} \); neutral radioactive DT fuel replaced with charged, nonradioactive deuterium, giving rise to compact aneutronic reactor with direct conversion into RF power [4].

1[1] Physics Scripta, 23, 143 (1981);

12:03PM T34.00005 High Performance and Economic Supercapacitors for Energy Storage Based on Carbon Nanomaterials1, VLADIMIR SAMUULOVIĆ, BEHZAD FARSHID, ALEXANDER FRENKEL, Department of Materials Science and Engineering, Sensor CAT, State University of New York at Stony Brook, Stony Brook, NY 11794-2275, USA, SENSOR CAT AT STONY BROOK TEAM — We designed and manufactured very inexpensive prototypes of supercapacitors for energy storage based on carbon nanomaterials comprised of: reduced graphene oxide (RGO) and carbon nanotubes (CNTs) as electrodes filled with polymer gel electrolytes. The electrochemical properties of supercapacitors made using these materials were compared and analyzed. A significant tradeoff between the energy density and the power density was determined; RGO electrodes demonstrated the highest energy density, while composite RGO/CNT electrodes showed the highest power density. The thickness of the RGO electrode was varied to determine its effect on the power density of the supercapacitor and results showed that with decreasing electrode thickness power density would increase. The specific capacitances of over 600 F/g were observed.
12:15PM T34.00006 Nanoporous Hydrogen-Reduced BiVO$_4$: better charge separation with Ni-B, Electrocatalysts for Photoelectrochemical Water Oxidation, JIAYONG GAN, YUEBING ZHENG, Department of Mechanical Engineering, Materials Science and Engineering Program, and Texas Materials Institute, The University of Texas at Austin — Layered Li-excess Li$_2$MnO$_3$ has been of great interest for lithium-ion battery cathodes because of its high theoretical capacity. The compound is also an important component in Li$_2$MnO$_3$:1−x)LiMO$_2$ and other high-capacity cathode materials. It has been reported that Li$_2$MnO$_3$ can be made electrochemically active by acid leaching or charging to high voltages. Several different mechanisms have been proposed to explain its unconventional lithium extraction behavior, including one that involves oxidation at the oxygen site. In this talk, we will present a comprehensive computational approach based on first-principles hybrid density functional defect calculations, and illustrate how it helps uncover the defect physics and chemistry and the intrinsic mechanisms for delithiation and electronic and ionic conduction in layered Li$_2$MnO$_3$. In light of our results, we discuss the relevance of the proposed mechanisms and suggest solutions for improving the electronic conduction and hence the electrochemical performance of Li$_2$MnO$_3$ and related materials.

12:27PM T34.00007 Uncovering the intrinsic delithiation mechanism in Li-excess Li$_2$MnO$_3$ through defect calculations, KHANG HOANG, North Dakota State University — Layered Li-excess Li$_2$MnO$_3$ has been of great interest for lithium-ion battery cathodes because of its high theoretical capacity. The compound is also an important component in Li$_2$MnO$_3$:1−x)LiMO$_2$ and other high-capacity cathode materials. It has been reported that Li$_2$MnO$_3$ can be made electrochemically active by acid leaching or charging to high voltages. Several different mechanisms have been proposed to explain its unconventional lithium extraction behavior, including one that involves oxidation at the oxygen site. In this talk, we will present a comprehensive computational approach based on first-principles hybrid density functional defect calculations, and illustrate how it helps uncover the defect physics and chemistry and the intrinsic mechanisms for delithiation and electronic and ionic conduction in layered Li$_2$MnO$_3$. In light of our results, we discuss the relevance of the proposed mechanisms and suggest solutions for improving the electronic conduction and hence the electrochemical performance of Li$_2$MnO$_3$ and related materials.

12:39PM T34.00008 Bias-dependent local structure of water molecules at an electrochemical interface$^1$, LUANA PEDROZA, ICTP-SAIFR - Brazil, PEDRO BRANDIMARTE, University of Sao Paulo - Brazil, ALEXANDRE R. ROCHA, IFT-UNESP, Brazil, MARIVI FERNANDEZ-SERRA, Stony Brook University — Following the need for new - and renewable - sources of energy worldwide, fuel cells using electrocatalysts can be thought of as a viable option. Understanding the local structure of water molecules at the interfaces of the metallic electrodes is a key problem. Notably the system is under an external potential bias, which makes the task of simulating this setup difficult. A first principle description of all components of the system is the most appropriate methodology in order to advance understanding of electrochemical processes. There, the metal is usually charged. To correctly compute the effect of an external bias potential applied to electrodes, we combine density functional theory (DFT) and non-equilibrium Green's functions methods (NEGF), with and without van der Waals interactions. In this work, we apply this methodology to study the electronic properties and forces of one water molecule and water monolayer at the interface of gold electrodes. We find that the water molecule has a different torque direction depending on the sign of the bias applied. We also show that it changes the position of the most stable structure indicating that the external bias plays an important role in the structural properties of the interface.

12:51PM T34.00009 Effect of Transition Metal Ordering on the Electronic Properties of LiNi$_{1−x}$Co$_x$Mn$_2$O$_4$ Cathode Materials for Li-ion Batteries$^1$, ROBERTO LONGO, FANTAI KONG, SANTOSH KC, University of Texas at Dallas, USA, DONG-HEE YEON, JAEGU YOON, JIN-HWAN PARK, SEOK-KWANG DOO, Samsung Electronics, Republic of Korea, KYEONGJAE CHO, University of Texas at Dallas, USA, MSL TEAM, SAIT TEAM — Current Li-ion batteries use layered oxides as cathode materials, specially LiCoO$_2$ or LiNi$_{1−x}$Co$_x$Mn$_2$O$_4$ (NCM), and graphite as anode. Co alloyed oxides are taken from the high cost and toxicity of cobalt, together with certain instability at high operational temperatures. To overcome these difficulties, the synthesis of novel materials composed of layered oxides with different sets of Transition Metals (TM) has become the most successful way to solve the particular drawbacks of each single-oxide family. Although layered materials can deliver larger capacity than other families of cathode materials, the energy density has yet to be increased in order to match the expectations deposited on the NCM oxides. To acquire a high capacity, they need to be cycled at high operational voltages, resulting in voltage and capacity fading over a large number of cycles. In this work, we examine the phase diagram of the Li-Ni-Co-Mn-O system and the effect of TM ordering on the electronic properties of NCM cathode materials, using density-functional theory. Our findings will provide conceptual guidance in the experimental search for the mechanisms driving the voltage and capacity fading of the NCM family of cathode materials, in an attempt to solve such structural instability problems and, thus, improving the performance of the NCM cathode materials.

1:03PM T34.00010 Organic-inorganic hybrid lead iodide perovskite with zero-dipole-moment guanidinium (GA=[C(NH$_3$)$_3$])$^+$ cations: a Density Functional based analysis, GIACOMO GIORGI, Department of Chemical System Engineering, The University of Tokyo, JUN-ICHI FUJISAWA, HIROSHI SEGAWA, Research Center for Advanced Science and Technology, The University of Tokyo, KOICHI YAMASHITA, Department of Chemical System Engineering, The University of Tokyo — BiVO$_4$ photoanode material has attracted broad attention recently as an inexpensive and robust semiconductor for potential application for solar water oxidation. In comparison to pristine BiVO$_4$, the hydrogen-treated BiVO$_4$ (H-BiVO$_4$) show superior photocurrent and electron-hole separation yield of 0.95 at 1.23 V vs. reversible hydrogen electrode (RHE) due to enhanced carrier density and conductivity. Significantly, we adopt a layer of nickel-borate (Ni-B$_4$) complex on the BiVO$_4$ surface as an oxygen evolution catalyst. Modification of H-BiVO$_4$ photoanode with Ni-B$_4$ has yielded a large (∼300 mV) cathodic shift in the onset potential at pH 7. It shows an outstanding performance in the low bias region and the maximum power point for solar water oxidation was achieved at potential as low as 0.75 V vs. RHE with a photocurrent density of 2.25 mA/cm$^2$. We attribute these improved PEC performances to the enhanced charge separation, carrier density and conductivity in these photoanodes.

1:15PM T34.00011 Properties of adsorbed hydrogen films in nanospaces, ELMAR DOHNLKE, ANDREW GILLESPIE, PETER PFEIFER, University of Missouri Columbia — Various high surface area materials were evaluated for their gas storage properties. From supercritical hydrogen isotherms at 77 Kelvin, we estimated the adsorbed film densities, film thicknesses and intrapore gas densities. Intrapore gas density is a measurement of the average hydrogen density within a pore. Furthermore, we investigated the correlation between the isosteric heat of adsorption, surface chemistry, and pore size distribution with an adsorbed film. In most of the samples both saturated film densities and intrapore gas densities exceed the liquid hydrogen density at 1 bar and 20 Kelvin. The saturated film density surpassed it even by 40%. The adsorbed film seems to be independent of the isosteric heat of adsorption or the samples pore size distribution. They behave like a universal constant for all carbon-based surfaces.
1:27PM T34.00012 Pickering Emulsification to Mass Produce Nanoencapsulated Phase-change-material. XUEZHEN WANG, LECHENG ZHANG, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX, 77843-3122, USA, S. SAM MANNAN, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX, 77843-3122, USA, S. SAM MANNAN, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX, 77843-3122, USA, YING CHEN, Soft matter center, Guangdong Province Key Laboratory on Functional Soft Condensed Matter, School of materials and energy, Guangdong University of Tec, ZHENGDONG CHENG, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX, 77843-3122, USA. DR. CHENG'S GROUP TEAM — Phase changing materials (PCM) have useful applications in thermal management. However, mass production of micro and nano encapsulated PCM has been a challenge. Here, we present a simple and scalable method via a two-step Pickering emulsification method. We have developed interface active nanoparticles by asymmetric modification of nanoparticles of layered crystal materials. Nanoencapsulated PCM is realized with exfoliated monolayer nanoparticles surfactants using very little energy input for emulsification. Further chemical reactions are performed to convert the emulsions into core-shell structures. The resulted capsules are submicron in size with remarkable uniformity in size distribution. DSC characterization showed that the capssulation efficiency of NEPCM was 58.58% and was thermal stable which was characterized by the DSC data for the sample after 200 thermal cycling.

1:39PM T34.00013 Application of Henry’s Law for Binding Energies of Adsorbed Hydrogen. ANDREW GILLESPIE, ELMAR DOHNIKE, DAVID STALLA, MARK SWEANY, PETER PFEIFFER, University of Missouri — The method of isosteres is the simplest method used to calculate the differential enthalpy of adsorption. However, it is incredibly sensitive to the choice of model and respective fitting parameters. For a set of isotherms measured on a specific sample, most models converge upon a similar value at high coverage, but are inconsistent in the low pressure regime. In this talk, we investigate the application of various models for localized and mobile adsorption at low pressures in order to obtain binding energy of hydrogen to the adsorbent surface. Henry’s Law analysis of the Langmuir Model of adsorption yield binding energies in excellent agreement with those obtained from the Clausius Clapeyron relation.

11:15AM T36.00001 Chiral and helical superfluid in cold atom system. XIAOHUI LI, TINGPONG CHOY, TAI-KAI NG, The Hong Kong University of Science and Technology — Recently, a chiral spin superfluid has been proposed in weakly interacting boson systems [1]. In this work, we study the properties of bosonic superfluids in a cold atom system with two inequivalent band minima in momentum space related by time reversal symmetry. The system is mapped into an effective spinor-boson model. Without additional symmetries we show that in general there are two possible phases in this model, a ferromagnetic (easy axis) phase and a “x-y” (easy plane) phase. In the presence of nonzero k-space Berry curvature at the two band minima points, we show that the ferromagnetic state is “chiral” and the x-y state is “helical.” The bulk and edge properties of these states are studied where the similarities and differences between the present bosonic superfluids and the corresponding fermionic superconductors are pointed out.

11:27AM T36.00002 Interplay between Kondo screening and local singlets in $SU(N)$-symmetric cold atoms. LEONID ISAEV, ANA MARIA REY, JILA, NIST and Department of Physics, University of Colorado, Boulder, CO, USA — We study collective phenomena in strongly interacting fermionic alkaline-earth atoms (AEAs) loaded in an optical lattice. Owing to the strong decoupling between electronic orbital and nuclear-spin degrees of freedom, AEAs prepared in the two lowest electronic states are predicted to obey an accurate $SU(N > 2I + 1)$ symmetry in their two-body collisions ($I$ is the nuclear spin). The $SU(N)$ symmetric models offer a great opportunity to generate exotic many-body behavior emerging from the increased degeneracy and strict conservation laws. We focus on a parameter regime that realizes an $SU(N > 2)$ (Caoqblin-Schrieffer) generalization of the usual Kondo lattice model, and show that for band fillings above one atom per site, the system exhibits a peculiar interplay between Kondo screening and formation of singlets between localized atoms. In the limit of large Kondo coupling, we derive an effective Hamiltonian and determine its phase diagram. Our results can be tested in experiments with ultracold $^{173}$Yb or $^{87}$Sr atoms and are relevant for the physics of heavy-fermion materials with magnetic frustration.

11:39AM T36.00003 Chiral magnetism and spontaneous spin Hall effect of interacting Bose superfluids. XIAOPENG LI, STEFAN NATU, Univ of Maryland-College Park, ARUN PARAMEKANTI, University of Toronto — Recent experiments on ultracold atoms in optical lattices have synthesized a variety of tunable bands with degenerate double-well structures in momentum space. Such degeneracies in the single particle spectrum strongly enhance quantum fluctuations, and may lead to exotic many-body ground states. We consider weakly interacting spinor Bose gases in such bands, and discover a universal quantum “order by disorder” phenomenon which selects a novel chiral spin superfluid with remarkable properties such as spontaneous anomalous spin Hall effect and momentum space antiferromagnetism. For bosons in the excited Dirac band of a hexagonal lattice, such a state supports staggered spin loop currents in real space. We show that Bloch oscillations provide a powerful dynamical route to quantum state preparation of such a chiral spin superfluid. Our predictions can be readily tested in spin resolved time-of-flight experiments.

11:51AM T36.00004 Engineering Ferromagnetism with Shaken Optical Lattices1, COLIN PARKER.
University of Chicago — Conventional methods of quantum simulation rely on kinetic energy determined by free particle dispersions or simple sinusoidal optical lattices. Solid state systems, by contrast, exhibit a plethora of band structures which differ quantitatively, qualitatively, and even topologically. To what extent does this variety explain the many electronic phenomena observed in these materials? Here we address this question by subjecting an otherwise simple Bose superfluid to a customized band structure engineered by dynamically phase modulating (shaking) an optical lattice. The engineered dispersion contains two minima which we associate with a pseudospin degree of freedom. Surprisingly, in such a system the Bose superfluid exhibits many new behaviors. The pseudospin develops a ferromagnetic order, which can lead to polarization of the entire sample or to sub-division into polarized domains. The excitations of the system also exhibit the roton-maxon structure associated with strong interactions in superfluid helium. I will also discuss recent progress on engineering further exotic behavior.

12:27PM T36.00005 Weyl Superfluidity in a Three-dimensional Dipolar Fermi Gas, BO LIU,
Department of Physics and Astronomy, University of Pittsburgh, XIAOPENG LI, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, LAN YIN, School of Physics, Peking University, W. VINCENT LIU, Department of Physics and Astronomy, University of Pittsburgh & Wilsen Quantum Center, Zhejiang University of Technology — Weyl superconductivity or superfluidity, a fascinating topological state of matter, features novel phenomena such as emergent Weyl fermionic excitations and anomalies. Here we report that an anisotropic Weyl superfluid state can arise as a low temperature stable phase in a 3D dipolar Fermi gas. A crucial ingredient of our model is a direction-dependent two-body effective attraction generated by a rotating external field. Experimental signatures are predicted for cold gases in radio-frequency spectroscopy. The finite temperature phase diagram of this system is studied and the transition temperature of the Weyl superfluidity is found to be within the experimental scope for atomic dipolar Fermi gases. Work supported in part by U.S. ARO, AFOSR, DARPA-OLE-ARO, Charles E. Kaufman Foundation and The Pittsburgh Foundation, JQI-NSF-PFC, ARO-Atomtronics-MURI, and NSF of China.

12:39PM T36.00006 Spin liquid phases of large spin Mott insulating ultracold atoms, TODD C. RUTKOWSKI, Binghamton Univ, MICHAEL J. LAVALER, Binghamton Univ, Cornell Univ — Understanding exotic forms of magnetism, primarily those driven by large spin fluctuations such as the quantum spin liquid state, is a major goal of condensed matter physics. But, the relatively small number of viable candidate materials poses a difficulty. We believe this problem can be solved by Mott insulating ultracold atoms with large spin moments that interact via whole-atom exchange. The large spin fluctuations of this exchange could stabilize exotic physics similar to condensed matter systems, all in an extremely tunable environment. We have approached the problem by performing a mean field theory for spin-f bosons in an optical lattice which is exact in the large-f limit. This setting is similar to that of SU(N) magnetism proposed for alkali-earth atoms but without the SU(N) symmetry. We find that states with long-range order, such as the spin nematic phase of f = 1 Na atom, become highly entangled spin-liquid-like states for f = 3 Cr atoms. This is evidence that the magnetic phase diagram for Mott insulating atoms at larger spins generically contains exotic forms of magnetism.

12:51PM T36.00007 Superfluid-insulator transition in a fermionic optical superlattice, RUBEM MONDAINI, The Pennsylvania State University, PREDRAG NIKLIC, George Mason University, MARCOS RIGOL, The Pennsylvania State University — Despite some of the high-temperature superconductivity properties can be expected in clean and simple cold-atom systems, attempts to simulate the d-wave pairing of cuprates with cold atoms is difficult because the required temperatures are much lower than what is experimentally feasible today. However, the “pseudogap” physics of s-wave pairing is far more accessible. In this paper we consider a simple Mott insulator of tightly bound Cooper pairs as an s-wave analogue of a pseudogap state. The XY transition to a superfluid and the crossover to a band-insulator (conventional unpaired state) in the phase diagram are the phenomena that give this Mott insulator a similar role to the pseudogap of cuprates. We numerically investigate this transition of locally attractive fermions at half-filling and T = 0 in the presence of a checkerboard potential in two dimensions, using quantum Monte Carlo and exact diagonalization. We can identify that it belongs to (2+1)-XY universality class similarly to the superfluid-normal transition in hard-core bosons. Moreover, we show a crossover of charge excitations, in finite systems, from a fermionic to bosonic character when the attraction between the fermions is increased.

1:03PM T36.00008 Spin Liquid Condensate of Spinful Bosons, BIAO LIAN, SHOUCHENG ZHANG, Stanford Univ — We introduce the concept of a bosonic spin liquid condensate (SLC), where spinful bosons in a lattice form a zero-temperature spin disordered charge condensate that preserves the spin rotation symmetry, but breaks the U(1) symmetry due to a spinless order parameter with charge one. It has an energy gap to the spin excitations, and shows many features of SLC. Here we show this SLC shows many behaviors of spin-1/2 fermions. In particular, we analyze the SLC phase diagram in the spin 1/2 case using a mean-field variational wave function method. We show that the SLC shows many new behaviors of spin-1/2 fermions in SLC.

1:15PM T36.00009 Ultracold Molecules in Crystals of Light: A Highly Tunable System for Exploring Novel Materials, Quantum Dynamics, and Quantum Complexity1, LINCOLN CARR, KENJI MAEDA, Colorado Sch of Mines, MICHAEL L. WALL, JILLA, NIST and U. Colorado Boulder — Ultracold molecules trapped in optical lattices present a new regime of physical chemistry and a new state of matter: complex dipolar matter. Such systems open up the prospect of tunable quantum complexity. We present models for the quantum many-body statics and dynamics of present experiments on polar bi-alkali dimer molecules. We are developing Hamiltonians and simulations for upcoming experiments on dimers beyond the alkali metals, including biologically and chemically important naturally occurring free radicals like the hydroxyl free radical (OH), as well as symmetric top polyatomic molecules like methyl fluoride (CHF3). These systems offer surprising opportunities in modeling and design of new materials. For example, symmetric top polyatomics can be used to study quantum molecular magnets and quantum liquid crystals. We use matrix-product-state (MPS) algorithms, supplemented by exact diagonalization, variational, perturbative, and other approaches. MPS algorithms not only produce experimentally measurable quantum phase diagrams but also explore the dynamical interplay between internal and external degrees of freedom inherent in complex dipolar matter. We maintain open source code (openTEBD and openMPS) available freely and used widely.

1:27PM T36.00010 Spontaneous quantum Hall effect in an atomic spinor Bose-Fermi mixture, ZHI-FANG XU, University of Pittsburgh, XIAOPENG LI, Univ of Maryland-College Park. PETER ZOLLER, University of Innsbruck, W. VINCENT LIU, University of Pittsburgh — We study a mixture of spin-1 bosonic and spin-1/2 fermionic cold atoms, e.g., Rb-87 and Li-6 confined in a triangular optical lattice. With fermions at 3/4 filling, Fermi surface nesting leads to spontaneous formation of various spin textures of bosons in the ground state, such as collinear, coplanar and even non-coplanar spin orders. The phase diagram is mapped out with varying boson tunneling and Bose-Fermi interactions. Most significantly, in one non-coplanar state the mixture is found to exhibit spontaneous quantum Hall effect in fermions and crystalline superfluidity in bosons, both driven by interaction.

[1] C. Senko, P. Richerme, J. Smith, A. Lee, I. Cohen, A. Retzker, and C. Monroe. “Experimental Realization of a Quantum Integer-Spin Chain with Controllable Chain should be experimentally realizable in a recently developed trapped-ion quantum simulator [1]. Our work will enable further study of various topological algorithms, and is also consistent with analytical calculations using renormalization group theory. The topological phase of this long-range interacting spin-1 chain should be experimentally realizable in a recently developed trapped-ion quantum simulator [1]. Our work will enable further study of various topological phases under the presence of long-range interactions.

MAD MAGHREBI, MICHAEL FOSS-FEIG, ALEXEY GORSHKOV, Joint Quantum Institute, NIST/University of Maryland — Topological phases of matter, including symmetry protected topological phases, typically require the underlying many-body system to possess only short-range interactions, such that the notion of locality is well defined. Whether various topological phases can survive in the presence of long-range interactions, however, is largely unknown. Here we show that a paradigmatic example of a symmetry protected topological system, known as the spin-1 Haldane chain, surprisingly remains in its topological phase under arbitrary algebraically-decaying long range interactions. Our conclusion is supported by strong numeric evidence using variational Matrix Product State (vMPS) algorithms, and is also consistent with analytical calculations using renormalization group theory. The topological phase of this long-range interacting spin-1 chain should be experimentally realizable in a recently developed trapped-ion quantum simulator [1]. Our work will enable further study of various topological phases under the presence of long-range interactions.

2:03PM T36.00013 Stoner ferromagnetism in a thermal pseudospin-1/2 Bose gas, JURAJ RADIC, STEFAN NATU, VICTOR GALITSKI, Joint Quantum Institute, NIST/University of Maryland — We compute the finite-temperature phase diagram of a pseudospin-1/2 Bose gas with contact interactions, using two complementary methods: the random phase approximation and self-consistent Hartree-Fock theory. We show that the spin-dependent interactions, which break the (pseudo) spin-rotational symmetry, generally lead to the appearance of a magnetically ordered phase at temperatures above the superfluid transition. In three dimensions, we predict a normal easy-axis/easy-plane ferromagnet for sufficiently strong repulsive/attractive inter-species interactions respectively. The normal easy-axis ferromagnet is the bosonic analog of Stoner ferromagnetism known in electronic systems. For the case of inter-species attraction, we also discuss the possibility of a bosonic analogue of the Cooper paired phase. This state is shown to significantly lose in energy to the transverse ferromagnet in three dimensions, but is more energetically competitive in lower dimensions. Extending our calculations to a spin-orbit-coupled Bose gas with equal Rashba and Dresselhaus-type couplings (as recently realized in experiment), we investigate the possibility of stripe ordering in the normal phase. Within our approximations however, we do not find an instability towards stripe formation.

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T37 GQI: Focus Session: Semiconductor Qubits - Optically Addressed Dots and Impurities II 212A - Danny Kim, HRL Laboratories, LLC

11:15AM T37.00001 All-optical coherent control of energy transfer between a quantum dot and a cavity mode, TAO CAI, RANOJOY BOSE, KAUSHIK CHOUDHURY, Department of Electrical Engineering, University of Maryland, College Park, GLENN SOLOMON, Joint Quantum Institute, University of Maryland, College Park and National Institute of Standards and Technology, Gaithersburg, EDO WAKS, Department of Electrical Engineering, University of Maryland, College Park — Here we demonstrated all-optical coherent control of energy transfer in a quantum dot strongly coupled to a photonic crystal molecule at optical frequency. The photonic crystal molecule comprises two photonic crystal cavities, supporting a pair of strongly coupled normal modes. One of the modes strongly couples with a quantum dot and the other induces a cavity enhanced a.c. Stark shift to rapidly tune the quantum dot resonance on timescales much shorter than the vacuum Rabi period of the strongly coupled dot-cavity system. The quantum dot initially detunes from the cavity mode. By tuning the quantum dot onto resonance with the cavity mode on picosecond timescales, we achieved coherent transfer of energy between a quantum dot and the cavity mode through vacuum Rabi oscillation. We investigated the energy transfer as a function of stark laser power to confirm the coherence of the energy transfer process. We further demonstrated coherent control of light-matter states by implementing a Ramsey-type experiment. These results pave the path for achieving gigahertz controlled generation of quantum states of light and synthesis of photon wavefunctions using integrated semiconductor nano-photonic platform.

11:27AM T37.00002 Control of the cavity reflectivity using a single quantum dot spin, SHUO SUN, HYOCHUL KIM, Univ of Maryland-College Park, GLENN SOLOMON, NIST, EDO WAKS, Univ of Maryland-College Park — The implementation of quantum network and distributive quantum information processing relies on interaction between stationary matter qubits and flying photons. The spin of a single electron or hole confined in a quantum dot is considered as promising matter qubit as it possesses microsecond coherence time and allows picosecond timescale control using optical pulses. The quantum dot spin can also interact with a photon by controlling the optical response of a strongly coupled cavity. Yet all the experimental demonstrations of the cavity spectrum control have used neutral dots. The spin-dependent cavity spectrum for a strongly coupled charged quantum dot and cavity system has not been reported. Here, we report an experimental realization of a spin-photon interface using a strongly coupled quantum dot and cavity system. We show large modulation of the cavity reflection spectrum by manipulating the spin states of the quantum dot. The spin-photon interface is crucial for realizing a quantum logic gate or generating hybrid entanglement between a quantum dot spin and a photon. Our results represent an important step towards semiconductor based quantum logic devices and on-chip quantum networks.
11:39AM T37.0003 Optical Control of Semiconductor Quantum Dot Spin Qubits with Microcavity Exciton-Polaritons , SHRUTI PURI1, PETER L. McMAMON, Ginzton Laboratory, Stanford University, YOSHISUI YAMAMOTO2, Ginzton Laboratory, Stanford University and National Institute of Informatics, Tokyo — The work being presented was carried out at Stanford University. Currently the author is at University of Sherbrooke, Canada

11:51AM T37.0004 Explorations with a new qubit system: Exchange Interactions between Quantum Dot Spin Qubits and Quantum Well Excitons1, PETER McMAMON, Stanford University - Ginzton Lab — In this talk I will present some of our recent work on constructing and optically investigating nanostructures consisting of quantum dots coupled to a nearby quantum well, all embedded in a planar microcavity. The overall goal of this line of work is to develop a platform in which long-range (∼1 micron) two-qubit interactions between quantum dots are possible, following the pioneering proposal of Piermarocchi, Chen, Sham, and Steel (Phys. Rev. Lett. 89 (16) 167402 [2002]). We have succeeded in demonstrating several fundamental aspects of this platform. We have realized a coupled exciton-dot–quantum–well system in a microcavity, and show that quantum dots in this system can be charged (allowing the storage of a spin qubit), and show that both the quantum dots and the quantum well retain favourable optical properties. Most importantly, we have fairly strong evidence suggesting that the operative mechanism of the theoretical proposals, the spin-dependent exchange interaction, is achievable, and an exciton in the quantum well, is observable, and can be engineered to be of the magnitude required for the implementation of universal quantum gate and state manipulation operations. I will discuss these results, and highlight other recent work on site-controlled quantum dots, including with quantum dots in positioned nanowires.

12:27PM T37.0005 Proposed method of optical spin read-out in a quantum dot using the AC Stark effect, EDWARD FLAGG, GARY LANDER, CABOT ZABRISKIE, West Virginia University — We propose a method to read-out the spin-state of a single electron trapped in a quantum dot via a cycling transition induced by the AC Stark effect. Optical spin initialization and manipulation are allowed by a magnetic field in the Voigt configuration, which modifies the polarization selection rules of the transitions. The lack of a cycling transition in the Voigt configuration, however, makes read-out of the spin-state very difficult. We show that cycling transitions can be made possible by a red-detuned, circularly-polarized laser, which modifies the spin eigenstates and polarization selection rules via the AC Stark effect.

12:39PM T37.0006 Ground state initialization in a doubly-charged, vertically-stacked InAs quantum dot molecule1, AARON ROSS, COLIN CHOW, Department of Physics, University of Michigan, LU SHAM, University of California San Diego, ALLAN BRACKER, DANIEL GAMMON, Naval Research Laboratory, DUNCAN STEEL, Department of Physics, University of Michigan — We report on the rapid optical initialization of a subset of the two-electron ground states of a self-assembled, vertically stacked InAs quantum dot molecule, where the states of the electron are approximately localized to separate quantum dots with very little spatial overlap. Four eigenstates, a singlet and three triplets (S, T0, T−1, T−2), arise from the exchange coupling and are identified via bias-dependent photoluminescence measurements. The degeneracy of the triplet states is lifted using an in-plane magnetic field (Voigt geometry). This allows for the determination of the in-plane electron and hole g-factors by differential transmission in the Voigt configuration, however, makes read-out of the spin-state very difficult. We show that optical spin initialization and manipulation can be possible by a red-detuned, circularly-polarized laser, which modifies the spin eigenstates and polarization selection rules via the AC Stark effect.

12:51PM T37.0007 Nuclear Spin Locking and Extended Two-Electron Spin Decoherence Time in an InAs Quantum Dot Molecule1, COLIN CHOW, AARON ROSS, DUNCAN STEEL, H. M. Randall Laboratory of Physics, University of Michigan - Ann Arbor, L. J. SHAM, Department of Physics, University of California - San Diego, ALLAN BRACKER, DANIEL GAMMON, Naval Research Laboratory, Washington DC — The spin eigenstates for two electrons confined in a self-assembled InAs quantum dot molecule (QDM) consist of the spin singlet state, S, with J = 0 and the triplet states T−1, T0 and T+1, with J = 1. When a transverse magnetic field (Voigt geometry) is applied, the two-electron system can be initialized to the different states with appropriate laser excitation. Under the excitation of a weak probe laser, non-Lorentzian lineshapes are allowed by a magnetic field in the Voigt configuration, which modifies the polarization selection rules of the transitions. The lack of a cycling transition in the Voigt configuration, however, makes read-out of the spin-state very difficult. We show that cycling transitions can be made possible by a red-detuned, circularly-polarized laser, which modifies the spin eigenstates and polarization selection rules via the AC Stark effect.

1:03PM T37.0008 Quantum Dot Molecule Polaritons and a Voltage-Tunable Vacuum Rabi Splitting, PATRICK VORA, George Mason University, ALLAN BRACKER, SAMUEL CARTER, Naval Research Laboratory, MIJIN KIM, Sotera Defense Solutions, Inc., CHUL SOO KIM, SOPHIA ECONOMOU, DANIEL GAMMON, Naval Research Laboratory — InAs quantum dots (QDs) are a popular system for realizing quantum information protocols and studying cavity-QED. An additional class of optical transitions can be accessed by using quantum dot molecules (QDMs); a pair of tunnel-coupled QDs. Recombination can occur within one of the QDs (intradot) or across the tunnel barrier (intertot). Intertot transitions are typically weaker due to reduced wavefunction overlap. Recently, our team embedded a QDM within a GaAs photonic crystal cavity and demonstrated photonic enhancement of a singlet-triplet qubit. Here, we realize a strongly-coupled cavity-QDM system and demonstrate cavity-QED effects inaccessible in single QDs. These include the first observation of molecular polaritons in InAs QDs and a voltage-tunable vacuum Rabi splitting (2γ). The tunable vacuum Rabi splitting can only occur in QDMs and provides an advantage as s is typically fixed post-fabrication. This flexibility could be useful for optical signal processing schemes that exploit the anharmonicity of the Jaynes-Cummings ladder.
1:15PM T37.00009 Screening nuclear field fluctuations to generate highly indistinguishable photons from negatively charged self-assembled InGaAs quantum dots , RALPH MALEIN, TEO SANTANA, JOANNA ZAJAC, Heriot Watt University, PIERRE PETROFF, University of California Santa Barbara, BRIAN GERARDOT, Heriot Watt University — Quantum dots (QDs) can generate highly coherent and indistinguishable single photons. However, a ground-state electron spin interacts with a QD’s nuclear spins to create an effective Overhauser field ($\delta B_n$) of $\sim$30mT. We probe this interaction using resonance fluorescence. We observe the effect of $\delta B_n$ in high resolution (27 MHz) spectroscopy of the elastic and inelastic scattered photons, and characterize the effect of $\delta B_n$ on photon indistinguishability by monitoring the visibility of two-photon interference. With no external magnetic field ($B_z = 0$), $\delta B_n$ effectively splits the ground state, and at low Rabi frequencies we observe two broad ($\Gamma = 200$ MHz) peaks equally spaced by $\sim$100MHz from the central elastic peak. The ratio of elastic to inelastic photons in the spectra gives a dephasing time $T_2 = 0.52T_1 = 400$ps, far from the transform limit. With an external field $B_z > \delta B_n$, we can successfully screen the fluctuating nuclear field. For $B_z = 300$ mT, nearly all photons in the spectrum are elastically scattered and we extract $T_2 = 1.94T_1 = 1512$ps. This transform limited linewidth enables us to demonstrate very high visibility two-photon interference. These results point towards robust generation of indistinguishable photons.

1:27PM T37.00010 Optical Hyperpolarization of Donor Electron Spins in Silicon Using a Widely-Tunable DBR Laser , BRENDON ROSE, Department of Electrical Engineering, Princeton University, GARY WOLFOVICZ, London Centre for Nanotechnology, University College London, ALEXEI TYRYSHKIN, Department of Electrical Engineering, Princeton University, MICHAEL THEWALT, Department of Physics, Simon Fraser University, KOHEI ITOH, School of Fundamental Science and Technology, Keio University, Japan, JOHN MORTON, London Centre for Nanotechnology, University College London, STEPHEN LYON, Department of Electrical Engineering, Princeton University — We report on measurements of isotopically enriched silicon samples (45 ppm Si-29) with very low donor densities (1e12-1e14 cm$^{-3}$). Pushing the donor density limit necessitates optimizing the experimental sensitivity and enhancing spin polarization. Donor spin polarization greater than Boltzmann (hyperpolarization) can be established by optically exciting the no-phonon bound exciton transitions followed by Auger recombination. We established significant donor spin hyperpolarization with a distributed Bragg reflector laser, tunable across all donors including P-31 and Bi-209. For phosphorus doped silicon we observed combined electron-nuclear spin polarizations of 100%-200% depending on donor density. For bismuth donors at a clock transition ($B_z = 80.6$ mT), we observed about 50% spin polarization, and 500% away from the clock transition. This increase in spin polarization allows for single shot measurement of low density samples ($4e12$ P/cm$^3$, and $1e14$ Bi/cm$^3$).

1:39PM T37.00011 Hybrid optical-electrical detection of donor electron spins with bound excitons in silicon , C. C. LO, M. URDAMPILLET, P. ROSS, University College London , M. F. GONZALEZ-ZALBA, Hitachi Cambridge Laboratory, J. MANSIR, University College London, S. A. LYON, Princeton University, M. L. W. THEWALT, Simon Fraser University, J. J. L. MORTON, University College London — Electrical detection of spin resonance is a powerful technique for understanding the dynamics of spins in semiconductors. For electrons bound to shallow donors in silicon, thus far it has been demonstrated by coupling donors to spin readout partners, such as paramagnetic defects or conduction devices, which fundamentally limit the donor coherence times. Here we demonstrate electrical detection of donor bound excitons in a silicon device, and show that the spin-selective bound exciton transition can be exploited for the electrical detection of coherent spin manipulation of isolated donors. We use this method to measure electron spin Rabi oscillations, and we are able to obtain long intrinsic electron spin coherence times, limited only by the donor concentration. Furthermore, we address critical issues for adopting such a hybrid optical-electrical detection scheme for single spin detection in silicon nanodevices, laying the foundations for realizing a versatile readout method for single spin readout with relaxed magnetic field and temperature requirements compared with spin-dependent tunneling. [arXiv:1411.1324]

1:51PM T37.00012 Nearly degenerate light- and heavy-hole trions bound to isoelectronic centers , GABRIEL ETHEIER-MAJCHER, PHILIPPE ST-JEAN, SEBASTIEN FRANCOEUR, Polytechnique Montreal — Many optical quantum control schemes of spin qubits in semiconductors rely on the existence of trion states. In this work, we investigate the fine structure of negative trions bound to isoelectronic centers formed from a pair of nitrogen isovalent impurities in GaAs, which represent interesting candidates for optical quantum information processing. Using optical polarization resolved microluminescence, we find that the fine structure is composed of two unpolarized lines, characteristic of light- and heavy-hole trion states, evolving into two quadruplets under a longitudinal magnetic field. The availability of both light- and heavy-hole states on the same trion could lead to new powerful optical quantum control schemes where both spin initialization and single-shot readout could be conveniently realized.

2:03PM T37.00013 Initialization of a hole spin bound to an isoelectronic center , PHILIPPE ST-JEAN, GABRIEL ETHEIER-MAJCHER, SEBASTIEN FRANCOEUR, Polytechnique Montreal — Hole spins are promising candidates for solid-state qubits because they interact weakly with nuclear spins, leading to long relaxation and coherence times. In this work, we demonstrate the ability to optically initialize a single hole spin bound to an isoelectronic center, which is an atomic defect formed from a small number of isovalent impurities in a semiconductor host. Using time-resolved magneto-photoluminescence of a positive trion bound to a Te dyad in ZnSe, we measured the degree of polarization of the emission under various conditions of excitation and magnetic field. Under non-resonant excitation, the trion emission is partially polarized and becomes completely unpolarized under a longitudinal magnetic field. In contrast, resonant excitation of the heavy-hole valence band of the ZnSe host leads to highly polarized emission, implying that the hole has been initialized in a known spin state.

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T38 GQI: Quantum Characterization and Tomography 212B - Joshua Combes, Perimeter Institute

11:15AM T38.00001 Iterated benchmarking to separate unitary errors from decoherence$^1$, LEV BISHOP, SARAH SHELDON, STEFAN FILIPP, MATTHIAS STEFFEN, JERRY M. CHOW, JAY M. GAMBITTA, IBM TJ Watson Research Center, Yorktown Heights, NY, USA — We describe a scalable experimental protocol for estimating the relative contribution of unitary errors and decoherence to the fidelity of individual quantum gates. As an extension to interleaved randomized benchmarking (Magesan PRL 109, 080505 2012), this protocol consists of interleaving random Clifford gates between $n$-fold repetitions of the gate of interest. The type of error is revealed by the scaling with number of repetitions: linear in the case of errors due to decoherence; quadratic in the case of pure unitary errors. This protocol has recently been implemented experimentally for transmon superconducting qubits and found useful for calibrating microwave pulses as well as identifying new error sources that may be affecting gate fidelity.

11:27AM T38.00002 Non-Markovianity in Randomized Benchmarking , HARRISON BALL, ARC Centre for Engineered Quantum Systems, School of Physics, The University of Sydney, NSW 2006 Australia, TOM M. STACE, ARC Centre for Engineered Quantum Systems, University of Queensland, Brisbane 4072, Australia, MICHAEL J. BIERCUK, ARC Centre for Engineered Quantum Systems, School of Physics, The University of Sydney, NSW 2006 Australia — Randomized benchmarking is routinely employed to recover information about the fidelity of a quantum operation by exploiting probabilistic twirling errors over an implementation of the Clifford group. Standard assumptions of Markovianity in the underlying noise environment, however, remain at odds with realistic, correlated noise encountered in real systems. We model single-qubit randomized benchmarking experiments as a sequence of ideal Cliffords operations interleaved with stochastic dephasing errors, implemented as unitary rotations about $\sigma_z$. Successive error rotations map to a sequence of random variables whose correlations introduce non-Markovian effects emulating realistic colored-noise environments. The Markovian limit is recovered by turning off all correlations, reducing each error to an independent Gaussian-distributed random variable. We examine the dependence of the statistical distribution of fidelity outcomes on these noise correlations, deriving analytic expressions for probability density functions and related statistics for relevant fidelity metrics. This enables us to characterize and bear out the distinction between the Markovian and non-Markovian cases, with implications for interpretation and handling of experimental data.

11:39AM T38.00003 Hyperaccuracy and Error Scaling in Gate Set Tomography1, KENNETH RUDINGER, ERIK NIELSEN, JOHN KING GAMBLE, ROBIN BLUME-KOHOUT, Sandia National Laboratories — Standard quantum tomographic procedures are limited in their usefulness by errors in the prior knowledge of the implemented POVMs and prepared states. Gate set tomography (GST) is a tomographic framework introduced to solve this problem of self-referential calibration [arXiv:1310.4492]. GST seeks to simultaneously and self-consistently characterize the set of implemented gates, prepared states, and POVMs. This talk will provide detailed analysis of imperfections in GST-based estimations. From simulations, we establish 1) lower bounds on the experimental resources required to ensure that GST will provide a reliable and useful estimate of the gates, and 2) the scaling of GST’s accuracy with number of samples per experiment, maximum length of experiment, and rate of incoherent error. These results demonstrate that GST can be far more accurate than standard tomography. Lastly we show (from both simulations and experiments) that experiment-by-experiment $\chi^2$ tests are extremely effective at diagnosing inconsistencies in the model caused by non-Markovian noise.

11:51AM T38.00004 Gate Set Tomography on a trapped ion qubit, ERIK NIELSEN, ROBIN BLUME-KOHOUT, JOHN GAMBLE, KENNETH RUDINGER, JONATHAN MIKRACHI, JOHATHAN STERK, PETER MAUNZ, Sandia National Laboratories — We present enhancements to gate-set tomography (GST), which is a framework in which an entire set of quantum logic gates (including preparation and measurement) can be fully characterized without need for pre-calibrated operations. Our new method, “extended Linear GST” (eLGST) uses fast, reliable analysis of structured long gate sequences to deliver tomographic precision at the Heisenberg limit with GST’s calibration-free framework. We demonstrate this precision on a trapped-ion qubit, and show significant (orders of magnitude) advantage over both standard process tomography and randomized benchmarking. This work was supported by the Laboratory Directed Research and Development (LDRD) program at Sandia National Laboratories. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under Contract DE-AC04-94AL85000.

12:03PM T38.00005 Gate Set Tomography of a 3D Transmon Qubit, YUDAN GUO, Dept. of Physics, Reed College, SERGEY NOVIKOV, Dept. of Physics, University of Maryland-College Park, DANIEL GREENBAUM, ANDREW SKINNER, Altamira Technologies Corporation, B.S. PALMER, Lab. for Physical Sciences — Quantum gate set tomography is a recently developed tool for characterizing quantum gates that does not suffer from the inaccuracies inherent in standard quantum process tomography. We present the results of a gate set tomography (GST) experiment done on a superconducting 3D transmon qubit. $\pi$ and $\pi/2$ rotations over the $x$- and $y$-axes were used as the initial calibrated gates. We performed linear inversion on data from a 4-fiducial experiment to obtain an initial tomographic estimate, which was then used as the starting point for a maximum likelihood procedure. The calibrated gates all achieved fidelity above 98%, which was further verified by randomized benchmarking. The robustness of GST was also examined by introducing errors deliberately. We show that GST with maximum likelihood estimation is able to discern errors due to a mixed initial state, as well as due to a tilted rotation axis in our gate operation.

12:15PM T38.00006 Self-consistent verification of quantum measurements properties1, MARCUS DA SILVA, Raytheon BBN Technologies — Measurements are an important aspect of quantum mechanics, as they represent the controlled extraction of information about quantum systems. Recent approaches for quantum tomography, such as gate-set tomography, have demonstrated that is is possible to recover a self-consistent description of a quantum system (including measurements) without assuming perfect knowledge about any of its components. However, these approaches typically focus on destructive measurements, and the inherent gauge freedom of quantum experiments makes many of the familiar properties quantum measurements (e.g., efficiency and projectiveness) difficult or impossible to verify. Here we describe how the characterization of non-destructive measurements avoids some of these problems, and propose alternate measurement properties that have the advantage of being gauge invariant, so that can be verified through experiments.

1M.S. would like to acknowledge the support of ARO under U. S. Army Research Office contract W911NF-14-C-0048.

12:27PM T38.00007 Precision measurements with a single quantum system, KLAUS MOLMER, ALEXANDER KILERICH, PINJA HAIKKA, Department of Physics and Astronomy, Aarhus University — Continuous probing of a single quantum system provides information about physical parameters that govern its evolution. The stochastic character of the quantum measurement process and the back action on the system accompanying different outcomes makes the extraction of precision information a dynamical process. Quantum trajectory theory of light emitting systems yields an efficient Bayesian estimation, and full photodetection records reveal much more information than integrated signals [1,2]. We present an analysis of the Cramer-Rao bound, quantifying the asymptotic scaling of the estimation error after long time probing of light from a single emitter [2]. The choice of measurement strategy significantly influences the estimation sensitivity of different parameters, but for Markovian decay, a deterministic equation provides the maximally possible estimation sensitivity by any measurement on the system and its emitted radiation [3]. 1. S Gammelmark and K Molmer, Bayesian parameter inference from continuously monitored quantum systems; Phys. Rev. A 87, 032115 (2013). 2. A. H. Kilerich and K. Molmer, Estimation of atomic interaction parameters by photon counting, Phys. Rev. A 89, 052110 (2014). 3. K. Molmer, Hypothesis testing with open quantum systems; arXiv:1408.4568
12:39PM T38.00008 Applying Model Selection to Quantum State Tomography: Choosing Hilbert Space Dimension. TRAVIS SCHOLTEN, University of New Mexico. Sandia National Laboratories — Reconstructing the quantum state of a continuous variable system (e.g., an optical mode) using quantum tomography presents a unique problem: the dimension of its Hilbert space is infinite. Its density matrix has infinitely many parameters, which cannot all be estimated from finite data. Brute force reconstruction (e.g., via the Radon transform or deconvolution) produces undesirable overfitting artifacts. Smoothing is one solution, but lacks a good theoretical justification. I introduce a statistically well-motivated approach based on model selection and log likelihoods. Maximum likelihood estimates in a sequence of D-dimensional subspaces (spanned by the first D Fock states) are ranked by their log likelihood. This ranking allows one to find an estimate whose dimension is smaller while simultaneously providing a good fit to data. I apply this method to heterodyne tomography and demonstrate the method can indeed eliminate overfitting by choosing a good dimension (D) in which to reconstruct optical states. Sandia is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the US Department of Energy’s National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

12:51PM T38.00009 Informationally complete measurements from compressed sensing methodology. AMIR KALEV, University of New Mexico, CARLOS RIOFRIO, Freie Universitat Berlin, ROBERT KOSUT, SC Solutions, IVAN DEUTSCH, University of New Mexico — Compressed sensing (CS) is a technique to faithfully estimate an unknown signal from relatively few data points when the measurement samples satisfy a restricted symmetry property (RIP). Recently this technique has been ported to quantum state tomography with a substantially reduced number of measurement settings. In this work we show that the constraint that a physical density matrix is positive semidefinite provides a rigorous connection between the RIP and the informational completeness (IC) of a POVM used for state tomography. This enables us to construct IC measurements that are robust to noise using tools provided by the CS methodology. The exact recovery no longer hinges on a particular convex optimization program; solving any optimization, constrained on the cone of positive matrices, effectively results in a CS estimation of the state. From a practical point of view, we can therefore employ fast algorithms developed to handle large dimensional matrices for efficient tomography of quantum states of a large dimensional Hilbert space.

1 Supported by the National Science Foundation

1:03PM T38.00010 Quantum Bootstrapping via Compressed Quantum Hamiltonian Learning. NATHAN WIEBE, Microsoft Research, CHRISTOPHER GRANADE, DAVID CORY. Institute for Quantum Computing — Recent work has shown that quantum simulation is a valuable tool for learning empirical models for quantum systems. We build upon these results by showing that a small quantum simulator can be used to characterize and learn control models for larger devices for wide classes of physically realistic Hamiltonians. This leads to a new application for small quantum computers: characterizing and controlling larger quantum computers. Our protocol achieves this by using Bayesian inference in concert with Lieb-Robinson bounds and interactive quantum learning methods to achieve compressed simulations for characterization. Whereas Fisher information analysis shows that current methods which employ short-time evolution are suboptimal, interactive quantum learning allows us to overcome this limitation. We illustrate the efficiency of our bootstrapping protocol by showing numerically that an 8-qubit Ising model simulator can be used to calibrate and control a 50 qubit Ising simulator while using only about 750 kilobits of experimental data.

1:15PM T38.00011 Practical variational tomography for critical 1D systems. JONG YEON LEE, OLIVIER LONDON-CARDINAL, California Institute of Technology — We further investigate a recently introduced efficient quantum state reconstruction procedure targeted to states well-approximated by the multi-scale entanglement renormalization ansatz (MERA). First, we introduce an improved optimization scheme that can be easily generalized for MERA states with larger bond dimension. Second, we provide a detailed analysis of the error propagation and quantify how it affects the distance between the experimental state and the reconstructed state. Third, we explain how to bound this distance using local data, providing an efficient scalable certification method. Fourth, we examine the performance of MERA tomography on the ground states of several 1D critical models.

1:27PM T38.00012 Controlling qubit drift by recycling error correction syndromes. ROBIN BLUME-KOHOUT, Computing Science Research Institute, Sandia National Laboratories — Physical qubits are susceptible to systematic drift, above and beyond the stochastic Markovian noise that motivates quantum error correction. This parameter drift must be compensated — if it is ignored, error rates will rise to intolerable levels — but compensation requires knowing the parameters' current value, which appears to require halting experimental work to recalibrate (e.g. via quantum tomography). Fortunately, this is untrue. I show how to perform on-the-fly recalibration on the physical qubits in an error correcting code, using only information from the error correction syndromes. The algorithm for detecting and compensating drift is very simple — yet, remarkably, when used to compensate Brownian drift in the qubit Hamiltonian, it achieves a stabilized error rate very close to the theoretical lower bound. Against 1/f noise, it is less effective only because 1/f noise is (like white noise) dominated by high-frequency fluctuations that are uncompensatable.

1 Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE

1:39PM T38.00013 Heat bath algorithmic cooling using electron-nuclear spin ensemble in the solid state: characterization of the open quantum system control. KYUNGDEOCK PARK, ROABEDEH DARABAD, GUANRU FENG, STEPHANE LABRUYERE, JONATHAN BAUGH, Institute for Quantum Computing, University of Waterloo, RAYMOND LAFLAMME, Institute for Quantum Computing, University of Waterloo, Perimeter Institute for Theoretical Physics — The ability to perform multiple rounds of Quantum Error Correction (QEC) is an essential task for scalable quantum information processing, but experimental realizations of it are still in their infancy. Key requirements for QEC are high control fidelity and the ability to extract entropy from ancilla qubits. Nuclear Magnetic Resonance (NMR) quantum processors have demonstrated high control fidelity with up to 12 qubits. A remaining challenge is to prepare nearly pure ancilla qubits to enable QEC. Heat Bath Algorithmic Cooling (HBAC) is an efficient tool for extracting entropy from qubits that interact with a heat bath, allowing cooling below the bath temperature. For implementing HBAC with spins, a hyperfine coupled electron-nuclear system in a single crystal is more advantageous than conventional NMR systems since the electron, with higher polarization and faster relaxation, can act as a heat bath. We characterize 3 and 5 qubit spin systems in gamma-irradiated malonic acid and present simulation and experimental results of HBAC to benchmark our quantum control. Two control schemes are compared: electron nuclear double resonance and indirect control of nuclei via the anisotropic hyperfine interaction.
1:51PM T38.00014 Characterization of Qudit Entanglement Through the Visualization of Spin-Coherent-State Wigner Functions, TODD TILMA, Tokyo Institute of Technology, MARK EVERITT, Loughborough University, KAE NEMOTO, National Institute of Informatics, WILLIAM MUNRO, NTT Basic Research Labs — The purpose of our research is to determine whether or not there is a general relationship between the degree of entanglement and the total amount of negativity in the Wigner function of various combinations of finite-dimensional quantum states. Specifically, by using the Stratonovich-Weyl correspondence we can take the density matrix of a known, finite-dimensional quantum state (hereafter known as a “qudit”) and generate its corresponding, finite-dimensional Wigner function. This Wigner function reproduces the qudit density matrix through a known volume integral. By doing the same volume integral, but with the absolute value of the Wigner function as the kernel, we get a measure of the total amount of negativity of the Wigner function instead of reproducing the density matrix. Our question is thus, is this “negative volume” equivalent to the amount of entanglement in the initial qudit state? Our results for general two-qudit states have confirmed a monotonic relationship between concurrence and this negative volume for specific cases. By analyzing the various Wigner functions of three and more qubits, as well as qubit-qudit Wigner functions we hope to build a consensus on whether or not the negativity in the Wigner function is a measure of, or witness to, entanglement.

2:03PM T38.00015 Adaptive characterization of coherent states1, MARKKU P.V. STENBERG, KEVIN PACK, FRANK K. WILHELM, Theoretical Physics, Saarland University, 66123 Saarbrucken, Germany — We present a method for efficient characterization of an optical state. Our algorithm significantly outperforms nonadaptive schemes. While our standard approach works when we are interested in (i) searching a crude estimate, (ii) rapidly improving the accuracy, and (iii) the phase where the improvement of the accuracy slows down due to the quantum nature of the coherent state. Our algorithm significantly outperforms nonadaptive schemes. While our standard approach works when we are interested in the phase of an unknown frequency, our adaptive algorithm uses sequential weak measurements of a Bell state that are implemented with four superconducting qubits. In this second of two talks, we present experimental detail on the measurement of the CHSH correlator and the analysis of error mechanisms.

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T39 GQ1: Focus Session: Quantum Foundations Studies with Superconducting Qubits

11:15AM T39.00001 Continuous measurement of two spatially separated superconducting qubits: quantum trajectories and statistics, NICOLAS ROCH, CNRS and Universite? Grenoble Alpes, Institut N?el, 38042 Grenoble, France — Measurement can be harnessed to probabilistically generate entanglement in the absence of local interactions, for example between spatially separated quantum objects. Continuous weak measurement allows us to observe the dynamics associated with this process. In particular, we perform joint dispersive readout of two superconducting transmon qubits separated by one meter of coaxial cable. We track the evolution of a joint quantum state under the influence of measurement, both as an ensemble and as a set of individual quantum trajectories. Analyzing the statistics of such quantum trajectories can shed new light on the underlying entangling mechanism.

11:51AM T39.00002 Quantum Measurement in Superconducting Circuits, KATER MURCH, Physics Department, Washington University, St. Louis — In recent years, there has been immense progress in the ability to control and measure superconducting circuits. These abilities have enabled several different experiments that address the fundamental physics of quantum measurement, ranging from the observation of non-classical weak values, to the generation of entanglement through measurement and the tracking of individual quantum trajectories. I will review recent progress in the field and discuss how these advances add to the foundations of quantum mechanics.

12:27PM T39.00003 Steady-state entanglement of spatially separated qubits via quantum bath engineering, CAMILLE ARON, Princeton University, MANAS KULKARNI, New York City College of Technology, HAKAN TURECI, Princeton University — We propose a scheme for driving a dimer of spatially separated qubits into a maximally entangled non-equilibrium steady state. A photon-mediated retarded interaction between the qubits is realized by coupling them to two tunnel-coupled leaky cavities where each cavity is driven by a coherent microwave tone. The proposed cooling mechanism relies on striking the right balance between the unitary and driven-dissipative dynamics of the qubit subsystem. We map the dimer to an effective transverse-field XY model coupled to a non-equilibrium bath that can be suitably engineered through the choice of drive frequencies and amplitudes. We show that both singlet and triplet states can be obtained with remarkable fidelities. The proposed protocol can be implemented with a superconducting circuit architecture that was recently experimentally realized and paves the way to achieving large-scale entangled systems that are arbitrarily long lived.

12:39PM T39.00004 Experimental violation of a Bell-Leggett-Garg inequality using weak measurements, Part I: Avoiding loopholes, J. DRESSEL, UC Riverside, T. WHITE, UC Santa Barbara, J. MUTUS, R. BARENDS, Google, Santa Barbara, A. MEGRANT, UC Santa Barbara, E. JEFFREY, D. SANK, Google, Santa Barbara, J. KELLY, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara, Z. CHEN, B. CHIARO, A. DUNSWORTH, I.-C. HOI, C. NEILL, P.J.J. O’MALLEY, UC Santa Barbara, P. ROUSHAN, Google, Santa Barbara, C. QUINTANA, A. VAINSENCHER, J. WENNER, UC Santa Barbara, A. FOWLER, Google, Santa Barbara, A. N. CLELAND, UC Santa Barbara, A. N. KOROTKOV, UC Riverside, A. N. CLELAND, UC Santa Barbara, J. M. MARTINIS, University of California and Google, Santa Barbara — We demonstrate the violation of a hybrid Bell-Leggett-Garg inequality that avoids both the disjoint sampling and fair sampling loopholes that are common to traditional Bell inequalities. Our algorithm uses sequential weak measurements of a Bell state that are implemented with four superconducting Xmon qubits. In this first of two talks, we detail the high-fidelity partial projections that are needed for this violation, which are realized by entangling an ancilla qubit to each data qubit using a controlled-Z two-qubit gate. After calibration of the ancilla readout, these partial projections indirectly measure qubit expectation values with a tunable amount of state disturbance. For sufficiently weak disturbance, the inequality can be violated using all the data collected in a single configuration.

12:51PM T39.00005 Experimental violation of a Bell-Leggett-Garg inequality using weak measurements, Part II: The Violation, T.C. WHITE, UC Santa Barbara, J. MUTUS, Google Santa Barbara, J. DRESSEL, UC, Riverside, J. KELLY, UC Santa Barbara, R. BARENDS, Google, Santa Barbara, A. MEGRANT, UC Santa Barbara, E. JEFFREY, D. SANK, Google, Santa Barbara, B. CAMPBELL, UC Santa Barbara, Y. CHEN, Google, Santa Barbara, Z. CHEN, B. CHIARO, A. DUNSWORTH, UC Santa Barbara, A. FOWLER, Google, Santa Barbara, I.-C. HOI, C. NEILL, P.J.J. O’MALLEY, UC Santa Barbara, P. ROUSHAN, Google, Santa Barbara, C. QUINTANA, A. VAINSENCHER, J. WENNER, UC Santa Barbara, A. N. KOROTKOV, UC Riverside, A. N. CLELAND, UC Santa Barbara, J. M. MARTINIS, University of California and Google, Santa Barbara — We experimentally demonstrate the violation of a hybrid Bell-Leggett-Garg inequality that avoids both the disjoint sampling and fair sampling loopholes that are common to traditional Bell inequalities. Our algorithm uses sequential weak measurements of a Bell state that are implemented with four superconducting Xmon qubits. In this second of two talks, we present experimental detail on the measurement of the CHSH correlator and the analysis of error mechanisms. We find that the dependence of the correlation (i) on the measurement strength shows excellent agreement with theoretical predictions, but the magnitude of the correlator varies greatly with system fidelity. For sufficiently weak and high fidelity measurements, we achieve a violation that is many standard deviations above the classical limit.
In the presence of realistic experimental noise, the cost advantage of unambiguous state discrimination is completely destroyed; however, other cost bound violations are more robust, and thus could be experimentally tested with modern superconducting qubit implementations.

Casimir-Polder-like Effect in a Superconducting Circuit System. PETER GROSKOWSKI, EDUARDO MARTIN-MARTINEZ, CHRIS WILSON, Univ of Waterloo, FRANK WILHELM, Saarland University — Casimir-type forces arise when the ground state energy of a quantum field depends on a classically-treated degree of freedom. The first example of such forces was proposed by Casimir, when he considered the attractive force that arises between two neutral, conducting plates placed in a vacuum. In this talk, we will discuss a variation of the Casimir-Polder effect, the force between an atom and a conducting plate, in a superconducting circuit consisting of a tunable cavity coupled to a qubit. We will describe an analogus "Casimir force" on the cavity's effective boundary condition, outline the consequences of longitudinal versus transverse coupling between the qubit and cavity, and discuss the relevance of the field self-interaction term $\mathcal{A}$. Finally, we will briefly touch on prospects related to measurement.

Vacuum-Induced Berry Phase Measured Via a Phase-Tunable Atom-Field Interaction. S. GASPARINETTI, S. BERGER, A. A. ABDUMALIKOV, M. PECHAL, S. FILIPP, A. WALLRAFF, ETH Zurich — Geometric phases incorporate a fundamental aspect of quantum mechanics. They are at the heart of many quantum phenomena in solid-state physics, from the quantum Hall effect to topologically protected phases, and may provide a resource for quantum computation. We present the first experimental observation of the vacuum-induced Berry phase [1], a geometric effect that arises when the phase of a quantized field mode coupled to an atom is adiabatically steered. Our atom-field system is a transmon embedded in a 3D microwave cavity. A phase-coherent microwave tone induces a tunable interaction between the third level of the transmon and a long-lived mode of the cavity [2]. By adiabatically steering the phase of the interaction, we demonstrate that the qubit accumulates a geometric phase even when the cavity mode is empty. We characterize this effect by varying the effective atom-field detuning as well as the photon number in the cavity mode.

11:27AM T41.00002 Effects of temperature on structure and mechanical properties of alkane-
ethiol coated gold nanoparticle membranes1. K. MICHAEL SALERNO, GARY GREST, Sandia National Laboratories — Single-
nanoparticle-thick membranes have a variety of potential uses due to unique mechanical properties. While these membranes have been studied experimentally and computationally at 300K, the effects of thermal annealing on structure and properties have not been investigated. We present atomistic molecular dynamics simulations that study the effects of temperature on nanoparticle membrane properties. Nanoparticles are made of a gold core coated with organic oligomer ligands. At high grafting density, ligands with CH$_3$ end groups exhibit local crystallinity at 300K while those with COOH end groups orient to form dimers due to electrostatics. Both features influence membrane mechanical properties. As temperature increases ligand crystallinity and COOH affinity are disrupted, and mechanical strength is reduced. Immediately after cooling back to 300K, membranes are weaker and more soluble and ligand interdigitation and COOH affinity are reduced. Over time, interdigitation and end-group interactions rejuvenate and samples that undergo high-temperature annealing have mechanical properties comparable to the original membranes. The structure/property temperature dependence points to ways that membranes could be tailored for temperature-dependent/resistant properties.

1Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s NNSA under contract DE-AC04-94AL85000.

11:39AM T41.00003 Quantitative Analogy Between Polymer Grafted Nanoparticles and
Patchy Particles2, MAKOTO ASAI, Chemical Engineering, Columbia University, ANGELO CACCIUTTO, Chemistry, Columbia University, SANAT KUMAR, Chemical Engineering, Columbia University — We establish a quantitative analogy between polymer grafted nanoparticles (PGNPs) and patchy nanoparticles (NPs). Over much of the experimentally relevant parameter space, we show that PGNPs behave quantitatively like Janus NPs, with the patch size having a universal dependence on the number of grafted chains and the ratio of the size of the NPs to the grafted chain size. The widely observed anisotropic self-assembly of PGNPs into superstructures can thus be understood through simple geometric considerations of single patch model, in the same spirit as the geometry-based surfactant models of Israelachvili

11:51AM T41.00004 Reversible Thermal-Stiffening in Polymer Nanocomposites. ERKAN SENSES,
PINAR AKCORA, Stevens Institute of Technology — Silica nanoparticles adsorbed with a high glass-transition temperature polymer, PMMA (T$_g$: 130 °C) are shown to uniformly disperse in a low-T$_g$ polymer matrix, PEO (T$_g$: -60 °C). These nanocomposites exhibit an unusual reversible liquid-to-solid transition at temperatures above T$_g$s of both polymers. Mechanical adaptivity of PEO nanocomposites to temperatures underlies the existence of dynamically asymmetric bound layers on particles, and more importantly their impact on mechanical behavior, which sets these materials apart from conventional polymer composites that soften upon heating. Moreover, the growth rate of elastic moduli at temperatures above T$_g$ of PMMA presents an Arrhenius-type relaxation with activation energy well-matching with the α-β merging region of PMMA. These results suggest that the mobility of the surface-bound polymer is essential for reinforcement contrary to commonly accepted glassy-layer hypothesis.

12:03PM T41.00005 SANS Study on the Behaviors of Polymeric Ligands on the Nanoparticle Surfaces, SEYONG KIM, Department of Chemical and Biological Engineering, Korea Univ., SOO-HYUNG CHOI, Department of Chemical Engineering, Hongik Univ., JUNE HUH, JOONA BANG, Department of Chemical and Biological Engineering, Korea Univ. — In this work, we employed small angle neutron scattering (SANS) and contrast variation technique to characterize the behaviors of polymer ligands on the nanoparticle (NPs) surfaces. The Janus-type Au NPs were coated with a mixture of two different ligands, PMMA-SH and deuterated PS-SH, and the Au NPs coated only with P(MMA-r-dS)-SH were also prepared for the control case of NPs with homogeneous ligand. From the SANS analysis, it was observed that the Janus ligands become phase separated with increasing the molecular weight of ligands. Furthermore, computational simulation was performed to examine how ligands are phase separated on the curved NPs surfaces.

12:15PM T41.00006 Semi-crystalline polymer nanocomposites: interplay of matrix crystal-
lization and nanoparticle self-assembly. DAN ZHAO, JACQUES JESTIN, LONGXI ZHAO, SANAT K. KUMAR, Columbia University, MOHAMMAD MOHAMMADKHANI, BRIAN C. BENICEWICZ, University of South Carolina — We investigate a new class of nanocomposite materials made of semi-crystalline poly(ethylene oxide) and poly(methyl methacrylate) grafted silica nanoparticles (NPs). The results indicate that NPs do not act as nucleating agents as indicated from the lowering of the onset of crystallization temperature with addition of NPs. Although the crystal sizes and rate of crystallization are reduced in the presence of NPs, the equilibrium melting temperature seems to be unaffected. Furthermore, no remarkable change was observed in the spatial dispersion of NPs upon fast crystallization. However, for slow crystallization, both TEM and X-ray scattering reveal that the system starts to be organized in a “layer-by-layer” architecture, where the NPs are aligned in the amorphous phases intercalated by the crystalline lamellar phases.

12:27PM T41.00007 Chemically Designed Molecular Interfaces in Cross-Linked Poly(ethylene glycol)/Silica Nanocomposites Reveal Strong Size-Dependent Trends in Gas Permeability. NORMAN SU, Univ of California - Berkeley, JEFFREY URBAN, Lawrence Berkeley National Lab — Polymer nanocomposite membranes can exhibit gas separation performance that surpasses conventional polymeric membranes. While promising, the optimization of nanocomposite membranes requires a fundamental understanding of the transport mechanism and interfacial effects between the inorganic and polymer phase that is currently limited to empirical relationships. Synthesized nanocomposites often consist of poorly dispersed and polydisperse inorganic nanomaterials. It is known that polymer dynamics can change drastically upon introduction of an inorganic phase, which can dramatically alter polymer transport behavior. Here, we systematically explore the role of nanoparticle sizes from 12 to 130 nm on polymer dynamics and permeability in a series of cross-linked poly(ethylene glycol)/silica nanocomposite membranes. The nanocomposites are well-dispersed and display excellent homogeneity throughout. Size-dependent broadening of the Tg indicates strong attractive interactions especially at high surface area loadings, which lead to deviations in permeability not captured by Maxwell’s model. Chemical modifications of silica at this interface can yield significantly different polymer dynamics than previously observed with enhanced transport and mechanical properties.

12:39PM T41.00008 Interactions between Nanoparticles and Polymer Brushes: Molecular Dynamics Simulations and Self-consistent Field Theory Calculations1, SHENGFENG CHENG, CHENGYUAN WEN, Virginia Polytechnic Institute and State University, SERGEI EGOROV, University of Virginia — Molecular dynamics simulations and self-consistent field theory calculations are employed to study the interactions between a nanoparticle and a polymer brush at various densities of chains grafted to a plane. Simulations with both implicit and explicit solvent are performed. In either case the nanoparticle is loaded to the brush at a constant velocity. Then a series of simulations are performed to compute the force exerted on the nanoparticle that is fixed at various distances from the grafting plane. The potential of mean force is calculated and compared to the prediction based on a self-consistent field theory. Our simulations show that the explicit solvent leads to effects that are not captured in simulations with implicit solvent, indicating the importance of including explicit solvent in molecular simulations of such systems. Our results also demonstrate an interesting correlation between the force on the nanoparticle and the density profile of the brush.

12:51PM T41.00009 Dispersion/Aggregation of polymer grafted nanorods in a polymer matrix studied by Dissipative Particle Dynamics , JOAO MAIA, SHAGHAYEGH KHANI, Case Western Reserve University — Nanorods are incorporated into polymer matrices for fabricating composite materials with enhanced physical and mechanical properties. The final macroscopic properties of the composites are strongly related to the dispersion and organization of the nanoparticles in the matrix. For instance, a significant improvement in the mechanical properties of the nanorod-polymer composites is observed upon formation of a percolating network. One way of controlling the assembly of nanorods in the polymer medium is adjusting the chemical interactions which is done through grafting polymer chains on the surface of the rods. The recent developments in the computational techniques have paved the road for further understanding of the controlled dispersion and aggregation of nanorods in polymer matrices. In this study, Dissipative Particle Dynamics (DPD) is employed in order to investigate the effect of enthalpic and entropic variables on the phase behavior of the abovementioned nanocomposites. In DPD, the interaction parameter between the components of the systems can be mapped onto the Flory-Huggins \( \chi \)-parameter via well-known Groot-Warren expression. This work studies the effect of the enthalpic and entropic variables on phase transitions. The main goal is to provide a phase diagram that can be used to guide the experiments in designing new materials.

1:03PM T41.00010 Phase Behavior of Polymer-Grafted Nanoparticles in a Polymer Matrix , KATRINA IRENE MONGCPOA, University of Houston, RANA ASHKAR, PAUL BUTLER, National Institute of Standards and Technology, RAMANAN KRISHNAMOORTI, University of Houston — We examine the thermodynamic interactions of polystyrene (PS) grafted onto spherical silica nanoparticles blended with a poly(vinyl methyl ether) (PVME) matrix using light, x-ray and neutron scattering techniques. PS/PVME systems are known to exhibit a lower critical solution temperature, with blending thermodynamics greatly affected by the chain length of the components. Thus, we study how enthalpic and entropic effects play a role in the dispersion of PS-grafted nanoparticles in a chemically-distinct matrix, especially as the system approaches a phase boundary. Scattering techniques are used to examine the effect of molecular weight on the blend thermodynamics and concentration fluctuations for such strongly interacting polymer blends. x-ray scattering data and analysis of the structure factor reveal that for a grafted deuterated polystyrene brush (33,000 Da) in a PVME matrix (226,000 Da), an initial dispersion of nanoparticles occurs at low temperatures. The system then gradually transitions to an aggregated state as temperature is increased, suggesting the presence of strong inter-particle interactions that lead to fractal formation as the system approaches a phase boundary. Complementary neutron scattering experiments confirm this phenomenon.

1:15PM T41.00011 Study of Polymer/Graphene Nanocomposites through Atomistic Molecular Dynamics Simulations , ANASTASSIA RISSANOU, Institute of Applied and Computational Mathematics (IACM), Foundation for Research and Technology Hellas (FORTH), GR-71110 Heraklion, Crete, Greece, VAGELIS HARMANDARIS, Department of Applied Mathematics, University of Crete, GR-71409, Heraklion, Crete, Greece — Polymer/graphene nanostructured systems have attracted great attention the last years both for scientific and technological reasons. A main challenge in the study of graphene based polymer nanocomposites is to predict their properties at the molecular level. In the current study we focus on the effect of the weight fraction of graphene in a polymer matrix, as well as the size of the graphene sheet, on the properties of polymer chains are examined. Density profiles, structural and conformational characteristics as well as mobility aspects are studied. All the above properties are examined, as a function of the distance from the substrate. Results are compared with the interfacial properties of polymer chains confined between two periodic (i.e., "infinite") frozen graphene layers. In addition dynamical and conformational properties of the graphene sheet are studied as a function of the size and the weight fraction of the sheet in the polymer matrix. Furthermore, thermal as well as matrix induced fluctuations (i.e. wrinkling) of graphene sheets are examined. The extent of the fluctuations and the frequency of conformation interchange between crests and troughs are computed. All above properties are presented for different polymeric systems.

1:27PM T41.00012 Thermally Tunable Metallodielectric Photonic Crystals from Self-assembly of Brush Block Copolymers and Gold Nanoparticles, DONGPO SONG, CHENG LI, NICHOLAS COLELLA, XUEMIN LU, JAMES WATKINS, University of Massachusetts Amherst — Photonic crystals (PCs) based on the self-assembly of block copolymers (BCPs) are under intense investigations, providing a unique platform for the self-assembly of inorganic nanoparticles (NPs) into specific domains of the microphase separated BCPs, to tune the optical constant of the target domains and create hybrid materials with unique optical properties. In this work, we demonstrate a simple strategy for rapid fabrication of well-ordered metallodielectric 1-D PCs using PS-b-P2VP brush BCPs as the templates and H-bonding as the driving force for selective incorporation of phenol-coated gold nanoparticles (NPs) into PEO domains. By varying gold NP loading or molecular weight of the brush BCP, periodic layered metallodielectric structures with the domain spacing controlled from 120 nm to 261 nm were readily created resulting in reflection of light widely tunable from the visible to near IR regions (458-1010 nm). The control over size as well as the distribution of the gold NPs in the well-ordered structure was realized through simple thermal treatment, showing significant effects on the optical properties.

1:39PM T41.00013 Design and organization of nanoparticles in thin film copolymer/homopolymer hosts , JUNNAN ZHAO, PETER GREEN, University of Michigan, Ann Arbor — The organization of polystyrene (PS) grafted gold (Au) nanoparticles (NPs) in supported thin film mixtures of polystyrene-b-poly(2-vinylpyridine) (PS-b-P2VP) diblock copolymers (BCP) with PS homopolymers was examined. The copolymer chains formed micelles, composed of inner cores of P2VP blocks and outer coronae of PS blocks, within the PS hosts. The spatial distribution of nanoparticles within this thin film BCP/homopolymer system is characterized by a morphological diagram of the curvature of the Au cores, \( 1/R_C \), vs. the degree of polymerization \( N_c \) of the grafted PS-chains. The distribution is quantified by five basic regimes, largely dictated by competing entropic and enthalpic intermolecular interactions. The NP distributions range from predominantly residing at external interfaces (free surface and substrate) to primarily "decorating" the surface of micelles. The phase behavior of PS-Au/BCP/homopolymer (PS) systems is necessarily more intriguing than PS-Au/homopolymer (PS) systems, as the relative roles of specific intermolecular interactions on local NP distributions become more apparent.

1:51PM T41.00014 ABSTRACT WITHDRAWN —

2:03PM T41.00015 Directed Phase Separation of Brush-coated Nanoparticles in Miscible and Immiscible Polymeric Thin Films , REN ZHANG, Univ of Akron, BONGJOON LEE, Carnegie Mellon University, JACK DOUGLAS, National Institute of Standards and Technology, SANAT KUMAR, Columbia University, MICHAEL BOCKSTALL, Carnegie Mellon University, ALAMGIR KARIM, Univ of Akron — Fascinating as the combined properties of polymer/inorganic nanoparticle composite system, it is challenging to manipulate the distribution and assembly structures of the nanofilizers at nanoscale with high loading fraction. Inspired by polymer blend phase separation, we expect similar behavior for blend-brushed nanoparticles and a polymer matrix with unfavorable enthalpic interactions. We confirm this relationship in blend thin films of polystyrene (PS) grafted gold nanoparticles (AuPS) in immiscible poly (methyl methacrylate) (PMMA). We show that application of soft-shear dynamic thermal zone annealing (DZA-SS) generates tunable directional aligned anisotropic nanoparticle structures. Alternatively, the phase-separated nanoparticle domains can also be organized into periodic nanostructures with well-defined shape and order with a simple geometric patterned elastomer confinement. These simple yet powerful strategies to fabricate nanomembranes can be exploited for many nanotechnology applications.
11:15AM T42.00001 Dynamics and rheology of living polymers, SUBHAS DHAKAL, Department of Biomedical and Chemical Engineering, Syracuse University, RADHAKRISHNA SURESHKUMAR, Department of Biomedical and Chemical Engineering, and Department of Physics, Syracuse University — Molecular dynamics simulations are used to study the dynamics and stress relaxation in “living” polymers such as wormlike micelles (WLMs) of surfactants. These systems exhibit complex dynamical properties due to incessant chain scission and inter-chain recombination events over time scales that range from few ns to milliseconds. We study the structure and energetics of WLMs obtained from large-scale coarse-grained Molecular Dynamics simulations that consist of millions of atoms. Various dynamical properties such as the non-monotonic variation of the zero shear viscosity with salt concentration, as well as the recombination time and a possible reptation-based stress relaxation mechanism will be discussed.

1We acknowledge the computational resources provided by XSEDE which is supported by NSF grant number OCI-1053575 and the financial support by National Science Foundation under Grant No. 1049489 and 1049454.

11:27AM T42.00002 Extreme value statistics of work done in stretching a polymer in a gradient flow, MARIJA VUCELJA, Center for Studies in Physics and Biology, The Rockefeller University, 1230 York Avenue, New York, NY 10065, USA, KONSTANTIN TURYSYN, Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA, 02139, US, MICHAEL CHERTKOV, Theory Division & Center for Nonlinear Studies at LANL and with New Mexico Consortium, Los Alamos, NM 87545, US — We study the statistics of work on a finitely extensible polymer subjected to a gradient flow and thermal fluctuations. The flow breaks the detailed balance and stretches the polymer, the work to stretch the molecule is stored as elastic energy, which later dissipates with fluctuations of the molecule’s elongation. The whole system is in a non-equilibrium dynamical state, which is sustained by the energy flow into the molecule and back. We obtain the Large Deviation Function (LDF) of the work in the full range of appropriate flow, elasticity and thermal noise parameters by combining analytical and numerical tools. The LDF shows two distinct asymptotes: “near tails” are linear in work and dominated by coiled polymer configurations, while “far tails” are quadratic in work and correspond to preferentially fully stretched polymers. We find the extreme value statistics of work for several elastic potentials, as well as the mean and the dispersion of work near the coil-stretch transition. The dispersion shows a maximum at the transition. In our work, we use non-equilibrium work relations to study the extension of a polymer in a flow. Relations like these are becoming instrumental in studies of soft matter materials.

11:39AM T42.00003 Importance of chain tumbling and finite extension on the start-up and relaxation behavior of transient networks, MICHELLE SING, Massachusetts Inst of Tech-MIT, ZHEN-GANG WANG, California Institute of Technology, GARETH MCKINLEY, BRADLEY OLSEN, Massachusetts Inst of Tech-MIT — Associative polymer networks are ubiquitous in tissue and biomedical engineering. However, the particular molecular attributes that contribute to the macroscopic behavior like shear thinning, self-healing, and yield stress are less well known. Here we incorporate chemical kinetics in the Smoluchowski Equation capable of modeling the full network chain end-to-end distance distribution while tracking the fraction of looped, bridged, and dangling chains in the gel. In steady shear, we see the development of non-monotonic flow instabilities when the rate of chain association grows larger than the rate of chain relaxation. These instabilities arise due to a combination of chain finite extensibility and tumbling. During start-up of steady shear, the combination of these two phenomena also results in stress overshoots followed by multiple damped oscillations toward steady-state. The timescale of chain relaxation after the cessation of shear is dominated by the chain kinetics of association and dissociation as a function of the fraction of dangling chains present at any time post-shear.

1Institute for Soldier Nanotechnologies, Department of Defense National Defense Science and Engineering Fellowship Program

11:51AM T42.00004 Mesoscopic Simulation Methods for Polymer Dynamics, RONALD LARSON, University of Michigan, Ann Arbor, MI — We assess the accuracy and efficiency of mesoscopic simulation methods, namely Brownian Dynamics (BD), Stochastic Rotation Dynamics (SRD) and Dissipative Particle Dynamics (DPD), for polymers in solution at equilibrium and in flows in microfluidic geometries. Both SRD and DPD use solvent particles to carry momentum, and so account automatically for hydrodynamic interactions both within isolated polymer coils, and with other polymer molecules and with nearby solid boundaries. We assess quantitatively the effects of artificial particle inertia and fluid compressibility and show that they can be made small with appropriate choice of simulation parameters. We then use these methods to study flow-induced migration of polymer chains produced by: 1) hydrodynamic interactions, 2) streamline curvature or stress-gradients, and 3) convection of wall depletion zones. We show that large concentration gradients can be produced by these mechanisms in microfluidic geometries that can be exploited for separation of polymers by size in periodic contraction-expansion geometries. We also assess the range of conditions for which BD, SRD or DPD is preferable for mesoscopic simulations. Finally, we show how such methods can be used to simulate quantitatively the swimming of micro-organisms such as E. coli.

In collaboration with Lei Jiang and Tongyang Zhao, University of Michigan, Ann Arbor, MI.

12:27PM T42.00005 Multi-fluid simulations of polymer dynamics, DOUGLAS TREE, KRIS DELANEY, GLENN FREDRICKSON, Univ of California - Santa Barbara — In many industrially important polymeric materials, a discrepancy exists between the time scale intrinsic to the system and processing time scales. As a consequence, models which go beyond equilibrium thermodynamics are required to understand the evolution of the microstructure of such systems. Building a tractable model to address such a system becomes especially challenging when process dynamics coexist with complex flow-induced behaviors (e.g. chain association and dissociation schemes (e.g. Brownian or molecular dynamics or dynamic field theories), cost constraints become prohibitive for 3D dynamic simulations as length and time scales increase. To address such problems, we explore a framework of meso-scale dynamic phase field models originally proposed by Brochard and de Gennes. Expanding on the “two-fluid” formalism of Doi and Onuki, we find that such models are capable of incorporating many phenomena relevant for industrially important polymer materials, including phase separation dynamics and viscoelastic fluid flow. In addition, we explore numerical methods capable of solving such models, with the goal of developing a framework for inexpensive “multi-fluid” simulations of polymer dynamics.

12:39PM T42.00006 Tightening the noose on tube models: a priori determination of equilibration time and other tube model parameters for 1,4-polybutadiene, PRIYANKA DESAI, RONALD LARSON, University of Michigan, XUE CHEN, Dow Chemical Company, SEUNG JOON PARK, Korea Polytechnic University — Linear viscoelastic G’ and G” master curves for multiple linear, star, H, and comb 1,4-polybutadienes from the literature were compared and found with only one exception to agree well in the high deformation range, at 25°C, regardless of chain architecture. From a study by Carella et al. (Macromolecules 17:2775, 1984), the plateau modulus for 1,4-polybutadiene is expected to vary by only 2% for 1,2 content ranging from 0.06 to 0.10, and a similar variability of the entanglement molecular weight over this range can be inferred for this range of 1,2 content. Accordingly, for typical 1,4-polybutadienes, with 1,4 content ranging from 6-10%, all three canonical parameters of the tube model can be taken as fixed within a tight range, for 1,4-polybutadienes of any architecture, thus providing tight constraints on parameter adjustments that might be used to fit theories, such as tube theories, to rheological data.
1:03PM T42.00008 Entanglement effect in polymer melts by Dissipative Particle Dynamics (DPD). SHAHAYEGH KHANI, JOAO MAIA, Case Western Reserve University — Dissipative Particle Dynamics (DPD) is a mesoscale simulation method that has shown a very good potential in modeling different soft matter systems from colloidal suspensions to highly entangled polymers. Like any other simulation technique DPD is associated with some deficiencies, for instance in the case of entangled polymers soft repulsions used in DPD allow particle overlap which may result in topology violations that prevent the correct capturing of the entanglement effect. Therefore, in the present work in order to properly reproduce the dynamics and viscoelastic properties of polymers the soft repulsions between the particles are substituted with a repulsive potential between non-adjacent bonds of different FENE chains. Also, DPD is a coarse-grained simulation method that can be used to model time and length scales longer than atomistic models; however, due to the existence of an upper level limit for the level of coarse graining this method is not applicable for the whole mesoscopic range. Thus, this work represents a new approach for tuning the level of coarse-graining by adjusting the simulation parameters. The ability of the method in capturing the entanglement effects is validated by simulating dynamic and viscoelastic properties of polymers.

1:15PM T42.00009 Manipulating and Separating Polymers and Particles at the Microscale using Conformation-dependent Electrophoretic Mobility. PATRICK UNDERHILL, HARSH PANDEY, Rensselaer Polytech Inst — Many separation techniques rely on different physical or chemical characteristics of the objects being separated. This includes separations based on size, total charge, or strength of interaction with a substrate. Recently there are many contexts in which it is important to manipulate or separate objects with different deformabilities. The deformability of an object is also important because it is related to the rheological response. We have developed a coarse-grained Brownian dynamics simulation method that incorporates the change in electrophoretic mobility of rigid as well as flexible objects with conformation. The model incorporates the effect in a computationally efficient way, and has been validated by comparing with experiments with double-stranded DNA. In this talk, we will describe the results of computer simulations using the new model in which we quantify the stretch and residence time of polymers in a combination of electric field gradients and pressure-driven flow. The coupling of the stretch and mobility leads to a new way to trap and manipulate biomaterials. A comparison of the simulations with single molecule experiments will also be shown.

1:27PM T42.00010 Long-time diffusivity of DNA chains in nanochannels: A Brownian dynamics study. AASHISH JAIN, KEVIN DORFMAN, Univ of Minn - Minneapolis — The simplest approach to calculate the diffusivity of any polymer chain is to use the double sum Kirkwood formula, which is based on preaveraging approximation of diffusion tensor. The error due to the preaveraging approximation has been reported by a number of researchers in the context of free solution by computing both Kirkwood diffusivity $D^{(K)}$ (also known as short-time diffusivity) and long-time diffusivity $D_L$. In nanochannels, the main approach to compute the diffusivity is the Kirkwood formula. However, the error due to the preaveraging approximation is not known in a confined system. We use Brownian dynamics simulation algorithm with excluded volume and hydrodynamic interactions to calculate both short-time and long-time diffusivities of DNA chains in nanochannels, and compare them for a range of channel sizes and DNA chain sizes. Our results indicate that the long-time diffusivity is always smaller than the short-time diffusivity, which is consistent with the result obtained in free solution using linear response theory $D_L < D^{(K)}$ [M. Fixman, Macromolecules 14, 1710 (1981)]. We show that this preaveraging error decreases as channel size decreases. Even for weakly confined channels, errors are found to be about 1% for chains up to 40 nm.

1:51PM T42.00012 Nanovoid formation in cross-linked epoxy and poly(dicyclopentadiene) networks during high strain rate deformation. ROBERT M. ELDER, DANIEL B. KNORR, JR., JOSEPH L. LENHART, JAN W. ANDZELM, TIMOTHY W. SIRK, US Army Research Laboratory — Cross-linked polymer networks are widely used as structural and protective materials under extremes of temperature, pressure, or strain rate. In particular, substantial effort has been devoted to improving the high strain rate impact resistance of epoxy resins. Although epoxy resins are widely used in applications requiring impact resistance, epoxy resins with the strength and stiffness necessary in structural applications typically have poor toughness. Recent work showed that other chemistries in cross-linked polymers can overcome this trade-off between strength and toughness. Specifically, cross-linked poly(dicyclopentadiene) (pDCPD) was found to have exceptional performance compared to epoxy resins, which is related to the high toughness of pDCPD. Based on the physicochemical properties of epoxy and pDCPD, it was hypothesized that the excellent toughness of pDCPD was due to the formation and growth of nanovoids during impact events. Void growth dissipates energy that otherwise would contribute to failure. We use atomistic molecular dynamics simulations to quantify void formation in these cross-linked polymer networks and to examine the molecular-level properties of the voids. Our findings suggest methods to increase void formation and growth, which may improve toughness.

2:03PM T42.00013 Modelling poly(p-phenylene teraphthalamide) at Extreme Tensile Loading using Reactive Potentials1. DUNDAR YILMAZ, Zirve University — Aromatic polyamides classified as rigid-rod polymers due to orientation of their monomers. Because of their excellent mechanical and thermal properties, aramids are widely used in the industry. For example DuPont’s brand Kevlar, for its commercial aromatic polyamide polymer, due to wide usage of this polymer in ballistic applications, habitually used as a nickname for bulletproof vests. In order to engineer these ballistic fabrics, material properties of aramid fibers should be studied. In this work we focused on the poly(p-phenylene teraphthalamide) PPTA fiber, known as brand name Kevlar. We employed Reactive potentials to simulate PPTA polymer under tensile loading. We first simulated both amorphous and crystalline phases of PPTA. We also introduced defects with varying densities. We further analysed the recorded atomic positions data to understand how tensile load distributed and failure mechanisms at extreme tensile loads.

Session T43 DPOLY: Focus Session: Dynamics of Glassy Polymers Under Confinement II 214C
- Rodney Priestley, Princeton University
11:15AM T43.00001 Cooperative Motion as a Unifying Principle to Understand Confinement Effects on Glass Formation, FRANCIS STARR, Wesleyan University — We examine how confinement scale and interfacial interactions affect glassy network formation, studied via molecular dynamics simulations. We consider both thin supported polymer films and polymer-nanoparticle composites. By varying the film thickness, nanoparticle loading fraction, or polymer-interfacial interactions, we can significantly alter both $T_g$ and the fragility of glass formation, leading to a seemingly intractable degree of complexity. However, we find that all our observations can be described in unified way by using the scale of collective motion as a measure of “cooperatively rearranging regions” in the Adam-Gibbs (AG) description of glass formation. For thin films, we show how the scale of cooperative motion relates to the scale of enhanced interfacial dynamics at the free surface, offering a promising route to experimentally determine the scale of cooperative motion. These string-like motions can further be described as a living polymerization. Combining polymerization theory with the AG approach, we theoretically predict the relaxation time at much lower $T$, which suggests a return to Arrhenius behavior that avoids a Kauzmann “entropy crisis.” Finally, we consider the applications of these ideas to ultra-stable polymer films formed by vapor deposition.

11:51AM T43.00002 Effects of Substrate Interaction on Slow Dynamics and Vitrification in Confined Thin Films, STEPHEN MIRIGIAN, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — The nanoscopic confinement of a glass-forming liquid can have major effects on its slow dynamics which depend on the nature of the confining surface in a nonuniversal manner. We generalize our force-level theory for free-standing films [1] to incorporate the effects of solid surfaces in supported and capped films. A solid surface is treated as locally modifying the liquid density as a consequence of packing-induced layering and/or physical adsorption. For films supported on a neutral surface where the former densification mechanism is dominant, the theory predicts that the physical behavior is akin to a free-standing film but with one interface behaving in a nearly unperturbed bulk manner, in agreement with experiment. With increasing interfacial attraction, the relaxation near the solid surface slows down dramatically and a very large local mobility gradient emerges. The competition between the dynamical effects of the adsorbed layer and the mobile layer near the vapor interface results in a rich behavior of an apparent vitrification temperature. Representative calculations of the full spatial gradient of the relaxation time as a function of temperature, film thickness, and interfacial densification will be presented.

12:03PM T43.00003 Slow Relaxation, Vitrification, and Mobility Gradients in Free Standing Thin Films, KENNETH SCHWEIZER, STEPHEN MIRIGIAN, University of Illinois at Urbana-Champaign — Glass forming molecular and polymeric liquids confined by free surfaces experience major changes of their slow dynamics beginning at relatively large film thickness. We have constructed a predictive, quantitative, force-field level theory of relaxation in free-standing films that addresses the nature of the spatial mobility gradient [1]. The theory predicts a generic speed up of relaxation near the free surface due to two coupled effects: a local, direct surface reduction of cages near the vapor interface, and a weakening of the spatially long ranged component of the activation barrier associated with collective elasticity. Effective vitrification temperatures, dynamic length scales and mobile layer thicknesses naturally follow. At low temperatures in the vicinity of the thickness-dependent $T_g$, highly mobile and immobile regions are predicted to coexist near the surface and in the film interior, respectively. The latter can result in mechanical stiffening which can commence at a large film thickness. Our results provide a theoretical basis for reconciling a variety of experimental results (e.g., probe mobility, dielectric relaxation, particle embedding, ellipsometry, creep) within a single framework.

12:15PM T43.00004 Fragility Nanoconfinement Effect in Thin Polymer Films: Novel Characterization by Ellipsometry, TIAN LAN, Department of Materials Science and Engineering, Northwestern University, JOHN TORKELSON, Department of Materials Science and Engineering, Department of Chemical and Biological Engineering, Northwestern University — A novel ellipsometry-based method was introduced to determine kinetic fragility in polymer films and to investigate the effect of nanoscale confinement on polymer fragility. Three systems were studied: polystyrene (PS), polycarbonate (PC), and PS doped with small molecule dilluents of 1,10-bis-(1-pyrene)decane (BPD). In bulk-like films, fragility index measured by ellipsometry agreed very well with that by differential scanning calorimetry. With confinement, a dramatic decrease in fragility was observed in highly fragile PS and PC. The fragility decreased by 58% from 166 to 69 in PS and by 65% from 214 to 75 in PC as film thickness decreased from bulk to 27-28 nm; a substantially muted response was observed in the strongest of the three: PS + 2 wt% BPD, where the fragility decreased only 21% from 134 to 106 from a bulk film to a 27-nm-thick film. The larger fragility-confinement effect in more fragile polymers strongly correlates with a previous discovery of the $T_g$-confinement effect: the strength of the $T_g$-confinement effect increases with increasing fragility of bulk polymers. It indicates that bulk fragility is associated with the susceptibility of polymers to effects of nanoscale confinement.

12:27PM T43.00005 Vitrification of thin polymer films: from linear chain to soft-colloid like behavior, EMMANOULIS GLYNOS, BRADLEY FRIEBERG, University of Michigan, GEORGIOS SAKELLARIOU, University of Athens, ALEXANDROS CHREMOS, Imperial University, PETER GREEN, University of Michigan — The glass transition temperature $T_g$ of sufficiently thin, supported polymer films is dependent on the film thickness. Based on the nature of the polymer substrate interactions $T_g$ may increase, $\Delta T_g > 0$, or decrease, $\Delta T_g < 0$, in relation to the bulk. We show that for star-shaped macromolecules the value of $\Delta T_g$ depends on the functionality $f$ of the molecule, for polymer films supported by the same substrate. Specifically in the case of polystyrene (PS) macromolecules, with arms of molecular weight $M_{arm} < 10$ kg./mol., supported by silicon oxide substrates, $\Delta T_g < 0$, when $f < 4$. For much higher functionalities, $f > 32$, where the polymer exhibits soft-colloid like behavior $\Delta T_g \sim 0$. For values of $4 < f < 32$, $\Delta T_g > 0$. The transition from the linear-chain to the soft-colloid behavior is gradual and occurs with increasing $f$ and/or decreasing $M_{arm}$. With the help of molecular dynamics simulations we rationalize this behavior in terms of competing entropic effects, associated with changes in $f$ and $M_{arm}$, which drives the stability of these molecules to efficiently pack at interfaces.

12:39PM T43.00006 Dynamics of Hyperbranched Polymers under Confinement1, KRYSTALLLENIA ANDROULAKI, KIRIAKI KRISSHOPPOULOU, SPIROS H. ANASTASIADIS, Foundation for Research and Technology-Hellas and Univ. of Crete, Greece, DANIELE PREVOSTO, MASSIMILIANO LABARDI, University of Pisa, Italy — The effect of severe confinement on the dynamics of three different generations of hyperbranched polymers (Boltorns) is investigated by Dielectric Spectroscopy. The polymers are intercalated within the galleries of natural Na+–MMT, thus, forming 1nm polymer films confined between solid walls. The $T_g$’s of the polymers determined by DSC show a clear dependence on the generation whereas the transition is completely suppressed when all the polymer chains are intercalated. Combining polymerization theory with the AG approach, we theoretically predict the relaxation time at much lower $T$, which suggests a return to Arrhenius behavior that avoids a Kauzmann “entropy crisis.” Finally, we consider the applications of these ideas to ultra-stable polymer films formed by vapor deposition.

1 Co-financed by the EU and Greek funds through the Operational Program ”Education and Lifelong Learning” of the NSRF-Research Funding Program: THALES-Investing in knowledge society through the Eur. Social Fund (MIS 377278) and COST Action MP0902-COINAPO
and thin films, as well as in a BLJ liquid that we have simulated. The glass-formation can equally well describe the relaxation data for a large range of fragility variations of glass-forming liquids, such as polymer nanocomposites, and the local volume accessible for particle motion, and the growth of the collective motion in supercooled liquids. Surprisingly, we find that each of these models of local dynamics can be used to understand such different perspectives. In this work, we find quantitative relations between emergent elasticity in terms of the average local dynamics of glass-forming liquids. Some of them emphasize the importance of a progressively growing cooperative motion which grows while the configuration changes from the two processes are different.

Thermodynamic theories have predicted that the observed Tg reduction in ultrathin polymer films may be tied to small shifts in the specific volume of the liquid-line above Tg. Here we use ellipsometry to investigate the temperature-dependent specific volume for supported polystyrene (PS) films of different thicknesses. Using the Lorentz-Lorenz parameter as a measure of the relative change in film density, we calculate the specific volume from temperature-dependent measurements of the index of refraction. While the slope of the liquid-line (thermal expansion coefficient) remains constant upon confinement, the Tg(h) decrease is accompanied with a broadening of the transition and a small increase in the glass-line thermal expansion, consistent with a larger fraction of the sample remaining liquid to lower temperatures. We find that both the liquid and glass specific volume lines shift together with decreasing thickness.

An open question at present is what material property changes correspond to the large shifts in film dynamics upon packing effects at the pore wall and the Tg depression arising from intrinsic size effects.

The effect of nanoconfinement on free radical equilibrium polymerization, HAOYU ZHAO, SINDEE SIMON, Texas Tech University — Free radical polymerization under nanoconfinement results in changes in reaction kinetics, reaction thermodynamics, and polymer properties. In this work, hydrophilic and hydrophobic nanoporous media (d < 13 nm) are employed as the nanoconfined matrix to perform polymerization of acrylate monomer. Differential scanning calorimetry (DSC) is used to study the reaction kinetics and thermodynamics, whereas gel permeation chromatography (GPC) is used to measure the molecular weight of the polymer produced. Although the polymerization is thermodynamically feasible at low temperature, as reaction temperatures increase, the depolymerization rates in acrylate polymerization become appreciable resulting in equilibrium polymerization at high temperature. For polymer synthesized in nanoconfined environment, the change in entropy upon propagation becomes a larger negative number resulting in a decrease in equilibrium conversion and a shift of the ceiling temperature to lower temperatures. The results are analyzed in the context of the scaling of the change in confinement entropy of chains on chain length.

The effect of film processes on the chain conformations of adsorbed polymer nanolayers, MANI SEN, MAYA K. ENDOH, TADANORI KOGA, Department of Materials, Stony Brook, NY 11794-2275, DAISUKE KAWAGUCHI, Education Center for Global Leaders in Molecular Systems for Devices, Kyushu University, Fukuoka 819-0395, Japan, KEIJI TANAKA, Department of Applied Chemistry, Faculty of Engineering, Kyushu University, Fukuoka 819-0395, Japan — Polymer chains adsorb even onto weakly attractive solid surfaces, resulting in the formation of adsorbed polymer nanolayers ("PNs")..

We report how film processing affects the chain conformations composed of PNs. 50 nm thick polystyrene (PS, Mw=290 kDa) thin films were prepared onto hydrogen-passivated silicon substrates by using two different processes (i.e., spin coating and dip coating). The PNs were then formed by high temperature thermal annealing and subsequent rinsing with a good solvent. We characterized the PNs using x-ray reflectivity (XR), atomic force microscopy (AFM), and sum-frequency generation spectroscopy. The XR and AFM data reveal that the homogenous PNs are composed of the two different architectures regardless of the film processing: flattened polymer chains that constitute the inner higher density region of PNs and loosely adsorbed polymer chains that form the outer bulk-like density region although adsorbed chain conformations from the two processes are different.

1:51PM T43.00007 Enhanced Tg-Confinement Effect in Crosslinked Polystyrene Characterized by Ellipsometry, KAILONG JIN, JOHN TORKELSON, Northwestern University — The effects of nanoscale confinement on the glass transition temperature, Tg, and related behavior are studied in crosslinked polystyrene (PS). Crosslinked PS films are achieved by thermally annealing the spin-cast linear precursor (polystyrene-vinylbenzocyclobutene) films with varying thicknesses at 250 °C. Tg reductions are observed with ellipsometry measurements of both supported linear and crosslinked PS films, with confinement effects being enhanced in crosslinked polystyrene compared to the linear precursor. The greater magnitude of Tg reduction observed in confined crosslinked PS films can be rationalized by the increased bulk fragility induced by crosslinking. Effects of confinement on fragility and physical aging in the crosslinked PS will also be discussed.

1:03PM T43.00008 Reaction Rate Acceleration and Tg Depression of Polycyanurate Under Nanopore Confinement, EVELYN LOPEZ, SINDEE L. SIMON, Texas Tech University — Material properties such as Tg and the reaction kinetics are known to deviate from the bulk when subjected to nano-sized confinement. Previous work from our laboratory on the trimerization of cyanoate esters found that the reaction kinetics were faster for a monofunctional reactant compared to a difunctional monomer, whereas the Tg depression was greater for the crosslinked product of the latter compared to the low molecular weight trimer of the former. The origin of the changes in nanoconfined reaction rates differs from those that govern changes in the Tg. The research objective is to further explore the effect that confinement has on reaction kinetics and Tg using a mixture consisting of mono- and di-cyanoate ester monomers. The product is an uncrosslinked polycyanurate with Mn = 5240 g/mol and PDI = 1.78. The confinement mediums are controlled pore glasses with diameters ranging from 8.1 to 111.1 nm. The nanopore-confined material was synthesized in-situ and the reaction kinetics are followed by DSC; after the reaction, the Tg values of the nanoconfined polymer where also measured by DSC. An acceleration factor of 13 and a Tg depression of 38 °C are observed for the material confined in the smallest 8.1 nm-diameter pores. The Tg depression is between those of the trimer and network previously studied, while the acceleration of the reaction rate is lower. Our results are consistent with the reaction acceleration arising from packing effects at the pore wall and the Tg depression arising from intrinsic size effects.

1:15PM T43.00009 The Effect of Nanoconfinement on Free Radical Equilibrium Polymerization, HAOYU ZHAO, SINDEE SIMON, Texas Tech University — Free radical polymerization under nanoconfinement results in changes in reaction kinetics, reaction thermodynamics, and polymer properties. In this work, hydrophilic and hydrophobic nanoporous media (d < 13 nm) are employed as the nanoconfined matrix to perform polymerization of acrylate monomer. Differential scanning calorimetry (DSC) is used to study the reaction kinetics and thermodynamics, whereas gel permeation chromatography (GPC) is used to measure the molecular weight of the polymer produced. Although the polymerization is thermodynamically feasible at low temperature, as reaction temperatures increase, the depolymerization rates in acrylate polymerization become appreciable resulting in equilibrium polymerization at high temperature. For polymer synthesized in nanoconfined environment, the change in entropy upon propagation becomes a larger negative number resulting in a decrease in equilibrium conversion and a shift of the ceiling temperature to lower temperatures. The results are analyzed in the context of the scaling of the change in confinement entropy of chains on chain length.

1:27PM T43.00010 Effect of film processes on the chain conformations of adsorbed polymer nanolayers, MANI SEN, MAYA K. ENDOH, TADANORI KOGA, Department of Materials, Stony Brook, NY 11794-2275, DAISUKE KAWAGUCHI, Education Center for Global Leaders in Molecular Systems for Devices, Kyushu University, Fukuoka 819-0395, Japan, KEIJI TANAKA, Department of Applied Chemistry, Faculty of Engineering, Kyushu University, Fukuoka 819-0395, Japan — Polymer chains adsorb even onto weakly attractive solid surfaces, resulting in the formation of adsorbed polymer nanolayers ("PNs"). We report how film processing affects the chain conformations composed of PNs. 50 nm thick polystyrene (PS, Mw=290 kDa) thin films were prepared onto hydrogen-passivated silicon substrates by using two different processes (i.e., spin coating and dip coating). The PNs were then formed by high temperature thermal annealing and subsequent rinsing with a good solvent. We characterized the PNs using x-ray reflectivity (XR), atomic force microscopy (AFM), and sum-frequency generation spectroscopy. The XR and AFM data reveal that the homogenous PNs are composed of the two different architectures regardless of the film processing: flattened polymer chains that constitute the inner higher density region of PNs and loosely adsorbed polymer chains that form the outer bulk-like density region although adsorbed chain conformations from the two processes are different.

1:39PM T43.00011 Investigation of the Temperature-Dependent Specific Volume of Supported Polystyrene Films Upon Confinement, XINRU HUANG, CONNIE ROTH, Dept. of Physics, Emory University — The experimentally observed large changes in the glass transition temperature Tg of ultrathin supported and free-standing polymer films with decreasing thickness h have puzzled the field for more than two decades. An open question at present is what material property changes correspond to the large shifts in film dynamics upon confinement. Thermodynamic theories have predicted that the observed Tg(h) decrease in ultrathin polymer films may be tied to small shifts in the specific volume of the liquid-line above Tg. Here we use ellipsometry to investigate the temperature-dependent specific volume for supported polystyrene (PS) films of different thicknesses. Using the Lorentz-Lorenz parameter as a measure of the relative change in film density, we calculate the specific volume from temperature-dependent measurements of the index of refraction. While the slope of the liquid-line (thermal expansion coefficient) remains constant upon confinement, the Tg(h) decrease is accompanied with a broadening of the transition and a small increase in the glass-line thermal expansion, consistent with a larger fraction of the sample remaining liquid to lower temperatures. We find that both the liquid and glass specific volume lines shift together with decreasing thickness indicative of small 0.5-1% changes in overall film density with decreasing thickness.

1:51PM T43.00012 Quantitative Relations Between Cooperative Motion and Emergent Elasticity in Model Glass-Forming Polymer Materials, BEATRIZ A PAZMINO BETANCOURT, Wesleyan/NIST, PAUL HANAKATA, FRANCIS W STARR, Wesleyan, JACK F. DOUGLAS, NIST — There are many semi-empirical models that allow us to understand the dynamics of glass-forming liquids. Some of them emphasize the importance of a progressively growing cooperative motion which grows while the configuration entropy of the liquid drops. Others from a solid-like nature of glass perspective look at the emergent elasticity. However, there has been limited success in finding a unified framework of understanding such different perspectives. In this work, we find quantitative relations between emergent elasticity in terms of the average local volume accessible for particle motion, and the growth of the collective motion in supercooled liquids. Surprisingly, we find that each of these models of glass-formation can equally well describe the relaxation data for a large range of fragility variations of glass-forming liquids, such as polymer nanocomposites, and thin films, as well as in a BLJ liquid that we have simulated.
2:03PM T43.00013 Molecular-weight Dependent $T_g$ Depression of Silica-supported Poly($\alpha$-methyl styrene) Films1, KUN GENG, FEI CHEN, Department of Physics, Boston University, OPHELIA K. C. TSUI, Department of Physics and Division of Materials Science and Engineering, Boston University — The glass transition temperature ($T_g$) of poly($\alpha$-methyl styrene) (P$\alpha$MS) films supported by silica is studied as a function of film thicknesses from 17 to 168 nm at three molecular weights of 1.3, 20 and 420 kg/mol. For the 20 and 420 kg/mol films, the glass transition temperature decreases with decreasing film thickness, consistent with previous results. But for the 1.3 kg/mol films, it becomes independent of the film thickness. We tentatively suggest the $T_g$ depression to be caused by free volume excess at the polymer-air interface and that its influence diminishes at low enough molecular weights because of a chain stiffness effect.

11:27AM T44.A00002 ABSTRACT WITHDRAWN –

11:39AM T44.A00003 Shear of ordinary and elongated granular mixtures1, ALEXANDER HENSLEY, MATTHEW KERN, Rochester Institute of Technology, THEODORE MARCHALL, STEPHEN TEITEL, University of Rochester, SCOTT FRANKLIN, Rochester Institute of Technology — We present an experimental and computational study of a mixture of discs and moderate aspect-ratio ellipses under two-dimensional annular planar Couette shear. Experimental particles are cut from acrylic sheet, are essentially incompressible, and constrained in the thin gap between two concentric cylinders. The annular radius of curvature is much larger than the particles, and so the experiment is quasi-2d and allows for arbitrarily large pure-shear strains. Synchronized video cameras and software identify all particles and track them as they move from the field of view of one camera to another. We are particularly interested in the global and local properties as the mixture ratio of discs to ellipses varies. Global quantities include average shear rate and distribution of particle species as functions of height, while locally we investigate the orientation of the ellipses and non-affine events that can be characterized as shear transformational zones or possess a quadrupole signature observed previously in systems of purely circular particles. Discrete Element Method simulations on mixtures of circles and spherocylinders extend the study to the dynamics of the force network and energy dissipated as the system evolves.

11:51AM T44.A00004 Maxwell Construction for a Nonequilibrium Steady-State Phase Separation in Granular Matter, MARCO G. MAZZA, JAMES CLEWETT, Max Planck Institute for Dynamics and Self-Organization, JACK WADE, ROGER BOWLEY, University of Nottingham, STEPHAN HERMINGHAUS, Max Planck Institute for Dynamics and Self-Organization, MICHAEL SWIFT, University of Nottingham — Experiments and computer simulations are carried out to investigate phase separation in a granular gas under external vibration in a large sample cell. The densities of the dilute and the dense phase are found to follow a lever rule, suggesting an equation of state. We show that this equation of state, which exhibits a non-monotonous pressure-volume characteristic, $P(v)$, can be obtained from simulations of a small cell. A Maxwell construction is found to predict both the coexisting pressure and binodal densities remarkably well, despite the fact that $P(v)$ is not an isotherm. Although the system is far from equilibrium and energy conservation is strongly violated, we can derive this finding from an energy minimization argument of fluctuating currents.

12:03PM T44.A00005 Electrical charging in shaken granular media1, FREJA NORDSIK, DANIEL LATHROP, University of Maryland College Park — Collisional electrification of granular particles and the resulting electric fields are seen but poorly understood in sand storms, volcanic ash clouds, thunderstorms, and thundersnow. We present results on the electrical charging of granular media (100 micron to 1 mm in size) shaken between two conducting plates. The voltage between the plates was measured. We saw particle electrification through capacitive coupling with the plates and electrical discharges for a diverse class of materials: polystyrene (polymer), soda-lime glass (glass), 69%:31% ZrO$_2$:SiO$_2$ (ceramic), and aluminum (metal). We found 1) a monotonic increase in charging with shaking strength, 2) a threshold in the number of particles to see charging of about the number of particles needed to form a monolayer on the plate, 3) material and diameter differences causing an order of magnitude spread in measured signal but little difference between mono-material sets with one size range and bi-material and/or bi-size range set combinations, and 4) long time scale transients. We argue that while two-body collisions and the physical properties of the particles (material and size) are relevant, collective phenomena are a necessary part of explaining natural charging of granular flows.

12:15PM T44.A00006 Complex Kepler Orbits and Particle Aggregation in Charged Microscopic Grains, VICTOR LEE, Univ of Chicago, SCOTT WAIKUKAITIS, Leiden University, MARC MISKIN, Cornell University, HEINRICH JAEGER, Univ of Chicago — Kepler orbits are usually associated with the motion of astronomical objects such as planets or comets. Here we observe such orbits at the microscale in a system of charged, insulating grains. By letting the grains fall freely under vacuum, we eliminate the effects of air drag and gravity, and by imaging them with a co-falling high-speed camera we track the relative positions of individual particles with high spatial and temporal precision. This makes it possible to investigate the behaviors caused by the combination of long-range electrostatic interactions and short-range, dissipative, contact interactions in unprecedented detail. We make the first direct observations of microscopic elliptical and hyperbolic Kepler orbits, collide-and-capture events between pairs of charged grains, and particle-by-particle aggregation into larger clusters. Our findings provide experimental evidence for electrostatic mechanisms that have been suspected, but not previously observed at the single-event level, as driving the early stages of particle aggregation in systems ranging from fluidized particle bed reactors to interstellar protoplanetary disks. Furthermore, since particles of different net charge and size are seen to aggregate into characteristic spatial configurations, our results suggest new possibilities for the formation of charge-stabilized “granular molecules”. We can reproduce the observed molecule configurations by taking many-body, dielectric polarization effects into account.
A nonlinear feedback model for granular and surface charging. TROY SHIN-BROT, LEO KOZACHKOV, THEO SIU, Rutgers University — Independent laboratories have experimentally demonstrated that identical materials brought into symmetric contact generate contact charges. Even the most basic features of this odd behavior remain to be explained. In this talk, we provide a simple,· Ising-like, model that appears to account for many of the observed phenomena. We calculate the electric field acting on surface molecules in a lattice, and we show that if the molecules are polarizable, then infinitesimal random polarizations typically build exponentially rapidly in time. These polarizations self-assemble to produce surface patterns that come in two types, and we find that one of these types accounts for strong localized charging, while the other produces a weaker persistent surface charge pattern. We summarize predictions for both ideal surfaces and for defects in granular beds.

1:03PM T44.00010 Effect of system and particle properties on closure relations for granular segregation models. ABHINENDRA SINGH, D. R. TUNUGUNTALA, A. R. THORNTON, Univ of Twente, MULTI SCALE MECHANICS TEAM — In recent years, much effort has been made on developing valid constitutive laws for continuum models to describe kinetic sieving driven segregation in granular flows over inclined channels. Surprisingly, the existing closure relations for such continuum models have not considered factors such as particle contact stiffness, coefficient of restitution etc. Using Discrete Element method simulations, we investigate the effects of these factors on particle segregation and thereby manifest the grain-to-wall effective friction force is reached. This can be related to a theoretical model which treats the silo as a thin cylindrical shell subjected to an axial stress with the profile predicted by Janssen’s model for the stresses in a silo filled with a granular material. This model predicts correctly the experimental scaling of with various parameters of the system.

1:15PM T44.00011 Formation and properties of a dynamic suspension. TESS HOMAN, VALÉRIE VIDAL, SYLVAIN JOUBAUD, Laboratoire de Physique, Ecole Normale Supérieure de Lyon — We experimentally study the behaviour of an immersed granular bed in a Hele-Shaw cell when perturbed by an airflow from a single inlet at the bottom. When the particles are slightly heavier than the liquid, the competition between particles being dragged up into the liquid and particles settling due to gravity results in a dynamic suspension. In the stationary regime, part of the initial granular bed never moves, and forms a so-called “dead zone.” We investigate its shape and extent as a function of the parameters (air flow-rate, initial grains and liquid height). We also focus on the formation and properties of the dynamic suspension by optically recording the full particle density field in the Hele-Shaw cell. The mean density and density fluctuations of the dynamic suspension are studied as a function of the gas flow-rate and the ratio between the initial granular bed never moves, and forms a so-called “dead zone.” We investigate its shape and extent as a function of the parameters (air flow-rate, initial grains and liquid height). We also focus on the formation and properties of the dynamic suspension by optically recording the full particle density field in the Hele-Shaw cell. The mean density and density fluctuations of the dynamic suspension are studied as a function of the gas flow-rate and the ratio between the amount of grains and liquid.

1:27PM T44.00012 Raindrop impact on sand: dynamic and crater formation. SONG-CHUAN ZHAO, RIANNE DE JONG, DEVARAJ VAN DER MEER, Univ of Twente — Droplet impact on a granular bed is very common in nature, industry, and agriculture and extends from raindrops falling on earth to wet granulation in the production process of many pharmaceuticals. In contrast to more traditionally studied impact phenomena, such as a droplet impact on solid substrate and solid object impact on fluid-like substrate, raindrop impact on sand induces more complicated interactions. First, both the intruder and the target deform during impact; second, the liquid composing the droplet may penetrate into the substrate during the impact and may, in the end, completely merge with the grains. These complex interactions between the droplet intruder and the granular target create the very diverse crater morphologies that has been described in the literature. An appealing and natural question is how the craters are formed. To gain insight in the mechanism of crater formation, we resolve the dynamics with high-speed laser profilometry and study the dependence of the dynamics on impact speed and packing fraction of the granular substrate. Finally, we establish a dynamical model to explain the various crater morphologies.

1:39PM T44.00013 Granular impact cratering by liquid drops: Understanding raindrop imprints through an analogy to asteroid strikes. XIANG CHENG, RUNCHEN ZHAO, QIANYUN ZHANG, HENDRO TJUGITO, University of Minnesota — When a granular material is impacted by a sphere, its surface deforms like a liquid yet it preserves a circular crater like a solid. Although the mechanism of granular impact cratering by solid spheres is well explored, our knowledge on granular impact cratering by liquid drops is still very limited. Here, by combining high-speed photography with high-precision laser profilometry, we investigate liquid-drop impact dynamics on granular surface and monitor the morphology of resulting impact craters. Surprisingly, we find that, despite the enormous energy and length difference, granular impact cratering by liquid drops follows a similar energy scaling and reproduces the same crater morphology as that of asteroid impact craters. Inspired by this similarity, we propose a simple, theoretical model that quantitatively describes all the main features of liquid-drop imprints in granular media. Our study sheds light on the mechanisms governing raindrop impacts on granular surfaces and reveals a remarkable analogy between familiar phenomena of raining and catastrophic asteroid strikes.
1:51PM T44.00014 Kinetics of Gravity-Driven Water Channels under Steady Rain, REMI DREYFUS, CESARE CEJAS, REMI BARROIS, CNRS-Solvay-UPenn UM13254, Complex Assemblies of Soft Matter, COMPASS, Bristol, PA, USA 19007, YULLI WEI, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19014, CHRISTIAN FREITIGNY, CNRS UMR 7615 Sciences et Ingénierie de la Matière Molle (SIMM), ESPCI, Paris, France 75005, DOUGLAS DURIAN, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19014 — We investigate the physical mechanisms that govern the formation of water channels that develop from finger instabilities at the wetting front. Using controlled experiments in a quasi-2D cell and varying physical parameters (particle size, fluid viscosity, etc.), we simulate rainfall and characterize the homogeneous wetting front as well as channel size and estimate relevant time scales associated with the instability as well as channel velocity. We validate the results by developing a model based on linear-stability analysis with the addition of another term describing the homogenization of the wetting front. This shows that the way we introduce a fluid into a granular medium affects the formation of water channels. Results permit us to calculate the ideal flow rate for maximizing water distribution and minimizing runoffs using granular and fluid properties.

2:03PM T44.00015 Splash Suppression by Solvent Viscosity in Dense Suspension Impact, WENDY ZHANG, KEVIN DODGE, IVO PETERS, MARTIN KLEIN SCHAARSBERG1, HEINRICH JAEGGER, University of Chicago — When a dense suspension droplet impacts a hard surface, it will either break apart (“splash”) or remain in a compact configuration without ejecting any particles. We use experiments and discrete particle simulations in which relative particle motions are penalized by lubrication-flow drag to analyze the influence of solvent viscosity on splashing. We find that suspension splash is driven by particle inertia. It can be suppressed in 2 different ways. At low solvent viscosity, lubrication drag due to viscous flow has a negligible effect. Splash is suppressed by surface tension overcoming particle inertia. At high solvent viscosity, lubrication drag alone suppresses splashing. Because impact produces an expanding flow that stretches the suspension radially, suppression in the high-viscosity regime is largely accomplished by lubrication-flow drag preventing initially nearby particle pairs from separating fully. Energy dissipation by viscous flow during collisions plays a smaller role.

1Present Address: Physics of Fluids Group, University of Twente

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T45 DPOLY: Transport in Polymer Membranes 216AB - Rajiv Taribagil, Infineum

11:15AM T45.00001 Three-Step Water Sorption of Thin Nafion Films, DAISUKE KAWAGUCHI, Education Center for Global Leaders in Molecular Systems for Devices, Kyushu University, YUDAI OGATA, Department of Applied Chemistry, Kyushu University, Japan, NORIFUMI YAMADA, Neutron Science Laboratory, High Energy Accelerator Research Organization, Japan, KELII TANAKA, Department of Applied Chemistry, Kyushu University, Japan — Nafion has been widely used as a proton exchange film in polymer electrolyte fuel cell (PEFC). Although downsizing PEFC is one of the interesting developments in the near future, it appears that most studies conducted so far are limited to bulk systems. Here we examined water sorption behavior in thin Nafion films based on optical and neutron reflectivity measurements. Nafion films were prepared on silver and silicon oxide substrates. It was found that the thicknesses of Nafion thin films increased with time after contacting water in three steps. The asymptotic swelling ratios in regimes I, II and III were 1.05, 1.26 and 1.41, respectively. These values were in-dependent of the substrate species, and were coincident with the transition points of different hydration states in the bulk Nafion; water binding to sulfonic acid groups, the formation of sphere-like ionic clusters, and bridge formation between clusters. The swelling was much slower in thin films than in the bulk due to the mobility restriction of Nafion near the substrate.

11:27AM T45.00002 Impact of Ageing on Properties of PFSA Ionomers1, AHMET KUSOGLU, MERON TESFAYIR, SHOUWEN SHI, WILL TONG, ADAM WEBER, Lawrence Berkeley National Laboratory — Perfluorosulfonic-acid (PFSA) ionomers are widely used as the solid-electrolyte in electrochemical energy applications due to their remarkable conductivity and chemical/mechanical stability. However, in various applications, it is not uncommon for the ionomer to be subjected to various operational environmental stressors that could impact their morphology and properties. In this talk, the impact of hygrothermal ageing on both bulk ionomer and ionomer thin films will be discussed. The intrinsic changes to the morphology and properties will be presented including water uptake and swelling behavior as well as nanostructure using both transmission and grazing-incidence small- and wide-angle x-ray scattering. It will be shown how ageing at intermediate humidities (50 to 70% relative humidity) induces higher mechanical properties and subsequently lower water uptake for both bulk and thin film ionomers due to a loss of accessible ionic sites, which are thought to form crosslinks. Ageing at higher and lower relative humidities shows a decrease in these changes. The ionomers to be studied include both Nafion and the short-side-chain analogue by 3M with higher ion-exchange capacity. Our findings provide new insights into how ageing alters the structure/function relationship of ionomers.

1Supported by U. S. Department of Energy under contract number DE-AC02-05CH11231 and Joint Center for Artificial Photosynthesis

11:39AM T45.00003 In-situ measurement of swelling induced stress of thin Nafion films during hydration cycles, BRADLEY FRIEBERG, KIRT PAGE, GERY STAFFORD, CHRISTOPHER SOLES, Natl Inst of Stds & Tech (NIST) — Perfluorinated ionomers, in particular Nafion, are a critical component in hydrogen fuel cells, as the binder within the membrane electrode assembly in which it can be confined to thicknesses on the order of ten nanometers. During normal operation of a hydrogen fuel cell the ionomer will progressively swell and de-swell in response to the changes in hydration, resulting in a mechanical fatigue and ultimately failure of the fuel cell with time. In this study we have developed and implemented a cantilever bending technique in order to investigate the swelling induced stresses in Nafion thin films. By monitoring the deflection of a cantilever beam coated with a polymer film as it is exposed to various humidity environments, the swelling induced stress-thickness of the polymer film can be measured. By combining the stress-thickness results with a measurement of the film thickness as a function of humidity, the swelling stress can be determined. Using this techniques we have measured the shear modulus and estimated the Young’s modulus of thin Nafion films as a function of film thickness (ranging from 30 nm to 200 nm), processing conditions and humidity.

11:51AM T45.00004 Elucidating the Role of Confinement on Structure and Water Transport in Nafion Thin Films, ERIC DAVIS, NICHOLE NADERMANN, EDWIN CHAN, CHRISTOPHER STAFFORD, KIRT PAGE, Materials Science and Engineering Division, National Institute of Standards and Technology, Gaithersburg, MD 20899 — Perfluorinated ionomers, specifically Nafion, are the most widely used polymer membranes for fuel cell applications. For these devices, Nafion is utilized in both a bulk (hundreds of microns) and confined (tens of nanometers) state. Therefore, a more complete understanding of the structure-processing-property relationships of these thin ionomer films, compared to the bulk membranes, is needed. In this study, water transport and structure of a series of Nafion thin film thicknesses were measured using a variety of experimental techniques. Water diffusion was measured via time-resolved in situ polarization modulation infrared reflection absorption spectroscopy (PM-IRRAS) and poroelastic relaxation indentation (PRI). The former probes through-thickness diffusion (direction of confinement), while the latter probes in-plane diffusion in the Nafion thin films. Suppressed water diffusion relative to the bulk was observed in both the through-thickness and in-plane directions of the thin film Nafion. Additionally, the structure of hydrated Nafion thin films was captured using small-angle neutron scattering (SANS). These results suggest that the nanostructure of the Nafion changes as the thickness of the film is decreased, resulting in a decrease in the effective water diffusivity of these thin ionomer films compared to the bulk membranes.
12:03PM T45.00005 Kinetics of swelling enhancement of polyelectrolyte brushes , XIAO CHU, JINGFA YANG, Institute of Chemistry, Chinese Academy of Sciences, GUANGMING LIU, University of Science and Technology of China, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences — The swelling of polystyrene sulfonate brushes is enhanced due to the break-up of the multiplets formed by dipole-dipole interactions inside, when external salt concentration is increased to moderate value. By quartz crystal balance with dissipation, the kinetics of this process is investigated and a systematic study on the effect of grafting density and salt concentration is conducted. The results demonstrate the effect of spatial hindrance due to uneven distribution of segments and osmotic pressure of the external ions.

12:15PM T45.00006 Nano Aggregation of Structured Ionic Copolymers: Molecular Dynamics Simulation Study1 , DIPAK ARYAL, DVORA PERAHIA, Clemson University, GARY S. GREST, Sandia National Laboratories — Driven by mutual segregation, block copolymers exhibit a fascinating ability to self-assemble into a variety of ordered mesoscopic structures. Incorporating an ionizable block enhances incompatibility that together with tailoring blocks for specific functions presents an immense step towards engineering controlled transport systems. Here the interplay between the interactions of solvents with the specific blocks of a pentablock with a randomly sulfonated polystyrene center, tailored for transport, tethered to flexible poly(ethylene-r-propylene) end-capped with poly-(t-butyl styrene) is studied by fully atomistic molecular dynamics simulations. The assembly of 2 to 30 macromolecules, in water results in a spherical tightly packed aggregate in which the ionizable blocks dominates the water interface. Transferred to a cyclohexane-heptane mixture, the hydrophobic blocks migrate to the interface. Surprisingly however, the ion blocks form a nano-network rather than a corona. Further, this network also develops when assembled from hydrophobic solvents, where now the hydrophobic blocks dominate the interface. This network only slightly contracts or expands as the solvent is changed while concurrently the hydrophobic blocks migrate towards or away from the solvent interface.

12:27PM T45.00007 Cluster Morphology in Lightly Sulfonated Polystyrene1 , ANUPRIYA AGRAWAL, DVORA PERAHIA, Clemson University, GARY S. GREST, Sandia National Laboratories — Aggregation of ionic groups into clusters in ionomers renders their unique properties that drive the use in energy applications. The ionic clusters however have a dramatic impact on the rheology of this polymer. Even small fractions of ionic groups (less than 5%), constrain their dynamics, making them difficult to process. Using molecular dynamics simulations, we show that in lightly sulfonated polystyrene melts, the ionic groups aggregate into ladder type clusters. These ladder morphologies prevail for a broad temperature range and degree of sulfonation, although with some variation due to steric effects of the chain. Reducing the electrostatic strength by tuning the dielectric constant changes the cluster morphology from ladder to spherical, which in turn, greatly increases the diffusion of the polymer. The effect of changing the electrostatic strength is comparable to the effect of addition of diluents to these melts. Enhancing the electrostatic screening results in breaking the clusters, whereas increasing temperature within the measured range, results in faster diffusion of the entire polymers while the clusters remain intact.

12:39PM T45.00008 Salt uptake and dynamics in thin, highly crosslinked polyamide membranes , KATHLEEN FELDMAN, EDWIN CHAN, CHRISTOPHER STAFFORD, National Institute of Standards and Technology — Water purification membranes have historically been developed through an Edsionian, trial and error approach. It has been challenging to establish fundamental structure-property-performance relationships, including salt/water permeability, in large part due to the typically rough and poorly-defined nature of the polyamide membrane active layer. By using molecular layer by layer (mLbL) deposition, we are able to produce thin, well-defined polyamide films with controlled chemistry analogous to commercial reverse osmosis and nanofiltration membranes. While water permeation in polyamide membranes is reasonably straightforward to measure, salt permeation is more challenging, particularly in ultrathin films. We measure both equilibrium salt uptake and dynamic behavior in nanofiltration-type membranes using x-ray photoelectron spectroscopy (XPS), electrochemical impedance spectroscopy (EIS), and quartz crystal microbalance (QCM). By connecting intrinsic material properties such as the salt permeability and permselectivity with macroscopic performance measures we can begin to establish design rules for improving membrane efficiency while lowering energy requirements.

12:51PM T45.00009 Fabrication of ultrafiltration membranes using dynamic thermal annealing of Block Copolymer films , ALAMGIR KARIM, YAN LUO, YAN SUN, The University of Akron — Block copolymer (BCP) thin films have attracted immense attention for fabrication of ultrafiltration membranes due to their potential to provide dense nanostructured pores giving high flux and good efficiency. We have demonstrated generation of well-ordered hexagonally packed perpendicular cylindrical BCP films with greater than 90 percent of perpendicular cylinder orientations over large areas with high cylinder density and desired porosity at the nanoscale via facile dynamic thermal annealing. The films are then transferred to a support membrane and subsequently the vertically oriented minority block is selectively etched to form a nanoporous membrane. The porosity of film and pore density is tuned by addition of selective homopolymer block component. The structure of nanoporous BCP membranes is characterized by Atomic Force Microscopy(AFM), Grazing Incidence Small Angle X-ray Scattering and Transmission Electron Microscopy(TEM). We further demonstrate the application of these membranes for separation of emulsions and correlate flux and efficiency to parameters such as porosity, membrane thickness and tortuosity.

1:03PM T45.00010 Super stretchy polymer multilayer thin films with tunable gas barrier , FANGMING XIANG, SARAH WARD, TARÁ GIVENS, JAIME GRUNLAN, Texas A&M Univ — Super stretchy multilayer thin film assemblies with tunable gas barrier were fabricated using layer-by-layer (LbL) assembly. Unlike ionically-bonded gas barrier coatings that exhibit mud-cracking after 10% strain, hydrogen-bonded polyethylene oxide (PEO) and polyacrylic acid (PAA) multilayer thin films show no cracking after 100% strain due to low modulus. It is believed that the exceptional elasticity of this thin film originates from the intrinsic elasticity of PEO and the moderate hydrogen bond strength between PEO and PAA. The oxygen transmission rate (OTR) of a 1.58 mm thick natural rubber sheet can be reduced 10 times with a 367-nm-thick PAA/PEO nanocoating. This gas barrier improvement is largely retained after 100% strain. The modulus and oxygen permeability of PAA/PEO assembly can be tailored through altering the barrier improvement is largely retained after 100% strain. The modulus and oxygen permeability of PAA/PEO assembly can be tailored through altering the modulus and oxygen permeability of PAA/PEO assembly can be tailored through altering the barrier properties such as the salt permeability and permselectivity with macroscopic performance measures we can begin to establish design rules for improving barrier properties such as the salt permeability and permselectivity with macroscopic performance measures we can begin to establish design rules for improving membrane efficiency while lowering energy requirements.

1:15PM T45.00011 A molecular study of gas solubility in nitrile rubber , MUSAB KHAWAJA, Imperial College London, London College of Drinking, London College of Materials and Physics, London College of Physics, London College of Physics, London SW7 2AZ, UK — One of the most important uses of elastomers in the oil industry is for seals to encase and protect sensitive monitoring equipment from contamination by gases and liquids at the high pressures and temperatures in the well. Failure of such seals sometimes occurs on decompression when they are returned to the surface. The conditions in the well lead to gases being absorbed by Nitrile rubber (NBR) seals. NBR exhibits a strong permselectivity towards CO2 compared to other gases; something attributed experimentally to the enhanced solubility of CO2. In this study an explanation is sought at the molecular level for this phenomenon. A series of molecular mechanics calculations are performed to compute solubilities of different gases in NBR. The effect of acrylonitrile content on their solubilities is studied for the first time by simulation, and we discuss the important issue of convergence with respect to the sampling of different elastomer configurations. It is observed that the presence of cyano groups has a marked impact on the solubility of CO2 and an explanation is offered.
1:27PM T45.00012 Liquid Crystalline Block Copolymers with Brush Type Architecture: Toward Functional Membranes by Magnetic Field Alignment1, YOUNGWOO CHOO, MANESH GOPINADHAN, Yale University, LALIT MAHAJAN, RAJESWARI KASI, University of Connecticut, CHINEDUM OSUJI, Yale University — We introduce a novel liquid crystalline block copolymer with brush type architecture for membrane applications by magnetic field directed self-assembly. Ring-opening metathesis of n-alkoxy cyanobiphenyl and poly lactide (PLA) functionalized norbornene monomers provides efficient polymerization yielding low polydispersity block copolymers. The molecular weight of the PLA side chains, spacer length of the cyanobiphenyl mesogens are systematically varied to form well-ordered BCP morphologies at varying volume fractions. Interestingly, the system features morphology dependent anchoring condition where mesogens adopt planar block interface while homeotropic anchoring was preferred on a planar block interface. The minority PLA domains from highly aligned materials can be readily degraded by hydrolysis to produce vertically aligned nanoporous polymer films which exhibit reversible thermal switching behavior. The polymers introduced here provide a versatile platform for scalable fabrication of aligned membranes and further functional materials based on such templates.

1:39PM T45.00013 Bubble Growth and Dynamics in a Strongly Superheated Electrolyte within a Solid-State Nanopore1, EDLYN LEVINE, GAKU NAGASHIMA, School of Engineering & Applied Sciences, Harvard University, MICHAEL BURNS, The Rowland Nanoscience Institute at Harvard, Harvard University, JENE GOLOVCHENKO, Dept. of Physics and School of Engineering & Applied Sciences, Harvard University — Extremely localized superheating and homogeneous vapor bubble nucleation have recently been demonstrated in a single nanopore in thin, solid state membranes. Aqueous electrolytic solution within the pore is superheated to well above its boiling point by Joule heating from ionic current driven through the pore. Continued heating of the metastable liquid leads to nucleation of a vapor bubble in the pore followed by explosive growth. Here we report on the growth dynamics of the vapor bubble after nucleation in the strongly superheated liquid. The process is modeled by numerically solving the Rayleigh-Plesset equation coupled with energy conservation and a Stefan boundary condition. The initial temperature distribution, peaked at the pore center, is taken to be radially symmetric. Energy conservation includes a Joule heating source term dependent on the bubble radius, which grows to constrict ionic current through the nanopore. Temperature-dependent properties of the electrolyte and the vapor are incorporated in the calculation. Comparison of the model to experimental results shows an initial bubble growth velocity of 50m/s and total bubble lifetime of 16ns.

1:51PM T45.00014 Self-assembly of Spherical Macroions in Solution: A Coarse-grained Molecular Dynamics Study1, ZHUONAN LIU, TIANBO LIU, MESFIN TSIGE, University of Akron, Department of Polymer Science, Akron, Ohio — Macroions (such as poloxomelatates) in solution can form a stable hollow spherical super-molecular structure called blackberry when they have moderate surface charge density and size (< 10 nm). Depending on the surface charge density of macroions, the size of the blackberry can be from 20 to more than 100 nm. Other macroions such as dendrimers can also self-assemble into similar super-molecular structure in solution. Existing theories such as Deby-Hückel and DLVO theories cannot explain this phenomenon and we are not aware of any other theory that can explain this. Previous studies using all-atom Molecular Dynamics simulations have shown identical macroions forming oligomers mediated by counterions. Due to the limitations in all-atom simulation and available computational capabilities, these studies handled only small systems with simple macroions, leading to less conclusive but still relevant results on the self-assembly behavior. To overcome these limitations, in this work large-scale coarse-grained modeling of macroions in solution is used. In order to understand the origin of the attractive force that is responsible for the self-assembly of macroions, different types of macroions in different solution conditions are studied.

2:03PM T45.00015 Effects of polymer hydrophobicity on the diffusivity of water and ethanol in acrylate copolymer gels, FARID KHABAZ, SRIRAM VIGNESHWAR MANI, RAJESH KHARE, Texas Tech University — Pervaporation is an energy efficient process for separating dilute alcohol-water mixtures. The efficiency of the pervaporation process is governed by the solubility and diffusivity of the water and alcohol molecules in the polymer. Molecular simulations can be used to provide detailed insights on the dependence of the diffusivity on the molecular structure of the polymer. Polyacrylate systems with varying degree of hydrophobicity are built by changing the relative concentrations of butyl acrylate and 2-hydroxy ethyl acrylate monomers which are hydrophobic and hydrophilic, respectively. In order to create the membrane structure, a random copolymer of these monomers that is cross-linked with pentaerythritol tetracrylate, is obtained using the simulated annealing polymerization technique. The volumetric properties of the systems such as density and glass transition temperature (T_g), are compared with the experimental values to validate the model structures. The diffusivity of the water and ethanol molecules inside the membrane is characterized by determining their mean squared displacement (MSD) in systems with varying degrees of hydrophobicity and cross-linker concentration. The calculated diffusion coefficients of water and ethanol from simulations will be compared with available experimental diffusion data. The correlation between the diffusivities and the degree of hydrophobicity as well as the molecular packing in these systems will be identified.

11:15AM T46.00001 Cell size control in microorganisms, ARIEL AMIR, Harvard University — Organisms in all kingdoms of life face a challenge of regulating the size of their cells, control of which is essential for their viability. How do cells decide when to divide? For decades, a popular hypothesis has been that cells can measure their absolute size, and that reaching a critical size triggers the division process. This would imply that a cell that was born smaller than average will not be smaller than average when it divides - in contrast to experiments showing that such correlations exist, and that size is partly inherited. I will present a biophysical model that sheds new light on this problem, showing that a cell does not need to know its absolute size to regulate size robustly, quantitatively explaining the experimentally measured correlations in both E. coli and budding yeast, and predicting that such correlations degrade by hydrolysis to produce vertically aligned nanoporous polymer films which exhibit reversible thermal switching behavior. The polymers introduced here provide a versatile platform for scalable fabrication of aligned membranes and further functional materials based on such templates.

11:51AM T46.00002 Determinants of Bacterial Cell Shape, AARON DINNER, The University of Chicago — We determine intergenerational shape dynamics of single Caulobacter crescentus cells. We use imaging techniques that enable us to study ~100 cells across ~4,000 total generations to achieve high statistical precision. Our data show that constriction initiates early in the cell cycle and that its dynamics is controlled by the time scale of exponential longitudinal growth. Furthermore, we find that the division plane location is inherited from the previous generation. Based on our observations, we develop a minimal mechanical model that qualitatively accounts for the cell shape dynamics and suggests that the asymmetric location of the division plane reflects the distinct mechanical properties of the stalked and swarmer poles. Generalization of the model can provide a common framework for understanding bacterial cell shape.
Contact guidance efficiency depends on the spacing between adjacent ridges. The greatest guidance efficiency occurs on 1.5-µm-spaced ridges. A larger average velocity of cell motion and actin waves, we found that the nanoridges exert bidirectional guidance on migrating cells and actin wave propagation. More cells that gels formed at lower temperature are more inhomogeneous, anisotropic, and compliant than those formed at high temperature, and cellularized samples rather than confined directional propagation along the 1.5-µm-spaced ridges. A Lagrangian implementation of this model allows us to calculate the full deformation of an initially spherical cell, when it is subjected to a band of overactivity at the cell equator that mimics the RhoA signaling pattern. Our simulations reproduce the formation and ingestion the actomyosin ring, with cell shapes and dynamics mirroring those of embryos. This model predicts cytokinesis completion above a well-defined threshold of equatorial contractility excess, and simple scaling arguments unveil the key mechanism for this first-order transition: cytoplasmic incompressibility results in a competition between the furrow line tension and the cell poles surface tension. Our theory explains how cytokinesis duration may be independent on cell size in embryos and predicts a critical role for actin turnover on the rate and success of furrow constriction. We extend our theoretical approach to explore cell shape dynamics in other essential cellular processes, such as cell polarization or cell-cell adhesion.

Session T47 DBIO: Focus Session: Mechanical Structure-Function Relations in Biological Matter II

11:15AM T47.00001 Heritable adhesion geometries and mechanosensing of surfaces by biofilm-forming bacteria, VERNITA GORDON, BENJAMIN COOLEY, CHRIS RODESNEY, NUMA DHAMANI, The University of Texas at Austin — Biofilms are dense, interacting communities of single-celled organisms that are bound to each other with a self-produced polymeric matrix. Biofilms have devastating clinical impact as they increase resistance to antibiotics and the immune system as well as the production of virulence factors that damage the host. Here we examine effects very early in biofilm development, when the infection is still in a stage of a few cells not yet characterized by high biofilm densities. *Pseudomonas aeruginosa*, an opportunistic human pathogen, produces multiple extracellular polysaccharides that form the biofilm's structuring matrix. We have recently shown that the two primary polysaccharides, Pel and Psl, have distinct roles in controlling the mechanics of single-cell adhesion to a surface – Psl dominates adhesion to the surface, and Pel impairs the bacterium lie down flat (Cooley et al., 2013 Soft Matter). Here, we show that expressing Pel alters the symmetry of Psl's distribution on the surface of rod-shaped *Pseudomonas*. We also show that expressing Pel decreases the work of detachment from the surface. It seems paradoxical that a biofilm-forming organism should pay the cost of maintaining and making a gene product that reduces the energy input required to detach it from a surface. Therefore, we probe the possibility that a flat-lying bacteria may better sense a solid surface and change its signaling state accordingly.

11:27AM T47.00002 How the velvet worm squirts slime, ANDRES CONCHA, PAULA MELLADO, Adolfo Ibañez University, BERNAL MORERA-BREÑES, Universidad Nacional de Costa Rica, CRISTIANO SAMPAIO, Universidade de Sao Paulo, L. MAHADEVAN, Harvard University, JULIÁN MONGE-NÁJERA, Universidad de Costa Rica — The rapid squirt of a proteinaceous slime jet endows the ancient velvet worms (*Onychophora*) with a unique mechanism for defense from predators and for capturing prey by entangling them in a disordered web that immobilizes their target. However, to date neither qualitative nor quantitative descriptions have been provided for this unique adaptation. Here we investigate the fast oscillatory motion of the oral papillae and the exiting liquid jet that oscillates with frequencies $f \sim \sim 30 - 60$ Hz. Using anatomical images, high speed videography, theoretical analysis and a physical simulacrum we show that this fast oscillatory motion is the result of an elastohydrodynamic instability driven by the interplay between the elasticity of oral papillae and the fast unsteady flow during squirting. Our results demonstrate how passive strategies can be cleverly harnessed by organisms, while suggesting future oscillating micro-fluidic devices as well as novel ways for micro and nano fiber production using bioinspired strategies.

11:39AM T47.00003 Micromechanics of cellularized collagen I networks, CHRISTOPHER JONES, MATT CIBULA, DAVID MINTYRE, BO SUN, Oregon State Univ — Collagen gels are commonly used in experiments on cell mechanics because collagen is the most abundant protein in the mammalian extracellular matrix. Collagen gels are often approximated as homogeneous elastic materials; however, variations in the collagen fiber microstructure and cell adhesion forces cause the mechanical properties to be inhomogeneous at the cellular scale. We study the mechanics of type I collagen on the scale of tens to hundreds of microns by using holographic optical tweezers (HOT) to apply pN forces to micron-sized particles embedded in the collagen fiber network. We calculate the local compliance and elastic modulus of the collagen network and find that particle displacements are inhomogeneous, anisotropic, and often have components perpendicular to the direction of the applied force. Confocal reflection microscopy (CRM) is used to reveal the local fiber structure and a simulation treating fibers as rigid rods is used for comparison to the HOT measurements. Collagen samples prepared at 21°C and 37°C show that gels formed at lower temperature are more inhomogeneous, anisotropic, and compliant than those formed at high temperature, and cellularized samples allow us to characterize the effects of cell adhesion forces on the network mechanics.

11:51AM T47.00004 Cellular Contact Guidance Through Dynamic Sensing of Nanotopography, XIAOYU SUN, SATARUPA DAS, CAN GUVEN, JOHN FOURKAS, WOLFGANG LOSERT, Univ of Maryland-College Park — We evaluated the contact guidance of nanoscale ridges on the cellular motion and actin waves in HL60 neutrophil-like cells, a model system for studying cell migration. By analyzing the velocity of cell motion and actin waves, we found that the nanoridges exert bidirectional guidance on migrating cells and actin wave propagation. More cells migrate parallel to the nanoridges than any other direction. Nanoridges nucleate actin polymerization waves which then proceed preferentially along the ridges. Contact guidance efficiency depends on the spacing between adjacent ridges. The greatest guidance efficiency occurs on 1.5-µm-spaced ridges. A larger average actin wave speed is observed on 5-µm-spaced than 1.5-µm-spaced ridges, which may arise from a larger portion of random propagation on 5-µm-spaced ridges rather than confined directional propagation along the 1.5-µm-spaced ridges.

212:27PM T46.00003 How do bacteria couple growth to division? MANUEL CAMPOS, Microbial Sciences Institute / Yale University — Cell size control is an intrinsic feature of the cell cycle. In bacteria, cell growth and division are thought to be coupled through a cell size threshold. Here, we provide direct experimental evidence disproving the critical size paradigm. Instead, we show through single-cell microscopy and modeling that the evolutionarily distant bacteria Escherichia coli and Caulobacter crescentus achieve cell size homeostasis by growing on average the same amount between divisions, irrespective of cell length at birth. This simple mechanism provides a remarkably robust cell size control without the need of being precise, abating size deviations exponentially within a few generations. This size homeostasis mechanism is broadly applicable for symmetric and asymmetric divisions as well as for different growth rates. Furthermore, our data suggest that constant size extension is implemented at or close to division, implying that the initiation of DNA replication or the formation of the FtsZ cytokinetic ring are unlikely to dictate the timing of division. Altogether, our findings provide fundamentally distinct governing principles for cell size and cell cycle control in bacteria.

12:03PM T47.00005 Cardiac tissue as a mechanically and electrically active medium. JASON ROCKS, KEVIN CHIOU, ANDREA LIU, University of Pennsylvania — The heart is an active solid in which energy is injected at the cell scale when cardiomyocytes contract. This energy is transmitted up to macroscopic scales, leading to a collective function—the pumping of the heart—where a wavefront of contraction propagates across the heart from one end to the other. We will present results for a model that couples a traditional model for electrical signaling to an overdamped biphasic model for tissue mechanics to look at the competition between mechanical and electrical signaling in the contractile wavefront in the embryonic heart. We speculate on the ramifications of our results for the adult heart, which is conventionally described exclusively in terms of electrical signaling.

12:15PM T47.00006 The dynamics of body elongation in vertebrate morphogenesis. IDO REGEV, Harvard School of Engineering and Applied Science, OLIVIER POURQUIÉ, Harvard Medical School/Brigham and Women’s Hospital, L. MAHADEVAN, Harvard School of Engineering and Applied Science — Vertebrate embryos have a body axis that grows by the addition of cells in a posterior growth zone in the embryo. Experiments show that these cells show a gradient in motility that decays towards the anterior of the embryo, consistent with a degradation of specific cellular signals (Fgf) that control cellular motility. However, this motility is primarily diffusive in nature, and converted into an advective gradient by virtue of inhomogeneous confinement. We use these observations to build a minimal mechanochemical model for tissue extension as a function of Fgf activity, cell motility and tissue rheology with results that allow us to explicitly test the model in a variety of in-vivo and ex-vivo situations, with implications for normal and pathological axis elongation.

12:27PM T47.00007 Quantitative analysis of actin monomer funneling: how capping protein enhances actin filament growth and nucleation on biomimetic beads1. RUIZHE WANG, ANDERS CARLSSON, Washington University — Capping protein (CP) caps the growing ends of actin filaments and thereby halts their polymerization. However, CP is required for actin-based motility, and experiments by Akin and Mullins [1] have shown that CP also enhances the rate of filament nucleation. Proposed explanations for these phenomena include the Actin Funneling Hypothesis (AFH) [1], in which the presence of CP increases the free-actin concentration, and structural changes of the actin networks induced by increasing CP [1]. In this article, we provide a quantitative analysis of the AFH based on rate equations including actin nucleation and branching, polymerization and capping, plus monomer depletion near the surface of the bead. With two adjustable parameters, our simulation results accurately match several aspects of the results of Akin and Mullins [1]. We find that CP increases the local monomer concentration at the bead surface, but has a much smaller effect on the global free-actin concentration. The increased local monomer concentration gives rise to an enhanced rate of branching events and thus a larger number of actin filaments. [1] O Akin and R. D. Mullins. Cell 133.5 (2008): 841-851. [2] M-F Carlier, and D. Pantaloni. Journal of molecular biology 269.4 (1997): 459-467.

12:39PM T47.00008 Measurement of DDR-Collagen interaction Forces with Atomic force Microscopy. ANWESA SARKAR, Department of Physics & Astronomy, Wayne State University, RAFAEL FRIDMAN, ANJUM SOHAIL, Department of Pathology, Wayne State University, PETER HOFFMANN, Department of Physics & Astronomy, Wayne State University, DEPARTMENT OF PATHOLOGY, WAYNE STATE UNIVERSITY AND KARMANOS CANCER INSTITUTE COLLABORATION — Discoid Domain Receptors (DDR) are membrane proteins of the tyrosine kinase receptor family. The binding of collagen to the extracellular domain of DDR stimulates activation of the tyrosine kinase inside the cell. Two types of DDR, DDR1 and DDR2, have been related to human cancers because of the discovery of alterations of DDR genes in several human cancers. However, not much is known about DDR behavior at the cell-collagen interface. We are combining biological information and force based microscopy to shed light on how DDRs function in physiological and pathological conditions. We have measured the kinetics, bond lengths and activation energy of DDR-collagen interactions at the single molecular level on live cells, including cells that are deficient in DDR and cells that overexpress DDR, as well as cancer cells. We have developed methods to take multiple attachments into account and obtain clean data. Interactions measured on live cells were compared to measurements between extracted extracellular domains of DDR and collagen plated on a substrate to determine how these interactions are altered by the microenvironment of the cell. The distribution of DDR receptors on live cells was determined by using a combination of fluorescence imaging and AFM-based adhesion mapping.

12:51PM T47.00009 Quantitative analysis of mass density fluctuation inside biological cells under the effect of alcohol using light localization properties1. HEMENDRA M. GHIMIRE, PEEYUSH SAHAY, HUDA ALMABADI, PRABHAKAR PRADHAN, Univ of Memphis — Light localization properties can be used to analyze the nanoscale level alterations inside the biological cells. We present study of mass density fluctuation in the nuclei of colon cells, under the effect of alcohol, by quantifying the degree of structural disorder, of nanoscale, from their transmission electron microscopy (TEM) images. The light localization properties of the disordered optical lattice system, created using the TEM image data, were studied by statistically analyzing the inverse participation ratio (IPR) of the localized eigenfunctions of the optical lattice. The study, conducted on rat model, shows that nanoscale morphology of the colon cells with symptoms of carcinogenesis increases further under the effect of alcohol (ethanol). The quantified structural disorder strength, measured in the length scale 12.5 – 75 nm, for the cells under the effect of ethanol was noted to be significantly higher in comparison to the cells not under the influence of ethanol. This study is first of its kind where the effect of alcohol on the biological cells has been studied by quantifying the nanoscale level of mass density fluctuation inside the cells, using the mesoscopic physics approach.

1:03PM T47.00010 Arterial mechanobiology: The interrelation of elastin, collagen, and GAGs1. KATHERINE ZHANG, Boston University — The complex network structure of elastin and collagen extracellular matrix (ECM) forms the primary load-bearing component in the arterial wall. Pathogenesis of many cardiovascular diseases is associated with loss of organization and function of the ECM. However the interrelation of the function of collagen and elastin and the effect of ECM structural changes on vascular mechanics are not well understood. This talk will focus on our recent study on the interrelations of ECM constituents and how they contribute to the mechanical function of the arterial wall. Our recent study coupling mechanical loading and multi-photon imaging demonstrates an interesting sequential engagement of elastin and collagen fibers in response to mechanical loading. Our study also suggests that the elastin fibers are under tension and impart an intrinsic compressive stress on collagen. Such delicate interrelation between elastin and collagen is essential for an artery to function normally. Studies of the structural components and mechanics of arterial ECM generally focus on elastin and collagen while glycosaminoglycans (GAGs) are often neglected, most likely because of the relatively low content in arterial tissue. Our study shows that GAGs play a role in engaging the elastin and collagen fibers in the arterial wall and thus indirectly affect the biomechanical function of arteries. Together these results provide a more comprehensive understanding of the mechanobiology of arteries with the goal of incorporating such information in understanding disease progressions and structurally based constitutive models.

fitness of a multicellular aggregate in a young bacterial biofilm of sequences, and a simple mechanistic model for the origin of the observed scaling laws. Our results define collective mutational pathways used by HIV to population stores memories of host-pathogen combat won by the virus. We describe an exactly solvable model that captures the main features of the sets branches of inquiry, and dynamics reminiscent of neural networks are observed. Like neural networks that store memories of past stimulation, the circulating to host. We show that the interplay between the diversity of human immune responses and the ways that HIV mutates to evade them results in distinct sets of the circulating HIV population has thus occurred in response to diverse, ultimately ineffective, immune selection pressures that randomly change from host to host. We attribute this competition-dependent growth advantage to an interplay between a spatially-structured nutrient environment and the spatial distribution of cells in the aggregate. We find that fluid waves propagate through the cell layer over multicellular length scales, accommodating these collective cell volume fluctuations. 1:51PM T47.00012 The effect of antiarrhythmic drugs on rate-dependent cardiac behavior, HANA DOBROVOLNY, BINAYA TULADHAR, Texas Christian Univ — While there are many studies examining the biomolecular effects of antiarrhythmic drugs and many studies examining their clinical effect, their effect on cardiac dynamics at the cellular and tissue levels is not well understood. We use a mathematical model of a human ventricular cell to study the effect of antiarrhythmic drugs on the appearance of alternans and 2:1 behavior over a range of doses. We study three different classes of drugs, calcium channel blockers, potassium channel blockers and sodium channel blockers, and compare their effects on cellular dynamics.

Thursday, March 5, 2015 11:15AM - 2:03PM — Session T48 DBIO: Focus Session: Physics of Evolutionary and Population Dynamics II 217C - Uwe Tauber, Virginia Tech University

11:15AM T48.00001 Noise-Induced Homochirality in Spatially Extended Chemical and Biological Systems, FARSHID JAFARPOUR, TOMMASO BIANCALANI, NIGEL GOLDENFELD, Department of Physics and The Institute for Genomic Biology, University of Illinois at Urbana-Champaign — Autocatalysis has long been assumed to be the primary mechanism for homochirality in chemical and biological systems. However, chirality has not been studied in the context of spatially extended systems. Here we remove this extra reaction, so that at the mean field level the only fixed point is the racemic state. Nevertheless, solving the full stochastic theory in zero dimensions, we show that homochiral states can arise due to intrinsic noise. Finally we explore whether these homochiral states are stable in spatially-extended systems.

11:27AM T48.00002 Moment Closure Analysis of SIRS Disease Model on Heterogeneous Networks, DANIEL T. CITRON, CHRISTOPHER R. MYERS, Cornell University — We perform a moment closure analysis of the stochastic susceptible-infected-recovered-susceptible (SIRS) model of infectious disease dynamics on heterogeneous networks. The SIRS model, which returns previously infected individuals to a susceptible state, supports a nontrivial steady state representing persistent endemic disease. In the context of networks, the heterogeneous mean field (HMF) method can be used to predict how network structure affects the SIRS model by dividing the network into classes with degree-dependent mean field coupling strengths. To verify the accuracy of the HMF, we simulate the SIRS model on heterogeneous networks. In our simulations we find, in disagreement with the HMF, the survival probability of the steady state depends on system size. This discrepancy stems from the fluctuations present in the stochastic model that are ignored by the HMF. We extend the HMF results by applying moment closure to each degree class. Our moment closure analysis provides a probabilistic description of the steady state for each degree class, which can be used to show how stochastic fluctuations and extinction depend on the size of the full network. We suggest that this technique may be used to analyze other stochastic models of dynamical processes.

11:39AM T48.00003 Scaling laws describe memories of host-pathogen riposte in the HIV population, JOHN BARTON, MEHRAN KARDAR, ARUP CHAKRABORTY, Massachusetts Institute of Technology — The enormous genetic diversity and mutability of the human immunodeficiency virus (HIV) has prevented effective control of this virus by natural immune responses or vaccination. Evolution of the circulating HIV population has thus occurred in response to diverse, ultimately ineffective, immune selection pressures that randomly change from host to host. We show that the interplay between the diversity of human immune responses and the ways that HIV mutates to evade them results in distinct sets of sequences defined by similar collectively coupled mutations. Scaling laws that relate these sets of sequences resemble those observed in linguistics and other branches of inquiry, and dynamics reminiscent of neural networks are observed. Like neural networks that store memories of past stimulation, the circulating HIV population stores memories of host-pathogen combat won by the virus. We describe an exactly solvable model that captures the main features of the sets of sequences, and a simple mechanistic model for the origin of the observed scaling laws. Our results define collective mutational pathways used by HIV to evade human immune responses, which could guide vaccine design.

11:51AM T48.00004 Environmental spatial structure and competition determine the relative fitness of a multicellular aggregate in a young bacterial biofilm, JAIME HUTCHISON, University of Texas at Austin, KASPER KRAGH, University of Copenhagen, GAVIN MELAUGH, University of Edinburgh, CHRISTOPHER RODESNY, University of Texas at Austin, YASUHIKO IRIE, University of Bath, ALED ROBERTS, STEVE DIGGLE, University of Nottingham, ROSALIND ALLEN, University of Edinburgh, VERNITA GORDON, University of Texas at Austin, THOMAS BJARNSHOLT, University of Copenhagen — The canonical description of biofilm development begins with free-swimming, single bacterial cells which land on and adhere to a surface, mature into three-dimensional structures, and eventually disperse to form new biofilms. However, the interplay between single cells and larger, three-dimensional structures in early biofilm development has not been studied. We use time-lapse confocal microscopy and quantitative measurements of biomass, combined with numerical, individual-based simulations to determine the relative fitness of single cells and preformed, multicellular aggregates. We find that the relative fitness of multicellular aggregates depends markedly on the density of surrounding single-cells. We attribute this competition-dependent growth advantage to an interplay between a spatially-structured nutrient environment and the spatial distribution of cells in the aggregate. Our findings suggest that when competition for resources is high and there is spatial structure in the distribution of resources, aggregates of cells can outperform single cells and may be a preferred way to seed new biofilms.
12:03PM T48.00005 Population Dynamics of Metastable Growth Rates1, LINDSAY MOORE, ELAD STOLOVICKI, EREZ BRAUN, Technion - Israel Institute of Technology — Neo-Darwinian evolution provides a paradigm for population dynamics built on random mutations and selection with a clear separation of time-scales between single-cell mutation rates and the rate of reproduction. By studying the adaptation dynamics of genetically rewired yeast cells adapting to a severe regulatory challenge, we have uncovered a novel type of population dynamics in which intracellular processes seem to play a role in shaping the population structure. Under constant environmental conditions, we measure a wide distribution of growth rates that persists even after both the population has been outgrown (10 generations). Remarkably, the fastest growing cell do not take over the population on the time-scale dictated by the width of the growth-rate distributions and simple selection. In fact, the population-average growth rate plateaux and even decreases over the course of the adaptation, on intermediate time-scales of tens of generations. Our data show that the phenotypic state of the cells in a constant environment is metastable and varies on time-scales that reflect the importance of long-term intracellular processes in shaping the population structure.

12:15PM T48.00006 Steering antibody evolution to combat rapidly mutating pathogens, SHEN-WANG WANG, JORDI MATA-FINK, MIT, DENNIS BURTON, The Scripps Research Institute, DANE WITTRUP, MEHRAN KARDAR, ARUP CHAKRABORTY, MIT — The adaptive immune system houses amazingly efficient evolutionary processes coordinated across multiple length and time scales to protect higher organisms from diverse infectious pathogens. The optimization problem to be solved is often intrinsically constrained and highly dynamical. Failure of solving the problem timely leads to loss of protection. One such devastating situation is posed by rapidly mutating viruses (e.g. HIV which infects the immune system itself). One major challenge of designing an effective vaccine is to contain a diversifying mixture of antigen variants from evading recognition by antibodies. To confront this challenge, we develop a multi-scale computational model to simulate the stochastic evolutionary process of antibody affinity maturation against time varying antigen. The model provides an optimal vaccination strategy which has been shown in mouse experiment to be very effective in focusing antibody response to the vulnerable part of the virus.

12:27PM T48.00007 Balancing the evolution advantages and drawbacks of CRISPR, PU HAN2, MICHAEL DEEM2, Rice University — CRISPR/Cas (Cluster Regularly Interspaced Short Palindromic Repeats/CRISPR associated proteins) is an adaptive immune system of prokaryotes. It can protect bacteria against invading genetic material. Besides providing immunity against lytic phages, the CRISPR/Cas system can block the acquisition of beneficial mobile genes, such as plasmids carrying antibody resistant genes. We discuss how bacteria balance the advantages and the drawbacks of CRISPR in an environment that has both lytic phages and beneficial mobile genes. We show that in the absence of lytic phages, bacteria lose CRISPR/Cas rapidly to acquire the beneficial mobile genes. We also discuss how CRISPR/Cas establishes in the bacterial population in the presence of both lytic phages and beneficial mobile genes.

12:39PM T48.00008 A Stochastic Cooperative Agent Model of Band-Pass Antibiotic Resistance1, LOUIS NEMZER, ROBERT SMITH, Nova Southeastern University — The recently described phenomenon of band-pass antibiotic resistance occurs when bacteria exposed to a periodic environment of oscillating antibiotic concentration grow fastest at intermediate period lengths. Previously, it has been shown that such behavior can arise from a non-linearity in individual fitness as a function of the initial colony density, called the “Allee effect,” as well as a fixed-point catastrophe that depends very strongly on the antibiotic concentration. Here, we present a new agent-based, in silico stochastic model of cooperative antibiotic resistance. This model attempts to capture the behavior of “cooperative” bacteria that, for example, expend resources to produce enzymes that break down β-lactam antibiotic molecules, but are subject to the problem of freeloadng by non-secretors that benefit but do not contribute. Colony survival can be threatened when exposed to a periodic antibiotic challenge. By creating a simulation in which the bacteria are modeled as stochastic agents, the effect of antibiotic concentration, period of antibiotic oscillation, and degree of cooperativity can be evaluated.

12:51PM T48.00009 Flow-driven waves during pattern formation of Dictostelium discoideum, AZAM GHOLAMI, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany, OLIVER STEINBOCK, Department of Chemistry and Biochemistry, Florida State University, Tallahassee, Florida, VLADIMIR ZYKOV, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany, ERBERHARD BODENSCHATZ, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — The slime mold Dictostelium discoideum (D.d.) is a well known model system for the study of biological pattern formation. In the natural environment, aggregating populations of starving Dictostelium cells may experience fluid flows that can profoundly change the underlying wave generation process. Recently we conducted experiments to study the effect of a differential flow in quasi one-dimensional colonies of the signaling D.d. cells. The external flow advects the signaling molecule CAMP downstream, while the chemotactic cells attached to the solid substrate and are not transported with flow. This transport anisotropy in the extracellular medium induced macroscopic wave trains that developed spontaneously, propagated with the velocity proportional to the imposed flow velocity with a unique period. In this work, we investigate the mechanism of flow-induced waves using the well-established Martiel-Goldbeter model. In the linear regime, our analytical calculations show that a convective transport of extracellular CAMP in a uniform field of signal-relaying cells leads to a flow-induced instability of the traveling-wave type. In the nonlinear regime, numerical simulations show a convective instability with propagating waves, in agreement with the predictions of linear analysis.

1:03PM T48.00010 Diffusion limited mutualism, KIRILL KOROLEV, Boston University — Microbes trade diffusible molecules to survive and maintain complex ecological functions. Physicists have substantially advanced our understanding of microbial populations, primarily relying on the evolutionary game theory. Game theory however was developed for higher organisms and cannot easily describe microbial cooperation, which involves the exchange of small, highly diffusible molecules. We formulated and solved a model that accurately represents the physics of diffusion in microbial colonies. In particular, we discovered a general approach that eliminates metabolite diffusion and recasts population dynamics in the traditional game theory framework, but with renormalized parameters. We applied this approach to the problem of two-way cross-feeding, a common interaction motif in the microbial world that is the subject of several experimental studies. Naively one would assume that nutrient diffusion should facilitate mutualistic interactions in microbial colonies. Indeed, because microbes are not completely mixed inside a colony, different species tend to form small domains, and diffusion should facilitate the exchange of the nutrients between the two cross-feeding species. We, however, find that nutrient diffusion reduces the strength of mutualism and leads to a phase transition that makes mutualism impossible. We analytically compute the critical diffusivity at which mutualism is lost and find the universality class of the phase transition. The distance to this phase transition controls the size of the domains formed by the species, a quantity of prime interest in empirical studies. Finally, we show that the differences in public good diffusivities affect mutualism only in the presence of nonlinearity in the public good dynamics. In particular, fitness nonlinearities suppress mutualism and favor the species producing nutrients that diffuse more slowly.
Coalescent theory analysis of phylogenetic trees in a model of evolutionary dynamics. DAWN KING, SONYA BAHAR, University of Missouri at St. Louis — Phylogenetic trees and the hierarchical, biological levels of organization that exist within them are of great importance to evolutionary theory. With a neutral, agent-based model of evolutionary dynamics, we have investigated the conditions under which organisms form clusters, analogous to species. Previous work has shown phase transition behavior as a function of the maximum mutation size ($\mu$) on a rugged landscape with assortative mating (Dees and Bahar, 2010), and, with the addition of bacterial fission, on a completely neutral landscape (Scott et al., 2013). The bacterial version was then classified as belonging to the directed percolation universality class (Scott, 2014). Here, we further investigate the emergent property of speciation by analyzing the genealogical tree structures created by the forward-in-time reaction-diffusion dynamics of the three mating types — assortative, bacterial, and random — as a function of the random death percentage. Specifically, we will use Kingman’s n-coalescent to investigate the distributions of the times to most recent common ancestor (TMRCA) and determine whether universal ratios exist.

12:03PM T49.00005 A Three-Dimensional Phase Diagram of Growth-Induced Surface Instabilities. QIMING WANG, XUANHE ZHAO, Massachusetts Institute of Technology — A variety of fascinating morphological patterns arise on surfaces of growing, developing or aging tissues, organs and microorganism colonies. These patterns can be classified into creases, wrinkles, folds, period-doubles, ridges and delaminated-ducts according to their distinctive topographical characteristics. One universal mechanism for the pattern formation has been long believed to be the mismatch strains between biological layers with different expanding or shrinking rates, which induce mechanical instabilities. However, a general model that accounts for the formation and evolution of these various surface-instability patterns still does not exist. Here, we take biological structures at their current states as thermodynamic systems, treat each instability-pattern as a thermodynamic phase, and construct a unified phase diagram that can quantitatively predict various types of growth-induced surface instabilities. We further validate the phase diagram with our experiments on surface instabilities induced by mismatch strains as well as data on growth-induced instabilities in various biological systems. It is expected that the unified phase diagram will not only advance the understanding of biological morphogenesis, but also significantly facilitate the design of new materials and structures by rationally harnessing surface instabilities.

12:15PM T49.00006 Mechanical Responses of a Polymer Graphene-sheet Nano-sandwich. XIGUANG LI, JULIUSZ WARZYWODA, GREGORY MCKENNA, Texas Tech University — The interfacial mechanics and reinforcement by graphene sheets in polymer matrix nanocomposites are important to their understanding. However, the methods available for their investigation remain a challenge. Here we report on a novel study in which the mechanical responses of a nano-sandwich model structure made of a single graphene sheet sandwiched between ultrathin polymer layers are determined using a nano-bubble inflation method. The stress-strain behavior of the graphene nano-sandwich shows that significant reinforcement is obtained at small strains and that the method also provides a measurement of the interfacial shear strength. In addition, the study provides data related to internal stresses that develop between the graphene layer and the polymer sandwich faces.

12:27PM T49.00007 Reconfiguring and Actuating Liquid Metals, Gels, and Polymers. MICHAEL DICKEY, NC State University — This talk will describe efforts in our research group to control the shape and function of soft materials (liquid metals, polymers and hydrogels) for applications that include reconfigurable electronics, soft robots, and self-folding origami. The research harnesses interfacial phenomena, micro fabrication, patterning, and thin films. The talk will discuss the underlying fundamental science that enables the following:
1. Shape reconfigurable liquid metal alloys based on gallium. The metal is a liquid at room-temperature with low-viscosity (water-like) and can be micromolded due to a thin, oxide skin that forms rapidly on its surface. The metal can be patterned in a number of ways including injection into microchannels or by direct-write 3D printing. Recently, we discovered that the oxide may be the best surfactant ever reported and can be removed or deposited using electrochemistry in electrolyte as a new method to control and reconfigure the shape of the metal.
2. Self-folding polymers sheets that change shape in response to light. These sheets are a form of shape memory polymers that are compatible with 2D patterning techniques including lithography, inkjet printing, and roll to roll processing. The appeal of this work is converting 2D patterns into 3D shapes in a hands free manner.
3. New methods for actuating hydrogels by patterning ions in these gels. This reversible process can imprint topography in the hydrogel using modest voltages, tune its local mechanical properties to create physically-reinforcing exoskeletons, and generate stresses sufficient to actuate or fold hydrogels over large distances within seconds.

1:03PM T49.00008 Osmotic robotics: Reversible shape change driven by local osmolarity gradients. TAO ZHANG, DUANDUAN WAN, J. M. SCHWARZ, MARK J. BOWICK, Syracuse University — Nature provides us with many examples of biomaterials that can change their shape in response to external stimuli and/or in response to varying internal stresses embedded within the structure of the biomaterial. Inspired by such biomaterials as well as recent experiments, we consider a three-dimensional network of aqueous droplets joined by single lipid bilayers to form a cohesive, tissue-like material. The droplets in these droplet networks can be programmed with different osmolarities. These osmolarity gradients generate internal stresses via local flows and the network then folds into designed structures. Using molecular dynamics simulations, we study the formation of shapes ranging from rings to spirals to tetrahedra and determine the optimal range of parameters for such structures. We also add an osmotic interaction with a dynamic environment, i.e. external stimuli, to realize a reversible folding-unfolding process. This finding contributes towards the development of osmotic robotics in bio-inspired materials.

1:15PM T49.00009 Free-Standing Temperature-Sensitive Hydrogel-Particle Membranes from Evaporating Drops. TIM STILL, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104, PETER YUNKER, School of Physics, Georgia Institute of Technology, Atlanta, GA 30332, KEVIN APTOWICZ, Department of Physics, West Chester University, West Chester, PA 19383, KASEY HANSON, ZOEY DAVIDSON, MATTHEW LOHR, A.G. YODH, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104 — We demonstrate a simple method using evaporating colloidal drops to prepare temperature-sensitive membranes composed of micron-sized colloidal hydrogel particles that are up to a few particle diameters thick. Sessile droplets of hydrogel particle suspension were evaporated on silicon wafers. The radially outward flows that drive the common coffee-ring effect push hydrogel particles towards the drop edge wherein the particles attach to the air-water interface. Most of these microgel particles move radially inward along the interface and coat the drop surface. The particles are then cross-linked, forming a membrane. The resultant thin films exhibit a temperature-responsiveness characteristic of the individual particles, permitting modulations of membrane size, shape, and optical transmission. We understand the optical properties using a Mie scattering model and an assumed membrane structure.

1:27PM T49.00010 Growth morphologies in active elastic bilayers. DAVID MAYETT, Syracuse University, SHILADITYA BANERJEE, James Frank Institute, The University of Chicago, J. M. SCHWARZ, M. CRISTINA MARCHETTI, Syracuse University — Many biological systems exhibit elastic instabilities ranging from buckling to folding to wrinkling. Such instabilities are typically driven by growth of the system. We explore the deformation properties of a layer of growing elastic material resting on a passive elastic substrate of finite thickness. We first show that there exists a mapping between the well-known Rodriguez formulation of growth and an active model where growth is incorporated via a component of the stress tensor describing the proliferation of active units in the elastic medium. Motivated by such systems as the epithelial cells making up the lining of the small intestines and sitting on top of the elastic stroma and the cerebral cortex of the brain that rests on the underlying white matter, we then use analytical and numerical approaches to show how the morphologies observed in different systems can be accounted for by different functional forms of the activity. Our active model of growth in elastic bilayer systems provides a simple, unified framework to classify the zoo of morphologies observed across seemingly different biological systems.
Evolution to increase the matrix composition of clinical biofilm infections makes them stiffer, consistent with a mechanical fitness benefit. MEGAN DAVIS-FIELDS, KRISTIN KOVACH, VERNITA GORDON, University of Texas at Austin — Pseudomonas aeruginosa is an opportunistic, bacterial pathogen that forms biofilms in long-term infections. Biofilms are aggregates of bacteria in a matrix composed of extracellular polymeric substance (EPS). Biofilm P. aeruginosa infections in the lungs of cystic fibrosis patients can persist for decades, ample time for the infecting microbes to evolve. Evolutionary pressures include clearance by antibiotics and the immune system; being within a biofilm makes the bacteria more resistant to both of these. To date, most research has focused on chemical benefits conferred on the biofilm by the EPS matrix. Other researchers have recently found that long-term lung infections of P. aeruginosa increase production of Psl, one type of EPS polysaccharide. Increasing Psl must therefore confer some benefit to P. aeruginosa in the lung. We do bulk rheological measurements of biofilms grown from chronological clinical isolates from cystic fibrosis patients and find that strains that have evolved higher production of Psl have increased storage modulus — i.e., they are stiffer. From others’ estimates of the stresses that phagocytic cells can apply, we estimate that the stiffening we measure could provide a mechanical benefit to biofilms, helping them avoid immunological clearance.

Switchable and Tunable Aerodynamic Drag on Cylinders, MARK GUTTAG, PEDRO REIS, Massachusetts Institute of Technology — We report results on the performance of Smart Morphable Surfaces (Smorphs) that can be coated onto cylindrical structures to actively reduce their aerodynamic drag. Our system comprises of an elastomeric substrate that contains a series of optimally designed undersurface cavities that, once depressurized, lead to a dramatic deformation of the surface topography, on demand. Our design is inspired by the morphology of the giant cactus (Carnegia gigantea) which possesses an array of axial grooves, which are thought to help reduce aerodynamic drag, thereby enhancing the structural robustness of the plant under wind loading. We perform systematic wind tunnel tests on cylinders covered with our Smorphs and characterize their aerodynamic performance. The switchable and tunable nature of our system offers substantial advantages for aerodynamic performance when compared to static topographies, due to their operation over a wider range of flow conditions.

Chiral liquid crystal droplets near the isotropic phase. JOSE MARTINEZ-GONZALEZ, MOHAMMAD RAHIMI, YE ZHOU, JUAN DE PABLO, Univ of Chicago — Liquid crystalline blue phases (BPs) are found between the helical and the isotropic phase of highly chiral compounds. A common feature of BPs is that the local director field forms double twist cylinders leading to defects that form regular, periodic patterns. As a result of their physical properties, which include selective light reflection, high viscosity and a small elastic shear modulus, BPs could find intriguing potential applications in photonic materials, micro-lasers, electrically switchable colour displays and light filters, to name a few. In the bulk, BPs are only formed in a narrow range of temperature. In this work, we use theory and simulations to examine the phase behavior of chiral liquid crystal droplets with weak planar anchoring in the vicinity of the isotropic phase, with special emphasis on the effects of confining blue phase I and blue phase II. We identify several new morphologies, whose complexity increases with the chirality of the medium, and we find that confinement of blue phases in micro-droplets increases their range of stability.

Probing helical structures in liquid crystals with resonant soft x-ray scattering at carbon edge1. , CHENHUI ZHU, CHENG WANG, ANTHONY YOUNG, ILJA GUNKEL, ALEXANDER HEXEMER, ALS, Lawrence Berkeley National Lab, FENG LIU, MSD, Lawrence Berkeley National Lab, DONG CHEN, DAVID WALBA, NOEL CLARK, LCMRC, Uni. of Colorado Boulder, WIM BRAS, DUBBLE CRG, European Synchrotron Radiation Facility, France — We report the first in-situ measurement of the helical pitch in nanofilm B4 phase, using resonant soft x-ray scattering at carbon resonant edge. A strong scattering peak was observed corresponding to ~100 nm periodicity in layer orientation variation. The scattering is anisotropic due to the nano-filament helical structure and bond orientation sensitivity enabled by the linearly-polarized soft x-rays. In-situ measurements of the helical pitch as a function of temperature provide unique information on the B4 structure and the nature of the B2-B4 phase transition. This approach can be extended to other helical structures in liquid crystals and beyond.

Biosensing using smectic and cholesteric liquid crystals. PIOTR POPOV, ELIZABETH MANN, Kent State University, ANTLAL JAKLI, Liquid Crystal Institute — Liquid-crystal-based biosensors utilize liquid crystal alignment’s high sensitivity to the presence of lipids and proteins self-assembled at the liquid crystal/aqueous solution interface. The optical response of the bulk liquid crystal to the interface offers inexpensive, easy optical detection of such biologically relevant molecules. Present technique uses nematic liquid crystal phase state that typically has a planar-to-homeotropic response only. Here we show that smectic and cholesteric phase states of liquid crystals can be used as new sensing modes that can provide additional information or improve the characteristics of a potential biosensor device. Smectic-A phase extends the detection range both toward the lower and higher concentration. Cholesteric phase (nematic with a chiral dopant) may be sensitive to the chirality of biological surface-active molecules such as phospholipids. Additionally, the “finger-print” texture of a cholesteric phase may show the differences between biomolecule homologues, thus providing a promising way of distinguishing between subtle differences of hydrocarbon chain or head-group size and structure.
12:15PM T50.00006 Topological defects in cholesteric liquid crystal shells . ALEXANDRE DARMON, EC2M - UMR CNRS 7083 Gulliver - ESPCI ParisTech, MICHAEL BENZACUEN, PCT - UMR CNRS 7083 Gulliver - ESPCI ParisTech, OLIVIER DAUCHOT, TERESA LOPEZ-LEON, EC2M - UMR CNRS 7083 Gulliver - ESPCI ParisTech — Confining rod-like molecules, such as the nematogens of liquid crystals, on a curved surface inevitably yields topological defects. Remarkably, in the specific case of a nematic sphere, Poincaré stated that the sum of the topological charges of the defects is equal to \( q = \frac{1}{2} \). Recent studies have shown that, in the case of nematic shells, three kinds of configuration are possible. Each of these configurations correspond to different arrangements of defects that satisfy Poincaré’s theorem. But much richer scenarios appear when playing with the shell thickness, since bulk effects start competing with surface effects. In particular, we show that inducing chirality in the liquid crystal can have a dramatic effect in the defect structure of the shell, where the ratio \( q \) between the cholesteric pitch and the shell thickness becomes the control parameter. We also study in details the equilibrium configuration obtained for \( q > > 1 \), which corresponds to the structure with a single disclination line of charge \( \pm 2 \), also known as the Frank-Précig system. The strong electric fields, due to the permanent dipole moment of the FNPs, trapped some mobile ions, reducing the free ion concentration in the LC media.

12:27PM T50.00007 Geometry and topology of the cholesteric pitch axis: Which way is everything twisting?1, DANIEL BELLER, Harvard University, University of Pennsylvania, THOMAS MACHON, University of Warwick, SIMON COPAR, University of Ljubljana, Jozef Stefan Institute, University of Pennsylvania, DANIEL SUSSMAN, University of Pennsylvania, GARETH ALEXANDER, University of Warwick, RANDALL KAMIEN, University of Pennsylvania, RICARDO MOSNA, Universidade Estadual de Campinas, University of Pennsylvania — In a cholesteric with distortions and topological defects, it is not obvious how to even define the pitch axis and locate its singularities. We propose a construction of the cholesteric pitch axis for an arbitrary director field as an eigenvalue problem. With this tool we are able to compare the defects of the cholesteric phase with seemingly analogous defects in the biaxial nematic and smectic phases. Our results show the limitations of these analogies and indicate in what ways the cholesteric’s topology is intermediate between, and distinct from, the topologies of the biaxial nematic and smectic phases.

12:39PM T50.00008 Spontaneous Ferromagnetic Ordering of Nanoplatelets in Isotropic Solvent1. MIN SHUAI, ARTHUR KLITTNICK, MICHAEL TUCHBAND, MATTHEW GLASER, JOSEPH MACLENNAN, NOEL CLARK, Department of Physics and Liquid Crystal Materials Research Center, University of Colorado Boulder, ROLFE PETSCHEK, Physics Department, Case Western Reserve University, ALEKNA MERTELJ, DARJA LIŠIJAK, J. Stefan Institute, MARTIN COPIC, J. Stefan Institute, Faculty of Mathematics and Physics, University of Ljubljana — Room-temperature ferroelectric fluids were first experimentally demonstrated by Mertelj, et al (Nature, 504: 237–241, 2013), by suspending surfactant wrapped coated barium hexaferrite (BHF) nanoparticles in the liquid crystal 5CB. We have studied the liquid crystal phase behavior of BHMF magnetic platelets suspended in isotropic solvent (1-butanol) at high volume fraction, where simulations predict a N-I transition for monodisperse hard platelets. In these suspensions, the anisotropic particles can be aligned by magnetic fields as weak as 2 gauss, leading to a state with substantial birefringence and dichroism. When the volume fraction of the magnetic platelets is higher than 28%, we observe a phase coexistence, with an isotropic state at the top of a capillary and a birefringence phase at the bottom. In the lower phase, domains are found to have different magneto-optical response from each other and the response is dependent on the sign of the magnetic field, showing broken time-reversal symmetry and ferromagnetism. Spike structures are observed at the interface between the isotropic and ferromagnetic states.

1:03PM T50.00010 Smectic Liquid Crystals in the Immediate Vicinity of the Superstructure of a Nanoparticle in a Nanocomposite1. LUZ J. MARTINEZ-MIRANDA, University of Maryland, College Park, MD — We have studied how the nanoparticle (or the superstructure the nanoparticle forms) aligns the liquid crystal in smectic liquid crystal nanocomposites to determine how charges are transferred between the liquid crystal and the nanoparticle superstructure [1,2,3]. This superstructure depends on the density of aliphatic functionalizations at the surface of the nanoparticle [4]. We have found evidence that the asymmetry of the liquid crystal distorts those superstructures that belong to the cubic structure. In addition, we have observed some differences in how the smectic liquid crystal behaves depending on the nanoparticle used and how the nanoparticle (or the superstructure the nanoparticle forms) aligns the liquid crystal in smectic liquid crystal nanocomposites to determine how charges are transferred between the liquid crystal and the nanoparticle superstructure. Following the idea brought by the simulations of Sec et al. on cholesteric droplets, we show experimentally that this structure is not a pure \( \pm 2 \) line but is actually found to be two non-singular \( \pm 1 \) lines that are wound around each other.

1:27PM T50.00012 ABSTRACT WITHDRAWN —
1:39PM T50.00013 Nanoparticle interfacial assembly in liquid crystal droplets1, MOHAMMAD RAHIMI, TYLER ROBERTS, JULIO ARMAS-PEREZ, Institute for Molecular Engineering, University of Chicago, Chicago, Illinois 60637, USA, XIAOGLANG WANG, EMRE BUKUSOGLU, NICHOLAS L. ABBOTT, Department of Chemical Engineering, University of Wisconsin - Madison, Wisconsin 53706, USA, JUAN J. DE PABLO, Institute for Molecular Engineering, University of Chicago, Chicago, Illinois 60637. Controlled assembly of nanoparticles at liquid crystal interfaces could lead to easily manufacturable building blocks for assembly of materials with tunable mechanical, optical, and electronic properties. Past work has examined nanoparticle assembly at planar liquid crystal interfaces. In this work we show that nanoparticle assembly on curved interfaces is drastically different, and arises for conditions under which assembly is too weak to occur on planar interfaces. We also demonstrate that LC-mediated nanoparticle interactions are strong, are remarkably sensitive to surface anchoring, and lead to hexagonal arrangements that do not arise in bulk systems. All these elements form the basis for a highly tunable, predictable, and versatile platform for hierarchical materials assembly.

1:51PM T50.00014 Translational and Rotational Diffusion of Nanoparticle Aggregates of Irregular Shape in 2D Fluid Membranes1, KYLE MEIENBERG, JOHN PAPAIOANNOU, CHEOL PARK, MATT GLASER, JOE MACLENNAN, NOEL CLARK, Physics, University of Colorado, TATIANA KURIABOVA, Physics Department, California Polytechnic State University, THOMAS POWERS, School of Engineering and Department of Physics, Brown University — We observe directly the diffusion and aggregation of nanoparticles (buckyballs) embedded in thin, freely suspended smectic A liquid crystal films of 8CB using reflected light microscopy. Individual buckyballs, initially homogeneously dispersed in the film, are too small to see but after some hours form nanoscale clusters. These, in turn, aggregate to form extended, micron-scale objects which diffuse in the film, enabling the measurement of 2D rotational and translational mobilities of inclusions with a wide variety of different shapes. The experimental mobilities are compared with predictions of the extended Saffman-Delbrück (SD) model used successfully to describe the diffusion of micron-sized objects in thin fluid membranes in a variety of experimental systems.

2:03PM T50.00015 Towards 2D nanocomposites, HYUN-SOOK JANG, CHANGQIAN YU, ROBERT HAYES, STEVE GRANICK, Univ of Illinois - Urbana — Polymer vesicles (“polymersomes”) are an intriguing class of soft materials, commonly used to encapsulate small molecules or particles. Here we reveal they can also effectively incorporate nanoparticles inside their polymer membrane, leading to novel “2D nanocomposites.” The embedded nanoparticles alter the capacity of the polymersomes to bend and to stretch upon external stimuli.

Thursday, March 5, 2015 11:15AM - 2:15PM — Session T51 GSOFT DCMP: Invited Session: Soft Matter Nanophotonics: DNA-Directed Assemblies of Metal Clusters and Metal Nanoparticles — Grand Ballroom C1 - Elisabeth Gwinn, University of California, Santa Barbara

11:15AM T51.00001 DNA base pairing by noble metal cations: Structure and electronic properties from Density Functional Theory, OLGA LOPEZ-ACEVEDO, Aalto University — Metallo-base pair interactions are two to three times larger than the conventional hydrogen-bond pair interaction. Such high stability can drive the formation of helices and higher-order structures with the possibility to design novel DNA-based nanomaterials. Nucleobases and noble metal atoms (Au,Ag) have wide range of possible interacting sites depending on both the metal charge (ion, cation or neutral) and chemical nature. I will overview the electronic properties, both ground state and optical, of metallo-DNA structures obtained by global optimization and Density Functional Theory, discussing the effect of pairing and inclusion of backbone on the metal-base elementary unit.

11:51AM T51.00002 DNA templates silver clusters with magic sizes and colors for multi-cluster fluorescent assemblies, STACY COPP, University of California, Santa Barbara — The natural inclusion of information in DNA, a vital part of life’s rich complexity, can also be exploited to create diverse structures with multiple scales of complexity. Now emerging in novel photonic applications, DNA-stabilized silver clusters (AgN-DNA) are compelling examples of multi-scale DNA-directed assembly: individual fluorescent clusters, each templated by specific DNA base motifs, can then be arranged together in DNA-mediated multi-cluster assemblies with nanoscale precision. We discuss how DNA imbues AgN-DNA with unique features. Our optical data on pure AgN-DNA show that DNA base-cationic silver ligands impose rod-like shapes for neutral silver clusters, whose length primarily determines fluorescence color [1]. This shape anisotropy leads to the aspherical AgN-DNA magic number cluster sizes and “magic color” groupings [2]. We exploit DNA’s sequence properties to extract multi-base motifs that select certain magic cluster sizes, using machine learning algorithms applied to large data sets [3]. With these base motifs, we design DNA scaffolds to arrange multiple atomically precise AgN together in nanoscale proximity. We demonstrate that clusters are stable when held at separations below 10 nm, both in bicolor, dual cluster DNA clamp assemblies [4] and in one-dimensional assemblies of atomically precise clusters arrayed on DNA nanotubes.

12:27PM T51.00003 Plasmonic Enhancement of Raman Signal using Complex Metallic Nanostructures based on DNA Origami. GLEB FINKELSTEIN, Duke University — DNA-based nanostructures, such as “DNA origami,” have recently emerged as one of the leading techniques for precise positioning of nanoscale materials in fields ranging from computer science to biomedical engineering. The origami is composed of a single scaffold DNA strand to which smaller “staple” strands are attached through DNA complementarity. The staples help to fold the scaffold strand into the desired structure of a predetermined shape. The resulting templates are highly addressable and have proven to be versatile tools for site-specific placement of various nanomaterials, such as metallic nanoparticles, quantum dots, fluorophores, etc. Building upon massively parallelized assembly mechanism of the origami and its ability to position nanomaterials, one may hope to utilize it for biosensing purposes. One attractive goal is the Raman spectroscopy, which provides a highly specific chemical fingerprint. Unfortunately, the Raman scattering cross section is small; Surface Enhanced Raman Spectroscopy (SERS) enhances the otherwise weak Raman signal by trapping the analyte molecules in the regions of intense electric field produced near rough metallic surfaces. These “hot spots” can be understood as resulting from localized surface plasmon modes resonantly exited by the incident laser excitation. We have earlier shown that metallic nanoparticles controllably attached to DNA origami can be further enlarged via an in-solution metallization; this technique allowed us to build metallic structures of complex topology. Recently, we have performed Raman spectroscopy of molecules attached to these metallic assemblies. Specifically, DNA origina is first used to organize the metallic structures, followed by a covalent attachment of Raman-active molecules to the metal. We found that the substrates with four nanoparticles per origami produce a strongly enhanced Raman signal compared to the control samples with only one nanoparticle per origami for the same particle density. Furthermore, in the samples with four particles per origami the Raman signal systematically decayed as a function of the laser exposure time. Similar behavior has been previously reported and attributed to photo-damaging effects of the high intensity fields at the “hot spots.” In the samples with four nanoparticles per origami, the hot spots are located between the pairs of NPs; the one-particle control samples lacking the inter-particle hot spots showed no decay of the Raman signal, confirming our conclusion.

1:03PM T51.00004 DNA-bridged Chiroplasmonic Assemblies of Nanoparticles. NICHOLAS KOTOV, University of Michigan — Chirality at nanoscale attracts a lot of attention during the last decade. A number of chiral nanoscale systems had been discovered ranging from individual nanoparticles to helical nanowires and from lithographically defined substrates. DNA bridges make possible in-silico engineering and practical construction of complex assemblies of nanoparticles with of both plasmonic and excitonic nature. In this presentation, expected and unexpected optical effects that we observed in chiral plasmonic and excitonic systems will be demonstrated. Special effort will be placed on the transitioning of theoretical and experimental knowledge about chiral nanoscale systems to applications. The most obvious direction for practical targets was so far, the design of metamaterials for negative refractive index optics. The results describing the 3D materials with the highest experimentally observed chiral anisotropy factor will be presented. It will be followed by the discussion of the recent developments in analytical application of chiral assemblies for detection of cancer and bacterial contamination.

1:39PM T51.00005 DNA-mediated self-assembly of polyhedral plasmonic clusters. VINOTHAN N. MANOHARAN, Harvard University — A metafluid is a collection of electromagnetic resonators that have an isotropic response to incoming light. Because the resonators need not be oriented in any particular direction, metalfluids are perhaps the simplest metamaterial to fabricate – if one can first design resonators with an isotropic response. Such structures can in principle be self-assembled from metallic colloidal particles. The challenge is to organize these 100-nm-scale metallic particles into high-symmetry clusters, such as tetrahedra, that have very little variability between structures, so that the electric and magnetic resonances of all the clusters are at the same frequency. I will discuss how DNA can be used to assemble bulk suspensions of polyhedral colloidal clusters, using both equilibrium and non-equilibrium methods. I will also discuss how the yield of the structures is related to statistical mechanical and geometrical considerations.
12:27PM T52.00003 Ultrahigh mobility and giant magnetoresistance in the Dirac Semimetals Cd$_3$As$_2$ and Na$_3$Bi$^1$, N. PHUAN ONG, Dept of Physics, Princeton University — Dirac semimetals and Weyl semimetals are 3D analogs of graphene in which crystalline symmetry protects the nodes against gap formation. Na$_3$Bi and Cd$_3$As$_2$ were predicted to be Dirac semimetals, and recently confirmed to be so by photoemission. Several novel transport properties in a magnetic field $H$ have been proposed for Dirac semimetals. Here we report an interesting property in Cd$_3$As$_2$ that was unpredicted, namely a remarkable protection mechanism that strongly suppresses backscattering in zero $H$. In single crystals, the protection results in a very high mobility, $10^7$ cm$^2$/Vs at 5 K. Suppression of backscattering results in a transport lifetime 10$^4$ longer than the quantum lifetime. The lifting of this protection by $H$ leads to very large magnetoresistance with a striking $H$-linear profile. I will also report transport results on Na$_3$Bi and compare them with results in Cd$_3$As$_2$. I discuss how this may relate to changes to the Fermi surface induced by $H$.

1:03PM T52.00004 Valley-Polarized Interlayer Conduction of Anisotropic Dirac Fermions in SrMnBi$_2$, JUN SUNG KIM, Department of Physics, POSTECH — We report anisotropic Dirac fermions in a Bi square net of SrMnBi$_2$ and their valley-selective interlayer conduction under in-plane magnetic fields. In contrast to the commonly-observed isotropic Dirac Fermi surfaces, the Dirac Fermi surface in SrMnBi$_2$ is highly anisotropic with strong momentum-dependence of Fermi velocity as well as interlayer coupling. The resulting $c$-axis resistivity exhibits clear angular magnetoresistance oscillations indicating coherent interlayer conduction. Strong fourfold variation of the coherent peak in the $c$-axis resistivity reveals that the contribution of each Dirac valley is significantly modulated by the in-plane field orientation. Furthermore, we found a signature of broken valley symmetry at high magnetic fields. These findings demonstrate that a quasi-two-dimensional anisotropic Dirac system can host a valley-polarized interlayer current through magnetic valley control.

Thursday, March 5, 2015 11:15AM - 2:15PM –
Session T53 DMP: Invited Session: DMP Prize Session Grand Ballroom C3 - John Mitchell, Argonne National Laboratory

11:15AM T53.00001 James C. McGroddy Prize Lecture: Iron-Based Superconductors: Discovery and Progress, HIDEO HOSONO, Tokyo Institute of Technology — The largest breakthrough in the history is the discovery of high $T_c$ Cuprates by G.Bednorz and A.Muller in 1986 and the maximum $T_c$ exceeded 77K, boiling temperature of liquid nitrogen in 1987. However, no new superconductors with high $T_c$ had been reported since then except MgB$_2$ ($T_c=39K$) discovered by J.Akimitsu in 2001. We found LaFePO superconductor with $T_c=3K$ in 2006 and LaFeAsO$_1$-F$_x$ with $T_c=56K$ (42K at under high pressure of 5GPa) in early 2008. The latter discovery rekindled the extensive superconductivity research globally, and more than 10,000 papers have been published to now. This excitement originates from disprovement of a widely accepted belief that iron with a large magnetic moment is harmful for emergence of superconductivity and relatively high $T_c$. Extensive research on iron-based superconductors pushed up the maximal $T_c$ to 58K, which is next to high $T_c$ cuprates and has led to the discovery of more than 50 new iron-based superconducting materials to date. Seen are so many advances in elucidation of superconducting properties and pairing mechanism. In this talk, I introduce a tale to the discovery and show the current status by reviewing progresses in materials, properties, mechanism and the application covering the recent hot topics. Emphases are placed on the unique characteristics arising from multi-orbital nature which totally differs from high $T_c$ cuprates.

11:51AM T53.00002 David Adler Lectureship Award Talk: Friction and energy dissipation mechanisms in adsorbed molecules and molecularly thin films$^1$, JACQUELINE KRIM, North Carolina State University — Studies of the fundamental origins of friction have undergone rapid progress in recent years, with the development of new experimental and computational techniques for measuring and simulating friction at atomic length and time scales [1]. The increased interest has sparked a variety of discussions and debates concerning the nature of the atomic-scale and quantum mechanisms that dominate the dissipative process by which mechanical energy is transformed into heat. Measurements of the sliding friction of physisorbed monolayers and bilayers can provide information on the relative contributions of these various dissipative mechanisms. Adsorbed films, whether intentionally applied or present as trace levels of physisorbed contaminants, moreover are ubiquitous at virtually all surfaces. As such, they impact a wide range of applications whose progress depends on precise control and/or knowledge of surface diffusion processes. Examples include nanoscale assembly, directed transport of Brownian particles, material flow through restricted geometries such as graphene membranes and molecular sieves, passivation and edge effects in carbon-based lubricants, and the stability of granular materials associated with frictional and frictionless contacts.

12:27PM T53.00003 Nanoscale Impedance Imaging of Novel Quantum Materials, KEJI LAI, University of Texas at Austin — The research of complex quantum materials, in which a dazzling number of emergent phenomena take place in the nanoscale, is a major theme in modern condensed matter physics. For real-space mapping of complex systems, electrical impedance microscopy fills an important void that is not well represented by the existing local probes. Using shielded cantilever probes and sensitive microwave electronics, we can now perform non-invasive electrical imaging with unprecedented resolution (10-100nm) and sensitivity (sub-aF). To date, this powerful technique has enabled us to visualize the electronic inhomogeneity in colossal magnetoresistance manganites, spatially resolve the topological edge channels, image the metal-insulator transition in novel field-effect transistors, and probe the anomalous conduction in multiferroic domain walls. The sub-surface imaging capability is also ideal for understanding the evolution of chemical reaction involving low-dimensional layered materials. Further development of the technique will allow us to perform local dielectric spectroscopy across a large frequency span, explore the localized microwave magnetic resonance, and study the nanoscale nonlinear electromagnetic response in complex materials.

Entanglement and Quantum Error Correction with Superconducting Qubits

Matthew Reed, Yale University — Quantum information science seeks to take advantage of the properties of quantum mechanics to manipulate information in ways that are not otherwise possible. Quantum computation, for example, promises to solve certain problems in days that would take a conventional supercomputer the age of the universe to decipher. This power does not come without a cost however, as quantum bits are inherently more susceptible to errors than their classical counterparts. Fortunately, it is possible to redundantly encode information in several entangled qubits, making it robust to decoherence and control imprecision with quantum error correction. I studied one possible physical implementation for quantum computing, employing the ground and first excited quantum states of a superconducting electrical circuit as a quantum bit. These transmon- qubits are dispersively coupled to a superconducting resonator used for readout, control, and qubit-qubit coupling in the cavity quantum electrodynamics (cQED) architecture. In this talk I will give an general introduction to quantum computation and the superconducting technology that seeks to achieve it before explaining some of the specific results reported in my thesis. One major component is that of the first realization of three-qubit quantum error correction in a solid state device, where we encode one logical quantum bit in three entangled physical qubits and detect and correct phase- or bit-flip errors using a three-qubit Toffoli gate. My thesis is available at arXiv:1311.6759.

Single crystal growth and magnetic excitations of transition metal oxide CoV$_2$O$_6$

Christopher Stockdale, F. Wallington, Univ of Edinburgh, J. W. Taylor, V. Garcia-Sakai, Rutherford Appleton Laboratory, A.M. Arevalo-Lopez, P. Attfield, C. Stock, Univ of Edinburgh — Low-dimensional magnetic materials are an area of interest due to their unusual properties such as metamagnetism and magnetization plateaus [1]. Solid state synthesis has produced polycrystalline CoV$_2$O$_6$ which exists in two polymorphs: one with a monoclinic structure, and the other with a triclinic structure [2]. Single crystals have been grown from polycrystalline CoV$_2$O$_6$ using the flux method under vacuum and are large enough to aid in single crystal neutron diffraction [3]. Magnetic excitations have been measured using powder neutron diffraction in the low temperatures regime with variable energies. The magnetic excitations have been compared between the two phases. The energy of the system has been modelled in terms of the spin-orbit coupling, structural distortions, and the crystal field and compared to neutron data.

V1.00004 Atomic Processes and Diagnostics of Low Pressure Krypton Plasma 1, RAJESH SRIVASTAVA, DIPTI GOYAL, DIPTI GOYAL, R. Gangwar, L. Sharma, R. Srivastava and A. D. Stauffer, Université de Montréal — Optical emission spectroscopy along with suitable collisional-radiative (CR) model is used in plasma diagnostics. Importance of reliable cross-sections for various atomic processes is shown for low pressure argon plasma [1,2]. In the present work, radially-averaged Kr emission lines from the $2p_i \rightarrow 1s_j$ were recorded as a function of pressure from 1 to 50mTorr. We have developed a CR model using our fine-structure relativistic-distorted wave cross sections [3].

V1.00005 Effect of nonlinear nonlinear coupling to a pure dephasing model, LI GE, NAN ZHAO, Beijing Computational Science Research Center, Beijing 100084, China — We investigate the influence of the nonlinear coupling to the coherence of a pure dephasing model. The total system consists of a qubit and a Bosonic bath, which are coupled by an interaction $H_i = g_1 \sigma_x \otimes 1 + g_2 \sigma_z \otimes x^2$ with $x = \frac{1}{\sqrt{2}} (a + a^\dagger)$. It’s shown that no matter how small $g_2$ is, the long time behavior of the coherence is significantly changed by the nonlinear coupling for free induction decay (FID), while the effect of $g_1$ can be neglected as long as $g_1$ is much smaller than the energy splitting of the qubit. In the case that many-pulse dynamical decoupling control is exerted on the qubit, $g_2$ also modulates the oscillation of the coherence. Our results indicate that the nonlinear coupling must be taken into account for long time dynamics.

V1.00006 Hartree-Fock Theory of a Harmonically Trapped Dirty Bose-Einstein Condensate via the Replica Method, T. KHELLIL, Department of Physics, Freie Universität Berlin, Germany, A. PELSTER, Technische Universität Kaiserslautern, Germany — A recent non-perturbative approach towards the dirty boson problem relies on the Hartree-Fock theory which is worked out on the basis of the replica method [1]. Here we extend this approach for a weakly interacting Bose-gas at finite temperature in a quenched delta-correlated disorder potential from the homogeneous case to an anisotropic harmonic confinement within the Thomas-Fermi approximation. In this way we obtain and solve coupled self-consistency equations, which relies on a decomposition of the particle density into the condensate density, the thermal density as well as the density of fragmented local Bose-Einstein condensates within the respective minima of the random potential landscape. Although we reproduce for weak disorder and at zero temperature the seminal results of Huang and Meng from a Bogoliubov theory [2,3] only qualitatively, we yield for strong enough disorder a quantum phase transition to a Bose-glass phase [4].

V1.00007 Formation and dynamics of anti-ferromagnetic correlations of ultracold fermions in tunable lattices, RÉMI DESBUQUOIS, DANIEL GREIF, GREGOR JOTZU, MICHAEL MESSER, FREDERIK GÖRG, TILMAN ESSLINGER, ETH Zürich, Switzerland — The observation of anti-ferromagnetic spin correlations of ultracold fermions in optical lattices is an important milestone towards an experimental study of the Hubbard model. In this model many questions on the low-temperature phase diagram still remain open, both for simple cubic and square configurations, as well as for more complex lattice geometries. Additionally, for creating an equilibrated low-temperature state and a successful implementation of advanced cooling schemes based on entropy redistribution, an understanding of the formation time for spin correlations is of paramount importance. In our experiment we load a two-component, repulsively interacting fermionic quantum gas into an optical lattice of tunable geometry. For very low temperatures we observe anti-ferromagnetic correlations on neighbouring sites in both isotropic 3D cubic and 2D square lattices. We also study the strength of the spin correlations in more complex lattice geometries, such as honeycomb, 1D-dimerized and spin-ladder lattice configurations. Furthermore, we investigate the characteristic formation time of spin correlations in optical lattices by changing the lattice geometry on variable timescales.

V1.00008 Direct probe of topological order for cold atoms, DON-LONG DENG, SHENG-TAO WANG, LU-MING DUAN, Department of Physics, University of Michigan, Ann Arbor, Michigan 48109, USA — Cold-atom experiments in optical lattices offer a versatile platform to realize various topological quantum phases. A key challenge in those experiments is to unambiguously probe the topological order. We propose a method to directly measure the characteristic topological invariants (order) based on the time-of-flight imaging of cold atoms. The method is generally applicable to detection of topological band insulators in one, two, or three dimensions characterized by integer topological invariants. Using detection of the Chern number for the two-dimensional anomalous quantum Hall states and the Chern-Simons term for the three-dimensional chiral topological insulators as examples, we show that the proposed detection method is practical, and robust to typical experimental imperfections such as limited imaging resolution, inhomogeneous trapping potential, and disorder in the system.

3We thank S.-L. Zhu for discussions. This work was supported by the NBRPC (973 Program) Grants No. 2011CBA00302, the IARPA MUSIQC program, the ARO, and the AFOSR MURI program.

V1.00009 Collisional Microscopy and Generation of Entanglement with Ultracold Quantum Gases, QI LIU, CRAIG PRICE, NATHAN GEMELKE, The Pennsylvania State University — We describe an apparatus for cold collisional microscopy of quantum gases, in which pairwise entanglement is produced between a many-body gas and an optical-lattice-bound array of secondary atoms used as quantum-non-destructive probes. We discuss detailed implementation of collisional entanglement schemes based on Ramsey-style interferometer sequences, as well as tunnel-assist and -inhibit schemes, in which probe atoms are conditionally shuffled according to the presence or state of a sample atom. The technical implementation for precise manipulation of multichromatic optical lattices is discussed, including achromatic holographic projection microscopy at high numerical aperture and methods for achieving sufficient quantum state control within a lattice site. Applications of collisional microscopy will also be discussed, ranging from imaging of dynamical and non-equilibrium quantum many-body systems, to characterization of strongly entangled gases through extraction of entanglement entropy, to algorithmic cooling of quantum critical gases.
V1.00010 Cutoff frequency of sound velocities for a multi-slab Bose-Einstein condensate\footnote{We acknowledge partial support from PAPIIT IN111613.}, O.A. RODRÍGUEZ, Posgrado en Ciencias Físicas, UNAM, M.A. SOLÍS, Instituto de Física, UNAM — An inhomogeneous multi-slab 3D Bose gas is produced by applying to the gas a Kronig-Penney potential in one direction, while the bosons are free to move in the other two directions. The variable density produces a dispersive effect over the sound waves, making the phase and group sound velocities frequency dependent. Below the critical temperature the dispersion relation between wavenumber and frequency \( \omega(k) \) is determined by a constant factor called the curvature of the density, within the Klein-Gordon equation which describes the sound wave propagation in the condensate. Since the curvature of the density profiles between and inside the barriers are completely different, the sound velocities are distinct too. More importantly, in the region occupied by the slabs waves propagate only if their frequencies are greater than a cutoff frequency, otherwise evanescent waves arise. We show the density profile, the phase and group sound velocities and we give the curvature dependent cutoff frequency as obtained from the group velocity equation for the region occupied by the barriers. For high frequencies both phase and group velocities approach to that of a homogeneous gas at the same temperature.

V1.00011 Bose gas in disordered, finite-layered systems\footnote{We acknowledge support from grant UNAM-PAPIIT IN111613.}, Mauricio Fortes\footnote{Instituto de Física}, V.E. Barragán\footnote{Posgrado en Ciencia e Ingeniería de Materiales}, M.A. Solís\footnote{Instituto de Física}, Instituto de Física, UNAM — We report the isocoric specific heat for an ideal Bose gas confined in a periodic array of filaments with finite rectangular cross section and infinite length, set together to form a cable. The filament structure is created by applying to the gas two, mutually perpendicular, Kronig-Penney delta-potentials, while the bosons are free to move along the third direction. The energy spectrum accessible to the particles is obtained and introduced into the grand potential to calculate the specific heat of the system as a function of temperature for different values of the periodic structure parameters such as: the number, the area of the cross section and wall permeability, of the filaments. The specific heat shows a dimensional crossover from 3D to 1D, in temperature regions where the de Broglie wavelength of the bosons is comparable to twice the separation between the walls of the filaments. Furthermore, we provide and discuss a criterion for identifying the critical temperature based on the behavior of the chemical potential and its first derivatives, as well as the population of the ground state.

V1.00012 Specific heat for boson matter in multifilament cables\footnote{We acknowledge partial support from PAPIIT IN111613 and CONACYT 221030.}, Grecia Gujarró, Posgrado en Ciencias Físicas, UNAM, M.A. Solís, Instituto de Física, UNAM — We report the isocoric specific heat for an ideal Bose gas confined in a periodic array of filaments with finite rectangular cross section and infinite length, set together to form a cable. The filament structure is created by applying to the gas two, mutually perpendicular, Kronig-Penney delta-potentials, while the bosons are free to move along the third direction. The energy spectrum accessible to the particles is obtained and introduced into the grand potential to calculate the specific heat of the system as a function of temperature for different values of the periodic structure parameters such as: the number, the area of the cross section and wall permeability, of the filaments. The specific heat shows a dimensional crossover from 3D to 1D, in temperature regions where the de Broglie wavelength of the bosons is comparable to twice the separation between the walls of the filaments. Furthermore, we provide and discuss a criterion for identifying the critical temperature based on the behavior of the chemical potential and its first derivatives, as well as the population of the ground state.

V1.00013 Intrinsic Versus Extrinsic Which-Way Information and the Use of Extrinsic WW Information in a Delayed Choice Experiment to Send Information Immediately Between 2 Paired Particles, Douglas Snyder\footnote{None — Intrinsic states characterize a quantity inherent in the particle itself, such as spin. Extrinsic states characterize a quantity that is not in the particle itself but that describes the particle. An example is the specific path a particle is taking through an interferometer. Extrinsic states such as the specific path of a particle can be eliminated before a measurement is made. An experiment is described to show the impact that this ability to eliminate extrinsic states can make. This experiment relies on a delayed choice for an idler photon that immediately affects the signal photon with which it is entangled. The delayed choice concerns whether to maintain or eliminate the entanglement before any measurements are made. The idler photon can essentially be lost before any measurements are made because the states of the idler photon that enters the optical microcavity related to its entanglement are eliminated when the idler photon enters the optical microcavity. One of the reasons is that the states of the idler photon are extrinsic to the particle itself (they characterize the particular path of the particle, a characteristic not inherent to the particle itself) where the information underlying the entropic state is eliminated when the particle enters the cavity situated at the confluence of the two possible particle paths. Over a number of runs with this choice, the resulting distribution of the paired signal photons shows interference. If the entanglement is instead maintained, the resulting distribution of the paired signal photons shows WW information.}, None — Intrinsic states characterize a quantity inherent in the particle itself, such as spin. Extrinsic states characterize a quantity that is not in the particle itself but that describes the particle. An example is the specific path a particle is taking through an interferometer. Extrinsic states such as the specific path of a particle can be eliminated before a measurement is made. One of the reasons is that the states of the idler photon are extrinsic to the particle itself (they characterize the particular path of the particle, a characteristic not inherent to the particle itself) where the information underlying the entropic state is eliminated when the particle enters the cavity situated at the confluence of the two possible particle paths. Over a number of runs with this choice, the resulting distribution of the paired signal photons shows interference. If the entanglement is instead maintained, the resulting distribution of the paired signal photons shows WW information.

V1.00014 The Immediate Affect of Information in a Delayed Choice on a Distant Distribution as Seen in Different Inertial Reference Frames: The “Effect” May Occur Before the “Cause”, Douglas Snyder. None — An experiment is described in the laboratory reference frame that relies on delayed choices for idler photons that immediately affects the distribution of signal photons with which the idler photons are initially entangled. The delayed choices on the idler photons concern whether to maintain or instead eliminate the entanglement between the paired idler and signal photons before any measurements are made. Eliminating the entanglement is done through eliminating the which-way information carried by the idler photon. If the entanglement is maintained, the result is which-way information in the distribution of the signal photons. If the entanglement is instead eliminated, the result is the elimination of which-way information and the presence of interference in the distribution of the signal photons. In other inertial reference frames, the change in state in the signal photon may occur before the delayed choice on the paired idler photon is made. A Minkowski diagram depicts the situation for the laboratory reference frame and another inertial reference frame where the change in state in the signal photon occurs before the delayed choice on the paired idler photon.

V1.00015 FDTD study of the formation of optical vortices associated with core-shell nanoparticle cluster\footnote{The authors would like to acknowledge the valuable support from Masdar Institute and Massachusetts Institute of Technology for the solar thermal project grant.}, Md Mahfuzur Rahman, Jin You Lu, Masdar Institute of Science and Technology, George Ni, Nicholas Xuanlai Fang, Massachusetts Institute of Technology, Tiejun Zhang, Amal Al Ghaferi, Masdar Institute of Science and Technology — Light absorbing plasmonic metal-dielectric nanoparticles suspended in water, or nanofluids have recently been experimentally demonstrated to produce steam at high efficiencies upon solar illumination. This approach localizes high temperatures to the interior of the liquid through efficient trapping of incoming light via scattering and absorption mechanisms. In suspensions, nanoparticles may form clusters due to surface wetting properties, and little work has focused on understanding the optical properties of clusters. In this work, we use the FDTD method to accurately visualize the optical power flow through various plasmonic metal-silica core-shell nanoparticle pairs at different inter-particle separations (10-100 nm). At these separations phase singularities of the power flow can occur, such as vortices of light inside the dielectric core which can enhance the absorption cross-section of the cluster. We study the conditions required to form these vortices. We also consider titanium nitride as shell, other than the widely studied noble metals to visualize the extinction cross-section of a cluster which depends on the separation, and the permittivity of the dielectric core.
V1.00016 Nanometer Scale Microscopy via Graphene Plasmons, XIAODONG ZENG, MOHAMMAD AL-AMRI, MOHAMMAD SUHAIR ZUBAIRY, Institute for Quantum Studies and Department of Physics and Astronomy, Texas A&M University — Using graphene plasmons (GPs), we can realize a nanometer scale microscopy. Our scheme takes advantage of the extremely large wave number of GPs and the low loss of graphene. Comparing with conventional nonlinear structured illumination microscopy basing on high order nonlinearity associated with high intensity light, our proposal only requires linear response. Consequently we need very weak field, which means less damage to the sample and may play a significantly important role in imaging of the biological systems. 

V1.00017 Efficient Non-Resonant Absorption in Thin Cylindrical Targets: Experimental Evidence, ANDREY AKHMETELI, LTASolid Inc., Houston, Texas, USA, NIKOLAY KOKODY, BORIS SAFRONOV, VALERY BALKASHIN, IVAN PRIZ, V. N. Karazin Kharkiv National University, Kharkiv, Ukraine, ALEXANDER TARASEVITCH, University of Duisburg-Essen, Institute of Experimental Physics, Duisburg, Germany — A theoretical possibility of non-resonant, fast, and efficient (up to 40 percent) heating of very thin conducting cylindrical targets by broad electromagnetic beams was predicted in [Akhmeteli, arXiv:physics/0405091 and 0611169] based on rigorous solution of the diffraction problem. The diameter of the cylinder can be orders of magnitude smaller than the wavelength (for the transverse geometry) or the beam waist (for the longitudinal geometry) of the electromagnetic radiation. This can be used for numerous applications, such as pumping of active media of short-wavelength lasers, e.g., through efficient heating of nanotubes with laser radiation. Experimental confirmation of the above results is presented [Akhmeteli, Kokody, Safrovnov, Balkashin, Priz, Tarasevitch, arXiv:1109.1626 and 1208.0066]. Significant (up to 6%) absorption of microwave power focused on a thin fiber (the diameter is three orders of magnitude less than the wavelength) by an ellipsoidal reflector is demonstrated experimentally. For the longitudinal geometry, experiments provide a confirmation of significant absorption (up to 35%) of the power of a wide CO2 laser beam propagating along a thin wire (the diameter of the wire can be orders of magnitude less than the beam waist width).

V1.00018 Scattering of near-zero-energy positronium by H2, JUN-YI ZHANG, Division of Physical Science & Engineering, King Abdullah University of Science and Technology, Thuwal 23955-6900, Saudi Arabia, YING QIAN, Department of Computer Science and Technology, East China Normal University, Shanghai 200241, China, YU-JUN YANG, Institute of Atomic and Molecular Physics, Jilin University, Changchun 130012, China, ZONG-CHAO YAN, Department of Physics, University of New Brunswick, Fredericton E3B 5A3, Canada, UDO SCHWINGENSCHLÖGL, Division of Physical Science & Engineering, King Abdullah University of Science and Technology, Thuwal 23955-6900, Saudi Arabia — The scattering length and pick-off annihilation probability for the S-wave scattering of zero-energy positroniums (Ps) by H2 are calculated by the stabilization method using explicitly correlated Gaussians. The confined variational method is used to optimize the Gaussians in order to describe the short-range interaction of the incident Ps with H2 in the fixed nucleus approximation. By applying a confining potential to the center-of-mass of Ps, the problem of continuum states can be converted to a problem of discrete energy levels. For scattering at very low energies, the convergence of the scattering parameters can be improved by including exterior basis functions to describe the asymptotic region, which are given by products of Gaussians with H2 wave function and Ps wave function. In addition, the effect of van der Waals interaction between the Ps and H2 on scattering parameters will be taken into account.

V1.00019 Experimental and theoretical studies of excited-state angular-momentum alignment and orientation signals in atomic rubidium in the presence of an external magnetic field, MARCIS AUZINS, ANDRIS BERNIS, RUVIN FERBER, FLOURIAN GAHSAUER, LINARIS KALVANS, ARTHURS MOZERS, AGNIS SPIESS, Laser Centre, University of Latvia, Rainis Blvd. 19 LV-1586, Riga, Latvia — We present level-crossing signals for the hyperfine transitions of the D2 line of rubidium and show that these signals can be described very precisely by a theoretical model that is based on optical Bloch equations. The crossings occur when the levels are shifted by the nonlinear Zeeman effect in an external magnetic field B, whose direction defines the quantization axis z. A coherent state is said to be aligned if the population of atoms varies as a function of mF, the projection of the total atomic angular momentum F on the quantization axis z, but is equal for +mF and −mF. When the energies of two magnetic sublevels for which ΔmF = 2 cross, an aligned state can be created by excitation with coherent radiation. An oriented state can be created for crossings with ΔmF = 1. Because the theoretical model has been extended to include the hyperfine structure of the atomic levels, strong magnetic sublevel mixing in an external magnetic field, and the Doppler effect, precise agreement between theory and experiment is possible even at excitation power densities where optical pumping plays a role. We present experimental results and theoretical calculations, showing their dependence on laser power density and frequency.

1 We thank Latvian Council of Science project 119/2012 for financial support.

V1.00020 Stimulated and coherent Raman spectroscopy with 0? pulses, SUMAN DHAYAL, YURI ROS-TOVTSEV, University of North Texas — We developed a new variant of stimulated and coherent Raman spectroscopy with shaped short pulses, applicable to multi-scattering media. The technique is based on the spectral modulation of the laser pulse due to the Raman scattering. Using discrete dipole approximation we modeled the scattering from nanoparticles and calculated response from molecules in vicinity of nanoparticles to demonstrate the effects of 0?-short laser pulses. The obtained results may have a broad range of applications from spectroscopy and pathogen detection to microscopy.

V1.00021 Second quantization of squeezed light through non-linear medium, ZHIHIAO XIAO, R. NICHOLAS LANNING, Department of Physics and Astronomy, Louisiana State University, MI ZHANG, IRINA NOVIKOVA, EUGENIY E. MIKHAILOV, Department of Physics, College of William & Mary, JONATHON P. DOWLING, Department of Physics and Astronomy, Louisiana State University — We investigated the interaction of Rb atoms and squeezed light which is treated quantum mechanically. We establish the model of Gaussian beam propagating through the non-linear medium. The spatial modes of the output beam include high order Laguerre-Gaussian (LG) modes. We find the differential equation describing the second-quantized input-output relations. Since the spatial LG modes of the output beam are entangled with the squeezed states, we apply various schemes of spatial selection in order to produce the squeezed states which can lead to various applications. We also explain the result of the experiment where a Gaussian pump field is put through a Rb cell and a sub-shot noise is found.

V1.00022 Possibility of vibrationally resolved cross section measurements for low energy charge transfer in H + H2, C.I. GUILLEN, R.A. STROM, J.A. TOBAR, D.I. PANCHENKO, V.M. ANDRIANARIJAONA, Department of Physics, Pacific Union College, Angwin, CA 94508 — Charge transfer (CT) in H + H2 → H+ + H2 has fundamental implications because it involves the smallest atomic ion, atom, molecular ion, and molecule possible. The current merged-beam apparatus at Oak Ridge National Laboratory (ORNL) in Oak Ridge, Tennessee, can reliably create and access low collision energies; the existing ion-atom merged beams apparatus there is the only apparatus currently able to benchmark the CT of these fundamental systems at energies below 0.1eV/u (Phys. Rev. A 84, 062716, 2011). However, the data analysis suffers from the lack of information on the initial states of H2, which makes comparison to state-to-state calculations (PRA 67 022708 (2003) impossible without educated guesses. We are exploring the possibility of inserting a three-dimensional imaging technique at the end station of the ORNL apparatus in order to measure the vibrational state distribution of H2 that are produced by the electron cyclotron resonance ion source. Our initial design for the insertion of this technique in the aforementioned system will be presented here.

V1.00023 The Utilization of Chloroform Post-Treatment to Improve the Adhesion of Au Thin Films onto PMMA. KATHLEEN KRIST, CHRIS HUGHES, XIAOFENG HU, James Madison University, BRIAN AUGUSTINE, High Point University — The metallization of Au onto plastics is an important processing step in the fabrication of microfluidic devices. While its corrosion resistance and excellent electrical and thermal conductivity make Au a good choice, its inertness results in poor adhesion to polymer surfaces. Previous studies have indicated that exposing commercially available Poly(methyl methacrylate) (PMMA) sheets to chloroform vapor following Au deposition significantly improves adhesion.

In this study, we deposited 6 nm of Au onto 1.50 mm thick PMMA and exposed the samples to vapor released from chloroform heated on a hot plate set at 70°C. The force required to remove the Au thin films was determined by placing samples on a polisher spinning at 150 rpm and utilizing UV-VIS spectroscopy to measure the transmittance of 700 nm light through the films to quantify their removal as a function of applied polishing force. The Au thin films were also characterized using AFM. AFM images demonstrated a progressive roughening of the surface corresponding to an increase in applied force. Additionally, these images support a model in which the chloroform treatment softens the PMMA surface, producing a softened layer that the polisher removes simultaneously with the Au thin film.

V1.00024 Spatial Modes of a Squeezed Vacuum Field1. MI ZHANG, College of William & Mary, R. NICHOLAS LANNING, ZHIHAO XIAO, JONATHAN P. DOWLING, Louisiana State University, IRINA NOVIKOVA, EUGENII E. MIKAHLIOV, College of William & Mary. We prepared a quantum noise suppressed squeezed vacuum field by propagating a beam with a wavelength of 795nm through a hot Rb cell. Observation of the quadrature noise showed that we achieved a noise suppression of -2.0 dB below the quantum noise limit. When a spatial mask was applied to the beam after its interaction with atoms, we observed that the detected quantum noise suppression strongly depended on the shape of the mask. An exploration of the spatial distribution of noise in the squeezed field illustrated that the squeezed field was in a different spatial mode from the pump field used as a local oscillator. Our research showed that the squeezed field consisted of several spatial modes with various squeezing parameters. If a pure squeezed mode could be extracted, it would enhance the signal to noise ratio, which would impact precision metrology and quantum memory applications.

V1.00026 Experimental apparatus for quantum simulation with two-dimensional 9Be+ Coulomb crystals . KARSTEN PYKA, HARRISON BALL, TERRY MCRAE, CLAIRE EDMUNDS, MICHAEL W. LEE, SAMUEL HENDERSON, MICHAEL J. BIERCUK, The University of Sydney, QUANTUM CONTROL LAB TEAM — We report on the development of a new experimental setup designed for Quantum Simulation studies at a computationally relevant scale using laser-cooled 9Be+ ion-crystals in a Penning trap. The trap geometry is optimized using numerical calculations for trapping large ion crystals with enhanced optical access and reduced anharmonic perturbations. Separate loading and spectroscopy zones prevent long term drifts of the trapping parameters due to contamination of the trap electrodes with Be deposits. Our customized superconducting magnet provides a homogenous (dB/B < 10-6) magnetic field at 3T required for ion trapping. Laser frequencies required for cooling/detection and spin-motion entanglement are generated from telecom wavelength fiber laser systems in the IR via nonlinear conversion. Our new approach employs high-efficiency telecom modulators and mode-selecting cavities to generate multiple beamslines from a single Sum-frequency-Generation step. Ultimately, this newly developed setup will allow for studies of many-body spin systems with tunable interaction strength from infinite-range to nearest-neighbour type interaction.

V1.00027 Complete and Partial Transfer of Energy in Bremsstrahlung Should Include Rotational and Vibrational Kinetic Energies . STEWART BREKKE, Northeastern Illinois University (former grad student) — In complete braking achievement the rotational and vibrational as well as the linear kinetic energies of the charged particle results in a photon: \( h\nu = \frac{1}{2m^2} + \frac{1}{2I\omega^2} + \frac{1}{2k^2} \). In partial transfer of kinetic energies of the decelerating particle the resulting photon is \( h\nu = \left[\frac{1}{2m^2} + \frac{1}{2I\omega^2}\right] + \frac{1}{2k^2} \). The linear kinetic energy of the charged particle is \( \frac{1}{2m^2} \), the rotational kinetic energy is \( \frac{1}{2I\omega^2} \) and the vibrational kinetic energy is given by \( \frac{1}{2k^2} \).

V1.00028 Evolution of quantum wave packets in the presence of time-dependent absorption . MAXIMILIEN BARBIER, Northumbria University, MATHIEU BEAU, School of Theoretical Physics, Dublin Institute for Advanced Studies, ARSENI GOUSSEV, Northumbria University — The dynamics of a quantum particle submitted to a barrier is strongly influenced by the wave nature of matter, and may for instance lead to the classically forbidden phenomenon of tunneling. While the case of a real potential barrier is a standard problem in quantum mechanics, different approaches are possible to model an absorbing barrier. Here we present a quantitative comparison between two such approaches. The first one describes an absorbing point-like barrier by means of certain time-dependent boundary conditions of Kottler’s type, while the second approach treats the wave function of the moving particle as a component of a spinor evolving under the action of a matrix Hamilton operator.

V1.00029 Magneto-optical resonances and relaxation mechanisms in an extremely thin cell: experiment and theory for the cesium D1 line1. MARCIS AIZINSH, ANDRIS BERZINS, RUVIN FERBER, FLORIAN GAHBHAER, ULDIS KALNINS, LINARDS KALVANS, RONALDS RUNDANS, Laser Centre, University of Latvia, Rainis Blvd. 19 LV-1586, Riga, Latvia, DAVID SARKISYAN, Institute for Physical Research, NAS of Armenia, Ashtarak-0203, Armenia — Magneto-optical resonances are a sensitive effect that allows to make stringent tests for theoretical models, which in turn, can help to improve devices that measure magnetic field. The experiments were carried out with an extremely thin cell (ETC) that provides high spatial resolution and allows sub-Doppler spectroscopy. At the same time the theoretical description of the signal requires delicate treatment of effects peculiar to thin cells. The cell, manufactured in Armenia, consists of two YAG glass windows separated by a distance of less than one micrometer. The experimental measurements of magneto-optical resonances were done using LIF signals of a cesium atomic vapor layer with a thickness varying from about 350 nm to of about 900 nm. In this study we obtained an accurate theoretical description of magneto-optical resonances using a theoretical model based on the optical Bloch equations that is an expanded version of earlier models and now includes a more detailed treatment of relaxation processes and the saturation of the atom-laser interaction in the high-intensity areas of the beam.

V1.00030 Efficiency of multi-wave mixing in a sphere . SUMAN DHAYAL, YURI ROSTOVTSVE, University of North Texas — We consider nonlinear multi-wave mixing in a sphere. We compare the efficiency of wave mixing in a sphere with the efficiency in a bulk or in the slab where, as well-known, the phase-matching plays an important role. We have found the optimal conditions for nonlinear generation in a sphere. The obtained results can be applied to coherent Raman microscopy and allow us to maximize the signal for arbitrary shape of nanoparticles.

V1.00031 Efficiency of multi-wave mixing in a sphere . SUMAN DHAYAL, YURI ROSTOVTSVE, University of North Texas — We consider nonlinear multi-wave mixing in a sphere. We compare the efficiency of wave mixing in a sphere with the efficiency in a bulk or in the slab where, as well-known, the phase-matching plays an important role. We have found the optimal conditions for nonlinear generation in a sphere. The obtained results can be applied to coherent Raman microscopy and allow us to maximize the signal for arbitrary shape of nanoparticles.
V1.00031 Modelling Spatial Modes of Squeezed Vacuum – When it Comes to Squeezing, Plane Waves Are Just Too Plan, R. NICHOLAS LANNING, ZHIHAO XIAO, Louisiana State University, MI ZHANG, IRINA NOVIKOVA, EUGENIY E. MIKHAILOV, College of William and Mary, JONATHAN P. DOWLING, Louisiana State University — Recent research relying on the polarization self-rotation (PSR) effect in Rb$^8$ has revealed a squeezed vacuum field consisting of several spatial modes with various squeezing parameters [Mi Zhang, Spatial Modes of a Squeezed Vacuum Field, 2015 APS March Meeting]. In order to explain these results, we re-derive the beam propagation model describing the creation of squeezed vacuum via PSR and incorporate more realistic multimode input-output relations in the paraxial approximation. We solve the propagation equation and use it to predict the spatial distribution of squeezed vacuum via the proper Laguerre-Gauss modal structure. This modal structure is instrumental in the development of a complete second quantized beam propagation formalism also being reported at this meeting [Zhihao Xiao, Second quantization of squeezed light through non-linear medium, 2015 APS March Meeting].

V1.00032 Photoionization of Fe$^{7+}$ from the ground and metastable states1, SWARAJ TAYAL, Clark Atlanta University, OLEG ZATSARINNY, Drake University — The B-spline Breit-Pauli $R$-matrix method is used to investigate the photoionization of Fe$^{7+}$ from the ground and metastable states in the energy region from ionization thresholds to 172 eV. The present calculations were designed to resolve the large discrepancies between the recent measurements and available theoretical results. The multiconfiguration Hartree-Fock method in connection with B-spline expansions is employed for an accurate representation of the initial and final states wavefunctions. The close-coupling expansion includes 99 fine-structure levels of Fe$^{7+}$ in energy region up to $3s^23p^54s^4$ states. It includes levels of the $3s^23p^5$, $3s^23p^53d$, $3s^23p^54s$, and $3s^23p^53d$ configurations which lie in the energy region under investigation. The present photoionization cross sections agree well with the Breit-Pauli $R$-matrix calculation of Sossah et al. and is governed by the configuration of the background cross sections, but show new rich structure which qualitatively agree with the measurements. The calculated cross sections, however, are several times lower than the measured cross sections depending upon photon energy. The cross sections for photoionization of metastable states

V1.00033 Two-color x-ray pump x-ray probe study of the core-hole decay dynamics in XeF2, ANTONIO PICON, C. STEFAN LEHMANN, STEPHEN SOUTHWORTH, PHAY HO, GILLES DOUMY, ELLIOT KANTER, BERTOLD KRAESSIG, ANNE MARIE MARSH, DOOSHAYE MOONSHIRAM, LINDA WONG, STEVE PRATT, Argonne National Laboratory, DIPANWITA RAY, Lawrence Berkeley National Laboratory, DANIEL ROLLES, BENJAMIN ERK, CEDRIC BOMME, CFEL, DESY, ARTEM RUDENKO, Kansas State University, TIMUR OSIPOV, NORA BERRAH, Department of Physics, UCONN, LAN CHENG, JOHN STANTON, University of Texas — To resolve the femtosecond inner-shell dynamics and the subsequent induced electron transfer in a molecule, the core-hole decay dynamics in XeF2 have been directly studied using femtosecond time-resolved x-ray pump x-ray probe coincidence imaging. The study of XeF2 molecule allows us to compare the molecular core-hole decay with the atomic case, Xe atom. To study these processes, the recently developed capability at LCLS was used to generate two-color x-ray pulses with variable delay. A time and position sensitive detector has been used to record the ion fragments in coincidence. The correlated ion kinetic energies make it possible to select and assign different excitation pathways, being able to track the atomic and the molecular core-hole decay dynamics.

V1.00034 Electron Impact Inner-shell Ionization of Ions1, A.K.F. HAQUE, M.A.R. PATOARY, M.A. UDDIN, A.K. BASAK, Department of Physics, University of Rajshahi, Rajshahi-6205, Bangladesh, B.C. SAHA, Department of Physics, Florida A&M University, Tallahassee, FL-32307. — Electron impact ionization cross-sections (EIICS) for H to Sc isoelectronic series over incident energies ranging from threshold to 10 keV have been measured. Recent work and theoretical results are described. The experiment is based on the electron impact ionization of the K-, L- and M-shell ions, "Physica Scripta, 81, 045301 (2010)."

1Work is partially supported by DOE project (NNSA)

V1.00035 Absorption spectra of monolayer MoS2 in high magnetic field, HUNG-DUEN YANG, Natl Sun Yat Sen Univ, JIN-MONG HER, Chang Gung University, SHOJOIRO TAKEYAMA, YASUHIRO MATSUDA, The University of Tokyo, The Institute for Solid State Physics Kashiwano 5-1-5, Kashiwa, Chiba #277-8581 Japan, KAI-HSUAN WANG, Natl Sun Yat Sen Univ — We have measured the absorption spectra of monolayer MoS2 at several temperatures in pulsed high magnetic fields up to 52 T. At room temperature, the observed spectrum dominated by two peaks, which are located at 660 nm and 606 nm. These peaks are ascribed to excitation and trion absorption peaks respectively [1]. At low temperature (4.2 K), two peaks show the blue shift to 633 nm and 588 nm, respectively. Irrespective of the temperature, applying magnetic field does not show pronounced influence on the peaks even in 52 T.

V1.00036 Measuring the conductivity dependence of the Casimir force1, JUN XU, ROBERT SCHAFFER, ALEXANDR BANISHEV, UMAR MOHIDEEEN, University of California, Riverside, CA 92521 — The strength and distance dependence of the Casimir force can be controlled through the conductivity of the material bodies, with lower conductivity in general leading to lower Casimir forces. However low conductivity, large bandgap materials which are insulating, have drawbacks as any surface electrostatic charges cannot be easily compensated. This restricts experiments to metallic or highly doped semiconductor materials. We will report on measurements of the Casimir force gradient using the frequency shift technique. Improvements in the measurement technique will be discussed. Measurements of the Casimir force gradient using low and high conductivity silicon surfaces will be reported.

1The authors thank G.L. Klimchitskaya and V.M. Mostepanenko for help with the theory and the US National Science Foundation for funding the research.

V1.00037 Nonlinear dynamical phase diagram of ultra-cold atoms in periodic lattices, WAKUN LAM, GIL SUMMY, MARIO BORUNDÁ, Oklahoma State Univ — We study the dynamics of ultra-cold bosonic gases in periodic deep optical potential by incorporating the nonlinear inter-site coupling into the discrete nonlinear Schrödinger equation (DNLS). We numerically solve the DNLS to analyze and compare the evolution of Gaussian wave packets reported in [Phys. Rev. Lett., 86, 11(2001)]. Our result corroborates the validity of the phase diagram calculated by the variational method within a certain range of parameters of the initial wave packets. We calculate the long-term evolution of solutions of DNLS to generate a fine phase diagram to elaborate the transitions between different dynamic modes. We propose an experimental scheme to verify the phase diagram based on the Bose-Einstein condensates in optical traps.
V1.00038 Superfluidity and Chaos, GEVA ARWAS, AMICHAY YARDI, DORON COHEN, Ben-Gurion University — The hallmark of superfluidity is the appearance of a quantized metastable circulating current. The Landau criterion links the metastability of a vortex state to its spectral stability, i.e., to the inaccessibility of elementary excitations connecting it to other states with the same energy. In low dimensional systems, superfluid vortex states can exist due to their dynamical stability even if they are spectrally unstable. This traditional paradigm associate superfluid vortex states with stationary fixed points in phase space. Hence, Bogoliubov de Gennes (BdG) stability analysis is normally used to determine the feasibility of such states. In this work we challenge this traditional criterion and highlight the role of chaos in the analysis, thus explaining the existence of current carrying eigenstates which are neither spectrally-stable nor dynamically-stable.

V1.00039 Interaction and Disorder Effects across BCS-BEC Crossover in Two-Dimensional Fermi Gases, B. TANATAR, A. KHAN, Bilkent University — We investigate the effect of static impurities in two-dimensional ultracold atomic Fermi gases. We incorporate disorder from impurities through fluctuations and study its effects on the BCS-BEC crossover. We analyze the effect of quenched disorder for various physical quantities such as chemical potential, pairing gap, density of states, spectral function, and ground-state energy. We extend our study further towards the experimentally viable quantities such as condensate fraction, sound velocity and Landau critical velocity. The results are presented as a function of binding energy and scattering length. We observe negligible effect of disorder in 2D for BCS Cooper pairs and considerable amount of depletion in the BEC regime but intriguingly the results also reveal that disorder effect is masked at the crossover region.

V1.00040 Direct laser cooling of the BH molecule, DARREN HOLLAND, STEFAN TRUPPE, RICHARD HENDRICKS, BEN SAUER, MICHAEL TARBUtT, Imperial College London — Ultracold polar molecules are of interest for a variety of applications, including tests of fundamental physics, ultracold chemistry, and simulation of many-body quantum systems. The laser cooling techniques that have been so successful in producing ultracold atoms are difficult to apply to molecules. Recently however, laser cooling has been applied successfully to a few molecular species, and a magneto-optical trap of SrF molecules has now been demonstrated. We have investigated the BH molecule as a candidate for laser cooling. We have produced a molecular beam of BH and have measured the branching ratios for the excited electronic state, \( \Lambda^1\Sigma^+(v'=0) \), to decay to the various vibrational states of the ground electronic state, \( \Sigma^1\Sigma^- \). We verify that the branching ratio for the spin-forbidden transition to an intermediate triplet state is inconsequentially small. We measure the frequency of the lowest rotational transition of the X state, and the hyperfine structure in the relevant levels of both the X and A states, and determine the nuclear electric quadrupole and magnetic dipole coupling constants. Our results show that a relatively simple laser cooling scheme can be used to cool, slow and trap BH molecules.

V1.00041 Trapping effect on the sound velocity of a multilayer Fermi gas\(^1\), PATRICIA SALAS, M. A. SOLiS, Instituto de Física, UNAM — We present the trapping effect on the behavior of the isothermal compressibility and sound velocity for an interactionless Fermi gas immersed in a periodic interconnected multilayer structure created by an external Dirac comb potential which can vary both in spacing and in the intensity that controls the impenetrability of the layer edge (the wall) \([1]\). At \( T = 0 \), for a given layer width and respect to the free ideal Fermi gas values, the isothermal compressibility as a function of the impenetrability starts in one and then monotonically increases to reach a larger constant value which is width dependent. The sound velocity as a function of impenetrability starts in one and for a range of impenetrabilities shows a bump which suggests that the presence of the structure increases the sound velocity. For a finite temperature, given a separation between the walls and several values of their impenetrabilities, both properties start their evolution in temperature from the ideal Fermi gas value, unfold at temperatures near and under \( T^\gamma \), and then recover the behavior of a classical gas at higher temperatures.

\(^1\)We acknowledge partial support from PAPIIT IN111613 and CONACyT 221030.

V1.00042 Superfluidity in 1D and 3D Spin-Imbalanced Fermi Gases\(^1\), BEN A. OLSEN, MELISSA REVELLE, JACOB A. FRY, RANDALL G. HULET, Department of Physics & Astronomy and Rice Quantum Institute, Rice University, Houston, TX 77005 — The phase separation between superfluid and normal phases (both polarized and unpolarized) in trapped Fermi gases in the BEC-BEC crossover reveals the interplay between superfluid pairing, interactions, and dimensionality. We measure density profiles of both spins of a two-component, spin-polarized fermions cooled to \( \sim 100 \) nK. In a 3D gas, an unpolarized superfluid core is surrounded by a polarized shell. We observe gradual suppression of this core as interactions are weakened from unitarity. For a 1D gas in an optical lattice, the phase separation matches 1D models, where the central phase is partially polarized, and is predicted to exhibit FFLO correlations\(^2\). By increasing the inter-tube tunneling rate, we investigate the dimensional crossover between 1D and 3D Fermi gases. In this regime, the FFLO order parameter is predicted to be correlated between tubes\(^3\) and its modulation length constant over larger regions of the trap.\(^4\) These features are predicted to enhance the observable signatures of FFLO correlations; we report progress towards such measurements.

V1.00043 APPLICATONs —

V1.00044 Feature Selection via Modified Gravitational Optimization Algorithm, NOOSHIN NABIZADEH, NIGEL JOHN, University of Miami — Feature selection is the process of selecting a subset of relevant and most informative features, which efficiently represents the input data. We proposed a feature selection algorithm based on \( n \)-dimensional gravitational optimization algorithm (NGOA), which is based on the principle of gravitational fields. The objective function of optimization algorithm is a non-linear function of variables, which are called masses and defined based on extracted features. The forces between the masses as well as their new locations are calculated using the value of the objective function and the values of masses. We extracted variety of features applying different wavelet transforms and statistical methods on FLAIR and T1-weighted MR brain images. There are two classes of normal and abnormal tissues. Extracted features are divided into groups of five features. The best feature is selected in each group using \( n \)-dimensional gravitational optimization algorithm and support vector machine classifier. Then the selected features from each group make several groups of five features again and so on till desired number of features is selected. The advantage of NGOA algorithm is that the possibility of being drawn into a local optimal solution is very low. The experimental results show that our method outperforms some standard feature selection algorithms on both real-data and simulated brain tumor data.
V1.00045 Optically Pumped NMR Studies of Mechanically Induced Strain in GaAs Films . CLIFFORD BOWERS, RYAN WOOD, JOHN TOKARSKI III, LAUREN MCCARTHY, DIPTA SAHA, CHRISTOPHER STANTON, Univ. of Florida - Gainesville, JESUS MORENO, MIT — We present a new methodology for measuring strain in semiconductor films based on optically pumped NMR (OPNMR). Single crystals of GaAs were epoxy bonded to Si wafers at 100 °C. The GaAs is then thinly thinned by selective chemical etching. Upon cooling, biaxial tensile strains are induced in the GaAs films since the coefficient of thermal expansion in GaAs is different than in the Si support. OPNMR experiments were carried out at 6-10 K. The OPNMR spectra are sensitive to nuclei within a phonon coherence depth from the surface. When illuminated with a 0.635 μm thick Si support, the strain, which is proportional to the observed quadrupole splitting, is found to decrease with increasing thickness of the GaAs films and appears to approach a residual value. When the same GaAs film is mounted on a thicker 5mm Si block, the strain increased. To explain the observations, we consider effects of dislocation relaxation of strain and bending of the composite. The interface strain extracted from the measurements is 5.5 × 10^{-4}, in good agreement with the value estimated using the differential thermal contraction of Si and GaAs. The strain resolution of the technique is about 10^{-5} in GaAs.

V1.00046 Theoretical study of the structural, vibrational and dielectric properties of PbSnTe alloys . HORACIO W. LEITE ALVES, ANTONIO R.R. NETO, Univ. Fed. de Sao Joao del Rei, JOHN E. PETERSEN, Texas State University, PAULO D. BORGES, Univ. Fed. de Viçosa, LUISA M.R. SCOLFARO, Texas State University — Thermoelastic devices have promise in dealing with the challenges of the growing demand for alternative clean energy and Te-based materials well-known candidates for them. Recently [1], we have shown that the high values for the dielectric constant, together with anharmonic LA-TO coupling, reduces the lattice thermal conductivity and enhances the electronic conductivity in PbTe. Also, it was shown that by alloying this material with Se, the electronic conductivity of the alloys is also enhanced [2]. But, it is not clear if the same occurs when alloying with Sn. We show, in this work, our ab initio results for the structural, vibrational and dielectric properties of Pb_{1-x}Sn_xTe alloys. The calculations were carried out by using the Density Functional Theory, and the alloys were described by the Virtual Crystal Approximation. Our results show that their structural properties do not obey the Vegard rule. However, we have detected that the anharmonic LA-TO coupling still exists and the obtained values for the dielectric constant show higher values than that obtained for PbTe.

V1.00047 Experimental observation of amplification death via asymmetric gain . MAHBOOBEH CHITSAZI, SAMUEL FACTOR, JOSEPH SCHINDLER, HAMIDREZA RAMÉZANI, FRED ELLIS, TSAMPIKOS KÖTTOS, Department of Physics, Wesleyan University, Middletown CT-06459, USA — The amplification action of a photon coupled RLC circuit is experimentally controlled via a spatially inhomogeneous gain. Specifically we have demonstrated that the overall gain of this uneasy RLC circuit can result in its stabilization. This counterintuitive phenomenon has its roots in managing impedance matching and thus can be applicable to a variety of wave systems.

V1.00048 Laser Induced Breakdown Spectroscopy of Glass and Crystal Samples . PRAKASH SHARMA, ALEJANDRA SANDOVAL, MICHAEL CARTER, AKSHAYA KUMAR, Department of Physics, Tuskegee University, Tuskegee, Alabama — Different types of quartz crystals and rare earth ions doped glasses have been identified using the laser induced breakdown spectroscopy (LIBS) technique. LIBS is a real time technique, can be used to identify samples in solid, liquid and gas phases. The advantage of LIBS technique is that no sample preparation is required and laser causes extremely minimal damage to the sample surface. The LIBS spectrum of silicate glasses, prepared by sol-gel method and doped with different concentration of rare earth ions, has been recorded. The limit of detection of rare earth ions in glass samples has been calculated. Total 10 spectra of each sample were recorded and then averaged to get a final spectrum. The ocean optics LIBS2500 plus spectrometer along with a Q-switched Nd:YAG laser (Quantel, Big Sky) were used to record the LIBS spectrum. This spectrometer can analyze the sample in the spectral range of 200 nm to 980 nm. The spectrum was processed by OOI LIBS-plus(v1.0) software. This study has application in the industry where different crystals can be easily identified before they go for shaping and polishing. Also, concentration of rare earth ions in glass can be monitored in real time for quality control.

V1.00049 Optical spectrum measurement of a cell-adhered microcavity for the cell-cycle analysis applications . RYUSUKE SAITO, MITSUHIRO TERAKAWA, TAKASUMI TANABE, Department of Electronics and Electrical Engineering, Keio University — We build a setup and demonstrate successful measurement of the transmittance spectrum of a whispering gallery mode silica optical microcavity in which NIH 3T3 cells adhered on the top surface to achieve real-time and label-free measurement of the cell cycle. Label-free measurement is expected to prevent the cells to exhibit secondary effect. We build a system that enables the control of the gap distance between the microcavity and the tapered fiber, both of which are placed in the cell culture medium. The optimization of the tapered fiber diameter is the key to measure the spectrum of a microcavity in liquid. A swept wavelength laser light at a wavelength of 766 to 780 nm is used for the measurement. The cavity exhibit a Q of 1.0 × 10^{10} in air, where the value is 1.0 × 10^{10} in the medium and drops to 3.1 × 10^{4} after the cell-adhesion. Still the Q of the microcavity is sufficiently high to detect the change at the cavity surface. Indeed we observe slight spectrum shift toward a longer wavelength, which we believe is due to the adherence of NIH 3T3 cells on the silica microcavity. The successful measurement of the transmittance spectrum of a microcavity in cell culture medium is the first step to realize the analysis of the cell-cycle based on microcavity system.

V1.00050 Laser performance at 1064 nm in Nd^{3+} doped oxi-tellurite glasses . MARIA JOSE BELL, VIRGILIO ANJOS, LYANE MOREIRA, RODRIGO FALCI, Federal University of Juiz de Fora, LUCIANA KASSAB, Faculdade de Tecnologia de Sao Paulo, D. SILVA, Escola Politécnica da USP, JEAN LOUIS DOULAN, PATRICE CAMY, RICHARD MONCORGE, Université de Caen, France — The search for Nd^{3+} doped new solid-state laser hosts having specific thermo-mechanical and optical properties is very active. Among tellurites, the TeO_2-ZnO glass combines good mechanical stability, chemical durability, high linear and nonlinear refractive indices, low phonon energies (~750 cm^{-1}) and a wide transmission window (0.4-6 μm). Their high nonlinear optical properties can be used for the development of Kerr-lens mode-locked subpicosecond lasers. The present work concentrates on the luminescence properties and the laser performance of a TeO_2-ZnO tellurite glasses doped with Nd^{3+}. True continuous-wave laser action is achieved by pumping the sample with a CW Ti:Sapphire laser inside a standard two-mirror laser cavity. A low laser threshold of 8 mW and a laser slope efficiency of 21% could be obtained for an output coupler transmission of 2.7%, which is an encouraging improvement compared to what was reported in the past with other Nd-doped tellurite bulk glasses.

V1.00051 Mie plasmon-polariton modes in two-dimensional metallic photonic crystals . BRAYAN DIAZ, Universidad del Valle, RICARDO MEJIA, Ciudad Universitaria, Maceió, NELSON PORRAS, Universidad del Valle — We have studied the Mie plasmon-polariton resonances in cylindrical metallic hollow rods by calculating the scattering (Q_{scat}), extinction (Q_{ext}) and absorption (Q_{abs}) coefficients, which were compared with results for the photonic band structure (PBS) of the corresponding periodic 2D system, showing that Bloch plasmon-polariton modes in the periodic system shift toward a longer wavelength, which is due to the relaxation of the resonances in both cases, we show that the symmetry properties remain similar, indicating a robustness of these localized plasmon modes.
V1.00052 Optical “Bernoulli” forces\(^1\). RAMIS MOVASSAGH, Massachusetts Institute of Technology and Northeastern University, STEVEN JOHNSON, Massachusetts Institute of Technology — By Bernoulli’s law, an increase in the relative speed of a fluid around a body is accompanied by a decrease in the pressure. Therefore, a rotating body in a fluid stream experiences a force perpendicular to the motion of the fluid because of the unequal relative speed of the fluid across its surface. It is well known that light has a constant speed irrespective of the relative motion. Does a rotating body immersed in a stream of photons experience a Bernoulli-like force? We show that, indeed, a rotating dielectric cylinder experiences such a lateral force from an electromagnetic wave. In fact, the sign of the lateral force is the same as that of the fluid-mechanical analogue as long as the electric susceptibility is positive (\(\epsilon > 0\)), but for negative-susceptibility materials (e.g. metals) we show that the lateral force is in the opposite direction. Because these results are derived from a classical electromagnetic scattering problem, Mie-resonance enhancements that occur in other scattering phenomena also enhance the lateral force. [This talk is based on Phys. Rev. A 88, 023829 (2013).]

V1.00053 Extraordinary transverse magneto-optical Kerr effect in a superlens. EDWIN MONCADA, Universidade del Valle, ANTONIO GARCIA; Instituto de Microelectronicas de Madrid, JUAN CARLOS CUEVAS, Universidad Autonoma de Madrid — It has been shown that a slab of a negative index material can behave as a superlens enhancing the imaging resolution beyond the wavelength limit. We show here that if such a slab possesses in addition some magneto-optical activity, it could act as an ideal optical filter and exhibit an extraordinary transverse magneto-optical Kerr effect. Moreover, we show that losses, which spoil the imaging resolution of these lenses, are a necessary ingredient to observe this effect.

V1.00054 Characterization/Selection of a Continuous Wave Laser for RIMS Analysis in Nuclear Forensics. SUNNY LAU, F. ALVES, G. KARUNASIRI, C. SMITH, Naval Postgraduate School, B. ISSELHARDT, Lawrence Livermore Laboratory — The effort to implement the technology of resonance ionization mass spectroscopy (RIMS) to problems of nuclear forensics involves the use of multiple lasers to selectively ionize the elements of concern. While current systems incorporate pulsed lasers, we present the results of a feasibility study to determine alternative (Continuous Wave) laser technologies to be employed for analysis of the actinides and fission products of debris from a nuclear detonation. RIMS has the potential to provide rapid isotope ratio quantification of the actinides and important fission products for post detonation nuclear forensics. The current approach to ionize uranium and plutonium uses three Ti-Sapphire pulsed lasers capable of a fundamental wavelength range of 700-1000 nm. In this work, we describe the use of a COTS CW laser to replace one of the pulsed lasers used for the second resonance excitation step of plutonium near 847.282 nm. We characterize the critical laser parameters necessary to achieve high precision isotope ratio measurements including the stability over time of the mean wavelength, bandwidth and spectral mode purity. This far narrower bandwidth laser provides a simpler setup, more robust hardware (greater mobility), and more efficient use of laser irradiance.

V1.00055 Multi-level Capacitive Memory Effect in Metal/Oxide/Floating-Schottky Junction\(^1\), GAHYUN CHOI, SUNGCHUL JUNG, HOON HAHN YOON, YOUNGEUN JEON, KIBOG PARK*, Ulsan National Institute of Science and Technology — A memory computing (memcomputing) system can store and process information at the same physical location simultaneously. The essential components of memcomputing are passive devices with memory functionality, such as memristor, memcapacitor, and meminductor. We report the realization of a Schottky contact memcapacitor compatible with the current Si CMOS technology. Our memcapacitor is formed by depositing a stack of metal and oxide thin films on top of a Schottky contact. Here, the metal electrode of the Schottky contact is floating. The working principle of our memcapacitor is based on the fact that the depletion width of the Schottky contact varies according to the amount of charge stored in the floating metal electrode. The voltage pulse applied across the Metal/Oxide/Floating-Schottky junction controls charge flow in the Schottky contact and determines the amount of charge stored eventually. It is demonstrated experimentally that our memcapacitor exhibits hysteresis behaviors in capacitance-voltage curves and possesses multiple capacitance values that are switchable by the applied voltage pulse.

V1.00056 High mobility field effect transistors of SnO\(_x\) on glass substrates made by reactive sputtering of Sn metal. CHANJONG JU, CHULWON PARK, HYEONSEOK YANG, USEONG KIM, YOUNG MO KIM, KOOKRIN CHAR, Seoul National University — We report on the electrical properties of SnO\(_x\) thin films and the performance of their field effect transistors on glass substrates made by reactive sputtering of a Sn metal target. We investigated the electrical properties of SnO\(_x\) films as a function of the oxygen pressure. The mobility of the SnO\(_x\) films on glass substrates after post-deposition annealing at 400 C was as high as 15.3 cm\(^2\)V\(^{-1}\)s\(^{-1}\) while its carrier density was 4.42 \(\times\) 10\(^{18}\) cm\(^{-3}\). By x-ray diffraction, we have found that the films are mixture of SnO and SnO\(_2\) phases, suggesting possibility of further enhancement of the electrical properties if the phase can be controlled. Nevertheless, we will report on the performance of thin film transistors using polycrystalline SnO\(_x\) as the channel layer and the atomic-layer-deposited AlO\(_x\) and HfO\(_x\) as the gate oxide.

V1.00057 Integrated silicon nanophotonics: structure and electro-optic properties of BaTiO\(_3\) on Si(001). KRISTY KORMONDY, University of Texas at Austin, FLORIAN FALLEGGER, STEFAN ABEL, YOUI POPOFF, IBM Research - Zurich, PATRICK PONATH, AGHAM POSADAS, University of Texas at Austin, MARYLINE SOUSA, DANIELE CAIMI, HEINZ SIEGWART, EMANUELE UCCELLI, LUKAS CZORNOMAZ, CHIARA MARCHIORI, JEAN FOMPEYRINE, IBM Research - Zurich, ALEXANDER DEMKOV, University of Texas at Austin — High-quality epitaxial BaTiO\(_3\) (BTO) on Si has emerged as a promising material for future electro-optic (EO) devices based on BTO’s large effective Pockels coefficient. In order to achieve strong EO coupling, a film must have (1) correct crystallographic orientation with respect to the applied electric field, and (2) low leakage current in the film to sustain a strong electric field. We report on the EO response of BTO films deposited on Si by molecular beam epitaxy. \(\alpha\) \(_2\) rapid thermal anneal at 600C for 30 min ensures full oxidation of BTO for minimal leakage current with minor change in crystalline structure. EO characterization was performed by analyzing changes of the polarization of a laser beam transmitted through pairs of lithographically defined electrodes. The EO response shows signatures of ferroelectric domains with in-plane polarization. Comparison with normalized responses of c-axis and a-axis films illustrate that a strong EO response is observed even for a mixed film. These results quantify the relationship between BTO structure and EO properties, an important step towards future silicon photonic devices based on ferroelectric oxides.

V1.00058 ABSTRACT WITHDRAWN —
V1.00059 Optimizing Energy Conversion: Magnetic Nanomaterials1, DYLAN MCINTYRE, MARTIN DANN, CAROLINA C. ILIE, State University of New York at Oswego — We present herein the work started at SUNY Oswego as a part of a SUNY 4E grant. The SUNY 4E Network of Excellence has awarded SUNY Oswego and collaborators a grant to carry out extensive studies on magnetic nanoparticles. The focus of the study is to develop cost effective rare-earth-free magnetic materials that will enhance energy transmission performance of various electrical devices (solar cells, electric cars, hard drives, etc.). The SUNY Oswego team has started the preliminary work for the project and graduate students from the rest of the SUNY 4E team (UB, Alfred College, Albany) will continue the project. The preliminary work concentrates on analyzing the properties of magnetic nanoparticle candidates, calculating molecular orbitals and band gap, and the fabrication of thin films.

1SUNY 4E Network of Excellence Grant

V1.00060 Prevention of Initial Defect of Low-Noise Solid-State-Nanopore Device, KAZUMA MATSUI, ITARU YANAGI, KENICHI TAKEDA, Hitachi Ltd — To achieve DNA sequencing using solid-state-nanopore, it is necessary to reduce an electric noise current. In this study, the noise was decreased by reducing the capacitance(C) of the nanopore device. We coated an insulating material near a nanopore on a membrane of the device, and confirmed that the capacitance of the device needs to be decreased down to 100 pF in order to reduce the noise. However, electric-charge difference (∆Q) between electrolyte in the one and the other chamber occurred high voltage (∆V = ∆Q/C) to the membrane because the capacitance(C) was reduced. The electric-charge difference defected the membrane when pouring the electrolyte onto the both sides of the membrane. In order to prevent the initial defects, we established new procedures to reduce the electric-charge difference using electric bypass between the one and the other chamber. Then, we confirmed that there were no defects on the membrane with this procedure.

V1.00061 Development of Multifunctional Luminomagnetic Nanoparticles as Bioimaging Contrast Agents1, LAWRENCE C. MIMUN, CHRIS RIGHTSSELL, G.A. KUMAR, FRANCISCO PEDRAZA, SERGIO A. MONTELONGO, TEJA GUDA, University of Texas at San Antonio, VINAYAK P. DRAVID, Northwestern University, DHIRAJ K. SARDAR, University of Texas at San Antonio — Trivalent rare earth doped nanocrystalline materials with multiple functionalities have drawn special attention in biomedical industry. Current research is focused on the use of various materials with dual functionality for potential multifunctional applications. In this project, we are developing near infrared(NIR) based nanocrystals (NCs) as contrast agents with multimodal features comprising of strong NIR fluorescence, X-ray fluorescence and magnetic properties by utilizing the super-paramagnetic features of Gd3+, the high X-ray excitation cross section of Lu3+, and the NIR fluorescence of Nd3+. Halides, such as MgGdLuF7 (M=K,Na), were doped with NIR active rare earth ions, Nd3+, where synthesis conditions have been optimized to obtain the brightest phosphor with a size of sub-50 nm. Characterization of the NCs were performed to explore the excitation and emission properties, crystal structure, morphology, magnetization properties, and X-ray fluorescence properties. The potential use of these NCs can be utilized as contrast agents for medical imaging application such as optical imaging, magnetic resonance (MRI) and X-ray imaging.

1This research was, in part, funded by NIGMS MBRs-RISE GM060655 and from the National Science Foundation Partnerships for Research and Education in Materials (NSF-PREM) grant N0-DMR-0934218

V1.00062 Intracellular Imaging Applications of Rare Earth doped Multifunctional Metal Oxy-sulphide Nanomaterials1, JULIO C. AVALOS, C. MIMUN, G.A. KUMAR, D.K. SARDAR, Univ of Texas, San Antonio — Nanomaterials with multiple imaging features have a lot of attention in the medical industry where there is always a high demand for contrast agents that can give more information about the intracellular level mechanisms. Nanomaterials with specific size, shapes, surface functionalities, and properties are needed for intracellular level optical imaging. Rare-earth doped inorganic nanophosphors are the best choice for these applications due to their several advantages such as excellent optical properties, size and composition control, etc. Though there are several efficient rare earth based halide nanophosphors, an efficient halide free nanophosphor is still lacking. In this work we are presenting a series of rare earth doped metal oxysulphide host, M2O2S:Re (M=Ca,Gd, La, Re=Yb,Er,Tb), as an alternate host with fluorescence efficiency equal or even higher than that of halides. Following a detailed study on the optical and magnetic properties we evaluated the potentiality of this material as nanoscale multifunctional contrast agents by in vitro and in vivo animal experiments. Our experimental results show that by adjusting the dopant concentrations and host structures the material property can be tuned over a wide range for multimodal imaging applications and optimized compositions can be achieved for high contrast intracellular imaging.

1This research was funded by the National Science Foundation Partnerships for Research and Education in Materials (NSF-PREM) grant N0-DMR-0934218 and partially funded by NIH/NIGMS MARC U*STAR GM07717.

V1.00063 MP04: Nd3+ (M=Ca, Gd), Luminomagnetic Nanophosphors with Optical and Magnetic Features for Multimodal Imaging Applications1, CHRIS RIGHTSSELL, LAWRENCE C. MIMUN, AJITH G. KUMAR, DHIRAJ K. SARDAR, Univ of Texas, San Antonio — Nanomaterials with multiple functionalities play a very important role in several high technology applications. A major area of such applications is the biomedical industry, where contrast agents with multiple imaging modalities can provide better results than conventional materials. Many of the contrast agents available now have drawbacks such as toxicity, photobleaching, low contrast, size restrictions, and overall cost of the imaging system. Rare-earth doped inorganic nanophosphors are alternatives to circumvent several of these issues, together with the added advantage of super high resolution imaging due to the excellent near infrared sensitivity of the phosphors. In addition to optical imaging features, by adding a magnetic ion such as Gd3+ at suitable lattice positions, the phosphor can be made magnetic, yielding dual imaging functionalities. In this research, we are presenting the optical and magnetic imaging features of sub-nanometer size MP04:Nd3+ (M=Ca, Gd) phosphors for the potential application of these nanophosphors as multimodal contrast agents. Cytotoxicity, in vitro and in vivo imaging, penetration depth etc. are studied for various phosphor compositions, and optimized compositions are explored.

1This research was funded by the National Science Foundation Partnerships for Research and Education in Materials (NSF-PREM) grant N0-DMR-0934218.

V1.00064 Measurement of Quantum Yield and Upconversion Brightness in Red, Blue and Green on NIR Excited M2O2S:Yb/Er/Ho/Tm Phosphors1, IVAN BEEKS, AJITH G. KUMAR, DHIRAJ K. SARDAR, Univ of Texas, San Antonio — A series of broadly color tunable upconversion phosphors were synthesized from M2O2S (M=Y,Gd,La) using a flux fusion method. We investigate their upconversion properties as a function of the dopant concentrations and excitation power density. The phosphor compositions were determined for their upconversion characteristics under 800, 980 and 1550 nm excitations. By measuring the quantum yield and luminous brightness, we investigate their potential applications in biomedical imaging as well as NIR display applications. Results are compared with the well-known upconversion phosphor NaYF4:Yb/Er/Ho/Tm and found that the M2O2S phosphor systems are more efficient compared to NaYF4. By adopting various synthesis protocols, we were able to examine M2O2S in the size range of 10 nm to 10 µm.

1This research is supported by the National Science Foundation Partnerships for Research and Education in Materials (NSF-PREM) grant N0-DMR-0934218.
V1.00065 Synthesis and Characterization of Down-converting $\text{Ca}_9(\text{PO}_4)_6\text{Nd}^{3+}$ Nanocrystals for Biomedical Imaging Applications, NICOLAS BALLI, LAWRENCE MIMUM, FRANCISCO PEDRAZA, AJITH KUMAR, DIRAJ SARDAR, University of Texas at San Antonio — Currently, fluorescent probes (FPs), such as organic dyes and fluorescent proteins, are widely used for biomedical imaging, but exhibit undesirable characteristics such as small Stokes shifts, large spectral overlaps, short fluorescence lifetimes, and photobleaching. In recent years rare earth doped nanoparticles (NPs) have shown promising results for use as FPs with properties that overcome the limitations of traditional fluorophores. Our current work utilizes the rare-earth ion, Nd$^{3+}$, which exhibits NIR-NIR excitation and emission wavelengths that are within the low absorption and scattering region for biological tissues. Calcium phosphate was chosen as the host crystal because of its biocompatibility. The nanocrystals were then characterized by X-ray diffraction and TEM imaging. Spectroscopic studies were done to determine the emission and absorption intensity, quantum yield, and fluorescence lifetime. Analysis of the data was performed and the NPs were shown to possess superior properties when compared to those of traditional fluorophores.

V1.00066 Novel conduction behavior in nanopores coated with hydrophobic molecules, VENKAT BALAGURUSAMY, GUSTAVO STOLOVITZKY, ALI AZZALI-ARDAKANI, IBM T.J. Watson Research Center, Yorktown Heights, NY — Nanopores that are hydrophilic either by the nature of their pore surface or after suitable treatment are well studied in the context of solid-state nanopores. The ionic conduction in these nanopores typically exhibit a near no-concentration-dependence region low concentrations of salt (<1 mM salt concentrations), followed by the high concentration region where it is proportional to the concentration. A simple cylindrical model for pore conduction can explain these behaviors based on surface and bulk conduction of the ions in the buffer solution [Smeets et al 2006 Nano Letters 6, 89]. However, in nanopores coated with hydrophobic pores we find that the pore conductance is $c^3$ (c: concentration). This behavior is in stark contrast with the behavior of hydrophilic pores. We will present these results for different hydrophilic molecular coatings that exhibit this behavior.

V1.00067 Mechanical Properties of Pentaerythritoltetranitrate (PETN) Single Crystals from nano-indentation: Depth Dependent Response at the Nano Meter Scale, MEIYU ZHAI, GREGORY MCKENNA, Texas Tech Univ — This paper presents the investigation of the mechanical behaviors of the energetic material pentaerythritol tetranitrate (PETN) single crystals using a nanoindentation technique. The indentation tests have been performed on the (110) crystal face, using both spherical and wedge-shaped tips. The load displacement curves along with analysis has been used to extract the mechanical properties and to identify the anisotropic indentation elastic constants for the PETN. The calculated indentation moduli of the PETN single crystal were found to decrease as indentation depth increases and become displacement independent when the indentation depth is higher than 200nm. The indentation modulus obtained from spherical tip indentation is compared with results calculated by using literature values of the anisotropic elastic constants. The wedge indenter tip measurements at various tip orientations are different due to the anisotropy of the PETN. The yield behaviors of the PETN single crystal were also explored using both spherical and wedge tip indentation and differences are discussed. Key Words: PETN, nano-indentation, anisotropic elastic constants, single crystal, plastic yield

V1.00068 All-optical near-field self-alignment in sub-nanoscale induced by Fano-resonance, HUI DONG, ZHENG WANG, University of Texas at Austin, UNIVERSITY OF TEXAS AT AUSTIN TEAM — Fano-resonance of photonic crystal (PC) slabs generally possesses extremely high quality-factor (Q-factor) which indicates large optical force produced via radiation pressure with low input power. Unlike atoms, nano- and micro-particles, periodicity of PC slab creates identical force field in every unit cell, which enables the manipulation of much wider area in millimeter scale. Here we developed a novel mechanism to construct a conservative optical force field to automatically align PC slabs with sub-nanometer resolution, a technique has a potential application in 3D photonic crystal fabrication. The phase response of our system can be predicted after the features of PC slab are precisely depicted using temporal coupled-mode theory. The conservation of optical force is then theoretically demonstrated based on Response Theory of Optical Force (RTOF) which has a perfect agreement with numerical simulation results of Maxwell Stress Tensor (MST) and Kelvin Force. In the end, we show no non-conservative component exists in the force field from Finite-element Method (FEM) simulation after applying Helmholtz-Hodge decomposition to it.

V1.00069 Effects of Metal Nanoparticles on Optical Behavior Tunability of Multi-layer MoS$_2$, SHERMIN ARAB, STEPHEN CRONIN, University of Southern California — We investigate the effects of metal nanoparticles (NP) on tunability of the optical response from relatively thick MoS$_2$ flakes. The plasmonic interactions and charge transfer at the metal-semiconductor interface is studied through metal NP deposition on mechanically exfoliated MoS$_2$. The optical quenching effect of metal NP capping is observed. Our photoluminescence results show that the surface charge transfer at the metal-semiconductor interface and creation of possible defect points at the semiconductor surface can lead to quenching of the photoluminescence response. Our optical observation of thicker MoS$_2$ flakes shows that, by using a metal NP capping layer, one can selectively exclude photoluminescence response from the peak due to indirect transition. This approach provides a controlled method for tuning the optical response of relatively thick MoS$_2$ flakes. In this study the effects of Au, Cu and Ag NPs are investigated. Micro-PL spectroscopy of the MoS$_2$ flakes is performed; where, PL spectra are collected in the 1.2 eV to 2.3 eV energy range and a 532 nm CW laser is used for excitation. X-ray photoelectron spectroscopy (XPS) is performed to investigate the nature of the metal-semiconductor interface.

V1.00070 Metrology for Nanoscale Manufacturing, ALEXANDER MUNOZ, Arizona State Univ — The extension of optical techniques to the nanoscale is increasingly powerful because manufacturing requires fast, in-line, non-destructive metrology. As part of the NASCENT NSF Engineering Research Center led by the University of Texas at Austin, the focus of the effort is on the tools necessary for establishing manufacturing infrastructure required for process control of nanoscale printing. The initial exploration of scatterometry involved the use of a 244 nm laser to evaluate the zero-order reflectivity as a function of angle of incidence for two polarizations. Measurements of the wire-grid polarizer were then repeated with 405 nm to investigate the extensibility of scatterometry. In conjunction with the scatterometry data, rigorous coupled wave analysis simulations were used to determine the behavior of the reflectivity as a function of five critical dimensions. Varying the parameters led to the ability to fit the simulation curves to the experimental data, thus revealing the dimensions of the wire-grid polarizer. Grating profiles are established continuously allowing for the implementation of roll-to-roll manufacturing as envisioned by NASCENT. Scatterometry is a workhorse of Si lithography because of its fast, non-contact measurements at extreme sub-wavelength scales.

1 This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science by Los Alamos National Laboratory (Contract DE-AC52-06NA25396) and Sand.

V1.00071 SEMICONDUCTORS —
V1.00072 Spin-valley coupling study in transition metal dichalcogenides. LU XIE, the University of Hong Kong — A single layer (monolayer) of transition metal dichalcogenide (TMD), a two-dimensional (2D) crystal with a Honeycomb lattice structure, has attracted tremendous interests thanks to its unique optical and electronic properties. Unlike graphene, TMD monolayer is a direct-gap semiconductor with interband transition in the visible energy range. The direct gap is located at the corners of the 2D hexagonal Brillouin zone which are technologically called valleys. The two degenerate but inequivalent valleys (denoted by ±k) constitute a binary degree of freedom, which is potentially treated as a new kind of information carrier just like the traditional charges and spin. In TMD monolayer, the inversion symmetry is originally broken. This leads to valley-selective circular dichroism meaning that the ±k valleys can only be exclusively excited by right-(r+) or left-circularly (l-) polarized light, which enables optical manipulation of the valley pseudospin. Besides, the strong spin-orbital coupling (SOC) mainly stemming from the transition metal atoms gives a remarkable valence band splitting ranging from 0.1 eV to 0.5 eV for different TMDs. Together with the above mentioned inversion symmetry breaking, this leads to strong coupled spin and valley which makes the valley and spin robust against scattering by smooth deformations and long wavelength phonons. As a result, the valley-dependent optical selection rule is often accompanied by a spin-dependent optical selection rule. Here, we will present the experimental demonstration of the spin-valley locking in TMD monolayer. The spin polarization is realized by the circular polarized optical fields and is electrically detected.

V1.00073 Coherent Manipulation of a Single Magnetic Atom Using Polarized Single Electron Transport in a Double Quantum Dot. WENXI LAI, Dr, WEN YANG, collaboration tutor — We consider theoretically a magnetic impurity spin driven by polarized electron tunneling in a double quantum dot transport. Spin blockade effect and spin conservation in the system make the magnetic impurity to sufficiently interact with each transported electron. This effect yields the nanomagnet coherently driven by a single electron which carries information about the magnetic impurity spin. The present scheme may develop all electrical manipulation of manomagnets by means of single electrons, which is significant for the implementation of scalable logical systems in information processing.

V1.00074 Spin textures for surface states with non-Rashba-type spin-orbit interaction. KOKIN NAKAJIN, SHUICHI MURAKAMI, Tokyo Institute of Technology — Surface states in Ti/Si and Bi/Si surfaces show non-Rashba-type spin splitting due to spin-orbit interaction (SOI). We construct effective tight-binding models on the triangular lattice for the surface states of B/Si and Ti/Si surfaces with spin-orbit interaction, respecting the crystal symmetries. Consequently, band structures and spin textures calculated from these models qualitatively agree with the experimental results. We find a new term in the Ti/Si model, which does not exist in Rashba systems. In addition, we numerically find bound states at the junction between two surface regions which have different signs of the SOI parameters in the Bi/Si system and in the Ti/Si system. Interestingly, the spin direction of the bound states is perpendicular to the crystal surface, whereas the spins of the bulk states are in-plane in the Bi/Si junction model. We compare the results with calculations using continuum models in two junction models. We also discuss physical realizations of such junctions.

V1.00075 A comparative analysis of deposition methods for nickel contacts onto CZT. JONATHAN LASSITER, SAMUEL UBA, MAXX JACKSON, SATILMIS BUDAK, Alabama A&M Univ, CLAUDIU MUNTELE, Cygnus Scientific Services, STEPHEN BABALOLA, TRENT MONTGOMERY, Alabama A&M Univ — Our studies have demonstrated quality of material surface, interface and interface contacts must be considered in fabrication of an optimally functioning radiation detector. Dangling bonds, poor surface processing, contamination of the surface and the quality of the contacts negatively contribute to detector energy resolution, and increased leakage currents. A Cadmium Zinc Telluride (CZT) crystal had nickel contacts deposited and characterized for these three cases: a) PVD, b) sputter cleaned plus PVD, and c) Ion Beam Assisted Deposition. In each of these cases the materials were characterized through use of current voltage (IV) measurements, Gamma Ray response and Scanning Electron Microscopy. The IV curves, resistivities, gamma responses, and surface features of the sample have been analyzed and compared. These results elucidate the influence of surface processing on quality of contacts and interfaces in optimizing the fabrication of a functioning radiation detector.

V1.00076 Characterization of deposited nickel contacts for CZT. JONATHAN LASSITER, SAMUEL UBA, MAXX JACKSON, SATILMIS BUDAK, Alabama A&M Univ, CLAUDIU MUNTELE, Cygnus Scientific Services, STEPHEN BABALOLA, TRENT MONTGOMERY, Alabama A&M Univ — Cadmium Zinc Telluride (CZT), a material used in room temperature radiation detectors, has many surface features which contribute to suboptimal functioning as a radiation detector. Dangling bonds, quality of polished surface, and the contacts are contributing factors to reduced detector energy resolution, and increased leakage currents. Nickel contacts were deposited, characterized and compared to the gold chloride electroless contact, and deposited gold. We took current voltage (IV) characteristics of CZT-based detectors and obtained their Gamma response spectra. These measurements enabled us to determine an optimal metal contact deposition process and material with improved detector performance as measured by leakage current and charge collection efficiency. The work functions of the contacts were chosen to work well with CZT. Quality surfaces, and contacts may serve as a means to improve the functioning of CZT in detector applications.

V1.00077 Effects of annealing conditions on the structural and electrical properties of a-oriented ZnO thin films. C.W. CHANG, Q.Y. CHEN, National Sun Yat-Sen University, Taiwan, P.V. WADEKAR, University of Liverpool, UK, H.C. HUANG, C.F. CHANG, H.H. KO, W.C. HSEIH, National Sun Yat-Sen University, Taiwan, C.H. LIAO, ROC Military Academy, Taiwan, H.W. SEO, University of Arkansas, Little Rock, Arkansas, USA, W.K. CHU, University of Houston, Houston, Texas, USA, H.H. LIAO, Enli Technology Inc., Taiwan — We studied the structural and optical properties of non-polar a-plane ZnO films grown on r-plane Al2O3 substrates by RF-spattering with different annealing conditions and oxygen partial pressure. Epitaxial relationships between the ZnO films and Al2O3 substrates was determined by ϕ-scan to be ZnO[0001]//[Al2O3][10-1], ZnO[1-100]//[Al2O3][1-101], and ZnO[1-210]//[Al2O3][1-210]. Photoluminescence spectra showed that band gap depended on annealing times, which is sensitive to intrinsic emission and surface defects in the a-plane ZnO. Hall Effect was measured on all samples by a PPMS system to find the relations amount annealing times, carrier concentrations and mobilities.

V1.00078 Enhancement of UV upconversion emission under near infrared excitation from NaYF4 nanocrystals doped with different lanthanide dopants. CAROLINA VALDES, MADHAB POKHREL, YUANBING MAO, None — Lanthanide doped nanocrystals have been attracted intensive attentions recently due to their interesting photoluminescence properties. Each lanthanide exhibits its own unique optical property, allowing for emission of light at different wavelengths. Consequently, different dopants can be used at varying concentrations to fine-tune desired emission wavelengths. The hexagonal crystal structure with low phonon energy and high photon efficiency has made NaYF4 a very efficient host for lanthanide dopants. Excitation of this material occurs at low energy in the near infrared (NIR) region and through energy transfer between dopants, emission at higher energy in visible regions is observed. A lot of work has been reported on upconversion to visible light; however, there is limited work on UV upconversion and enhancement of emission. Our current work focused on synthesizing a pure crystalline phase of NaYF4 and doping these nanocrystals with different lanthanides, including Tm, Nd and Gd using various concentrations. These nanocrystals have been systematically characterized by X-ray diffraction (XRD), scanning electron microscope (SEM), and photoluminescence (PL).
V1.00079 Transition Dynamics for Muonium in Silicon Germanium Alloys, GANGA JAYARATHNA, ROGER LICHTI, PATRICK MENGYAN, Texas Tech University, YASAR CELEBI, Istanbul University, BRITTANY BAKER, Texas Tech University — We use a longitudinal field muon spin relaxation technique to observe charge-state and site-change transitions of muonium in Si_{1-x}Ge_{x} samples (x = 0.45, 0.77, 0.81, 0.84, and 0.94). We primarily focus on modeling the temperature and field dependence of the relaxation data to investigate the donor and acceptor ionization energies, paramagnetic hyperfine frequencies and charge-state/site-change cycles. We compare donor/acceptor energies from relaxation data to those from asymmetric fits and verify assignments of specific transitions to each observed relaxation feature and access energy values not previously determined. Previous studies have shown that the T-site muonium acceptor level enters the valence band near x = 0.92. We find separate muonium acceptor states with muonium trapped at a Si within the tetrahedral Si_{1-x}Ge_{x} cage region and propose a new charge cycle that involves valence band resonant states.

V1.00080 Modeling of Transition Metal Color Centers in Diamond, NICK GORTHARD, University of Dayton Research Institute, DOUG DUDIS, LUKE BISSELL, Air Force Research Laboratory — Diamond stands out among single-photon sources due to an intrinsically large band gap, efficient electrical excitation, the ability to host bright optical centers, photo-stable emission, room-temperature operation, short excited state lifetimes, and the ability to host hundreds of different color centers. Currently, most of these centers are active in the optical spectrum, but a single-photon source in the IR would represent a significant advancement. In pursuit of this end, the effects of a number of different transition metal atoms upon the diamond lattice have been investigated via cluster calculations using the General Atomic Molecular and Electronic Structure System (GAMESS) code. The importance of cluster size and electron correlation effects is considered, and time-dependent DFT and multi-configurational SCF approaches are compared.

V1.00081 Vacancies and Temperature Effects on the Mechanical Properties of Silicene Nanoribbons, MA. RAYO CHAVEZ-CASTILLO, Instituto de Fisica BUAP, MARIO ALBERTO RODRIGUEZ-MEZA, Depto. de Fisica, ININ, LILIA MEZA-MONTES, Instituto de Fisica BUAP — The study of two-dimensional materials has been increasing. In the past few years a large variety of these kinds of materials has been studied, such as boron nitride, molybdenum disulfide, and silicene. The main potential application of silicene is found in electronic devices, nevertheless, other possible applications can be found. It is necessary to understand the mechanical properties of the material, because it can help us to determine the stability and useful lifetime thereof. We study vacancies and temperature effects on the Young’s Modulus (YM) of silicene nanoribbons (SNRs). To determine the mechanical properties of the nanoribbons, different structural parameters are introduced. We analyze the YM of three square shaped SNRs, whose lengths varies from 3 to 8 nm. Results at room temperature showed that the YM for the ribbon respectively increase with the length in both directions of chirality. On the other hand, for SNRs in the presence of defects (mono- and bi-vacancies) the YM depends on the defect position. It increases as the vacancy approaches the SNRs boundary. We observed that the higher the temperature, the lower the YM with and without vacancies. However, dependence on the length remains the same.

V1.00082 Optical properties of TiO_{2-x} based Re-RAM switching devices under the effect of oxygen vacancies, MAAMAR BENKRAOUDA, NOUREDDINE AMRANE, UAE University — The tuning of the optical properties of TiO_{2-x} based materials can be achieved by varying the mole fraction. The accurate calculations of linear optical function (refractive index, reflectance, coefficient of absorption, and both imaginary and real dielectric function) were carried out. The dependence of these properties under the effect of the oxygen mole fraction were analyzed. Using controllable mole fraction, various intermediate resistance states are induced. Furthermore, the presence of oxygen vacancies which is linked to the on-state conduction and resistance switching mechanism in the optical properties is studied.

This work was funded by UPAR2013. UAE University

V1.00083 High Efficiency Alternative Current Driven Organic Light Emitting Device, JUNWEI XU, GREGORY SMITH, CHAOCHAO DUN, DAVID CARROLL, Center for Nanotechnology and Molecular Materials, Department of Physics, Wake Forest University, CENTER FOR NANO TECHNOLOGY AND MOLECULAR MATERIALS TEAM — In this work, we introduce the use of field-activated organic light emitter, coupled with a semiconducting gate electrode to create a novel, highly efficient lighting device. A layer of ZnO nanoparticles between the interface of an ITO contact and a PEDOT:PSS injection layer facilitates improved current control over the capacitative characteristics of the device. The advanced capacitive behavior of our devices gives rise to a barrier for carrier injection at low frequencies. Conversely, it promotes the generation of a field-induced polarization current in the active layer at high frequencies. The alternative current driven organic light emitting device obtains the power efficiency over 300 lm/W A at >500 cd/m2, which is the highest efficiency to date among high-lumiance organic light emitting devices, to the best of the authors' knowledge. We interpret these findings as the negative magnetoresistance induces the 'secondary' carriers that would contribute to light.

V1.00084 Technological Concepts for Enhancing Semiconductor Ion Implantation Sources, ADY HERSCHCOVITCH, Brookhaven National Laboratory — Two novel ideas for improving ion sources for the two energy extremes of ion implantation for semiconductor manufacturing are described. Since the invention of the transistor, semiconductor devices have been miniaturized. As semiconductors become smaller shallow implantation is desired and ion energy needed for implantation decreases, resulting space charge (intra-ion repulsion) effects, which reduced beam currents and production rates. To increase production rates, molecular ions are used. Carborane, which is the most stable molecular boron ion leaves unacceptable carbon residue on extraction grids. Special O2 elliptical cross section dissociator that injects O unto the grid can in-situ prevent carbon deposition without loading up power supplies. Pure gaseous processes are desired for enable rapid switch among ion species. For deep implantation and for avoiding the use of molecular phosphorous and arsenic can be generated by introducing phosphi in dissociators via 4PH = P4 + 6H2 in a pure gaseous process (same for arsenic AsH3). In the ion source molecular or high charge state phosphorous and arsenic can be generated. Concepts and devices will be presented.

1 Work supported by Contract No. DE-AC02-98CH1-886 with the US DOE and support from Russian Skolkovo Grant.

V1.00085 Effect of Boron doping on the structural, optical and electrical properties of ZNO nanoparticles produced by the Hydrothermal method, OZGUR OZTURK, Kastamonu University, SEVIM DEMIROZ SENOL, CADIR TERZIOGLU, Abant Izzet Baysal University — Effect of boron doping with B-11 at. % concentration on structural, optical and electrical properties of Zinc oxide nanopowder synthesized by Hydrothermal method has been reported. XRD results reveal that all B doped ZnO nanopolowders have single phase hexagonal structure without any impurity. Positions of main diffracted peaks of ZnO shifted slightly towards small 2θ angle and grain size decreases from 60.39 nm to 34.34 nm with an increase of B doping. SEM analyses indicate that the doping concentration of B affected the surface morphology of ZnO nanoparticles. Optical properties were examined by UV–Vis absorption/diffuse reflectance spectroscopy. The optical band gap of ZnO_{1-x}B_{x} nanoparticles increased from 3.27 to 3.75 eV with increase in B doping. The role of B doping on the transport properties was searched by temperature dependent Hall measurements in range of 180–350 K. The carrier concentration of the samples increased from 0.11x10^{14} to 4.08x10^{14} cm^{-2}, the Hall mobility decreased from 5.61 to 1.22 cm^{2}V^{-1}s^{-1} and electrical resistivity decreased from 10.89 x 10^{4} to 1.25 x 10^{4} ohm-cm with the increase of B doping at room temperature. The electrical resistivity was observed to decrease with both the increase in dopant concentration and the temperature.

V1.00086 Growth and characterization of CH$_3$NH$_3$PbX$_3$ (X=I, Br) single crystals by solution method$^1$. SU JING, SANG LI, Nanjing University of Information Science & Technology, WANG DI, Nanjing University, LIN MIN, Nanjing University of Information Science & Technology — Solar energy conversion using solar cells requires materials that absorb in a broad spectral range, from visible to near infrared, to harvest most of the solar photons, as well as with the capability to convert effectively the incident light into free charges that produce electrical current and voltage. Organic-inorganic perovskite-structured hybrids CH$_3$NH$_3$PbX$_3$ (X = Cl, Br, I or a combination) exhibit good application potentials in the next generation solid-state solar cells. In order to improve the properties of CH$_3$NH$_3$PbX$_3$ based solar cell, the studies on the basic materials are of great necessities. In this work, we present the results of the successful growth of large single crystals of CH$_3$NH$_3$PbI$_3$ and CH$_3$NH$_3$PbBr$_3$ with size up to cm's using hydrochloric acid solution method. The solubilities of CH$_3$NH$_3$PbI$_3$ and CH$_3$NH$_3$PbBr$_3$ in hydrochloric acid were determined by weight method at the temperature range between 300-360K. X-ray diffractometry, scanning electron microscopy were used to study the structure and morphology, and the lattice parameters were estimated using Rietveld refinement method. The study of crystal nucleation, morphology and dimensions show that these are strongly dependent on the supercooling state occurred to the liquid during crystal growth, in which the (100) always exhibits the largest faces on the as-grown crystals. Optical properties of these single crystals were characterized by FT-IR, Raman, photoluminescence and cathode fluorescent spectroscopy.

$^1$National Natural Science Foundation of China (Grant Nos. 51472123) National Natural Science Foundation of China (Grant Nos. 51302268).

V1.00087 Large-scale Synthesis of monolayer MoSe$_2$ via Chemical Vapor Deposition. BYEONGGIL KANG, SKKU Advanced Institute of Nanotechnology(SAINT), Sungkyunkwan University, Suwon, 440-746, Korea, CHANGGU LEE, Department of Mechanical Engineering and SKKU Advanced Institute of Nanotechnology(SAINT), Sungkyunkwan University, Suwon, 440-746, Korea — Molybdenum diselenide (MoSe$_2$) has a direct band gap of 1.55eV for a monolayer utilized photodetector and optoelectronics. Recently, its synthesis methods have been briskly researched as a material for electronic devices from reason why it has similar properties with molybdenum disulfide (MoS$_2$). We present synthesis method for large-scale monolayer MoSe$_2$ through the chemical vapor deposition using Se and MoO$_3$ powder as a precursor. Raman and X-ray photoelectron microscopy confirmed the quality of synthesized MoSe$_2$. Moreover, electrical property was investigated with field effect transistor.

V1.00088 Synthesis of MoS$_2$ flakes by Electrical Arc Discharge of Molybdenum Wire and sulfidization of MoO$_3$ $^1$. VICENTE GONZALES, JOHN SANCHEZ, JESUS VELAZQUEZ-SALAZAR, MIGUEL YACAMAN, University of Texas at Santonio, UTSA DEPARTMENT OF PHYSICS AND ASTRONOMY COLLABORATION — Molybdenum Disulfide (MoS$_2$) is an important inorganic compound in industry due to its robustness, ability to withstand high temperatures, and physical properties. It acts a solid lubricant in oils as well as functioning as an excellent co-catalyst in desulfurization for uses in petroleum refining. In this project, we used electrical arc discharge to first synthesize Molybdenum Trioxide (MoO$_3$), then sulfidized the MoO$_3$ at 800°C to form our MoS$_2$ flakes. We then used a scanning transmission electron microscope (Hitachi 5500) to analyze the structure of our MoS$_2$ flakes and perform a chemical analysis. Electrical arc discharge is an innovative and favorable synthesis method due to the simplicity of the setup, and the large volume of particles produced. We varied parameters such as the voltage and amperage in our electrical arc discharge process to maximize the amount of MoS$_2$ flakes that we could produce. Characterization were done to ensure that the Molybdenum Disulfide was of correct structure (flakes) and to ensure that these flakes were of correct chemical composition. Future applications in industry of these particles directly depend on the ability for us to produce these particles in the correct shape (flakes) and the efficiency by which we can produce them.

V1.00089 Pin diodes based on n-ZnO/i-Al$_2$O$_3$/p-Si. Y.S. WANG, Q.Y. CHEN, W.Y. LIN, C.F. CHANG, W.C. HSIEH, H.C. HUANG, L.W. TU, National Sun Yat-Sen University, P.V. WADEKAR, W.K. CHU, University of Houston, H.H. LIAO, Enli Technology Inc., C.H. LIAO, ROC Military Academy — We focus on the pin-diodes fabricated with n-type ZnO thin films deposited on p-type silicon by RF-sputtering, using very-thin Al$_2$O$_3$ as an insulation layer. By annealing at various temperatures, the domain sizes of the ZnO films would vary accordingly as viewed under scanning electron microscope (SEM). With larger grains, the leakage current was lowered, suggesting that grain boundaries are responsible for the leakage. However, the ZnO films largely remain textured along the c-axis as judged by their clear ZnO (0002) peaks of the XRD theta-2theta scans that are related to the phi-scans of off-axis planes. Furthermore, the XRD data also showed the structural changes of the insulation layer after annealing above certain temperature. For the samples annealed at 750°C and 850°C, the I-V curves showed characteristic pin diodes behaviors. The photoconductivity was measured as a function of intensity of a pulsed laser beam of wavelengths 1064nm, 532nm, 266nm. The photoelectronic IV responses will be discussed in regards to the electronic tunneling structures of the pin junctions and their dependence on the fabrication processes.

V1.00090 Calculation of effective magnetic field of phonon dynamics in the Born Oppenheimer approximation. BANGGUO XIONG, LIFA ZHANG, QIAN NIU, Univ of Texas, Austin — Phonon dynamics with an effective magnetic field can lead to phonon hall effect. We study the effect magnetic field on phonon dynamics due to the coupling to electrons in the Born Oppenheimer approximation. Symmetry properties of the effective magnetic field are discussed in crystals. Two methods to calculate the effective magnetic field are brought up, with model calculations on the honey comb lattice. The application of the methods can be directly applied in first principle calculation.

V1.00091 Rigid Unit Modes; their energy and temperature dependence with aluminium phosphate. ADAM BERLIE$^1$, The Bragg Institute. ANSTO, YUN LIU, Australian National University, DEHONG YU, GORDEN KEARLEY, The Bragg Institute, ANSTO, CHRIS LING, University of Sydney, RAY WITHERS, Australian National University — One of the problems within crystallography is the concept of the average structure where due to dynamical translations or librations the structure is not truly static. This type of behaviour is common within polyhedral based compounds such as APO$_4$ where, in this case, the rigid tetrahedra can move or tilt with respect to each other as a consequence of the instability of the 180° Al-O-P bond. We explore the energy and temperature dependence of these modes using inelastic neutron scattering and heat capacity measurements as well as using computational modelling to assign the observed behaviour to these rigid unit modes.

$^1$Also affiliated to the Australian National University

V1.00092 Phase transition of MoS$_2$ using laser irradiation$^1$. JAE SU KIM, JUNSUK KIM, JINHEE LEE, YOUNGJO JIN, TAESOO KIM, YOUNG HEE LEE, SEONG CHU LIM, Institute for Basic Science, Center for Infragated Nanostucture physics, Department of Energy Science, Sungkyunkwan University, Suwon 440-746 — The multi-layer 2H-MoS$_2$ flakes are transferred to SiO$_2$/Si substrate by mechanical exfoliation method and transformed into 1T-MoS$_2$ by Li intercalation. The phase change by Li doping leads semiconducting 2H-MoS$_2$ to metallic 1T-MoS$_2$ that is confirmed by Raman and PL spectroscopy and I-V measurements. Then, 1T-MoS$_2$ flakes are locally heated to recover to 2H-MoS$_2$ using 532nm-laser beam that can increase the irradiated power up to 10 mW. The characteristics of thermally patterned 2H-MoS$_2$ are investigated by confocal PL and photo-current and I-V measurements. Also, the junction characteristics of 2H- and 1T-MoS$_2$ flakes will be discussed further in this presentation.

$^1$HBS-R011-D1
other two-dimensional transition metal dichalcogenides. Monolayer T-phase TaS
The combination of inherent spin polarization with a semiconducting nature distinguishes the monolayer fundamentally from the bulk compound as well as from strongly localized, which explains the formation of significant magnetic moments. The spin polarization transforms the material into a magnetic semiconductor.

1 Research reported was supported by the King Abdullah University of Science and Technology (KAUST). Computational resources have been provided by KAUST IT.

V1.00094 Spin polarization driven by a charge-density wave in monolayer 1T-TaS
2 QINGYUN ZHANG, LI-YONG GAN, YINGCHUN CHENG, UDO SCHWINGENSCHLOGL, Physical Sciences and Engineering, King Abdullah University of Science and Technology, COMPUTATIONAL PHYSICS AND MATERIALS SCIENCE TEAM — Using first-principles calculations, we investigate the electronic and vibra-
tional properties of monolayer T-phase TaS
2. Our results demonstrate that the formation of a CDW is energetically favorable at low temperature, similar to bulk 1T-TaS
2. Electron-phonon coupling is found to be essential for the lattice reconstruction. In the CDW phase the electronic states near the Fermi level are strongly localized, which explains the formation of significant magnetic moments. The spin polarization transforms the material into a magnetic semiconductor. The combination of inherent spin polarization with a semiconducting nature distinguishes the monolayer fundamentally from the bulk compound as well as from other two-dimensional transition metal dichalcogenides. Monolayer T-phase TaS
2 therefore has the potential to enable two-dimensional spintronics.

V1.00095 Giant valley drifts in uniaxially strained monolayer MoS
2 QINGYUN ZHANG, YINGCHUN CHENG, LI-YONG GAN, UDO SCHWINGENSCHLOGL, Physical Sciences and Engineering, King Abdullah University of Science and Technology, COMPUTATIONAL PHYSICS AND MATERIALS SCIENCE TEAM — Using first-principles calculations, we study the electronic structure of monolayer MoS
2 under uniaxial strain. We show that the energy valleys drift far off the corners of the Brillouin zone (K points), about 12 times the amount observed in graphene. Therefore, it is essential to take this effect into consideration for a correct identification of the band gap. The system remains a direct band gap semiconductor up to 4% uniaxial strain, while the size of the band gap decreases from 1.73 to 1.54 eV. We also demonstrate that the splitting of the valence bands due to inversion symmetry breaking and spin-orbit coupling is not sensitive to strain.

V1.00096 Electronic structure and bonding in fluorapatites crystals: A
10(PO
6)F
2 (A=Ba, Ca, Pb and Sr)
1. CLAUDIA LOYOLA, Universidad Andres Bello, EDUARDO MENENDEZ-PROUPIN, Universidad de Chile, KRISHNA RAJAN, Iowa State University — In this work we report a computational study of electronic properties of fluorapatites (A
10(PO
6)F
2 with A=Ba, Ca, Pb and Sr) using ab initio calculation. We employed Density Functional Theory using a Plane Wave basis set and pseudopotentials to obtain the band structure, total and partial density of states, electronic charge density and electron localization function. We obtain that Ba-, Ca- and Sr-fluorapatite have a wide band gap in the range of ~5.4 eV, while the Pb-fluorapatites have a band gap of ~3.8 eV and different band structure compared with the rest of fluorapatites. The electron charge density and the electron localization function reveal covalent character of the bond between the oxygen and phosphorus in the tetrahedral substructure for all fluorapatites. We analyze the results and possible causes behind the differences in the electronic structure of these fluorapatites.

V1.00097 Excitonic valley polarization and coherence in atomically thin MoS
2 DONG HAK KIM, DAEYOUNG LIM, Department of Applied Physics, KyungHee University — We study the excitonic valley polarization and coherence in few-layer MoS
2 by circular- and linear-polarization-resolved photoluminescence. The valley polarization is largest in monolayer MoS
2 and decreases with the increase in the number of layers or temperature. Contrary to the valley polarization, the linear polarization is negligibly small in monolayer MoS
2 and increases with the increase in the number of layers or temperature. The valley decoherence in monolayer MoS
2 is at least an order of magnitude faster than the valley depolarization or exciton decay at low temperature, implying it has a pure dephasing origin. The valley coherence is steady against the increase in temperature or photoexcitation intensity, excluding phonon or carrier-carrier scattering from the dominant decoherence process. The temperature dependence of the valley polarization can be explained by the center of mass momentum dependent long range electron-hole exchange interaction, whereas that of the linear polarization may be due to relatively temperature-insensitive valley decoherence.

V1.00098 Photoluminescence Saturation and Exciton Decay Dynamics in Transition Metal Dichalcogenide Monolayers DONG HAK KIM, MIN JU SHIN, DAEYOUNG LIM, Department of Applied Physics, KyungHee University — We study the photoluminescence saturation and exciton decay dynamics in monolayer transition transition-metal dichalcogenides (TMDs). Monolayer MoSe
2 shows a PL saturation at a very low excitation intensity, more than two orders of magnitude lower than monolayer MoS
2. Transient reflection spectroscopy shows that nonlinear exciton-exciton annihilation is the dominant exciton decay mechanism in monolayer MoSe
2, in contrast to the exciton decay in monolayer MoS
2. Furthermore, we measure exciton lifetime >125 ps for monolayer MoSe
2 much longer than the several-ps exciton lifetime in MoS
2. We find that that the difference in their exciton lifetime can explain both the dramatically different exciton decay mechanism and PL saturation behavior of MoSe
2 and MoS
2 monolayers.

V1.00099 Carrier recombination in m-plane InN thin film WEI-SHENG CHEN, WEN-JING ZHAO, J.-Y. ZENG, DER-JUN JANG, LI-WEI TU, Department of Physics, Natl Sun Yat Sen Univ — Nonpolar m-plane InN thin films grown on LiAlO
2 substrates by plasma-assisted molecular beam epitaxy have been studied using time-resolved photoluminescence (TRPL) upconversion technique. The carrier densities of 1.97 x 10
19 cm
−3 and mobility of 420 cm
2/Vs were measured by van der Pauw–Hall geometry. The carrier temperature curves at different temperatures, derived from the time-resolved photoluminescence (TRPL) spectra at different time delay, indicate that hot carriers lost most of their excess energy by releasing LO-phonons. The effective LO phonon emission times increase with the lattice temperature, from 53 to 197 fs for 35 and 250 K, respectively. We found that the effective LO emission time of m-plane InN is smaller than that of c-plane InN. The recombination rates were derived from the TRPL measured at the energy closed to the bandgap energy. Similar to c-plane InN, the Shockley-Read-Hall recombination coefficient of m-plane InN shows a 3-fold increase for temperature increasing from 35 to 250 K. The Auger recombination was less effective as compared to that in c-plane InN.
V1.00100 Optical properties of non-polar ZnO using Terahertz time domain spectroscopy, MING-GEN CHUANG, SHU-YU YAO, DER-JUN JANG, QUARK Y. CHEN, Department of Physics, Natl Sun Yat Sen Univ — The m-plane ZnO thin films grown on m-plane sapphire substrates by atomic layer deposition were investigated with the terahertz time domain spectroscopy. The terahertz emission was generated by exciting a LT-GaAs antenna with laser pulses from Ti:sapphire at the wavelength of 800 nm. One of the ZnO samples was thermally annealed with a rapid thermal annealing system with O2 at a temperature of 700 °C. The other ZnO sample was studied without annealing. The refractive indices and extinction coefficients of m-plane ZnO along c- and a-axis were derived and found significant different. For both samples, the extinction coefficient and refractive index decreases monotonically with frequency. While the mobility along a-axis was found about the same after annealing, the mobility along c-axis has been improved significantly due to annealing. The annealing treatment has shown its impact on reducing the carrier concentration of 4.5 × 10^{19} to 3.5 × 10^{18} cm^{-3} for unannealed and annealed ZnO, respectively.

V1.00101 Carrier localization in green emitting InGaN/GaN multiquantum well structure, CHOU-JEN CHENG, Department of Physics, Natl Kaohsiung Normal Univ, ANTARYAMI MOHANTA, DER-JUN JANG, Department of Physics, Natl Sun Yat Sen Univ, MENG-EN LEE, Department of Physics, Natl Kaohsiung Normal Univ — Green emitting InGaN/GaN multiquantum well sample is investigated using photoluminescence (PL) and time-resolved photoluminescence (TRPL) spectroscopy. Carrier localization of energy ∼ 12 meV due to inhomogeneous distribution of In in the InGaN quantum well (QW) layer is observed. The temperature dependence of PL peak energy exhibits S-shape phenomenon and is controversially discussed. We propose that localization is connected to the double-well behavior with increase in temperature. The temperature dependence of radiative life time (τr) shows τr ∼ T^{1/2} dependence with temperature above 200 K which confirms the significant effect of carrier localization at room temperature. Transmission electron microscopy (TEM) study reveals the absence of In-rich regions known for strong carrier localization in the InGaN QW layer which is consistent with the results of PL and TRPL.

V1.00102 Hot carrier cooling in Si-doped InN, JHENG-YU WU, CHIA-SHIA WANG, ANTARYAMI MOHANTA, MING-SUNG WANG, DER-JUN JANG, LI-WEI TU, Department of Physics, Natl Sun Yat Sen Univ — Temperature and excitation power dependent time-integrated photoluminescence of Si doped InN thin films are investigated. Photoluminescence (PL) spectra at low temperatures are described by single emission peak ensued due to free-to-bound? recombination; whereas PL spectra at higher temperatures above 150K are characterized by both band-to-band- and free-to-bound transition. Carrier dynamics of Si doped InN thin films is studied using pump-probe reflection spectroscopy at room temperature. The hot electron cooling process is well described by electron-electron scattering. The dependence of the hot electron cooling rate on total electron density shows sublinear to linear behavior with increase of background electron density. The variation of the carrier recombination lifetime with total electron density implicates the dominance of the defect-related nonradiative recombination channel over other recombination processes.

V1.00103 Comparison between stamping method and one-by-one dry-transfer method for the fabrication of h-BN sandwiched graphene FET in the quantum Hall regime, JEONGMIN PARK, HAEYONG KANG, JOONGGYU KIM, JOEONG-GYUN KIM, YOOHOO YUN, NAHEE PARK, KIEU TRUONG, YORKACK LEE, DONGSUB CHUNG, DONGGYUN KIM, CINAP, IBS, DOES, SKKU, HOYEOL YUN, SANGWOOK LEE, Konkuk University, YOUNGhee LEE, DONGSEOOK SUHN, IBS, DOES, SKKU — We have fabricated a dual-gate graphene field-effect-transistor (FET) for the study of integer Quantum Hall Effect in terms of its edge-state transport. The graphene was encapsulated by hexagonal boron-nitride (h-BN) flakes without any interlayer residues using the ‘stamping-transfer’ method, which is critical for the observation of graphene’s intrinsic transport properties. Using the polypropylene carbonate (PPC) and Polydimethylsiloxane (PDMS), initially top h-BN flake is picked up and graphene flake is picked up by van der Waals’ force between graphene and top h-BN. These two layers are dropped down on the bottom h-BN flake to complete the encapsulated formation. To make the source/drain (S/D) and top-gate electrodes, whole area of graphene is not covered by top h-BN flake. The open areas of graphene, located at both ends, are covered by S/D metal electrodes, which made whole graphene channel region sandwiched by top and bottom hBN. We compared this method with the old one which put the two-dimensional flakes one by one using ‘dry-transfer’ method, and found out a significant difference in the device quality especially at low temperatures and high magnetic fields in the quantum Hall regime.

V1.00104 Exact solutions of fractional Chern insulators: interacting particles in the Hofstadter model at finite size, THOMAS SCARRIDI, STEVEN SIMON, University of Oxford — We show that all the bands of the Hofstadter model on the torus have an exactly flat dispersion and Berry curvature when a special system size is chosen. This result holds for any hopping and Chern number. Our analysis therefore provides a simple rule for choosing a particularly advantageous system size when designing a Hofstadter system whose size is controllable, like a qubit lattice or an optical cavity array. The density operators projected onto the flat bands obey exactly the Girvin-MacDonald-Platzman algebra, like for Landau levels in the continuum or an optical cavity array. The density operators projected onto the flat bands obey exactly the Girvin-MacDonald-Platzman algebra, like for Landau levels in the continuum or an optical cavity array.

V1.00105 Nature of Quasi-electrons and the Continuum of Neutral Bulk Excitations in Laughlin Quantum Hall Fluids, BO YANG, Institute of High Performance Computing, F.D.M. HALDANE, Princeton University — We construct model wavefunctions for a family of single-quasielectron states supported by the ν = 1/3 fractional quantum Hall (FQH) fluid. The charge e∗ = e/3 quasielectron state is identified as a composite of a charge-2e∗ quasiparticle and a −e∗ quasihole, orbiting around their common center of charge with relative angular momentum nh > 0, and corresponds precisely to the “composite fermion” construction based on a filled n = 0 Landau level plus an extra particle in level n > 0. An effective three-body model (one 2e∗ quasiparticle and two −e∗ quasiholes) is introduced to capture the essential physics of the neutral bulk excitations. We also explore different ways of representing many-body wavefunctions in fractional quantum Hall fluids, including the holomorphic wavefunctions, Jack polynomial formalisms and the diagrammatic representations. (Bo Yang and F.D.M. Haldane, PRL 112, 206804).

V1.00106 STRONGLY CORRELATED SYSTEMS INCLUDING QUANTUM FLUIDS AND SOLIDS —

V1.00107 Coexistence and competition of on-site and intersite Coulomb interactions in Mott-molecular-dimers, ALBERTO ARRUDA, RAFFAEL JULIANO, THIAGO WERLANG, LUIS CRACO, Instituto de Física - Universidade Federal de Mato Grosso — Recent findings of Mott-Hubbard physics in ultracold atoms trapped in periodic potentials have reinvigorated the search for quantum simulators of fermionic and bosonic Hubbard-like models. With this in mind, we performed a systematic study of a two-site realization of the Hubbard model, i.e. in a regime where this model can exactly treated. Particularly, we reveal the interplay between on-site (U) and intersite (V) Coulomb interactions in the extended two-site Hubbard model. Due to its atomic-like form quantum correlations intrinsic to Mott-molecular-dimers are exactly computed. Our results for physical quantities such as double occupancy and specific heat are consistent with those obtained for the one-band Hubbard model, suggesting that a two-site Hubbard model is able to capture the essential thermodynamic properties of strongly interacting electron systems. It is shown that intersite Coulomb interactions promotes the formation of doublons, which compete with the spin-singlet state induced by the on-site Coulomb repulsion. Our results are expected to be relevant for understanding electronic and thermodynamical properties of interacting electrons in strongly coupled magnetic atoms.
V1.00108 ABSTRACT MOVED TO G22.00015 –

V1.001109 Carrier dynamics in EuTiO$_3$ films probed by femtosecond pump-probe spectroscopy$^1$

ZHONGGUO LI, Harbin Institute of Technology, RUN ZHAO, WEIWEI LI, Soochow University, HAIYAN WANG, Texas A&M University, HAO YANG, Soochow University, XUERU ZHANG, YUXIAO WANG, TAI-HUEI WEI, YING-LIN SONG, Harbin Institute of Technology — Recently, perovskite oxide EuTiO$_3$ has attracted considerable attention due to its intriguing multiferroic properties. To gain a deeper understanding of its fascinating properties, it is essential to characterize the competing interactions between charge, lattice, spin, and orbital parameters. Here we present optical studies of the ultrafast carrier dynamics in EuTiO$_3$ films grown on SrTiO$_3$ substrates by probing photo-induced transient absorption (TA) in the weak excitation limit. All the signals were measured at room temperature. The transient curve of EuTiO$_3$ exhibits a fast rise after photo excitation (approximately 2 ps) and a long decay component with time constant of several nanoseconds, which are attributed to carrier-phonon coupling and carrier recombination respectively. The absorption change of EuTiO$_3$ near zero temporal delay is found to be quite different from the SrTiO$_3$ substrates, implying carrier-phonon interactions differ distinctively between these two materials. Our results could be helpful to understand the microscopic interactions in perovskite oxide.

V1.001110 Investigation of 2-dimensional electron liquid at the interface of La(1-x)Al(1+x)O$_3$/SrTiO$_3$ $^1$

MING SHIU TSAI, WEI FAN HSIU, HAO YU CHEN, WEI LI LEE, Academia Sinica, Taiwan, ACADEMIA SINICA. TAIWAN TEAM — The emergence of two dimensional electron liquid (2DEL) at the interface between two insulating oxides of lanthanum aluminate (LaAlO$_3$) and strontium titanate (SrTiO$_3$) shows unusual superconductivity and magnetism compared to conventional semiconductor-based 2DEG systems. One important issue resides on the influence of the stoichiometry to the 2DEL. Here, we report the structural analysis and magneto-transport results on a series of La(1-x)Al(1+x)O$_3$/SrTiO$_3$ with different x grown by oxide molecular beam epitaxy (OMBE) with in-situ growth monitoring using reflection high electron energy diffraction (RHEED). Detailed low temperature magneto-transport data and its correlation to the stoichiometry and film strain will be presented and discussed.

V1.001111 Double Charge Ordering States and Spin Ordering State Observed in a RAF$_2$O$_4$ System$^1$

1. FEI SUN, RUI WANG, Institute of Physics, Chinese Academy of Sciences, CYNTHIA AKU-LEH, IScences, Ann Arbor, Michigan, USA, HUAIXIN YANG, Institute of Physics, Chinese Academy of Sciences, RUI HE, Department of Physics, University of Northern Iowa, Cedar Falls, USA, JIMIN ZHAO, Institute of Physics, Chinese Academy of Sciences — Charge, spin, and lattice degrees of orderings are of great interest in the layered quantum material RFe$_2$O$_4$ (R = Y, Er, Yb, Tm, and Lu) system. Recently many unique properties have been found using various experimental methods. However so far the nature of the two-dimensional (2D) charge ordering (CO) state is not clear and no observation of its fine structure in energy has been reported. Here we report unambiguous observation of double 2D CO states at relatively high temperature in a polycrystalline Er$_{1.4}$Y$_{0.6}$Fe$_2$O$_4$ using Raman scattering. The energy gaps between the 3D and the double 2D states are 170 meV (41.2 THz) and 193 meV (46.6 THz), respectively. We also observed a spin ordering (SO) state at below 210 K with characteristic energy of 45 meV (10.7 THz). Our investigation experimentally identified new fine structures of quantum orders in the system, which also extends the capability of optical methods in investigating other layered quantum materials.

V1.001112 Ultrafast dynamics of titanate octahedra tilting modes in a THz laser pulse

MINGQIANG GU, JAMES M. RONDINELLI, Northwestern University — Using first-principles calculation, the electronic band structure and electric dipole moment for orthorhombic titanate are examined. To explore the energy dissipation after pulse excitation, the light-lattice coupling is treated with the mode oscillator model. By solving the equation of motion, we investigate the dynamics of the tilting modes. The evolution of the optical transition matrix elements as functions of different octahedra tilting modes and mode amplitudes are also evaluated, which provides theoretical base for the future experiments.

V1.001113 Correlating valence state, site preference and co-substitution to the magnetoelastic properties of cobalt ferrite$^1$

1. CAJETAN NLEBEDIM$^2$, Ames Laboratory, U.S. Department of Energy, DAVID JILES$^3$, Department of Electrical and Computer Engineering, Iowa State University — Understanding how to influence the physics of magnetism, especially the relationship between magnetic susceptibility and stress, can be very useful in designing non-contact stress and torque sensors using magnetoelastic materials. This is particularly important considering that materials rarely occur in states desirable for direct applications. In this work we show that the magnetoelastic properties of cobalt ferrite are strongly dependent on the valence states and site preferences of substituted cations. It was found that co-substitution of magnetic and non-magnetic cations, is key to achieving simultaneous improvement in magnetostrection amplitude and strain sensitivity to applied magnetic field. Nevertheless, Curie temperature decreased, irrespective of the valence state, site preference or co-substitution. This presentation will show why tetravalent Ge resulted in superior magnetostrictive properties compared to other tetravalent, trivalent and divalent cations substituted into the crystal lattice of cobalt ferrite.

V1.001114 Quantum Monte Carlo calculations of structural and electronic properties in the correlated oxide NiO$^1$

1. CHANDRIMA MITRA, JARON KROGEL, JUAN A. SANTANA PALACIO, FERNANDO A. REBOREDO, Oak Ridge National Laboratory — Transition metal oxides pose difficulties for condensed matter theories due to the presence of strong electronic correlations. The complex interplay among correlation and exchange in d subshells, crystal field effects, p-d hybridization and charge transfer gives rise to a rich variety of structural and electronic phases. NiO is one such challenging d system, where conventional band theory fails. Compared to the experimental value, the cohesive energy of bulk NiO computed within DFT-LDA differs by almost a factor of 18 %. Band gap computed within standard local or semi-local functionals are off by a factor of 80 %. A quasi-particle correction like the G$^W$ approach cannot correct the band gap and is still far too low. In this work we adopt the Diffusion Monte Carlo (DMC) approach to study the structural and electronic properties of NiO. Trial wave-functions were self consistently generated in a Slater-Jastrow form. To test pseudopotentials used, DMC calculations were done on atomic Ni and O and their computed ionization potentials showed excellent agreement with experiments (within 0.04%). The equilibrium bond length and binding energy of the NiO dimer were also computed that were 0.001% and 0.03%, respectively, from experimental values. DMC calculations of equation of state and band gap of bulk NiO will be presented.

$^1$We gratefully acknowledge support from U.S Department of Energy, Basic Energy Sciences, Materials Science and Engineering Division.
Investigation of the Band Gap in Co$_3$O$_4$. MARK SHOLTE, CHUNGWEI LIN, KRISTY KORMONDY, University of Texas System, TIMOTHY NUNELEY, New Mexico State University, AGRAM POSADAS, University of Texas System, STEFAN ZOLLNER, New Mexico State University, ALEXANDER DEMKOV, University of Texas System — Co$_3$O$_4$ is a strongly correlated oxide with a spinel structure and G-type antiferromagnetic order at temperatures below 40 K. It is a widely studied material owing to its applications in gas sensing, spintronics, batteries, and catalysis. The strong correlation and magnetism make it a difficult material to model from first principles. Density functional theory calculations require the use of a Hubbard U to correctly model its magnetic behavior. The band gap is sensitive to the choice of U allowing one to tailor the gap to a wide range of values. This often provides a phenomenological approach to determining U, but in the case of Co$_3$O$_4$ there is no experimental consensus on the actual value of the band gap. We utilize an alternate approach by matching the theoretical valence band structure to the actual valence band data obtained via x-ray photoemission spectroscopy. This generated set of U values is used to compute an absorption spectrum, which is in good agreement with ellipsometry results.

Electronic Structures of the Charge Density Wave System RTe$_2$ (R=Ce, Pr) investigated by ARPES. JEONGSOO KANG, EUNSOOK LEE, D.H. KIM, The Catholic University of Korea, JONATHAN DENLINGER, Lawrence Berkeley National Laboratory, B.H. MIN, Y.S. KWON, DGIST, JUNWON KIM, KYOO KIM, B.I. MIN, Pohang University of Science and Technology — The rare-earth (R)-based RTe$_2$ compounds are known as the charge-density-wave (CDW) systems. In this work, we have investigated the electronic structures of RTe$_2$ (R=Ce, Pr) by employing angle-resolved photoemission spectroscopy (ARPES) experiment and the first-principles band structure calculations. The overall shapes and sizes of the measured Fermi surfaces (FSs) of RTe$_2$ are found to be similar to those of the calculated FSs for the undistorted structures. The metallic states crossing the Fermi level (E_F) are observed in ARPES even in the CDW state, indicating that the metallic states remain under the CDW transition with the remnant ungapped FSs. R 4f/ PES spectra exhibit that the 4f hybridization peak (4f$^n$$e_{5/2}$) in R=Pr is located deeper than in R=Ce, resulting in the much weaker 4f spectral intensity near E_F in R=Pr. The shadow bands and the corresponding very weak FSs are found to arise from the band folding due to the interaction of Te(1) layers with R-Te(2) layers and the CDW-induced FS reconstruction. The E_F-crossing states are stronger with the linear vertical polarization than with the linear horizontal polarization. The photon-energy maps in ARPES demonstrate the two-dimensional character of the near-E_F states.

Circular dichroism of chiral photon crystal liquid layers with enclosed defect inside. ASHOT GEVORYAN, Yerevan State University, Armenia, ARMEN KOCHARIAN, California State University, Los Angeles, GAGIK VARDANYAN, NNN Inc., Granada Hills, CA — The photonic crystals of artificial and self-organizing structures with spatial periodic changes in dielectric and magnetic properties have attracted considerable interest recently due to unusual physical properties and wide practical applications. The chiral periodic structure in the scale of optical wavelength gives rise to strong and characteristic circular dichroism responses at visible wavelengths. Here we investigate photonic density, circular dichroism and peculiarities of absorption and emission spectra at various eigen polarizations in multilayered one-dimensional chiral soft matter with two layers of CLCs and an isotropic defect layer inside. The circular dichroism is defined by differences in light energy absorption A(l, l') in the system (l, l') are the reflection and transmission coefficients, respectively) and A(l, l') are the light absorptions, if the incident light has left and right circular polarizations, respectively. This problem can be solved by the modified Ambartsumian's layer addition method. The influence of absorption and gain on the circular dichroism, absorption and emission spectra is established in cholesteric liquid crystal (CLC) cell with an isotropic defect layer inside.

Fermion-sign-free Majorana-quantum-Monte-Carlo studies of quantum critical phenomena of Dirac fermions in two dimensions. ZIXIANG LI, YIFAN JIANG, HONG YAO, Institute for Advanced Study, Tsinghua University, Beijing, 100084, China — Quantum critical phenomena may be qualitatively different when massless Dirac fermions are present at criticality. Using our recently-discovered fermion-sign-free Majorana quantum Monte Carlo (MQMC) method, we investigate the quantum critical phenomena of spinless Dirac fermions on the honeycomb lattice having N_s = 2L^2 sites with largest L = 24, at their charge-density-wave (CDW) phase transitions. By finite-size scaling, we accurately obtain critical exponents of this so-called Gross-Neveu chiral-ising universality class of two (two-component) Dirac fermions in 2+1D: $\eta = 0.45(2)$, $\nu = 0.77(3)$, and $\beta = 0.60(3)$, which are qualitatively different from the mean-field results but are reasonably close to the ones obtained from renormalization group calculations.

Beyond structural bottleneck: the nature of nonthermal optically induced ultrafast phase switching in V$_2$O$_3$. ZHENHENG TAO, JILA, Univ of Colorado - Boulder, TZONG-RU T. HAN, FARAN ZHOU, Department of Physics and Astronomy, Michigan State University, DAVID TORGES, TONY WANG, NELSON SEPULEVIDA, Department of Material Science Engineering, Michigan State University, CHONG-YU RUAN TEAM, NELSON SEPULEVIDA TEAM — Ultrafast manipulation of the electronic states of strongly correlated electron crystal near room temperature, such as V$_2$O$_3$, encompasses enormous opportunities in high-speed electronics and photonics. However, its strong coupling to the first-order structural phase transition presents a bottleneck effect, which leads to cracking and various instabilities. Here, we show that repetitive ps or even sub-ps phase switching can be initiated by using mid-infrared photons where the rapid transformation is driven by instantaneous shift of chemical potential, rather than lattice or electronic heating. Using fs electron crystallography, we establish the cooperative doping-induced multi-step atomic pathway, which leads to a metal-insulator transition at a fractional energy dose.

First-principles study of Sr$_2$Ir$_{1-x}$Rh$_x$O$_4$: charge transfer, spin-orbit coupling change, and the metal-insulator transition. JAE-HOON SIM, Department of Physics, KAIST, Daejeon 305-701, Korea, HEUNG-SIK KIM, Department of Physics, University of Toronto, Toronto, Ontario MSS 1AT, Canada, MYUNG JOON HAN, Department of Physics, KAIST, Daejeon 305-701, Korea — Using first-principles density functional theory (DFT) calculations, we investigated the electronic structure of Rh-doped iridate Sr$_2$Ir$_{1-x}$Rh$_x$O$_4$ for which the doping (x) dependent metal-insulator transition (MIT) has been reported experimentally and the controversial discussion developed regarding the origin of this transition. Our DFT+U calculation shows that the value of $\langle L,S \rangle$ remains largely intact over the entire doping range considered here for $\langle x = 0.0, 0.125, 0.25, 0.50, 0.75, \text{ and } 1.0 \rangle$ in good agreement with the branching ratio measured by x-ray absorption spectroscopy. Also contrary to a previous picture to explain MIT based on the charge transfer between the transition-metal sites, our calculation clearly shows that those sites remain basically isoelectronic while the impurity bands of predominantly rhodium character are introduced near the Fermi level. As the doping increases, this impurity band overlaps with lower Hubbard band of iridium, leading to metal-insulator transition. The results will be discussed with comparison to the case of Ru doping.

V1.00121 Evidence of a quantum critical point in Ce$_{1-x}$Yb$_x$CoIn$_5$ alloys at high Yb doping$^1$. Y.P. SINGH, D.J. HANEY, X.Y. HUANG, Kent State University, B.D. WHITE, M.B. MAPLE, University of California, San Diego, M. DZERO, C.C. ALMASAN, Kent State University — We performed this study on single crystals of Ce$_{1-x}$Yb$_x$CoIn$_5$ alloys with the motivation to further explore some of the previously reported unusual behaviors such as robust coherence and superconductivity, non-Fermi liquid (NFL) behavior, and the possibility of quantum criticality in higher Yb doping. Our specific heat and electronic magneto-transport measurements on the alloy with $x = 0.75$ nominal doping down to temperatures ($T$) as low as 0.5 K and magnetic fields ($H$) as high as 14 T. Our analysis of both specific heat and resistivity data unveils the presence of a crossover from NFL behavior at high temperatures to Fermi-liquid (FL) behavior at lower temperatures. Our analysis also indicates that the origin of the NFL behavior is a result of quantum fluctuations of unknown origin. The H-T phase diagram extracted from resistivity and specific heat shows that the crossover from NFL to FL behavior at zero temperature occurs at $H = 0$. This implies that the alloy with $x = 0.75$ Yb concentration is quantum critical, i.e., $\chi_c = 0.75$. This result of zero field quantum critical point at $x = 0.75$ is also confirmed from our analysis of magneto-resistance data.

V1.00122 Two-channel Kondo physics from arsenic bond oscillations in zirconium arsenide selenide, STEFAN KIRCHNER, Center for Correlated Matter, Hangzhou, TOMASZ CICHOREK, L. BOCHENEK, Institute of Low Temperature and Structure Research, Polish Academy of Sciences, MARCUS SCHMIDT, Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany, RAINER NIEWA, Institute of Inorganic Chemistry, University of Stuttgart, Germany, A. CZULUCKI, G. AUFLERMAN, FRANK STEGLICH, RUEDIGER KNIEP, Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany — The two-channel Kondo effect is a fascinating but extremely fragile many-body state that has been theoretically discussed extensively. We address metallic compounds of a specific (PdFCI) structure for which a $-AT^{1/2}$ term to $p(T)$ is frequently observed, in line with the two-channel Kondo effect. The origin of this anomaly has remained enigmatic since here, solely the interaction between electrons may account for this behavior, and the two-channel Kondo state is not expected to occur. By combining chemical and structural investigations with various physical property measurements we show that the magnetic field-independent $-AT^{1/2}$ term to the low-T resistivity observed over two decades in ZrAs$_2$Se$_2$ with $1.90 \leq x + y \leq 1.99$ originates from vacancies in the layer exclusively built up by As. Furthermore, we can trace back the two-channel Kondo effect in this material to a dynamic Jahn-Teller effect operating at these vacancies. All physical properties of the investigated compounds support this conclusion. Our findings will be relevant also for other metallic systems with pnictogen-pnictogen bondings, e.g., cage-forming compounds like the skutterudites.

V1.00123 When do interactions with Goldstone bosons lead to non-Fermi liquids, HARUKI WATANABE, ASHVIN VISHWANATH, UC Berkeley — There are few general physical principles that protect the low-energy excitations of a quantum phase. Of these, Goldstone’s theorem and Landau-Fermi liquid theory are the most relevant to solids. In this talk, I will present a general analysis of when non-Fermi liquid behavior can arise in electronic systems due to coupling to Goldstone modes. We unify previously known cases using a single criterion and predict a new candidate involving phonons under a magnetic field.

V1.00124 Evaluation of the magnetic field induced glassy behavior and oscillating magneto-caloric effect in Zn$_{0.05}$Ni$_{0.95}$Cr$_2$O$_3$ spinel oxide, KAKARLA DEVI CHANDRASEKHAR, Department of Physics, National Sun Yat Sen University, Taiwan, JYOTHINAGARAM KRISHNA MURTHY, ADYAM VENIMADHAV, Cryogenic Engineering Centre, Indian Institute of Technology Kharagpur, India, HUNG-DUEN YANG, Department of Physics, National Sun Yat Sen University, Taiwan, PROF. H. D. YANG TEAM, PROF. A. VENIMADHAV COLLABORATION — Polycrystalline Zn (5%) doped NiCr$_2$O$_3$ sample was prepared by standard solid state reaction method. Room temperature structural refinement through X-ray diffraction confirm the cubic crystal structure with Fd-3m space group. Temperature dependent dc and AC magnetic measurements revealed multiple magnetic transitions. Doping small amount of non Jahn-Teller (J-T) ion (Zn$^{2+}$) in place of J-T site (Ni$^{2+}$) shows pronounced influence on the magnetosstructural transitions. We have found a frequency independent magnetic transitions in the AC susceptibility measurement indicate the absence of glassy magnetic behavior under zero applied dc bias field. However, an unusual new glassy magnetic transition was discerned under the small dc magnetic field (3 kOe) in the AC susceptibility measurement. We have demonstrated oscillating magneto-caloric effect through isothermal magnetization measurements at low temperature. The observed unusual magnetic properties can be ascribed to the strong magnetic coupling and competing interaction between the spin-lattice-orbital interactions.

V1.00125 INSULATORS AND DIELECTRICS —

V1.00126 Crystal structure and physical properties of Cr oxide with K$_2$NiF$_3$-type structure, TING-HUI KAO$^1$, National Sun-Yat Sen University, Kaohsiung 804, Taiwan, HIROYA SAKURAI, TARAS KOLODIAZHNYI, National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan, YUTARO SUZUKI, MOMOKO OKABE, TORU ASAKA, KAKARLA DEVI CHANDRASEKHAR, Department of Physics, National Sun Yat Sen University, Kaohsiung 804, Taiwan, National SUN-YET SEN UNIVERSITY TEAM, NATIONAL INSTITUTE FOR MATERIALS SCIENCE TEAM, NAGOYA INSTITUTE OF TECHNOLOGY COLLABORATION, KOBE UNIVERSITY COLLABORATION — Ruddlesden-Popper (RP) structure materials have been attracted much attention due to their interesting physical properties including high-Tc superconductivity, charge stripe, itinerant ferromagnetism and so on. In this work we are presenting physical properties of some of the K$_2$NiF$_3$-type structure compounds. YSrCrO$_4$ is first synthesized and found to be a hetto-type K$_2$NiF$_3$ structure. The space group of YSrCrO$_4$ is determined to be orthorhombic Pccn by the electron diffraction and the powder X-ray diffraction. YSrCrO$_4$ shows two-dimensional (2D) spin correlations and a canted antiferromagnetic (AF) ordering. Evidence of AF ordering of the Cr oxides is obtained microscopically from ESR. The dielectric measurements suggest existence of in-gap states, while no magneto-dielectric coupling was observed in the above compounds.

$^1$National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan
V1.00127 Creep-free ac hysteretic dynamics in epitaxial ferroelectric BiFeO$_3$ films$^1$. YEONGJAE SHIN, BYUNG CHUL JEON, SANG MO YANG, CCES-IBS, Dept of Physics & Astronomy, Seoul N. Univ., Seoul, Republic of Korea, INROK HWANG, EMRC, KIST, Seoul, Republic of Korea, MYUNG RAE CHO, Dept of Physics & Astronomy, Seoul N. Univ., Seoul, Republic of Korea, DANIEL SANDO, SEUNG RAN LEE, CCES-IBS, Dept of Physics & Astronomy, Seoul N. Univ., Seoul, Republic of Korea, JONG-GUL YOON, Dept. of Physics, Univ. of Suwon, Hawseong, Gyeonggi-do, Republic of Korea, TAE WON NOH, CCES-IBS, Dept of Physics & Astronomy, Seoul N. Univ., Seoul, Republic of Korea — Dynamics of domain wall (DW) in ferroelectric (FE) films principally governs their switching properties under applied electric field ($E$). At finite temperature ($T$), the DW motion and their FE switching characteristics can be understood only by introducing the creep motion. Despite this importance, there have been little studies on creep motion of FE films under ac-driven force. In this work, we investigate ac-driven hysteretic dynamics of FE domains in epitaxial BiFeO$_3$ (BFO) films through polarization-electric field hysteresis loops with varying frequency and other switching characters. All BFO films were grown at the optimized growth condition, by employing different bottom electrodes of La$_{0.67}$Sr$_{0.33}$MnO$_3$ (LSMO) and SrRuO$_3$ (SRO); only BFO/SRO shows nearly creep-free hysteretic dynamics. We argue that inhomogeneous internal $E$ plays a significant role in such distinctive FE dynamics of BFO domains, which are affected by surface morphologies of bottom electrodes. Our results highlight that growth-mode-induced interfacial structure between an FE film and a bottom electrode result in engineering domain dynamics of FE switching characteristics.

$^1$This work was supported by IBS-R009-D1.

V1.00128 Application of the Wang-Landau Algorithm applied to Ferroelectrics. SAAD BINOMRAN, King Saud Univ, IGOR KORNEV, Laboratoire SPMS, UMR 8580 du CNRS, Ecole Centrale Paris, 92295 Chatenay-Malabry, France, LAURENT BELLAICHE, Institute for Nanoscience and Engineering and Physics Department, University of Arkansas, Fayetteville, Arkansas 72701, USA — The conventional description of phase transitions in ferroelectrics is based on canonical thermodynamic functions and always assumes the thermodynamic limit of an infinite system. However, ferroelectrics at nanoscale recently became of high interest due to their potential applications in miniaturized devices. It is this timely and more appropriate to use the microcanonical ensemble when mimicking ferroelectric systems. Here, a first-principles-derived scheme, combined with an efficient Monte Carlo microcanonical technique, is used to gain new insight into the paraelectric to ferroelectric phase transition and the effect of the electric field on properties of BaTiO$_3$ systems. In this presentation, we will show the temperature variation of the specific heat for different lattice sizes in BaTiO$_3$ systems. The nature of the phase transition and the behaviour of the specific heat versus the lattice size will be documented. In addition, the effect of the electric field on the character of the phase transitions in BaTiO$_3$ systems will be investigated by showing the free energy ($F$) versus the internal energy ($U$) curves. Electrocaloric effects can also be easily computed and will be discussed.

V1.00129 Evolution of multiple dielectric responses and relaxor-like behaviors in pure and nitrogen-ion-implanted (Ba, Sr)TiO$_3$ thin films. JING YANG, YANHONG GAO, WEI BAI, YUANYUAN ZHANG, East China Normal University, HONG SHEN, JINGLAN SUN, XIANGJIAN MENG, Shanghai Institute of Technical Physics, CHUNGANG DUAN, XIAODONG TANG, JUNHAO CHU, East China Normal University, MENG XIANGJIAN TEAM, CHU JUNHAO TEAM — Multiple dielectric responses are comparatively investigated in the pure and nitrogen-ion-implanted (Ba, Sr)TiO$_3$ (BST) films. Larger diffusive degree of phase transition and more relaxor-like features than those of pure BST films are observed in implanted ones, where the long-range-dipolar-correlated-orders were further segregated into local polar orders after the implantation.

V1.00130 Effect of ferroelectric layer on the magnetic properties of ferromagnetic layer. SRINIVASA RAO SINGAMANENI, North Carolina State University, JOHN T. PRATER, Army Research Office, JAY NARAYAN, North Carolina State University — In this presentation, we show the integration of classical two-phase multiferroic heterostructures composed of room-temperature ferroelectric BaTiO$_3$ (BTO) and ferromagnetic La$_{0.67}$Sr$_{0.33}$MnO$_3$ (LSMO) epitaxial thin films grown on technologically important substrate Si (100) [1-3]. Bilayers of BTO/LSMO thin films display ferromagnetic Curie transition temperatures of ~350 K, close to the bulk value, that are independent of BTO films thickness in the range of 25-100 nm. Discontinuous magnetization jumps associated with BTO structural transitions were suppressed in $M(T)$ curves, probably due to substrate clamping effect. Interestingly, at cryogenic temperatures, the BTO/LSMO structure with BTO layer thickness of 100nm shows almost 2-times higher magnetic coercive field, 3-times reduction in saturation magnetization and improved squareness compared to the sample without BTO. We attribute that to the strong in-plane spin pinning of the ferroelectric layer induced by BTO layer at BTO/LSMO interface. This work demonstrates that it is possible to manipulate the magnetic properties of ferromagnetic layer by varying the thickness of ferroelectric layer, without applying external electric field.

V1.00131 On Structural States of Multiferroic InMnO$_3$. TREVOR TYSON, TIAN YU, New Jersey Institute of Technology, JIANNING BAI, MILINDA ABEEKOON, Brookhaven National Laboratory, ROGER LALANCELLETTE, Rutgers University — InMnO$_3$ (with small site ion) was recently found to be ferroelectric and to crystallize with space group P63cm under certain preparation conditions (Appl. Phys. Lett. 102, 172901 (2013)). We have conducted detailed structural studies to explore the phase diagram and to identify the structural forms of InMnO$_3$ under varying preparation conditions. Detailed diffraction measurement results will be presented. This work is supported by DOE Grant DE-FG02-07ER46402.

V1.00132 Anderson Chern insulators. JAMES JUN HE, TONG ZHOU, YAO LU. The Hong Kong Univ of Science and Technology, Z.C. GU, Perimeter Institute, Canada, K.T. LAW. The Hong Kong Univ of Science and Technology — Previously, it was shown that quantum spin Hall insulators (QSHI) with helical edge states can be turned into a trivial insulator with Chern number $N = 0$ by applying magnetic fields. Further increase of the magnetic fields can result in a quantum anomalous Hall insulator (QAHI) which supports chiral edge state with $N = 1$. In this work, we show that for intermediate magnetization strengths, before the QSHI is turned into a QAHI, a topologically non-trivial phase which supports a single branch of chiral edge states can be obtained by increasing non-magnetic disorder. We call this phase the Anderson Chern insulator phase. In contrast to QAHI in which the chiral edge states are protected by the bulk gap, the gapless chiral edge states in Anderson Chern insulators survive even though the bulk gap is closed by disorder. Moreover, an Anderson Chern insulator exhibits quantized conductance of $e^2/h$ instead of $2e^2/h$ as for topological Anderson insulators. Therefore, we propose that this Anderson Chern insulator phase is a new phase of topological matter.

V1.00133 Topological properties of linear circuit lattices, VICTOR V. ALBERT, LEONID I. GLAZMAN, LIANG JIANG, Yale University — Motivated by the topologically insulating (TI) circuit of capacitors and inductors proposed and tested in [1], we present a related circuit with less elements per site [2]. The normal mode frequency matrix of our circuit is unitarily equivalent to the tight-binding matrix of a quantum spin Hall insulator. Spinful fermionic time-reversal symmetry manifests itself in the TI circuit context as a result of a discrete symmetry of the circuit; elastic backscattering between edge normal modes does not occur whenever a circuit perturbation is invariant under such a symmetry. We also generalize the idea and provide a platform to simulate tunable and locally accessible lattices with arbitrary spin-orbit hopping. A simulation of a non-Abelian Aharonov-Bohm effect using such linear circuit designs is discussed.

V1.00134 ABSTRACT MOVED TO S22.0008

V1.00135 ABSTRACT WITHDRAWN

V1.00136 Growth and Characterization of Large Scale (Sb\textsubscript{1−x}Bi\textsubscript{x})\textsubscript{2}Te\textsubscript{3} Thin Films on Mica\textsuperscript{1}, YAN NI, ZHEN ZHANG, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University — Topological insulators (TIs) attract attentions for both fundamental science and potential applications because of their bulk band inversion arising from the strong spin orbit coupling. However, it is necessary to tune the Fermi level and Dirac cone in 3D TI (Sb\textsubscript{1−x}Bi\textsubscript{x})\textsubscript{2}Te\textsubscript{3} to make an ideal system for TI applications. In this work, we report high quality (Sb\textsubscript{1−x}Bi\textsubscript{x})\textsubscript{2}Te\textsubscript{3} thin films grown on mica substrate by molecular beam epitaxy. The surface roughness of the thin film can reach as low as 0.7 nm in a large area by van der Waals epitaxy. (Sb\textsubscript{1−x}Bi\textsubscript{x})\textsubscript{2}Te\textsubscript{3} thin film with x = 0.04 shows a local maxima in the room temperature sheet resistance, which indicates a minimization of the carrier density due to band structure engineering. Moreover, for higher Bi concentration, due to an increase of the surface roughness and corresponding reduction of electron mobility, the sheet resistance increases. Our results on the feasibility of depositing (Sb\textsubscript{1−x}Bi\textsubscript{x})\textsubscript{2}Te\textsubscript{3} in wide Bi range on mica substrate will be helpful for the application of TI at room temperature and flexible electronics.

V1.00137 Evidence of a Positron bound state on the surface of Bi\textsubscript{2}Te\textsubscript{3}Se\textsubscript{2}, K. SHASTRY, Z.H. LIM, P.V. JOGLEKAR, VARGHESE ANTO CHIRAYATH, University of Texas at Arlington, B.A. BADIH, D. HEIMAN, B. BARBIELLINI, Northeastern University, A.H. WEISS, University of Texas at Arlington — We describe experiments aimed at probing the sticking of positrons to the surfaces of topological insulators performed at University of Texas at Arlington using the Positron Annihilation induced Auger electron Spectrometer. A magnetically guided beam was used to deposit positrons at the surface of Bi\textsubscript{2}Te\textsubscript{3}Se\textsubscript{2} sample at energy of ∼ 2 eV. Peaks observed in the energy spectra and intensities of electrons emitted as a result of positron annihilation showed peaks at energies corresponding to Auger peaks in Bi and Te providing clear evidence of Auger emission associated with the annihilation of positrons in a surface bound state. Theoretical estimates of the binding energy of this state are compared with estimates obtained by measuring the incident beam energy threshold for secondary electron emission and the temperature dependence positronium emission. The experiments provide strong evidence for the existence of a positron bound state at the surface of Bi\textsubscript{2}Te\textsubscript{3}Se\textsubscript{2} and indicate the practicality of using positron annihilation to selectively probe the critically important top most layer of topological insulator system.

V1.00138 Collective modes at a surface of a topological insulator\textsuperscript{1}, JHIH-SHENG WU, M.M. FOGLER, D.N. BASOV, UCSD — We investigate hybrid plasmon-phonon modes of a polar topological insulator that originate from interaction among the quasiparticles of surface and bulk states, and also optical phonons. As an example, we study electron-doped Bi\textsubscript{2}Se\textsubscript{3}. We analyze the dispersion of the collective modes of this compound for (i) a bulk sample with a depletion layer created by acceptor adsorbates on the surface and (ii) a thin film. In the first case, we show that a depletion layer gives rise to two energy-momentum regions, where the surface states dominate the collective modes over the bulk carriers. In a thin film, the phonons are more prominent than the bulk carriers. The anisotropy of the phonon response makes the thin film behaves as a waveguide. We discuss how these various collective modes can be detected by scanning near-field optical microscopy.

V1.00139 Magnetic properties of graphite nanostructures in carbon microspheres\textsuperscript{1}, EDUARE SHAROYAN, ARAM MANUKYAN, ARMEN MIRZAKHANYAN, ARMEEN KOCHARIAN, OSCAR BERNAL, California State University, Los Angeles — Carbon microspheres with interesting magnetic properties are prepared by solid-phase pyrolysis using as a precursor the metal-free phthalocyanine H\textsubscript{2}PC\textsubscript{5}. At any other temperature, a mixture of oxides consisting of V2O5 and VO2 was observed in the films. Annealing \begin{equation*} t=60\text{min} \end{equation*} carbon microspheres have average \begin{equation*} d=5-300 \end{equation*} diameter, and \begin{equation*} N=3-10 \end{equation*} in wide Bi range on mica substrate will be helpful for the application of TI at room temperature and flexible electronics.

V1.00140 Reduction of Vanadium Oxide (VOx) under High Vacuum Conditions as Investigated by X-Ray Photoelectron Spectroscopy\textsuperscript{1}, A. CHOURASIA, Texas A&M University—Commerce — Vanadium oxide thin films were formed by depositing thin films of vanadium on quartz substrates and oxidizing them in an atmosphere of oxygen. The oxidation was done by the e-beam technique. The oxide films were annealed at different temperatures for different times under high vacuum conditions. The technique of x-ray photoelectron spectroscopy has been employed to study the changes in the oxidation states of vanadium and oxygen in such films. The spectral features in the vanadium 2p, oxygen 1s, and the x-ray excited Auger regions were investigated. The Auger parameter has been utilized to study the changes. The complete oxidation of elemental vanadium to VO2 was observed to occur at 700°C. At any other temperature, a mixture of oxides consisting of VO2 and VO2 was observed in the films. Annealing of the films resulted in the gradual loss of oxygen following by reduction in the oxidation state from +5 to 0. The reduction was observed to depend upon the annealing temperature and the annealing time.

V1.00141 Investigation of InBi intermetallic compounds as possible topological insulators, Y.T. LIN, Q.Y. CHEN, W.C. HSEIH, C.F. CHANG, F.C. CHUANG, National Sun Yat-Sen University, H.H. LIAO, Enli Technology Inc., Kaohsiung, Taiwan — InBi intermetallic compounds were found to be potentially 2-dimensional topological insulators from first-principle calculations. In our experiment, InBi, In$_2$Bi$_3$ and In$_3$Bi$_5$ were fabricated either in bulk or thin film, by depositing In and Bi into 2 layers by e-beam evaporation of proper thickness ratios for each stoichiometry. The bi-layers were rapid thermal annealed to accomplish the reaction or intermixing well above their temperatures of phase transition. EDS and secondary electron imaging were used to determine the obtained stoichiometry. CVD using a 3-zone furnace was as tested with various combinations of zone temperatures, types and flow rates of carrying gases to investigate the feasibility of epitaxial growth. Samples were characterized by XRD to obtain the crystalline phase, magneto-transport measurements to determine the carrier concentration and mobility using a PPMS to correlate the measured results. We will ponder on the implication of our findings in regards to the possibilities of being a candidate for topological insulator as predicted by the calculations.

V1.00142 Optical and Electronic Properties of Diisopropylammonium Bromide molecular ferroelectric crystal (DIPAB), AHMAD ALSAAD, Jordan university of Science and Technology, NABIL AL-AQTASH, RENAT SABIRIANOV, University of Nebraska at Omaha — Diisopropylammonium Bromide molecular ferroelectric crystal (DIPAB) could be considered as a potential alternative for perovskite ferroelectric materials. We report the results of ab-initio calculations of electronic band structure and density of states to underline and explain the optical properties of P$^2$$_1$/c ferroelectric phase of DIPAB. In particular, we present the results on complex dielectric function, absorption, reflectivity, energy-loss spectra, and complex refractive index, as functions of the frequency of the incident electromagnetic wave. We found that the optical band gap of the polar ferroelectric phase of DIPAB is $\approx 5$ eV consistent with the steepest rise in the absorption spectra. Furthermore, we found that the ferroelectric phase of DIPAB exhibits two fundamental oscillator bands at 5.91 and 6.4 eV, which correspond to the optical transitions from the valence band of bromine to the conduction band of nitrogen and carbon. Analysis of optical spectra in the 0-4.8 eV photon energy range reveals that this phase is characterized by high transparency, no absorption and a small reflectivity in this range. We found that the sharp maxima in the energy-loss occur at 14.35 and 15.82 eV in polar phase. The peak value of volume loss, 15.82 eV in polar phase, coincides with the zero values of the real part of the corresponding dielectric functions.

V1.00143 Electromagnetic Wave Transmission Through a Nano-Hole, NORMAN HORING, DESIRE MIESSEIN, Stevens Institute of Technology, GODFREY GUMBS, Hunter College, CUNY, HUNTER COLLEGE-CUNY COLLABORATION. STEVENS INSTITUTE OF TECHNOLOGY COLLABORATION — An integral equation formalism is presented to describe electromagnetic wave transmission through a subwavelength nano-hole in a thin plasmonic sheet. The dyadic Green’s function for the associated Helmholtz problem is employed. Taking the subwavelength radius of the nano-hole to be the smallest length of the system, we have obtained an exact solution of the integral equation for the dyadic Green’s function analytically. This dyadic Green’s function is then used in the numerical calculations of EM wave transmission through the nano-hole for normal incidence of the incoming wave train. The EM transmission involves two distinct contributions, one emanating from the nano-hole and the other is directly transmitted through the thin plasmonic layer itself. The transmitted radiation exhibits interference fringes in the vicinity of the nano-hole, and they tend to flatten as a function of increasing lateral separation from the hole.

V1.00144 PT-symmetric Floquet Lattices, NICHOLAS BENDER, MAHBOOBEH CHITSAZI, HUANAN LI, FRED ELLIS, TSAMPIKOS KOTTOSS, Wesleyan University — We investigate spectral and dynamical properties of periodically driven PT-symmetric dimer systems and show that in the Floquet space they are described by Parity-Time symmetric lattices. The topology of the Floquet lattice depends on the complexity of the driving. For the simplest driving scheme associated with a sinusoidal coupling, we show that as the gain/loss parameter increases, the Floquet spectrum and the corresponding eigenvectors undergo a transition from an exact to a broken PT-symmetric phase via an Exceptional Point singularity. The phase transition is also reflected in the associated Floquet dynamics. This paves the way to experimentally investigate extended lattice dynamics in PT-systems. Arealization in the RF domain is reported and compared with the theoretical analysis.

V1.00145 Effects of stoichiometry and crystalline morphology on transport in topological insulator nanowires$^1$, INA KORZHOVSKA, HAIMING DENG, LUKAS ZHAO, The City College of New York, MARCIN KONCZYKOWSKI, TRAVIS WADE, Ecole Polytechnique, France, LIA KRUSIN-ELBAUM, The City College of New York — In nanostructured topological insulators with increased surface-to-volume ratio the contribution of charge transport through topological surfaces relative to the bulk will be enhanced. Here we report on electrochemical synthesis and characterization of Bi$_2$Te$_3$ and Sb$_2$Te$_3$ nanowires in which the effect of materials’ stoichiometry as well as nanowire size was investigated. Nanowires were grown in porous anodic aluminum oxide membranes with pore diameters varying from 18 to 150 nm. Stoichiometry and the wire morphology were tuned by electrochemical cell voltages in the 30 - 150 mV range. Topological signatures and surface conductance are affected by both crystallinity and chemical composition. We found that in the narrow range of the electrochemical potential (130 mV-150 mV) when stoichiometry changes were very small the nanowire conductance could still be hugely different. The results of high-field magnetotransport and I-V characteristic measurements on nanowires with crystallinity and morphology controlled by a suitable annealing protocol and imaged using transmission (TEM) and scanning (SEM) electron microscopies will be presented.

$^1$Supported by NSF-DMR-1312483, and DOD-W911NF-13-1-0159

V1.00146 Laser induced oxidation and optical properties of bismuth telluride nanofilaments, ZHIPENG YE, Univ of Northern Iowa, SUKRIT SUCHARITAKUL, Case Western Reserve Univ, COURTNEY KEISER, TIM E. KIDD, Univ of Northern Iowa, XUAN P. A. GAO, Case Western Reserve Univ, RUI HE, Univ of Northern Iowa — Bi-Te nanofilaments (NPs) grown by low pressure vapor transport method were studied by Raman spectroscopy, atomic force microscopy (AFM), energy-dispersive X-ray spectroscopy (EDS), and Auger electron spectroscopy (AES). We find that the surface of relatively thick (more than tens of nanometers) Bi$_2$Te$_3$ NPs is oxidized in the air and forms a bump under heating with moderate laser power, as revealed by the emergence of Raman lines characteristic of Bi$_2$O$_3$ and TeO$_2$ and characterization by AFM and EDS. Further increase of laser power burns holes on the surface of the NPs. Thin (thicknesses less than 20 nm) NPs with stoichiometry different from Bi$_2$Te$_3$ were also studied. Raman lines from non-stoichiometric NPs are different from those of stoichiometric ones. Thin NPs with the same thickness but different stoichiometries show different color contrast compared to the substrate in the optical image. This indicates that the optical absorption coefficient in thin Bi-Te NPs strongly depends on their stoichiometry. Controlling the stoichiometry in the Bi-Te NPs growth is thus very important for their thermoelectric, electronic, and optical device applications.

$^3$Supported by American Chemical Society Petroleum Research Fund (Grant 53401-UNI10), NSF (No. DMR-1206530, No. DMR-1410496, DMR-1151534), UNI Faculty Summer Fellowship and a UNI capacity building grant.
V1.00147 Investigation of Interactions between the Doped Rare Earth Ions and Encaged Radicals in C12A7:RE3+ — Using Optical and EPR Spectroscopy, CARTER LAYFIELD, LI MA, XIAO-JUN WANG, Georgia Southern Univ — Doped calcium aluminates (C12A7) (C12A7:Eu3+ and C12A7:Mn2+) have been prepared using solid state reaction methods. The Eu3+ and Mn2+ dopants can both occupy the Ca2+ positions in C12A7. The unique cage-like structure of C12A7 allows different anions, such as oxygen, hydrogen to be trapped in cage by modifying the sample preparation or treatment conditions. The effects of these encaged anions/radicals on the local symmetries of Ca2+ have been studied using photoluminescence from C12A7 doped with Eu3+, which is a sensitive environmental probe. The effects can also be independently observed from the hyperfine structure of electron paramagnetic resonance spectra in C12A7 doped with Mn2+. Our results showed: 1) the presence of 5D0 to 7F0 transition implies that Eu3+ sits at a non-centrosymmetric site in all caged radical centers; 2) this singlet transition is doubled when superoxides are encaged in C12A7, indicating that the sites of calcium (or Eu2+) ions are not identical due to the distortion of the encaged anions; 3) a blue shift of the transition occurred due to nephelauxetic effects in asymmetry sites. We have also observed double sets of EPR signals of sextet hyperfine splitting for Mn2+ in C12A7-O but single sets in C12A7-H. We conclude that the local symmetry around Ca2+ positions are distorted more when superoxide is encaged in C12A7. Finally, RE3+ doped C12A7 samples have been systematically prepared and the interactions between the encaged ions and RE3+ emission centers studied using EPR spectroscopy.

V1.00148 Enhanced spin orbit interaction of graphene by Ir cluster decoration, PEI-QUN WANG, YUJUN QIN, ZHAOQIU LI, SIQI WANG, BAIGENG WANG, Nanjing University, COLLABORATIVE INNOVATION CENTER OF ADVANCED MICROSTRUCTURES TEAM — Enhancing the strength of the intrinsic spin orbit (SO) coupling in graphene is a critical issue in achieving the quantum spin Hall effect predicted by Haldane et al. Here we report the measurements of the weak localizations in graphene, which has been decorated by Ir clusters. The SO scattering rate ($\tau_{SO}$) is extracted by fitting the curves using the formula of E. MacCan. It is found that $\tau_{SO}$ is monotonically dependent on the electronic relaxation time. Further analysis points that it obeys an Elliot-Yafet relaxation, which can be attributed to the dominance of Kane-Mele $\tau_{SO}$ interaction. The SO interaction strength can be extracted by fitting the $\tau_{SO}$ data dependent on the gate voltage. After considering the temperature effect, an SO strength value of $5 \sim 7$ meV is achieved, which has been greatly enhanced as compared to that of pristine graphene.

V1.00149 Zero modes in superconducting nanowires with Desselhaus spin-orbit coupling, HSICHIANG KAO, National Taiwan Normal University — Using chiral decomposition, we are able to find analytically the zero modes in the Kitaev ladder model and superconducting nanowires with Desselhaus spin-orbit coupling. Analytic conditions for the existence of zero modes are obtained. As a result, we are able to predict the number of zero modes in these systems. Moreover, we find that when suitable resonance condition is satisfied exact zero modes exist even in finite systems contrary to the common belief.

V1.00150 Chiral Majorana edge modes in d-wave superconductor/antiferromagnet heterostructures, PIN GAO, TAI KAI NG, VIC KAM TUN-E LAW, Hong Kong Univ of Sci & Tech — In this work, we study the heterostructure of a d-wave superconductor coupled to an antiferromagnet. We show that Majorana fermion edge states can be created in the system even in the absence of spin-orbit coupling, given that a supercurrent is induced in the superconductor. The Majorana edge states exist even the bulk is gapless and they propagates perpendicular to the direction of the supercurrent. The Majorana modes can be detected through tunneling and heat transport measurements.

V1.00151 Chiral magnetic effect in two-band lattice model of Weyl semimetal, MIN-FONG YANG, Tunghai University, MING-CHE CHANG, National Taiwan Normal University — Employing a two-band model of Weyl semimetal, a definite result on the existence of the chiral magnetic effect (CME) is established within the linear-response theory. The crucial role played by the limiting procedure in deriving correct transport properties is clarified. Besides, in contrast to the prediction based on linearized effective models, the value of the CME coefficient in the uniform limit shows nontrivial dependence on various model parameters. Even when these parameters are away from the region of the linearized models, such that the concept of chirality may not be appropriate, this effect still exists. This implies that the Berry curvature, rather than the chiral anomaly, provides a better understanding of this effect.

V1.00152 Magnetic ordering at the topological insulator-magnetic insulator interface, KARAN BANERJEE, JEAN BESBAS, Nati Univ of Singapore, PENG REN, Nanyang Technological University, LAN WANG, RMIT University, HYUNSOO YANG, Natl U of Singapore — The spin momentum locking property of topological insulators is key to their practical utility. However, due to large bulk contribution and defects, it has been difficult to harness it. One of the possible solutions is to use heterostructures of topological insulators and magnetic insulators which can make the spin momentum locking robust at the interface. Here we report on the angular dependence of magnetoresistance on heterostructures of the topological insulator BiSbTeSe$_2$ and the magnetic insulator YIG. We find that a four-fold symmetry arises in the in-plane angular dependence spectrum above a critical external field indicating the presence of magnetic ordering at the interface. We demonstrate that the interfacial magnetic ordering arises from a spin polarized interface state which is distinct from the topological surface state.

V1.00153 Superlattice valley engineering for designer topological insulators, XIAO LI, The University of Texas at Austin, FAN ZHANG, The University of Texas at Dallas, QIAN NIU, The University of Texas at Austin, JI FENG, Peking University — A topological insulator is a novel state of quantum matter, characterized by symmetry-protected Dirac interfacial states within its bulk gap. Tremendous effort has been invested into the search for topological insulators. To date, the discovery of topological insulators has been largely limited to natural crystalline solids. Therefore, it is highly desirable to tailor-make various topological states of matter by design. Starting with but a few accessible materials or elements. Here, we establish that valley-dependent dimerization of Dirac surface states can be exploited to induce topological quantum phase transitions, in a binary superlattice bearing symmetry-unrelated interfacial Dirac states. This mechanism leads to a rich phase diagram and allows for rational design of strong topological insulators, weak topological insulators, and topological crystalline insulators. Our ab initio simulations further demonstrate this mechanism in [111] and [110] superlattices of calcium and tin tellurides. While our results reveal a remarkable phase diagram for the binary superlattice, the mechanism is a general route to design various topological states.

V1.00154 Orbital and spin magnetization induced by electric current in crystals with helical structure, TAIKI YODA, TAKEHITO YOKOYAMA, SHUICHI MURAKAMI, Tokyo Institute of Technology — Crystals with helical lattice structure lack inversion and mirror symmetries. In such systems with low symmetry, we expect various physical phenomena which never occur in systems having high symmetry. In particular, because a helix is similar to a solenoid, we expect that an electric current will induce orbital and spin magnetization. To confirm this scenario, we introduce a simple tight-binding model with helical lattice structure. Using this model, we calculate the orbital and spin magnetization induced by electric field along the helical axis. The resulting orbital magnetization in response to the electric field is along the helical axis. The direction of the induced orbital magnetization is opposite for the right-handed helix and the left-handed one. Furthermore, when the spin-orbit coupling is included, the spin magnetization is also induced along the helical axis as well. This spin magnetization comes from a radial spin texture on the Fermi surface, which is totally different from the Rashba system having tangential spin texture. We also show that by changing the model parameters the model shows characteristic phase transitions into a Weyl semimetal and a weak topological insulator.
V1.00155 Linked Temperature Evolution of the bulk gap and helical topological surface states in SmB$_6$1, J.D. DENLINGER, Lawrence Berkeley National Lab, J.W. ALLEN, KAI SUN, U. of Michigan, JEONGSOO KANG, Catholic U. of Korea, J.W. KIM, C.J. KANG, J.H. SHIM, B.I. MIN, POSTECH, D.-J KIM, Z. FISK, UC Irvine — The paradigm mixedvalent insulator SmB$_6$ with a temperature dependent bulk gap has recently become the first paradigm example of a strongly correlated topological insulator with f-d band inversion and with experimental evidences for in-gap surface states and surface transport. In this work temperature- and polarization-dependent angle-resolved photoemission on cleaved SmB$_6$ quantifies the T-evolution of (i) the Sm 4f state coherency, (ii) the X-point f-conduction band energy and many-body gap destabilization, and (iii) the intimately connected state of topologically protected in-gap states. DFT and DFT-DMDFT calculations confirm early theory [1] that hybridization between boron 2p and Sm 4f states provides crucial assistance in the full opening of the many-body f-d gap. Also a dimensional crossover above 100K from 3D bulk d-band states crossing $E_F$ at high T to low T 2D in-gap surface states is shown to coincide with the development of a circular dichroism signature of in-gap state helicity.

V1.00156 Low temperature magnetoresistance studies in MBE grown topological insulator thin films1, RIK DEY, ANUPAM ROY, TAMNOY PRAMANIK, SAMARESH GUCHHAIT, SUSHANT SONDE, AMRITESH RAI, SARMITA MAJUMDER, BAHINIMAN GHOSH, LEONARD REGISTER, SANJAY BANERJEE, Microelectronics Research Center, Univ of Texas at Austin — We studied low temperature magnetoresistance in molecular beam epitaxy grown topological insulator Bi$_2$Se$_3$ and Bi$_2$Te$_3$ thin films. The surface and structural characterization of the grown films showed smooth epitaxial growth on Si(111). The magnetoresistance has been measured at low temperatures (2 - 20 K) with magnetic fields upto 9 T. The full range perpendicular field magnetoresistance has been explained with the original Hikami-Larkin-Nagaoka theory. Altshuler-Aronov theory of localization has been used to understand the full range parallel field magnetoresistance. Various scattering times have been estimated by fitting the magnetoresistance data with the theory. It is shown that the Zeeman effect is not needed to explain the magnetoresistance and has not been considered in the theory either. The angle dependent anisotropic magnetoresistance has also been observed and explained using the above theories.

V1.00157 Dirac Semimetal Films as Spin Conductors on Topological Substrates1, XIAOXIONG WANG, Nanjing University of Science and Technology, GUANG BIAN, University of Illinois at Urbana-Champaign, PENG WANG, Shandong University of Science and Technology, T.-C. CHANG, University of Illinois at Urbana-Champaign — Spin-momentum locked states, notably those found on the surfaces of topological insulators, are promising for low-power electronic devices based on spin transport. Here we report a much more versatile case involving a Dirac semimetal film on a topological insulator substrate. Such a film can carry highly spin-polarized conduction channels by electronic coupling to the substrate. The spin channel width, defined by the film thickness, is at the designer’s disposal, thus permitting optimization of the system parameters. The concept and underlying physics of such quasi-bulk spin channels are confirmed by calculations of a model system involving Bi$_2$Se$_3$ as the substrate and its low-Z substitute as the overlayer film. The results demonstrate Dirac semimetals as an important class of material for spintronic applications.

V1.00158 Detection of entanglement by helical Luttinger liquids, KOJI SATO, Tohoku Univ, YAROSLAV TSERKOVNYAK, University of California, Los Angeles — A Cooper-pair or electron-hole splitter is a device capable of spatially separating entangled fermionic quasiparticles into mesoscopic solid-state systems such as quantum dots or quantum wires. We theoretically study such a splitter based on a pair of helical Luttinger liquids, which arise naturally at the edges of a quantum spin Hall insulator. Equipping each helical liquid with a beam splitter, current-current cross correlations can be used to construct a Bell inequality whose violation would indicate nonlocal orbital entanglement of the injected electrons and/or holes. Due to the Luttinger-liquid correlations, however, the entanglement is suppressed depending on ambient temperature and voltage bias.

V1.00159 SUPERCONDUCTIVITY –

V1.00160 Hole doping study in antiferromagnetic BaFe$_2$Se$_3$ and BaMn$_2$As$_2$1, JIN-KE BAO, GUANG-HAN CAO, Zhejiang Univ — Motivated by the close relationship between antiferromagnetism and superconductivity, we studied hole doping in two antiferromagnetic compounds BaFe$_2$Se$_3$ and BaMn$_2$As$_2$. BaFe$_2$Se$_3$ has a block antiferromagnetic transition around 250 K with a magnetic moment 2.8 $\mu_B$/Fe and BaMn$_2$As$_2$ exhibits a C-type antiferromagnetism with a large Néel temperature $T_N = 625$ K and a large order moment 3.9 $\mu_B$/Mn. We did the explicit investigations on the Ba$_{0.8}$K$_{0.2}$Fe$_2$Se$_3$ compound which had anisotropic Heisenberg-like spin glass and variable range hopping conductivity [J. K. Bao et al., J. Phys.: Condens. Matter 26, 026002 (2014)]. As for the semiconducting BaMn$_2$As$_2$, potassium doping introduces holes into this system and makes it a metal. Moreover, weak ferromagnetic transition appears for the heavily potassium doping [J. K. Bao et al., Phys. Rev. B 85, 144523 (2012)]. However, the origin of weak ferromagnetism in the heavily doped Ba$_{1-x}$K$_x$Mn$_2$As$_2$ is still an open question.

V1.00161 ABSTRACT WITHDRAWN

V1.00162 Doping effects of transition metals on superconducting properties of (Ca,RE)FeAs$_2$, HIROYUKI YAKITA, HIRAKU OGINO, TOMOYUKI OKADA, AKIYASU YAMAMOTO, KOJI KISHIO, JUN-ICHI SHIMOYAMA, Univ of Tokyo, AKIRA IYO, HIROSHI EISAKI, AIST, ALBERTO SÁLA, Univ of Tokyo, AIST, Univ of Genova — At the previous March Meeting, we reported new iron based superconductors (Ca,RE)FeAs$_2$ (Ca112) (RE = La-Nd, Sm-Gd)1,2. Superconducting transition was observed in all samples except for Ce-doped sample, and $T_c$ of La-doped sample exceeded 30 K. In this study, we have synthesized transition metals (TM = Mn, Co, Ni) co-doped Ca112 samples. Mn co-doping suppressed superconductivity. On the contrary, enhancement of $T_c$ with sharp superconducting transitions was observed in most of the Co or Ni co-doped samples. $T_c$ of Co co-doped samples decreased with a decrease in ionic radii of $RE^{3+}$ from 38 K for $RE$ = La to 29 K for $RE$ = Gd, though Eu doped sample showed exceptionally low $T_c$. $J_e$ value of La and Co co-doped sample estimated from magnetization measurement is approximately 2.0 x 10$^4$ Acm$^{-2}$ at 2 K suggesting bulk superconductivity. [1] H. Yakita et al., J. Am. Chem. Soc. 136 (2014) 846 [2] H. Yakita et al. APS March Meeting 2014 C1 00090

V1.00163 Work supported by National Basic Research Program of China (No. 2011CB00137) and National Science Foundation of China (No. 11101003).

V1.00164 Work supported by National Basic Research Program of China (No. 2011CB00137) and National Science Foundation of China (No. 11101003).
V1.00163 Magnetic, Transport Properties, Lower Critical Field, Penetration Depth, Anisotropy and Gap Evidences of Ca_{10} (Pt_{n}As_{x}) (Fe_{2−n}Pt_{n}As_{2})_{5} (n = 3 And 4) Superconductors, KALYAN SAMSAL, YUYI XUE, PAUL C.W. CHU, Texas Center for Superconductivity, Department of Physics, University of Houston — Platinum iron arsenides Ca_{10}(Fe_{2−n}Pt_{n}As)_{5} (n = 3 & 4) are first Fe based superconductors with metallic spacer layers. Crystal structure have stacks of Ca (Pt_{n}As_{x}) Ca (Fe_{2−n}Pt_{n}As) consists of superconducting Fe_{2−n}As layers alternating with Pt_{n}As layers, forming a triclinic P1, 1038phase with n = 3 and tetragonal P4/n, 1048phase with n = 4. Two different negatively charged layers [(FeAs)_{1−x}^{1+}−] and (Pt_{1−x}As)_{m+} compete for electrons provided by Ca^{2+}. In parent compound Ca_{10}(FeAs)_{5}(PtAs), no excess charge dopes FeAs-layer, and superconductivity is induced by Pt-substitution. Additional Pt in Pt_{n}As layers shift charge balance between layers and T_{c} raises to 38 K, but decreases again if additionally Pt is substituted for Fe. Charge doping is supported by T_{c} ≈ 30 K in electron-doped La-1038, x ≈ 0.2 (Ca_{1−x}La_{x})_{5}(Pt_{2}As)_{5} without significant Pt-substitution. Magnetic properties were explored. Magnetization measurements reveal fish-tail hysteresis loop and relatively high critical current density at low T. Lower critical field, H_{c2} derived from vortex penetration into single crystals. Ginsburg-Lauder parameters extracted from reversible magnetizations data. Upper critical field determined by resistive transition shows large anisotropy. With La doping, the structural/magnetic phase transitions are suppressed. T-dependency of the H_{c2} is compared with BCS-gap models and anisotropy of H_{c1} will be discussed.

V1.00164 Nematic phase in strain free detwined BaFe2-xNixAs2, HAORAN MAN, Rice Univ, XINGYE LU, None, JUSTIN CHEN, EMILIA MOROSAN, PENGCHENG DAI, Rice Univ, PENGCHENG DAI'S GROUP TEAM — Here I present the transport and neutron scattering results in BaFe2−xNixAs2. The crystal is detwined using pressure and then the pressure is released at base temperature before the experiment. In the detwined sample, the anisotropy persist at a temperature higher than the both structural and magnetic transition, but the temperature range is much lower than the anisotropy induced by pressure.

V1.00165 Disorder induced correlation gap suppresses superconductivity in the 5d metallic perovskite Ba_{1−x}La_{x}PbO_{3}, CAROLINA ADAMO, Stanford University, DANIEL SHAI, BREDAFA FAETH, Cornell University, PHILIP WU, Stanford University, KYLE SHEN, DARRELL SCHLOM, Cornell University, MALCOLM BEASLEY, Stanford University — We report the synthesis and characterization of the electronic structure of thin films of the perovskite Ba_{1−x}La_{x}PbO_{3} grown by oxide molecular-beam epitaxy. Using angle-resolved photoemission spectroscopy our measurements reveal a Fermi surface consistent with density functional calculations at low doping, but indicate the formation of an energy gap at higher doping values (x ∼ 0.2), consistent with electrical transport measurements. By comparison with temperature-dependent point contact tunneling spectroscopy measurements, we show this behavior is consistent with a disorder-driven correlation gap. Moreover the photoemission data reveal a density of states that is not linear at high binding energies, suggesting discrepancy with previous tunneling density of states measurements of superconducting oxides.

V1.00166 Superconductivity and Eu Valence Instability in Undoped Eu3Bi2S4F4, HUI-FEI ZHAI, PAN ZHANG, GUANG-HAN CAO, Department of Physics, Zhejiang University, Hangzhou 310027, P. R. China — We recently synthesized a novel bismuth sulfurofluoride, EuBiSF_{2}.[1] A CDW-like transition occurs at 280 K, below which SC emerges at 0.3 K. The Eu ions show an anomalously mixed valence about +2.2. With structural design, we successfully synthesized a new europium bismuth sulfofluoride, EuBi_{2}F_{5}.[2] Two crystallographic twins, EuBi_{2}F_{5}−type EuBiSF_{2}[1] and EuBi_{2}F_{5}−type EuBiS_{2}[2], stack alternately along the crystallographic c axis. There are two crystallographically distinct Eu sites, Eu(1) and Eu(2) at the Wyckoff positions 4e and 2a, respectively. Our bond valence sum calculation, based on the refined structural data, indicates that Eu(1) is essentially divalent, while Eu(2) has an average valence of +2.64(5). This anomalous Eu valence state is preserved at low temperatures and magnetic properties, but indicated by Mössbauer and magnetization measurements. The Eu^{3+} components donate electrons into the conduction bands that are mainly composed of Bi 6px and 6py states. Consequently, the material itself shows metallic conduction and superconducts at 1.5 K without extrinsic chemical doping. [1] Hui-Fei Zhai et al., Phys. Rev. B90, 064518 (2014). [2] Hui-Fei Zhai et al., J. Am. Chem. Soc. 2014, 136, 15386−15393.

V1.00167 Polycrystalline Silicon Thin Films at Low Temperature using SiF_{4} / SiH_{4} mixture, MONIRUZZAMAN SYED, Lemoine Owen College, TAKAO INOKUMA, YOSHIHIRO KURATA, SEIIICHI HASEGAWA, Kanazawa University — Polycrystalline silicon films with a strong (110) texture were prepared at 400°C by a plasma-enhanced chemical vapor deposition using different SiF_{4} flow rates ([SiF_{4}] = 0−0.5 sccm) under a fixed SiH_{4} flow rate ( [SiH_{4}] = 1 or 0.15 sccm). The effects of the addition of SiF_{4} to SiH_{4} on the structural properties of the films were studied by Raman scattering, X-ray diffraction (XRD), Atomic force microscopy and stress measurements. For [SiH_{4}] = 1 sccm, the crystallinity and the (110) XRD grain size monotonically increased with increasing [SiF_{4}] and their respective maxima reach 90% and 900 Å. However, for [SiH_{4}] = 0.15 sccm, both the crystallinity and the grain size decreased with [SiF_{4}]. Mechanisms causing the change in crystallinity are discussed, and it was suggested that an improvement in the crystallinity, due to the addition of SiF_{4}, is likely to be caused by the effect of a change in the surface morphology of the substrates along with the formation of SiF_{4} by reaction of SiF_{4} and the substrate.

V1.00168 Electronic conduction in Sr_{2}RuO_{4} and Sr_{2}RhO_{4} thin films, YOSHIHARU KROCKENBERGER, HIROSHI IRIE, JOSH KUO, HIDEKI YAMAMOTO, NTT Basic Research Labs — Transition metal oxides belonging to the Ruddlesden-Popper series, e.g., T^{2+}La_{2−n}Cu_{n}O_{3}, Sr_{2}RuO_{4}, and Sr_{2}RhO_{4}, share several geometrical- and associated electronic features. In all cases, squares of transition metal oxide layers are separated by insulating layers, hence, the observed electronic conduction is anisotropic. So far, much attention has been attributed to the metallic conduction in cuprates and ruthenates and metallic conduction in rhodates has been sparsely acknowledged. This is partly due to the absence of superconductivity in the RhO_{2} planes. We show that the metallic conduction in RhO_{2} planes is subject to d[Rh-O] distance which can be tuned by epitaxial strain.

V1.00169 Investigation of the changes in the density of states in the Copper-Titanium system, A. CHOURASIA, Texas A&M University-Commerce — The density of states and structure parameters in the copper-titanium system have been investigated by DFT. Various compounds of the copper and titanium (such as CuTi, CuTi_{2}, CuTi_{3}, Cu_{3}Ti) have been studied. The DFT calculations were performed using the GGA exchange-correlation potential. For each compound the atoms were relaxed by minimizing the forces and allowing changes in the unit cell. Geometrical structure and variations in the density of states in the vicinity of the Fermi level have correlated with the near neighbors of copper/titanium.

V1.00170 A Model Approach to Flux-Pinning Properties of YBCO Vortex States via Non-Superconducting Impurities, RONALD GAMBLE, KLINTON DAVIS, ABEBE KEEBEDE, North Carolina A&T State Univ — Thin film YBCO samples with added non-superconducting nanodot defects of CeO2 and BaSnO3 are the focus of recent high-temperature superconductor studies. Examining the structure shows that quantized magnetic fluxortices from within the sample arrange themselves in a self-assembled lattice. The nanodots, with non-superconducting properties, serve to present structural properties to restrict motion of these vortices under a pinning-force card to enhance the critical current density. A formulation of a new model for the system by a variation in the electron pair velocity via the virtual work from the nanodot defects in accordance to the Abrikosov-Gor'kov theory is presented. With the zero net force on the vortex, the vortex-core radius and pinning force constant don't set in for the optimal deposition parameters of number density, growth geometry and mass density of these nanodot structures. With a calculation of pair velocities from a similar work, a comparison is made between experimental and theoretical velocity calculations using growth geometry and chemical potential. This will yield insight into how the current density for a doped high-temperature superconductor will be modified and tuned based on the density of the nanodots themselves.

V1.00171 Superconductivity enhanced by Se-doping in Eu2Bi2S4F4, PAN ZHANG, HUI-FEI ZHAI, GUANGHAN CAO, ZHUAN XU, Department of Physics, Zhejiang University — We investigated the negative chemical pressure effect of Eu2Bi2S4F4 by partially substituting S with Se. The "parent" compound Eu2Bi2S4F4 is a new member of the BiS2-based superconductors. [H.-F. Zhai et al., J. Am. Chem. Soc. 136, 15386–15393, (2014)] It shows anomalous Eu valence and superconductivity of $T_c = 1.5$ K without chemical doping. With S/Se-doping, we found that a CDW-like anomaly is gradually suppressed to lower temperatures, and meanwhile the superconductivity ($SC$) is enhanced. For Eu2Bi2Se2F4, $T_c$ reaches 3.4 K. Magnetization measurements reveal an average Eu valence of $\sim 2.06$, which means that Se doping does not introduce extra electrons but instead, lowers down to a low electron doping level of $x \sim 0.1$. Therefore, the present system manifested itself as a rare example of existence of SC at very low doping levels.

V1.00172 Characterization of Titanium Nitride thin films Sputtered at Room Temperature, WEIQI HUANG, STEPHEN ARNASON, MATTHEW BELL, University of Massachusetts Boston — Thin film titanium nitride (TiN) has become widely used in photon detection with microwave kinetic inductance detectors and recently as resonant structures in superconducting quantum information circuits. The attractive properties of the material are its widely tunable critical temperature, large surface inductance, and low losses at microwave frequencies when incorporated into resonant circuits. We report on thin films of TiN sputter-deposited on intrinsic silicon substrates at room temperature for various nitrogen flow rates and deposition pressures. Characterization of the inductance and microwave losses in lumped-element resonators fabricated from these films will also be discussed.

V1.00173 Anisotropy of superconducting properties of flexible magnesium-diboride-coated carbon nanotube yarns, JULIA BYKOVA, MÁRCIO DIAS LIMA, AUSTIN HOWARD, NanoTech Institute, The University of Texas at Dallas, M. TARANOV, K. KONYUKHOV, Moscow Institute of Steel and Alloys, MYRON SALAMON, MPA-CMMS, Los Alamos National Laboratory, RAY BAUGHMAN, ANVAR ZAKHIDOV, NanoTech Institute, The University of Texas at Dallas — Flexible ultralight magnesium-diboride-coated carbon nanotube (MgB$_2$-CNT) yarns have critical temperatures up to 37 K, high critical fields and currents comparable with conventional superconducting wires. Superconducting yarns containing MgB$_2$-CNT nanofibers were prepared by conformal coating of CNT sheets with boron in photothermal chemical vapor deposition, and annealing in magnesium vapors. Magnetic transport measurements in a magnetic field, whose direction is varied relative to the sample orientation, showed anisotropy in superconducting properties. The critical field anisotropy ratio $H_{c2}/H_{c1}$ reaches 1.2-1.4 over a wide temperature range below $T_c$, comparable to but slightly lower than the factor 1.4-2 of epitaxial MgB$_2$ thin films. An X-ray diffraction study confirmed the crystalline anisotropy of composite wires and showed, that the MgB$_2$ grains prefer to grow with the a-plane parallel to the carbon nanotube walls and the yarn axis.

V1.00174 Plasma and thermal assisted selenization for the preparation of chalcopyrite light-absorbing layers, ZEHRA CVHER, ZHI HUANG, YUHANG REN, Hunter College, City University of New York, HUNTER COLLEGE, CITY UNIVERSITY OF NEW YORK TEAM — Chalcopyrite compound has attracted much attention recently because of their application in high efficient photovoltaic devices. In order to obtain a decent chalcopyrite photovoltaic device, it is very critical to optimize the metallic precursor layers and choose a suitable selenization technique. We demonstrate plasma and thermal assisted selenization methods for preparing Cu(In,Ga)Se$_2$ (CIGS) semiconductor films using elemental selenium vapor. The selenization process includes the modification of the ionization state of Se species by radio frequency plasma and/or thermal heating and homogenous control of interactions with CuInGaSe$_2$ metallic precursors. We obtained CIGS absorber layers with improved homogeneity and crystallinity. The result is explained by the enhancement of reaction kinetics between the reduced Se phase and metallic precursor layers.

V1.00175 A15 compounds, HTSC and strong coupling superconductors, SNEHADRI OTA, Institute of Physics, Bhubaneswar 751005, Orissa, India — We suggest that it is possible to understand the origin of high $T_C$ in the framework of strong coupling theory of superconductors. An exploratory investigation of materials with promising structural or electronic motifs is presented. The electron-phonon coupling constant $\lambda$ has been found to be inversely proportional to the molecular weight. The analysis is based on the numerically derived equation for $T_C$ from strong coupling theory for superconductivity by McMillan. The Coulomb pseudopotential $\mu^*$ has been found to be negative for YBa$_2$Cu$_3$O$_y$. The $T_C$ of YBa$_2$(Cu$_{1-x}$Zn$_x$)$_3$O$_7$ decreases linearly from 89 K to the nonsuperconducting state at a rate of about 15 K/at% of Zn substitution. Similar analysis YBa$_2$(Cu$_{1-x}$Zn$_x$)$_3$O$_7$ shows that $\mu^*$ changes sign from negative to positive as $T_c$ reduces. The isotope effect exponent $\alpha$ is found to go through a maximum as $T_C$ decreases and is found to be equal to 1/2 for $x=0.026$ which can be verified experimentally.

V1.00176 Topological Superconductivity in Ferromagnetic Metal Chains: Part II, JIAN LI, Princeton University, RUHAN CHEN, University of Texas at Austin, ILYA DROZDOV, ALI YAZDANI, BOGDAN BERNEVIG, Princeton University, ALLAN MACDONALD, University of Texas at Austin — One most important feature of the Majorana end states observed in the STM experiments is their sharply localized spatial profile. This cannot be explained by a conventional model for the magnetic flux, zero net flux, and non-Abelian states wouldn't be observable in a chain much shorter than the superconducting coherence length. In this second talk we resolve this issue by showing the fundamental difference between the naive 1D model and a proper one, where the 1D-3D hybrid nature of the real experimental structure is taken into account. The strong hybridization between the chain and the higher-dimensional host superconductor introduces long-range (power-law) coupling into the 1D system and significantly modifies the spatial profile of possible Majorana states. As a consequence the superconducting coherence length becomes irrelevant to the decay of the Majorana wavefunctions at a small length scale whereas the Fermi wavelength prevails. We will show concrete examples of eigenstates in a finite-size hybrid system where the Majorana end states are indeed localized within a length scale determined by the Fermi wavelength. This is in good agreement with experimental observations. We will also discuss the implication of this new regime, where the superconducting coherence length is irrelevant by realistic measure, in terms of the coupling energy between Majorana states and the operation time when braiding them.

Research at Hunter was supported by the Sun Harmonics Ltd and by NYSTAR through the Photonics Center for Applied Technology at CUNY.
V1.00177 Magnetic Anisotropy in DyNi2B2C system, W.C. LEE, Dept. of Physics, Sookmyung Women's Univ. Seoul 140-742, Korea — To figure out the magnetic and transport anisotropy in DyNi2B2C which have superconducting critical temperature \( T_c \) lower than the antiferromagnetic Neel temperature \( T_N \) among RNi2B2C (R= rare earth elements) compounds, we have measured the static magnetization curves M(H,T) with the applied magnetic fields parallel and perpendicular to the crystallographic c-axis at various temperatures and applied magnetic fields. We have observed several magnetic transitions only for the applied magnetic field perpendicular to the c-axis and such magnetic transitions have shift sensitively to the higher temperature regions. We compared our results with the Dy\(^{1.1}\) magnetic sublattice structure previously reported from neutron scattering experiments.

V1.00178 ABSTRACT WITHDRAWN —

V1.00179 Anisotropic bias dependent transport property in defective phosphorene Layer, JISANG HONG, M. FAROOQ, Department of Physics, Pukyong National University, Korea — We present the electronic band structure, defect formation energy and bias dependent transport property. Both single and divacancy defects have been considered. We found that the defect formation energy is much less than that in graphene. The defect configuration strongly affects the electronic structure. The band gap vanishes in single vacancy layer, but the band gap reappears in divacancy layers. Interestingly, a single vacancy defect behaves like a p-type impurity for transport property. Unlike the common beliefs, we observe that the vacancy defect can contribute to greatly increasing the current. Along the zigzag direction, both single and divacancy defects contribute to enhancing the current while the I-V characteristics along the armchair direction are dependent on the defect configurations. Despite this defect configuration dependency, we have found that the current along the armchair direction is always greatly larger than that found along the zigzag direction and the anisotropic current ratio of armchair to zigzag direction is an order of \( 10^3 \). This was supported by NRF (No. 2013R1A1A206071) and by the Supercomputing Center/Korea Institute of Science and Technology Information with supercomputing resources including technical support (KSC-2014-C3-052).

V1.00180 Enhanced superconducting properties of Bi2Sr2CaCu2O8+\( \delta \) thin films by incorporating Iridates nanoparticles, JONGHYUN SONG, JEFFREY VERO, INWOONG HWANG, Chungnam Natl Univ, A.C.L. SANTIGO, University of Philipine, JEONGWON JANG, Korea University, JINHEE KIM, Korea Institute of Science and Standards, R.V. SARMAGO, University of Philipine — We incorporated CaIrO\(_2\) (Ca-iridate) nanoparticles at the interface of Bi\(_2\)Sr\(_2\)CaCu\(_2\)O\(_{8+\delta}\) (Bi-2212) thin films and substrates by pulsed laser deposition and post-growth ex situ annealing. The density of incorporated Ca-iridate strongly affected the superconducting properties and microstructure of the Bi-2212 thin films. For the incorporation of low density Ca-iridate (450 laser pulses) in the Bi-2212, its superconducting properties enhanced (\( T_{c-onset} = 97 \) K, \( T_{c-zero} = 84 \) K) over those of pure Bi-2212 (\( T_{c-onset} = 94 \) K, \( T_{c-zero} = 80 \) K). However, incorporating a higher density (1,800 pulses) significantly reduced \( T_{c-zero} \), to \( \approx 57 \) K. Incorporating a low density of Ca-iridate also decreased the c-axis lattice constant. Films with incorporated Ca-iridate exhibited greater critical current density, \( J_c(90\)K), than the pure Bi-2212 film. These results indicate that incorporating low densities of Ca-iridate nanoparticles into Bi-2212 can improve its superconducting properties.

V1.00181 Dipolar couplings in Li\(_0.9\)Mo\(_6\)O\(_{17}\) purple bronze, GUOQING WU, Yangzhou University, BING WU, Fayetteville State University — We report the study of the internal magnetic field at the atomic scale at the Li site in the quasi-one-dimensional (Q1D) metal Li\(_0.9\)Mo\(_6\)O\(_{17}\) (purple bronze), with theoretical calculations based on the structure of its crystal lattice and the result of our \(^{7}\)Li-NMR measurements on a single crystal sample at an externally applied magnetic field \( B_0 = 6 - 12 \) T. We find that the anisotropic dipolar couplings to the paramagnetic Mo electron spins are the dominant source of the local magnetic field at the lithium site. Other local magnetic field sources such as the dipolar couplings between the \(^7\)Li to \(^{7}\)Li nuclei, isotropic contact hyperfine couplings to the Mo electron spins, and demagnetization and Lorentz fields are also estimated. Significant changes of the distribution of the dipolar couplings are observed at the "metal-insulator" crossover temperature and lower temperatures along the direction of \( B_0 \parallel c \), indicating a significant local magnetic field inhomogeneity due to the spin effect from the Mo electrons. No evidence of charge effect at the "metal-insulator" crossover temperature or lower temperatures is observed.

V1.00182 \(^{11}\)B NMR Study of HoB\(_4\), MOOHEE LEE, KI-HYEOK KANG, JUNG-HOON KIM, Konkuk University, J.Y. KIM, B.K. CHO, Kwangju Institute of Science and Technology — \(^{11}\)B NMR measurements were performed on a single crystal of HoB\(_4\) to investigate disorder induced effects on the 4\(^f\) spin structures and dynamics. The \(^{11}\)B NMR spectrum, shift, linewidth, \( 1/T_1 \), and \( 1/T_2 \), were measured down to 3.5 K at 8 T perpendicular to the c-axis. Above \( T_N = 5.7 \) K, the \(^{11}\)B NMR linewidth is very large and the shift is also large and negative. In addition, both depend on temperature strongly and increase at lower temperature, which is similar to the susceptibility. This fact confirms that the hyperfine field at the boron site originates from the 4\(^f\) spins of Ho. Below \( T_N \), the \(^{11}\)B NMR spectrum shows a single broad shape with an extremely large linewidth. This behavior is an unexpected result compared with usual NMR spectra in an ordered state for a single crystal specimen, where the single broad peak splits into several narrow peaks below \( T_N \), because of the different local magnetic fields at the each boron sites in the AF state. Considering frustration and disorder effects on the NMR data, we conclude that this behavior originates from the magnetic frustration and quadrupole moment disorder effects on the NMR static data. Above \( T_N \), the both rates are very large and then increase toward \( T_N \). Below \( T_N \), the both rates decrease tremendously.

V1.00183 Casimir Levitation: Stabilization of a neutral atom above a dielectric ring, JOHN JOSEPH MARCHETTA, None — Levitation, in popular culture, is the phenomenon of an object rising against gravity by supernatural means. However, levitation is not the work of anything supernatural, nor do you need to have attended Hogwarts School of Witchcraft and Wizardry in order to learn how to achieve it. The goal of my project is to propose a method to levitate a neutral, anisotropically polarizable, atom above a dielectric ring using the Casimir effect. In particular, we have already shown that an anisotropically polarizable atom experiences a repulsive force when it approaches the dielectric ring along the symmetry axis of the ring. But, the atom is not stable on this axis. We are working on the proposal that a spinning anisotropically polarizable atom above a dielectric ring will achieve stability, and thus get trapped. Our goal is to prove this very appealing hypothesis analytically.

V1.00184 RF-sputtered NbN superconducting thin film for the usage as an electrode of graphene FET and a flexible superconducting wire, Jeong-Gyun Kim, Haeyeong Kang, Jong-Gyu Kim, Young Hee Lee, Dongseok Su, CINAP, IBS, DOES, Sungkyunkwan Univ. — Recent report on the usage of NbN as an electrode for two-dimensional electronic system such as graphene encourage the study of noble physical phenomena which makes the injection of superconducting charge carriers into the channel of graphene FET inducing the combination of superconductivity with quantum Hall effect. In this study, we examined NbN thin film deposited by rf-sputtering method in various conditions. We checked the effects of deposition temperature, working pressure, and relative flow-rate ratio between argon and nitrogen gases during sputtering. Structural analysis by XRD and SIMS showed that the NbN film was successfully deposited on the silicon-oxide substrate and the highest T\(_c\) obtained was 10.5K with high Hc2 over 14 T at 5.5K for the film deposited at 600 oC. On the basis of optimal conditions, the change of superconducting properties depending on the deposition temperature was carefully examined for the development of low temperature deposition process that can be applied to the graphene FET fabrication. Additionally we tested the usage of flexible substrate for the deposition of this superconducting material on the purpose of highly flexible superconducting wire with greatly enhanced mechanical properties as reported recently for the MgB\(_2\) superconductor.

Scanning tunneling microscopy study on new layered superconductor Ta4Pd3Te16 single crystal.

Characterisation of the CDW in the novel superconducting family Na2Ti2X2O7.

Possible importance of charge fluctuation in BiS2 superconductors.

Variable frequency characterization of interaction at nanoscale in linear dynamic AFM.

An ultra-low temperature scanning Hall probe microscope (SHPM) for magnetic imaging below 40 mK.

LF-1mHz/Hz Noise Level Low Temperature Atomic Force & Magnetic Force Microscope (LT-AFM/MFM) in 20mK-300K Temperature Range.
V1.00192 Development of low temperature scanning tunneling microscope and test results at university of ulsan (Korea)1, SANG-UI KIM, JUNGDAE KIM, Department of Physics and EHSRC, University of Ulsan, Ulsan, 680-749, Korea — Thanks to the development of software and electronics in the last few decades along with advanced UHV technology, the scanning tunneling microscope (STM) has made a tremendous impact on various fields of surface science. In order to build an STM system and make it perform as expected, every component of STM needs to serve the others well. Recent progress on the development of low temperature STM at University of Ulsan (Korea) will be discussed. Advantages of our STM system are following: (1) compact design with in-situ sample preparation and tip/sample exchange capability, (2) simple and effective vibration isolation damper, (3) copper-stainless steel welding technique for cryostat, (4) simple liquid helium bath pumping setup for tunneling spectroscopy. Results of recent performance test will be discussed as well. *kimjud@ulsan.ac.kr

V1.00193 The SQCRAMscope: Scanning Quantum CRyogenic Atom Microscope . RICHARD TURNER, JACK DISCIACCA, SHENGLAN QIAO, BENJAMIN LEV, Stanford University — Microscopy techniques co-opted from nonlinear optics and high energy physics have complemented solid-state probes in elucidating exotic order manifest in condensed matter materials. Up until now, however, no attempts have been made to use modern techniques of ultracold atomic physics to directly explore properties of strongly correlated or topologically protected materials. This poster will present the SQCRAMscope, a novel Scanning Quantum Cryogenic Atom Microscope technique for imaging magnetic and electric fields near cryogenically cooled materials. With our SQCRAMscope, we aim to image inhomogeneous transport and domain percolation in technologically relevant materials whose order has evaded elucidation.

V1.00195 Biological Cell Manipulation by Magnetic Nanoparticles , ALEXANDER KHITUN, FREDERICK GERTZ, University of California Riverside — We report experimental data on biological cells (erythrocytes) manipulation by magnetic (Fe3O4) nanoparticles. The experiments were accomplished on the top of the device consisting of two conducting contours. An electric current flowing through these contours generates a non-uniform magnetic field making magnetic nanoparticles to move towards the magnetic energy minima. In turn, magnetic nanoparticles drag biological cells in the same direction. We present experimental data showing cell manipulation by controlling the electric current. This technique allows us to capture and move cells located in the vicinity (5-10 microns) of the current-carrying wires. One of the most interesting results shows a periodic motion of erythrocytes, which frequency is controlled by the electric circuit. The obtained results demonstrate the feasibility of non-destructive cell manipulation by magnetic nanoparticles with micrometer-scale precision.

V1.00196 The Extended Core Coax: A Novel Nanoarchitecture for Electrochemical Sensing of Infectious Disease Biomarkers1, AMY E. VALERA, MICHELLE M. ARCHIBALD, JEFFREY R. NAUGHTON, TIMOTHY CONNOLLY, MICHAEL J. BURNS, THOMAS C. CHILES, MICHAEL J. NAUGHTON, Boston College — We report the development and fabrication of a novel nanoarchitecture for electrochemical sensing, the extended core coax (ECC). Each ECC is a vertically oriented nanocoax, comprised of an extended inner metal core and an outer metal shield, separated by a dielectric annulus. The inner (gold) and outer (chrome) metals serve as the working and counter electrodes, respectively, with the gold core working electrode, which protrudes ∼200 nm above the shield of the ECC. Additionally, the extended gold core provides a substrate for biofunctionalization, making the ECC an attractive candidate for further development towards electrochemical detection of infectious disease biomarkers such as cholera toxin. [1] B. Rizal, et al., Anal. Chem. 85, 10040 (2013).

V1.00197 Fabrication and characterization of MoS2 chemiresistor for pH sensing , FENG ZHAO, ALLEN LIM, ZECONG FANG, School of Engineering and Computer Science, Washington State University Vancouver — Chemical and biological sensing is critical in security, driving, navigation and other applications. Development and implementation of sensors with adaptable parameters would provide optimal use of sensing resources. Voltage-tunable, three-dimensional nanoscale profile created by charged quantum dots provides an effective tool to manage nanoscale processes. We experimentally investigate the effects of selective bipolar doping of quantum dot media on the dark current, noise current, photoresponse, and photoelectron lifetime. We also study the redistribution of the built-in dot charge under the voltage bias and tunability of the above characteristics. The preliminary results show a strong effect of nanoscale barriers on noise and photoresponse characteristics of IR nanomaterials.

V1.00198 Adaptable Quantum Dot Nanomaterials for IR Sensing , XIANZHANG, ANDREI SERGEEV, VLADIMIR MITIN, State Univ of NY - Buffalo, KIMBERLY SABLON, U.S. Army Research Laboratory, MICHAEL YAKIMOVA, SERGE OKTYABRYSKAYA, State Univ of NY - Albany, STATE UNIV OF NY - BUFFALO TEAM. U.S. ARMY RESEARCH LABORATORY COLLABORATION, STATE UNIV OF NY - ALBANY COLLABORATION — IR nanomaterials with the effective control of photoelectron processes will strongly enhance sensing technologies for security, driving, navigation and other applications. Development and implementation of sensors with adaptable parameters would provide optimal use of sensing resources. Voltage-tunable, three-dimensional nanoscale profile created by charged quantum dots provides an effective tool to manage nanoscale processes. We experimentally investigate the effects of selective bipolar doping of quantum dot media on the dark current, noise current, photoresponse, and photoelectron lifetime. We also study the redistribution of the built-in dot charge under the voltage bias and tunability of the above characteristics. The preliminary results show a strong effect of nanoscale barriers on noise and photoresponse characteristics of IR nanomaterials.
V1.00199 High performance multilayer surface plasmon sensors, KUNAL TIWARI, SURESH SHARMA, NADER HOZHABRI, University of Texas at Arlington — Though high performance SPR sensors are readily available, it remains desirable to fabricate sensors with enhanced sensitivity, resolution and evanescent fields for numerous applications. Since SPR characteristics of bimetallic (Ag/Au) and bimetallic waveguide coupled (Bi-WC) sensors are known to be better than those of single metal sensors, we have undertaken investigations of the performance of multilayer structures. We employ the transfer matrix method (TMM) for calculating SPR characteristics of such structures as functions of Ag/Au and Si$_3$N$_4$ waveguide thickness. Several quartz/Ag/Si$_3$N$_4$/Au structures were deposited in a class-100 clean room facility. The thicknesses of Ag and Au were fixed at 35 and 28 nm respectively. However, the thickness of the intermediate Si$_3$N$_4$ waveguide layer was varied from 50 - 150 nm. The SPR curves were measured for all these structures by using the Kretschmann configuration system. We observe excellent agreement between the experimental SPR data and computational results. For an optimized 150 nm thickness of Si$_3$N$_4$ waveguide, we observe high sensitivity to changes in the refractive index ($n$, $\approx$ 520/RIU), extremely narrow SPR curves ($FWHM \lesssim 0.28$, yielding high figure-of-merit of 60-180) and increased decay length of evanescent fields ($\delta \approx 258 \text{ nm}$).

V1.00200 Study of parameters for designing Barkhausen noise sensing elements using finite element analysis, NEELAM PRABHU GAUNKAR, ORFEAS KYPRIS, CAJETAN NLEBEDIM, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University — Barkhausen noise emissions occur in ferromagnetic materials on application of externally varying magnetic field. These emissions primarily occur due to the presence of pinning sites or discontinuities within the material which act as inhibitors to domain wall motion. The emissions can be sensed using an induction coil placed above the sample. This coil senses the variations in magnetic flux which translates to the induced emf. In this study, we optimize the design of the sensing coil with finite element simulations. The selection of optimum number of turns, choice of sensor core material and arrangement will be discussed. The approach to optimization of the sense-coil design will be presented.

V1.00201 Design details of a new positron beam system for materials studies$^1$, Z. H. LIM, R. GLADEN, VARGHESE ANTO CHIRAYATH, P.V. Joglekar, K. Shastery, A.R. Koymen, A.H. Weiss, Univ of Texas, Arlington — We report here the current status of the development of a state of the art high flux variable energy spin-polarized positron beam facility. Monoenergetic positrons are obtained using high efficiency rare gas moderator (RGM-1). This will allow us to collect data 100 times faster than our current beam system. This beam line will include a 2 meters Time-Of-Flight (TOF) tube, which will result in a higher energy resolution for the TOF spectrometer. The design of the beam line also allows for ambient pressure two gamma coincidence measurements. The ultra-high vacuum system for the beam line has been constructed and was tested for a vacuum of ~ 10$^{-8}$ mbar. The magnetic field for the positron transport has been achieved using a combination of Helmholtz and a series of short solenoid coils, and the magnetic field is ~ 40-100 gauss along the beam line. The E x B positron energy filter and the transport magnetic field were successfully tested using an electron beam. We will discuss the installation of the RGM-1 and the 2 meters TOF spectrometer to the beam line and the final beam tuning in conjunction with the SIMION simulation.

$^1$NSF DMR MRI 1338130

V1.00202 Simulation of the positron and electron trajectories for a new Time of flight (TOF) Spectrometer for positron annihilation induced Auger electron spectroscopy (PAES) with high flux positron beam$^1$, R. GLADEN, Z. H. LIM, VARGHESE ANTO CHIRAYATH, P. V. Joglekar, K. Shastery, A. R. Koymen, A. H. Weiss, Univ of Texas, Arlington — A new high flux positron beam line is under construction for TOF-PAES as well as for spin polarized coincidence Doppler broadening spectroscopy for surface characterization at the University of Texas at Arlington (UTA). This beam line has a high efficiency rare gas moderator system and employs a combination of axial and transverse magnetic fields for the selection of positron beam energy. The moderator system feeds the mono-energetic positron beam into the TOF-PAES system where transverse electromagnetic fields (trophoidal analyzer) allow the simultaneous passage of the positron beam and the electrons emitted from the sample. Here we describe the characteristics of the positron beam trajectories from the source to the target through this beam line using SIMION. These simulations have been used to optimize the axial and transverse magnetic field values at the energy selector as well as the electrostatic potentials at the trochoideal energy analyzer. The trajectories of the secondary electrons ejected from the sample as a result of the positron beam interaction are also described for various ejection angles and energies. These later simulations have been utilized to optimize the height of the channel plate used for the detection of electrons.

$^1$NSF DMR MRI 1338130

V1.00203 Anomalous scattering and redirection of sound in narrow liquid channels, ANDRIII BOZHKO, ARKADII KROKHIN, University of North Texas, VICTOR M. GARCIA-CHOCANO, JOSÉ SÁNCHEZ-DEHESA, Universidad Politécnica de Valencia — Propagation of sonic waves through a finite-length channel clad between two identical liquid-immersed metal plates with accounting for excitation of coupled surface Rayleigh waves propagating near metal-liquid interfaces is studied. The transmission coefficient is calculated for the wide range of frequencies of the incident sound wave, $f = 0.2 \pm 1.4 \text{ MHz}$. At discrete frequencies the transmission and reflection is anomalously suppressed that is shown to be accompanied by unusual redirection of sound from the liquid into metal at the edges of the channel. Proposed theory is in excellent agreement with experimental data obtained for water channels formed by Al and Cu plates.

V1.00204 Development and Characterization of Dynamic Light Scattering Instrumentation to Determine Nanoparticle Size$^1$, T.J. SEBASTIAN, J. HARDING, T. VOLPE, J.R. SIMPSON, M. SCHULZE, S.M. LEV, Towson Univ — Dynamic Light Scattering (DLS) provides a high-throughput and quantitative measurement of particle sizes for monodisperse (MD) spherical nanoparticles (NPs). We report on the development and characterization of homebuilt DLS instrumentation to measure the size of MD NPs of gold, polystyrene, and ZnO. HeNe and Ar-ion lasers comprise the excitation sources for the scattering experiment. An avalanche photodiode detects scattered light and an autocorrelation card analyzes the signal to provide a measurement of the translational diffusion coefficient, which for MD and spherical particles allows for the determination of NP radius. We have tested our apparatus using commercially produced gold NPs in the range of 10 nm to 200 nm and synthesized ZnO NPs. DLS measurements were compared to those obtained by Atomic Force Microscopy (AFM). After size characterization, the ZnO NPs will be employed in ongoing toxicity studies.

$^1$T.J.S. and J.H. acknowledge support from Towson University. J.R.S., M.S. and S.M.L. acknowledge support from NSF - CBET #1236083.
V1.00205 Super-resolution imaging using fluorescent soft micro-lens, KEXIN JIAO, PUNIT KOHLI, Department of Chemistry and Biochemistry, Southern Illinois University Carbondale, ANNIE LU, SRINIVASA RAGHAVAN, Department of Chemical & Biomolecular Engineering, University of Maryland, PUNIT KOHLI TEAM, SRINIVASA R. RAGHAVAN COLLABORATION — Spatial resolution of conventional optical microscope is limited by the diffraction of roughly half the wavelength of the incident light. Among strategies of obtaining resolution beyond the diffraction limit, near-field scanning optical microscopy (NSOM) is widely used. In previous work, we performed NSOM using a simple design constituted by attaching a glass micro-lens (MLs) or a liquid MLs on a cantilever. However, NSOM achieves super-high resolution sacrificing its mobility and imaging speed comparing with far-field imaging, especially when the specimen has uneven surfaces. In this work, we showed that a polydimethylsiloxane (PDMS) micro-sized sphere can be used as MLs as well. Images having enhanced contrast resolutions were achieved when the PDMS MLs was mechanically deformed along z-axis. On the other hand, the focal length of PDMS MLs can be tuned when being deformed by the pressure along x-axis. The scanning mobility of the whole device was further improved when attaching PDMS MLs onto a flexible cantilever. We also introduced different fluorophores into PDMS spheres, which resulting fluorescent MLs (FMLs). The advantages of FMLs involve the feasibility of locating MLs during a fluorescent imaging while having tunable focal length.

V1.00206 Compact scanning probe microscope with 3-D positioning capabilities, FERNANDO GARCIA, JORGE OLIVARES, FRANCISCO OLVERA, JULIE GERZINA, ALEX DE LOZANNE, University of Texas at Austin — We developed a new design for scanning probe microscopes (SPM) intended for low temperature operation. The main design philosophy is to make the SPM body compact and rigid, with an outer diameter of one inch. A secondary goal is to make this instrument easier to build, use and repair compared to our previous designs. While all the positioners are based on the stick-slip principle, the motion along the three axes is implemented very differently: motion along Z, or tip-sample approach, is accomplished by two vertical rods running along the length of the body. Motion along X is done by sliding on a single rod, and along Y by sliding the sample stage on top of the tube scanner used for generating images. Initial test results will be presented.

V1.00207 Photon Counting with an Embedded Micro Mojo V3 FPGA, SARA LENTRICCHIA, CARL GROSSMAN, Swarthmore College — We used an inexpensive Field Programmable Gate Array (FPGA) to generate time stamps from a photon counting experiment. The FPGA was configured to receive signals from an avalanche photodiode, latch onto a 32 bit, 400 MHz clock/counter, and transmit the time stamps to a host computer. These time stamps were then analyzed on the host machine in real time to calculate the intensity auto-correlation function of the signal source, in our case a fluorescence correlation spectroscopy experiment. The basic state machines for the system are a clock/counter/trigger, FIFO data buffer, and serial I/O to an onboard processor that handles communication with the host. The trigger state machine is similar to a clock except the cycle is based on the signal positive edge. The trigger cycle stores the counter and initiates data transfer to the FIFO buffer.

V1.00208 Construction for Cryogen free 3He/4He dilution refrigerator integrated with conduction cooled 15T magnet, JUNGHYUN SHIN, SUN-GYU PARK, EUNSEONG KIM, Center for Supersolid and Quantum matter Research and Department of physics, KAIST — We constructed a cryogen-free 3He/4He dilution refrigerator (DR) integrated with a conduction cooled 15T superconducting magnet. The integrated magnet and 3He/4He dilution system is precooled by a commercial two stage pulse tube refrigerator (PTR). 3He/4He mixture gas compressed at 4 Bar is first introduced into the heat exchangers mounted on the first (40K) and the second (2.5K) stage of PTR. The mixture is condensed at the second stage without Joule-Thomson stage due to its high pressure. Once the liquid 3He/4He mixture is obtained, a conventional DR design including a still, counterflow heat exchangers, and a mixing chamber is adopted for the continuous operation. The 15T superconducting magnet is directly connected to the second stage and cooled by conduction cooling down to about 3K after being pre-cooled with liquid N2 flow. The current leads for superconducting magnet up to 120A require careful considerations of low thermal-conductance with high electrical-conductance and robust electrical isolation.

V1.00209 The power of three-dimensional imaging for an unambiguous identification of the ro-vibrational state of H$_2^+$, D$_2^+$, and HD$^{+1}$, J.B. SAUZI, C.I. GUILLEN, A.C. DUOT, V.M. ANDRIANARUADNO, Department of Physics, Pacific Union College, Angwin, CA 94508 — We are presenting a three-dimensional imaging technique that could efficiently measure the ro-vibrational states of small diatomic molecular ions such as H$_2^+$ in two steps. First, the molecular ion is sent toward a jet of alkali atoms to undergo a resonant dissipative charge exchange. Then, the positions of the fragments and their flight time difference are measured with two position sensitive detectors. From these measurements, we obtained the value of the kinetic energy release, which is directly related to the original vibrational excitation of H$_2^+$. This technique scheme was first developed by D. P. de Brujin and J. Los (Rev. Sci. Instrum. 53, 1020, 1982). Details and examples will be presented.

V1.00210 The speed of light is the inflection point matter and dark matter, YONGQUAN HAN, 15811860790 — The gravitational field of the object is due to radiation and rotation. The reason of the objects can radiation is that linear velocity of objects rotation is less than the speed of light. When the linear velocity of object rotation is equal to the speed of light, the object won’t radiate any more, radiate particle(electromagnetic wave particle) rotate by the radius of itself radius, now the state is the inflection point of the matter and dark matter. The rotation of the object’s gravitational field radius equal to the radius of the object, and then continue to change that is dark matter, the velocity of dark matter rotation is faster than the light. Dark matter rotation doesn’t radiate. The gravitational field radius is equal to the radius of the dark matter, that is why dark matter is difficult to be observed also detected. The curvature of the radiation—the the linear velocity of the object divide the speed of the light. The rotation speed of the object—the speed of light multiply the linear velocity and then divide the radius of the object.

V1.00211 Examination of Humidity Effects on Measured Thickness and Interfacial Phenomena of Exfoliated Graphene on SiO$_2$ via AC-AFM, KATHERINE JINKINS, JORGE CAMACHO, LEE FARINA, YAN WU, Univ of Wisconsin, Platteville — Tapping (AC) mode Atomic Force Microscopy (AFM) is commonly used to determine the thickness of graphene samples. However, AFM measurements have been shown to be sensitive to environmental conditions such as adsorbed water, in turn dependent on relative humidity (RH). In the present study, AC-AFM is used to measure the thickness and loss tangent of exfoliated graphene on silicon dioxide (SiO$_2$) as RH is increased from 10% to 80%. We show that the measured thickness of graphene is dependent on RH. Loss tangent is an AFM imaging technique that interprets the phase information as a relationship between the stored and dissipated energy in the tip-sample interaction. This study demonstrates the loss tangent of the graphene and oxide regions are both affected by humidity, with generally higher loss tangent for graphene than SiO$_2$. As RH increases, we observe the loss tangent of both materials approaches the same value. We hypothesize that there is a layer of water trapped between the graphene and SiO$_2$ substrate to explain this observation. Using this interpretation, the loss tangent images also indicate movement and change in this trapped water layer as RH increases, which impacts the measured thickness of graphene using AC-AFM.
V1.00213 Long-range interaction of anisotropic systems. JUN-YI ZHANG, UDO SCHWINGENSCHLÖGL. Division of Physical Science & Engineering, King Abdullah University of Science and Technology — The first-order electrostatic interaction energy between two far-apart anisotropic atoms depends not only on the distance between them but also on their relative orientation, according to Rayleigh Schrödinger perturbation theory. Using the first-order interaction energy and the continuum model, we study the long-range interaction between a pair of parallel graphene sheets. The asymptotic form of the obtained potential density, \( \epsilon(D) \propto -D^{-3} - O(D^{-4}) \), is consistent with the random phase approximation and Lifshitz theory. Accordingly, neglectance of the anisotropy, especially the nonzero first-order interaction energy, is the reason that the widely used Lennard-Jones potential approach and dispersion-corrections in density functional theory give a wrong asymptotic form, \( \epsilon(D) \propto -D^{-4} \).

This work is supported by the King Abdullah University of Science and Technology (KAUST).

V1.00214 Moments and Lanczos Study of the Anisotropic One Dimensional XY Model in a Skewed Magnetic Field, JUN HUI LIANG, ZHI HUA CHENG, YICK HONG CHAN, Kingsborough Community College of CUNY, ERIC ASHENDORF, Brooklyn College, J.D. MANCINI, Kingsborough Community College of CUNY, V. FESSATIDIS, Fordham University, S.P. BOWEN, Chicago State University — Here we wish to study the ground-state and energy gap of the one dimensional spin \( \frac{1}{2} \) anisotropic antiferromagnetic XY Heisenberg model given by

\[
H = \sum_{i=1}^{N} \left[ (1 + \gamma) S_i^x S_{i+1}^x + (1 - \gamma) S_i^y S_{i+1}^y - h (1)^i S_i^z \right]
\]

where \( \gamma \) is the anisotropy parameter and \( h \) is an external magnetic field. We shall investigate the ground-state energy as well as the energy gap as a function of both the anisotropy parameter as well as the number of holes as a function of the external magnetic field.

Authors Liang, Cheng, Chan, and Ashendorf are undergraduate students.

V1.00215 Moments and Lanczos Study of the Anisotropic One Dimensional \( t-J \) Model with Holes, YICK HONG CHAN, JUN HUI LIANG, ZHI HUA CHENG, Kingsborough Community College of CUNY, ERIC ASHENDORF, Brooklyn College, J.D. MANCINI, Kingsborough Community College of CUNY, V. FESSATIDIS, Fordham University, S.P. BOWEN, Chicago State University — In this work we wish to study the ground-state energy as well as the energy gap of the one-dimensional \( t-J \) model given by

\[
H = \sum_{i} \left[ S_{i+1}^x S_i^x + \frac{1}{2} \alpha \left( S_{i+1}^y S_i^y + S_{i+1}^z S_i^z \right) \right]
\]

where \( \alpha \) is the anisotropy parameter. We will investigate both the ground-state energy as well as the energy gap as the number of holes is increased for lattices of length 16 sites.

Authors Chan, Liang, Cheng, and Ashendorf are undergraduate students.

V1.00216 A Variational Moments Approach to the One Dimensional Hubbard Model, ZHI HUA CHENG, YICK HONG CHAN, JUN HUI LIANG, Kingsborough Community College of CUNY, ERIC ASHENDORF, Brooklyn College, J.D. MANCINI, Kingsborough Community College of CUNY, V. FESSATIDIS, Fordham University, S.P. BOWEN, Chicago State University — In this work we shall study the one dimensional Hubbard model

\[
H = t \sum_{i=1}^{N} c_i^\dagger c_i \delta_{ij} + \frac{1}{2} \alpha \left( c_i^\dagger c_{i+1}^\dagger c_i^\sigma c_{i+1} + c_i^\dagger c_{i+1}^\dagger c_{i+1}^\sigma c_{i} \right) + U \sum_{i} n_{i\uparrow} n_{i\downarrow}
\]

using both a connected moments approach as well as a Lanczos triadiagonal scheme. Following the work of Eichenberger and Baeriswyl (PRB 76, 180504(R), 2007) we use a modified variational wavefunction which includes the hopping term of the Hamiltonian. Our results show a marked improvement in our estimation of the ground-state energy in the region of intermediate coupling \( t/U \approx 0.1 \).

Zhi Hua Cheng, Yick Hong Chan, Jun Hui Liang and Eric Ashendorf are undergraduate students.

V1.00217 Quantum Monte Carlo Applied to Binary Transition Metal-Oxides, JUAN A. SANTANA, Oak Ridge Assoc Univ, JARON T. KROGEL, CHANDRIMA MITRA, PAUL R.C. KENT, FERNANDO REBOREDO, Oak Ridge National Laboratory — Materials based on transition metal-oxides (TMO) play a central role in many applications and in the fundamental research of advanced materials. However, this class of materials is one of the most challenging for computation. The standard computational methods to study them are based on Density Functional Theory (DFT), which often fails to provide the required level of accuracy. A natural solution to overcome the intrinsic limitations of DFT approximations is to directly solve the many-body problem in TMO. For large systems, this can be made practical by applying quantum Monte Carlo (QMC) methods. These methods are very expensive computationally, but recent developments in algorithms and computational infrastructures have enabled their application to real materials. We will show that QMC methods, such as diffusion Monte Carlo (DMC), are now practical to study multiple properties of TMO. The application of DMC to study the structural, electronic and ionic defect properties of various binary TMO, including FeO, CoO, NiO, and ZnO will be discussed. We will also outline current limitations in hardware and algorithms.

The work is supported by the Materials Sciences & Engineering Division of the Office of Basic Energy Sciences, U.S. Department of Energy (DOE).
V1.00218 A GPU enhanced approach to identify atomic vacancies in solids materials\textsuperscript{1}. JOAQUIN PERALTA, CLAUDIA LOYOLA, Universidad Andres Bello, SERGIO DAVIS, Universidad de Chile — Identification of vacancies in atomic structures plays a crucial role in the characterization of a material, from structural to dynamical properties. In this work we introduce a computationally improved vacancy recognition technique, based in a previous developed algorithm. The procedure is based in the use of Graphics Processing Unit (GPU) instead of Central Processing Unit (CPU), taking advantage of random number generation as well the use of a large amount of simultaneous threads as available in GPU architecture, improving the spatial mapping in the sample and the speed during the identification process of atomic vacancies. The results show that with this technique, efficiency is improved. Along with the above a reduction of required parameters in comparison with the original algorithm is presented. We show that only the lattice constant and a tunable overlap are enough as input parameters in the process, and are also highly related. A study of those parameters is presented, suggesting how the parameter choice must be addressed. Benchmarks were made using one standard CPU and GPU between the original code and the present work, revealing an improvement in the execution time.

V1.00219 A Time Parallel Implementation of the Time Decomposition Strategy for the Dirac equation. HYUN LIM, South Dakota State Univ, ARTHUR KURLEJ, University of Massachusetts, Amhrest, JUNG-HAN KIM, South Dakota State Univ — For certain formulations of partial differential equations, proper time-space pre conditioners can be successfully applied in space-time finite element simulations. Such an approach may enable the extraction of more parallelism to better utilize high performance computing resources. In this work, we examine the behavior of the gauge free, low-mass regime Dirac equation using space-time finite elements. The purpose of this research is to present a stable parallel implementation algorithm of the physical system. We discretize space and time together for the entire domain using a finite element space which does not separate space and time basis functions. We also explore the effectiveness of the time decomposition pre conditioner, additive Schwarz preconditioner with KSP (Krylov Subspace Methods) solvers for this problem. We show that proper time parallel implementation allows for physically intuitive boundary conditions, improvement of numerical efficiency, and reduces the overall error of the computed solution

V1.00220 A Multiscale computational approach to predict the elastic deformation fields in Moiré Patterns of 2D van der Waals interfaces and heterostructures. HEMANT KUMAR, VIVEK SHENOY, University of Pennsylvania — Recent technological advancements in isolation and transfer of different 2-dimensional (2D) materials have led to renewed interest in Van der Waals (vdW) heterostructures. We report a multiscale computational method to predict the deformation of vdW heterostructures using density functional theory (DFT) informed continuum simulations. We validate our method by comparing its predictions with all atom atomicistic simulations for the graphene-hBN bilayer system and computing the in-plane strains, local curvature for different misorientation angles between two lattices. We also present closed form solutions for the elastic field as a function of lattice mismatch, relative rotations and predict the deformation fields for MoS2-WSe2, MoSe2-WSe2 systems that have been recently synthesized experimentally.

V1.00221 Atomistic Computational Model of Radiation Damage of Nano-sized Systems in Intense X-ray Pulses\textsuperscript{1}. PHAY HO, CHRISTOPHER KNIGHT, LINDA YOUNG, Argonne National Laboratory — We present a combined Monte-Carlo/molecular- dynamics (MC/MD) computational model that is suitable for monitoring the physics of intense, femtosecond XFEL pulses interacting with complex systems of various sizes, from nanometers to micrometers, and matters of various compositions. In this model, the occurrences of x-ray absorption, ionization, relaxation and electron-impact processes are treated by a MC method, and the subsequent dynamics of the all the electrons, ions and atoms are tracked using an MD method. Our model extends previous MC/MD model and provides new capabilities to probe the impacts of transient states on radiation damage dynamics. Recently, we have added LAMMPS as the driver of MD dynamics. This is a critical addition as now our code can run on Mira, a new petascale supercomputer with 786K core processors at the Argonne Leadership Computing Facility. Also, it can treat micron-sized systems with trillions of particles and both homogeneous and heterogeneous composition. Using our model, we examine the ionization dynamics of Argon clusters in an XFEL pulse as a function of particle sizes and pulse parameters, and we compare our results with the experimental data [S. Schorb \textit{et al.}, \textit{PRL} 108, 233401 (2012)].

V1.00222 Easy GROMACS: A Graphical User Interface for GROMACS Molecular Dynamics Simulation Package. AYTEN DIZIKIRICI, MUSTAFA TEKPINAR, Yuzuncu Yil University — GROMACS is a widely used molecular dynamics simulation package. Since it is a command driven program, it is difficult to use this program for molecular biologists, biochemists, new graduate students and undergraduate researchers who are interested in molecular dynamics simulations. To alleviate the problem for those researchers, we wrote a graphical user interface that simplifies protein preparation for a classical molecular dynamics simulation. Our program can work with various GROMACS versions and it can be performed essential functions of GROMACS trajectories as well as protein preparation. We named our open source program ‘Easy GROMACS’. Easy GROMACS can give researchers more time for scientific research instead of dealing with technical intricacies.

V1.00223 Calculating Relativistic Transition Matrix Elements for Hydrogenic Atoms Using Monte Carlo Methods. STEVEN ALEXANDER, Southwestern University, R.L. COLDWELL, Retired — The nonrelativistic transition matrix elements for hydrogen atoms can be computed exactly and these expressions are given in a number of classic textbooks. The relativistic counterparts of these equations can also be computed exactly but these expressions have been described in only a few places in the literature. In part, this is because the relativistic equations lack the elegant simplicity of the nonrelativistic equations. In this poster I will describe how variational Monte Carlo methods can be used to calculate the energy and properties of relativistic hydrogen atoms and how the wavefunctions for these systems can be used to calculate transition matrix elements.

V1.00224 Automated discovery of novel solid-state ionic conductors enabled by large-scale molecular dynamics computations. BORIS KOZINSKY, PRATEEK MEHTA, Bosch Research, Cambridge MA — Fast solid-state inorganic Li-ion conductors offer a path toward safer batteries with high energy density, but apart from a few material classes, the inorganic solid-state space remains mostly unexplored. Computational approaches using density functional theory (DFT) have been proven to be successful for the design of electrode materials, but have had few applications for the discovery of electrolytes. This is because the physiochemical factors that regulate ionic conductivity are poorly understood, and conductivity can be very sensitive to small structural and compositional variations. In this work, we present relationships between the ionic conductivity and several potential structural descriptors, like the size and dimensionality of ion-conducting pathways, void fraction, Li-concentration, sensitivity to volume change, etc. We identify these relationships from massive ab-initio molecular dynamics simulations on a comprehensive dataset of approximately 1500 crystalline materials. Our investigation is enabled by computational resources at the Oak Ridge Leadership Computing Facility and the high-throughput automation platform AiiDA.
V1.00225 First Principles Study of Phosphor Host Materials
CLAIRE-ALICE HEBERT, Physics Department, University of California Santa Barbara, RAM SESHADEH, Materials Research Lab, University of California Santa Barbara — Solid state lighting uses light-emitting diodes (LEDs) instead of incandescent filaments. Blue LEDs are combined with an inorganic phosphor consisting of a host lattice doped with Ce$^{3+}$. Electronic transitions between the 4f and 5d levels convert blue light from the diode to light ranging from green (~510 nm) to red (~700 nm) and the combination of yellow with blue creates white light. The most efficient phosphors have been found to have rigid crystal structures, along with band gaps large enough that the 4f to 5d transition of the dopant ion can occur without interference. Using Debye temperature as a proxy for structural rigidity, we use density functional theory (DFT) to calculate and plot $\Theta_D$ versus band gap to give us a prediction of phosphor suitability for forty different materials. PBE functionals and the quasi-harmonic Debye model were used to estimate $\Theta_D$, and band gaps were calculated with a hybrid functional. DFT was also used to probe six potential host materials more closely: AIO$_3$, LaBr$_3$, Ba$_2$SiO$_4$, Sr$_2$SiO$_4$, Sr$_2$Si$_2$N$_8$, and Y$_3$Al$_5$O$_{12}$. The electronic states of these compounds were aligned with vacuum using a supercell slab model and will be compared with the Ce$^{3+}$ levels to determine suitability as host materials.

V1.00226 Transport properties of carbon dioxide and ammonia in water - ethylene glycol mixtures from molecular dynamics simulations
EUGENIYA ISKRENOVA, Air Force Research Laboratory - WPAFB and UES, Inc., SOUMYA S. PATNAIK, Air Force Research Laboratory - WPAFB, OH 45433 — The endothermic decomposition of ammonium carbamate has been proposed as a novel heat sink mechanism for aircraft thermal management (Johnson et al. SAE Technical Paper 2012-01-2190, 2012, doi:10.4271/2012-01-2190). The products of this decomposition are carbon dioxide and ammonia which need to be efficiently removed in order to better control the decomposition reaction. Molecular dynamics simulations can provide insight into the transport properties of carbon dioxide and ammonia in the carrier fluid. In this work, an extensive set of molecular dynamics simulations was performed to better quantify the concentration dependence of solubility and diffusivity of carbon dioxide and ammonia in water, ethylene glycol, and their mixtures at standard temperature and pressure and at elevated temperature. The simulation results confirm the experimental observations that ammonia is more soluble than carbon dioxide in either water or ethylene glycol and that both carbon dioxide and ammonia are more soluble in ethylene glycol than in water. The simulations of water - ethylene glycol mixtures show that increasing the molar fraction of ethylene glycol leads to increased solubility of carbon dioxide and ammonia in the mixture.

V1.00227 A Simple Pythagorean Interpretation of $E^2 = p^2c^2 + (mc^2)^2$
J.A. TOBAR, E.L. VARGAS, V.M. ANDRIANARIJAONA, Department of Physics, Pacific Union College, Angwin, CA 94508 — We are considering the relationship between the relativistic energy, the momentum, and the rest energy, $E^2 = p^2c^2 + (mc^2)^2$, and using geometrical means to analyze each individual portion in a spatial setting. The aforementioned equation suggests that $p$ and $mc^2$ could be thought of as the two axis of a plane. According to de Broglie’s hypothesis $\lambda = h/p$ therefore suggesting that the $p$c-axis is connected to the wave properties of a moving object, and subsequently, the $mc^2$-axis is connected to the particle properties. Consequently, these two axis could represent the particle and wave properties of the moving object. An overview of possible models and meaningful interpretations will be presented.

V1.00228 A Testable Unified Theory That Works
DONALD CHAKERES, The Ohio State University, RICHARD VENTO, Retired, Columbus State Community College — The harmonic neutron hypothesis is a unified theory of a dimensionally consistent harmonic point space defining physical phenomena. It is based on equality-pair transformations (EPTs), of the $n^i$; $e_0^i$; and the Rydberg constant, R, and 3 finite integer sets: $(V_i)$, defined below; the first 12 natural numbers to derive the first generation of particles and bosons; and a finite set of primes for higher generations. All of the derivations/predictions are made using the natural units and the 3 number sets. The purpose is to demonstrate that it is possible to derive, sets of integers, which inter-relate and predict many of the physical constants from Planck time to the Higgs boson starting with just these 4 sets within a harmonic system. All the physical constants are evaluated as frequency equivalent ratios. The fundamental EPT is based on the transformation of electromagnetic energy into matter via the set $(V_i)$, scaled from neutron pair production. Elements $v_i$ in $(V_i)$ are based on the ratio of the annihilation frequency equivalent of the neutron and 1 Hz, $2.271859078 \times 10^{21}$ Hz.

V1.00229 Several notes on physics
XIAO-FAN CHEN, Harbin Institute of Technology — Several notes on physics are presented, which include our views of quantum mechanics, general relativity, special relativity, electric charge, nonlinear electrodynamic, general transformation in hyperspace, solutions to equations of operators, superstring, shapes of particles and statistical mechanics.

V1.00230 SURFACES, INTERFACES AND THIN FILMS

V1.00231 A direct measurement of built-in potential across LaAlO3/SrTiO3(001) heterojunctions
YANG ZHOU, DI WU, Nanjing Univ — The quasi-two-dimensional electron gas (q2DEG) at the oxide interface LaAlO3/SrTiO3 has attracted a lot of attention in recent years due to its rich phenomena. The ?polar catastrophe? model is one of the conducting mechanisms, which relies on the polar potential built-in LaAlO3 layer. Although several experiments have been tried to measure the electrostatic potential in LaAlO3, the magnitude of the polar potential is still under debate.[1][2][3] We present a systematically study on the electronic transport properties of the LaAlO3/SrTiO3 interface capping with several different metals, whose work functions vary from 4.28 to 5.6 eV. The barrier height between the capping layer and the q2DEG estimated by the tunneling resistance shows strong correlation with the metal work function. The carrier density of q2DEG increases as decreasing the capping metal work function. These results strongly suggest the existence of the built-in potential in LaAlO3 and the residual polar potential is estimated to be 1.3 eV. [1]E. Slooten, et al, Phys. Rev. B 87, 085128 (2013). [2]H. Liang, et al, Sci. Rep. 3, 1975 (2013). [3]G. Berner, et al, Phys. Rev. B 88, 115111 (2013).

V1.00232 Surface structures and defect control during epitaxy of crystal
LIXIN ZHANG, Nankai University — In this talk, I will show a few examples in which the surface structures play important roles on the defect incorporation into the crystal lattice. The surface orientations and the atomic structures have strong influence on the solubility, the type, and even the direction of the incorporated defects.

V1.00233 First-principles studies of S-doping and adsorption with hematite $\alpha$-Fe$_2$O$_3$ (0001) film
JIAO AN, PRABATH WANAGURU, QIMING ZHANG, University of Texas at Arlington — Based on spin-polarized density functional theory, we have investigated the atomic, electronic, and magnetic structures of hematite $\alpha$-Fe$_2$O$_3$ (0001) film. An S atom adsorption on the surface of the film has then been studied. The preferred site on the surface has been identified. The changes of the electronic structure of the film have been analyzed when an O atom is substituted by an S atom at different locations inside the film. The change with the concentration of S-doping will also be discussed.

2 Authors wish to give special thanks to Pacific Union College Student Senate in Angwin, California, for their financial support.
V1.00234 Revisitation of the frictional properties of Si02 as the LFM (lateral force microscopy) reference1, SUNG HYUN KIM, SUENNE KIM, Department of Applied Physics, Hanyang University — Recently, experimental studies concerning frictional properties at the nanoscale using AFM (atomic force microscopy), specifically with LFM, are made on various kinds of materials including noble 2D graphene sheets and 1D nanotubes. The LFM technique requires calibration of a stable substrate as a reference of importance. Si02 is often used as the standard to calibrate LFM data obtained from a material of interest. However, according to our observation, the friction of cleansed Si02 substrate can change gradually by long-time continuous LFM scanning. The friction increases up to about 1.5 times (50%) in comparison to the initial state while minute topographical difference, at the Å level, is detected. The friction depends on the number of scanning events, and the change follows an inverse exponential function, \( F(t) = A(1-\exp[-Bt]) + F(0) \), where \( F \) is friction, \( t \) means time when continuous measurements are made, and \( A, B, F(0) \) are constants. Here, friction shift accompanied by z-scanner movement has been observed concurrently and corrected for the long-time AFM measurements. In this regard, proper correction for the LFM shift induced by the z-scanner drift will also be introduced.

V1.00235 ABSTRACT WITHDRAWN —

V1.00236 Determination of Superlattice Effect on Hafnium nitride/Vanadium nitride Nanostructures, P. PRIETO, CENM Universidad del Valle, J.C. CAICEDO, C. ESCOBAR, Material Department Universidad del Valle, M.E. GOMEZ, CENM Universidad del Valle, MATERIAL DEPARTMENT UNIVALLE TEAM, CENM UNIVALLE TEAM — Binary nitrides multilayers systems were grown on silicon (100) substrates with the aim to study the coherent assembly in HfN/VN material. The multilayers films were grown via reactive r.f. magnetron sputtering technique by systematically varying the bilayer period (\( \Lambda \)) and the bilayer number (\( n \)) while maintaining constant the total coating thickness (\(~2.4 \mu m\)). The multilayers were characterized by High system X-ray diffraction (HA-XRD), low angle X-ray diffraction (LA-XRD), HfN and VN layers were analyzed by X-ray Photoelectron Spectroscopy (XPS) and electron and transmission microscopy (TEM). HA-XRD results showed preferential growth in the face-centered cubic (111) crystal structure for HfN/VN multilayers system with the epitaxial relation (111)[100]HV//\langle200\rangle[100]HV. The maximum coherent assembly was observed with presence of satellite peaks. With this idea, ternary and binary nitrides films have been designed and deposited on Si (100) substrates with bilayer periods (\( \Lambda \)) in a broad range, from nanometers to hundreds of nanometers to study the structural evolution, coherent assembly progress and optical properties like The critical angle, dispersion coefficient, index of refraction for HfN/VN multilayers with decreasing bilayer thickness.

V1.00237 The thickness dependence of surface energy and contact angle of water on ultrathin MoS2 film1, YANHUA GUO, College of Materials Science and Engineering, Nanjing Tech University; Department of Materials Science and Engineering, University of Utah, FENG LIU, Department of Materials Science and Engineering, University of Utah — The properties of ultrathin 2D materials generally show a strong thickness dependence. Using first-principles methods, we have systematically calculated surface energy and surface stress of MoS2 films as a function of thickness from one to 12 layers, using two van der Waals functional based approaches (vdW-DF and DFT-D2). Based on the calculated surface energies, which increases with the increasing thickness, we further analyze the surface contact angle of water droplet on MoS2 film surface using Young’s equation as a function of thickness, in comparison with experiments, from which the water-MoS2 interfacial energy and its MoS2 thickness dependence is derived. These results will be useful for future studies of physical and chemical properties of ultrathin MoS2 films.

1This work is supported by China Scholarship Council (Grant No. 201408320015) and DOE-BES (Grant No. DEFG02-04ER46148).

V1.00238 Integration of a DC magnetron sputtering system into an ultra-high vacuum chamber for fabrication of Schottky diodes1, NICHOLAS Pieniazek, CHRISTOPHER DURCAN, ROBERT RALSON, VEINCENT LABELLA, The College of Nanoscale Science and Engineering — A DC magnetron sputtering system was installed into a UHV chamber for sputtering of metal thin films with little contamination. Control of the DC power, chamber pressure and deposition time is crucial to deposit metal films with reproducible thicknesses and topographies. A graphical user interface was created to efficiently control all potential process variations. Thin films of tungsten were deposited on both n-Si and p-Si using Argon as the ionizing gas. Scanning tunneling microscopy was used in situ to analyze the surface roughness. Ballistic electron emission microscopy was utilized to provide nanometer scale insight into the homogeneity of the tungsten-silicon Schottky barrier.

1Schottky Diode UHV Deposition and Analysis Processes

V1.00239 Depth-Resolved X-Ray Reciprocal Space Mapping for Surface Microstructure Measurements, FRANCES WILLIAMS, Norfolk State University, KELI HU, QIGUANG YANG, UltraHighScore LLC, XIN ZHAO, Vertical Carbon Technologies, Inc. ANNE-MARIE VALENTE-FELICIANO, CHARLES REECE, Thomas Jefferson National Accelerator Facility — A depth-resolved X-ray reciprocal space mapping technology has been developed to investigate crystal microstructures from top of the surface to few micrometers under the surface. The depth-dependent microstructures were successfully used to reveal structure evolution occurred in both crystal-growth process and post growth treatments in few different thin films and/or crystals. Our results show that depth-resolved reciprocal space mapping is a powerful tool to monitor thin film and/or crystal microstructures and provide important information for optimization of the crystal-growth process and post-growth treatments.

V1.00240 Depth of origin of sputtered atoms and isotopic angular distribution of atoms sputtered from metal alloys, NARESH DEOLI, KARL HASENSTEIN, LOUIS HOUSTON, Univ of Louisiana, DUNCAN WEATHERS, Univ of North Texas, LOUISIANA ACCELERATOR CENTER TEAM, ION BEAM MODIFICATION AND ANALYSIS LABORATORY COLLABORATION — Angular distribution of atoms sputtered from the surface and the near surface region under ion bombardment provides critical information about the sputtering mechanism. In the present study Monte-Carlo based SRIM simulation is used to explore the depth dependent energy and angular distribution of the sputtered atoms from liquid metal alloys, Ga:In and Ga:Bi, using normally incident keV Ar ions. These alloys are known to exhibit Gibbvsan segregation where lightly bound species tend to segregate on the top of the alloy. The isotopic distributions of sputtered atoms from the alloy are also presented.
the thermal conductivity $\kappa$ showed that the conductivity and thermoelectric power are conveyed by electrons with different effective masses in the Brillouin zone. In point of view masses contribute to different transport phenomena in the crystal. The discrepancy between the effective mass for the conductivity and the thermoelectric mechanism behind the high power factor from calculation about the transport properties. The key to understanding the power factor is that different effective calculation about layered oxychalcogenides. In addition, we calculated thermoelectric properties Blotch-Boltzmann equation, semi-classically. We indicate the for new type thermoelectric materials. Firstly, from DFT and DFPT calculations, we performed the electronic structure calculation and the thermal structure FUNASHIMA, Osaka Univ — In order to restrain global warming and realize a sustainable global energy system, the researches of various energy resources are

thin 2D crystals, including graphene, hexagonal boron nitride (hBN), molybdenum disulphide (MoS$_2$) etc.; at the same time pristine graphene and other 2D materials are impermeable to molecules and atoms including helium. Protons represent somewhat intermediate case, which, together with the fact that hydrogen technologies are extremely important nowadays, motivated us to study proton permeation through thin 2D crystals. Employing both liquid and solid proton conducting electrolytes we demonstrate that monolayers of graphane and hBN are permeable to protons at ambient conditions, while MoS$_2$, bilayer graphene and multilayer hBN show no proton conduction. Temperature dependence confirms the thermionic nature of the proton permeation with the activation energies of 0.3, 0.6 and 0.8 eV for monolayer hBN, monolayer graphene and bilayer hBN, respectively. Our findings suggest that atomically thin crystals can be promising for various hydrogen technologies, for instance, as proton exchange membranes for fuel cells.

Visualization of Exciton Transport in Molecular and Quantum Dot Solids, GLEB AKSELROD, PARAG DEOTARE, FERRY PRINS, NICHOLAS THOMPSON, LISA POULIKAKOS, ELIZABETH LEE, MARK WEIDMAN, JOLENE MORK, JIYE LEE, ADAM WILLARD, MARCO BALDO, Center for Excitons, Center of Materials Science, Massachusetts Institute of Technology, VINOD MÉNON, City College of New York, WILLIAM TISDALE, VLADIMIR BULOVIC, Center for Excitons, Massachusetts Institute of Technology — Transport of nanoscale energy in the form excitons is at the core of the operation of a wide range of nanostructured optoelectronic devices such as solar cells, light emitting diodes and excitonic transistors. Particularly important is the relationship between exciton transport and nanoscale disorder, the defining characteristic of molecular and nanostructured materials. Here we report a spatial, temporal, and spectral visualization of exciton transport in molecular crystals and quantum dot solids. Using tetracene as an archetype molecular crystal, the imaging reveals that exciton transport occurs by random walk diffusion, with a transition to subdiffusion as excitons become trapped. By controlling the morphology of tetracene, we show that the transition to subdiffusive transport occurs at earlier times as disorder is increased. In colloidal quantum dot films, we show that diffusion does not occur by a random-walk process; instead, energetic disorder causes the exciton diffusivity to decrease over time. Our findings demonstrate that the mechanism of exciton transport depends strongly on the nanoscale morphology and disorder.

Self-consistent theory of helium atom scattering by a thermally excited monolayer solid, L.W. BRUCH, Dept. of Physics, Univ of Wisconsin-Madison, F.Y. HANSEN, Dept. of Chemistry, Technical University of Denmark — The inelastic scattering of a helium atom beam by an incommensurate monolayer solid of Xe/Ph(111) for incident energies in the range 4 – 16 meV and monolayer temperatures of 25 – 75 K is evaluated self-consistently (SC) in the one-phonon approximation. The target is very corrugated and the final scattering state comprises strong diffraction and inelastic terms. At 50 and 75 K, the atom energy gain (phonon annihilation) processes have strength comparable to the energy loss (phonon creation) processes; there are pervasive and large departures from expectations based on weak-coupling detailed balance ratios. The SC results are compared to experimental data and to results from a simpler non-self-consistent approximation (NSC) that relies on harmonic approximations to the Debye-Waller attenuations of elastic and inelastic strengths. There are major differences in the trends seen in the SC and NSC results.

EN能, RESEARCH AND APPLICATIONS

Transient Heat Conduction in Strongly Correlated Systems, RITA AGHJAYAN, ARTHUR LUNIEWSKI, KAMIL WALCZAK, Department of Chemistry and Physical Sciences, Pace University, 1 Pace Plaza, New York, NY 10038, NANOscale PHYSICS DIVISION TEAM — We examine the electronic heat transport phenomena in nanoscale junctions composed of organic molecules weakly coupled to two heat reservoirs of different temperatures. The electronic heat flux and its dynamical noise properties are calculated within the scattering (Landauer) formalism with the transmission probability determined by using non-equilibrium Green’s functions technique. The perturbative computational scheme is used to determine nonlinear corrections to the electronic heat flux and its noise power spectral density with up to the second order terms in relation to the temperature difference. Our results show the limited applicability of ballistic Fourier’s law and the fluctuation-dissipation relations to nanoscale heat flow carried by electrons. Further, we discuss the influence of quantum interference and dimensionality of heat reservoirs onto the transport characteristics and shot noise spectra related to molecular systems under consideration. Importantly, the nonlinear transport theory developed by us may be extended to higher order terms to address a huge variety of problems associated with nonlinear thermal effects, which may occur at nanoscale.

Nonlinearities and Noise Properties of Electronic Heat Transfer in Molecular Junctions, ARTHUR LUNIEWSKI, RITA AGHJAYAN, KAMIL WALCZAK, Department of Chemistry and Physical Sciences, Pace University, 1 Pace Plaza, New York City, NY 10038, NANOscale PHYSICS DIVISION TEAM — We examine the electronic heat transport phenomena in nanoscale junctions composed of organic molecules weakly coupled to two heat reservoirs of different temperatures. The electronic heat flux and its dynamical noise properties are calculated within the scattering (Landauer) formalism with the transmission probability determined by using non-equilibrium Green’s functions technique. The perturbative computational scheme is used to determine nonlinear corrections to the electronic heat flux and its noise power spectral density with up to the second order terms in relation to the temperature difference. Our results show the limited applicability of ballistic Fourier’s law and the fluctuation-dissipation relations to nanoscale heat flow carried by electrons. Theoretical Study of Layered Oxychalcogenides as Thermoelectric Materials, HIROKI FUNASHIMA, Osaka Univ — In order to restrain global warming and realize a sustainable global energy system, the researches of various energy resources are done. In these various energy resources, attracted technology is thermoelectric technology. Recently Layered oxychalcogenides has interesting properties useful for new type thermoelectric materials. Firstly, from DFT and DFPT calculations, we performed the electronic structure calculation and the thermal structure calculation about layered oxychalcogenides. In addition, we calculated thermoelectric properties Blotch-Boltzmann equation, semi-classically. We indicate the mechanism behind the high power factor from calculation about the transport properties. The key to understanding the power factor is that different effective masses contribute to different transport phenomena in the crystal. The discrepancy between the effective mass for the conductivity and the thermoelectric power showed that the conductivity and thermoelectric power are conveyed by electrons with different effective masses in the Brillouin zone. In point of view the thermal conductivity $\kappa$, we discuss the electronic part $\kappa_e$ from Bloch-Boltzmann equations, and $\kappa_{ph}$ from DFT calculations.
V1.00248 Separating Lattice and Electronic Thermal Conductivity Contributions in Bi$_2$Se$_3$ and Bi$_2$Te$_3$ Single Crystals, CYRIL OPEIL, MENGLIANG YAO, Boston College, Chestnut Hill, MA 02467, STEPHEN WILSON, University of California, Santa Barbara, CA 93106, MONA ZEBARIJADI, Rutgers University, Piscataway, NJ 08854 — Nanostructured materials are an effective approach in reducing lattice thermal conductivity and improving overall thermoelectric efficiency. A challenge for experimental measurements of thermal conductivity is separating the contributions from both carriers and phonons. Building on the work of K. Lukas et al., Phys. Rev. B 85, 205410 (2012), we report measurements of thermal and electrical conductivity of single crystal thermoelectrics: Bi$_2$Se$_3$ and Bi$_2$Te$_3$ in a transverse magnetic field up to 9 Tesla. Our experiments provide a separation of the lattice/electronic components and make possible a better theoretical model of the lattice portion of the thermal conductivity in materials.

V1.00249 Computational screening of organic materials towards improved photovoltaic properties, SHUO DAI, Dept. Physics, Oklahoma State Univ, ROBERTO OLIVARES-AMAYA, Dept. Chemistry, Princeton Univ, CARLOS AMADOR-BEDOLLA, Dept. Chemistry, UNAM, ALAN ASPURU-GUIZIK, Dept. Chemistry, Harvard Univ, MARIO BORUNDA, Dept. Physics, Oklahoma State Univ — The world today faces an energy crisis that is an obstruction to the development of the human civilization. One of the most promising solutions is solar energy harvested by economical solar cells. Being the third generation of solar cell materials, organic photovoltaic (OPV) materials is now under active development from both theoretical and experimental points of view. In this study, we constructed a parameter to select the desired molecules based on their optical spectra performance. We applied it to investigate a large collection of potential OPV materials, which were from the CEPDB database set up by the Harvard Clean Energy Project. Time dependent density functional theory (TD-DFT) modeling was used to calculate the absorption spectra of the molecules. Then based on the parameter, we screened out the top ten performing molecules for their potential OPV usage and suggested experimental efforts toward their synthesis. In addition, from those molecules, we summarized the functional groups that provided molecules certain spectrum capability. It is hoped that useful information could be mined out to provide hints to molecular design of OPV materials.

V1.00250 First-principles study of amorphous carbon: a promising candidate for Na-ion batteries, KONSTANTINOS KOTSIS, FLEUR LEGRAIN, SERGEI MANZHOS, National University of Singapore — The perspective of a widespread use of clean but intermittent sources of electricity (wind and solar) as well as that of hybrid electric vehicles calls for alternatives to Li-ion batteries as Li resources are limited. Na being abundant, cheap, and a relatively light and small atom, Na-ion batteries have attracted a lot of interest the past few years. However, while most of the Na-ion batteries studies focus on the positive electrode, the negative electrode remains little investigated and an efficient anode providing all a good capacity, a high cycle life, and a decent rate of charge/discharge, is still not available. The efficient electrode materials for Li, in particular diamond Si and graphite C, have been shown to not allow the intercalation of Na [1, 2]. Computational studies report positive intercalation energies [3, 4] and therefore suggest that the insertion of Na into the crystalline framework (C and Si) is thermodynamically not favored: Na atoms prefer to gather into Na clusters rather than to intercalate into the crystalline phase. Amorphization of Si was found to be a valid strategy to improve the interaction between Si and Na [3]. We investigate here the effects of amorphization of C on its storage properties vis-à-vis Na (as well as Li for reference).

V1.00251 First-Principles Density Functional Theory Modeling Study on the Redox Chemistry of Graphene Oxides Affected by Placement Geometry of Oxygen Functional Groups, SUNGHEE KIM, KI CHUL KIM, SEUNG WOO LEE, SEUNG SOON JANG, Georgia Inst of Tech — To date, lithium-ion batteries have been extensively gained attention due to their promising potential in the industry. Despite their promising properties, improving their poor power density is still needed for practical applications. In addition, sustaining the high redox potential in the lithium-ion batteries is prerequisite for exhibiting the high energy and power densities. Recently, layered carbon materials including graphene and carbon nanotubes have been paid special attention as promising electrode materials with high power densities due to their exceptionally high surface area and active oxygen functional groups on their surfaces. However, the lack of reliable information on the redox chemistry of the candidates is the obstacle to be uncovered for practical applications. In this study, we investigated the redox chemistry of graphene oxides cluster models with well-controlled hydroxyl functional groups at the edge. First-principles density functional theory approach was employed to understand the geometric effect of the incorporated hydroxyl functional groups on the redox chemistry. Our study will provide an insight on the strategy for improving the redox potentials of graphene-based electrode candidates.

V1.00252 Temperature dependent study of impurities in LiFePO$_4$/C nanoparticles and their impact on electrochemical performance, KULWINDER SINGH DHINDSA, KHADJUE BAZZI, Gholam-Abbas NAZRI, Wayne State University, Detroit, MI, US, VAMAN M.NAIK, University of Michigan-Dearborn, Dearborn, Michigan, US, VIJAYENDRA K. GARG, Universidade de Brasilia, Instituto de Fisica, Brasilia – DF, Brazil, ADERBAL C. OLIVEIRA, Unidade Universitaria De Ciencias Exatas E Tecnologicas, Universidade, PREM VAISHNAVA, Kettering University, Flint, Michigan, US, RATNA NAIK, ZHIXIAN ZHOU, Wayne State University, Detroit, MI, US — We have synthesized LiFePO$_4$/C nanoparticles using a simple sol-gel method followed by calcination at various temperatures from 600 °C to 900 °C. X-ray diffraction shows that samples annealed at 600°C are phase pure while those treated at higher temperatures contain Fe$_2$P and Li$_3$PO$_4$ impurity phases, which increase with increasing annealing temperature. Mossbauer spectroscopy and magnetic measurements were used to quantify the amount of Fe$_2$P impurity phase. Scanning electron microscopy measurement reveals a noticeable increase in particle size as the annealing temperature increases from 700 °C to 900 °C. Optimal results are obtained in LiFePO$_4$/C samples annealed at 700 °C, which show the lowest charge transfer resistance, highest Li-ion diffusion coefficient, the highest specific capacity of 166 mAh/g at a rate of 1C and the best rate capability and cycling stability among all samples.

V1.00253 Porous MnO$_2$ prepared by sol-gel method for electrochemical supercapacitor, K. BAZZI, A. KUMAR, Wayne State University, O.D. JAYAKUMAR, Bhabha Atomic Research center, G.A. NAZRI, Wayne State University, V.M. NAIK, University of Michigan-Dearborn, R.A. NAIK, Wayne State University — MnO$_2$ has attracted great attention as material for electrochemical pseudocapacitor due to its high theoretical specific faradic capacitance (∼ 1370 F g$^{-1}$), environmental friendliness and wide potential window in both aqueous and nonaqueous electrolytes. However, the MnO$_2$ has a low surface area which depresses its electrochemical performance. The amorphous α-MnO$_2$ composite was synthesized by sol gel method in the presence of the tri-block copolymer P123. Our aim is to investigate the role of P123 on the electrochemical performance of MnO$_2$. The samples with and without P123 were prepared and characterized by x-ray diffraction (XRD), SEM, TEM and Brunauer–Emmett–Teller (BET) method. The electrochemical performances of the amorphous MnO$_2$ composites as the electrode materials for supercapacitors were evaluated by cyclic voltammetry and AC impedance measurements in a 1M Na$_2$SO$_4$ solution. The results show that the sample prepared without P123 exhibited a relatively low specific capacitance of 28F g$^{-1}$, whereas the porous MnO$_2$ prepared with P123 exhibited 117 F g$^{-1}$ at 5 mV/s. The results of crystalline MnO$_2$ composites will also be presented.

The authors acknowledge the support from the Richard J. Barber Foundation for Interdisciplinary Research.
V1.00254 Synthesis and electrochemical characterization of mesoporous Li$_2$FeSiO$_4$/C composite cathode material for Li-ion batteries, AJAY KUMAR, Wayne State University, O.D. JAYAKUMAR, Bhabha Atomic Research Centre, KHADIE BAZZI, GHOULAM-ABBAS NAZRI, Wayne State University, VAMAN M. NAIK, University of Michigan Dearborn, RATNA NAIK, Wayne State University — Lithium iron silicate (Li$_2$FeSiO$_4$) has the potential as cathode for Li ion batteries due to its high theoretical capacity (∼330 mAh/g) and improved safety. The application of Li$_2$FeSiO$_4$ as cathode material has been challenged by its poor electronic conductivity and slow lithium ion diffusion in the solid phase. In order to solve these problems, we have synthesized mesoporous Li$_2$FeSiO$_4$/C composites by sol-gel method using the tri-block copolymer (P123) as carbon source. The phase purity and morphology of the composite materials were characterized by x-ray diffraction, SEM and TEM. The XRD pattern confirmed the formation of ∼12 nm size Li$_2$FeSiO$_4$ crystallites in composites annealed at 600 °C for 6 h under argon atmosphere. The electrochemical properties were measured using the composite material as positive electrode in a standard coin cell configuration with lithium as the active anode and the cells were tested using AC impedance spectroscopy, cyclic voltammetry, and galvanostatic charge/discharge cycling. The Li$_2$FeSiO$_4$/C composites showed a discharge capacity of ∼240 mAh/g at a rate of C/30 at room temperature. The effect of different annealing temperature and synthesis time on the electrochemical performance of Li$_2$FeSiO$_4$/C will be presented.

V1.00255 Synthesis of Nanostructured Graphene/Metal-oxides Hybrid for High-performance Supercapacitors, JUN-BO SIM, Department of Nuclear and Quantum Engineering, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Republic of Korea, SUNDAR MAVAYAN, Division of Corrosion & Materials Protection, Central Electrochemical Research Institute, Karaikudi-630006, Tamil Nadu, India, SUNG-MIN CHOI, Department of Nuclear and Quantum Engineering, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Republic of Korea — Graphene has been considered as promising material for supercapacitor electrodes due to their large surface area, good chemical stability and excellent electrical conductivity. However, until now, conventional graphene-based supercapacitors cannot provide enough energy storage ability due to irreversible restacking behavior of graphene sheets. Various methods have been explored to solve this problem, but most of methods require complex and multi-step process, which will prevent scalable synthesis. Here, we present an easy and scalable synthesis method for nanostructured graphene/metal-oxides hybrid starting from graphene-oxide. The hybrid material prepared in this method provides high specific capacitance with high electrochemical stability. The sample characterization using XRD, XPS, FE-SEM, FE-TEM and Cyclic-Voltammetry will be presented.

V1.00256 Superstructured Carbon Nanotube/Porous Silicon Hybrid Materials for Lithium-Ion Battery Anodes, JUN-KI LEE$^1$, SHIN-HYUN KANG$^2$, SUNG-MIN CHOI$^3$, KAIST — High energy Li-ion batteries (LIBs) are in great demand for electronics, electric-vehicles, and grid-scale energy storage. To further increase the energy and power densities of LIBs, Si anodes have been intensively explored due to their high capacity, and high abundance compared with traditional carbon anodes. However, the poor cycle-life caused by large volume expansion during charge/discharge process has been an impediment to its applications. Recently, superstructured Si materials were received attentions to solve above mentioned problem in excellent mechanical properties, large surface area, and fast Li and electron transportation aspects, but applying superstructures to anode is in early stage yet. Here, we synthesized superstructured carbon nanotubes (CNTs)/porous Si hybrid materials and its particular electrochemical properties will be presented.

V1.00257 Charge Transport and Structural Dynamics in Deep Eutectic Mixtures, TYLER COSBY, ADAM HOLT, LOGAN TERHEGGEN, University of Tennessee, Knoxville, PHILIP GRIFFIN, University of Pennsylvania, ROBERTO BENSON, JOSHUA SANGORO, University of Tennessee, Knoxville — Charge transport and structural dynamics in a series of imidazole and carboxylic acid-based deep eutectic mixtures are investigated by broadband dielectric spectroscopy, dynamic light scattering, $^1$H nuclear magnetic resonance spectroscopy, calorimetry, and Fourier transform infrared spectroscopy. It is found that the extended hydrogen-bonded networks characteristic of imidazoles are broken down upon addition of carboxylic acids, resulting in an increase in dc conductivity of the mixtures. These results are discussed within the framework of recent theories of hydrogen bonding and proton transport.

V1.00258 Understanding Iron-based catalysts with efficient Oxygen reduction activity from first-principles calculations, HASNAH HAFIZ, B. BARBIELLINI, Q. JIA, Northeastern U., U. TYLUS, Northeastern U. and LANL, K. STRICKLAND, A. BANSIL, S. MUHERJEE, Northeastern U. — Catalysts based on Fe/N/C clusters can support the oxygen-reduction reaction (ORR) without the use of expensive metals such as platinum. These systems can also prevent some poisonous species to block the active sites from the reactant. We have performed spin-polarized calculations on various Fe/N/C fragments using the Vienna Ab initio Simulation Package (VASP) code. Some results are compared to similar calculations obtained with the Gaussian code. We investigate the partial density of states (PDOS) of the 3d orbitals near the Fermi level and calculate the binding energies of several ligands. Correlations of the binding energies with the 3d electronic PDOS’s are used to propose electronic descriptors of the ORR associated with the 3d states of Fe. We also suggest a structural model for the most active site with a ferrous ion (Fe$^{2+}$) in the high spin state or the so-called Doublet 3 (D3).

V1.00259 Plasmon Enhanced Hetero-Junction Solar Cell, GEN LONG, LEVINE CHING, MOSTAFA SADOQI, HUIZHONG XU, Department of Physics, College of Liberal Arts and Sciences, St John’s University, 8000 Utopia Parkway, Jamaica, NY 11439 — Here we report a systematic study of plasmon-enhanced hetero-junction solar cells made of colloidal quantum dots (PbS) and nanowires (ZnO), with/without metal nanoparticles (Au). The structure of solar cell devices was characterized by AFM, SEM and profilometer, etc. The power conversion efficiencies of solar cell devices were characterized by solar simulator (OAI TriSOL, AM1.5G Class AAA). The enhancement in the photocurrent due to introduction of metal nanoparticles was obvious. We believe this is due to the plasmonic effect from the metal nanoparticles. The correlation between surface roughness, film uniformity and device performance was also studied.
V1.00260 Local Structure and Electrical Performance of Pulsed Laser Deposited CdTe/CdS Thin-Film Solar Cells¹. ARYA NABIZADEH, DARREN LESINSKI, LUIS CERQUEIRA, MEHMET SAHINER, Seton Hall Univ, SAHINER-AMSC Team — The photovoltaic thin films of CdS/CdTe were prepared by pulsed laser deposition (PLD) on indium tin oxide (ITO) coated glass. The local structural variations in the thin films around Cd atom upon variations in the thin film growth parameters were investigated by X-ray absorption near-edge spectroscopy (XANES) and extended X-ray absorption fine-structure spectroscopy (EXAFS) and X-ray diffraction. X-ray absorption spectroscopy measurements were performed at the National Synchrotron Light Source of Brookhaven National Laboratory. The effect of the thicknesses of the CdS and CdTe layers, laser energy and the substrate temperature on the local crystal structure and coordination around the Cd atoms were investigated through quantitative multiple scattering analysis and modeling of the x-ray absorption spectroscopy data. The induced local structural modifications upon varying synthesis conditions are correlated with the electrical performance of these photovoltaic thin-films. The quantitative multiple scattering analyses and modeling of X-ray absorption spectroscopy data revealed the local environment around the Cd atoms are highly sensitive to thin film deposition parameters and the variations of the Cd local structure influences interface quality consequently, affect the electrical performance of these photovoltaic thin films.

V1.00261 Electrowetting-Controlled Dual Liquid Prism for Adaptive Beam Steering, JIANGTAO CHENG, University of North Texas — The use of concentrating photovoltaic (CPV) technology has been the most promising method of harvesting solar radiation. These CPV systems often require motor-driven tracking devices to steer the sun's beams onto solar cells. The cost of maintaining these tracking systems is the primary inhibitor for widespread application. We aim to overcome the need for mechanical trackers through the use of an electrowetting-driven solar tracking system. The electrowetting-driven solar tracking system consists of an array of novel electrowetting-controlled dual liquid prisms, which are filled with immiscible fluids that have large differences in refractive indices. The naturally formed meniscus between the fluids can function as a dynamic optical prism. Via the full-range modulation of the liquid prisms, incident sunlight can be adaptively tracked, steered, and focused onto CPV cells through a fixed optical condenser. Furthermore, unlike the conventional and cumbersome motor-driven tracking systems used today, the liquid prism system would be suitable for rooftop applications. The results of this project reveal that the EWST system has the potential to generate ~ 70% more green energy at 50% of the conventional capital cost.

V1.00263 A possibility as a new type of thermoelectric application on organic-inorganic hybrid perovskite ABI3 system: A density functional theory study¹. CHANGHOON LEE, JISOOK HONG, JJ HOON SHIM, Pohang Univ of Sci & Tech, MYUNG-HWAN WHANGBO, NC State Univ, POSTECH Team — The electronic structures of organic-inorganic hybrid systems ABI₃ (A = CH₃NH₃, NH₂CHNH₂; B = Sn, Pb; X = I) in the distorted phase from their patent cubic phase are systematically studied using the first-principles calculations. Here, we examine thermoelectric properties for ABI₃ compounds based on the DFT electronic structures of their optimized crystal structures. The ABI₃ compounds should be considered for good thermoelectric application. We reveal that good thermoelectric performance of ABI₃ systems originate from large Seebeck coefficients and low thermal conductivities. As a consequence, we predict that ABI₃ system is a promising material for new thermoelectric application compared to thermoelectric properties of well-known thermoelectric material Bi₂Te₃.

V1.00264 Graphene oxide as a candidate material for natural gas storage: A first principles study¹. RAJIV KUMAR CHOIHOUN, KANCHAN ULMAN, TSU, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur, Bangalore, India, SHOBHANA NARASIMHAN, TSU, and Sheikh Saqr Laboratory, ICMS, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur, Bangalore, India — Alternative sources of clean energy will be much in demand in the coming days. To store methane (CH₄) in sorbent materials at ambient conditions for on-board vehicular usage, minimum adsorption energy of 18.8 KJ/mol is desirable. In this work, we have investigated methane adsorption on graphene oxide using first principles calculations. To accurately capture the weak interactions between CH₄ and the substrate we have included van der Waals interactions in our calculations. We show that the adsorption energy falls within the target range. Careful analysis of the various contributions to the binding shows that the enhancement in adsorption energy on going from graphene to graphene oxide arises from a subtle synergy between various effects.

V1.00265 Solar photocatalytic conversion of CO2 to fuels by nanostructured oxides, OOMMAN VARGHESE¹, IVY AHIABU², GIWAN KATIUWAL³, MAGGIE PAULOSE¹. University of Houston — Converting the carbon dioxide and water vapor to hydrocarbon fuels through photocatalytic processes using sunlight is a promising route for limiting the CO2 accumulation in the atmosphere. This CO2 recycling process facilitates the unabated use of hydrocarbon fuels as well. Nevertheless, the photocatalytic CO2 conversion process has not yet demonstrated a reasonable light-to-fuel energy conversion efficiency for it to be considered as a viable technology. Nanostructured oxide semiconductors have recently shown potentials for efficiency enhancement. Appropriate band gap and band alignment, sufficient surface area for light absorption and low loss transfer of photocarriers to the surface are important criteria for the selection of photocatalysts. We will present the results of study on solar photocatalytic conversion of CO2 and water vapor using three oxide nanostructured materials, TiO2, ZnO and Cu2O, with different band gaps and flat band positions in converting CO2 to fuels. We will compare the quantum efficiencies and discuss possible reaction routes studied by using isotopic form of water for the reaction.

**V1.00266 Vacuum force**, YONGQUAN HAN, 15611860790 — To study on vacuum force, we must clear what is vacuum, vacuum is a space do not have any air and also ray. There is not exist an absolute the vacuum of space. The vacuum of space is relative, so that the vacuum force is relative. There is a certain that vacuum vacuum space exists. In fact, the vacuum space is relative, if the two spaces compared to the existence of relative vacuum, there must exist a vacuum force, and the direction of the vacuum force point to the vacuum region. Any object rotates and radiates. Rotate bend radiate—centripetal, gravity produced, relative gravity; non gravity is the vacuum force. Gravity is centripetal, is a trend that the objects who attracted wants to Centripetal, or have been do Centripetal movement. Any object moves, so gravity makes the object curve movement. That is to say, the radiation range curve movement must be in the gravitational objects, gravity must be existed in non vacuum region, and make the object who is in the region of do curve movement (for example: The earth moves around the sun), or final attracted in the form gravitational objects, and keep relatively static with attract object. (for example: objects on the earth moves but can’t reach the first cosmic speed).

**V1.00267 Using Simple Circuits as Thermal Models for your Home**, ADELE POYNOR, Allegheny College — One of the most cost effect ways to improve the energy efficiency of your home is to increase your home’s insulation. But would it be better to insulate your walls or by new windows? Not all options are equally effective, nor do they have equal costs. So how can you determine which option improves your homes insulation the most? I present an analogy to simple resistor circuits that can be used by introductory students to answer these questions.

**V1.00268 Anisotropic O vacancy formation and diffusion in LaMnO3**, OMOTAYO SALAWU, LIYONG GAN, UDO SCHWINGENSCHLOGL, King Abdullah Univ — Anisotropy effects in solid oxide fuel cells are typically not considered because of the high operating temperatures. Focusing on the prototypical perovskite LaMnO3, we apply first-principles calculations to demonstrate that this approximation is no longer valid when the operating temperature is reduced and discuss the consequences for the material properties. In addition, we show that strain and Sr doping can be used to further increase the anisotropy. Tensile strain promotes both the O formation and diffusion in pristine and Sr doped LaMnO3, while Sr doping enhances the O vacancy formation but not the diffusion barrier. Both in LaMnO3 and La0.75Sr0.25MnO3 the O diffusion is found to be favorable in the [011] and [01$ar{1}$] directions.

**V1.00269 Electronic structure and vacancy formation in La(1-x)B(x)CoO3 (B=Mg,Ca,Ba and x=0.125)**, OMOTAYO SALAWU, LIYONG GAN, UDO SCHWINGENSCHLOGL, King Abdullah Univ — The LaCoO3 class of materials is of interest for cathodes of solid oxide fuel cells. Spin-polarized density functional theory is applied to cubic La0.75(Mg/Ca/Ba)0.125CoO3. The effect of this cation doping on the electronic and magnetic properties as well as oxygen vacancy formation energy is studied. Oxygen vacancies with proximity to the dopant are energetically favourable in most cases. We discuss the effect of distortions of the CoO6 octahedron on the electronic structure and the formation energy of oxygen vacancies. The order of formation oxygen is found to be Mg > Ca > Ba. Cation doping incorporates holes to the Co-O network which enhances the oxygen vacancy formation.

**V1.00270 Thin Film Evaporation of Receding Meniscus within Micro Pillar Arrays**, MOHAMED H. ALHOSANI, AMMAR A. ALSHEGHRI, AMAL ALGHAFERI, TIEJUN ZHANG, Masdar Institute of Science and Technology — Evaporation is a key process in power generation, water desalination, and thermal management applications. It has been proved that hydrophilic micro structured surfaces can enhance the convection heat transfer by promoting high-performance thin film evaporation and enlarging the total heat transfer surface area. When depositing a water droplet on hydrophilic structured surfaces, two distinct regions can be observed, a) central region with water level higher than the micro pillar height (droplet region), b) thin film region as a result of liquid meniscus receding among micro structures. In this study, we are able to probe the physics of thin film evaporation of receding liquid meniscus among micro pillar arrays with different pillar heights, spacings and diameters. Heat transfer is systematically studied in the droplet and thin film region for each sample. Also, Young-Laplace equation and kinetic theory of mass transport are used to model the thin film evaporation around micro pillars. With the proposed model, the shape of meniscus around micro pillars and the diameter of droplet extended thin film region can be predicted and compared with the experimental measurement. The model can also be extended to model thin film evaporation of meniscus within nano structured surfaces.

**V1.00271 Positron Annihilation Spectroscopy of Common Mineral Constituents of Shale**, JOAH CHUN*, Colorado College, JAMES BUFKIN*, Angelo State University, HELGE ALSLEBEN, TCU Department of Geology, FNU AMEENA, C.A. QUARLES, TCU Department of Physics and Astronomy — Recent investigation of positron lifetime and Doppler broadening in Barnett Shale samples have shown a small intensity of positronium (Ps) formation. The samples studied have XRF information on 35 elements, XRD information on mineral constituents, and chemical information on total organic carbon (TOC). It is not known where Ps is formed in the shale. Previous research has shown that Ps is not formed in quartz-rich sandstone, calcite-rich limestone or dolomite-rich rocks, which contain minerals that also constitute a significant part of most shale samples. No information about Ps formation in clay minerals, which are often dominant in shale, has been available. The purpose of the present study is to determine which clay minerals form Ps. Twenty-five different common rock-forming minerals have been studied. Hydration of some of the minerals has also been varied. As a result of this work, a better idea of where Ps is formed in the shale samples has been obtained, but there still remains some uncertainty regarding the hydration in the shale and the possibility of direct Ps formation in the organic carbon itself. *Participant in the summer 2014 TCU REU program in Physics and Astronomy funded by the National Science Foundation under grant PHY-1358770.

**V1.00272 METALS AND METALLIC ALLOYS —**

**V1.00273 Effect on stabilities of self-Interstitials in HCP-Zirconium**, QING PENG, WEI JI, JIE LIAN, Rensselaer Polytechnic Institute, XIAO-JIA CHEN, Chinese Academy of Sciences, HANCHEN HUANG, Northeastern University, FEI GAO1, Pacific Northwest National Laboratory, SUVRANU DE, Rensselaer Polytechnic Institute — The self-interstitial atoms (SIAs) mediate the evolution of micro-structures which is crucial in understanding the instabilities of hexagonal close packed (HCP) structures. Taking zirconium as a prototype, we investigate the pressure effect on the stabilities of SIAs using first-principles calculations based on density-functional theory. We found that the pressure greatly affects the stability of the SIAs. The SIAs in basal planes are more stable under pressure. The SIA configuration of the lowest formation energy changes from basal octahedral (BO) to octahedral (O) at a pressure of 21 GPa. The lowest formation enthalpy configuration switches from BO to S (split-dumbbell) at the pressure of 30 GPa. The formation volumes of SIAs decrease monotonically in response to an increase in pressure. Our results reveal that it is important to take pressure effects into account when predicting the micro-structural evolution of HCP structures. (Scientific Reports, 4, 5735)

**V1.00274 Electrical Properties of the Ln$_{3-x}$Y$_x$TaO$_7$ (Ln=Dy, Gd) solid solution.** JOSE FRANCISCO GOMEZ-GARCIA, Facultad de Química, ALEJANDRO DURAN, Centro de Nanociencias y Nanotecnología, PABLO DE LA MORA$^1$, Facultad de Ciencias, GUSTAVO TAVIZON, Facultad de Química, Universidad Nacional Autónoma de México — Systems with the formula Ln$_{3-x}$Y$_x$TaO$_7$ (Ln=Dy, Gd) crystallizing in the website related structure (SG C222, No. 20) were synthesized by the solid-state reaction method. Structural characterization through Rietveld reflections indicates that a solid solution in the whole range 0<x<3 exist in both Gd and Dy systems. Structural cell parameters as a function of the rare-earth content are shown in this work, as well as the AC electrical properties in the 30-700°C range. We have performed impendence (400-600°C) and electric polarizability measurements (at room temperature); the results indicate that the polarizability reaches its maximum values at $x=0.67$, 1.67 and 2.33 for the Gd samples, meanwhile these values were $x=0.67$ and 2.0 for the Dy samples. In intermediate composition values, the Ln$_{3-x}$Y$_x$TaO$_7$ samples exhibit null polarization.

$^1$On sabbatical leave at the University of Texas at Austin

**V1.00275 The 4f multipole ordering effect on core-level spectroscopies of Ce intermetallics.** NORIMASA SASABE, HIRONORI TONAI, TAKAYUKI UOZUMI, Osaka Prefecture Univ — The 3d transition metal compounds and 4f rare earth compounds show attractive phenomena, such as superconductivity and Kondo effect, due to strong electron correlations among localized 3d and 4f electrons. Especially, multipole ordering of orbital and/or spin in 4f and 5f compounds is attracting much attention these years. For example, CeB$_6$ is known to show antiferro-quadrupolar (AFQ) ordering below 3.2K. X-ray core-level spectroscopy is an efficient technique to investigate the electronic states of strongly correlated systems. Recent years, experimental techniques have been rapidly developing and, especially, the progress in experimental resolution has enabled us to observe fine spectral features, which were not formerly observed. These advantages will enable us to observe spectral fine features related with the multipole ordering. In this study, we discuss multipole ordering effects on X-ray spectra for CeB$_6$, especially paying attention on the polarization dependence. In order to simulate the electronic state of CeB$_6$ with the multipole ordering, we use an impurity Anderson model including a simplified RKKY interaction.

**V1.00276 Low temperature heat capacity of Uranium-Plutonium MOX single crystals.** JEAN-CHRISTOPHE GRIVEAU, ERIC COLINEAU, RACHEL ELOIRDI, ROBERTO CACIUFFO, European Commission, Joint Research Centre (JRC), Institute for Transuranium Elements (ITU), Postfach 2340, D-76125 Karlsruhe, Germany — The establishment of the basic properties of actinides based materials is crucial for the understanding of conventional and advanced nuclear fuels. Accessing ground state properties at very low temperature for these systems gives a direct overview of their fundamental features. Moreover, when these materials can be produced as single crystals, side effects due to the presence of grains and impurities phases are drastically reduced, giving a very powerful add-in for theoretical and industrial oriented studies. This clearly ensures the reliability of the parameters determined while existing models of these strategic materials can be probed especially in the purpose of applications/developments and safety concerns. Here we report on heat capacity measurements performed on U-Pu MOX in single crystal form. Tiny crystals with mass of 2 to 15 mg have been produced by solid-solid chemical vapour transport technique with several different compositions ranging from pure UO$_2$ to PuO$_2$. Compositions close to UO$_2$ (U rich) present a persistent signature similarly to the magnetic transition reported for the pure phase $T_N \sim 31$ K while plutonium rich concentrations do not show any hint of the magnetic transition down to the minimum temperature achieved.

**V1.00277 Thermodynamics of plastic flow of BCC metals from atomistic studies of isolated screw dislocations.** ROMAN GRÖGER, Institute of Physics of Materials and CEITEC IPM, Academy of Sciences of the Czech Republic, VACLAV VITEK, Department of Materials Science and Engineering, University of Pennsylvania. — The thermodynamic description of dislocation glide in BCC metals depends crucially on the shape of the Peierls barrier that 1/2⟨111⟩ screw dislocations have to overcome when moving in the lattice. While the height of this barrier can be obtained unequivocally using saddle-point search algorithms such as the Nudged Elastic Band (NEB) method, its exact shape depends on the chosen approximation of the transition pathway of the system. We formulate a procedure that allows to identify the position of the dislocation directly from the displacements of atoms in its core. We investigate the performance of this model by calculating curved paths of a 1/2⟨111⟩ screw dislocation in tungsten from a series of images obtained recently using the NEB method at zero applied stress and for positive/negative shear stresses perpendicular to the slip direction. The Peierls barriers plotted along these curved paths are shown to be quite different from those obtained previously by assuming a straight dislocation path. We demonstrate how these results can be utilized to develop a new thermodynamic model of plasticity of BCC metals that is systematically linked to the atomic-level properties of isolated 1/2⟨111⟩ screw dislocations.

**V1.00278 Temperature Dependence of the Dielectric Function of Ni near the Curie Temperature.** STEFAN ZOLLNER, DENNIS TRUJILLO, LAURA PINEDA, LINA ABDALLAH, New Mexico State Univ — Onstein et al. (Physica V, 1938) observed a discontinuity in the normal-incidence reflectance of Ni at the Curie temperature. A similar phenomenological observation of a temperature related slope change in resistivity versus temperature in Ni was made by Litschel et al. (J. Phys. Chem. Solids, 1985). To follow up on these observations we carried out measurement of the dielectric function $\epsilon$ as a function of temperature for a magnetized thin film Ni sample (1000 Å Ni on SiO$_2$) and bulk polycrystalline Ni via ellipsometric measurement at a fixed photon energy (1.9 eV). For a magnetized sample, we observe a discontinuity in the dielectric function versus temperature just below the Curie temperature for both thin film and bulk polycrystalline Ni. In an unmagnetized Ni sample (obtained by heating above the Curie temperature), this continuity is not present. We believe that this observation is due to a change in the on-diagonal dielectric tensor elements for Ni in the magnetized samples, not due to the off-diagonal elements related to the Koofer effect.

**V1.00279 GENERAL —

**V1.00280 A theoretical investigation of the origins of atoms and sub-atomic particles.** CATHERINE DEROW, No Company Provided — It seems the universe was at some very early stage shortwave energy. When the universe cooled some of this became matter, others delved into particles of sub-atomic parts. The positive charge and motion of the negative charge of the atom keep them from merging and yet the attractive forces stop them from parting, apart from when radiation activity is observed. The neutral charge may add a motion which loosens the attraction of the positive protonic attractive force for the negative electronic force. It seems thus the atom is relatively immobilized negative, positive and neutral waves held in confined motion. These waves can be loosed into travelling as waves by forces which break the balance of intra-atomic attractive forces and thus cause the emission of sub-atomic “particles” as waves. Thus the attractive forces in normal circumstances balance the “wave motion” forces, keeping stable atomic structure intact.
V1.00282 Democracy is a historical urgency. MIROSLAV SYNEK, No Company Provided — Survival of humanity, on this planet, may depend, heavily, on coping with advancing technology of nuclear missiles. Let us consider critical alternatives of powerful governments: democracy, as an alternative to dictatorship. Democracy is based on free elections, as a government of the people, by the people, and for the people. Democracy is a historical urgency, in the age of inter-continental nuclear missiles, computerized on a push-button, conceivably controllable by a very powerful, miscalculating and/or insane, dictator, capable of producing global nuclear holocaust, on our entire planet. Diplomacy, together with supporting activities, should be utilized, to help, in important steps, at this time, for achieving democracy in critical areas.

V1.00283 Geometric Implications of Maxwell’s Equations. FELIX T. SMITH, None — Maxwell’s synthesis of the varied results of the accumulated knowledge of electricity and magnetism, based largely on the searching insights of Faraday, still provide new issues to explore. A case in point is a well recognized anomaly in the Maxwell equations: The laws of electricity and magnetism require two 3-vector and two scalar equations, but only six dependent variables are available to be their solutions, the 3-vectors E and B. This leaves an apparent redundancy of two degrees of freedom (J. Rosen, AJP 48, 1071 (1980); Jiang, Wu, Povineili, J. Comp. Phys. 125, 104 (1996)). The observed self-consistency of the eight equations suggests that they contain additional information. This can be sought as a previously unnoticed constraint connecting the space and time variables, r and t. This constraint can be identified, It distorts the otherwise Euclidean 3-space of r with the extremely slight, time dependent curvature &kappa;= k(t) = Rcrit/r(t) of the 3-space of a hyperspace whose radius has the time dependence dRcrit/dt = ±ic nonrelativistically, or dRcrit/dt = ±ic relativistically. The time dependence is exactly that of the Hubble expansion. Implications of this identification will be explored.

V1.00284 Prof. Jakob Narkiewicz-Jodko’s Discoveries and his Laboratory. VLADIMIR SAMUILOV, State University of NY at Stony Brook, LARRISA SAMUILOVA, Department of Mathematics, SCCC — Prof. Jakob Narkiewicz-Jodko (1947–1995) major discoveries are: Electrography — the method of the visualization of electric discharge from the bodies due to the application of high strength and high frequency electric fields [3,4], and the first observation of the propagation of the electromagnetic waves for information transfer over the distances [5,6]. They were made in his laboratory located at his manor home Nadniemen. We describe these experiments and the Lab equipment used for the discoveries. Unfortunately the Nadniemen manor designed and built in Neogothic style was destroyed at the WWII. Our goal is to restore the Lab of Prof. Jakob Narkiewicz-Jodko as a museum. We also introduce our hypothesis regarding architectural design of the manor home Nadniemen. [1] Decrespe M. V1.00285 Relativistic Navier-Stokes Equation, (Navier-Stokes Equation with Estakhr’s Correction). AHMAD REZA ESTAKHR1, Researcher — At relativistic speeds Navier-Stokes equation is incorrect unless Estakhr’s correction is included. This equation relates energy flux as vector at relativistic speeds. (-1/c²) (ωf) = at low speeds Estakhr’s relativistic correction vanishes. ργv(ωf) = ργv(ωf + v·∇v) = −∇p + f, T = −1/c² (ωf) + f, where v is the flow velocity, ρ is the fluid density, p is the pressure, T is the (deviatoric) component of the total stress tensor, which has order two, f represents body forces (per unit volume) acting on the fluid, V is the del operator, γ is the Lorentz factor.

V1.00286 The Crisis in Scholarly Communication, Open Access, and Open Data Policies: The Libraries’ Perspective. RACHEL BESARA, Florida State University Libraries — For years the cost of STEM databases have exceeded the rate of inflation. Libraries have reallocated funds for years to continue to provide support to their scientific communities, but they are reaching a point at many institutions where they are no longer able to provide access to many databases considered standard to support research. A possible or partial alleviation to this order of inflation. Libraries have reallocated funds for years to continue to provide support to their scientific communities, but they are reaching a point at many institutions where they are no longer able to provide access to many databases considered standard to support research. A possible or partial alleviation to this dilemma is the open access movement. However, this shift challenges the current model of publishing and data management in the sciences. This talk will discuss these topics from the perspective of research libraries supporting physics and the STEM disciplines.

V1.00287 Climate Change & Social Justice: Why We Should Care1. NATHAN T. NESBITT, Boston College — In the past several years the global impacts brought about by climate change have become increasingly apparent through the advent of numerous natural disasters. In these events the social costs of climate change have materialized demonstrating high costs in lives, livelihoods, and equity. Due to geographic bad-luck many of the countries most affected by climate change are those that contributed least, a challenge that’s exacerbated by a lack of robust infrastructure in these countries. Wealthy nations remain at risk themselves and incidents such as Hurricanes Sandy & Katrina have demonstrated that in times of crisis even institutions like the Red Cross will abandon the poor to their deaths. As necessary action on climate change would cost the fossil fuel industry $20 trillion, money in politics has stymied action. Recently, however, a groundswell grassroots movement (e.g. People’s Climate March in NYC) and great strides in energy technology and policy have begun to create necessary change. Reports quantifying the impacts of climate change will be discussed, as well as an update on the current state of the global climate justice movement. The important contributions from scientists to this movement will be highlighted.

V1.00288 The Evolution of Carbon Burning Flames Inside Super-Asymptotic Giant Branch Stars. CARL FIELDS, ROBERT FARMER, FRANCIS TIMMES, Arizona State University, SPIDER COLLABORATION — We explore how carbon burning impacts the bifurcation region separating stars whose final fate is a massive white dwarf from stars whose final fate is a massive star supernova. A dense grid of models with initial mass (Mini) from 6.0 M⊙ to 11.0 M⊙ are evolved from pre-main-sequence to the end of nuclear burning using the open-source toolkit, Modules for Experiments in Stellar Astrophysics (MESA). For stars between 7.0 M⊙ ≤ Mini ≤ 9.0 M⊙, energy losses at the center of the core due to neutrino cooling causes a temperature inversion resulting in off-center ignition. First ignition occurs where the minimum temperature of 7.1010 K, and a density (ρcrit) of 2·106 g/cm³ is met. We conclude that for stars within this range, the location of first ignition decreases as a function of initial mass. Moreover, we show that there exist a unique ignition density of 2·106 g/cm³.
V1.00289 A Type of Dark Matter May be found by Neutron Emissions, RICHARD KRISKE, University of Minnesota — This author has previously suggested that Neutrons in Neutron Stars are arranged in a Quasi-Crystal Structure and when they are ejected at Relativistic Velocities maintain some of that structure in forming Very large Nuclei of many Neutrons. When the Neutrons are ejected a Nuclear Electron and a Neutroino are emitted, making Neutron Stars Neutroino Sources, both from the Surface and from the Ejected matter. Likewise large collections of the Ejected matter form Dark Matter in Outer space as they are Super Heavy Hydrogen and sometimes just large Collections of Neutrons. As time passes the Large Collections of Neutrons break apart and form many Super Heavy Hydrogen Nuclei, but of smaller mass. Each breaking produces Neutroino emissions. The Super Heavy Hydrogen combines with Oxygen to produce Super Heavy water, which collects in Comets, on Planets like Earth and on moons such as Europa. Europa should be emitting Neutrinons, as there should be some emissions from the Earth itself and from the Earth’s Atmosphere. The Neutrinons emitted from around Black Holes and Neutron stars should be particularly easy to detect, as there should be a lot of them.

V1.00290 A Synchrotron Radiation Research Facility for Africa, HERMAN WINICK, SLAC National Accelerator Lab — Africa is the only habitable continent without a synchrotron light source. Dozens of African scientists use facilities abroad. Although South Africa has become a member of ESRF, the number of users is limited by distance and travel cost. A light source in Africa would give thousands of African scientists access to this tool. Momentum is now building for an African light source, as a collaboration involving several sub-Saharan African countries. An interim Steering Committee has been formed. SESAME, now nearing completion in Jordan as a collaboration of 9 countries in the Middle East (www.sesame.org.jo) may be the example followed. UNESCO became the umbrella organization for SESAME at its Executive Board 164th session, May 2002, as it did in the case of CERN in the 1950s. UNESCO’s Executive Board described SESAME as “a quintessential UNESCO project combining capacity building with vital peace-building through science” and “a model project for other regions”. It is likely that UNESCO, if asked, would play a similar role as a facilitator for an African light source.

V1.00291 Analytical Model for the Diffusion Process in a In-Situ Combustion Tube, PATRICIA GUTIERREZ, ADRIAN REYES, Universidad Nacional Autónoma de México — The in-situ combustion process (ISC) is basically an air or oxygen enriched gas injection oil recovery process, inside an extraction well. In contrast to a conventional gas injection process, an ISC process consists in using heat to create a combustion front that raises the fuel temperature, decreasing its viscosity, making extraction easier. The oil is taken toward the producer by means of a vigorous gas thrust as well as a water thrust. To improve and enhance this technique in the field wells, it has been widely perform experimental laboratory tests, in which an in-situ combustion tube is designed to simulate the extraction process. In the present work we propose to solve analytically the problem, with a parabolic partial differential equation associated to the convection-diffusion phenomenon, equation which describes the in-situ combustion process. The whole mathematical problem is established by completing this equation with the correspong boundary and initial conditions, the thickness of the combustion zone, flow velocity, and more parameters. The theoretically obtained results are compared with those reported in literature. We further, fit the parameter of our model to the mentioned data taken from the literature.

V1.00292 Flexo-Opto-Electric Studies of fullerene (C$_{60}$) nano-colloids in namatic liquid crystal, JON FOUST, ANGELO VISCO, KEVIN SOBCZAK, RIZWAN MAHMOOD, Slippery Rock University — We have explored the effects of fullerene (C$_{60}$) nano colloids on the elastic, dielectric and optical properties of thermotropic liquid crystal in nematic phase as a function of C$_{60}$ concentration and temperature. Data suggest softening of elastic behavior and divergence of dielectric properties as the temperature approaches to the isotropic phase. We will also report critical concentration and the critical exponent as extracted by fitting data to a model equation. These studies are important because of the potential applications in liquid crystal devices, drug delivery vehicles, and solar energy systems.

V1.00293 Metallicities of Low Mass Inefficient Star Forming Dwarfs in S4G: Testing the Closed Box Paradigm, MYLES MCKAY, South Carolina State University, SABRINA STIREWALT, University of Virginia, KARTIK SHETH, National Radio Astronomy Observatory, BONITA DE SWARDT, Square Kilometre Array South Africa, DONALD WALTER, South Carolina State University — Low mass dwarf galaxies are the most numerous extragalactic population in the Local Universe. Many gas-rich dwarfs appear to be forming stars less efficiently than normal, massive disk galaxies and are therefore important laboratories for the study of star formation. Here we present new observations using the Palomar Double Spectrograph for 19 dwarf galaxies from the S4G Survey with the lowest stellar to HI mass ratios. Preliminary analysis of the data indicate a wide range of metallicities which vary by as much as 0.5 dex in a single galaxy in different star forming regions. Such a dispersion in metallicities favors an open box model and the results suggest a varid star formation history, possibly induced via minor mergers and accretion.

V1.00294 A phenomenological model for tunneling rate of nonequilibrium quasiparticles in superconducting qubits, MOHAMMAD ANSARI, Kavli Institute for Nanoscience, Delft University of Technology — In superconducting qubits the lifetime of quantum states cannot be prolonged arbitrarily by decreasing temperature. At low temperature quasiparticles tunneling between electromagnetic environment and superconducting islands takes the condensate state out of equilibrium due to charge imbalance. We obtain tunneling rate from a phenomenological model for non-equilibrium, where a fixed non-equilibrium quasiparticle density leads to a temperature-dependent chemical potential shift. This deduces a non-monotonic behavior of the relaxation rate as function of temperature. As a result electromagnetic environment can dramatically influence qubit transitions. This leads to crucial fabrication hints for improvement in quantum control of superconducting qubits.

V1.00295 Simulation of a Solid-Solid Transition in Confined Colloidal Hard Spheres, WEIKAI QI, Soft Condensed Matter, Debye Institute for Nanomaterials Science, Utrecht University, The Netherlands, YI PENG, YI-HONG HAN, Department of Physics, Hong Kong University of Science and Technology, Hong Kong, China, RICHARD BOWLES, Dept. Chemistry, University of Saskatchewan, Canada, MARJOLEIN DIJKSTRA, Soft Condensed Matter, Debye Institute for Nanomaterials Science, Utrecht University, The Netherlands — Recent experiments on a system of colloidal particles confined between two flat plates showed a two-stage nucleation process involving the transition of a solid, consisting of n-1 crystalline layers with a square symmetry (n=1 s-phase), to another solid consisting of n triangular layers (n t-phase), via an intermediate metastable liquid droplet [1]. Using event-driven molecular dynamics and Monte Carlo simulations, we study the 5s → 4t solid-solid transition in colloidal hard spheres confined between two planar hard walls. The 5s solid initially melts, forming a liquid droplet, within which the 4t solid nucleates. Calculations of the free-energy landscape confirm that the optimal kinetic pathway is a two-stage nucleation process with a critical nucleus consisting of liquid-like and t-solid-like particles. In addition, we find that the t-solid-like cluster nucleates near the planar hard walls, and contains both face-centered-cubic and hexagonal-close-packed ordered particles.

3 Current Address: Dept. Chemistry, University of Saskatchewan, Canada
V1.00296 A Pseudopotential Approach to Compute Thermodynamic Properties of Liquid Semiconductors, ANAND PRAJAPATI, PANKAJ THAKOR, Department of Physics, Veer Narmad South Gujarat University, Surat 395 007, Gujarat, India, YOGESH SONVANE, Department of Applied Physics, S. V. National Institute of Technology, Surat 395 007, Gujarat, India — This paper deals with the theoretical approach for calculating the thermodynamical properties viz. Enthalpy(E),Entropy(S) and Helmholtz free energy(F) of some liquid semiconductors (Si, Ga, Ge, In, Sn, Ti, Bi, As, Se, Te and Sb). The Gibbs-Bogoliubov(GB) variational method is applied to compute the thermodynamical properties. Our well established model potential is used to define the electron-ion interaction. Charged Hard Sphere (CHS) reference system is used to describe the structural contribution to the Helmholtz free energy in the liquid phase. Local field correction function proposed by Farid et al is adopted to see the screening effect. Lastly, our newly constructed model potential is an effective one to produce the data of thermodynamical properties of some liquid semiconductor.

V1.00297 Electronic and Optical Properties of Core/Shell Pb16X16/Cd52S52 (X=S, Se, Te) Quantum Dots, PATRICK TAMUKONG, North Dakota State University, MICHAEL MAYO, Retired, SVETLANA KILINA, North Dakota State University — The electronic and optoelectronic properties of semiconductor quantum dots (QDs) are mediated by surface defects due to the presence of dangling bonds producing trap states within the HOMO-LUMO energy gap, and contributing to fluorescence quenching. Surface capping ligands are generally used to alleviate this problem and increase the quantum yields of QDs. An alternative way is to synthesize core-shell QD structures, i.e., a QD due to the shell composition of another semiconductor material. We have investigated the effects of Cd52S52 shells on the photoexcited dynamics of Pb16X16 (X=S, Se, Te) QDs. The thin (≈ 0.50 nm) shells were found to result largely in type I core/shell structures and a blue shift of the absorption spectra. Our studies revealed fairly strong core-shell hybridization in the electronic states close to the conduction band (CB) edge for Pb16S16 and Pb16Se16 cores, whereas for the Pb16Te16 core, such CB states were largely shell-like in nature. Nonadiabatic DFT-based dynamics, coupled with the surface hopping method, was used to study the effects of the core and shell compositions on energy relaxation rates in these systems.

V1.00298 Role of Radio Frequency Power in the Plasma Enhanced Chemical Vapor Deposition, SUDIP SEN, Claflin University, SC and College of William & Mary, VA — PECVD. Plasma Enhanced Chemical Vapor Deposition, is used to deposit thin films from a gas state to a solid state on a substrate. Experimental study from the X-ray diffraction spectra of Silicon-Oxide films deposited as a function of radio frequency (rf) power apparently indicates that RF power might be playing a stabilizing role and produces better deposition. The results show that the rf power results in smoother morphology, improved crystallinity, and lower sheet resistance value in the PECVD process. The PECVD processing allows deposition at lower temperatures, which is often critical in the manufacture of semiconductors. In this invited talk we will address two aspects of the problem, first to develop a model to study the mechanism of how the PECVD is affected by the RF power, and second to actually simulate the effect of rf power on PECVD. As the PECVD is a very important component of the plasma processing technology with many applications in the semiconductor technology and surface physics, the research proposed here has the prospect to revolutionize the plasma processing technology through the stabilizing role of the rf power. Recent results obtained after the abstract submission will also be included.

V1.00299 Magnetoelastic coupling in superconducting Sr2VO3FeAs revealed by scanning tunneling microscopy, SEOKHWAN CHOI, HYUNWOO CHOI, HYUN-JUNG LEE, JIN-OH JUNG, DONGHYON SON, Department of Physics, KAIST, Daejeon 305-701, Korea, JUN SUNG KIM, JONG MOK OK, Department of Physics, POSTECH, Pohang 790-784, Korea, JHINHWAN LEE, Department of Physics, KAIST, Daejeon 305-701, Korea — Sr2VO3FeAs is known to exhibit high Tc (~ 37K) superconductivity with no magnetic ordering in the FeAs layer but weak magnetic moment in the V sublattice. From the density functional theory study, there is found to be a band gap between the electronic levels of V 3d orbitals. We have studied on Sr2VO3FeAs single crystal using spectroscopic imaging scanning tunneling microscopy (SI-STM) with variable temperature from 4.6K to 100K, and magnetic field up to 7T. Our results show that Sr2VO3FeAs has charge density wave (CDW) modulation in the V sublattice with the same wave vector observed in the neutron scattering experiment. The modulation strength is reduced with applying magnetic field. An electronic Fermi surface with largest V 3d character shows suppressed superconductivity possibly due to strong V-site correlation. However the multi-orbital nature of FeAs allows overall unsuppressed superconductivity at high Tc.

V1.00300 Carbon Nanotube Charge Collectors in Doped Hybrid Perovskite Solar Cells, ZANE OLDS1,2, ROSS HAROLDSON2, KAMIL MIELCZAREK, ANVAR ZAKHIDOV1, Univ of Texas - Dallas — Hybrid organo-metallic solar cells based on perovskite crystals have had steadily improved power conversion efficiencies over the past two years, and within this period have achieved efficiencies over 19%. We show that additions of Metal-Halide dopants, such as Cobalt (II) Iodide or Indium and Bismuth materials, can cause substitutional doping at the Lead atom. This may result in structural distortions (as in isovalent Co-doping) from the lattice causing change in the spatial distribution of charge carriers. We show that Co-doping results in an increased open circuit voltage upon light soaking due to possible higher charge accumulation. We also have investigated effects of p-doping the hole transport layer. We also incorporate composite sheets of MW carbon nanotubes and silver nanowires as charge collectors. These sheets provide a transparent and flexible electrode with lower sheet resistance due to integration of Ag nanowires. This has an effect on the work function of the sheet, p-doping the hole transport layer. We also incorporate composite sheets of MW carbon nanotubes and silver nanowires as charge collectors. These sheets provide a transparent and flexible electrode with lower sheet resistance due to integration of Ag nanowires. This has an effect on the work function of the sheet, p-doping the hole transport layer.

V1.00301 Pressure-induced magneto-structural transition in iron via a modified solid-state nudged elastic band method, NIKOLAI A. ZARKEVICH, DUANE D. JOHNSON2, Ames Laboratory, U.S. Department of Energy at Iowa State University, Ames, Iowa 50011-3020 — Materials under pressure may exhibit critical electronic and structural transitions that affect equation of states, as known for superconductors and the magneto-structural transformations of iron with both geophysical and planetary implications. While experiments often use constant-pressure (diamond-anvil cell, DAC) measurements, many theoretical results address a constant-volume transitions, which avoid issues with magnetic collapse but cannot be directly compared to experiment. We establish a modified solid-state nudged elastic band (MSS-NEB) method to handle magnetic systems that may exhibit moment (and volume) collapse during transformation. We apply it to the pressure-induced transformation in iron between the low-pressure body-centered cubic (bcc) and the high-pressure hexagonal close-packed (hcp) phases, find the bcc-hcp equilibrium coexistence pressure and a transitional pathway, and compare to shock and DAC experiments.

V1.00302 POSTDEADLINE ABSTRACTS —
V1.00303 Theoretical Investigation Optical Properties of Si$_{12}$C$_{12}$ Clusters and Oligomers having Potential as Excitonic Materials$^1$, XIAOFENG DUAN, Air Force Research Laboratory, AFRL RCM, LARRY BURGGRAF, Air Force Inst of Tech - WPAFB — SIC clusters may have potential in 2-D exciton circuits. We determined the most stable Si$_n$C$_m$ isomer structures ($n \leq 12$) out of hundreds to thousands isomers using a method combining Stochastic Potential Surface Search and Pseudopotential Plane-Wave Density Functional Theory Car-Parinello Molecular Dynamics simulated annealing (PSWP-CPMD-SA). Four low-energy Si$_{12}$C$_{12}$ isomer structures are discussed to illustrate the varying optical properties of clusters with structures: i) cage type with C- and Si- segregations, ii) symmetric type formed having n-stacked C aromatic rings and exterior Si regions, iii) nearly planar bowl with C fullene fragment surrounded by Si atoms, and iv) symmetrical SIC cluster having alternate SiC bonding in the structure. We employed B3LYP and PBE0 functionals and both cc-pVTZ and aug-cc-pVTZ basis sets to perform TDDFT calculations of excitation energies and photo-absorption spectra to show how structure and bonding patterns affect photo excitations in different types of SIC clusters. The electron and the hole charge distribution patterns in excitation were calculated for major photoabsorption transitions, reported for the most stable isomer, closo Si$_{12}$C$_{12}$. To understand electric field effects we also calculated dynamical polarizabilities for all the four structures using Coupled Perturbed Hartree-Fock (CPHF) at B3LYP/aug-cc-pVTZ and PBE0/aug-cc-pVTZ level of theory.

$^1$We gratefully acknowledge support from the Air Force Office of Scientific Research in a program managed by Dr Michael Berman.

V1.00304 Use of atomic hydrogen source in collision: technological challenges$^2$, R.T. HOVEY, E.L. VARGAS, D.I. PANCHENKO, D.A. RIVAS, V.M. ANDRIANARIJAONA, Department of Physics, Pacific Union College, Angwin, CA 94508 — Atomic hydrogen was extensively studied in the past due to its obvious fundamental aspect. Also, quite few investigations were dedicated to atomic hydrogen sources because the results of experimental investigations on systems involving H would provide very rigorous tests for theoretical models. But even if atomic hydrogen sources are currently widespread in experimental physics, their uses in experiments on collisions are still very challenging mainly due to threefold problem. First, there is the difficulty to create H in the laboratory in sufficiently large number densities. Second, there is the strain to adjust the velocities of the produced atomic hydrogen. And third, there is the toll to control the internal energies of these atomic hydrogens. We will present an outline of different techniques using atomic hydrogen sources in collisions, which could be found in the libraries, such as merged-beam technique, gas cell technique, and trap, and propose an experiment scheme using a turn-key atomic hydrogen source that experiments such as charge transfer could benefit from.

$^2$This work is supported by the National Science Foundation under Grant No. PHY-1068877.

V1.00305 Spatially and temporally resolved exciton dynamics and transport in single nanostuctures and assemblies, LIBAI HUANG, Purdue University — The frontier in solar energy conversion now lies in learning how to integrate functional entities across multiple length scales to create optimal devices. To address this new frontier, I will discuss our recent efforts on elucidating multi-scale energy transfer, migration, and dissipation processes with simultaneous femtosecond temporal resolution and nanometer spatial resolution. We have developed ultrafast microscopy that combines ultrafast spectroscopy with optical microscopy to map exciton dynamics and transport with simultaneous ultrafast time resolution and diffraction-limited spatial resolution. We have employed pump-probe transient absorption microscopy to elucidate morphology and structure dependent exciton dynamics and transport in single nanostructures and molecular assemblies. More specifically, (1) We have applied transient absorption microscopy (TAM) to probe environmental and structure dependent exciton relaxation pathways in sing-walled carbon nanotubes (SWNTs) by mapping dynamics in individual pristine SWNTs with known structures. (2) We have systematically measured and modeled the optical properties of the Frenkel excitons in self-assembled porphyrin tubular aggregates that represent an analog to natural photosynthetic antennae. Using a combination of ultrafast optical microscopy and stochastic exciton modeling, we address exciton transport and relaxation pathways, especially those related to disorder.

V1.00306 Pressure-induced magnetic quantum critical point in the itinerant helimagnet MnP, JINGUANG CHENG, Institute of Physics, Chinese Academy of Sciences, KAZUYUKI MATSUBAYASHI, ISSP, University of Tokyo, WEI WU, FUKUN LIN, JIANPING SUN, JIANLIN LUO, Institute of Physics, Chinese Academy of Sciences, YOSHIYA UWATOKO, ISSP, University of Tokyo, JIAQIANG YAN, MASAAKI MATSUDA, Oak Ridge National Laboratory — manganese monophosphide, MnP, is an interesting magnetic material that has been investigated since 1960s in the context of rich magnetic phase diagram, Lifshitz multicritical point, and magnetocaloric effect [1-4]. It adopts in the orthorhombic B31-type structure derived from the hexagonal NiAs-type structure. At ambient pressure, MnP is ferromagnetic below $T_c = 291$ K and $T_c \approx 50$ K, below which the magnetic structure changes into a screw-type order with Mn spins rotating in the a-b plane and propagating along the c axis [1,2]. We have performed comprehensive high-pressure studies on MnP single crystals up to 10 GPa with a suite of experimental probes, including resistivity, ac magnetic susceptibility, and stochastic exciton modeling, we address exciton transport and relaxation pathways, especially those related to disorder.

V1.00307 On The Nature Of Spacetime, ASEEM GUPTA$^3$, None — While Einstein made spacetime relative for observers and an active player in physical phenomena he tacitly assumed that all observers experience spacetimes that are always synchronized We propose extension of concept of spacetime by considering possibility of an observer experiencing spacetimes that cannot synchronize with that of a system due to impossibility of transfer of any information between them. This coupled with fundamental premise of quantized action leads to increasing desynchronisation between spacetime experienced by observer and that of system leading to only probability distribution functions connecting spacetime coordinates of two. This desynchronisation of spacetimes is postulated as the root cause of fundamental probabilistic nature of Quantum Physics. It is shown that Schrodinger’s equation models space desynchronization but not that of time inclusion of which leads to Quantum Field Theory. Desynchronization explains fundamental difference in quantum statistics and classical statistics and also existence of dynamic symmetry in addition to geometric symmetry. Nested desynchronized spacetime model of our Universe is proposed. It is shown how desynchronization can allow modeling of elementary particles as extended systems and not point-like explaining why these may be modeled as representations of Lie groups.

$^3$This is a study to discern one fundamental premise of spacetime conception in classical physics and demonstrating how this premise does not hold in quantum physics. Desynchronization is presented as fundamental aspect of ontology of quantum theory.
V1.00308 Coexistence of three-wave, four-wave and five-wave mixing processes and Autler-Townes splittings in a superconducting artificial atomic system

GUO-QIN GE, HAICHAO LI, Huazhong University of Science and Technology — We present a theoretical study of multi-wave mixing in a driven superconducting quantum qubit (artificial atom) with \( \Delta \)-type three-level structure. We first show that three-wave mixing (TWM), four-wave mixing (FWM) and five-wave mixing (FWM) processes can coexist in the microwave regime in such an artificial system due to the absence of selection rules. Because of electromagnetically induced transparency suppression of linear absorption in a standard ladder-type configuration, the generated FWM is enhanced greatly and its efficiency can be as high as \(0.1\%\) for only a single artificial atom, which is comparable to or even larger than that of many previous schemes in atomic systems. Moreover, it is possible to obtain a more higher conversion efficiency by using an array of such artificial atoms. We also show that quantum interference between TWM and FWM signals has a significant impact on the total signal intensity being a coherent superposition of these two signals. Our scheme for the generation of microwave signals may have potential applications in solid-state quantum information processing.

This work was supported in part by the National Natural Science Foundation of China under the Grant No. 11274132 and the Hubei Provincial Natural Science Foundation of China.

V1.00309 Highly Ordered and Highly Aligned Two-Dimensional Binary Superlattice of a SWNT/Cylindrical-Micellar System

SUNG-HWAN LIM, HYUNG-SIK JANG, JAE-MIN HA, KAIST, TAE-HWAN KIM, KAERI, PAWEL KWASNIEWSKI, THEYENCHERI NARAYANAN, ESRF, KYEONG SIK JIN, POSTECH, SUNG-MIN CHOI, KAIST — The synthesis of binary nanoparticle superlattices, which may provide new properties through synergetic coupling between different types of nanoparticles, are of great interest for various potential applications as well as its own scientific merit. While existing progress has been made in the fabrication of binary spherical-nanoparticle superlattices with various symmetries by using an interplay of entropic and enthalpic interactions, systematic experimental studies on the formation of binary 1D nanoparticle superlattices have been very rare. Here, we report a highly ordered intercalated hexagonal binary superlattice of hydrophobically functionalized single-walled carbon nanotubes (p-SWNTs) and surfactant (C12E5) cylindrical micelles. When p-SWNTs (with a diameter slightly larger than that of the C12E5 cylinders) were added to the hexagonally packed C12E5 cylindrical-micellar system, p-SWNTs positioned themselves in such a way that the free-volume entropies for both p-SWNTs and C12E5 cylinders were maximized, thus resulting in the intercalated hexagonal binary superlattice. The binary superlattice can be highly aligned in one direction by an oscillatory shear field and remains aligned after the shear is removed.

This research was supported by NRF grants funded by the MEST of the Korean government (No. 2014R1A2A1A05007109 and 2011-0031931) and the BK21.

V1.00310 Optical studies of photoactive states in mixed organic-inorganic hybrid perovskites stabilized in polymers

BEATA KARDYNAL, LIFEI XI, PGI 9, Forschungszentrum Jülich, Germany, TEDDY SALIM, MSE, NTU, Singapore, SVEN BORGHARDT, TOMA STOICA, PGI 9, Forschungszentrum Jülich, Germany, YENG MING LAM, MSE, NTU, Singapore — Mixed organic-inorganic hybrid perovskites \( \text{MAX-PbY}_2(X,Y=\text{I, Br, Cl}) \) have been demonstrated as very attractive materials for absorbers of solar cells and active layers of light emitting diodes and optically driven lasers. The bandgap of the perovskites can be tuned by mixing halogen atoms in different ratios. In this presentation we study mixed \( \text{MAX-PbY}_2(X,Y=\text{I, Br, Cl}) \) particles synthesized directly in protective polymer matrices as light emitters. Both, time integrated and time resolved photoluminescence have been used to study the materials. So synthesized \( \text{MAX-PbX}_2 \) are very stable when measured at room temperature and in air with radiative recombination of photogenerated carriers as the main decay path. In contrast, \( \text{MAX-PbY}_2 \) with mixed halogen atoms display luminescence from sub-bandgap states which saturate at higher excitation levels. The density of these states depends on the used polymer matrix and increases upon illumination. We further compare the \( \text{MAX-PbY}_2 \) synthesized in polymers and as films and show that these states are inherent to the material rather than its microstructure.

This work has been supported by EU NWs4LIGHT grant.

V1.00311 Phase Transition Study of Ammonia Borane/Polymer Composites: Potential Hydrogen Storage Systems

OZGE GUNAYDIN-SEN, RAMESH SUVVARI, Lamar University — Ammonia Borane \((\text{NH}_3\text{BH}_3)\), a potential hydrogen storage material exhibits a phase transition at \( T_P \sim 223 \text{ K} \) but the underlying mechanism is unclear. Ammonia borane \((\text{AB})\) blended with polymers (e.g. polyacrylamide) significantly improves the dehydrogenation kinetics and suppression of byproducts/impurities. We carried out heat capacity measurements over a temperature range of 180–300 K, and detected an anomaly at around 223 K, indicating a first-order transition. The change in enthalpy and entropy was calculated for \( \text{AB} \) as well as the composites and compared. The transition enthalphy and entropy revealed a decrease by increasing the polymer content and the transition temperature showed a small shift to lower temperatures for \( \text{AB}/\text{Polymer} \) composites both of which could be due to the interaction between polyacrylamide and \( \text{AB} \) after blending. This phenomena was also supported by infrared measurements.

This work was supported by Lamar University and Welch Foundation.

V1.00312 Pure spin current transport in Alq3 by spin pumping

SHENWEI JIANG, PENG WANG, ZHONGZHI LUAN, XINDE TAO, HAIFENG DING, DI WU, Nanjing University — The use of organic semiconductors (OSCs) in spintronics has aroused considerable interests, owing to their much longer spin-relaxation times of OSCs than those of inorganic counterparts. The most studied example is the organic spin valve (OSV), in which magnetoresistance (MR) effect is frequently reported. However, studies on pure spin current injection and transport in OSCs are scarce. Recently, the pioneering work by Watanabe et al. demonstrated that pure spin current can be pumped into and propagates in semiconducting polymers \([1]\). In the present work we extend the study to small molecule OSCs, and demonstrate that pure spin current can be injected into Alq3 from the adjacent magnetic insulator \( Y_2\text{Fe}_5\text{O}_3 \text{(YIG)} \) by spin pumping. The pure spin current is detected by inverse spin Hall effect (ISHE) in Pd after propagation through Alq3. From the ISHE voltage \( V_{\text{ISH}} \) as a function of the Alq3 thickness, the spin diffusion length is determined to be \( \sim 50 \text{ nm} \) and does not depend on temperature. This result indicates the MR decrease as increasing temperature in OSVs is not due to the reduced spin diffusion length.

V1.00313 Second-harmonic rotational anisotropy and circular dichroism of a Sb$_2$Te$_3$ topological insulator nanoplate, YONG AN, ROBIN JACOBS-GEDRIM, AVERY GREEN, SAMUEL O'MULLANE, ALAIN DIEBOLD, SUNY College of Nanoscale Science and Engineering — Topological insulators are an exotic class of materials that are electrically insulating in the bulk but conducting at the surface due to the presence of topological surface states. Spin-momentum locking of the surface states makes topological insulators potential candidates for spintronic applications. Experimental detection of the surface states and their spin polarization due to spin-momentum locking remains difficult because of the lack of surface-specific analytical techniques. Optical second-harmonic generation (SHG) is a surface-specific probe and thus it should probe the topological surface states preferentially over the bulk states. Here we present an experimental study of SHG from a Sb$_2$Te$_3$ topological insulator nanoplate, which is a 30-µm wide, hexagonal-shaped, and (001)-faced single crystal grown via chemical vapor deposition on an oxidized Si(001) substrate. We show that SHG rotational anisotropy can identify the crystalline symmetry of the nanoplate and also probe spin-polarized currents excited by circularly polarized light. Furthermore, by measuring SHG circular dichroism (the differential SHG of left- and right-handed circularly polarized excitation), we show that a non-zero SHG circular dichroism signal when the incident plane lies in the mirror symmetry plane of the nanoplate corresponds to time reversal symmetry breaking due to photo-induced spin polarization.

V1.00314 ABSTRACT WITHDRAWN —

V1.00315 Trapping and manipulating single nano-objects with dynamic temperature fields, FRANK CICHOS, MARCO BRAUN, ANDREAS BREGGULLA, University Leipzig, Germany, MOLECULAR NANOPHOTONICS GROUP TEAM — One of the challenges of single molecule experiments in solution is the ability to trap and manipulate one or even multiple molecules against the erratic Brownian motion. The Brownian fluctuations are fueled by thermal energy and increase in strength with increasing temperature. Therefore, it is at first glance counterintuitive to confine Brownian fluctuations with the help of elevated temperatures. In thermal nonequilibrium, however, temperature gradients induce thermo-phoretic and thermo-osmotic drifts, which provide the means for single particle manipulation in solution. Here we describe experiments which use optically heated metal nanostructures to create dynamical temperature profiles in solution. These temperature profiles induce thermo-phoretic drift fields that act as effective potentials for objects suspended in liquids. Combined with optical feedback mechanisms, such effective potentials can be shaped to store and manipulate single or even well-defined number of multiple objects in a small observation volume. The developed thermophoretic trapping system therefore paves the way for extended single molecule studies in solution or even well controlled bi- or multi molecular interaction studies.

V1.00316 Large Chern number topological superfluids in bilayer system, MING GONG, BEIBING HUANG, The Chinese University of Hong Kong, GONG TEAM — We investigate the topological phase transition with large Chern number in a coupled layer system. The topological transitions between different topological superfluids can be realized by controlling the binding energy, interlay tunneling and layer asymmetry etc. These topological phase transitions can be characterized by energy gap closing and reopening at the critical points at zero momentum, where the Pfaffian and Chern number undergo a discontinuous change. The bulk-edge correspondence ensures that the number of edge modes exactly equals the Chern number. However, all these edge modes localized at the same edge have the same chirality and propagate along the same direction. These topological phases can be detected by spin texture at or near zero momentum, which changes discontinuously across the phase transition point due to band inversion. This model can be easily generalized to multilayer system in which the Chern number equals any positive integer — similar to that in integer quantum Hall effect — can be realized. This work paves a new way in the realization of topological superfluids with large Chern number.

V1.00317 Two distinct superconducting fluctuation diamagnetisms in Bi$_2$Sr$_{2-x}$La$_x$CuO$_{6+y}$, H. XIAO, Institute of Physics, Chinese Academy of Sciences — Superconducting fluctuations were studied through the angular dependent torque measurements on a series of Bi$_2$Sr$_{2-x}$La$_x$CuO$_{6+y}$ (BSCCO) single crystals. Two distinct superconducting fluctuation diamagnetisms were observed: one is the superconducting thermal fluctuation, with a boundary close to the superconducting phase boundary; while another one, up to the temperature as high as about 180 K, showing maximum signal in the sample with hole carrier density $p = 0.125$, could be due to preformed pairs. In addition, we observed linearly temperature dependent paramagnetic torque signals in BSCCO samples, possibly a result of quantum criticality from a quantum critical point at the optimal doping.

3We acknowledge support from the MOST of China, Projects No. 2011CBA00107 and No. 2012CB210302 and NSFC, project No. 11104335.

V1.00318 Straining graphene with low-temperature compatible electrostatic comb-drive actuators, TYMOFYI KHODKOV, MATTHIAS GOLDSCHE, JARA-FIT and II. Institute of Physics A, RWTH Aachen, SVEN REICHARDT, II. Institute of Physics A, RWTH Aachen, CHRISTOPH STAMPFER, JARA-FIT and II. Institute of Physics A, RWTH Aachen — Graphene holds great promises as an active element in future nano electromechanical systems. Therefore, thorough study of electromechanical properties of this 2D material is a crucial step towards its applications in flexible electronics. We present the fabrication and characterization of silicon-based electrostatic comb-drive actuators made for integrating individual graphene sheets. The micromachined comb-drive actuators are designed such that they can induce significant mechanical forces for straining graphene allowing to systematically investigate mechanical and electromechanical properties of high-quality graphene. By using highly doped silicon the comb-drive actuators become compatible with low temperatures, i.e. cryogenic temperatures allowing for quantum electromechanical experiments. Further device functionality is introduced by a local gate that enables the tunability of the chemical potential of the graphene. This approach makes possible a detailed study of the graphene under controlled high strain allowing simultaneous and independent tuning of other external parameters, i.e temperature, charge density, magnetic field. With Raman spectroscopy we measure and characterize mono and bilayer graphene samples at room temperature under applied strains up to 1%. A detailed analysis of data allows clear separation of strain and doping. It is demonstrated that with this technique graphene sheet reproducibly experiences only strain while operating the comb-drive actuator.

V1.00319 Fragmentation, vortices and phantom vortices in rotating Bose-Einstein Condensates, MARIOS C. TSATSOS, University of Sao Paulo, STORM WEINER, University of California at Berkeley, AXEL LODE, University of Basel — Superfluids are a superfluid subject to external rotation. In this work we study a trapped ultracold Bose gas of $N = 100$ atoms in two spatial dimensions that is either stirred by a rotating beam or by a rotating anisotropy. We extend the time-dependent multiconfigurational Hartree method for bosons, that extends the mainstream mean-field theory, to calculate the dynamics of the gas in real time. As the gas is rotated the wavefunction of the system changes symmetry and topology. Fragmentation accompanies the resonances and change of symmetry of the wavefunction of the gas. We see a series of resonances as the rotating frequency is increased and a variety of different excitations. Most importantly, we identify a novel type of topological defect as a phantom vortex. A phantom vortex cannot be seen in the density of the gas but it leaves its signature in the correlation function. We conclude that fragmentation of the gas appears hand-in-hand with resonant absorption of energy and angular momentum from the external agent of rotation.
V1.00320 Influence of $^{13}$C isotopic labeling location of $^{13}$C DNP of acetate using TEMPO free radical. CHRISTOPHER PARISH, PETER NIEBDSALSKI, LLOYD LUMATA, University of Texas System — Dynamic nuclear polarization (DNP) via the dissolution method enhances the liquid-state magnetic resonance (NMR or MRI) signals of insensitive nuclear spins by at least 10,000-fold. The basis for all these signal enhancements at room temperature is the polarization transfer from the electrons to nuclear spins at cryogenic temperature and high magnetic field. In this work, we have studied the influence of the location of $^{13}$C isotopic labeling on the DNP of sodium acetate at 3.35 T and 1.4 K using a wide ESR linewidth free radical 4-oxo-TEMPO. The carbonyl $[^{1-^{13}}]$Cacetate spins produced a polarization level that is almost twice that of the methyl $[2-^{13}]$Cacetate spins. On the other hand, the polarization of the methyl $^{13}$C spins doubled to reach the level of $[1-^{13}]$Cacetate when the methyl group was deuterated. Meanwhile, the solid-state nuclear relaxation of these samples are the same and do not correlate with the polarization levels. These behavior implies that the nuclear relaxation for these samples is dominated by the contribution from the free radicals and the polarization levels can be explained by a thermodynamic picture of DNP.

V1.00321 Dynamic nuclear polarization of carbonyl and methyl $^{13}$C spins in acetate using trityl OX063. PETER NIEBDSALSKI, CHRISTOPHER PARISH, LLOYD LUMATA, Univ of Texas - Dallas — Hyperpolarization via dissolution dynamic nuclear polarization (DNP) is a physics technique that amplifies the magnetic resonance signals by several thousand-fold for biomedical NMR spectroscopy and imaging (MRI). Herein we have investigated the effect of carbon-13 isotopic location on the DNP of acetate (one of the biomolecules commonly used for hyperpolarization) at 3.35 T and 1.4 K using a narrow ESR linewidth free radical trityl OX063. We have found that the carbonyl $^{13}$C spins yielded about twice the polarization produced in methyl $^{13}$C spins. Deuteration of the methyl group, beneficial in the liquid-state, did not produce an improvement in the polarization level at cryogenic conditions. Concurrently, the solid-state nuclear relaxation of these samples correlate with the polarization levels achieved. These results suggest that the location of the $^{13}$C isotopic labeling in acetate has a direct impact on the solid-state polarization achieved and is mainly governed by the nuclear relaxation factor.

V1.00322 Key to formation of two-dimensional electron gas and two-dimensional superconductivity at LaAlO$_3$/SrTiO$_3$. YINLONG HAN, SHENCHUN SHEN, CHENGJIAN LI, ZHONGZHANG LIOU, GUOSHANG QI, JIACAI NIE, Department of Physics, Beijing Normal University, JIACAI NIE TEAM — In this report, we systematically studied the band alignment and interfacial atomic structure of (110) LaAlO$_3$/SrTiO$_3$ (LAO/STO) interfaces. We show that for both (110) and (001) LAO/STO heterojunctions, the intrinsic or extrinsic coexistence of La and Ti in ABO$_3$ perovskite unit cells at the interface reduces the valence of Ti, generating a local field and further leading to band bending of the STO. The free electrons would be trapped in the bended conduction band forming 2DEG. This opens new insights of band engineering for controlling the behavior of complex oxide heterojunctions. Besides, the two-dimensional superconductivity of (110) LAO/STO samples is demonstrated based on the systematical transport measurements. The two dimensional characteristics of the superconductivity is confirmed by analyzing the Berezinskii-Kosterlitz-Thouless transition. The estimated superconductivity thickness is about 18 nm. This discovery may inspire a new round of upsurge on study of LAO/STO interfaces.

V1.00323 Nontrivial anomalous Hall effect in ultrathin Pt/permalloy bilayers. YANQING ZHANG, RONG SHAN, Tongji Univ — Anomalous Hall effect of Pt (2.5 nm)/permalloy bilayers with the thickness $t_{Py}$ = 0.6–10 nm; Pt/permalloy (2.2 nm) bilayers with the thickness $t_{Py}$ = 1.5–10 nm and Pt (2.5 nm)/permalloy (2.2 nm) bilayers with the post-annealing temperature $100\text{–}500^\circ$C grown on MgO (001) substrates are investigated. The Pt/permalloy bilayer showed distinguished performance from the single permalloy layer due to the interfacial influence. Effective magnetic anisotropy of the bilayer with $t_{Py}$ <2.2 nm turns to be perpendicular to the film plane and it increases with decreasing measured temperature. More interestingly, the anomalous Hall effect is also greatly enhanced in these Pt/permalloy bilayers, comparing with that in bulk permalloy. The parameters presenting skew scattering, side jump and intrinsic contribution become extremely large, indicating a strong influence of spin orbit coupling coming from Pt/permalloy interface on the anomalous Hall effect.

V1.00324 Evolution of Anomalous Hall Behavior in Pt/Co/ Pt Trilayers. NIU YI SUN, RONG SHAN, Tongji University — A series of Pt (t nm)/Co (0.5 nm)/Pt (5–t nm) trilayers with various thickness were prepared and post annealed for changing the proportions among the skew scattering (a), side jump and intrinsic contributions (b), which dominate the anomalous Hall effect in these films from a general point of view. The shape of Hall angle curve ($\rho_{xx}/\rho_{xy}$ versus $\rho_{xx}$) is expected, turned from bending to linear and then bending again with raising the annealing temperature. The conventional scaling expression $\rho_{xx}/\rho_{xy} = a + b\rho_{xx}$ is not adequate for the analysis of anomalous Hall effect, especially in those very thin films since side jump is suppressed by surface roughness and the skew scattering is enhanced by the interfacial scattering. The evolution of anomalous Hall behavior with temperature demonstrates the reliability of identifying the skew scattering as a cooperation of a residual resistance of impurities and a phonon scattering. Likewise, the thermal treatment can also tune the side jump contribution, so as to the ratio between the side jump scattering and the skew scattering, leading to a change of the shape of Hall angle curve. The distinct physical image was exhibited by 3D maps of correlation coefficient for $\rho_{xx}/\rho_{xy}$ and $\rho_{xx}$, which may help to build a proper synergy between theory and experiment on the research of anomalous Hall effect.

V1.00325 Proton transfer along water bridges in biological systems with density-functional tight-binding. KRYSLE REISS, ABIAGAIL WISE, JAMES MAZZUCA, Alma College — When examining the dynamics of charge transfer in high dimensional enzymatic systems, the exact chemical mechanism of electrons increases exponentially with the size of the system. As a semi-empirical method, density-functional tight-binding aids in shortening these calculation times, but can be inaccurate in the regime where bonds are being formed and broken. To address these inaccuracies with respect to proton transfer in an enzymatic system, DFTB is being used to calculate small model systems containing only a single amino acid residue donor, represented by an imidazole molecule, and a water acceptor. When DFTB calculations are compared to B3LYP geometry calculations of the donor molecule, we observe a bond angle error on the order of 1.2 degrees and a bond length error on the order of 0.011 Å. As we move forward with small donor-acceptor systems, comparisons between DFTB and B3LYP energy profiles will provide a better clue as to what extent improvements need to be made. To improve the accuracy of the DFTB calculations, the internuclear repulsion term may be altered. This would result in energy profiles which closely resemble those produced by higher-level theory.

V1.00326 The Effect of Isotopic Substitution on Quantum Proton Transfer Across Short Water Bridges in Biological Systems. JACOB BLAZEJEWSKI, CHASE SCHULTZ, JAMES MAZZUCA, Alma College — Many biological systems utilize water chains to transfer charge over long distances by means of an excess proton. This study examines how quantum effects impact these reactions in a small model system. The model consists of a water molecule situated between an imidazole donor and acceptor group, which simulate a fixed amino acid backbone. A one dimensional energy profile is evaluated using density functional theory at the 6-31G*/B3LYP level, which generates a barrier with a width of 0.6 Å and a height of 20.7 kcal/mol. Quantum transmission probability is evaluated by solving the time dependent Schrödinger equation on a grid. Isotopic effects are examined by performing calculations with both hydrogen and deuterium. The ratio of hydrogen over the deuterium shows a 130-fold increase among the skew scattering (a), side jump and intrinsic contributions (b), which dominate the anomalous Hall effect in these films from a general point of view. The distinct physical image was exhibited by 3D maps of correlation coefficient for $\rho_{xx}/\rho_{xy}$ and $\rho_{xx}$, which may help to build a proper synergy between theory and experiment on the research of anomalous Hall effect.

V1.00327 Selective Label-free Electrokinetic Cell Tracker (SELECT): a novel liquid platform for cell characterization. RAJESHWARI TARUVAI KALYANA KUMAR, IZABELLE DE MELLO GINDRI, DAVID KINNAMON, PRADYOTHA KANCHUSTAMBH, DANIELI RODRIGUES, SHALINI PRASAD, University of Texas at Dallas, BIOMATERIALS FOR OSSEOINTEGRATION AND NOVEL ENGINEERING LAB COLLABORATION — Characterization and analysis of rare cells provide critical cues for early diagnosis of diseases. Electrokinetic cell separation has been previously established to have greater efficiency when compared to traditional flow cytometry methods. It has been shown by many researchers that buffer solutions in which cells are suspended in, have enormous effects on producing required dielectrophoretic (DEP) forces to characterize cells. Most commonly used suspension buffers used are deionized water and cell media. However, these solutions exhibit high level of intrinsic noise, which greatly masks the electrokinetic signals from cells under study. Ionic liquids (ILs) show promise towards the creation of conductive fluids with required electrical properties. The goal of this project is to design and test ILs for enhancing DEP forces on cells while creating an environment for preserving their integrity. We analyzed two methylimidazolium based ILs as suspension medium for cell separation. These dicationic ILs possess slight electrical and structural differences with high thermal stability. The two ILs were tested for cytotoxicity using HeLa and bone cells. The effects of electrical neutrality, free charge screening due to ILs towards enhanced electrokinetic signals from cells were studied with improved system resolution and no harmful effects.

V1.00328 Designing the bandgap of ZnO via Alloying of Magnesium and Sulfur1. JESSE HUSO, DINESH THAPA, HUI CHE, AMRAH CANUL, Department of Physics, University of Idaho, CALEB COROLEWSKI, M.D. MCCLUSKEY, Department of Physics, Washington State University, LEAH BERGMAN, Department of Physics, University of Idaho — ZnO is emerging as one of the materials of choice for UV applications. It has a benign chemical nature, a deep excitonic energy level, and a direct bandgap of 3.4 eV. The latter two properties make ZnO a highly efficient light-emitter at and above room temperature. Alloying ZnO with magnesium and sulfur creates the Mg$_x$Zn$_{1-x}$O$_2$ alloy systems which can tune the bandgap by design and add new optical and electronic functionalities to ZnO. In Mg$_x$Zn$_{1-x}$O$_2$, annealing studies were performed to overcome the phase segregation tendency, reduce intrinsic defects, and enhance the UV luminescence. It was found that annealing under an argon environment significantly improved the material and optical properties of the films due to the removal of intrinsic defects and completion of alloying. In Mg$_x$Zn$_{1-x}$O$_2$, phase segregation is expected to occur during growth due to the various crystal structures of end members and large difference in anion radii of S and O. However, this alloy system may form intermediate compounds such as zinc sulfate (ZnSO$_4$) which significantly impact material and optical properties. The removal of undesirable compounds will be discussed in terms of the growth conditions.

V1.00329 Correlation between local crystal structure and physical properties in BiS$_2$-based superconductors1. YOSHIKAZU MIZUGUCHI, JOE KAIJITANI, TAKAFUMI HIROI, OSUKE MIURA, Tokyo Metropolitan University, NAURANG SAINI, Sapienza University of Rome — Recently, layered superconductors with BiS$_2$ conduction layer have been discovered. Since the layered structure and low-dimensional electronic states are similar to cuprates and Fe-based superconductors, studies on exploration of new superconductors and discussion of superconductivity mechanisms of the BiS$_2$-based superconductors have got attention of researchers in the field of condensed matter physics. To understand the mechanisms of induced superconductivity in the BiS layer, we have investigated the physical properties and established superconductivity phase diagrams of various series of RE01-xFxBiS$_2$. To understand these phase diagrams, powder x-ray diffraction and x-ray absorption fine structure were carried out. It was found that optimization local crystal structure and reduction of in-plane disorder should be correlating with the physical properties of BiS$_2$-based compounds. We will discuss how superconductivity is induced and the Tc is enhanced, on the basis of local crystal structure such as atomic coordinates, atomic distances and in-plane disorder.

V1.00330 Critical anomalous Hall behavior in Pt/Co/Pt trilayers grown on paper with perpendicular magnetic anisotropy. WENRU CHE, XIAOFEI XIAO, NIUYI SUN, YANQING ZHANG, RONG SHAN, ZHENGANG ZHU. None — Perpendicular magnetic anisotropy was observed in Pt/Co/Pt trilayers prepared on three kinds of paper substrates with conspicuous difference of roughness by sputtering. Anomalous Hall effect exhibits well magnetic transport properties for partial samples. The trends of Hall resistivity over longitudinal resistivity ($\rho_{Hall}/\rho_{xx}$) versus $\rho_{xx}$ are bending instead of a traditional linear relationship for thick single-layer Co films. Further, study reveals that this behavior strongly depends on ratios among contributions from the skew scattering induced by residual resistance and phonons, the side jump and the intrinsic parts in anomalous Hall effect. A 3D map of correlation coefficients ($R$) of $\rho_{Hall}/\rho_{xx}$ and $\rho_{xx}$ shows the ratios locate at a critical and ultra-narrow area for our trilayers. This study may throw new light on the understanding of anomalous Hall effect as well as lead to an economical and practical method to fabricate Hall devices on flexible substrates.

V1.00331 ABSTRACT WITHDRAWN —

V1.00332 The origin of the UV Luminescence and its Enhancement in nanocrystalline ZnO film1. DINESH THAPA, JESSE HUSO, HUI CHE, AMRAH CANUL. Department of Physics, University of Idaho, CALEB COROLEWSKI, M.D. MCCLUSKEY, Department of Physics, Washington State University, LEAH BERGMAN, Department of Physics, University of Idaho — ZnO is an excellent luminescent material in the UV range with a potentially wide range of applications. However, many as-grown films are observed to contain some intrinsic defects which can diminish UV-emission efficiency, limiting their practical usefulness. This study presents a route to enhance UV luminescence from ZnO sputtered films. The photoluminescence (PL) spectra of the as-grown film exhibits prominent visible PL attributed to zinc interstitial (Zn$_i$) related defects, and a weak UV PL peak. To understand the route toward enhanced UV PL, one set of as-grown films were annealed in O$_2$ atmosphere and another set in Ar atmosphere. PL spectra of O$_2$-annealed samples revealed enhanced UV PL and elimination of the Zn$_i$-related defect emission, however, an O$_2$-related defect emission was evolved. In contrast, Ar annealed films showed significantly enhanced UV emission with nearly completely quenched visible emissions. The origin of UV PL was studied by low temperature measurements which indicate that an emission related to structural defects is dominant in the UV region.

1We acknowledge the US Department of Energy, Office of Basic Energy Science, Division of Materials Science and Engineering under Grant No. DE-FG02-07ER46386.

V1.00333 Leveraging zinc interstitials and oxygen vacancies for sensitive biomolecule detection through selective surface functionalization. NANDHINEE RADHA SHANMUGAM, SRIRAM MUTHUKUMAR, SHAJEE CHAUDHRY, SHALINI PRASAD, The University of Texas at Dallas, Richardson, TX 75080 — In this study, functionaly engineered EIS technique was implemented to investigate the influence of surface functionalization on sensitivity of biomolecule detection using nanostructured ZnO platform. Organic molecules with thiol and carboxylic functional groups were chosen to control biomolecule immobilization on zinc and oxygen-terminated 2D planar and 1D nanostructured ZnO surfaces. The amount of functionalization and its influence on charge perturbations at the ZnO-electrolyte interface were studied using fluorescence and EIS measurements. We observed the dependence of charge transfer on both the polarity of platform and concentration of cross-linker molecules. Such selectively modified surfaces were used for detection of cortisol, a major stress indicator. Results demonstrated preferential binding of thiol groups to Zn terminations and thus leveraging ZnO interstitials increases the sensitivity of detection over larger dynamic range with detection limit at 10fg/mL.
V1.00334 Spin transport of the frustrated quasi-two-dimensional Heisenberg antiferromagnet

, LEONARDO DOS SANTOS LIMA, Centro Federal de Educacão Tecnológica de Minas Gerais — We use the Self Consistent Harmonic Approximation together with the Kubo formalism of the Linear Response Theory to study the spin transport in the quasi-two-dimensional frustrated Heisenberg antiferromagnet in a square lattice with easy-plane ion single anisotropy at zero temperature. The regular part of the spin conductivity $\sigma^{reg}(\omega)$ is determined for several values of the critical ion single parameter $D_D$, that separates the low $D$ region from the large $D$ quantum paramagnetic phase. We have obtained an abrupt change in the spin conductivity in the point of phase transition indicating a strong influence of frustration on the spin transport properties.

V1.00335 The Vibrational Dynamics of 3D HOCl Above Dissociation1, YI-DER LIN, LINDA REICHL, University of Texas at Austin, CHRISTOF JUNG, Universidad Nacional Autonoma de Mexico — We have analyzed the vibrational dynamics of HOCl above dissociation using a 3D energy surface which governs the vibrational dynamics of HOCl above dissociation. The dynamics is dominated by an invariant manifold which is transversally unstable for small spacing between Cl and HO complex, and stable for large spacing. Above dissociation, the inM separates two mirror image periodic orbits, embedded in a large chaotic sea, that can hold a large number of quantum states. These periodic orbits have the capability of forming significant quasibound states of the molecule above dissociation.

1Welch Foundation

V1.00336 Development of Micro-Four-Point Probe Compatible with an Scanning Tunneling Microscope, CANHUA LIU, Shanghai Jiao Tong Univ — As miniaturization of electronic devices goes on, while more attention has to be paid to the influence of the existence of surfaces and interfaces on the electronic and/or magnetic properties of the electronic materials, some researchers have proposed to use the intrinsic surface properties for the development of future devices. On the other side, the existence of crystal surface and interface may reduce the spatial degrees of freedom of the carriers, and thus results in various novel quantum phenomena related to the reduction of dimensionality. It is highly desirable to obtain the electronic structure, morphology information and transport property of a material in situ, since they are strongly related. Based on a commercial apparatus equipped with STM and MBE systems, we developed an electronic transport measurement system that is compatible with the STM. A micro-four-point probe (MFPp) is utilized to increase the surface sensitivity in the transport measurement, which can be conducted at low temperature ($T_{min}$=1 K) and high magnetic field ($B_{max}$=11 T). With this system, we succeeded in detecting superconductivity above 100 K in a single unit-cell layer of FeSe film grown on an Nb-doped strontium titanate.

V1.00337 Coherent single-spin source based on topological insulators1, YANXIA XING, ZHONG-LIU YANG2, Beijing institute of technology, QING-FENG SUN, Peking University, JIAN WANG, HongKong University — We report on the injection of quantized pure spin current into quantum conductors. In particular, we propose an on-demand single-spin source generated by periodically varying the gate voltages of two quantum dots that are connected to a two-dimensional topological insulator via tunneling barriers. Due to the nature of the helical states of the topological insulator, one or several spin pairs can be pumped out per cycle giving rise to a pure quantized alternating spin current. Depending on the phase difference between two gate voltages, this device can serve as an on-demand single-spin emitter or single-charge emitter. Again, due to the helicity of the topological insulator, the single-spin emitter or charge emitter is dissipationless and immune to disorder. The proposed single-spin emitter can be an important building block of future spintronic devices.

V1.00338 Thermoelectric properties of bulk nanowire-nanoparticle composites, VENKATA VASIRAJU, Materials Science and Engineering Department, Texas &M University, LANCE BROCKWAY, Artie McFerrin Department of Chemical Engineering, Texas A&M University, SREEJAM VADDIRAJU, Artie McFerrin Department of Chemical Engineering, Materials Science and Engineering Department, Texas A&M University — Towards realizing highly efficient bulk thermoelectrics based on nanowire-nanoparticle composites, the effect of microstructure and composition on thermoelectric properties of an illustrative composite system composed of copper nanoparticles and zinc phosphate ($Zn_3P_2$) nanowires is studied. Here, the intent is to extend high efficiencies achieved in individual nanowire devices to bulk nanowire assemblies. To study these effects of microstructure, thermoelectric performances of compositionally non-uniform copper nanoparticle- unfuctionalized $Zn_3P_2$ nanowire pellets (composite-I) were compared against those of compositionally uniform copper nanoparticle-benzenedithiol functionalized $Zn_3P_2$ nanowire pellets (composite-II). These results indicated that compositional non-uniformity, coupled with copper doping of $Zn_3P_2$ nanowires, offers more room for optimizing the thermoelectric performances of the composites. Overall, a high thermoelectric figure of merit of 0.23 at 770K was achieved in composite-I. This is two orders of magnitude higher than any achieved to date in $Zn_3P_2$ system. This study indicates that tuning the microstructures and composition of materials is a route for enhancing their thermoelectric efficiencies.

V1.00339 Quantum phase transition of light in the resonator array, CHUN-WANG WU, MING GAO, ZHI-JIAO DENG, HONG-YI DAI, PING-XING CHEN, CHENG-ZU LI, College of Science, National University of Defense Technology, Changsha 410073, China, QUANTUM COMPUTATION GROUP OF NUDT TEAM — We give a concrete experimental scheme for engineering the insulator-superfluid transition of light in a one-dimensional (1-D) array of coupled superconducting stripline resonators. In our proposed architecture, the on-site interaction and the photon hopping rate can be tuned independently by adjusting the transition frequencies of the charge qubits inside the resonators and at the resonator junctions, respectively, which permits us to systematically study the quantum phase transition of light in a complete parameter space. By combining the techniques of photon-number-dependent qubit transition and fast read-out of the qubit state using a separate low-Q resonator mode, the statistical property of the excitations in each resonator can be obtained with a high efficiency. An analysis of the various decoherence sources and disorders shows that our scheme can serve as a guide to coming experiments involving a small number of coupled resonators.

V1.00340 Frustrated spin-spin interactions between trapped ions using longitudinal and transverse phonon modes1, YANLI ZHOU, College of Science, National University of Defense Technology — We present a scheme of quantum simulation of many-body interactions with trapped ions via the exchange of virtual phonons, where the motion from both the longitudinal and the transverse directions is considered. By tuning the detunings of Raman lasers, the long-range and locally tunable interaction is easily obtained between different spins. We show that the competing spin-spin couplings mediated by all motion modes can give rise to higher levels of frustration and richer phase transitions than the conventional approaches based on the longitudinal or the transverse phonon modes alone.

V1.00341 Single laser beam photothermal microscopy, ANDRE HEBER, MARKUS SELMKE, MARCO BRAUN, FRANK CICHO; Leipzig University — Fluorescence microscopy provides a tool to study dynamics in soft matter materials on a molecular level. However, the observation time for fluorescent objects is limited due to bleaching. One way to overcome this limitation is the use of gold nanoparticles as labels. They are chemically inert under typical situations. These particles are selectively imaged using a modulated heating laser and a non-absorbed detection laser even in the presence of background scatterers. The absorbed power results in a localised temperature profile and to a refractive index change which only occurs for absorption. For finite thermal diffusivities the temperature profile does not instantly follow temperature changes present on the nanoparticle’s surface. This results in an out-of-phase modulation of the detection laser. By exploiting the limited thermal diffusivity we show that a single laser beam being intensity modulated is enough to selectively image and quantify absorption. The use of a single laser makes photothermal microscopy easier to implement into existing microscopy setups

V1.00342 Quantum Computational Resource Quality of a Symmetry-Protected Topologically Ordered Phase, JACOB MILLER, AKIMASA MIYAKE, University of New Mexico — Symmetry-protected topologically ordered (SPTO) states are many-body quantum states invariant under an on-site symmetry group, which can be grouped into distinct SPTO phases based on their non-local entanglement structure. While originally arising in the context of condensed matter physics, SPT states have also attracted interest in quantum information for their ability to be used as resource states for quantum computation. We investigate entanglement naturally present in the 1D SPTO phase associated with on-site octahedral symmetry and show that, as long as certain characteristic lengths are finite, all its ground states can be used to efficiently implement any one-qubit gate operation with arbitrary accuracy. This feature is an intrinsic property of the entire phase, and we show that it can also be probed by means of a particular string-order parameter. Our approach may pave the way toward a novel program to classify quantum many-body systems based on their operational use for quantum information processing.

V1.00343 Thermal and laser induced sintering in Pt nanoparticles studied by conventional and synchrotron x-ray diffraction, BRIAN KELLY, AARON LOETHER, Department of Physics and Astronomy, University of Delaware, RONALD CICHOCKI, Department of Chemistry and Biochemistry, University of Delaware, GERALD Poirier, Delaware Environmental Institute, University of Delaware, MATTHEW DECAMP, KARL UNRUH, Department of Physics and Astronomy, University of Delaware — The thermal and laser induced sintering behavior of 5 – 6 nm Pt nanoparticles self-assembled into 50 nm diameter spherical aggregates has been studied by conventional and synchrotron-based x-ray diffraction (XRD) measurements. In the first instance, the aggregated Pt nanoparticles were solution annealed at temperatures between 120 and 215 °C over time periods from 10s to 100s of minutes. In each case the linewidth of the conventionally measured diffraction pattern consisted of a single component which systematically narrowed suggesting an increase in the size of the as-prepared nanoparticles. In a second set of experiments, the aggregated Pt nanoparticles were exposed to about 10,000 laser pulses, each with a duration of about 1 ps and an energy density of 250 mJ/cm². XRD spectra were acquired after each 100 lasers pulses corresponding to 100 ps of sample irradiation. A narrow line component was observed in the diffraction pattern after the first 100 laser pulses and dominated the lineshape after a few thousand laser pulses. These measurements reflect the effects of long term, low temperature atomic transport in comparison with high energy, short time transport.

V1.00344 Single file diffusion in microtubules, ANDREW RUTENBERG, SPENCER FARRELL, AIDAN BROWN, Dalhousie University — We investigate the single file diffusion (SFD) of large particles entering a confined tubular geometry, such as luminal diffusion of proteins inside microtubules or flagella. While single-file effects have no effect on particle density, we report significant single-file effects for individually-tracked tracer particle motion. Both exact and approximate ordering statistics of particles entering semi-infinite tubes agree well with our stochastic simulations. Considering initially empty semi-infinite tubes, with particles entering at one end starting from an initial time t = 0, tracked particles display super-diffusive effective exponents just after they enter the system and trends towards diffusive exponents at later times. Equivalently, if diffusive exponents are assumed the effective diffusivity is reduced at early times and enhanced at later times through a logarithmic factor \( \log N \), where \( N \) is the number of particles in the tube. When we number each particle from the first (\( n = 1 \)) to the most recent (\( n = N \)), we find good scaling collapse of the effective diffusivity for all \( n \). Techniques that track individual particles, or local groups of particles, such as photo-activation or photobleaching, will exhibit single-file effects.

V1.00345 Temperature dependent thermal conductivity of single- and bi-layer MoS\textsubscript{2} and MoSe\textsubscript{2}, XIAN ZHANG, DEZHENG SUN, YILEI LI, Columbia University, GWAN-HYOUNG LEE, Yonsei University, YUMENG YOU, TONY HEINZ, JAMES HONE, XU CUI, Columbia University, JAMES HONE TEAM, TONY HEINZ TEAM — Thin layer transition metal dichalcogenide (TMDC) materials have received extensive interests in recent years. In this work, for the first time we systematically investigated and compared the thermal transport properties of two TMDC materials, MoS\textsubscript{2} and MoSe\textsubscript{2}, and in single-layer (1L) and bi-layer (2L) forms. The optothermal Raman technique is used in the measurement process. With an improved and more robust experimental data processing protocol, we discovered the thermal contact resistance and the interfacial thermal conductance of the four materials for the first time. These factors provide boundary conditions and are crucial in generating the final thermal conductivity for the suspended materials. For 1L MoS\textsubscript{2} and MoSe\textsubscript{2}, the room-temperature thermal conductivities are (80 ± 17) W/mK and (72 ± 19) W/mK, respectively. For 2L MoS\textsubscript{2} and MoSe\textsubscript{2}, we obtain values of (73 ± 25) and (39 ± 13) W/mK. The thermal conductivity of suspended 1L MoS\textsubscript{2} decreases to (66 ± 16) W/mK upon heating to 500K.

V1.00346 Substrate-Phonon-Mediated Plasmon Hybridization in Coplanar Graphene Nanoribbons, QING DAI, XIAOXIA YANG, XIAN-TIAN KONG, BING BAI, ZHENJUN LI, HAI HU, XIAOHUI QIU, National Center for Nanoscience and Technology — Mode hybridization between adjacent graphene nanoribbons determines the integration density of graphene-based plasmonic devices. Here we demonstrate this plasmon hybridization by characterizing the temperature dependence of plasmons in graphene nanoribbon arrays in terms of graphene Fermi level and inter-ribbon spacing. Both experimental and computational results showed that the plasmon coupling is strongly mediated by the substrate phonons. For polar substrate, the plasmon coupling strength was limited by the plasmon-phonon interaction. In contrast, nonpolar substrate affects neither the energy distribution of original plasmon modes in graphene nanostructures nor their plasmon interactions, which increase exponentially as the inter-ribbon spacing decreases. To further explore the potential of graphene broadband plasmonics on nonpolar substrate, we propose a scheme that uses a metal-dielectric heterostructure to preserve the overlap of plasmons between neighboring graphene nanoribbons. The device structures retain the plasmon resonance frequency of the graphene ribbons and maximally isolate the plasmonic components from the surrounding electromagnetic environment, allowing modular design in integrated plasmonic circuits.

1Supported by National Natural Science Foundation of China (No. 51372045)
V1.00347 New Method for Storing Information based on the Magnetic Permeability, ALAN EDELSTEIN, JONATHAN PETRIE, KRISTOPHER WIELAND, RAYMOND MENCIA, US Army Research Laboratory, SY-HWANG LIOU, Physics Dept., University of Nebraska, GEORGE NEWBURGH, US Army Research Laboratory, CORY CRESS, Naval Research Lab, JOHN TIMMERWILKE, US Army Research Laboratory, SERGEI URAGHINDIN, Dept. of Physics, Emory University — We present a new approach for storing information based on bits with different values for their magnetic permeability. Unlike present magnetic recording, information stored in this way should be ideal for archiving since it is unaffected by exposure to a magnetic field or moderate changes of temperature. Using heating with laser pulses as short as 100 ns, we have decreased the permeability of micron sized bits of an amorphous ferromagnet, Metglas, by crystallizing them. The permeability of micron sized bits of Cu/permalloy bilayers was decreased by using ohmic heating to cause the Cu to diffuse into the permalloy (80% Ni 20% Fe). This occurs because Ni is no longer ferromagnetic if the Ni atoms have too many Cu neighbors. The changes in the permeability are read by using either a magnetic tunnel junction or a spin transfer oscillator to measure whether the flux lines of a probe field are affected by the bits. The permeability of Cu/permalloy bilayers is not affected by 10 mega rads of gamma radiation from Co 60. Using heat assisted recording (HAMR) will permit writing permeability bits on a nm scale.

V1.00348 Thermal stability of organic-inorganic hybrid perovskite structures from first principles, AMIR FARAJIAN, Department of Mechanical and Materials Engineering, Wright State University — Organic-inorganic hybrid perovskites are currently the focus of intense research owing to their impressive efficiency as photovoltaic devices. Specifically, methylammonium lead tri-halides are of interest in this regard, however, some of their basic properties are not completely known yet. We investigate structural stability of organic-inorganic hybrid perovskites of methylammonium lead tri-halide type (MAPb\(_{1-x}\)Cl\(_x\), n = 0-3) at different temperatures, using ab initio structure optimization, energy calculations, and molecular dynamics. Different crystal structures and free energies are compared, and effects of temperature change are discussed. The results provide insight toward understanding stable methylammonium lead tri-halides for photovoltaic applications.

V1.00349 Multiple sharp lattice plasmon modes in 2D Au nanoparticle superlattices, DANQING WANG, ANKUN YANG, ALEXANDER HRYN, GEORGE SCHATZ, TERI ODOM, Northwestern Univ, ODOM GROUP TEAM — Periodic metal-nanoparticle (NP) 1D chains and 2D arrays can produce sharp lattice plasmon modes due to the coupling between the diffraction mode of the periodic lattice and the localized surface plasmon resonance of the metal NPs. 2D Au NP superlattices, new structures that combine multiple length scales, have the potential for new optical properties such as mode coupling. They differ from periodic 2D arrays in that the spacing between NP patches introduces an additional microscale patch periodicity while the sub-microscale NP periodicity is maintained within one patch. In the reciprocal space, the small periodicity corresponds to a large wavevector while the large periodicity corresponds to a small one. For 2D NP superlattices, the two wavevectors sum together and show additional, satellite diffraction modes at higher and lower energies than the modes for periodic 2D arrays. We found that multiple sharp lattice plasmon modes exist in the 2D Au NP superlattices as the satellite diffraction modes couple with the localized surface plasmon mode. Multiple peaks with narrow linewidths in the transmission spectrum were observed in both numerical calculations and experiments. 2D Au NP superlattices provide flexibility in tuning the lattice plasmon mode through changing the microscale periodicity of the patches. The multiple sharp lattice plasmon modes can also serve as potential cavity modes for surface-emitting lasing.

V1.00350 Modularity Enhances the Rate of Evolution in a Rugged Fitness Landscape, DONG WANG, RICE UNIVERSITY, JEONG-MAN PARK, RICE UNIVERSITY AND THE CATHOLIC UNIVERSITY OF KOREA, MAN CHEN, MICHAEL DEEM, RICE UNIVERSITY — Biological systems are modular, and this modularity affects the evolution of biological systems over time and in different environments. We here develop a theory for the dynamics of evolution in a rugged, modular fitness landscape. We show analytically how horizontal gene transfer couples to the modularity in the system and leads to more rapid rates of evolution at short times. The model, in general, analytically demonstrates a selective pressure for the prevalence of modularity in evolution. We use this model to show how the evolution of the influenza virus is affected by the modularity of the proteins that are recognized by the human immune system. A modular model of the fitness landscape of the virus better fits the observed virus evolution data.

1This research was supported by the US National Institutes of Health under grant 1 R01 GM 10046801. JMP was also supported by the National Research Foundation of Korea Grant (NRF-2013R1A1A2006983).

V1.00352 Magnetic properties of MnF\(_3\), BAEKSOON CHO, KAIST, CHANGSOO KIM, KBSI, SEJUN PARK, SOONCHIL LEE, KAIST — MnF\(_3\) which is A-type antiferromagnetic material has been reported to show the negative thermal expansion (NTE) below Neel temperature. In this work, the temperature and magnetic field dependence of the magnetization of MnF\(_3\) was measured to find the spin order. The M(T) curve measured by NMR fits well with the theory for antiferromagnet with anisotropy, T^2 e^{−(J/κ_a)}1, and the measured energy gab(E_G) is about 30 K. The M(H) curve shows that the ferromagnetic phase is mixed with the antiferromagnetic phase below the transition temperature. From the comparison of the M(H) curve at 30 K with theory, the relation between K_a and J_1 was obtained which is given by K_a ∼ 1.9 J_1 + 10.3 in absolute temperature unit.

V1.00353 Excitonic Josephson effect in \(E \ell = 1\) quantum Hall bilayer effect, YA-FEN HSU, Department of Electrophysics, National Chiao Tung University, Hsinchu 300, Taiwan — The many similarities between exciton condensates and cooper pairs have driven intense interests to search for exciton-superfluidity effect. The Josephson-like tunneling conductance peak in a single quantum Hall (QH) has been viewed as a strong signature of exciton superfluidity. However, in fact, the Josephson-like effect is not an exact analogy of Josephson effect in superconducting junctions. Therefore, we study three kinds of excitonic Josephson junctions (JJs) composed of QH bilayers: SS, SNS, and SS’S junctions in a pseudospin picture. By solving the Landau-Lifshitz-Gilbert equations, we find, in contrast with superconducting JJs, interlayer single-particle tunneling raises spatial inhomogeneity in supercurrent and system-size dependent current-phase-relation. In addition, under the effect of the tunneling, the supercurrent could not flow through the normal metal via Andreev reflection. Interestingly, anomalous supercurrents occur in SNS junctions even in absence of Josephson interference: the tunneling would set the phase to zero at NS interfaces, which will lead to a phase bias across a Josephson-like junction (i.e. single condensate system) with a nonzero ground state phase, and hence induces the anomalous supercurrent.
V1.00354 Screening effect on electronic and field-emission properties of graphene nanoribbons

WAN-SHENG SU, National Center for High-performance Computing, HAN HU, TSAN-CHIEN LEUNG, Department of Physics, National Chung Cheng University — The electronic and field-emission properties of zigzag graphene nanoribbons (ZGNRs) influenced by manipulated nanostructure width (Lw) and nanostructure-to-nanostructure separation (Dx) are investigated using first-principles calculations. The corresponding characteristics, including band gap, magnetic moment, field enhancement factor and work function are explored and presented. It is found that the behavior of those properties under saturation versus Dx is observed, and the corresponding values approach their limits as Dx increases to a certain value. In addition, the electric-field-induced changes in band gaps of the ZGNRs with and without separated gaps are much more significant than that of ZGNRs with little separation. These phenomena can be attributed to physical origins such that the greater the separation between ZGNRs, the less significant the screening effect becomes. Finally, the altered magnetic moment of the ZGNRs due to the presence of an external electric field is analyzed and discussed.

V1.00355 Controlling magnetic order and quantum disorder in molecule-based magnets

SAMAN GHANNAZADEH, High Field Magnet Laboratory, Netherlands, TOM LANCASTER, Durham University, UK, PAUL GODDARD, STEPHEN BLUNDELL, FRANCESCA FORONDA, ISABEL FRANKE, University of Oxford, UK, JOHANNES MÖLLER, ETH Zürich, Switzerland, LINGEN HUANG, JOACHIM WOSNITZA, High Magnetic Field Laboratory, Germany, JAMIE MANSON, Eastern Washington University, USA — Metal-organic coordination polymers are materials in which transition metal ions are linked via organic molecules into chain or plane-like structures. Strong hydrogen bonds enable these units to form three-dimensional lattices, while the underlying anisotropy causes low-dimensional magnetism to evolve. Here the magnetic properties of a number of these compounds are investigated through high-field magnetization, heat capacity, and magnetic susceptibility measurements. It is shown that [Cu(pyz)H2O(gly)]ClO4 is a highly one-dimensional antiferromagnet, whilst the compounds [Cu(pyz)(gly)]ClO4 and Cu(H2O)VCF3 are dimerized with a non-magnetic singlet ground state and behave as zero-dimensional disordered magnets at zero field. Furthermore, these two materials are shown to undergo a field-induced transition through a quantum critical point into an XY ordered phase, which in the case of [Cu(pyz)(gly)]ClO4, is reminiscent of Bose-Einstein condensation of triplons.

V1.00356 ABSTRACT MOVED TO Q8.00008

V1.00357 The Structural Bases for Polymer Glass-Transition Temperatures

JIALONG SHEN, ALAN TONELLI, North Carolina State Univ — The glass-transition temperatures (Tgs) observed for chemically distinct polymers range over several hundred K, and the molecular bases for this wide variability are largely unknown, though the following three factors are often mentioned as being pivotal: 1. Their inherent conformational flexibilities; 2. The sizes or steric bulk of their side-chains; and 3. Their inter-chain interactions. These three factors are generally interdependent, making it difficult to predict or even rationalize the Tgs of polymers. Structurally analogous aliphatic copolymers, copolymides, and copoly(ester/amide)s can be synthesized to produce amorphous samples with Tgs that are unaffected either by crystallinity or polymer chain lengths. Their conformations are virtually identical, and each can be synthesized with or without side-chains, so we can begin to evaluate the relative importance of the above three factors. The Tgs of un-branched analogous samples should differ solely due to factor 3, while analogous samples with singly-branched repeat units should provide a measure of the relative importance of factors 1 and 2.

V1.00358 Optically Excited Graphene - Non - Equilibrium Many Body Theory

REGINE FRANK, Institut für Theoretische Physik, Eberhard-Karls University Tübingen, Germany, ANDREAS LUBATSCH, Georg-Simon-Ohm University of Applied Sciences, Nuremberg, Germany — A generalized non-equilibrium dynamical mean field theory (DMFT) for graphene is presented. The NE-DMFT describes graphene in the presence of an external field coupling to the electrons and thus changing in a severe but controllable way the electronic properties of graphene. The non-equilibrium DMFT derives properties such as electronic density of states (LDOS) and occupation numbers of the optically driven system. It fully characterizes the system in its time dependent state. It is demonstrated, how such a setup may be employed in order to realize all-optical switching processes. Results for relevant time scales in setups as well as wave-mixing influences are presented.

Thursday, March 5, 2015 2:30PM - 5:30PM
Session W1*DMP: Focus Session: Graphene: Nanostructures 001A - An-Ping Li, Oak Ridge National Laboratory

2:30PM / W1.00001 Semiconductor half-metal transition in zigzag-graphene-nanoribbons/graphene

MINGXING CHEN, MICHAEL WEINERT, Department of Physics, University of Wisconsin-Milwaukee — Magnetic and electronic properties of H-terminated zigzag graphene nanoribbons supported by graphene substrate are investigated using first-principles calculations. A critical width of 3 nm is found for the onset of electron-electron interactions between the edges. Weak edge magnetism of the nanoribbons is well preserved upon the presence of the graphene substrate due to the weak interaction between them, which on the other hand drives a size-dependent spin splitting of the edge states. As a result of the interaction, a semiconductor-halfmetal transition is observed. Our findings not only are of fundamental interest but also have practical implications in potential applications of graphene-based nanoelectronics.

2:42PM W1.00002 Observations of superlattice Dirac points in one-dimensionally-ripped graphene on hexagonal BN using scanning tunneling spectroscopy

WON-JUN JANG, MIN WOOK LEE, SOON-HYEONG LEE, Department of Physics, Korea University, MIN WANG, SUNG KUYO JANG, MINWOO KIM, SUNCJOO LEE, SANG-WOO KIM, YOUNG JAE SONG, SKKU Advanced Institute of Nanotechnology (SAINT), Sungkyunkwan University (SKKU), SE-JONG KAHNG, Department of Physics, Korea University — It has been predicted that superlattice potentials in graphene would induce new Dirac points due to lattice-induced chirality of charge carriers. In this talk, we present our experimental observations of new Dirac points in one-dimensionally-ripped graphene on hexagonal BN using scanning tunneling microscopy and spectroscopy. The ripples, formed by thermal cycles, showed two new Dirac points of which energy levels were proportional to 1/L, where L was the period of a ripple. The agreement with theoretical predictions. Our study shows that one-dimensional periodic potential is an accessible component for controlling electronic properties of graphene.

2:54PM W1.00003 Imaging coherent transport in a mesoscopic graphene ring

DAMIEN CABOSART, SEBASTIEN FANIEL, FREDERICO R. MARTINS, Université catholique de Louvain (UCL), IMCN/NAPS, BORIS BRUN, Institut Neel et Université Joseph Fourier, ALEXANDRE FELTEN, Université de Namur (Unamur), VINCENT BAYOT, BENOIT HACKENS, Université catholique de Louvain (UCL), IMCN/NAPS — Mesoscopic graphene devices often exhibit complex transport properties, stemming both from the peculiar electronic band structure of graphene, and from the high sensitivity of transport to local disorder in this two-dimensional crystal. To disentangle contributions of disorder in the different transport phenomena at play in such devices it is necessary to devise new tools in physics of metals, and to establish links between transport and the microscopic structure of the devices. Here, we present a spatially-resolved investigation of coherent transport inside a graphene quantum ring (QR), where Aharonov-Bohm conductance oscillations are observed. Thanks to scanning gate microscopy, we firstly identify spatial signatures of Coulomb blockade, associated with disorder-induced localized states. We then image resonant states which decorate the QR local density of states (LDOS). Simulations of the LDOS in a model disorder graphene QR confirm the presence of such scarred states.
3:06PM W1.00004 Electronic Transport in Hexagonal Boron Nitride Encapsulated Graphene Nanoribbon. WON JONG YOO, DAEYOUNG LEE, EUYHEON HWANG, Sungkyunkwan Univ, PHILIP KIM, Harvard Univ — The electronic transport properties of the hexagonal boron nitride (hBN) encapsulated graphene nanoribbon (GNR) are studied. We find that the transport gap of the hBN encapsulated GNR is almost identical to that of the same size GNR on silicon dioxide (SiO₂) substrate in spite of their quantitatively different physical parameters, indicating that the transport gap of the hBN encapsulated GNR is affected mainly by edge disorders rather than surface disorders. The relatively lower density of Coulomb diamonds (20/√4m), larger charge island diameter (80 nm), longer hopping length (200 nm), and other results obtained from electrical and temperature dependent measurements show that the hBN encapsulated GNR has the less degree of disorder than the surface disorder. The insulating behavior within the transport gap of the hBN encapsulated GNR is maintained up to temperatures and evolves with magnetic field. We comment on the implication of our observations with respect to the electronic properties of sidewall EGNRs.

3:18PM W1.00005 Semiconducting Graphene Ribbons Grown on Nitrogen-Seeded SiC. FENG WANG, Georgia Inst of Tech, GANG LIU, Rutgers University, SARA ROTHWELL, University of Minnesota, MERIDITH NEVIUS, MATTHEW CONRAD, Georgia Inst of Tech, PHILIP COHEN, University of Minnesota, LEONARD FELDMAN, Rutgers University, EDWARD CONRAD, Georgia Inst of Tech — A wide band gap semiconducting form of graphene can be produced by growing a buckled form of graphene from a SiC(0001) surface randomly seeded with nitrogen. In this work, we show that the disorder observed in this form of graphene can be substantially reduced by pre-patterning the nitrogen seeded SiC surface into trenches. The result of the patterning is highly improved film thickness variations, orientational epitaxy, domain size, and electronic structure. In addition, the ordering induced by this patterned growth offers a way to take advantage of the extremely high mobilities and switching speeds in C-face graphene devices while having the thickness uniformity and fabrication scalability normally only achievable for graphene grown on the SiC(0001) Si-face.

3:30PM W1.00006 Surface-assisted formation of graphene nanoribbons on Au surfaces. CLAUDIA CARDOSO, DEBORAH PREZZI, ELISA MOLINARI, ANDREA FERRETTI, S3 Center, Istituto Nanoscience, CNR via Campi 213/A, 41125, Modena, Italy — The formation of graphene nanoribbons (GNRs) on Au(110) and Au(111), as based on the surface-mediated reaction of 10,10'-dibromo-9,9' bithiophene (DBBA) molecules was investigated by means of first-principles calculations. The study was done in direct collaboration with experimental groups performing structural and spectroscopic characterization by means of STM, XPS/UPS, NEXAFS. Comparison between the Au(110) and Au(111) surfaces unveils the delicate interplay between surface atomic corrugation, molecular mobility, and adsorption energies, that drive the GNR growth. Concerning the Au(110) surface, we have studied the molecule/surface interaction at different stages of the GNR formation. The role of different reconstructions has been investigated, showing that both precursors and GNRs interact differently with different surfaces. Calculations for the precursor molecules showed that initial stages of the reaction crucially determine the final configuration and orientation of the GNRs. In the specific case of Au(111) we have also studied the evolution of the Au Shockley surface state as a function of GNR bonding state. We show that the GNR/Au interaction results in an upshift of the Shockley surface state of Au(111) by 0.2 eV, together with an increased electron effective mass.

3:42PM W1.00007 Ballistic nanostructures for epitaxial graphene nanoelectronics. VALT DE HEER, Georgia Institute of Technology — Epitaxial graphene nanoelectronics [1] was inspired by carbon nanotube electronics. While carbon nanotubes demonstrated advantageous electronic properties, like room temperature ballistic transport, immunity to electromigration and significant bandgaps, manufacturability remains a problem. Independent of other graphene work research at Georgia Tech evolved from the premise that epitaxial graphene on silicon carbide could serve as a viable platform for graphene based electronics. Epitaxial graphene (EG), known since the 1970's, is produced by sublimation of Si from the SiC surface. The 2D electronic and structural properties of EG are significantly superior to transferred graphene, EG is scalable[2]. Nanopatterning is achieved by selective high temperature graphene growth on the sidewalls of structures that are etched in the SiC. These annealed graphene nanostructures demonstrate a host of remarkable properties. Recently 10 μm scale single channel room temperature ballistic transport (R = h/e² ≈ 26 kOhm) has been observed in neutral graphene sidewall nanoribbons [3] (in contrast, similarly sized exfoliated graphene ribbons are insulators due to disorder). These ballistic nanoribbons, as well as other nanostructures are readily and reliably produced using optical lithography. Remarkably, the ballistic transport does not depend on the microstructure of the ribbon edges, thereby precluding current models for the effect. These ballistic ribbons can be used as quantum wires in graphene based nanoelectronics. This high mobility has been observed in neutral graphene sidewall nanoribbons. These devices are promising candidates for graphene transistors, because of the ability to control structural parameters of GNRs, such as their width, edge structure and termination, with atomic precision. These properties of the GNRs can also be modified by their doping with heteroatoms, such as nitrogen, resulting in nitrogen-doped GNRs or N-GNRs. These graphene nanoribbons are promising materials for future electronics and photovoltaics. The ability to control structural parameters of silicon nanowires, such as their width, edge structure and termination, with atomic precision is the key for practical realization of these intriguing nanoscale properties. Physical properties of GNRs can also be modified by their doping with heteroatoms, such as nitrogen, resulting in nitrogen-doped GNRs or N-GNRs. In this talk I will demonstrate that large quantities of narrow atomically precise N-GNRs can be synthesized via Yamamoto coupling of molecular precursors containing nitrogen atoms followed by cyclohydrogenation using Scholl reaction. Several types of N-GNRs with different doping levels have been synthesized and systematically studied by means of spectroscopic, microscopic and transport methods. Incorporation of nitrogen atoms in graphene lattice is shown to be an effective route to affect GNRs' band gap, doping level as well as aggregation behavior.

4:18PM W1.00008 Atomically precise nitrogen-doped graphene nanoribbons1. ALEXANDER SINITSKII, University of Nebraska - Lincoln — There is a considerable interest in graphene nanoribbons (GNRs), few-nm-wide strips of graphene with high aspect ratios, because of their intriguing physical properties. For example, GNRs with zigzag edges are predicted to exhibit low-dimensional magnetism, while GNRs with armchair edges can possess large energy band gaps, making them promising materials for future electronics and photovoltaics. The ability to control structural parameters of GNRs, such as their width, edge structure and termination, with atomic precision is the key for practical realization of these intriguing nanoscale properties. Physical properties of GNRs can also be modified by their doping with heteroatoms, such as nitrogen, resulting in nitrogen-doped GNRs or N-GNRs. In this talk I will demonstrate that large quantities of narrow atomically precise N-GNRs can be synthesized via Yamamoto coupling of molecular precursors containing nitrogen atoms followed by cyclohydrogenation using Scholl reaction. Several types of N-GNRs with different doping levels have been synthesized and systematically studied by means of spectroscopic, microscopic and transport methods. Incorporation of nitrogen atoms in graphene lattice is shown to be an effective route to affect GNRs’ band gap, doping level as well as aggregation behavior.

4:30PM W1.00009 Superconducting Proximity Effect in Sidewall Graphene Nanoribbons. OWEN VAIL, JOHN HANKINSON, School of Physics, Georgia Tech, CLÉMENT BOUVIER, CLAIRE BERGER, Gatech - School of Physics, CNRS-Institut Neel, WALT DE HEER, ZHIGANG JIANG, School of Physics, Georgia Tech — Epitaxial graphene nanoribbons (EGNRs) grown on sidewall SiC have recently emerged as a novel material system enabling single channel room temperature ballistic transport over micrometer distance. In this work, we fabricate Al-EGNR-Al junctions and study the electronic transport as a function of bias voltage, temperature, and magnetic field. We show that although the measured resistance across the junction is dominated by the EGNR, spectral features associated with superconductivity of Al electrodes are evident. These features are fully developed at low temperatures and evolve with magnetic field. We comment on the implication of our observations with respect to the electronic properties of sidewall EGNRs.
4:42PM W1.00010 Spin orbit coupling and electron pairing instabilities in superconductors1. ARMEN KOCHARIAN, California State University, Los Angeles, CA, GAYNATH FERNANDO, KUN FANG, University of Connecticut, Storrs, CT, ALEXANDER BALATSKY, Nordic Institute for Theoretical Physics, Stockholm, Sweden — Exact diagonalization, Lanczos and variational cluster approximation (VCA) have been used for accurate studies of Rashba spin-orbit effects in the presence of electron correlations. These have been carried out in order to address current challenging problems in superconductivity, magnetism, topological insulators and spin dependent transport associated with numerous interfaces and heterostructures. The modeled spin-orbit coupling in assembled nano-ribbons (as arrays of clusters) in various two-dimensional square and topological honeycomb structures (generated by periodically repeated Betts lattices) provide an ideal playground for understanding various competing phases, electron pairing and phase separation instabilities in conventional and unconventional superconductors. Our models allow us to calculate the spectral functions and accurately extract electronic, magnetic properties including spin transport and electron pairing in these systems. The results also highlight important aspects of the interplay of the spin-orbit coupling with magnetic fields in graphene-like systems and unconventional superconductors induced by weak, moderate and strong electron interactions.

4:54PM W1.00011 ABSTRACT WITHDRAWN –

5:06PM W1.00012 Bound states in single and bilayer graphenes by a one-dimensional potential well: continuum model versus lattice model, AKIHIRO OKAMOTO, TAKEHITO YOKOYAMA, Department of Physics, Tokyo Institute of Technology, SHUICHI MURAKAMI, TIES, Tokyo Institute of Technology — Edges of a graphene show characteristic edge states depending on its edge shapes such as zigzag or armchair. Instead of these edge states, we consider bound states on a graphene with a one-dimensional potential well. We set the potential well which has a finite width in one direction and is infinitely extended in the other direction. We consider both the single layer and bilayer graphenes. In the continuum model of Dirac cones, we can analytically calculate the bound states, and discuss their properties. Then we also calculate analytically the bound states, also for the tight-binding model for single-layer graphene. It reproduces the results for the continuum model, such as a linear dispersion of bound states near K and K’ points. We discuss how the bound states dispersion change for various potential profiles.

5:18PM W1.00013 Graphene nanopatterning with 2.5 nm precision: combining bottom-up and top-down techniques, JOSE M. GOMEZ-RODRIGUEZ, ANTONIO J. MARTINEZ-GALERA, IVAN BIHRUEGA, Dept. Fisica de la Materia Condensada, Universidad Autonoma de Madrid, Spain, ANGEL GUTIERREZ-RUBIO, TOBIAS STAUBER, Instituto de Ciencia de Materiales de Madrid, CSIC, Spain — The selective modification of pristine graphene represents an essential step to fully exploit its potential. Here we merge bottom-up and top-down strategies to tailor graphene with nanometer accuracy. In a first step, graphene electronic properties are macroscopically modified using the periodic potential generated by the self assembly of metal cluster superlattices on a graphene/Ir(111) surface. Then, we show that individual metal clusters can be selectively removed at room temperature by a STM tip with perfect reproducibility, which enables one to nanopattern the system down to the 2.5 nm limit given by the distance between neighbouring clusters, i.e., the periodicity of the moire-pattern. The method can be carried out on micrometer sized regions, with clusters of different materials which allows tuning the strength of the periodic potential and the structures so created are stable even at room temperature. As a result, we can strategically combine graphene regions that should present large differences in their electronic structure to design graphene nanostructures with specific functionalities.

Thursday, March 5, 2015 2:30PM - 5:30PM – Session W2 DMP: Focus Session: Beyond Graphene - Devices I 001B - Xia Hong, University of Nebraska-Lincoln

2:30PM W2.00001 Optically Induced PN Junction Diode and Photovoltaic Response on Ambipolar MoSe2 Field-effect Transistor, NIHAR PRADHAN, ZHENGGUANG LU, DANIEL RHODES, National High Magnetic Field Laboratory, Tallahassee, Florida, USA, MAURICIO TERRONES, Department of Physics, Pennsylvania State University, University Park, PA, USA, DMITRY SMIRNOV, LUIS BALICAS, National High Magnetic Field Laboratory, Tallahassee, Florida, USA — Transition metal dichalcogenides (TMDs) have emerged as an attractive material for electronic and optoelectronic devices due to their sizable band gap, flexibility and reduced dimensionality, which makes them promising candidates for applications in transparent optoelectronics components, such as solar cells and light emitting diodes. Here, we present an optically induced diode like response and concomitant photovoltaic effect in few-atomic layers molybdenum diselenide (MoSe2) field-effect transistors. Compared to recently reported PN junctions based on TMDs, ambipolar MoSe2 shows nearly ideal diode rectification under illumination, with a sizable photovoltaic efficiency. The observed light induced diode response under fixed gate voltage, yields a maximum open circuit voltage 0.28V and short circuit current 230mA at 30uW incident laser power. The sense of current rectification can be altered by changing the polarity of the applied gate voltage (Vbg). We show that the method can produce devices with external quantum efficiency ~ 30%.

2:42PM W2.00002 Electrical energy harvesting from single-atomic-layer MoS2, LEI WANG, Columbia University, WENZHUO WU, Georgia Institute of Technology, YILEI LI, TONY HEINZ, Columbia University, ZHONG LIN WANG, Georgia Institute of Technology, JAMES HONE, Columbia University — Monolayer MoS2 is predicted to be strongly piezoelectric, an effect that disappears in the bulk due to the opposite orientations of adjacent atomic layers. We observe the first experimental study of the piezoelectric properties of two-dimensional (2D) MoS2. We find that cyclic stretching and releasing of thin MoS2 flakes with an odd number of atomic layers produces oscillating piezoelectric voltage and current outputs, while no output is observed for flakes with an even number of layers. In agreement with theoretical predictions, the output increases with decreasing thickness and reverses sign when the strain direction is rotated by 90 degrees. Transport measurements show a strong piezoelectric effect in single layer MoS2, but not in bilayer and bulk MoS2. The coupling between piezoelectricity and semiconducting properties in 2D nanomaterials may enable applications in powering nanodevices, adaptive bio-probes and tunable/stretchable electronics/optoelectronics.

2:54PM W2.00003 Dimensionality effects on electronic properties of lateral two-dimensional junctions, HENRY YU, ALEX KUTANA, BORIS I. YAKOBSON, Materials Science and NanoEngineering, Rice University — We study lateral junctions of two-dimensional materials, including graphene, 2D BN, and transition metal dichalcogenides. A common feature of low-dimensional contacts is that unlike bulk devices, local charge transfer near the contact cannot equilibrate Fermi levels throughout the material, necessitating nonlocal charge redistribution. These nonlocal charges will affect the physical properties of the junction. We obtain the solution for carrier and potential distributions in symmetric and asymmetric 2D junctions with different densities of states and doping levels, using a macroscopic model and DFT calculations. The scaling of the depletion length with doping level and built-in voltage is determined by the dimensionality of the junction. The implications for operation of low-dimensional devices are discussed.
Control and characterization of the metallic surface state of bulk insulating Bi$_2$Se$_3$.

Michael Fuhrer, School of Physics, Monash University, 3800 Victoria, Australia and CNAM, University of Maryland, College Park, MD 20472-4111 USA — Bi$_2$Se$_3$ is a three dimensional strong topological insulator with a conducting two-dimensional surface state whose existence is guaranteed by topology. The bulk Bi$_2$Se$_3$ has a 300 meV bandgap, but is often a degenerately n-doped metal in as-grown material. I will discuss our efforts to remove this doping in thin crystals and films to achieve surface-dominated conduction. Electrochemical gating (using PEO+LiClO$_4$ electrolyte) or molecular doping (using F4-TCNQ) is shown to effectively bring the Fermi energy of thin (3-20 nm) exfoliated Bi$_2$Se$_3$ crystals to the conduction band edge, where it can be further modulated at low temperature using field-effect gating. These techniques allowed us to reveal the gapless ambipolar transport in the topological surface, and measure the minimum conductivity, electron-phonon phonon scattering, thermopower, and inter-surface coupling of the topological surface. Recently we have developed techniques to measure the transport properties of Bi$_2$Se$_3$ in situ during growth in ultra-high vacuum, enabling better understanding of the doping mechanisms.[6] We have also studied vacuum-deposited MoO$_3$ as a highly effective acceptor dopant which remains stable on air exposure for time scales of days.[1]

3:42PM W2.00005 Charge Transport of MoS$_2$ Supported by Thiol-Decorated Self-Assembled Monolayer

Doron Naveh, Vlad Artel, Moshe Kirshner, Dept. of Electrical Engineering, Bar-Ilan University, Ramat-Gan, Israel 52900 — Intrinsic charge transport in MoS$_2$ supported by thiols was recently reported[1] and was attributed to passivation of sulfur vacancies and suppression of charged impurities from the dielectric substrate. In this talk, we will present the transport characteristics of single layer and few-layer MoS$_2$ on thiol-decorated self-assembled alkyli-siloxane monolayer.

3:54PM W2.00006 Generation and electric control of spin–valley-coupled circular photogalvanic current in WSe$_2$.

Hongtao Yuan, Harold Y. Hwang, Yi Cui, Stanford University and SIMES SLAC — Compared to the weak spin-orbit-interaction (SOI) in graphene, layered transitionmetal chalcogenides MX$_2$ have heavy 4d/5d elements with strong atomic SOI, providing a unique way to extend functionalities of novel spintronics and valleytronics devices. Such a valley polarization achieved via valley-selective circular dichroism has been predicted theoretically and demonstrated with optical experiments in MX$_2$ systems. Despite the exciting progress, the generation of a valley/spin current by valley polarization in MX$_2$ remains elusive and a great challenge. A spin/valley current in MX$_2$ compounds caused by such a valley polarization has never been observed, nor its electric-field control. In this talk, we demonstrated, within an electric-double-layer transistor based on WSe$_2$, the manipulation of a spin-coupled valley photocurrent whose direction and magnitude depend on the degree of circular polarization of the incident radiation and can be further greatly modulated with an external electric field. Such room temperature generation and electric control of valley/spin photocurrent provides a new property of electrons in MX$_2$ systems, thereby enabling new degrees of control for quantum-confined spintronics devices. (In collaboration with S.C. Zhang, Y.L. Chen, Z.X. Shen, B. Tian, H.J. Zhang, G. Xu, Y. Xu, B. Zhou, X-Q. Wang, B. Shen X-F. Fang) Acknowledge the support from DoE, BES, Division of MSE under contract DE-AC02-76SF00515.

Ming-Wei Lin, Xufan Li, Kai Wang, Alexander Puretzky, Christopher Rouleau, David Geohegan, Kai Xiao, Oak Ridge National Laboratory, CNMS, ORNL TEAM — By changing the layer numbers, the electrical transport of field effect transistors based on CVD grown two-dimensional (2D) layered materials of transition metal dichalcogenides (TMDCs) such as MoS$_2$, WSe$_2$ and WS$_2$ shown the different characteristics will be demonstrated. The transport measurements show that the altered semiconductor characteristics of these 2D materials can be possibly attributed to the shift of Fermi level when changing the number of layers. Besides, the transport characteristics can be tuned by adjusting the W/Mo doping level and mobility is also increased with increasing the layer numbers. In addition, the annealing effect on these CVD grown 2D layered materials will be discussed.

This work is conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

4:18PM W2.00008 Coulomb blockade in few-layer MoS2 based single electron transistor.

Kyunghoon Lee, Zhaohui Zhong, Department of Electrical and Computer Science, University of Michigan — Transition metal dichalcogenides (TMDCs) based two dimensional materials are attracting much attention for their interesting electronic and optical properties, including high on/off current ratio, indirect to direct band gap transition, and valley polarized carrier transport. Nevertheless, study of the low temperature electron transport in atomic thin layered TMDCs is still in its infancy. One of the major hurdles for electron transport study lies in the large metal/semiconductor junction barrier for carrier injection, which leads to the contact resistance dominated charge transport in short channel nanoscale devices. Here, we report on the fabrication of few-layer MoS$_2$ single electron transistor using low work function metal for the contact electrodes. We observed Coulomb blockade phenomena attributed to single electron charging on a fairly clean quantum dot. The details of the bias, gate and temperature dependence will be discussed.

4:30PM W2.00009 Annealing and ionic liquid gating on suspended molybdenum disulfide devices.

Fenglin Wang, Petr Stepanov, Mason Gray, Mikhail Itkis, Robert Haddon, Chun Ning Lau, University of California Riverside — We fabricate suspended molybdenum disulfide (MoS$_2$) field effect transistors (FET) devices and develop an effective gas annealing technique that significantly improves device quality and increases conductance by 3-4 orders of magnitude. Temperature dependence measurements reveal two transport mechanisms: electron-phonon scattering at high temperatures and thermal activation over a gate-tunable barrier height at low temperatures. Our results suggest that transport in these devices is not limited by the substrates. Moreover, this suspended MoS$_2$ device structure provides double surface access for ionic liquid gating. We are able to extract the dielectric constant of the ionic liquid, and the latest experimental results will be presented.
4:42PM W2.00010 Influence of the Metal-MoS\(_2\) interface on MoS\(_2\) Transistor Performance

HUI YUAN, Dept of Electrical and Computer Eng, George Mason University, Fairfax, VA, GUANGJUN CHENG, ANGELA HIGHT WALKER, LIN YOU, JOSEPH J. KOPANSKI, Semiconductor and Dimensional Metrology Div, NIST, Gaithersburg, MD, QILIANG LI, Dept of Electrical and Computer Eng, George Mason University, Fairfax, VA, CURT A. RICHTER, Semiconductor and Dimensional Metrology Div, NIST, Gaithersburg, MD — We compare the electrical characteristics of MoS\(_2\) field-effect transistors (FETS) with Ag source/drain contacts with transistors with Ti contacts, and we demonstrate that the metal-MoS\(_2\) interface is crucial to the final device performance. The topography of Snm Au/Snm Ag (contact layer) and Snm Au/Snm Ti metal films deposited onto monofew-layer MoS\(_2\) was characterized by using scanning electron microscopy and atomic force microscopy. The surface morphology of the Au/Ti films on MoS\(_2\) shows a rough, dewetting pattern while Au/Ag forms smooth, dense films. These smoother and denser Au/Ag contacts lead to improved carrier transport efficiency. FETS with Ag contacts show more than 60 times higher on-current and a steeper subthreshold slope. Raman spectroscopy of MoS\(_2\) covered with Au/Ag or Au/Ti films revealed that the contact layer is Ag or Ti, respectively. In addition, there is a dramatic difference in the heat transfer between the MoS\(_2\) and the two metals: while laser heating is observed in Au/Ti covered MoS\(_2\), no heating effects are seen in Au/Ag covered MoS\(_2\). It is reasonable to conclude that the smoother and denser Ag contact leads to higher carrier transport efficiency and contributes to the improved thermal properties.

4:54PM W2.00011 Negative Differential Transconductance in a MoS\(_2\)/WSe\(_2\) Heterojunction Field Effect Transistor

AHMAD ZAUBIR, Massachusetts Institute of Technology, AMIRHASAN NOURBAKSH, Massachusetts Institute of Technology, IMEC, MILDRED DRESSELHAUS, Massachusetts Institute of Technology, STEFAN DE GENDT, IMEC, TOMAS PALACIOS, Massachusetts Institute of Technology — In this work, we demonstrate the negative transconductance in heterojunction transistors made of two-dimensional materials for the first time. Negative transconductance plays a key role in multi-valued logic/memory and frequency multiplication circuits. The simpler fabrication method of stacked van der Waals heterostructures compared to the conventional bulk semiconductors and large CVD growth of the layered 2D materials systems makes it a prime candidate for scalable novel applications of their heterostructures. Vertically stacked MoS\(_2\)/WSe\(_2\) heterostructures are fabricated by mechanical exfoliation and an in-house dry transfer process. A two-step process of e-beam lithography and metal deposition (Au on MoS\(_2\), and Pd on WSe\(_2\)) were performed to fabricate heterojunction field-effect transistors (HJFETs). The transfer characteristics of overlapping regions shows the expected characteristics of the n-type, MoS\(_2\) FET and ambipolar WSe\(_2\) FET. At the same time, the transfer characteristics of the overlapping region between MoS\(_2\) and WSe\(_2\) show negative differential conductance with proper scaling and careful optimization this negative differential transconductance will lead to novel applications.

5:06PM W2.00012 Quantum transport measurement of few-layer WTe\(_2\) field effect devices

JIANGHAO CHEN, XIN LIU, SHIBING TIAN, CHENGLONG ZHANG, SHUANG JIA, International Center for Quantum Materials, School of Physics, Peking University; Collaborative Innovation Center of Quantum Matter, Beijing, China — We have performed systematic quantum transport measurement on field effect devices fabricated from few-layer WTe\(_2\) single crystals. We found that the magnetoresistance of few-layer WTe\(_2\) could be very different from that of bulk samples, which may arise from the imbalance of electron and hole carriers in the samples. We shall discuss our findings in more details in light of recent progress in our experiment.

5:18PM W2.00013 Electronic Transport of Encapsulated WSe\(_2\) Fabricated by Pick-up of Pre-patterned hBN

YAFANG YANG, HUGH CHURCHILL, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — We report high quality WSe\(_2\) devices encapsulated between two hexagonal boron nitride (hBN) flakes using a pick-up method with etched hBN flakes. Previous work on graphene has shown that sample disorder can be greatly reduced via isolation from charge impurities in the substrate by means of encapsulation. However, the effect of encapsulation still remains unknown for dichalcogenides devices. Besides, the quality of contact to TMDs is also a critical factor limiting the transport performance of such devices. To measure the transport properties of dichalcogenide devices as a function of temperature, low resistance electrical contacts must be made to the material. To achieve this, we encapsulate few-layer WSe\(_2\) in hexagonal boron nitride that has been patterned to allow ionic liquid doping of the contact region. This technique simultaneously protects the WSe\(_2\) surface above and below, resulting in the highest mobility few-layer WSe\(_2\) devices reported to date.

Thursday, March 5, 2015 2:30PM - 5:30PM – Session W3 FEd: Invited Session: Growing the Physics Major 002AB - Duncan McBride, National Science Foundation

2:30PM W3.00001 Physics Majors in the US: Trends and Implications

THEODORE HODAPP, American Physical Society — The number of undergraduate physics majors has doubled over the last 15 years, with more growth in sight. In that same time period the total number of PhDs awarded as well as those earned by domestic students has seen a similar rise. The picture is not so rosy when we look at underrepresented groups including women, and minority students. Nevertheless, we are now educating record numbers of physics students. This talk will explore some of the underlying issues, and present evidence for why some of these trends are present. Part of the discussion will include implications for physics programs. How big can programs become? What changes might be needed? What do we sacrifice, and what do we gain as a discipline? Will our new graduates get jobs? Bring your questions and thoughts to the discussion.

3:06PM W3.00002 Strengthening the Physics Program at Brigham Young University – What Have We Learned?

SCOTT SOMMERFELDT, Brigham Young University — During the decade of the 1990s, the Department of Physics and Astronomy at Brigham Young University (BYU) experienced remarkable growth, growing from approximately 200 majors in the first half of the decade to over 300 majors by the end of the decade. Since that time, the number of majors has held fairly steady, fluctuating between 300-350 majors. One can naturally ask, what led to this significant growth? This is a difficult question to answer, as a number of variables are potentially involved, all of which may have had some impact on the outcome. This paper will explore a number of items that have been implemented in the program over this time that may have contributed to establishing a strong physics program that provides an excellent education for our undergraduate majors. Many of these possible contributors can be viewed as an outgrowth of perhaps one major characteristic of the department – a strong and unified commitment to providing excellent undergraduate training in physics. This commitment to undergraduate education has informed many of the decisions that have been made over the past several decades. Several examples that will be discussed include the implementation of the requirement that each student complete a mentored learning experience before graduation, the introduction of several different degrees to better accommodate the range of student interests, and moving the experimental and computational lab courses to earlier in the student’s program to allow later courses and research to build upon these skills. As a result of the greatly enhanced program of program assessment that has been put in place at BYU, these various elements are reviewed regularly, which provides feedback and allows us to make modifications as warranted to try and further strengthen the program.
3:42PM W3.00003 Losing and Saving and Losing Physics in Texas. MICHAEL MARDER. Univ of Texas, Austin — Texas has the second-largest population of the states, and played even a larger role in education reform movements of the past 15 years than its size would indicate. In the Fall of 2011, physicists across the country were surprised to learn that six university physics programs in Texas were threatened with closure because of small graduation numbers. Five of them ultimately closed. Many of the faculty at the institutions losing programs came together and formed a consortium that eventually made it possible to continue offering physics, by unconventional means, to their undergraduates. In the Spring of 2013 came an even larger change. PHS1, the state funded high school graduation plan in Texas. As part of a bill making sweeping changes to high school graduation requirements and accountability, the physics requirement was removed. Physics may partly be failing student to the national focus on STEM, which suggests that the various disciplines of science are interchangeable and not individually important. None of the changes in Texas are hard to imagine coming to other states as well.

4:18PM W3.00004 Morehouse Physics & Dual Degree Engineering Program: We C.A.R.E. Approach. WILLIE S. ROCKWARD, Morehouse College — Growing the physics major at any undergraduate institution, especially Morehouse College – a private, all-black, liberal arts HBCU, can be very challenging. To address this challenge at Morehouse, the faculty and staff in the Department of Physics and Dual Degree Engineering Program (Physics & DDEP) are applying a methodology and pedagogical approach called “We C.A.R.E.” which stands for Curriculum, Advisement, Recruitment/Retention/Research, and Extras. This approach utilizes an integrated strategy of cultural (family-oriented), collaborative (shared-governance), and career (personalized-pathways) modalities to provide the momentum of growing the physics major at Morehouse from 10-12 students to over 100 students in less than 5 years. Physics & DDEP at Morehouse, creatively, altered faculty course assignments, curriculum offerings, and departmental policies while expanding research projects, student organizations, and external collaborations. This method supplies a variety of meaningful, academic and research experiences for undergraduates at Morehouse and thoroughly prepares students for graduate studies or professional careers in STEM disciplines. Thus, a detailed overview of the “We C.A.R.E.” approach will be presented along with the Physics & DDEP vision, alterations and expansions in growing the physics major at Morehouse College.

4:54PM W3.00005 How to double the number of undergraduate physics majors. SACHA KOPP, SUNY Stony Brook — Many colleges and universities around the country have a solid physics program that prepares students bound for graduate physics study. For a variety of reasons, the number of students choosing to major in physics may be small, typically <1% of the student body. When compared to other majors, this population is experiencing negligible growth. I will describe a campaign launched while at the University of Texas at Austin aimed at recruiting and retaining of majors. This campaign includes actual programmatic changes in the curriculum and instruction of majors. Additionally, it includes a direct marketing campaign that attempted to change student attitudes about physics and its relation to their current major. Finally, it includes a program to reach out to high schools and engage students in a discussion about their career choices before they apply for college. I will share some numerical and attitudinal data that suggest positive changes in the student population.

Thursday, March 5, 2015 2:30PM - 5:18PM — Session W5 DMP DCOMP: Focus Session: Magnetism and Transport in Fe-Based Superconductors

3:30PM W5.00001 Intrinsic band pictures of (122) and (11) iron pnictides from magnetotransport measurements. K. HUYNH, WPI-AIMR, Tohoku University, Japan. Y. TANABE, T. URATA, Dep. Phys., Graduate School of Science, Tohoku University, S. HEGURI, K. TANIGAKI, WPI-AIMR, Tohoku University, Japan. M. HAGIWARA, T. KIDA, Center for advanced high magnetic field science, Osaka University. H. OGURO, K. WATANABE, High field laboratory for superconducting materials, Tohoku University — In this report, the band picture of the typical (122) BaFe$_2$As$_2$ and (11) FeSe single crystals will be discussed from the view point of transport properties under high magnetic fields. By applying the technique of mobility spectrum analysis, we are able to describe the numbers of electrons and holes in terms of distribution functions of mobility; the partial contribution of each Fermi pocket to the overall transport properties is thus can be clarified. The analyses show that in both (122) and (11) materials the conduction of mobility spectrum analysis, we are able to describe the numbers of electrons and holes in terms of distribution functions of mobility; the partial contribution of each Fermi pocket to the overall transport properties is thus can be clarified. The analyses show that in both (122) and (11) materials the conduction of electron is much more complex than that of hole. The mobility spectra of holes always indicates isotropic pockets. On the other hand, in the electron side the spectra are broad and associated with a long tail extended to very high mobility region, highlighting the existence of Dirac cones [1, 2]. The unusual features of the mobility spectra will be discussed in comparison with various models and observations of band structures.

1Department of Physics and Dual Degree Engineering Program, Atlanta, Georgia 30314

1Morehouse College.

2Approach will be presented along with the Physics & DDEP vision, alterations and expansions in growing the physics major at Morehouse College.

2:42PM W5.00002 Sharp enhancement of spin fluctuations by nematic order in iron pnictides. QIANG ZHANG, Ames Laboratory and Iowa state university, JIAQIANG YAN, SONGXUE CHI, Oak Ridge National Laboratory, GREGORY, S. TUCKER, Ames Laboratory and Iowa state university, DANIEL. K. PRATT, JEFFREY. W. LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology, R. W. MCCALLUM, PAUL. C. CANFIELD, THOMAS A. LOGRASSO, ALAN I. GOLDMAN, DAVID VAKNIN, ROBERT J. MCQUEENNEY, Ames Laboratory and Iowa state university — Inelastic neutron scattering was employed to investigate the impact of electronic nematic order on the magnetic spectra of LaFeAsO and Ba(Fe$_{0.5}$Co$_{0.5}$)$_2$As$_2$. These materials are ideal to study the paramagnetic-nematic state, since the nematic order, signaled by the tetragonal-to-orthorhombic transition at $T_N$, sets in well above the stripe antiferromagnetic ordering at $T_{NC}$. We find that the temperature-dependent dynamic susceptibility displays an anomaly at $T_N$ followed by a sharp enhancement in the spin-spin correlation length, revealing a strong feedback effect of nematic order on the low-energy magnetic spectrum. Our findings can be consistently described by a model that attributes the structural/nematic transition to magnetic fluctuations, and unveils the key role played by nematic order in promoting the long-range stripe antiferromagnetic order in iron pnictides.

1US DOE, Office of Basic Energy Sciences, DMSE, under Contract No. DE-AC02-07CH11358; DOE, under Award Number DE-SC0012336; DOE, Scientific User Facilities Division; US Department of Commerce

2:54PM W5.00003 Electrododynamic response in the electronic nematic phase of BaFe$_2$As$_2$. C. MIRRI, ETH Zurich — We measure the in-plane optical reflectivity of BaFe$_2$As$_2$ beyond the MIR interval, studied so far, covering the spectral range from the far infrared (FIR) to the ultraviolet (UV) at several combinations of pressure, used to detwin the specimen, and temperature. Our goal is to probe the anisotropic response in the real part of the optical conductivity $\sigma_1(\omega)$, extracted from the reflectivity data via Kramers-Kronig transformations. We thus elucidate how the anisotropic optical metallic response evolves as a function of pressure, considered as an external symmetry breaking field, and across the ferro-elastic structural transition. At the center of our attention we then place the analysis of the spectral weight reshuffling over a large energy interval. We provide evidence of how the anisotropic charge carriers, which allows a direct link to the yet astonishing dc transport properties.

Emergent Defect States as a Source of Resistivity Anisotropy in the Ne- 
matic Phase of Iron pnictides

4:30PM W5.00009 Critical Charge Fluctuations and Ingap Collective Modes in the Superconducting State of the NaFe$_{1-x}$Co$_x$As Iron Pnictide Superconductor$^1$. VERNER THORSMOLLE, University of California at San Diego, MAXIM KHODAS, Racah Institute of Physics, The Hebrew University, ZHIPING YIN, Rutgers, The State University of New Jersey, CHEGLIN ZHANG, The University of Tennessee, SCOTT CARR, PENGCHENG DAI, Rice University, GIRSH BLUMBERG, Rutgers, The State University of New Jersey — We use polarization-resolved Raman spectroscopy to study the Raman susceptibility ($\chi(\omega,T,x)$) of the x-T phase diagram of NaFe$_{1-x}$Co$_x$As [1]. Above the structural $T_S(x)$ and the superconducting $T_c(x)$ transition, $\chi(\omega,T,x)$ is dominated by a low-frequency quasielastic peak in B$_{2g}$ symmetry displaying critical behavior across the entire phase diagram. Below $T_c(x)$, sharp ingap modes emerge for $x>0.0165$ in A$_{1g}$ ($\approx 65$ cm$^{-1}$) and B$_{2g}$ ($\approx 25$ and $\approx 55$ cm$^{-1}$) symmetry. The critical charge fluctuations are interpreted in terms of plasma waves of quadruple excitations which below $T_c(x)$ undergo a metamorphosis into the ingap modes. The A$_{1g}$ mode is a particle-hole (p-h) charge exciton consistent with a non-conventional s$^\pm$ superconducting groundstate. The minor B$_{2g}$ mode is a Bardasis-Schrieffer Cooper pair exciton of d-wave symmetry which exists only in a narrow doping window of density wave and superconductivity coexistence. The major B$_{2g}$ mode is a bound state of d+-p-h plasma oscillations.

4:42PM W5.00010 Magnetic fluctuations under the superconducting dome of Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ from flux-flow resistivity$^1$. XINYI HUANG, DEREK HANEY, YOGESH SINGH, SHUAI ZHANG, Kent State University, HAI-HU WEN, Nanjing University, TAO HU, Shanghai Institute of Microsystem and Information Technology, CAS, MAXIM DZERO, CARMEN ALMASAN, Kent State University — We investigate the magnetism inside the superconducting phase of Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ crystals (on both sides of the optimal doping) by inducing superconducting vortices via applied field and performing current-voltage measurements. This allows us to measure the quasiparticle scattering within the normal cores, despite being inside the superconducting dome. Analysis of the free-flux-flow resistivity within the superconducting phase shows a sharp increase in the quasiparticle scattering with decreasing temperature and applied field, which we attribute to the presence of critical spin fluctuations inside the vortex core. The fluctuations are strongest in the doping with the highest critical temperature, and the behavior is suppressed as the material is more underdoped. For each doping measured, at different temperatures and applied fields, the vortex dissipation curves scale and show an exponential relationship. We will discuss the physics behind the exponential relationship for each doping range.

4:54PM W5.00011 Correlation, doping, and interband effects on the optical conductivity of iron superconductors$^1$. LUCA DE’ MEDICI, European Synchrotron Radiation Facility, Laboratoire de Physique et Etude des Matériaux, CNRS/ESPCI/UPMC, France, MARIA J. CALDERON, BELEN VALENZUELA, ELENA BASCONES, ICMM-CSIC, Spain — Optical conductivity is one of the tools traditionally used to study strongly correlated systems. For single band systems, the interpretation of these data is rather straightforward and very well known. This is not the case for multiorbital systems, where electronic interactions lead to nontrivial features in the optical spectrum. We have studied the case of iron superconductors by means of a model that introduces the orbital dependent interactions. We find that interband transitions make a non-negligible contribution to the low-energy plateau found in the optical spectrum of undoped compounds and account for a large fraction of the spectral weight at the cutoff frequencies currently used to determine the Drude weight. This fraction is strongly enhanced in hole-doped samples as the larger effect of interactions towards half-filling strongly suppresses the Drude weight. We analyze the relationship between the Drude weight and the kinetic energy and their renormalizations. We show that with orbital differentiation, the renormalization of both the Drude weight and the kinetic energy are not equal, not even within a Fermi liquid picture. Phys. Rev B 90, 115128 (2014).

2:42PM W6.00007 Dirac-like plasmons in Ag nanopillar honeycomb lattices , SIYING PENG, Thomas J. Watson Laboratory of Applied Physics, California Institute of Technology, Pasadena, California 91125, United States, BENJAMIN BRENNY, AMOLF, SONDRA HELLSTROM, Thomas J. Watson Laboratory of Applied Physics, California Institute of Technology, Pasadena, California 91125, United States, TOON COENEN, ALBERT POLMAN, AMOLF, HARRY ATWATER, Thomas J. Watson Laboratory of Applied Physics, California Institute of Technology, Pasadena, California 91125, United States — Surface plasmons in honeycomb lattices of Ag nanoparticles exhibit Dirac-like band structures, similar to the electronic band structure of graphene. Full wave simulations for an infinite honeycomb lattice of silver nano-pillars reveal hybridization of localized plasmonic modes between two neighboring pillars and the consequent formation of bonding and anti-bonding modes that are energetically degenerate at Dirac points. Electromagnetic simulations reveal the existence of plasmonic edge states in finite width nanoribbons of the honeycomb nanoparticle lattice. Nanoscale architecture of the honeycomb lattice may provide a new way to control plasmon propagation by selective excitation of directional surface plasmon edge states without backscattering. Experimentally, we have utilized cathodoluminescence (CL) spectroscopy to study angular emission patterns and construct band structures of the silver pillars in honeycomb lattices. In our initial CL measurement, silver pillars in honeycomb lattices, we have observed strong radiation patterns near the Brillouin zone edge, integrated over an interval of wavelength centered on the wavelength of the Dirac points.

2:54PM W6.00003 Super Resolution Measurements of the Near-Field Coupling of the Polarized Modes of Gold Nanorods to Fluorescent Emitters , BENJAMIN ISAACOFF, JESSICA DONEHUE, JULIE BITEEN, Univ of Michigan - Ann Arbor — The localized surface plasmon resonances of metal nanoparticles result in complex light-matter interactions that depend strongly on the nanoparticle geometry. In this work, we use single-molecule super-resolution imaging and single-particle spectroscopy to study the polarization dependent response of gold nanorods (GNRs), which support two orthogonal plasmon modes. Furthermore, we measure the emission intensity and polarization of single fluorescent molecules coupled to the GNR as a function of excitation polarization and spectral overlap with the GNR modes. Based on such differential excitation, we demonstrate polarization control of plasmon-enhanced fluorescence from single molecules coupled to single nanoparticles. These experiments are compared with broadband finite difference time domain (FDTD) simulations studying the role of fluoroaphore position and orientation, revealing the underlying mechanisms of this coupling. These super-resolution measurements and the associated simulations demonstrate how polarization can be used to actively control nanoparticle plasmonics and opens the door to a new framework for controlling and optimizing nanoparticle-fluorophore interactions.

3:06PM W6.00004 Influence of Surfactant Bilayers and Substrate Immobilization on the Refractive Index Sensitivity of Anisotropic Gold Nanoparticles , MOHAMAD SHAHJAMALI, NICOLAS LARGE, Northwestern University, ERIK MARTINSSON, Linkoping University, NEGIN ZARAAE, GEORGE SCHATZ, Northwestern University, DANIEL ALLI, Linkoping University, CHAD MIRKIN, Northwestern University — Shape-controlled synthesis of gold nanoparticles (AuNPs) generally involves the use of surfactants to regulate the nucleation growth process and to obtain colloidal stable AuNPs. The surfactants adsorb on the NP surface making further functionalization difficult and therefore limit their practical use in many applications such as bio- and molecular sensing, surface-enhanced spectroscopies, and NP assembly. Herein, we report on how cetyltrimethylammonium (CTAX, X=Cl−, Br−), a common surfactant used in anisotropic AuNPs synthesis, affects the nanoparticle sensitivity to local dielectric environment changes and limits refractometric plasmonic sensing. We experimentally and theoretically show that the CTAX bilayer significantly reduces the refractive index (RI) sensitivity of anisotropic AuNPs such as flat and concave nanocubes, nanorods, and nanoprism. We show that the RI sensitivity can be improved by up to 40% by removing the CTAX from immobilized AuNPs using oxygen plasma treatment. The substrate effect on the RI sensitivity caused by NP immobilization is also investigated. The strategy presented herein is a simple and effective method to improve the RI sensitivity of CTAX-stabilized AuNPs, thus increasing their potential in nanoplasmic sensing and in biomedical applications.

3:18PM W6.00005 Surface plasmons excitation and manipulation by low-energy electrons , MICHAEL J. BURNS, JUAN M. MERLO, YITZI M. CALM, MICHAEL J. NAUGHTON, Boston College — Surface plasmons coupled by optical fields have been widely used to control the propagation of electromagnetic fields in the nanoscale range. We propose numerically the use of low-energy electrons to excite and manipulate surface plasmons in metallic surfaces by using different configurations of tunneling junctions. Modeling the inelastic electron scattering at tunneling junctions as an electric dipole, it is possible to use an electromagnetic model to reproduce experimental results already reported [1]. Following this methodology, we demonstrate that is it possible to mimic novel plasmonic elements that can be excited only by optical fields, i.e. focused beams. Our results open a wide range of applications because it avoids the noise produced by direct light excitation in the detection of surface plasmons. Finally, as an application of our proposed scheme, we study the unidirectional surface plasmon coupler, getting similar results to those recently reported [2].

3:30PM W6.00006 Optical Properties of Scalable Nano-Mesh Films , KYLE ALVINE, BRUCE BERNACKI, WENDY BENNETT, ALAN SCHEMER-KOHRN, Pacific Northwest Natl Lab — We describe here the optical properties of a scalable nano-mesh film both experimentally measured and calculated by FDTD numerical modeling. Typically, applications for optically responsive nano-plasmonic or photonic films are limited by virtue of tractable fabrication techniques to several hundred microns or a few millimeters in size. The films described here have been demonstrated over an extent of several inches and could be readily scaled to larger sizes. The films are comprised of a quasi-regular periodic array of nanoscale holes in metallic film. The nanostructure is fabricated in a scalable fashion in a multi-step fashion via sputtering on a nanoscale template created by nanoparticle self-assembly. Both the numerical modeling and experimentally measured scattering demonstrate that these films are highly resonant with the resonance location in the visible or near infrared and set by the hole size and pattern geometry. Such films can also be readily made on flexible substrates if desired. Potential applications include new proposed photonic thermal management coatings or plasmoelectric devices.

3:42PM W6.00007 Optical Properties of Scalable Nano-Mesh Films , KYLE ALVINE, BRUCE BERNACKI, WENDY BENNETT, ALAN SCHEMER-KOHRN, Pacific Northwest Natl Lab — We describe here the optical properties of a scalable nano-mesh film both experimentally measured and calculated by FDTD numerical modeling. Typically, applications for optically responsive nano-plasmonic or photonic films are limited by virtue of tractable fabrication techniques to several hundred microns or a few millimeters in size. The films described here have been demonstrated over an extent of several inches and could be readily scaled to larger sizes. The films are comprised of a quasi-regular periodic array of nanoscale holes in metallic film. The nanostructure is fabricated in a scalable fashion in a multi-step fashion via sputtering on a nanoscale template created by nanoparticle self-assembly. 3:54PM W6.00008 MEMS for Tunable Plasmonic Coupling, TOM STARK, MATTHIAS IMBODEN, SABRI KAYA, ALKET MERTIRI, SHYAMSUNDER EMMONILLI, DAVID BISHOP, Boston Univ. — The localized surface plasmon resonance (LSPR) of sub-wavelength holes in metals depends upon the geometry, composition, refractive index, and near field coupling to neighboring particles. Sub-wavelength holes in metals can exhibit extraordinary optical transmission (EOT) at the resonance frequency and, for certain geometries, polarization-dependent transmission. We present a microelectromechanical system, tunable Fabry-Perot etalon. One interface is a suspended gold metatmaterial and the other is a gold reflector. The reflectance, measured with a Fourier transform infrared spectrometer, exhibits the convolution of the EOT through the holes and Fabry-Perot resonances. Using MEMS, we translate the etalon from the far to the near field by tuning the free spectral range from about 5000 to 250 cm\(^{-1}\) and shifting the reflection minima and maxima across the infrared. When the separation between the metatmaterial and gold reflector approaches the decay length of the LSP electric fields, interactions with image currents generated in the gold reflector become significant. By tuning the separation in this regime, we will tune the near field coupling between the LSPR and image currents and tune the LSPR of the system, effectively creating a sensing substrate with a tunable LSPR frequency.

4:06PM W6.00009 Digitally Programmable Micro Evaporation Source for Nanofabrication, HAN HAN, MATTHIAS IMBODEN, Boston University, PABLO DEL CORRO, Instituto Balseiro, THOMAS STARK, RICHARD LALLY, Boston University, FLAVIO PARDO, CRIS BOLLE, Bell Labs, Alcatel-Lucent, DAVID BISHOP, Boston University — There is a significant world-wide effort to develop nanomanufacturing methods that can extend into the deep nanoscale region, below 20 nm. Techniques include photolithography, nano-imprint and direct write methods such as dip-pen lithography and atomic calligraphy. A central component of any fabrication setup is the deposition control of the materials to be used. Here we present a MEMS based, multi-material evaporation source array with each source element consisting of a polysilicon plate suspended by two electrical constrictions. When resistively heating the plate, the pre-loaded material is thermally evaporated off of the plate. By arranging many of these devices into an array, one has a multi-material, digitally programmable evaporation source. Pulsing the source with precisely controlled peak voltage and timing can emit atom fluxes with an unprecedented level of control in terms of what, when and how many atoms get deposited. By varying their dimensions and arrangement, the source array can provide controllable atom fluxes ranging over ten orders of magnitude. Such a material source can provide precise control and flexibility when conducting nanopatterning and nanolithography.

4:18PM W6.00010 Soft Nanoimprint Lithography for Direct Printing of Crystalline Metal Oxide Nanostructures, ROHIT KOTHARI, MICHAEL BEAULIEU, JAMES WATKINS, Univ. of Massachusetts Amherst — We demonstrate a solution-based soft nanoimprint lithography technique to directly print dimensionally-stable crystalline metal oxide nanostructures. A patterned PDMS stamp is used in combination with a UV/thermal cure step to imprint a resist containing high concentrations of crystalline nanoparticles in an inorganic/organic binder phase. The as-imprinted nanostructures are highly crystalline and therefore undergo little shrinkage (less than 5% in some cases) upon thermal annealing. High aspect ratio nanostructures and sub-100 nm features are easily realized. Residual layer direct imprinting (no etching) was achieved by choosing the resist with the appropriate surface energy to ensure dewetting at stamp-substrate interface. The technique was further extended to stack the nanostructures by deploying a layer-by-layer imprint strategy. The method is scalable and can produce large area device quality nanostructures in a rapid fashion at a low cost. CeO\(_2\), ITO and TiO\(_2\) nanostructures are illustrated for their potential use in fuel cell electrodes, solar cell electrodes and photonic devices, respectively.

4:30PM W6.00011 Resolving the two-dimensional self-assembly of iron oxide nanoparticles on a liquid surface, JIAYANG HU, DATONG ZHANG, Columbia University, CHENGUANG LU, National Center for Nanoscience and Technology, SEUNG WHAN LEE, FAN YE, IRVING P. HERMAN, Columbia University — In situ small-angle X-ray scattering (SAXS) is used to monitor the self-assembly of iron oxide nanoparticles (NPs) dispersed in alkanes that are drop-cast on a diethylene glycol liquid surface. We found that the surface separations of NP cores in 2D superlattices (SLs) are generally farther apart than in 3D SLs with corresponding NPs. At these separations, the van der Waals (vdW) energy is smaller than the Brownian motion energy and so the previous 3D vdw force driven self-assembly models fail to explain the stable closed-packed structure. Strong ligand-ligand interactions likely bind the structure after the upper solvent dries. Entropy effects are found not to be the likely driving force for the observed close packing structures.

4:42PM W6.00012 Imaging of Bottom-up Graphene Nanoribbons Synthesized Using Combined Solution and Surface Reactions, DANNY HABERER, CHEN CHEN, ZAHRA PEDRAMRAZI, RYAN CLOKE, TOMAS MARANGONI, WON-WOO CHOI, FELIX FISCHER, CROMMIE MICHAEL, UC Berkeley, CROMMIE GROUP TEAM, FISCHER GROUP TEAM — Bottom-up graphene nanoribbons (GNRs) are a new class of material that has promising applications in next-generation electronic, spintronic, and optical devices. Bottom-up synthesis using molecular precursors provides precise control over GNR width and edge geometry, which determine GNR electronic structure. However, previously used on-surface polymerization techniques can be hindered by molecular diffusion barriers and by undesired side products. Alternative in-solution polymerization techniques potentially have better yield and higher selectivity. Using combined in-solution polymerization and on-surface cyclodehydrogenation reactions, we have successfully synthesized N\(_2\)-armchair GNRs. Scanning tunneling microscopy was used to reveal the precise width and edges of the resulting nanoribbons. This method may be generalized to synthesize graphene nanoribbons that are difficult to fabricate through exclusive on-surface reactions.

4:54PM W6.00013 Dynamically tunable graphene/dielectric photonic crystal transmission lines, IAN WILLIAMSON, S. HOSSEIN MOUSAVI, ZHENG WANG, Univ of Texas, Austin — It is well known that graphene supports plasmonic modes with high field confinement and lower losses when compared to conventional metals. Additionally, graphene features a highly tunable conductivity through which the plasmon dispersion can be modulated. Over the years these qualities have inspired a wide range of applications for graphene in the THz and infrared regimes. In this presentation we theoretically demonstrate a graphene parallel plate waveguide (PPWG) that sandwiches a 2D photonic crystal slab. The marriage of these two geometries allows a large two dimensional band gap that can be dynamically tuned over a very broad bandwidth. Our device operates in the low-THz band where the graphene PPWG supports a quasi-TEM mode with a relatively flat attenuation. Unlike conventional photonic crystal slabs, the quasi-TEM nature of the graphene PPWG mode allows the slab thickness to be less than 1/10 of the photonic crystal lattice constant. These features offer up a wealth of opportunities, including tunable metamaterials with a possible platform for large band gaps in 3D structures through tiling and stacking. Additionally, the geometry provides a platform for tunable defect cavities without needing three dimensional periodicity.

5:06PM W6.00014 Toward Controlled In-Solution Stacking of Solvent Exfoliated 2-Dimensional Nanoflakes and Heterostructures, DALE BROWN, A. NICOLE CHANG, RICHARD LIVINGSTON, DAVID ESTRADA, Boise State University — As a result of quantum confinement, materials with one dimension confined to a few atomic diameters, including single- and few-layer graphene and transition metal dichalcogenides (TMDs), often have properties unique from those of their bulk counterparts. Included in these emergent properties is photoluminescence in thin flakes of some semiconducting TMDs. Additionally, the creation of heterostructures via the stacking of 2D materials allows for the synthesis of new materials with properties unique from those of the starting materials. While much of the research published to date in this area relies on labor intensive methods, including stacking each subsequent layer by hand to synthesize these heterostructures, some researchers have demonstrated random stacking of suspended 2D flakes in solution, with limited control over the thickness of the resulting heterostructures. By modifying the surface energy mismatch between the solvent and the suspended, exfoliated 2D materials therein, we aim to demonstrate the ability to actively control the propensity for and duration of stacking in liquid suspensions of 2D materials.
5:18PM W6.00015 Bottom-up synthesis of N=11 armchair graphene nanoribbons via new sp3 to sp2 cyclization route. ZAHRA PEDRAMRAZI, CHEN CHEN, DANNY HABERER, WADE PERKINS, FELIX FICHERER, MICHAEL CROMMIE, UC Berkeley, CROMMIE GROUP TEAM. FISCHER GROUP TEAM. — Bottom-up synthesis is a powerful fabrication tool for controlling the atomic scale structures of graphene nanoribbons (GNRs). The electronic properties of GNRs, 1D strips of graphene that exhibit energy gaps in their electronic structure due to quantum confinement, is highly dependent on precise width and atomic edge structure. The molecular precursors used to date for bottom-up synthesis are based on conjugated systems of sp2-bonded carbon atoms. Here we demonstrate a new molecular precursor for synthesis of bottom-up N=11 armchair GNRs that exhibits cyclohydrogenation of ‘out-of-plane‘, sp3-bonded elements. Scanning tunneling microscopy imaging was used to characterize the GNR growth reaction at different annealing temperatures, allowing observation of the sp3 to sp2 cyclization process. This demonstrates a new chemical route for achieving armchair GNRs, as well as new insight into surface-based covalent self-assembly of organic molecules.

Thursday, March 5, 2015 2:30PM - 5:30PM – Session W7 DMP DCMP: Focus Session: Novel Topological Phases: Theory II 006B - Jens Bardarson, Max Plank Institute, Dresden

2:30PM W7.00001 disorder effect on quantum transport properties of ultra thin Fe film. XIAOTIAN ZHANG, Peking Univ, KOHJI NAKAMURA, Mie University, RYUICHI SHINDOU, ICOM, School of Physics, Peking University — Ferromagnetic ultrathin films are experimentally known to often exhibit perpendicular magnetic anisotropy, when being placed on certain substrates. Based on reported ab-initio band calculations of free-standing Fe-monolayer and that on MgO substrate, we will introduce an effective tight-binding model, which capture a part of an electronic structure near Fermi level for both cases. We will show that the model supports electronic bands with non-zero Chern number and chiral edge modes which cross a direct band gap on the order of 50meV. Unluckily, however, the direct band gap is also masked by another dispersive bands which has zero Berry’s curvature in the k-space. To demonstrate how disorder kills conducting characters of the latter bulk bands while leave intact those of the chiral edge modes, we will clarify behaviors of localization length and conductance in the effective model with on-site disorders.

2:42PM W7.00002 Complex Band Structure of the Topological Insulator Bi$_2$Se$_3$. SHIJIE LI, Univ of Nebraska - Lincoln, JESUAN BETANCOURT, University of Puerto Rico, J.D. BURTON, Univ of Nebraska - Lincoln, JULIAN P. VELEV, University of Puerto Rico, EVGENY Y. TSYMBAL, Univ of Nebraska - Lincoln — Recently there is a surge of interest in using topological insulators for electronic and spintronic applications. For applications it is important to understand the complex band structure (CBS) of the topological insulator, which determines the decay rate of the protected surface states into the bulk of the material. The Bi$_2$Se$_3$ family of three-dimensional topological insulators is the most studied and best understood. In this work we investigate the CBS of Bi$_2$Se$_3$ using first-principles density-functional calculations. We determine the decay rates and the symmetry of the evanescent states and we follow their evolution from those of the band insulator. We complement these results with Bi$_2$Se$_3$ (0001) slab calculations to explore the penetration depth, oscillatory behavior and spin texture of the surface states. The CBS provides a new insight into the topologically protected states and could be used for the search of new topological insulators and device concepts.

2:54PM W7.00003 Prediction of Large-Gap Two-Dimensional Topological Insulators Consisting of Hydrogenated Bilayers of Group III Elements with Bi. CHRISTIAN P. CRISOSTOMO, LIANG-ZI YAO, ZHI-QUAN HUANG, CHIA-HSIU HSU, FENG-CHUAN CHUANG, Natl. Sun Yat-sen U., HSIN LIN, Natl. U. of Singapore, MARVIN A. ALBAO, U. of the Philippines Los Banos, ARUN BANSIL, Northeastern U. — We use first-principles electronic structure calculations to predict a new class of two-dimensional (2D) topological insulators (TIs) in hydrogenated binary compositions of group III elements (B, Al, Ga, In, and TI) and bismuth (Bi). We identify band inversions in unhydrogenated pristine GaBi, InBi, and TIBi bilayers, with gaps as large as 556 meV for the TIBi case, making these materials suitable for room-temperature applications. Double-sided hydrogenation in which hydrogen was added on opposite sides also exhibited band inversions in the case of GaBi, InBi, and TIBi just as in the unhydrogenated pristine ones. Furthermore, we report the gap to be 885 meV for the hydrogenated TIBi case. Hydrogenation enhance the band gap without changing the band topology. Moreover, our study also aim to demonstrate the possibility of strain engineering in that the topological phase transition in systems whose phase was nontrivial could be driven by suitable strain. Finally, the effect of placing hydrogen to topological edges was also demonstrated. Our findings suggest that the buckled honeycomb structure is a versatile platform for hosting nontrivial topological states and spin-polarized Dirac fermions with the flexibility of chemical and mechanical tunability. The robustness of III-Bi upon hydrogenation shows that these materials are possible to synthesize by growing on substrates.

3:06PM W7.00004 Topological Crystalline Insulators. TIMOTHY HSIEH, Massachusetts Inst of Tech-MIT — Topological crystalline insulators (TCIs) are new phases of matter in which nontrivial band topology and crystal symmetry unite to protect metallic states on the boundary. Remarkably, TCIs have been predicted and observed in the conveniently simple rocksalt SnTe class of IV-VI semiconductors. Despite the simple crystal structure, the interplay between topology and crystal symmetry in these materials have led to a rich variety of new phenomena, including the coexistence of massless and massive Dirac fermions arising from ferroelectric distortion and strain-induced flat band superconductivity. These new physical mechanisms are not only of intrinsic interest but may also find application in new transistor devices. After discussing the topological nature and potential uses of IV-VI family TCIs, I will present recent predictions of TCIs in several anti-perovskite materials. The origin of TCI in this new class of materials is strikingly different and involves the band inversion of two J states, which cross a direct band gap on the order of 50meV. Unluckily, however, the direct band gap is also masked by another dispersive bands which has zero Berry’s curvature in the k-space. To demonstrate how disorder kills conducting characters of the latter bulk bands while leave intact those of the chiral edge modes, we will clarify behaviors of localization length and conductance in the effective model with on-site disorders.

3:42PM W7.00005 The nontrivial electronic structure of Bi/Sb honeycombs on SiC(0001). FENG-CHUAN CHUANG, CHIA-HSIU HSU, ZHI-QUAN HUANG, CHIEN-CHENG KUO, Natl. Sun Yat-sen U., YU-TZU LIU, HSIN LIN, Natl. U. of Singapore, ARUN BANSIL, Northeastern U. — We discuss two-dimensional (2D) topological insulators (TIs) based on planar Bi/Sb honeycombs on a SiC(0001) substrate using first-principles computations. The Bi/Sb planar honeycombs on SiC(0001) are shown to support a nontrivial band gap as large as 0.56 eV, which harbors a Dirac cone lying within the band gap. Effects of hydrogen atoms placed on either just one side or on both sides of the planar honeycombs are examined. The hydrogenated honeycombs are found to exhibit topologically protected edge states for zigzag as well as armchair edges, with a wide band gap of 1.03 eV and 0.14 eV in bismuth and antimony films, respectively. Our findings pave the way for using planar bismuth and antimony honeycombs as potential new 2D-TI platforms for room-temperature applications.
3:54PM W7.00006 Hydrogenated ultra-thin tin films predicted as two-dimensional topological insulators. ZHI-QUAN HUANG, BO-HUNG CHOU, CHIA-HSIU HSU, FENG-CHUAN CHUANG, Natl. Sun Yat-sen U., YU-TZU LIU, HSIN LIN, Natl. U. of Singapore, ARUN BANSIL, Northeastern U. — Using thickness-dependent first-principles electronic structure calculations, we predict that hydrogenated ultra-thin films of tin harbor a new class of two-dimensional (2D) topological insulators (TIs). A single bilayer (BL) tin film assumes a 2D-TI phase, but it transforms into a trivial insulator after hydrogenation. In contrast, tin films with 2 and 3 BLs are found to be trivial insulators, but hydrogenation of 2 to 4 BL films results in a non-trivial Tl phase. For 1 to 3 BLs, H-passivation converts the films from being metallic to insulating. Moreover, we examined iodine-terminated tin films up to 3 BLs, and found these to be non-trivial, with the films becoming semi-metallic beyond 1 BL. In particular, the large band gap of 340 meV in an iodine-terminated tin bilayer is not sustained in the iodine-terminated 2BL and 3BL tin films.

4:06PM W7.00007 Real-structure influence on topological states of HgTe quantum wells: Ab initio studies. SEBASTIAN KUEFNER, FRIEDHELM BECHSTEDT, Friedrich-Schiller Universitaet Jena — The electronic properties of HgTe quantum well structures are studied by means of ab-initio calculations including spin-orbit interaction and quasiparticle effects. In agreement with earlier kp calculations and experiments we find a topological transition from the trivial insulator into the quantum-spin Hall (QSH) state with increasing QW thickness. The QSH state is characterized by the existence of spin-polarized helical edge states bridging the fundamental gap giving rise to intrinsic spin currents. The occurrence and localization of the edge states are independent of the interface orientation and barrier material. Together with their spin polarization this indicates that they are topologically protected. The nonexistence of inversion symmetry, the atomic geometry, and the real QW barriers do not completely destroy the predictions within toy models but cause significant deviations. The deviations concern the critical thickness, the number and localization of edge states, and the possibility to find QW subbands between edge states.

1We gratefully acknowledge financial support of the Austrian Fond zur Foerderung der Wissenschaftlichen Forschung in the framework of SFB 25 Infrared Optical Nanostructures.

4:18PM W7.00008 Edge state transport in 2D topological insulators without inversion symmetry. YANG-ZHI CHOU, MATTHEW FOSTER, Department of Physics and Astronomy, Rice University, Houston, Texas 77005, USA — We investigate finite temperature transport within one and between two edges of a 2D Z_2 topological insulator. For experimentally relevant systems (e.g., HgTe and GaSb/InAs quantum wells), inelastic spin flip backscattering can occur in the absence of inversion symmetry. We use bosonization and the effective action formalism to compute the dc conductivity of helical Luttinger liquid edge states in the absence of inversion symmetry, due to interactions and disorder. These perturbations manifest as irrelevant operators that control the temperature dependence of the conductivity in a single edge. With respect to two edges, the importance of the inelastic mechanism and applications to Coulomb drag will be discussed.

4:30PM W7.00009 Twisting a topological phase on a lattice. MENG CHENG, Microsoft Research Station Q, YI-ZHUANG YOU, University of California, Santa Barbara — When a two-dimensional topological phase inhabits a torus, it possesses a ground state degeneracy robust to any local perturbations. These degenerate ground states can transform nontrivially under modular transformations of the torus, generated by Dehn twists. Representation of Dehn twists on the ground states characterizes the topological order. We propose that the Dehn twists can be obtained as a non-Abelian Berry phase of an adiabatic deformation of the lattice model. We apply this method to the example of a p_x + i p_y superconductor and provide a TQFT interpretation of the numerical results.

4:42PM W7.00010 Quantum criticality of 1D topological Anderson insulators. ALEX KAMENEV, University of Minnesota, DMITRY BAGRETS, ALEX ALTLAND, University of Koln — We present an analytic theory, based on exact transfer-matrix solutions of super-symmetric nonlinear sigma-models, of quantum criticality in quasi one-dimensional topological Anderson insulators. We describe these systems in terms of two parameters (g, χ) representing localization and topological properties, respectively. Certain critical values of χ (half-integer for Z classes, or zero for Z2 classes) define phase boundaries between distinct topological sectors. Upon increasing system size, the two parameters exhibit flow similar to the celebrated two parameter flow of the integer quantum Hall insulator. However, unlike the quantum Hall system, an exact analytical description of the entire phase diagram can be given. We check the quantitative validity of our theory by comparison to numerical transfer matrix computations.

1Support of NSF grant DMR1306734 is acknowledged.

4:54PM W7.00011 Berry Curvature and Chiral Plasmons in Massive Dirac Materials. JUSTIN SONG, Caltech, MARK RUDNER, University of Copenhagen — In the semiclassical model of carrier dynamics, quasiparticles are described as nearly free electrons with modified characteristics modified characteristics such as effective masses which may differ significantly from those of an electron in vacuum. In addition to being influenced by external electric and magnetic fields, the trajectories of electrons in topological materials are also affected by the presence of an interesting quantum mechanical field - the Berry curvature - which is responsible for a number of anomalous transport phenomena recently observed in Dirac materials including G/3hBN, and MoS2. Here we discuss how Berry curvature can affect the collective behavior of electrons in these systems. In particular, we show that the collective electronic excitations in metallic massive Dirac materials can feature a chirality even in the absence of an applied magnetic field. The chirality of these plasmons arises from the Berry curvature of the massive Dirac bands. The corresponding dispersion is split between left- and right-handed modes. We also discuss experimental manifestations.

5:06PM W7.00012 First-Principles Study on Dirac Cones in a Single-Component Molecular Crystal Under High Pressure. TAKAO TSUMURAYA, RIKEN/NIMS, HENG-BO CUI, RIKEN, HIORI KINO, NIMS-MANA, TSUYOSHI MIYAZAKI, NIMS, REIZO KATO, RIKEN — Most single-component molecular crystals show insulating or semiconducting properties at ambient pressure. Recently, metal dithiolene complexes have attracted much attention ever since a metallic state was realized in Ni(bdt)2 at ambient pressure. Even if the system is insulating at ambient pressure, it possibly turns into a metallic or superconducting state by application of pressure. In this study, we have found anisotropic linear (tilted Dirac cone) dispersions near the Fermi level in a single-component molecular crystal, Pd(ddt)2, at 8 GPa by first-principles density functional theory calculations. Recent electrical resistivity at 12.6 GPa shows temperature independent behavior as is observed in the massless Dirac fermion system, ϵ=-(BEDT-TTF)2I3. Our analysis of the electronic structure indicates that the band structure at ambient pressure has quasi-one-dimensional character, which corresponds to the stacking of Pd(ddt)2 molecules along the b-axis, and the dimensionality of the band structure near the Fermi level is changed under the pressure of 8 GPa, where intermolecular hybridization increases due to the reduced intermolecular distances. We also discuss anisotropy of the Dirac cones and their possible origin in the multi-orbital system.
the symmetry of the band edge states; in addition, the band crossing occurs at the band center with notice that all IFS’s appear in the plasmonic band gap of the 1DHMM, and the dielectric- or metallic-like properties of the 1DHMMs are strongly related to can occur in the dielectric/1DHMM interface. Furthermore, we show the existence of the IFS between the dielectric-like 1DHMM and metallic-like 1DHMM. 

\[ \text{light, we theoretically demonstrate an HCG focusing lens with transmissivity of 83.0\% and numerical aperture of 0.77, and a VLM with beam deflection angle} \]

2:30PM W8.00001 Broadband Tunable Transparency in rf SQUID Metamaterial. DAIMENG ZHANG, MELISSA TREPANIER, Univ of Maryland-College Park, OLEG MUKHANOV, Hyuples Inc, PHILIPP JUNG, SUSANNE BUTZ, ALEXEY USTINOV, KIT, STEVEN ANLAGE, Univ of Maryland-College Park — We demonstrate a metamaterial with broadband tunable transparency in microwave electromagnetic fields. This metamaterial is made of Radio Frequency Superconducting Quantum Interference Devices (rf SQUIDs) [1]. We show both experimentally and theoretically that the resonance of this metamaterial totally disappears when illuminated with electromagnetic waves of certain power ranges, so that waves can propagate through the metamaterial with little dissipation in a wide frequency spectrum. Unlike traditional electromagnetically induced transparency, high transmission through this metamaterial is due to the intrinsic nonlinearity of the rf SQUID. Transparency occurs when the metamaterial enters its bistability regime. We can control the metamaterial to be transparent or opaque by switching between the two states depending on the initial conditions and signal scanning directions. We also show that the degree of transparency can be tuned by temperature, power of the incident wave, and dc magnetic field and discuss analytical and numerical models that reveal how to systematically control the transparency regime. The metamaterial has potential application in fast tunable digital filter, power limiter and auto-cloaking.

2:42PM W8.00002 Plasmonic metastructures exhibiting a narrow transparency window within a broad extinction spectrum. LUCAS V. BESTEIRO, Department of Physics and Astronomy, Ohio University, HUI ZHANG, Department of Physics and Astronomy, Rice University, KIVANC GUNGOR, Institute of Materials Science and Nanotechnology, Bilkent University, HILM VOKLANKOY, Institute of Materials Science and Nanotechnology, Bilkent University; School of Physical and Mathematical Sciences, Nanyang Technological University, ALEXANDER GOVOROV, Department of Physics and Astronomy, Ohio University — Metallic nanostructures have proven to be a valuable resource in accessing new ways of manipulating light, allowing the creation of novel metamaterials with a number of different applications. By controlling the size and geometry of these structures they can be tailored to strongly interact with specific wavelengths of incident light. We propose an approach to the design of composite systems that takes advantage of that property. Using finite elements calculations, we have studied several structure geometries suitable to be deployed using lithographic or colloidal synthesis techniques, such as discs, nanorods and nanocrosses. We discuss specific layouts of these structures, arranged in a modular fashion, to construct plasmonic metamaterials with a wide extinction profile that also present a transparency window for a narrow range of frequencies. This kind of metamaterials, made in the form of plasmonic metasolutions or as a stacked solid-state metastructure, may be used to create frequency filters for electromagnetic radiation. To realize this objective, it is instrumental to choose the right ensemble of nanostructures and to control the interaction between them.

2:54PM W8.00003 Metasurfaces based on Gallium Nitride High Contrast gratings at Visible Range. ZHENHAI WANG, SHUMIN HE, QIFA LIU, WEI WANG, YONGJIN WANG, HONGBO ZHU, Grünberg Research Centre, Nanjing University of Posts and Telecommunications, Nanjing 210003, China, GRÜNBERG RESEARCH CENTRE TEAM — Metasurfaces are currently attracting global attention due to their ability to achieve full control of light propagation. However, these metasurfaces have thus far been constructed mostly from metallic materials, which greatly limit the diffraction efficiencies because of the ohmic losses. Semiconducting metasurfaces offer one potential solution to the issue of losses. Besides, the use of semiconductor materials can broaden the applicability of metasurfaces, as they enable facile integration with electronics and mechanical systems and can benefit from mature semiconductor fabrication technologies. We have proposed visible-light metasurfaces (VLMs) capable of serving as lenses and beam deflecting elements based on gallium nitride (GaN) high contrast gratings (HCGs). By precisely manipulating the wave-fronts of the transmitted light, we theoretically demonstrate an HCG focusing lens with transmissivity of 83.0\% and numerical aperture of 0.77, and a VLM with beam deflection angle of 6.03\° and transmissivity as high as 93.3\%. The proposed metasurfaces are promising for GaN-based visible light-emitting diodes (LEDs), which would be robust and versatile for controlling the output light propagation and polarization, as well as enhancing the extraction efficiency of the LEDs.

3:06PM W8.00004 Interface States between two one-dimensional Hyperbolic Metamaterials. IENG-WAI UN, TA-JEN YEN, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan, R.O.C — In this work, we investigate the interface state(IFS) between two 1D hyperbolic metamaterials(1DHMM). At first, we scrutinize the existence of IFS in three kinds of interface-dielectric/1DHMM, metal/1DHMM, and 1DHMM/1DHMM, respectively. We find that these interface states depend on three factors of thicknesses (d_a, d_m), dielectric constants (\varepsilon_a, \varepsilon_m), and the transverse momentum k_T in the 1DHMM. For the case of d_a > d_m, the 1DHMM behaves like metal(dieletric) as k_T > k_T^{(\text{max})} because IFS exists in the dielectric/1DHMM interface. For the case of d_a < d_m, there is no band crossing and IFS can occur in the dielectric/1DHMM interface. Furthermore, we show the existence of the IFS between the dielectric-like 1DHMM and metallic-like 1DHMM. Notice that all IFS’s appear in the plasmonic band gap of the 1DHMM, and the dielectric- or metallic-like properties of the 1DHMMs are strongly related to the symmetry of the band edge states; in addition, the band crossing occurs at the band center with k_T = k_T^{(\text{max})} and is contributed from the material dispersion. In conclusion, we present a simple method to determine the existence of the IFS in three kinds of interfaces and the surface properties of 1DHMM from its bulk properties.
3:30PM W8.00006 Metasurface-Enabled Anisotropic Quantum Vacuum over Macroscopic Distances, PANKAJ JHA, XINGJIE NI, CHIHUI Wu, YUAN WANG, XIANG ZHANG, University of California, Berkeley — Quantum vacuum (QV) of an electromagnetic field has a profound effect on the optical response of a quantum emitter. QV in the vicinity (few tens of nm) of a metallic interface is strongly anisotropic and can be harnessed to induce quantum interference among the spontaneous emission channels from nearly degenerate excited states in a multi-level atom. Unfortunately, trapping an atom within this range is extremely challenging in experiments. Here, utilizing the exceptional light manipulation properties, both phase dependent and polarization selective response, of a metasurface we engineer the reflected field, from the spontaneous emission, back to the atom itself. A strong anisotropy in the decay rate of the atom is induced even when the atom is located at some macroscopic distance from the metasurface. Quantum vacuum engineering with metasurfaces will create unprecedented opportunities for long-range interaction between quantum emitters, new regime of cavity-free QED, solid-state quantum optics, spintronics etc.

3:42PM W8.00007 Strategy for designing broadband vibration isolation systems through exactly solvable models of graded elastic networks, KA KI NG, WAI SOEN CHAN, KIN WAH YU, Department of Physics, The Chinese University of Hong Kong — Motivated by the need of seismic base isolation, we have proposed a strategy to design vibration isolation systems to achieve near-zero amplitude vibration under external excitations over a broad frequency band. The strategy combines two ideas from previous works: (i) zeros assignment for broadband epsilon-near-zero metamaterials [Sun, and Yu (2012)]; and (ii) the localization of vibrational modes in graded elastic networks [Xiao, Yakubo, and Yu (2006)]. Firstly, we aim to assign zeros (anti-resonance frequencies) over an operating frequency band. Starting from an exactly solvable model of zigzag diatomic chains, we demonstrate a one-to-one correspondence between the zeros and one type of the masses after solving the models. Hence, the zeros can be assigned at will by tuning the masses. Second, in order to achieve further vibrational suppression by gradon localization, a band overlapping picture is applied to tune the rest of the masses to an optimal value. The results can be generalized to 2D and 3D structures for more realistic applications.

3:54PM W8.00008 Ultra-broadband sound absorption by acoustic metamaterials, XUE JIANG, BIN LIANG, JIAN-CHUN CHENG, Nanjing University — Metamaterials with extraordinary properties unavailable in nature have opened up new design possibilities. Acoustic absorbers are of particular significances for acoustics-based devices and find applications in various scenarios, but subject to the inherent restriction of the natural acoustical parameters and limited operating bandwidth. We report the theoretical design, numerical calculation and experimental study on the realization of a metamaterial-based acoustic absorber with a simple yet efficient structure. The proposed acoustic absorber works in an ultra-broad band without restricted by the material type or requiring extra absorbing material. Such distinct effects stem from the localization and dissipation of different spectrum components at predesigned spatial positions. Theoretical predictions developed based on classical acoustic theory agree well with numerical and experimental results. The realization of ultra-broadband acoustic absorber with unique properties of stiffness and environmental-friendliness has paved the way for designing conceptual acoustical devices, and has potential applications in situations with special requirements on acoustic absorption characteristics.

4:06PM W8.00009 Strong Coupling of Terahertz Cyclotron Resonance with a One-Dimensional Photonic Crystal Cavity, MINHAN LOU, QI ZHANG, Department of Electrical and Computer Engineering, Rice University, Houston, Texas, USA, RODION KONONCHUK, ANDREY CHABANOV, Department of Physics and Astronomy, University of Texas at San Antonio, San Antonio, Texas, USA, JUNICHIRO KONO, Department of Electrical and Computer Engineering, Rice University, Houston, Texas, USA — Achieving strong light-matter interaction is essential for the study of cavity quantum electrodynamics. In the ultrastrong coupling regime, where the ratio of the vacuum Rabi splitting to the transition frequency is close to or larger than one, intriguing quantum effects, e.g., the Bloch-Siegert Shift and interaction-dependent ground states, are expected to appear, due to the breakdown of the rotating wave approximation. Since this ratio increases with the transition wavelength, going to the terahertz (THz) range is promising for exploring new strong-coupling phenomena. Here, we experimentally demonstrate strong coupling between the cyclotron resonance of a high-mobility two-dimensional electron gas and a photonic defect mode in a one-dimensional (1D) THz photonic crystal (PC) cavity. Compared to THz cavities based on split-ring metamaterials, the 1D PC cavity exhibits a higher quality $(\mathcal{Q})$ factor and lower loss, in spite of a larger mode volume. Our 1D PC cavities consist of quarter-wave intrinsic silicon / sapphire slabs and air gaps. The $\mathcal{Q}$ factor can be tuned in a wide range by changing the materials and the number of layers. An ultrathin modulation-doped GaAs quantum well is placed at the electric field maximum of the defect mode in the 1D THz PC cavity.

4:18PM W8.00010 Unidirectional Spectral Singularities, HAMIDREZA RAMEZANI, HAO-KUN LI, YUAN WANG, XIANG ZHANG, University of California, Berkeley — We introduce a new class of spectral singularities with directional response emerging from the interplay of parity-time (PT) symmetry and Fano resonances. We show that, without breaking the reciprocity, one is able to obtain a simultaneous unidirectional lasing and unidirectional reflectionless mode. For such a mode one side reflection tends to infinity, the other side reflection becomes zero, and the transmission coefficient remains finite. These singularities emerge from the resonance trapping and delay time associated with the reflected signal residing in the gain or loss part of the parity-time symmetric cavity. In addition, we show that in the absent of loss (gain) and at threshold gain (loss), the structure still acts as a unidirectional laser (reflectionless system). In the passive-loss case our structure acts as a unidirectional perfect absorber. When the system possesses pure balanced gain, transmission and reflection from the left and right side of the system tends to infinity and we recover the conventional lasing modes.
4:30PM W8.00011 Light propagation in synthetic pseudo-passive media with balanced gain and loss\textsuperscript{1}, ALLI BASIRI, TSAMPIKOS KOTTOS, Wesleyan Univ, ILYA VITEBSKIY, The Air Force Research Laboratory, Sensors Directorate — Optical materials exhibiting exotic values of permittivity \( \varepsilon \) and/or permeability \( \mu \) are often prohibitively lossy. This is especially true for composite optical metamaterials. A natural solution to the problem is to add a gain component and, thereby, to offset the losses. There are two different ways to do so. The first one involves a photonic structure composed of judiciously arranged loss and gain components. A well-known example of such balanced loss-gain structures is the so-called PT symmetric photonic crystals. An alternative approach is to compensate the losses with gain while preserving uniformity of the medium. Here we consider this second case where both constituents are complex such that \( \varepsilon = \varepsilon' + i\varepsilon'' \), \( \mu = \mu' + i\mu'' \) with \( p \) being real. In this case the material would have a uniform real refractive index \( n = \sqrt{\varepsilon \mu} = \text{constant} \).

We demonstrate that this type of pseudo-passive synthetic structures show novel transport characteristics uncommon to regular lossless structures.

\textsuperscript{1}AFOSR MURI grant FA9550-14-1-0037 and NSF DMR-1306984

4:42PM W8.00012 Localized Guided-Mode and Cavity-Mode Double Resonance in Photonic Crystal Nanocavities\textsuperscript{1} , XUQING LIU, TAKASHI SHIMADA, RYOHEI MIURA, SATOSHI IWAMOTO, YASUHIKO ARAKAWA, YUICHIRO K. KATO, The University of Tokyo — We investigate the use of guided modes bound to defects in photonic crystals for achieving double resonances. Photoluminescence enhancement by more than three orders of magnitude has been observed when the excitation and emission wavelengths are simultaneously in resonance with the localized guided mode and cavity mode, respectively. We find that the localized guided modes are relatively insensitive to the size of the defect for one of the polarizations, allowing for flexible control over the wavelength combinations. This double resonance technique is expected to enable enhancement of photoluminescence and nonlinear wavelength conversion efficiencies in a wide variety of systems. For example, such tuning of double resonance would be particularly effective for carbon nanotubes that show sharp absorption peaks [1].

4:54PM W8.00013 Self-assembled tunable photonic hyper-crystals\textsuperscript{1} , IGOR SMOLYANINOV, University of Maryland, VERA SMOLYANINOVA, BRADLEY YOST, DAVID LAHNEMAN, THOMAS GRESOCK, Towson University, EVGENII NARIMANOV, Purdue University — We demonstrate a novel artificial optical material, the photonic hyper-crystal, which combines the most interesting features of hyperbolic metamaterials and photonic crystals. Similar to hyperbolic metamaterials, photonic hyper-crystals exhibit broadband divergence in their photonic density of states due to the lack of usual diffraction limit on the photon wave vector. On the other hand, similar to photonic crystals, hyperbolic dispersion law of extraordinary photons is modulated by forbidden gaps near the boundaries of photonic Brillouin zones. Three dimensional self-assembly of photonic hyper-crystals has been achieved by application of external magnetic field to a cobalt nanoparticle-based ferrofluid. Unique spectral properties of photonic hyper-crystals lead to extreme sensitivity of the material to monolayer coatings of cobalt nanoparticles, which should find numerous applications in biological and chemical sensing.

\textsuperscript{1}This work was supported in part by NSF grant DMR-1104676, NSF Center for Photonic and Multiscale Nanomaterials, ARO MURI and Gordon and Berry Moore Foundation.

5:06PM W8.00014 Optical properties of self-induced plasma structures , ROTEM KUPFER, Department of Physics, The University of Texas at Austin, BORIS BARMASHENKO, ILANA BAR, Department of Physics, Ben Gurion University of the Negev — We show, using detailed particle-in-cell simulations and a simplified theoretical model, how to manipulate femtosecond laser produced plasma to form functional structures by using the interference pattern of two or more beams. Two examples will be presented: The use of Moiré pattern of two intersecting beams to create a waveguide array and plasma-made photonic crystal generated by two pairs of counter propagating beam. We will discuss the implications of this phenomenon to the prospect of plasma based lasers.

5:18PM W8.00015 Optical instabilities and spontaneous light emission in moving media\textsuperscript{1}, MARIO SILVERINHA, Univ de Coimbra - Instituto de Telecomunicacoes — We show that when an uncharged plasmatic material is set in relative motion with respect to another uncharged polarizable body the system may be electromagnetically unstable. Particularly, when the relative velocity of the two bodies is enforced to remain constant the system may support natural oscillations that grow exponentially with time, even in presence of realistic material loss and dispersion. It is proven that a friction-type force acts on the moving bodies to oppose their relative motion. Hence, the optical instabilities result from the conversion of kinetic energy into electromagnetic energy. This new purely classical phenomenon is analogous to the Cherenkov and Smith-Purcell effects but for uncharged polarizable matter. We link the optical instabilities to a spontaneous parity-time symmetry breaking of the system, and demonstrate the possibility of optical amplification of a light pulse in the broken parity-time symmetry regime.

\textsuperscript{1}This work is supported in part by Fundação para a Ciência e a Tecnologia grant number PTDC/EEI-TEL/2764/2012.

Thursday, March 5, 2015 2:30PM - 5:18PM – Session W10 DCMP: Topological Insulators: Optical and Other Properties (Theory) 007A - Bitan Roy, University of Maryland

2:30PM W10.00001 Skyrmion spin texture in ferromagnetic semiconductor-superconductor heterostructures , KRISTOFER BJÖRNSON, ANNICA BLACK-SCHAFFER, Uppsala Univ — Topological superconductors are of interest because they are predicted to host Majorana fermions. One example are two-dimensional ferromagnetic semiconductor-superconductor heterostructures, where Majorana fermions are predicted to appear in vortices. The system has previously been classified using a Chern number, but we show that the Chern number is related to a Skyrmion spin texture in the band structure. The Skyrmion spin texture has the advantage of enabling direct experimental measurements of the topological invariant through for example spin-polarized ARPES. The Skyrmion spin texture is also of interest from a conceptual point of view, as it provides a more intuitively accessible topological invariant than the otherwise rather abstract Chern number.
2:42PM W10.00002 Compressibility as a probe of topological quantum phase transitions in 1D systems\(^1\). DAVID NOZADZE, NANDINI TRIVEDI, Department of Physics, The Ohio State University, Columbus, OH 43210, USA — We investigate the behavior of the compressibility \(\kappa\) in the Kitaev chain using the Bogoliubov-de Gennes approach. For a closed chain, we show that the topological phase transition is signaled by the divergence of \(\kappa\) at the quantum critical point tuned by the chemical potential. We also explore the effect of disorder on the local compressibility \(\kappa(x)\). In the presence of disorder the compressibility across the transition becomes finite and the height of the peak becomes smaller with increasing disorder strength. Our results provide a direct method, the local compressibility, for detecting the quantum phase transition in a Kitaev chain that can be realized in superconductor-semiconducting nanowire hybrid structures with strong spin-orbit coupling.

2:54PM W10.00003 Quantized Electromagnetic Response of Three Dimensional Chiral Topological Insulators\(^1\). SHENG-TAO WANG, DONG-LING DENG, Univ of Michigan - Ann Arbor, JOEL MOORE, University of California, Berkeley, KAI SUN, LUMING DUAN, Univ of Michigan - Ann Arbor — Protected by the chiral symmetry, three dimensional chiral topological insulators are characterized by an integer-valued topological invariant. How this invariant could be realized in practice is an important question. Here, we quantized response with ultracold atoms in optical lattices.

\(^1\)NBRPC (973 Program) 2011CBA00300 (2011CBA00302), the IARPA MUSIQC program, the ARO, the AFOSR MURI program, NSF DMR-1206515, the Simons Foundation, NSF under Grant No. PHY1402971 and the MCubed program at University of Michigan

3:06PM W10.00004 Charged skyrmions on the surface of a 3D topological insulator. HILARY HURST, DMITRY EFIMKIN, VICTOR GALITSKI, Condensed Matter Theory Center, University of Maryland College Park — We consider the interplay between magnetic skyrmions in an insulating thin film and the Dirac surface states of a 3D topological insulator (TI), coupled by proximity effect. The nontrivial magnetic texture of skyrmions can lead to confinement of Dirac states at the skyrmion radius, where out of plane magnetization vanishes. This confinement results in charging of the skyrmion. We find that the bound states are robust in an external magnetic field, which is needed to stabilize skyrmions. It is expected that for reasonable experimental parameters skyrmions will have a small number of bound states that can be tuned using an external magnetic field. We argue that these charged skyrmions can be manipulated directly by an electric field, with skyrmion mobility proportional to the number of bound states at the skyrmion radius. Coupling skyrmionic thin films to a TI surface can provide a more direct and efficient way of controlling skyrmion motion in insulating materials.

3:18PM W10.00005 Braiding statistics of loop excitations in three dimensions\(^1\). CHENJIE WANG, MICHAEL LEVIN, University of Chicago — While it is well known that three dimensional quantum many-body systems can support non-trivial braiding statistics between particle-like and loop-like excitations, or between two loop-like excitations, we argue that a more fundamental quantity is the statistical phase associated with braiding two loops. The physical picture leads to a “natural” bulk dynamic topological quantum field theory (TQFT) description for the braiding of two loops, which is based on the loop statistics. The braiding phase is a universal quantity which can be measured in experiments. We also study the three-loop braiding statistics in the context of a topological field theory.

\(^1\)This work is supported by the Alfred P. Sloan foundation and NSF under grant No. DMR-1254721.

3:30PM W10.00006 Vortex-line condensation in three dimensions: A physical mechanism of bosonic topological insulators\(^1\). PENG YE, ZHENG-CHENG GU, Perimeter Inst for Theo Phys — 3d bosonic topological insulators (BTI) are symmetry protected topological(SPT) phases with U(1) and \(Z_N^2\) (time-reversal symmetry with \(T^2=1\)). BTI were first proposed based on the group cohomology theory which suggests two distinct root states. Soon after, surface anomalous topological orders were proposed to identify different root phases and also leads to a new root state beyond group cohomology. Nevertheless, it is still unclear what is the universal physical mechanism for BTI phases. In this work, we answer the question by proposing an universal physical mechanism via vortex-line condensation in a superfluid, e.g., helium-4 or cold atoms in optical lattices. Using such a simple physical picture, we find three root phases, of which two of them are classified by group cohomology theory while the other is beyond group cohomology classification. The physical picture also leads to a “natural” bulk dynamic topological quantum field theory (TQFT) description for BTI and gives rise to a physical pathway of practical realization. Finally, we generalize the vortex-line condensation picture to other symmetries and find that in three dimensions, even for a unitary \(Z_2\) symmetry, there is a nontrivial \(Z_2\) SPT phase beyond the group cohomology classification.

\(^1\)Research at Perimeter Institute is supported by the Government of Canada through Industry Canada and by the Province of Ontario through the Ministry of Economic Development and Innovation.

3:42PM W10.00007 Topological BF theory of the quantum hydrodynamics of incompressible polar fluids. APOORV TIWARI, XIAO CHEN, University of Illinois, Urbana Champaign, TITUS NEUPERT, Princeton Center for Theoretical Science, Princeton University, LUIZ SANTOS, Perimeter Institute for Theoretical Physics, Waterloo, Canada, SHINSEI RYU, University of Illinois at Urbana-Champaign, CLAUDIO CHAMON, Physics Department, Boston University, Boston, CHRISTOPHER MUDRY, Condensed Matter Theory Group, Paul Scherrer Institute, Villigen, Switzerland — We analyze a hydrodynamical model of a fluid in (3+1)-dimensional spacetime. We explore a spacetime symmetry — volume preserving diffeomorphisms — to construct an effective description of this fluid in terms of a topological BF theory. The two degrees of freedom of the BF theory are associated to the mass (charge) flows of the fluid and its polarization vorticities. We discuss the quantization of this hydrodynamic theory, which generically allows for fractionalized excitations. We propose an extension of the Girvin-MacDonald-Platzman algebra to (3+1)-dimensional spacetime by the inclusion of the vortex-density operator in addition to the usual charge density operator and show that the same algebra is obeyed by massive Dirac fermions that represent the bulk of \(Z_2\) topological insulators in three-dimensional space.
3:54PM W10.00008 Berry phase and Rashba fields in realistic semiconductor quantum rings under tilted magnetic field1. VIVALDO LOPES-OLIVEIRA, VICTOR LOPEZ-RICHARD, Univ Fed de Sao Carlos, SERGIO EDUARDO ULOA, Ohio University, OPTICAL, VIBRATIONAL, SPIN AND TRANSPORT PROPERTIES IN SEMICONDUCTOR NANOSTRUCTURES COLLABORATION, DEPARTMENT OF PHYSICS AND ASTRONOMY COLLABORATION — The geometric Berry phase has been experimentally measured and manipulated in InGaAs-based mesoscopic rings, as seen from magnetotransport data [1]. Motivated by these experiments, we present here an analysis of the influence of the magnetic field orientation and intensity on the Berry phase experienced by electrons in a realistic quantum ring structure (similar model has been used in ref. [2]). We use the $k\cdot p$ formalism and fully incorporate the effects of confinement asymmetry, as well as the resulting Rashba spin-orbit-coupling (SOC) fields within the same framework. We obtain spin maps for angle and magnetic field intensities for different levels. At the anticrossing regions, with strong level mixing produced by varying flux dependence, we observe pronounced asymmetry effects in the shape and character of excited states. The asymmetry plays an important role in determining the Berry phase of the different states. We also find that effects of varying magnetic field tilt and intensity, as well as SOC, are more pronounced in the ground state. The substantial phase modulation observed in the lower energy level manifold can be monitored and exploited in transport experiments. [1] F. Nagasawa et al. Nat. Comm. 4, 2526 (2013); [2] V. Lopes-Oliveira et al. PRB 90, 125315 (2014).

4:06PM W10.00009 Uhlmann Measure in Topological Insulators and Superconductors at Finite Temperature, OSCAR VIYUELA, ANGEL RIVAS, MIGUEL ANGEL MARTIN-DELGADO, Univ Complutense — I will introduce the Uhlmann geometric phase as a tool to characterise density matrices of 1D and 2D topological insulators and superconductors. We achieve this goal by constructing new topological invariants called Topological Uhlmann numbers. Since this phase is formulated for general mixed quantum states, it provides a way to extend topological properties to finite temperature situations. New effects appear such as the existence of critical temperatures, novel thermal-topological transitions in models with high Chern numbers, breakdown of the usual bulk-edge correspondence, etc. Moreover, as the Uhlmann phase is an observable itself, we analyse potential measurement schemes that could be applicable to current experimental setups like cold atoms in optical lattices.

4:18PM W10.00010 Equilibrium currents in chiral systems with nonzero Chern number, OLEG STARYKH, EUGENE MISHCHENKO, University of Utah — We describe a simple quantum-mechanical approach to calculating equilibrium particle current along the edge of a system with nontrivial band spectrum topology. The approach does not require any a priori knowledge of the band topology and, as a matter of fact, treats topological and nontopological contributions to the edge currents on the same footing. We illustrate its usefulness by demonstrating the existence of “topologically nontrivial” particle currents along the edges of three different physical systems: two-dimensional electron gas with spin-orbit coupling and Zeeman magnetic field, surface state of a topological insulator, and kagome antiferromagnet with Dzyaloshinskii-Moriya interaction.

4:30PM W10.00011 Surface plasmon polaritons in topological insulators, JUNJIE QI, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, HAIWEN LIU, X.C. XIE, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — We study surface plasmon polaritons on a topological insulator-vacuum interface. When the time-reversal symmetry is broken due to ferromagnetic coupling, the surface states exhibit a magneto-optical Kerr effect. This effect gives rise to a novel transverse-type surface plasmon polariton, within the same framework. We obtain spin maps for angle and magnetic field intensities for different levels. At the anticrossing regions, with strong level mixing produced by varying flux dependence, we observe pronounced asymmetry effects in the shape and character of excited states. The asymmetry plays an important role in determining the Berry phase of the different states. We also find that effects of varying magnetic field tilt and intensity, as well as SOC, are more pronounced in the ground state. The substantial phase modulation observed in the lower energy level manifold can be monitored and exploited in transport experiments. [1] F. Nagasawa et al. Nat. Comm. 4, 2526 (2013); [2] V. Lopes-Oliveira et al. PRB 90, 125315 (2014).

4:42PM W10.00012 Giant Faraday effect due to Pauli exclusion principle in 3D topological insulators, HARI PAUDEL, MICHAEL LEUENBERGER, Univ of Central Florida — Experiments using ARPES, which is based on the photoelectric effect, have shown that the surface states in 3D topological insulators (TI) are gapless. Here we consider Weyl interface fermions due to band inversion in narrow-bandgap semiconductors, such as Pb$_{1-x}$Sn$_x$Te. We determine the optical selection rules of electron-hole pair excitation by means of the solutions of the 3D Dirac equation. We calculate explicitly the electric dipole matrix elements by means of bandstructure calculations for Pb$_{1-x}$Sn$_x$Te. Using the 3D Dirac equation and bandstructure calculations, we show that the transitions between positive and negative energy solutions, giving rise to electron–hole pairs, obey strict optical selection rules. We apply our results to calculate the Faraday effect due to the Pauli exclusion principle in a pump–probe setup using a 3D TI double interface of a PbTe/Pb$_{0.31}$Sn$_{0.69}$Te/PbTe heterostructure. The Faraday rotation angle exhibits oscillations as a function of probe wavelength and thickness of the heterostructure. The maxima in the Faraday rotation angle are of the order of mrad.

4:54PM W10.00013 Effect of electron-phonon interaction on the finite frequency conductivity of 3D Dirac materials, BORIS PAULOVIC, ELISABETH J. NICOL, University of Guelph, Canada — Recently, interest has been directed toward identifying and characterizing materials with 3D Dirac energy dispersions. We present our theoretical results for the finite frequency optical conductivity of 3D Dirac materials with the inclusion of an electron-phonon (e-p) interaction. Using a Holstein e-p interaction and allowing for varying chemical potential, we show how the e-p self energy modifies the electronic density of states and the optical conductivity. The results for 3D are contrasted with their 2D analogs, as previously discussed for graphene.[1][1] J.P. Carbotte, E.J. Nicol and S.G. Sharapov, PRB 81, 045419 (2010).

5:06PM W10.00014 Thermoelectric Effect in Topological Insulators, YONG XU, SHOU-CHENG ZHANG, Stanford University — Improving the thermoelectric figure of merit $zT$ is one of the greatest challenges in material science. The recent discovery of topological insulators (TIs) offers new promise in this prospect. In this talk, we demonstrate theoretically that $zT$ is strongly size dependent in TIs, and the size parameter can be tuned to enhance $zT$ to be significantly greater than 1. Furthermore, we show that the lifetime of the edge states in TIs is strongly energy dependent, leading to large and anomalous Seebeck effects with an opposite sign to the Hall effect. Some recent experimental progress will also be introduced.

Thursday, March 5, 2015 2:30PM - 5:06PM –
Session W11 DMP: Cuprates: Josephson Junctions 0078 - Mike Osofsky, Naval Research Laboratory
We find that for hole doping level $T\in$ cuprates and Fe-base compounds using scanning tunneling spectroscopy (STS) will discuss the extension of these techniques to study atomic scale variations in Josephson current. Present superconducting Pb tip measurements performed at temperatures below 250mK in a dilution refrigerator STM. By controlling the junction resistance, scanning Josephson spectroscopy measurements have the potential to characterize of a wide variety of superconducting materials on the atomic scale. I will present superconducting Pb tip measurements performed at temperatures below 250mK in a dilution refrigerator STM. By controlling the junction resistance, we are able to explore a wide range of tunneling regimes. Josephson measurements on Pb samples exhibit features multiple Andreev reflections, and I will discuss the extension of these techniques to study atomic scale variations in Josephson current.

2:42PM W11.00002 High-resolution Josephson spectroscopy with a scanning tunneling microscope, MALLIKA T. RANDERIA, BENJAMIN E. FELDMAN, ILYA K. DROZDOV, ALI YAZDANI; Princeton University — Conventional scanning tunneling microscopy (STM) measurements use a normal metal tip to probe local quasi-particle density of states with atomic resolution. Using a superconducting tip to conduct spectroscopy significantly boosts the energy resolution of the measurements, thus expanding the STM capabilities. Moreover, superconducting tips make it possible to probe superconductivity via the Josephson effect, which provides a direct measure of the local superconducting order parameter. Therefore, scanning Josephson spectroscopy measurements have the potential to characterize of a wide variety of superconducting materials on the atomic scale. I will present superconducting Pb tip measurements performed at temperatures below 250mK in a dilution refrigerator STM. By controlling the junction resistance, we are able to explore a wide range of tunneling regimes. Josephson measurements on Pb samples exhibit features multiple Andreev reflections, and I will discuss the extension of these techniques to study atomic scale variations in Josephson current.

2:54PM W11.00003 Studies of superconductivity (SC) and competing-order (CO) interplay in cuprates and Fe-base compounds using scanning tunneling spectroscopy (STS), M.L. TEAGUE, C.-C. CHEN, N.C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, USA, Z.J. FENG, Dept. of Physics, Shanghai University, Shanghai, China — STS studies of $\text{YBa}_2\text{Cu}_4\text{O}_{7-\delta}$ ($\text{Y}-123$) and Ca-doped $\text{Y}-123$ from under- to over-doped regimes demonstrate that the origin of the pseudogap (PG) is due to competing orders (COs), and that the presence (absence) of PG above the SC transition $T_c$ is associated with a CO energy $\Delta_{\text{CO}}$ larger (smaller) than the SC gap $\Delta_{\text{SC}}$. We find that for hole doping level $p \leq 0.16$, $\Delta_{\text{CO}} > \Delta_{\text{SC}}$, whereas both $\Delta_{\text{SC}}$ and $\Delta_{\text{CO}}$ decrease with $p$ for $p > 0.16$, and $\Delta_{\text{CO}}$ ($\sim 10$ meV) $< \Delta_{\text{SC}}$ ($\sim 13$ meV) at $p \approx 0.23$. The CO wave-vectors $Q_{\text{SC}}$ and $Q_{\text{PDW}}$ along the Cu-O bond are determined from Fourier transformation of the STS as a function of $p$, and are found to occur at 1/3 and 2/3 of the reciprocal lattice constant (2$\pi/a$) for $p = 0.16$. The pairing symmetry also evolves from pure $d_{x^2-y^2}$ to $(d_{x^2-y^2} + s)$ for $p > 0.16$, where the $s$-wave component increases with $p$. Moreover, under a finite magnetic field the ratio of the vortex “halo” radius ($\xi_{\text{halo}}$) relative to the SC coherence length $\xi_{\text{SC}}$ decreases with $p$, from $\sim 8$ for $p = 0.16$ to $\sim 3$ for $p = 0.216$, suggesting PG contributions to the vortex halo. Magnetic resonance mode at $\Omega_0 \sim 2\Delta_{\text{SC}}$ is also observed as a function of $p$. Finally, we present comparative STS studies of Fe-based superconductors, including $\text{Fe}_1-x\text{Co}_x\text{Se}_2$ and $\text{Rb}_{0.8}\text{Fe}_1\text{Se}_2$. This work was supported by NSF.

3:06PM W11.00004 Interpretation of scanning tunneling quasiparticle interference and impurity states, ANDREAS KREISEL, Niels Bohr Institute, Denmark, P. CHOUBEY, University of Florida, USA, T. BERLIJN, Oak Ridge National Laboratory, USA, B.M. ANDERSEN, Niels Bohr Institute, Denmark, P.J. HIRSCHFELD, University of Florida, USA — We use a simple method of calculating inhomogeneous, atomic-scale phenomena in superconductors to obtain real-space conductance maps as measured in scanning tunneling spectroscopy (STM). Our approach makes use of first principles Wannier functions in conjunction with self-consistent solutions of the Bogoliubov-de Gennes equations on a lattice to image superconducting phenomena. This method is a powerful tool since it captures correctly local symmetries on the surface that can be lower than the global lattice symmetry; it improves the spatial resolution from one pixel per lattice point to the sub-atomic scale; and simplifies the interpretation of STM data. As an example, we show how the pattern observed around a Zn impurity in Bi-2201 can be understood by accounting for the tails of the Cu Wannier functions, and thus compare perfectly to experimental findings. Further applications of this method include the investigation of impurity states in multiorbital systems as well as the study of quasi particle interference phenomena to enable a better understanding of novel phenomena in high temperature superconductors.

3:18PM W11.00005 Relaxation Oscillations in Josephson STM Junctions at mK Temperatures, MICHAEL DREYER, ANITA ROYCHOWDHURY, RAMI DANA, WANTING LI, SHU-CHU LIAO, University of Maryland — Small Josephson junctions can exhibit relaxation oscillations between the superconducting and normal state. The switching time depends on the charging time of the junction capacitance and the R-L time constant of the electrical connections, usually in the $\mu$s range. We observed similar oscillations in the tunnel current between a Nb sample and a Nb tip in our STM operated at 30 mK. The oscillations occur in two forms, either of which is triggered by lowering the gap resistance. The first type occurs in voltage ranges where the I(V) curves show negative differential conductance, which in turn is caused by coupling to the electrical environment. The oscillations span only a fraction of the superconducting gap and run at maximum frequencies below 10 kHz. The possible existence of “minor” loops was already mentioned in the original article, though thought to be a result of an applied in plane magnetic field. The second type appears at lower gap resistances and affects the whole bias range. The frequency was too high to be determined by our current setup, and thus could be due to a conventional relaxation oscillation. Our results will be discussed in detail.

3:30PM W11.00006 Improved heat exhaust and the characteristics of the high $T_c$ superconducting terahertz emitter$^1$, T. KASHIWAGI, University of Tsukuba, T. YAMAMOTO, National Institute for Materials Science, T. KITAMURA, K. ASANUMA, T. YASUI, Y. SHIBANO, C. WATANABE, K. NAKADE, Y. SAIWAI, H. KUBO, K. SAKAMOTO, T. KATSURAGAWA, University of Tsukuba, M. TSUJIMOTO, Kyoto University, R. YOSHIZAKI, University of Tsukuba, H. MINAMI, Kyoto University, R.A. KLEMM, University of Central Florida, K. KADOWAKI, University of Tsukuba — In our previous study it is known that THz emitting efficiency improves greatly when the stand-alone type of mesa structure is used for the THz emitting device.$^2$ The principle reason for that lies in the heat removal from the mesa, in which a gigantic amount of heat is generated while the mesa is in the resistive state. Recently, we developed a new device structure based on the stand-alone type of mesa structure of Bi$_2$212 single crystal in order to make high exhaust of Joule heating. The results show that although the power is comparable and is not significantly increased, very wide the radiation frequencies ranging from 0.3 to 1.6 THz were obtained. We will discuss the details of the radiation characteristics of this one.$^3$

3:42PM W11.00007 Comparison of luminescent and scanning laser thermal micro-imaging of self-heating in Bi$_2$Sr$_2$CaCu$_2$O$_8$ mesa THz sources$^1$, TIMOTHY BENSEMAN, ALEXEI KOSHELEV, VITALII VLASKO-VLASOV, YANG HAO, WAI-KWONG KWOK, ULRICH WELP, Argonne Natl Lab, COURTNEY KEISER, Northern Iowa University, BORIS GROSS, MATTHIAS LANGE, DIETER KOELLE, REINHOLD KLEINER, University of Tuebingen, KAZUO KADOWAKI, University of Tsukuba — Scanning laser thermal microscopy of stacked Bi$_2$Sr$_2$CaCu$_2$O$_8$ Josephson junction terahertz sources has revealed both electromagnetic cavity resonance modes and strongly non-uniform self-heating in these devices. However, this technique — in which a modulated laser beam is rastered across the surface of a device — excites a number of physical phenomena, and thus the resulting images can be difficult to interpret. Here we compare scanning laser images taken on Bi$_2$Sr$_2$CaCu$_2$O$_8$ mesa THz sources with micro-images collected via a thermoluminescent technique under identical conditions. The latter technique directly measures the device surface temperature, and we find excellent agreement with the scanning laser results, confirming that scanning laser thermal microscopy is indeed primarily probing device temperature.

$^1$This research was supported by the Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

3:54PM W11.00008 The stability of current filaments in Bi$_2$Sr$_2$CaCu$_2$O$_8$ observed via luminescent thermal microscopy$^1$, YANG HAO, TIMOTHY BENSEMAN, ALEXEI KOSHELEV, VITALII VLASKO-VLASOV, WAI-KWONG KWOK, ULRICH WELP, Argonne Natl Lab, COURTNEY KEISER, Northern Iowa University, BORIS GROSS, MATTHIAS LANGE, DIETER KOELLE, REINHOLD KLEINER, University of Tuebingen, KAZUO KADOWAKI, University of Tsukuba — Stacks of Intrinsic Josephson Junctions (IJJs) in Bi$_2$Sr$_2$CaCu$_2$O$_8$ (Bi-2212) designed as emitters of THz-radiation are prone to strong self-heating and thermal instability due to the poor thermal conductivity and semiconducting resistivity along the c-axis. Recent theory and experimental evidence indicate a possible correlation between strong self-heating and THz power emission. Here we study the temperature distribution in stacks of IJJs using current-voltage (I-V) characteristics and direct thermal imaging. At low bias currents and at low temperature, we observe the nucleation of small hot-spots near the corners or edges of the sample. These hot-spots carry 20-30% of the entire bias current thus forming current filaments. With increasing current and at elevated temperatures the size of the hot-spot increases and it moves to the center of the sample. These observations are in excellent agreement with theoretical analysis regarding the stability of current filaments.

$^1$This research was supported by the Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

4:06PM W11.00009 A role of temperature inhomogeneity and hot-spot formation on the THz emission from high-$T_c$ superconducting intrinsic Josephson junction mesa devices, CHIHARU WATANABE, HIDETOSHI MINAMI, TAKEO KITAMURA, KENTARO ASANUMA, KURAMA NAKADE, TAKAKI YASUI, YOSHIHIKO SAIWAI, YUKI SHIBANO, University of Tsukuba, TAKASHI YAMAMOTO, National Institute for Materials Science, TAKANARI KASHIWAGI, University of Tsukuba, RICHARD KLEMM, University of Central Florida, KAZUO KADOWAKI, University of Tsukuba — It is well known that the mesa device fabricated from single crystalline Bi$_2$Sr$_2$CaCu$_2$O$_8$ (Bi-2212) gets heated enormously and forms very inhomogeneous temperature distribution along the c-axis. Recent studies have revealed both electromagnetic cavity resonance modes and strongly non-uniform self-heating in these devices. However, this technique — in which a modulated laser beam is rastered across the surface of a device — excites a number of physical phenomena, and thus the resulting images can be difficult to interpret. Here we compare scanning laser images taken on Bi$_2$Sr$_2$CaCu$_2$O$_8$ mesa THz sources with micro-images collected via a thermoluminescent technique under identical conditions. The latter technique directly measures the device surface temperature, and we find excellent agreement with the scanning laser results, confirming that scanning laser thermal microscopy is indeed primarily probing device temperature.

4:18PM W11.00010 Nano-(Bi$_{0.7}$Pb$_{0.3}$)Sr$_2$Ca$_2$Cu$_3$O$_{10}$ crystals synthesis by sol-gel improved with acrylamide and microwaves, E. CHAVIRA, F. FLORES, UNAM, A. CONDE, CINVESTAV, H. MONTIEL, D. CABRERO, C. FLORES, O. NOVELO, A. TEJEDA, G. ZAVALA, UNAM, L. ALMEIDA, G.E. TORRES, FQUJAT — We obtain (Bi$_{1-y}$Pb$_y$)$_3$Sr$_2$Ca$_2$Cu$_3$O$_{10}$ nano-crystals by sol-gel improved with acrylamide and microwaves, not reported in the literature. TGA gives an idea of the reaction temperatures (200-550 °C) for the formation of binary, ternary and unknown materials. SEM and TEM shows morphology and crystal size 30-33 nm. We studied the thermodynamic and kinetic stability of the gel quenching, by varying the temperature and time according to a previous thermal analysis. Starting compounds (bismuth oxide, strontium carbonate, copper acetate, lead nitrate and calcium sulfate) were analyzed by XRD. By AFM we observed the dehydrated gel surface absorbed water from the environment. From the micrographs we measured the size of the fibers, grains and nano-crystals. We found at 560 °C Bi$_{1.4}$Pb$_{0.6}$Sr$_2$Ca$_2$Cu$_3$O$_{10}$ compound with tetragonal crystal structure, corresponding to the 2:2:2:3 compound, with $T_c$ 110 K. At 860 °C seen a shift of some reflections corresponding to two phases. Xerogel magnetic measurement shows antiferromagnetic behavior at 63 K.

4:30PM W11.00011 A Study on Nucleation, Crystallization Kinetics, Microstructure and Mechanical Properties of Ru-Bi Partial Substituted BSCCO Glass Ceramics, AHMET TOLGA TASCI, OZGUR OZTURK, TUGBA GOKCEN, Kastamonu University, SUKRU CAVDAR, HALUK KORALAY, Gazi University, ABDULKADIIR SENOL, Kastamonu University — This study deals with the effects of Ru-Bi partial substitutions on the thermal, structural and mechanical properties of Bi$_{0.8}$-xRu$_x$Pb$_{0.2}$Sr$_2$CaCu$_2$O$_{8+4}$ ($x$=0.0, 0.025, 0.050, 0.075), produced with glass-ceramics method have been investigated. The effects of Ru-Bi Partial substitutions on glass transition, nucleation and crystallization temperature are analyzed by differential thermal analyzer (DTA). Furthermore, micro-structure and micro-mechanical properties of Ru-Bi partial substituted BSCCO glass ceramics have been investigated by X-ray diffraction (XRD), scanning electron microscopy (SEM) and Vickers micro-hardness measurements. From the DTA results, nucleation kinetics have been obtained by using Ozawa, Augis-Bennett, Takher and Kissinger equations. Also activation energies and Avrami parameters have been found. Oxidation amount is seen to be increased with increasing Ru concentration in consequence of thermogravimetric analyses results. Moreover, Lattice parameters, volume fractions and surface morphologies of the samples are obtained from XRD and SEM measurements, respectively.
4:42PM W11.00012 Oxygen Annealing in the Synthesis of the Electron-Doped Cuprates1, J. S. HIGGINS, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, Maryland, P. L. BACH, University of Santiago de Compostela, Spain, W. YU, Department of Physics, Renmin University of China, Beijing, China, B. D. WEAVER, Naval Research Laboratory, Washington, DC, R. L. GREENE, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, Maryland — Post-synthesis oxygen reduction (annealing) in the electron-doped, high-temperature superconducting cuprates is necessary for the establishment of superconductivity. It is not established what effect this reduction has microscopically on the lattice structure. Several mechanisms have been put forth as explanations; they range from disorder minimization1, antiferromagnetic suppression2, and copper migration3. Here we present an electronic transport study on electron-doped cuprate Pr2Cu3-xCxCuO4±δ (PCCO) thin films in an attempt to better understand the need for this post-synthesis process. Several different cerium doping concentrations of PCCO were grown. Within each doping, a series of films were grown with varying levels of oxygen concentration. As a measure of disorder on the properties of PCCO, several films were irradiated with various doses of 2 MeV protons. Analysis within each series, and among the different dopings, favors disorder minimization through the removal of apical oxygen as the explanation for the necessary post-synthesis annealing process. 1P. 4:54PM W11.00013 Fabrication of Small Edge Josephson Junctions Between Sr2RuO4 and Al, BRIAN ZAKRZEWSKI, XINXIN CAI, YIQUN YING, Pennsylvania State Univ, DAVID FOBES, TIJIANG LIU, ZHIQIANG MAO, Tulane University, YING LIU, Pennsylvania State Univ — Sr2RuO4 is predicted to have a chiral p-wave orbital pairing. However, attempts to measure the chiral edge currents have yielded results inconsistent with theoretical predictions. Josephson junctions between Sr2RuO4 and an s-wave superconductor such as Al may provide an avenue for directly measuring the edge currents. We report progress on fabricating these junctions, using Al electrodes with no oxide barrier. The Josephson junctions are placed on the naturally formed edges of cleaved Sr2RuO4 thin crystal, which is expected to feature a surface less disordered than ramped junctions prepared by focused ion beam and ion mills. Transmission electron microscope studies provide a powerful tool to characterize the interface. We have systematically investigated the effects of nanofabrication processes on the quality of the junction interface. In particular, several post-lithography processes appear to cause irreversible damage to the surface layer of Sr2RuO4, which highlights potential issues for general small scale device fabrication. We also report preliminary measurements of Josephson tunneling from these devices.

2:42PM W12.00002 Growth Mechanism of Pumpkin-Shaped Vaterite Hierarchical Structures1, GUOBIN MA, YIFEI XU, MU WANG, National Laboratory of Solid State Microstructures, and School of Physics, Nanjing University, Nanjing 210093 — CaCO3-based biominerals possess sophisticated hierarchical structures and promising mechanical properties. Recent researches imply that vaterite may play an important role in formation of CaCO3-based biominerals. However, as a less common polymorph of CaCO3, the growth mechanism of vaterite remains not very clear. Here we report the growth of a pumpkin-shaped vaterite hierarchical structure with a six-fold symmetrical axis and lamellar microstructure. We demonstrate that the growth is controlled by supersaturation and the intrinsic crystallographic anisotropy of vaterite. For the scenario of high supersaturation, the nucleation rate is higher than the lateral extension rate, favoring the “double-leaf” spherulitic growth. Meanwhile, nucleation occurs preferentially in <1120> as determined by the crystalline structure of vaterite, modulating the grown products with a hexagonal symmetry. The results are beneficial for an in-depth understanding of the biomineralization of CaCO3. The growth mechanism may also be applicable to interpret the formation of similar hierarchical structures of other materials.

2:54PM W12.00003 ABSTRACT WITHDRAWN –

3:06PM W12.00004 Athermal fading of luminescence in Al2O3 ceramic substrates, IAN TERRY, ETFYCHIA KOUROUKLA, IAN K. BAILIFF, University of Durham — Retrospective dosimetry aims to reconstruct ionising radiation dose to populations following a radiological incident using materials not designed for that purpose. Sintered alumina ceramic can function as a dosimeter with its luminescence properties and related trapped charge storage mechanism. Its widespread use as a substrate in surface mount devices and incorporation in devices such as mobile phones make it a ubiquitous potential dosimeter. We investigated the optically (OSL) and thermally (TL) stimulated luminescence properties of sintered alumina substrates. In contrast to their single crystal analogue developed for personal dosimetry, Al2O3:Cr, the substrates exhibit a significant loss of trapped charge (fading) within hours following irradiation at RT that seriously limits their utility for dosimetry over an extended timescale. The fading rates of OSL and TL signals of 0402 resistors were analysed under various storage conditions (time and temperature), complemented by a study of their microstructure. The results support a model of athermal loss of trapped charge due to electron tunnelling from trapping states; this contrasting behaviour is attributed to a physical modification of the trap environment arising from the manufacturing process.

3:18PM W12.00005 Ion Channeling study of Jahn-Teller lattice distortions and the phonon properties in magnetic transition element implanted SrTiO3 Crystals, KALYAN SASMAL, D. WIJESUNDERA, Y. HE, B. TILAKARATNE, Q. CHEN, J.H. MILLER, WEI-KAN CHU, Texas Center for Superconductivity & Physics at Univ of Houston — SrTiO3 is perovskite functional material. STO doped with magnetic transition element (Cr, Fe etc.) is important for electro- and magneto-optical applications. Cr4+ (d3), Cr5+ (d2) and Fe3+ (high-spin d5) substituting host Ti4+ exhibits Jahn-Teller distortion. Rutherford backscattering spectrometry (RBS) in ion channeling orientation is sensitive method for determining structure, position of impurity atom to study defects of crystals and provides direct evidence for JT effect at Cr4+, Cr5+ and Fe3+ centers in STO lattice. Different masses of STO elements helps to investigate such impurities using ICh method by determining distortions of sub lattices without taking into account of small ICh effect from impurities. Axial ion channeling of 2.0 MeV He ions was applied to study JT lattice distortions of ion implanted STO crystals. Angular ICh spectra of Sr and Ti sub lattices (crystal axes [110] & [100]) were obtained for pure and ion implanted STO crystals. The ratio of minima of ICh yield for Sr and Ti sub lattices was used for quantitative determination of lattice distortions observed in STO: Cr/Fe crystals due to presence of impurities. JT Cr4+ and Fe3+ impurity could induce Raman-active localized oxygen vibrational mode, which does not involve motion of nearest Fe or Ti ions.
3:30PM W12.00006 Rapid Microwave Synthesis of Perovskite Oxide Nanostructures with Enhanced Functionality

GREGORY SALAZAR, ANUJA DATTA, Florida Cluster for Advanced Smart Sensor Technologies and Department of Physics, University of South Florida, BRITTISH MUKHERJEE, Center for Integrated Functional Materials and Department of Physics, University of South Florida — Perovskite oxides are an important class of materials having high dielectric and piezoelectric coefficients, switchable ferroelectric (FE) polarization and interesting optical and electrical properties. Realization of functional devices based on classic perovskite oxides such as Pb(Zr0.52Ti0.48)O3 (PZT), and emerging Pb-free noncentrosymmetric (NCS) oxides, such as, ZnSnO3, ZnTiO3 and CaTiO3 have reinforced the investigation of these materials in multiple dimensions and length scales. However, large-scale synthesis and integration of ordered low-dimensional structures is a challenge, due to their complicated methodologies, high-cost and difficulties with phase stability. We discuss a generalized, cost-effective, rapid microwave synthesis route for size and shape selective nanostructure growth of these functional perovskite oxides on industrially viable flexible and hard substrates, stabilized by an enhanced ionic covalence. The rational synthesis approach allowed improved tunability of the size, shape, and orientation of the structures with improved electrical and FE properties. The facile fabrication route of these nanostructures may expand the outreach of probes for understanding the structure-property relationships in these hitherto unexplored and technologically important materials.

3:42PM W12.00007 Possible Phase Transition in H2O Ice Ih near 110 K

DAVID T. W. BUCKINGHAM, SUELI H. MASUNAGA, FORREST C. GILE, JOHN J. NEUMEIER, Montana State University — The thermal expansion of single-crystalline H2O ice Ih was measured with ~10^4 times greater relative resolution than has previously been done. Plots of the thermal expansion coefficient, µ, along the a- and c-axes reveal features which have never before been observed in thermal expansion measurements of H2O ice:

- A jump in µ of magnitude Δµ ≈ 10^{-5} K^{-1} in the temperature range 98–117 K along the c-axis, which appears to be a phase transition. No such transition is observed along the a-axis.

- Hysteresis of the transition temperature, Tc, of as much as 5 K for cooling rates from -5.0 to -0.1 K/min.

There is reason to believe this transition is the ferroelectric transition reported by Dengel et al. if so, the shift in Tc would result from the freezing-in of the H2O molecular configurations. We will discuss our own measurements of the dielectric constant in the vicinity of Tc.

3:54PM W12.00008 Raman and Luminescence Investigation of Rare Earth Doped Laser-Induced Crystals-in-Glass

BRIAN KNORR, Fairleigh Dickinson University, ADAM STONE, CEA Marcoule, HIMANSHU JAIN, VOLKMAR DIEROLF, Lehigh University — Laser induced crystallization of glasses is a highly spatially selective process which has the potential to produce compact, integrated optics within a glass matrix. In LaB6O7 low temperature Combined Excitation Emission Spectroscopy (CEES) revealed that erbium incorporates into both glass-ceramics and laser-induced crystals-in-glass in predominantly one type of environment (site). The energy levels of this site were quantified. The fluorescence characteristics of the erbium ions in any site in the laser-induced crystals were found to be only weakly influenced by the irradiation conditions during growth. On the other hand, a hidden parameter, potentially boron deficiency-related defects, resulted in a significant change in the incorporation behavior of the erbium ions. Scanning confocal Raman and fluorescence spectroscopy showed that the energies of the Raman modes are shifted and the erbium fluorescence intensity is inhomogeneously distributed, despite the host glass being homogeneously doped, across the cross-sections of laser-induced crystals in glass. These fluctuations within the Raman and fluorescence are spatially correlated, implying that different erbium sites form preferentially at different locations in the crystal cross-section.

This work is supported by NSF Award DMR-1204146.

4:06PM W12.00009 Brillouin light scattering as a probe for low frequency quasiparticles in solids

NIKITA KLIMOVICH, KEVIN OLSSON, KYONGMO AN, SEAN SULLIVAN, ANNIE WEATHERS, LI SHI, XIAOQIN LI, Univ of Texas, Austin — In increasingly small electronic and spintronic devices, electrons, optical phonons, acoustic phonons, and magnons are often driven out of local thermal equilibrium. Thermal transport based on equilibrium dynamics does not adequately describe these systems necessitating a better understanding of non-equilibrium transport processes. Measuring the specific temperatures of the different energy carriers is therefore crucial in understanding the thermal transport. Brillouin light scattering (BLS) has recently been explored as a temperature sensor for low frequency acoustic phonons in glass, and also magnons in metallic and insulating ferromagnetic materials. We report the measured BLS spectra of acoustic phonons in Silicon at different temperatures. The temperature dependence of the BLS peak frequency, linewidth, and integrated intensity are examined to evaluate their potential uses as temperature sensors of acoustic phonons. We also observe a large nonequilibrium in phonon-magnon temperature in YIG under the effects of laser heating and thereby extract a value for the phonon-magnon coupling coefficient.

4:18PM W12.00010 Model for Charge Injection with Electron Beams into Highly Disordered Insulating Materials

JOHN DENNISON, Utah State University, ALEC SIM, Irvine Valley College, GREG WILSON, Montana State University — The Walden-Wintle model for charge injection and transport through highly disordered insulating materials has been extended to include charge injection with a charged particle beam. The original model is applicable to charge injection in a dielectric material from a pair of electrodes in a parallel-plate geometry. It provides a versatile approach to predict the time-dependent current at a rear grounded electrode and the incident surface voltage, as the injection current density evolves over time with the development of a space charge barrier near the injection electrode. The Walden-Wintle model has been applied to many standard cases including Fowler-Nordheim injection, Schottky injection, space charge limited injection, and various tunneling mechanisms. The present model modifies the approach to include electrode-less charge injection via a charged particle beam, along with concomitant effects for the injection current, surface voltage, and electron emission as a charge is built up in the insulator. The approach is equally valid for near-surface injection and for bulk injection of both non-penetrating and penetrating radiation. The results are based on our dynamic emission model for electron emission yields dependent on accumulating charge in both the positive and negative charging regimes.

4:30PM W12.00011 Plasmon Polariton Modes in High Index Dielectric Structures, KODIAK MURPHY, KYLE HOKE, BRAD JOHNSON, JANELLE Leger, Western Washington University — The need to interface optical signals with high density electronic devices has led to an interest in subwavelength waveguides. Surface plasmon polaritons (SPPs) are surface charge density oscillations localized to a metal/dielectric interface, and as such are capable of confining energy in a structure which is not diffraction limited. Waveguides based on the excitation of SPPs are promising for short-range application, but in these structures Ohmic damping limits propagation length due to the bulk of the electric field propagating along a metal interface. Here we show that by selecting a core dielectric with a higher refractive index than the substrate, high index dielectric plasmon polariton modes (HP-PPMs) can be supported. Modes in the core dielectric exhibit electric fields with the bulk of their electric field confined in the dielectric layer. Therefore, damping may be reduced in such structures. Here we report the demonstration of HP-PPM in Au/TiO2/Au MIM devices using attenuated total reflectance. Characterization of these modes was performed for devices of differing core dielectric thickness. Results are in good agreement with theory. We will discuss the application of these waveguides to several technologies related to solar energy conversion.

4:42PM W12.00012 Optical and vibrational properties of YBO$_3$:Eu$^{3+}$, Ce$^{3+}$, Tb$^{3+}$ microstructures for light emitting diodes, SANDEEP SOHAL, Texas Tech University, MOHAMMAD NAZARI, Texas State University, X. ZHANG, E. HASSAN-ZADEH, V.V. KURYATKOV, J. CHAUDHURI, L. HOPE-WEEKS, JUYANG HUANG, Texas Tech University, MARK HOLTZ, Texas State University — Structural and optical properties of yttrium orthoborate YBO$_3$:Eu$^{3+}$, Ce$^{3+}$, Tb$^{3+}$ microstructures, focusing on the role of terbium concentration, are investigated by x-ray diffraction (XRD), photoluminescence (PL) ~ 363.8 nm excitation wavelength, photoluminescence excitation (PLE) and Raman spectroscopies. For constant cerium and europium concentrations, the PL bands belong to Ce$^{3+}$ and Tb$^{3+}$ color centers are diminished with increasing concentration of Tb$^{3+}$. Simultaneously, the intensities of PLE bands related to both Ce$^{3+}$ and Tb$^{3+}$ for red emission from the Eu$^{3+}$ are increased. The results are consistent with a Ce$^{3+}$$\rightarrow$ Tb$^{3+}$$\rightarrow$ Eu$^{3+}$ energy transfer scheme, where $n$ denotes a chain of terbium ions. Raman spectroscopy shows a systematic change, with Tb$^{3+}$ concentration, in the terminal oxygen bending mode of B$_2$O$_3$ ring structure related to the host lattice. The terminal oxygen atoms of the ring structure are coordinated to yttrium sites where dopant ions substitute. The structural changes are interpreted as variations in the local neighborhood of these sites in the YBO$_3$:Ce$^{3+}$, Tb$^{3+}$, Eu$^{3+}$ crystal structure.

4:54PM W12.00013 Scintillation properties of polycrystalline La$_x$Y$_{1-x}$O$_3$ ceramic, SUNIL SAHI, WEI CHEN, RASOOL KENARANGUI, Univ of Texas, Arlington — Scintillators are the material that absorbs the high-energy photons and emits visible photons. Scintillators are commonly used in radiation detector for security, medical imaging, industrial applications and high energy physics research. Two main types of scintillators are inorganic single crystals and organic (plastic or liquid) scintillators. Inorganic single crystals are expensive and difficult to grow in desirable shape and size. Also, some efficient inorganic scintillator such as NaI and CsI are not environmentally friendly. But on the other hand, organic scintillators have low density and hence poor resolution which limits their use in gamma spectroscopy. Polycrystalline ceramics can be an effective alternative to expensive inorganic single crystal scintillators. Here we have fabricated La$_{0.2}$Y$_{0.8}$O$_3$ ceramic scintillator and studied their luminescence and scintillation properties. Ceramic scintillators were fabricated by vacuum sintering of La$_{0.2}$Y$_{0.8}$O$_3$ nanoparticles at temperature below the melting point. La$_{0.2}$Y$_{0.8}$O$_3$ ceramic were characterized structurally using XRD and TEM. Photoluminescence and radioluminescence studies were done using UV and X-ray as an excitation source. We have used gamma isotopes with different energy to study the scintillation properties of La$_{0.2}$Y$_{0.8}$O$_3$ scintillator. Preliminary studies of La$_{0.2}$Y$_{0.8}$O$_3$ scintillator shows promising result with energy resolution comparable to that of NaI and CsI.

5:06PM W12.00014 Prediction of Silicon-Based Layered Structures for Optoelectronic Applications, WEI LUO, Fudan Univ, YANNING MA, JiJin Univ, XINGAO GONG, HONGJUN XIANG, Fudan Univ, CCMG TEAM — A method based on the particle swarm optimization (PSO) algorithm is presented to design quasi-two-dimensional (Q2D) materials. With this development, various single-layer and bilayer materials in C, Si, Ge, Sn, and Pb were predicted. A new Si bi-layer structure is found to have a much-favored energy than the previously widely accepted Si monolayer. The Si monolayer has an insulating gap of 5.25 eV and the Si nanolayer has an insulating gap of 4.75 eV, limiting their usages in optoelectronic applications. Hydrogenation has therefore been used to tune the electronic and optical properties of Si layers. We discover two hydrogenated materials of layered Si materials, WEI LUO, Fudan Univ, YANMING MA, Jilin Univ, XINGAO GONG, HONGJUN XIANG, Fudan Univ, CCMG TEAM — A method based on the particle swarm optimization (PSO) algorithm is presented to design quasi-two-dimensional (Q2D) materials. With this development, various single-layer and bilayer materials in C, Si, Ge, Sn, and Pb were predicted. A new Si bi-layer structure is found to have a much-favored energy than the previously widely accepted Si monolayer. Thursday, March 5, 2015 2:30PM - 5:30PM — Session W13 Focus Session: Manganite Thin Films and Interfaces 007D - Ganesh Panchapakesan, Oak Ridge National Laboratory

2:30PM W13.00001 Emergent Magnetic Phenomena at Manganite Interfaces, YURI SUZUKI, Stanford University — Emergent phenomena at transition metal oxide interfaces have been the focus of recent intense study since the discovery of metallic at the interface of LaAlO$_3$ and SrTiO$_3$ a decade ago. Emergent magnetic phenomena at transition metal oxide interfaces had been studied even earlier. However there have been surprisingly few systems demonstrating interfacial ferromagnetism especially combined with metallicity. Recently, we have developed a general picture describing the origin of interfacial ferromagnetism in CaMnO$_3$ based systems. Density functional theory attributed the interfacial ferromagnetism to a double exchange interaction among interfacial Mn ions (just in the single unit cell of CaMnO$_3$) mediated by conduction electrons from the neighboring itinerant layer. We have demonstrated interfacial ferromagnetism in superlattices composed of the antiferromagnetic insulator CaMnO$_3$ and an itinerant metal (CaRuO$_3$ or LaNiO$_3$). Through polarized neutron spectrometry, x-ray magnetic circular dichroism and bulk magnetometry, we have shown that the ferromagnetism originates from Mn ions in a single unit cell of the CaMnO$_3$:t at the interfaces as theoretically predicted. The modulation of interfacial ferromagnetic moment as a function of constituent layer thicknesses as well as long-range antiferromagnetic correlations in the CaMnO$_3$, observed by neutron diffraction, are indicative of the competing magnetic interactions at play.

3:06PM W13.00002 Thickness effect on magnetic and electronic response in phase separated manganese thin films, HYOUNG JEEN JEEN$^1$, Department of Physics, Pusan National University, S. Korea, AMLAN BISWAS, Department of Physics, University of Florida — Thickness variation can be used to observe confinement effects and to control the strain state of thin films. Such confinement and strain state variation often creates unconventional physical properties in thin films of complex oxides such as phase separated (La$_x$(Sr$_{1-x}$)Sr$_y$Ca$_{y-1}$)$_3$MnO$_7$. Because of the observed magnetic and electronic properties, a thin film of LPCMO shows different from bulk samples such as, in-plane magnetic anisotropy and strain-driven anisotropic dynamic percolation. In this presentation, we will show the relation between lattice strain and the formation of an antiferromagnetic charge ordered insulating phase and the effect of strain relaxation on the magnetic anisotropy and single domain to multi-domain transition in electronically phase separated LPCMO thin films. We observed an increase in residual resistivity, a reduction of in-plane magnetic anisotropy, and an increase of the domain transition temperature as the thickness of the thin films is increased.

**3:18PM W13.00003 First-principles study of magnetic electronic and optical properties of double perovskite Bi$_2$FeMnO$_6$**

TOWFIQ AHMED, DZMITRY YAROTSKI, QUANXI JIA, JIAN-XIN ZHU, Los Alamos Natl Lab — We study magnetic, electronic and optical properties of double perovskite Bi$_2$FeMnO$_6$ (BFMO) using density functional theory. In these systems, the exchange interaction between Fe and Mn sites gives rise to a ferromagnetic ordering, which is captured in our ab initio calculations. Thin film Bi$_2$FeMnO$_6$ (BFMO) are generally grown on substrates such as SrTiO$_3$ and Si. Significant strain has been experimentally observed in BFMO unit cells due to slight lattice mismatch between the thin film and substrate unit cells. In this work, we find that the net magnetic moment in BFMO depends on the “c”/“a” ratio of the unit cell, suggesting the strain dependence of magnetization in such system. We further calculate x-ray magnetic dichroism (XMCD) signals of Fe and Mn ions in BFMO for L2 and L3 edges. By applying the XMCD sum rules, we adopted an alternative approach to estimate the spin and orbital magnetic moment from our DFT calculations.

**3:30PM W13.00004 Pressure-induced modification of colossal magnetoresistive magnanites**

PETRO MAKSYMOWYCH, S. KELLY, R. VASUDEVAN, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, E. ELISEEV, Institute for Problems of Materials Sciences, National Academy of Science of Ukraine, A. MOROZOVSKA, Institute of Physics, National Academy of Science of Ukraine, M.D. BIEGALSKI, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, J.F. MITCHELL, H. ZHENG, Materials Science Division, Argonne National Laboratory, J. AARTS, Leiden Institute of Physics, Leiden University, Netherlands, S.V. KALININ, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Nanoscale chemical control of oxides using confined fields, conceptually similar to electrical switching of ferroelectrics, is not obvious. We investigated CMR manganites using UHV force microscopy and tunneling microscopy. Scanning the surface with a metal tip was found to create a strongly insulating state, at least a few nm deep, even at zero applied bias. The state could be due to charge order, polaron disorder, chemical disorder or a combination thereof. Based on concomitant changes of surface potential we propose that contact-pressure modifies electrochemical potential of oxygen vacancies via the Vegard effect, causing vacancy motion and changes of electronic properties. Given broad similarities in defect chemistry, mechanical control of oxides may be universal. (MD) supported by Center for Nanophase Materials Sciences, a DOE Office of Science User Facility. **3:42PM W13.00005 Ferroelectric control of spin injection in La0.7Sr0.3MnO3/BaTiO3/La0.5Ca0.5MnO3 multiferroic tunnel junctions with a bilayer barrier**

YUEWEI YIN, L.D. MIAO, R.Z. DU, Q. LI, Pennsylvania State Univ — Using a ferroelectric (FE) barrier with ferromagnetic electrodes has become a promising method for controlling spin injection by purely electrical means, which is an important challenge in spintronics. Recently, we have designed a La0.7Sr0.3MnO3/LSMO /BaTiO3/BTO /La0.5Ca0.5MnO3/LCMO /LSMO tunnel junctions in which the reversal of FE polarization of BTO will magnetoelectrically lead to a FM metallic - antiferromagnetic insulating phase transition in LCMO and result in an enhanced tunneling electromagnetoresistance (TER). [1] Using the bilayer barrier, we observed that the spin injection can be controlled by barrier polarization reversal as shown in the change of tunneling magnetoresistance (TMR). The temperature evolution of tunnel electromagnetoresistance (TEMR) (percentage ratio between the TMR values for the two polarization states), which is directly proportional to the change of tunnel-current spin polarization, was studied and larger TEMR was obtained with increasing temperature. Meanwhile, TEMR increases with TER effect for samples with different LCMO insertion thicknesses, suggesting a controllable strong electric control of tunnel-current spin polarization using a designed structure with proper interfaces. [1] Y. W. Yin et al, Nat. Mater. 12, 397 (2013)

**3:54PM W13.00006 Oxygen Pressure during Deposition on Atomic-Scale Surface Features of La$_{0.75}$Ca$_{0.25}$MnO$_3$ Films**

A. TSELEV, R.K. VASUDEVAN, ORNL, Oak Ridge, TN, USA, A. GIANFRANCESCO, ORNL/University of Tennessee Knoxville, TN, USA, L. QIAO, P. GANESH, T.L. MEYER, H.-N. LEE, M.D. BIEGALSKI, A.P. BADDORF, S.V. KALININ, ORNL, Oak Ridge, TN, USA — We have used in situ scanning tunneling microscopy to visualize atomic-scale surface structure of a mixed-valence manganite La$_{0.75}$Ca$_{0.25}$MnO$_3$ films grown by pulsed laser deposition. Surface termination and chemical composition were identified in situ with angle-resolved x-ray photoelectron spectroscopy. We find a strong effect of the background oxygen pressure during deposition on structural and chemical features of the film surface. Deposition at 50 mTorr leads to mixed-terminated films with atomic-scale structurally imperfect B-site (MnO$_6$)$_2$ termination. A small reduction of the pressure from 50 mTorr to 20 mTorr results in a dramatic change of the atomic-scale surface structure. The surface is dominated by nearly perfectly ordered B-site (MnO$_6$)$_2$ states. However, this was accompanied by surface roughening at a mesoscopic length scale with formation of mound-like structures. These results can be interpreted as a strong influence of oxygen on the adatom mobility during growth. The effect of the oxygen pressure on dopant surface segregation is also noticeable: Ca surface segregation is reduced with decrease of the oxygen pressure.

**4:06PM W13.00007 Trends in (LaMnO$_{3n}$/SrTiO$_3$)$_m$ superlattices with varying layer thicknesses**

JILI LIU, JIUER FABRIZIO COSSIL, UDO SCHWINGENSCHLOGL, KAUST, PSE Division, Thuwal 23955-6900, Kingdom of Saudi Arabia — We investigate the thickness dependence of the structural, electronic, and magnetic properties of (LaMnO$_{3n}$/SrTiO$_3$)$_m$ (n = 2, 4, 6, 8) superlattices using density functional theory. The structure relaxation turns out to be highly sensitive to the onsite Coulomb interactions. In contrast to bulk SrTiO$_3$, strongly distorted O octahedra are observed in the SrTiO$_3$ layers with a systematic off centering of the Ti atoms. The systems favour ferromagnetic spin ordering rather than the antiferromagnetic spin ordering of bulk LaMnO$_3$, and all show half-metallicity, while a systematic reduction of the minority spin band gaps as a function of the LaMnO$_3$ and SrTiO$_3$ layer thicknesses originates from modifications of the Ti d$_{xy}$ states.

**4:18PM W13.00008 Variational calculations for spin canting at ferromagnetic/antiferromagnetic interfaces**

G. RICHARD, Department of Physics and Astronomy, James Madison University, J.-X. ZHU, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, A.V. BALATSKY, Institute for Materials Science, Los Alamos National Laboratory, J.T. HARALDSEN, Department of Physics and Astronomy, James Madison University — Understanding the complex interaction between materials is critical for the development of spintronic and electronic devices in the technology industry. In this report, we examine the canting of local moments throughout a ferromagnetic/antiferromagnetic heterostructure, where a combination of interlayer mixing and orbital reconstruction can be described as a local exchange field at the interface. Using a variational method and semi-classical approach, we examine the canting of spins throughout the full multilayer heterostructure. We approximate the interlayer interactions as an effective field throughout the interface and apply a standard spin Hamiltonian with spin anisotropy for the intralayer interactions of the ferromagnetic and antiferromagnetic layers. Overall, we show that observed finite magnetization and rotation of the local moment observed in LSMO/BFO is due to the interface interactions. Furthermore, we predict a size limit for this effect in the antiferromagnetic (BFO) layer.
4:30PM W13.00009 Phase separation in strained ultrathin La$_{0.67}$Sr$_{0.33}$MnO$_3$/SrTiO$_3(100)$ films

IN HAE KWAK, SARAH TOTH, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — Atomically smooth and ultrathin La$_{0.67}$Sr$_{0.33}$MnO$_3$ (LSMO) films were grown on TiO$_2$ terminated SrTiO$_3$(100) (STO) substrates using pulsed laser deposition. The lattice mismatch between LSMO and STO generated uniform tensile strain on the LSMO film, and it significantly changed the electrical and magnetic properties of LSMO/STO thin films. Compared to the fully spin polarized ferromagnetic metallic state of bulk LSMO below a Curie temperature near 350 K, we observed a decrease in Curie temperature and the insulator to metal transition temperature as the thickness of LSMO was reduced down to 5 unit cells. Furthermore, the reduction of the saturation magnetization as the film thickness is reduced indicates phase separation in ultrathin LSMO/STO films. Therefore, it is possible to obtain a phase separated state close to room temperature in uniformly strained LSMO thin films.

1 NSF DMR-1410237

4:42PM W13.00010 Magnetic coercive field changes in microstructured (La$_{1-x}$Pr$_x$)$_{1-x}$Ca$_x$MnO$_3$ thin films

DANIEL GRANT, MICHAEL RYAN, AMLAN BISWAS, Department of Physics, University of Florida, Gainesville, FL 32611 — The hole-doped manganite (La$_{1-x}$Pr$_x$)$_{1-x}$Ca$_x$MnO$_3$ (LPCMO) shows effects such as phase coexistence and colossal magnetoresistance. Since the phase coexistence occurs at length scales of up to 10 micrometers, it is relatively straightforward to reduce the sample size to the scale of phase separation. We present magnetization data that show a change in the magnetic coercive fields of LPCMO thin films by a factor of about 2 when the sample size is reduced to 100 micrometers using a photolithography process. The amount of the increase of the coercive field increases with film thickness. We will discuss the increased coercive field in the context of the competition between shape and stress magnetic anisotropies. We will also describe the role of dimensionality in determining the coercive field behavior. This process can be used to control the phase separation and the magnetic hardness of manganites.

1 NSF DMR-1410237

4:54PM W13.00011 Effect of A-site ordering on the magnetoelectric properties in (111)-oriented LaMnO$_3$/SrMnO$_3$ superlattices

MINHUI HU, RUINAN SONG, JIANDONG GUO, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — It is expected that the chemical order that occurs over the crystallographic A-sites might strongly influence the distribution of the charges, magnetic and transport properties of the perovskite magnets. In this work, we focus on growing LaMnO$_3$/SrMnO$_3$ superlattices on (111)-oriented by PLD. The superlattices were characterized by magnetic as well as electronic transport measurements, and compared with the La$_2$/Sr$_1$/MnO$_3$ thin film having the same components in which the A-site dopants are randomly distributed. The superlattices had different properties from the thin film: higher Curie temperature of FM and metal-insulator transitions, larger magnetization, and lower resistivity. This will allow for an understanding of the dependence of the intrinsic properties with respect to the long-range ordering of dopants. These differences can be explained by Mn$^{3+}$/Mn$^{4+}$ double exchange separation arising from the artificially induced order of the A-site cations in the superlattices. Our proposed superlattices will allow for understanding of the fundamental magnetic and electronic interactions arising from dopant ordering in transition metal oxides.

5:06PM W13.00012 Large Relaxation (Polar distortion) of SrTiO$_3$ interfaced with La$_{2/3}$Sr$_{1/3}$MnO$_3$

ZHEN WANG, HANGWEN GUO, LINA CHEN, MOHAMMAD SAGHAYEZHIAN, E.W. PLUMMER, JIANDI ZHANG, Louisiana State Univ - Baton Rouge, JING TAO, LIJUN WU, HUOLIN XIN, YIMEI ZHU, Brookhaven National Laboratory — The physics of thickness-induced metal-insulator transition in metallic oxide thin films is very interesting. The question is the behavior intrinsic or extrinsic. We explore the origin of such transition by manipulating the thickness of La$_{2/3}$Sr$_{1/3}$MnO$_3$ (LSMO) thin film grown on SrTiO$_3$ (STO) substrate and detailed property measurements and structural characterization. We observed an unexpected structural relaxation in STO when interfaced with La$_{2/3}$Sr$_{1/3}$MnO$_3$ (LSMO) by using scanning transmission electron microscopy (STEM). A large out-of-plane polar distortion of STO extends up to 8 — 10 unit cell (u.c.) across the interface with the 4 u.c. insulating LSMO film, while only very moderate relaxation were found with thicker and metallic LSMO films. The energy loss electron spectrum (ELS) studies reveal that the charge transfer across the interface is similar in both films. The nature of such an overlayer-dependent structural relaxation will be discussed: Is this thickness dependent relaxation of the STO an inherent property of metallic/insulating properties of the ultrathin film?

Supported by U.S. DOE under Grant No. DOE DE-SC0002136.

5:18PM W13.00013 Interfacial intermixing in δ-doped oxide superlattices

VALENTINO R. COOPER, MSTD, Oak Ridge National Laboratory, HOULONG L. ZHUANG, P. GANESH, CNMS, Oak Ridge National Laboratory, HAIXUAN XU, Department of Materials Science and Engineering, The University of Tennessee, P. R. C. KENT, CNMS and CSMD, Oak Ridge National Laboratory — First principles studies of the interfaces between dissimilar insulating oxides have been fundamental in understanding both the origin of emergent interfacial phenomena and ways to control conduction pathways and charge carrier densities. However, these calculations often assume sharp interfaces; neglecting the effects of interfacial cation intermixing. Using density functional theory, we examine the effect of A-site interfacial intermixing on the stability and electronic structure of oxide δ-doped heterointerfaces. We find that the dominant effect of interfacial intermixing is the reduction in carrier densities of the 2DEG states at the interface. Our previous work suggest that this reduction in carrier density (i.e. fractional δ-doping) may lead to enhancements in electron mobilities. These results offer a plausible explanation for the deviations in carrier mobilities and densities measured in different experimental samples. Furthermore, our calculations show that intermixing above 1/4 concentration is unstable relative to a clean interface; thus having implications for large scale production, where experimental growth techniques, such as chemical vapor deposition, may be a viable alternative.

2:30PM W15.00001 Correlation of Local Structure and Electronic Properties of Glass Materials

VINCENTO LORDI, NICOLE ADELSTEIN, Lawrence Livermore National Lab — Wide band gap glasses such as silica and its derivatives are typically considered insulators. However, electronic transport in glasses can be important for certain applications, such as when used as the host material for a scintillator radiation detector. Here we explore the relationship between local structure in glass materials and the corresponding electronic properties of carrier transport and charge trapping. We present a novel analysis that decomposes the distribution of localized band tail states in terms of specific local structural features in the glass. Comparison of the structure-related transport properties of different glass compositions is given, using silica and sodium silicate as prototypes.

1 Prepared by LLNL under Contract DE-AC52-07NA27344.
2:42PM W15.00002 Structural manifestations of aging in Se-rich glasses1. S. DASH, S. RAVINDREN, P. CHEN, P. BOOLCHAND, Univ of Cincinnati — We examine weakly cross-linked Ge-Se100-x (0%<x<7%) binary glasses in modulated DSC and Raman scattering experiments. Homogeneity of melts was carefully verified using FT-Raman line profiling. Upon aging at RT for 4 months, we find the width of the glass transition W(x) steadily decreasing from 10°C at 7% Ge to 2°C for pure Se. The 5-fold reduction of W(x) with a decrease of Ge content is accompanied by a 2-fold increase in the non-reversing enthalpy. Rejuvenation of the aged glasses changes W(x) from 15°C at 7% Ge to 7°C for pure Se. Tg is found to decrease upon rejuvenation with the difference (Tg(aged)-Tg(rejuv)) showing a maximum near 3% Ge and vanishing for pure Se and 6% of Ge, which are topological thresholds. These results in Se-rich glasses are consistent with aging induced decoupling of Se6 crowns and growth of extended range structural correlations between polymeric Sen chains due to lone pair interactions. At higher x, near 8-10% of Ge, eustetic effects are manifested.

1Work supported by NSF grant DMR 08-53957

2:54PM W15.00003 The effect of semiconducting CdSe and ZnSe nanoparticles on the fluorescence of Sm3+ in lead borate glasses. SAISUDHA MALLUR, STEPHEN FATOKUN, P.K. BABU, Western Illinois Univ — We studied the fluorescence spectra of Sm3+ doped lead borate glasses containing zinc selenide (ZnSe) and cadmium selenide (CdSe) nanoparticles with the following compositions (x PbO: 96.5-x B2O3:0.5 Sm2O3:3ZnSe/CdSe, x = 36.5 and 56.5 mol%). These glass samples are prepared using the melt-quenching technique. Each sample is annealed just below the glass transition temperature at 400°C for 3 hrs and 6 hrs. We have chosen PbO-B2O3 glasses to incorporate Sm3+ ions because they have large glass forming region, high refraction index, and good physical and thermal stability. Fluorescence spectra of these samples are obtained with the excitation wavelength at 477 nm. Four fluorescence transitions are observed at 563 nm, 598 nm, 646 nm and 708 nm. The transition at 646 nm is found to be a hypersensitive transition that strongly depends on the covalency of the Sm-O bond and the asymmetry of the crystal field at Sm site. The 646 nm/598 nm fluorescence intensity ratio has been studied for different annealing times and PbO concentration for both ZnSe and CdSe samples. The presence of CdSe nanoparticles is seen to produce the greatest influence on the fluorescence intensity ratio. This could be due to the size of the CdSe nanoparticles and covalency of the Sm-O bond.

3:06PM W15.00004 Topological phases in Ba-Borate glasses1. CHAD HOLBROOK, ANDREW CZAJA, PUNIT BOOLCHAND, University of Cincinnati — Twelve compositions in the (BaO)x(B2O3)100-x pseudo binary, in the 15%<x<40% range, were synthesized by induction melting Boric acid and anhydrous BaCO3, taking care to handle the materials in a dry ambient environment. Modulated-DSC and Raman scattering experiments were undertaken systematically as function of BaO content (x). Calorimetric measurements reveal Tg(x) to show a broad maximum and the non-reversing enthalpy to show a Gaussian-like reversibility window2, both centered near x = 28%. Raman scattering displays rich lineshapes with modes similar to those observed in Na-Borates3. Modes near 808 cm−1, 770 cm−1, 740 cm−1 and 705 cm−1 are observed, and identified with breathing modes of pure and mixed rings from characteristic structural groupings4. These preliminary results suggest that glasses at x<24% are in the stressed-rigid phase, in the 24%<x<30% in the Intermediate Phase and at x>30% in the flexible phase.

3:18PM W15.00005 Revealing Structural Details of SiCO Ceramics with GIPAW Calculations of Model Structures and Analysis of Experimental 29Si Nuclear Magnetic Resonance Spectroscopy. JOHN NIMMO, PETER KROLL, The University of Texas at Arlington — The occurrence of the various SiC04-x (1≤x≤4) mixed tetrahedra in silicon oxy carbide (SICO) is often quantified by means of experimental 29Si nuclear magnetic resonance. The structural centers are assigned to individual peaks in the spectrum, which can be integrated to give the relative populations. Using a recently-developed method, we show that this is also possible to recover information on the connectivity of these tetrahedra. By combining a huge library of model structures an GIPAW calculations, we show that simple relations exist between the Si-O-Si linking angles and the 29Si NMR chemical shift. In this work, we perform detailed analyses of SICO 29Si NMR spectra available in literature. We extract angular distributions in agreement with the experimental X-ray and neutron diffraction data. Furthermore, in glasses with large amounts of so-called “free” carbon, we observe a significant portion of the {Si}4O4 tetrahedra which have disproportionally large angles. These angles indicate the presence of internal SiO2 surfaces or cages-like voids, similar to those found in zeolites or clathrates. This analysis suggests that in SiCO, the “free” carbon is incorporated into these voids, which produces strain on the bonding angles of the surrounding host glass.

3:30PM W15.00006 Correlations between dynamics and atomic structures in Cu64.5Zr35.5 metallic glass1. C.Z. WANG, Y. ZHANG, F. ZHANG, M.I. MENDELEV, M.J. KRAMER, K.M. HO, Ames Laboratory-USDOE, Iowa State University, Ames, Iowa 50011, USA — The atomic structure of Cu-Zr metallic glasses (MGs) has been widely accepted to be heterogeneous and dominated byicosahedral short range order (ISRO). However, the correlations between dynamics and atomic structures in Cu-Zr MGs remain an enigma. Using molecular dynamics (MD) simulations, we investigated the correlations between dynamics and atomic structures in Cu64.5Zr35.5 MG. The atomic structures are characterized using ISRO and the Bergman-type medium range order (BMRO). The simulation and analysis results show that the majority of the mobile atoms are not involved in ISRO or BMRO, indicating that the dynamical heterogeneity has a strong correlation to structural heterogeneity. Moreover, we found that the localized soft vibration modes below 1.0 THz are mostly concentrated on the mobile atoms. The diffusion was studied using the atomic trajectory collected in an extended time interval of 1.2 μs at 700 K in MD simulations. It was found that the long range diffusion in MGs is highly heterogeneous, which is confined to the liquid-like regions and strongly avoids the ISRO and the Bergman-type MO. All these results clearly demonstrate strong correlations between dynamics (in terms of dynamical heterogeneity and diffusion) and atomic structures in Cu64.5Zr35.5 MGs.

3:42PM W15.00007 Onset of plasticity and its relation to structure in CuZr metallic glasses: a molecular dynamics study1. GONZALO GUTIERREZ, MATIAS SEPULEDA, NICOLAS AMIGO, Departamento de Física, Facultad de Ciencias, Universidad de Chile — The plastic behavior of crystalline metals is well understood. It is known that this regime is mainly mediated by the nucleation and propagation of dislocations as well as by grain boundary sliding. In metallic glasses (MGs), the plastic behavior is quite different from their crystalline counterparts. It is well known that bulk metallic glasses, in addition to the high yield strength and a elastic deformation to a strain limit about 2% (i.e., more than an order of magnitude greater than conventional crystalline metals), are brittle at room temperature. Interestingly, MG nanowires present an important degree of ductility, and is an ideal system to study the onset of plasticity in MG. Here we present a computational tensile test which shows the evolution of the atomic structure of a Cu64.5Zr35.5 metallic glass nanowire at 300 K according to the applied strain increased. The system consists of a million atoms CuZr nanowire metallic glass. Local structure of atoms is analyzed by means of the Voronoi polyhedral technique and the nucleation and propagation of SBS by monitoring the atomic strain.

1Supported by grant Fondecyt-Chile 1120603
3:54PM W15.00008 Study the formation of metastable crystalline phases from amorphous metallic systems with an integrated approach, ZHUO YE, FENG ZHANG, Ames Laboratory, YANG SUN, University of Science and Technology of China, MIKHAIL MENDELEV, RYAN OTT, EUN-SOO PARK, MATT BESSLER, MATT KRAMER, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory — An efficient genetic algorithm (GA) is integrated with experimental diffraction data to solve a metastable Al_{20}Sm_{5} phase that evolves during rapid solidification of an amorphous Al-10%Sm alloy produced by magnetron sputtering. The excellent match between calculated and experimental X-ray diffraction patterns confirms that this new phase appeared in the crystallization of the alloy. We discover the strong similarity of the underlying atomic structure between the amorphous alloy and this phase. Both phases share the same Sm-centered motif, providing a low-barrier pathway to form this Al_{20}Sm_{5} phase in the glass matrix at low temperatures. Molecular dynamic simulations of crystal growth from the liquid phase predict the formation of disordered anti-site defects in the devitrified crystal.

4:06PM W15.00009 Ab Initio Simulation of Nickel-Palladium-Phosphorus Bulk Metallic Glasses, RAYMOND ATTA-FYNN, Department of Physics, University of Texas at Arlington, PARTHAPRATIM BISWAS, Department of Physics and Astronomy, The University of Southern Mississippi — Using first principles molecular dynamics simulations, we model the structural and electronic properties of Ni_{80}Pd_{20}P_{20} bulk metallic glasses. The calculations are carried out for large system sizes in order to probe structural features associated with the medium range order on the nanometer length scale. We discuss different approaches to modeling the glassy systems ranging from the cook-and-quench to the structural building block techniques. The nature of the medium range order on the nanometer length scale is examined using the theory of fluctuation electron microscopy. The localization nature of the electronic eigenstates and the dc conductivity (of the model configurations) will be discussed in relation to the real space atomic structure.

4:18PM W15.00100 Microscopic pathway of a polymorphic transformation in Al90Sn10 system by molecular dynamics simulations, YANG SUN, FENG ZHANG, ZHUO YE, MIKHAIL MENDELEV, RYAN OTT, MATTHEW KRAMER, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory — When as-quenched amorphous Al-10.4%Sn alloy is isochronally heated up, it can display a nearly perfect polymorphic transformation into a complex cubic phase. Knowledge about the pathway of this transformation plays a key role for understanding the phase selection in this system driven far from equilibrium. We successfully simulated the growth of this crystalline phase from the amorphous state using molecular dynamics, with the help of a preexisting crystalline seed. The as-grown structure is in good agreement with experimental X-ray diffraction measurement. By analyzing the atomic trajectories during growth, we show the microscopic pathway linking the amorphous and crystalline phases and how the transformation is controlled by the driving force, atomic diffusivities and structural topologies.

4:30PM W15.00111 Quasilattice-conserved molecular dynamics studies of the atomic structure of decagonal Al-Co-Ni quasicrystals, YU-JUN ZHAO, XIAOTIAN LI, South China University of Technology, ADVISOR- STUDENT COLLABORATION — The detailed atomic structure of quasicrystals has been an open question for decades. In this paper, we present a quasilattice-conserved molecular dynamics method (quasiMD), with particular quasiperiodic boundary conditions. As the atomic coordinates are described by basic cells and quasilattices, we are able to maintain the self-similarity characteristics of quasicrystals with the atomic structure of the boundary region updated timely following the relaxing region. Exemplified with the study of decagonal Al-Co-Ni (d-Al-Co-Ni), we propose a more stable atomic structure model based on Penrose quasilattice and our quasiMD simulations. In particular, ‘rectangle-triangle’ rules are suggested for the local atomic structures of d-Al-Co-Ni quasicrystals.

4:42PM W15.00112 Local density fluctuations and hyperuniformity in quasicrystals, ERDAL CELAL OĞUZ, SALVATORE TORQUATO, Department of Chemistry, Princeton University, Princeton, New Jersey 08544, USA — Local density fluctuations in many-body systems are of fundamental importance throughout various scientific disciplines, including physics, materials science, number theory and biology. In a point pattern, let the variance associated with the number of points contained in a spherical window of radius \( R \) be denoted by \( \sigma^2(R) \). Hyperuniform systems include all infinite periodic structures, aperiodic quasicrystals, and some special disordered systems. Previous investigations showed that the number variance for large \( R \) in hyperuniform systems serves as a useful metric to rank order systems according to the degree to which large-scale density fluctuations are suppressed. In this work, we investigate the number variance of two-dimensional quasicrystals with a variety of different rotational symmetries. We study how the number variance depends on the rotational symmetry and local isomorphism class of the quasicrystal. We compare these results to a number of different periodic systems as well as disordered hyperuniform systems.

4:54PM W15.00113 Growth of icosahedral quasicrystals, JOSHUA SOCOLAR, CONNOR HANN, Duke University, PAUL STEINHARDT, Princeton University — The discovery of an icosahedral quasicrystal that formed naturally in a rock sample originating from a meteorite highlights fundamental questions about quasi-crystal formation. The growth of a well-ordered quasicrystal through kinetics dominated by local energetics is known to be possible in principle for 2D systems: a Penrose tiling, for example, can be grown from a particular type of small seed by adding tiles only to surface sites where the tile type and orientation are unambiguously determined by already placed tiles that share a vertex. We consider the generalization of this result to icosahedral quasicrystal tilings comprised of Ammann rhombohedra. Numerical simulations strongly suggest that infinite, well-ordered, icosahedral quasicrystals can be generated. Unlike the 2D case, defects are generated outside the original seed, but the number of such defects appears to grow only linearly with the cluster radius. Analysis of the lift of the tiling to a 2D hypercubic lattice provides key insights into the growth mechanism.

5:06PM W15.00114 The Log-Lin Metric for Generic Responses in Logarithmic Structures, ANTONY J. BOURDILLON, Retired — The generic Log-Lin metric joins experimental quasicrystal data with its ideal structure. How does a periodic probe, e.g., an X-ray or electron beam, interact with an ‘aperiodic’ solid to produce sharp diffraction in geometric space? Based on the structure [1-2], and through its stretching factor in the hierarchical model, quasi-structure factors are expanded in geometric series. The Log-Lin metric is found to be a function of \( \tau^2 \) and \( \pi \) [3-4]. The solution is of special value in simulating not only icosahedral structures, but also defective logarithmic solids, and quasicrystals of lower symmetry. The metric, now analyzed and simulated, enables consistent measurement from the atomic scale to high order superclusters. It is essential in any wave interaction with logarithmic solids. The factor applies to physical clusters of extremely dense, binary, hard-sphere, icosahedral, unit cells.

2:30PM W16.00001 Extrinsic and Intrinsic Charge Trapping at the Graphene/Ferroelectric Interface, MOHAMMED HUMED YUSUF, BEN TIELSEN, MATTHEW DAWBER, XU DU, Stony Brook University — In previous works on graphene ferroelectric field effect transistors (GFeFETs), the characteristics of the devices were found to be largely affected by “anti-hysteresis” associated with charge trapping instead of ferroelectric domain switching. In this work, with PbTiO$_3$/SrTiO$_3$ (PTO/STO) superlattices, the effect of surface adsorbates was largely diminished by tuning the transition temperature of superlattices and depositing exfoliated graphene at an elevated temperature. With the removal of such extrinsic charge traps, the impact from the “intrinsic” defects of the ferroelectric substrate was revealed, inducing fast (~10 µs) charge-trapping and remaining active even at cryogenic temperatures. The defects manifested themselves as unit-cell deep square pits, which were evident from contact-mode Atomic Force Microscopy (AFM) of the interface. An asymmetry in electron and hole trapping was observed. Optimized superlattice growth conditions minimized the surface defects and subdued the charge trapping associated with it. The result was a robust, ramping speed independent, room temperature ferroelectric switching in GFeFETs. With an ideal interface, the work was further extended to study graphene transport across potential barriers/junctions.

This work was supported by NSF (Grant DMR-1105202). Part of this research was carried out at the Center for Functional Nanomaterials, Brookhaven National Laboratory.

2:42PM W16.00002 Sub-harmonic gap structure and Magneto-transport in suspended graphene—Superconductor ballistic junctions, PIRANAVAN KUMARAVADIVEL, XU DU, Stony Brook University — Inducing superconductivity in graphene via the proximity effect enables to study the rich transport of the massless Dirac fermions at the Superconductor(S) - Graphene(G) interface. Some of the predictions are pseudo diffusive transport in Ballistic SGS junctions at low carrier densities and the unique specular and retro Andreev reflections in graphene. One of the challenges in observing these experimentally is to fabricate highly transparent ballistic SGS junctions that can be probed at low carrier densities near the Dirac point. In this talk we will present our recent results on suspended graphene-Niobium Josephson weak links. Our devices exhibit a mobility of ~35 0000 cm$^2$/V$^{-1}$s$^{-1}$ with a carrier density as low as 10$^6$ cm$^{-2}$. Below the Superconducting transition temperature (T$_c$) ~ 9K, the devices show supercurrent and sub-harmonic gap structure due to Multiple Andreev reflections. In the vicinity of the Dirac point, the sub-harmonic gap structure becomes more pronounced, which as predicted, is indicative of pseudo-diffusive transport. With a fine scanning of gate voltage close to Dirac point we see emergence of some unusual sub-gap structures. We also report on our study of these samples below the upper critical field of Nb (~ 3.5T), where superconducting proximity effect coexists with Quantum Hall effect.

2:54PM W16.00003 Ultra-Short Channel Graphene Devices, M-JAVAD FARROKHJ, MATHIAS J. BOLAND, ABBISHAEK SUNDARARAJAN, DOUGLAS R. STRACHAN, Univ of Kentucky — Measurements and modeling of ultra-short nano-electronic devices consisting of metallic electrodes and graphene channels are presented. We will discuss the novel formation and characterization of these devices. The short channel of the devices permits the observation of high-field effects. This includes current saturation that has relevance to future size-scaling of atomically-thin nano-electronics in the sub-10 nm regime. Unusual features in the current-voltage characteristics are explained by an analytical ballistic model. In addition, we investigate the effect of contact induced energy level broadening of the electrodes and contact resistance on the current saturation.

3:06PM W16.00004 Ab initio simulation and design of graphene-based transistors at the atomic scale, WENCHANG LU, JERRY BERNHOLC, North Carolina State University, Raleigh, NC 27695 — Two-dimensional materials, such as graphene and molybdenum disulfide, have attracted much attention because of their unique properties. Graphene’s high mobility make it a very promising material for next generation electronics, but its zero band gap is a big hurdle for digital transistors. However, graphene nanoribbons can exhibit band gaps due to quantum confinement, and their electronic properties differ depending on the structures of their edges. Based on the real space multigrid method and the non-equilibrium Green functions technique for multi-probe systems, we have developed massively parallel DFT-based software to calculate quantum transport properties with several thousands atoms. We present results for transport properties of graphene-based transistors with different atomic structures and study the effects of nanoribbon length, width and gate structure.

3:18PM W16.00005 Low-Resistance Spin Filtering from Ferromagnet-Graphene-Ferromagnet Junctions, ENRIQUE COBAS, OLAOF VAN ‘T ERVE, SHU-FAN CHENG, BERRY JONKER, US Naval Research Laboratory — Nickel-graphene interfaces have been recently demonstrated to habor spin polarizations of up to 42% with Ni/Graphene/MgO/Co heterostructures exhibiting negative out-of-plane magnetoresistances of 31% [1]. These experiments agree qualitatively with theoretical predictions of spin filtering at planar Ni-Graphene and Co-Graphene interfaces [2]. We previously demonstrated room temperature magnetoresistance in vertical NiFe-Graphene-Co junctions [3]. Now we have fabricated high-quality NiFe(111)-Graphene-Co and NiFe(111)-Graphene-Fe junctions grown in-situ that exhibit high MR at room temperature while maintaining a very low interface resistance. Such junctions embody an excellent source of spin-polarized current for spintronics applications like fast and non-volatile magnetic random access memory.

3:30PM W16.00006 Plasma enhanced atomic layer deposition of ultrathin oxides on graphene, CHRISTIE J. TRIMBLE, ANNA M. ZANIEWSKI, MANPUNEET KAUR, ROBERT J. NEMANICH, Arizona State University — Graphene, a single atomic layer of sp2 bonded carbon atoms, possesses extreme material properties that point toward a plethora of potential electronic applications. Many of these possibilities require the combination of graphene with dielectric materials such as metal oxides. Simultaneously, there is interest in new physical properties that emerge when traditionally three dimensional materials are constrained to ultrathin layers. For both of these objectives, we explore deposition of ultrathin oxide layers on graphene. In this project, we perform plasma enhanced atomic layer deposition (PEALD) of aluminum oxide on graphene that has been grown by chemical vapor deposition atop copper foil and achieve oxide layers that are <1.5 nm. Because exposure to oxygen plasma can cause the graphene to deteriorate, we explore techniques to mitigate this effect and optimize the PEALD process. Following deposition, the graphene and oxide films are transferred to arbitrary substrates for further analysis. We use x-ray photoelectron spectroscopy, Raman spectroscopy, and atomic force microscopy to assess the quality of the resulting films.

This work is supported by the National Science Foundation under Grant # DMR-1206935.
3:42PM W16.00007 Energy gap formation and gap states analysis in bilayer graphene

KAOH KANAYAMA, The University of Tokyo, KOSUKE NAGASHIO, The University of Tokyo & PRESTO-JST — The targeted issue for bilayer graphene is low \( I_{on}/I_{off} \) at room temperature, which is explained by the variable range hopping in \( \text{gap states} \). However, there will be intrinsically no interface states in bilayer graphene because there is no dangling bonds, compared with \( \text{Pb} \) centers in \( \text{SiO}_2/\text{Si} \) system. The origin for the gap states is still open question. In spite of this, the detailed measurements on \( D_{\text{h}} \) and time constant for gap states have not been reported yet. One of reasons could be the leakage current through the top gate insulator since robust methodology is not established. Here, we demonstrates a considerable suppression of the low-field leakage in bilayer graphene by applying the high-pressure \( \text{O}_2 \) annealing to \( \text{Y}_2\text{O}_3 \) top gate insulator. The reliable \( \text{Y}_2\text{O}_3 \) top gate insulator provides the access to the carrier response issue in the largely-opened band gap. In this talk, we focus on the conductance measurements for bilayer graphene to extract \( D_{\text{h}} \), and time constant. Based on these measurements, two possible origins for the gap states, (i) border traps at the edge of \( \text{Y}_2\text{O}_3 \) and (ii) the local breakdown of A-B stacking in bilayer graphene, are discussed.

3:54PM W16.00008 ABSTRACT WITHDRAWN

4:06PM W16.00009 SrO(001) on graphene: a universal buffer layer for integration of complex oxides

ADAM AHMED, The Ohio State University, HUA WEN, University of California Riverside, IGOR PINCHUK, TIANCONG ZHU, ROLAND WAKAWAKI, The Ohio State University — We report the successful growth of high-quality crystalline SrO on highly-ordered pyrolytic graphite (HOPG) and single layer graphene by molecular beam epitaxy. The epitaxial SrO layers have (001) orientation as confirmed by x-ray diffraction (XRD), and atomic force microscopy measurements show rms surface roughness of optimal films to be 1.2 Å. Transport measurements of exfoliated graphene after SrO deposition show a strong dependence between the Dirac point and Sr oxidation. To show the utility of SrO as a buffer layer for complex oxide integration, we grew perovskite crystal \( \text{SrTiO}_3 \) on SrO, and it was also confirmed to have (001) orientation from x-ray diffraction. This materials advancement opens the door to integration of many other complex oxides to explore novel correlated electron physics in graphene.

JAMES HONE, Columbia University — Two-dimensional (2D) materials, such as graphene, hexagonal boron nitride (hBN), transition metal dichalcogenides, have shown great potential in nano-electronics because of their unique and superior physical properties. Among them, hBN has been known as an alternative crystal \( \text{SrTiO}_3 \) on SrO, and it was also confirmed to have (001) orientation from x-ray diffraction. This materials advancement opens the door to integration of many other complex oxides to explore novel correlated electron physics in graphene.

4:30PM W16.00011 Electronic transport in graphene structure: from weak to strong localization regimes

AURELIEN LHIBERI, Université catholique de Louvain, Institute of condensed matter and nanosciences, chemin des étoiles 8, 1348 Louvain-la-Neuve, Belgium — Graphene, often named the wonder material for its many fascinating properties, has sparked out intense research activities over the last decade. Electronic transport in graphene became rapidly an important research field because of the early reported extremely high charge carrier mobility which triggered large expectations for nanoelectronic devices. Besides mobilities, graphene samples can exhibit particularly long electronic coherence lengths which allow for phase-related quantum transport phenomena such as the weak and strong localization transport regimes. This makes graphene a remarkable playground for fundamental studies of localization theory in low-dimensional systems. In this presentation, using tight-binding models enriched by first principle calculations, and a real-space Kubo-Greenwood method, multiscale simulations of the electronic transport in various graphene-based systems will be discussed. Such an approach allows for computing transport properties of systems containing millions of atoms reaching therefore the experimental sample size. In order to tailor graphene properties, chemical and/or structural modifications are widely used. However, such modifications act as scattering defects and usually deteriorate transport properties. Open a band gap while maintaining good mobility is a typical illustration of this dual problem. The influence of various chemical and structural defects will be analyzed. In particular, the consequences of unbalanced sublattice nitrogen doping in graphene and the case of highly defective graphene structures exhibiting strong Anderson insulator behaviors will be examined. Defects being even more detrimental for transport in 1D structures, a synthesis method that is free of defects is highly desirable. A solution is provided by a bottom-up chemistry approach where precursor monomers are self-assembled. The electronic transport and the potential for nanoelectronics of such defect-free carbon ribbons will also be discussed.

5:06PM W16.00012 Aharonov-Bohm interference in gate-defined ring of high-mobility graphene

MINSOO KIM, HU-JONG LEE, Department of Physics, Pohang University of Science and Technology — Recent progress in preparing a high-quality graphene layer enables one to investigate the intrinsic carrier transport nature in the material. Here, we report the signature of conservation of the Berry’s phase with preserved valley symmetry in Aharonov-Bohm (AB) interferometers fabricated on monolayer graphene with high carrier mobility, where the graphene was sandwiched between two thin hexagonal boron nitride (h-BN) layers. In measurements, charge carriers were confined in an AB ring-shaped potential well formed by the dual-gate operation of the bottom and top gates and the four-terminal magneto-conductance (MC) was measured with varying magnetic flux through the ring. The signature of conservation of the Berry’s phase is clearly observed up to carrier density of \( 10^{12} \text{cm}^{-2} \) and MC agrees well with theoretical predictions. This is the first demonstration of Aharonov-Bohm interference in 2D materials.

5:18PM W16.00013 High-k Dielectric Nanosheets for Two-Dimensional material Electronics

YUFENG HAO, XU CUI, JUN YIN, GWAN-HYOUNG LEE, GHIDEWON AREFE, Columbia university, MINORU OSADA, TAKAYOSHI SASAKI, NIMS, Japan, JAMES HONE, Columbia University — Two-dimensional (2D) materials, such as graphene, hexagonal boron nitride (hBN), transition metal dichalcogenides, have shown great potential in nanoelectronics because of their unique and superior physical properties. Among them, hBN has been known as an alternative dielectric that is atomically flat and free of trapped charges, which drastically enhance the mobility of graphene or MoS2. However, low dielectric constant (\( k \sim 3.5 \)) of hBN limits its use in transistors as gate lengths are scaled down to tens of nanometers. Here we demonstrate high performance graphene and MoS2 field effect transistors by using ultrathin Ca2NaNb4O13 nanosheet as a dielectric and mechanically stacking 2D materials. We developed a facile transfer strategy to build 2D materials devices based on the Ca2NaNb4O13 nanosheets. We measured and found that the oxide nanosheet has high dielectric strength, along with high dielectric constant at thickness of a few tens of nanometer. Therefore, multiple-stacked heterostructure of 2D materials shows high mobility at small operating voltage. This study shows possibility of high-k dielectric nanosheets for 2D electronics.
2:30PM W17.00001 High Resolution Imaging of Graphene on SiC by Contact Resonance AFM: Experiment and Theory, QING TU, BJÖRN LANGE, Department of Mechanical Engineering and Materials Science, Duke University, Durham, NC, USA; JOAO MARCELO LOPES, Paul-Drude-Institut für Festkörperelektronik, Hausvogteiplatz 5-7, D-10117 Berlin, Germany; STEFAN ZAUSCHER, VOLKER BLUM, Department of Mechanical Engineering and Materials Science, Duke University, Durham, NC, USA — Contact resonance atomic force microscopy (CR-AFM) is a powerful tool for mapping differences of the mechanical properties of layered, 2D materials. The deconvolution of stiffness contributions arising from the different layers is, however, difficult. Here, density functional theory (DFT) calculations can help interpret experimental results. Few-layer graphene (FLG; mono-, bi-, or trilayer thickness) on silicon carbide (SiC) exhibits very clean and distinct surfaces and yields high-contrast CR-AFM images. To interpret the contributions from surface areas with different layer thickness and structure we use DFT to calculate atomic displacements for forces acting on FLG on SiC using the $\sqrt{3} \times \sqrt{3}$ and the $6\sqrt{3} \times 6\sqrt{3}$ structure models. Based on these displacements we calculate an effective modulus using a spring model. The resulting moduli can then be compared with those extracted from experimental CR-AFM measurements of FLG on SiC.

2:42PM W17.00002 Charging Ring Spectroscopy and Defect Identification in Graphene/Boron Nitride Through Scanning Tunneling Microscopy, JUWON LEE, DILLON WONG, JAIRO VALESCO, LONG JU, SALMAN KAHN, HHSINZON TSAI, CHAD GERMANY, Univ of California - Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Material Science, ALEX ZETTL, FENG WANG, MICHAEL CROMMIE, Univ of California - Berkeley — Tip-induced ionization of defects in semiconductors and surface adatoms is known to cause ring-like structures in scanning tunneling spectroscopy (STS). We report the observation and investigation of charging ring structures in bulk single crystalline graphene grown on SiC. These rings provide quantitative information on the energy levels of the partially filled BN defects, providing insight into their chemical identities. This new technique suggests exciting possibilities for quantitative spectroscopic studies of defects in other insulating systems.

2:54PM W17.00003 Scanning tunneling microscopy studies of graphene and hydrogenated graphene on Cu(111), SHAWNA M. HOLLEN, GRADY GAMBREL, STEVEN TJUNG, NANCY M. SANTAGATA, EZEKIEL JOHNSTON-HALPERIN, JAY A. GUPTA, The Ohio State University — Because of the innate sensitivity of 2D material surfaces, it is increasingly important to understand and characterize surface functionalization and interactions with environmental elements, such as substrate, metallic contacts, and adatoms. Here we have developed a method for reproducible, epitaxial growth of pristine graphene islands on Cu(111) in UHV and use scanning tunneling microscopy and spectroscopy (STM) to study the interaction of these graphene islands with the Cu substrate. Tunneling spectroscopy measurements of the electronic surface states over the graphene islands indicate a lower work function, decreased coupling to bulk Cu states, and a decreased electron effective mass. Additionally, we support the novel field electron dissociation technique to form hydrogen-terminated graphene at low temperatures and in UHV. This technique produced what may be the first STM images of crystalline hydrogenated graphene. The pristine graphene island is then recovered by scanning at a high tip-sample bias. The hydrogenation and its reversibility suggest writing lateral 2D devices using the STM tip. Toward this end, we are developing the capability to repeat the hydrogenation on working graphene devices.

3:18PM W17.00005 Probing Graphene by Low-Energy Electrons under Non-normal Incidence, JOHANNEZ JOBST, JAAP KAUTZ, DANIEL GEELEN, Leiden University, Huygens-Kamerlingh Onnes Laboratory, RUDOLF M. TROMP, IBM T.J. Watson Research Center, SENSE JAN VAN DER MOLEN, Leiden University, Huygens-Kamerlingh Onnes Laboratory — Low-energy electron microscopy (LEEM) is a powerful surface analysis tool for investigating samples in real and reciprocal space. Moreover, spectroscopic information can be obtained by measuring LEEM-IV, i.e., the energy dependence of the reflected electron intensity. Here, we focus on the study of monolayer and bilayer graphene grown on silicon carbide. The bilayer structure gives rise to minima in the LEEM-IV, which are used to unambiguously determine the layer thickness as the number of minima is equal to the number of conducting graphene layers. In a typical LEEM experiment it is crucial to align the sample such that the electrons impinge perpendicular on the surface in order to guarantee ideal imaging conditions. In this study we, however, present a systematic analysis of the effect of beam tilt on the LEEM-IV. We find pronounced changes in shape depending on the tilt angle with respect to crystallographic axes. These changes can be related to the band structure of few-layer graphene.

3:30PM W17.00006 Resonant Modes in Circular Graphene pn Junctions Created by STM Probes, JONATHAN WYRICK, Center for Nanoscale Science and Technology NIST, YUE ZHAO, Center for Nanoscale Science and Technology NIST; Maryland NanoCenter UMD, FABIAN NATTERER, Center for Nanoscale Science and Technology NIST, JOAQUIN RODRIGUEZ NIEVA, Department of Physics, Massachusetts Institute of Technology, CYPRIAN LEWANDOWSKI, Department of Physics, Imperial College London, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, LEONID LEVITOV, Department of Physics, Massachusetts Institute of Technology, NIKOLAI ZHITENEV, JOSEPH STROSCIO, Center for Nanoscale Science and Technology NIST — Electronic states in graphene (and similar 2D materials) are susceptible to yield 2 types of resonances in the tunneling spectrum: first as oscillations in the otherwise linear graphene dispersion, and second when they are pulled across the Fermi-level due to tip gating. Tunable with tip height/radius, and tip work-function, the oscillations act as fingerprints of an induced pn junction. We compare experimental results to theory for confined states in circular geometries, characterizing energy and spatial characteristics of these modes.
3:42PM W17.00007 Stacking defects and transport in bilayer graphene1, FRANCISCO GUINEA, CSC — 

Pristine bilayer graphene behaves in some instances as an insulator with a transport gap of a few meV. Intriguingly, however, some samples of similar mobility exhibit good metallic properties, with a minimal conductivity of the order of 2e^2/h. Here we propose an explanation for this dichotomy, which is unrelated to electron interactions and based on the reversible formation of boundaries between stacking domains (‘solitons’). We argue, using a numerical analysis, that the hallmark features of the previously inferred insulating state can be explained by scattering on boundaries between domains with different stacking order (AB and BA). We furthermore present experimental evidence, reinforcing our interpretation, of reversible switching between a metallic and an insulating regime in suspended bilayers when subjected to thermal cycling or high current annealing.

4:18PM W17.00008 Examination of Humidity Effects on Measured Thickness and Interfacial Phenomena of Exfoliated Graphene on SiO_2 via AC-AFM, KATHERINE JINKINS, JORGE CAMACHO, LEE FARINA, YAN WU, Univ of Wisconsin, Platteville — Tapping (AC) mode Atomic Force Microscopy (AFM) is commonly used to determine the thickness of graphene samples. However, AFM measurements have been shown to be sensitive to environmental conditions such as adsorbed water, in turn dependent on relative humidity (RH). In the present study, AC-AFM is used to measure the thickness and loss tangent of exfoliated graphene on silicon dioxide (SiO_2) as RH is increased from 10% to 80%. We show that the measured thickness of graphene is dependent on RH. Loss tangent is an AFM imaging technique that interprets the phase information as a relationship between the stored and dissipated energy in the tip-sample interaction. This study demonstrates the loss tangent of the graphene and oxide regions are both affected by humidity, with generally higher loss tangent for graphene than SiO_2. As RH increases, we observe the loss tangent of both materials approaches the same value. We hypothesize that there is a layer of water trapped between the graphene and SiO_2 substrate to explain this observation. Using this interpretation, the loss tangent images also indicate movement and change in this trapped water layer as RH increases, which impacts the measured thickness of graphene using AC-AFM.

4:30PM W17.00009 Visualization of Photo-induced Doping patterns in Graphene/Boron Nitride Heterostructures via Scanning Tunneling Microscopy1, JAIRO VELASCO JR., LONG JU, DILLON WONG, JUWON LEE, SALMAN KAHN, HSIN-ZON TSAI, CHAD GERMANY, University of California at Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, ALEX ZETTL, FENG WANG, MIKE CROMMIE, University of California at Berkeley — Photo-induced doping in graphene-boron nitride (G/BN) heterostructures enables flexible and repeatable writing and erasing of charge doping in graphene using optical irradiation. So far, however, this phenomenon has been explored using spatially averaging probes such as electron transport, and there have been no local studies into the underlying microscopic behavior. Here we report a combined scanning tunneling microscopy (STM) and optoelectronic measurement scheme that has been utilized to investigate the microscopic mechanisms at work in this process. We will discuss the latest experimental progress towards the visualization of light-induced charge doping patterns on G/BN heterostructures via STM.

4:42PM W17.00010 A Correlation of Raman and Single and Multiple Layer Graphene Conductivity As Detected With A Cryogenic Multiprobe AFM With On-line Raman, NSOM and Other SPM Modalities, AARON LEWIS, Hebrew University of Jerusalem, Benin School of Engineering & Applied Science, Jerusalem, Israel, OLEG ZINOVIEV, ANATOLY KOMISSAR, ERAN MAAYAN, DAVID LEWIS, Nanonics Imaging Ltd., Jerusalem, Israel — It is a challenge to study 2D materials, such as Graphene, MoS_2, WeSe_2, etc. at temperatures down to 10^3K when considering the wide variety of physical phenomena that must be applied for a full picture of the functionality of these materials. This involves questions of structure, nanometric photoconductivity, electrical properties, thermal properties, near-field optical in the apertured & scattering modes, Kelvin probe, and Raman. These phenomena are common not only to 2D materials but also to carbon nanotubes and related nanomaterials. This presentation will describe the instrumental development of such a multiprobe cryogenic system that allows for state of the art on-line optical measurements and will also include a review of the probe developments that permit such multifunctional multiprobe operation with on-line full optical access. This system has a completely free optical axis from above and below not obscured by electrical or other probes that have been developed for multiprobe operation. This permits on-line Raman and Tip Enhanced NanoRaman Scattering. With such a system we have investigated graphene and HFO2 using multiprobe electrical, Kelvin probe, NSOM and on-line Raman. The results have yielded new insights into chemical changes correlated to electrical conductivity.

4:54PM W17.00011 Electron Tunneling Spectroscopy of Single and Bilayer Graphene with Hexagonal Boron Nitride Tunneling Barrier, SUYONG JUNG, JAESUNG PARK, CHANYONG HWANG, DONGHAN HA, Korea Research Institute of Standards and Science, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, PILKYUNG MOON, New York University Shanghai, YOUNG-WOO SON, Korea Institute for Advanced Study — We have performed electron tunneling spectroscopy measurements on gated single and bilayer graphene devices with thin hexagonal boron nitride (h-BN) as a tunneling barrier. We can directly probe electronic structures of graphene devices by varying charge density and tunneling bias voltage. The evolution of bilayer energy gap identified as dI/dV dip in tunneling spectra is observed as the electric field between bottom gate and top tunneling probe varies. In addition, we can identify several spectra features which are in good agreement with the vibrational excitations; phonons of graphene and h-BN and a signature of local plasmonic excitation. Upon increasing external magnetic field, the development of Landau levels (LL) is observed as early as 0.2T and we are able to discern individual LL as many as 20 as an index for both filled and empty states, which is unprecedented in previous tunneling spectroscopy studies on graphene devices.

5:06PM W17.00012 Thermal mirror buckling transitions in a pristine freestanding graphene membrane investigated by scanning tunneling microscopy, KEVIN SCHOEIZ, University of Arkansas, VINCENT MEUNIER, Rensselaer Polytechnic Institute, PRADEEP KUMAR, University of Arkansas, MEHDHI NEEK-AMAL, Universiteit Antwerpen, PAUL THIBADO, University of Arkansas, FRAANCOIS PEETERS, Universiteit Antwerpen — Freestanding graphene membranes are not flat, but rather display an array of ripples with alternating curvature. By applying a local force using a scanning tunneling microscope tip, we can pull out these ripples, causing the graphene membrane to reversibly rise and fall. By increasing the tunneling current and exploiting the negative coefficient of thermal expansion, we can increase the strain in the graphene membrane causing an irreversible transition from this flexible state to a rigid configuration. This transition typically happens when the graphene membrane reaches 60-70% of the total graphene height. We successfully model this transition as the transition of a spin-half Ising magnet where the ripples are modeled as Ising spins. The buckling transition can be interpreted as the transition from an antiferromagnetic state, to a ferromagnetic state. In addition, four critical exponents are measured. These results provide insight into the role of the negative thermal expansion of graphene.

Thursday, March 5, 2015 2:30PM - 5:30PM —
Session W18 QGI DAMOP: Invited Session: Novel Approaches for Quantum Information Processing With Polar Molecules Mission Room 103A - Sabre Kais, Qatar Environment and Energy Research Institute & Purdue University

3:06PM W18.00002 Quantum matter based on ultracold molecules, JUN YE, JILA, NIST and University of Colorado — Molecules cooled to ultralow temperatures provide fundamental new insights to strongly correlated quantum systems, molecular interactions and chemistry in the quantum regime, and precision measurement. Complete control of molecular interactions by producing a molecular gas at very low entropy and near absolute zero has long been hindered by their complex energy level structure. Recently, a range of scientific tools have been developed to enable the production of molecules in the quantum regime. Here, molecular collisions follow full quantum descriptions. Chemical reaction is controlled via quantum statistics of the molecules, along with dipolar effects. Further, molecules can be confined in reduced spatial dimensions and their interactions precisely manipulated via external electromagnetic fields. For example, by encoding a spin-1/2 system in rotational states, we realize a spin lattice system where many-body spin dynamics are directly controlled by long-range and anisotropic dipolar interactions. These new capabilities promise further explorations of strongly interacting and collective quantum effects in exotic quantum matter.

3:42PM W18.00003 Abelian and non-abelian topological phases with dipoles, ALEXEY GORSHKOV, Joint Quantum Institute — Topological phases of matter offer a pathway towards fault-tolerant topological quantum computers, in which quantum information is encoded in nonlocal (topological) degrees of freedom and is processed robustly by braiding (i.e. moving around one another) topological defects called anyons. In this talk, we will develop schemes for taking advantage of the tremendous degree of control recently achieved in atomic, molecular, and optical systems – particularly in systems of interacting dipoles – to realize exotic topological phenomena, such as parafermions, Ising anyons, and Fibonacci anyons, that ultimately allow for universal topologically protected quantum computing.

4:18PM W18.00004 Getting trapped molecules into the quantum toolkit, BRIAN ODOM, Northwestern University — Obtaining control over the rotational quantum state of trapped molecules is a prerequisite for quantum information processing applications. However, this task has presented a significant challenge because of the large number of initial states typically populated and because of unwanted excitations generally occurring during optical manipulation. Using a single spectrally filtered broadband laser simultaneously addressing many rotational levels, we have optically cooled trapped AlH+ molecules from room temperature to 4 Kelvins, corresponding to an increase in ground rotational-vibrational state population from 3% to 95%. We anticipate that the cooling timescale can be reduced from 100 milliseconds to a few microseconds and that the cooling efficiency can also be improved. Our broadband cooling technique should also be applicable to a number of other neutral and charged diatomic species. Trapped AlH+, in particular, is a good candidate for future work on ultracold chemistry, coherent control and entanglement of rotational quantum states, non-destructive single-molecule state readout by fluorescence, and searches for time-variations of the electron-proton mass ratio.

4:54PM W18.00005 Universal Matchgate Quantum Computing With Cold Polar Molecules, FELIPE HERRERA, Harvard University — Polar molecules in optical lattices are attractive for quantum simulation and computation due to the ability to implement a variety of spin-lattice models using static, microwave and optical fields to engineer the long-range dipolar interaction between molecular qubits. Quantum simulation of spin models requires global control over the molecular ensemble, while quantum computation requires control of individual molecules with sub-wavelength resolution. In this talk, we describe the implementation of a matchgate quantum processor with an ensemble of polar molecules in an optical lattice. The scheme uses few-body qubit encoding and sequential control of two-body dipolar interactions over small plaquetes on a square lattice to perform universal quantum computing without single-site addressing. Effective spin-spin interactions with matchgate symmetry between open-shell polar molecules (e.g., SrF, OH) are driven by two infrared control pulses in the absence of static electric fields. The resulting matchgates are robust with respect to realistic imperfections in the driving fields and lattice trapping. Applications of the architecture for the simulation of interacting fermions in quantum chemistry are discussed, considering an imperfect lattice filling.

Thursday, March 5, 2015 2:30PM - 5:30PM – Session W19 DCOMP: Invited Session: Frontiers of Electronic Structure Theory for Materials Mission Room 103B - Volker Blum, Duke University

2:30PM W19.00001 Exchange-Correlation and Electronic Excitation Energies from Pairing Matrix Fluctuations and the Particle-Particle Random Phase Approximation, WEITAO YANG, Duke Univ — We have developed an adiabatic connection to formulate the ground-state exchange-correlation energy in terms of pairing matrix linear fluctuations, opening a new channel for density functional approximations. This resulting method has many highly desirable properties. It has minimal delocalization error with a nearly linear energy behavior for systems with fractional charges, describes van der Waals interactions similarly and thermodynamic properties significantly better than the conventional RPA, and eliminates static correlation error for single bond systems. It is the first known functional with closed-form dependence on orbitals, which captures the energy derivative discontinuity in strongly correlated systems. We also adopted pp-RPA to approximate the pairing matrix fluctuation and then determine excitation energies by the differences of two-electron addition/removal energies. This approach captures many types of interesting excitations: single and double excitations are described accurately, Rydberg excitations are in good agreement with experimental data and CT excitations display correct 1/R dependence.
3:06PM W19.00002 Towards a unified description of ground and excited state properties: GW vs RPA and beyond , PATRICK RINKE, Aalto University, School of Science, 00076 Aalto, Finland — In the quest for finding an "optimal" first principles electronic structure method, that combines accuracy and tractability with transferability across different chemical environments and dimensionalities (e.g. molecules, wires/tubes, surfaces, solids), the treatment of exchange and correlation in terms of "exact-exchange plus correlation in the random-phase approximation (EX+CPA)" offers a promising avenue. Likewise one can express the same level of theory in the Green's function context through the GW approximation, which has the additional advantage that quasiparticle spectra as measured by direct and inverse photoemission become accessible. In this talk I will contrast both approaches and present the latest results from our continuous assessment. We find that self-consistent (sc) GW provides excellent charge densities [1], which is particularly important for charge transfer systems [2]. Spectral properties for closed shell molecules are generally in good agreement with photoemission spectra, although a judicious choice of the starting point in perturbative GoH calculations can outperform scGW [1,3]. Other ground state properties do not improve over EX+CPA calculations [1]. EX+CPA, on the other hand, provides a good description of the ground state [4] even for challenging cases like chemical reaction barrier heights [5] and the f-electron metal cerium [6]. The notorious underbinding of EX+CPA can be corrected by going beyond RPA to renormalised second order perturbation theory (rPT2) [7] that gives the overall most balanced performance. I will also discuss the associated rPT2 self-energy that goes beyond GW.

3:42PM W19.00003 Range-separated Hybrid Functionals for Molecules and Interfaces , THOMAS KÖRZDÖRFER, University of Potsdam, Germany — Density functional theory (DFT) and its time-dependent extension (TD-DFT) are powerful tools enabling the theoretical prediction of the ground- and excited-state properties of many-electron systems with reasonable accuracy at affordable computational costs. The DFT treatment of particular electronic and structural properties, however, reveals severe qualitative failures of standard out-of-the-box functionals. Important examples include the wrong level alignment and spurious charge-transfer at organic-organic interfaces as well as the underestimation of bond-length alternations and excited-state energies in polymers. These failures can be traced back to the delocalization error inherent to semilocal and global hybrid functionals. In this talk, I will discuss recent efforts to reduce the delocalization error by using range-separated hybrid functionals combined with a non-empirical tuning procedure for the range-separation parameter [1-3]. The benefits and drawbacks of using range-separated hybrid functionals for the description of the ground and excited states of molecules and interfaces will be discussed. It will be demonstrated that this approach provides for robust and efficient means of calculating ionization potentials and electron affinities, for characterizing the electronic couplings in organic mixed-valence systems, for the calculation level alignment at organic/organic interfaces, and for the reliable prediction of the optical band-gap of low band-gap polymers. I will further motivate why RSH functionals provide for a superior starting point for non-self-consistent GW calculations as compared to standard semilocal or global hybrid functionals.

4:54PM W19.00005 Stochastic Quantum Chemistry for extended systems , GEORGE BOOTH, Department of Chemistry University of Cambridge — No abstract available.

Thursday, March 5, 2015 2:30PM - 5:30PM — Session W20 DPOLY: Invited Session: Physics of Biomacromolecules Ballroom B - Patrick Underhill, Rensselaer Polytechnic Institute

2:30PM W20.00001 Electrostatic self-assembly of biomolecules1 , MONICA OLVERA DE LA CRUZ, Northwestern Univ — Charged filaments and membranes are natural structures abundant in cell media. In this talk we discuss the assembly of amphiphiles into biocompatible fibers, ribbons and membranes. We describe one- and two-dimensional assemblies that undergo re-entrant transitions in crystalline packing in response to changes in the solution pH and/or salt concentration resulting in different mesoscopic morphologies and properties. In the case of one-dimensional structures, we discuss self-assembled amphiphiles into highly charged nanofibers in water that order into two-dimensional crystals. These fibers of about 6 nm cross-sectional diameter form crystalline arrays with inter-fiber spacings of up to 130 nm. Solution concentration and temperature can be adjusted to control the inter-fiber spacings. The addition of salt destroys crystal packing, indicating that electrostatic repulsions are necessary for the observed ordering. We describe the crystallization of bundles of filament networks interacting via long-range repulsions in confinement by a phenomenological model. Two distinct crystallization mechanisms in the short and large screening length regimes are discussed and the phase diagram is obtained. Simulation of large bundles predicts the existence of topological defects among bundled filaments. Crystallization processes driven by electrostatic attractions are also discussed.

3:06PM W20.00002 Theory and Computational Design of Protein Materials , JEFFERY SAVEN, University of Pennsylvania — Protein design opens routes to arrive at novel molecules, materials and nanostructures. Recent theoretical methods can identify the properties of amino acid sequences consistent with desired structures and functions. Such methods leverage concepts from statistical mechanics and address the structural complexity of proteins and their many possible amino acid sequences. Computationally designed protein-based systems have been experimentally realized to encapsulate nonbiological cofactors and assemble into predetermined crystalline structures.
diagonal wavevector (2013) to include a direct antiferromagnetic exchange coupling between the Cu sites. As in previous work, we invariably find that the primary instability has a

SCHROEDER, University of Illinois at Urbana-Champaign — Single molecule techniques allow for the direct observation of polymer dynamics under highly non-equilibrium conditions. Until recently, however, these methods have been largely confined to linear semi-flexible DNA molecules as "model" polymer chains. This talk will show recent work from our group in extending the field of single polymer dynamics to new materials, including branched polymers and truly flexible polymer chains. In this way, we explore new questions in classical polymer physics such as the role of architecture, topology, and backbone flexibility on chain dynamics at the molecular level. Recently, we used single molecule methods to directly visualize comb-shaped DNA polymers. Macromolecular DNA combs are synthesized utilizing a hybrid enzymatic-synthetic approach, wherein chemically modified DNA branches and DNA backbones are generated in separate polymerase chain reactions, followed by graft-onto reactions via "click" chemistry. This method allows for the synthesis of dual-color DNA combs, such that the backbone and side branches can be engineered to interact with each other to achieve specific mechanical, physical, and chemical properties. This is in contrast to many other physical hydrogels, where predictable tuning of bulk mechanics from the molecular level remains elusive due to the reliance on non-specific and non-stoichiometric chain interactions for network formation. Furthermore, the hydrogel network can be easily modified to deliver a variety of bioactive payloads including growth factors, peptide drugs, and hydroxyapatite nanoparticles. Through a series of in vitro and in vivo studies, we demonstrate that these materials may significantly improve transplanted stem cell retention and function.

HEILSHORN, Stanford University — Stem cell transplantation is a promising therapy for a myriad of debilitating diseases and injuries; however, current delivery protocols are inadequate. Transplantation by direct injection, which is clinically preferred for its minimal invasiveness, commonly results in less than 5% cell viability, greatly inhibiting clinical outcomes. We demonstrate that mechanical membrane disruption results in significant acute loss of viability at clinically relevant injection rates. As a strategy to protect cells from these damaging forces, we show that cell encapsulation within hydrogels of specific mechanical properties will significantly improve viability. Building on these fundamental studies, we have designed a reproducible, bio-resorbable, customizable hydrogel using protein-engineering technology. In our Mixing-Induced Two-Component Hydrogel (MITCH), network assembly is driven by specific and stoichiometric peptide-peptide binding interactions. By integrating protein science methodologies with simple polymer physics models, we manipulate the polypeptide chain interactions and demonstrate the direct ability to tune the network crosslinking density, sol-gel phase behavior, and gel mechanics. This is in contrast to many other physical hydrogels, where predictable tuning of bulk mechanics from the molecular level remains elusive due to the reliance on non-specific and non-stoichiometric chain interactions for network formation. Furthermore, the hydrogel network can be easily modified to deliver a variety of bioactive payloads.

Thursday, March 5, 2015 2:30PM - 5:30PM — Session W21 DCMP: Density Waves in Superconductors and Other Systems

2:30PM W21.00001 Charge ordering in three-band models of the cuprates, ALEXANDRA THOMSON, SUBIR SACHDEV, Harvard University — We examine trends in the wavevectors and form-factors of charge density wave instabilities of three-band models of the underdoped cuprates. For instabilities from a high temperature state with a large Fermi surface, we extend a study by Bulut et al. (Phys. Rev. B 88, 155132 (2013)) to include a direct antiferromagnetic exchange coupling between the Cu sites. As in previous work, we invariably find that the primary instability has a diagonal wavevector (+Q0, ±Q0) and a d-form factor. The experimentally observed wavevectors along the principal axes (+Q0, 0), (0, ±Q0) have higher energy, and their form factor is found to be predominantly d. Next, we gap out the Fermi surface in the anti-nodal regions of the Brillouin zone by including static, long-range antiferromagnetic order at the wavevector (τ, π): this is a simple model of the pseudogap in which we assume the antiferromagnetic order averages to zero by 'renormalized classical' thermal fluctuations in its orientation, valid when the antiferromagnetic correlation length is large. The charge density wave instabilities of this pseudogap state are found to have the optimal wavevector (±Q0, 0), with the magnitude of the d-form factor decreasing with increasing magnetic order.

1Supported by DOE Grant DE-FG02-07ER46352.
2:54PM W21.00003 Charge-order in the underdoped cuprates: a window into the normal state, DEBANJAN CHOWDHURY, SUBIR SACHDEV, Harvard University — Recent experiments in the underdoped regime of the hole-doped cuprates have found evidence for an incommensurate charge density wave state. We present an analysis of the charge ordering instabilities in a metal with antiferromagnetic correlations, where the electronic excitations are coupled to the fractionalized excitations of a quantum fluctuating antiferromagnet on the square lattice [1]. The resulting charge density wave state emerging out of such a fractionalized Fermi-liquid (FL*) is remarkably similar to the one observed in experiments on a number of different families of the cuprates [2]. Our results show that the observed charge density wave appears as a low-energy instability of a fractionalized metallic state linked to the proximity to an antiferromagnetic insulator, and the pseudogap regime can be described by such a metal at least over intermediate length and energy scales. We also describe the transition from a Fermi-liquid with a large Fermi-surface to a FL* around optimal doping via a Higgs-transition of a SU(2) gauge-theory. The implications of such Higgs criticality in two-dimensional metals on the physics of strange metal will be discussed.

3:06PM W21.00004 dc Resistivity at the Onset of Spin Density Wave Order in Two-dimensional Metals, AVISHKAR PATEL, SUBIR SACHDEW, Harvard Univ — The theory for the onset of spin density wave order in a metal in two dimensions flows to strong coupling, with strong interactions not only at the “hot spots,” but on the entire Fermi surface. We advocate the computation of dc transport in a regime where there is rapid relaxation to local equilibrium around the Fermi surface by processes which conserve total momentum. The dc resistivity is then controlled by weaker perturbations which do not conserve momentum. We consider variations in the local position of the quantum-critical point, induced by long-wavelength disorder, and find a contribution to the resistivity which is linear in temperature (up to logarithmic corrections) at low temperature. Scattering of fermions between hot spots, by short-wavelength disorder, leads to a residual resistivity and a correction which is linear in temperature.

3:18PM W21.00005 Are there quantum oscillations in an incommensurate charge density wave? YI ZHANG, AKASH MAHARAJ, STEVEN KIVELSON, Stanford University — Because a material with an incommensurate charge density wave (ICDW) is only quasi-periodic, Bloch’s theorem does not apply and there is no sharply defined Fermi surface. We will show that, as a consequence, there are no quantum oscillations which are truly periodic functions of 1/B (where B is the magnitude of an applied magnetic field). For a weak ICDW, there exist broad ranges of 1/B in which approximately periodic variations occur, but with frequencies that vary inexorably in an unending cascade with increasing 1/B. For a strong ICDW, e.g. in a quasi-crystal, no quantum oscillations survive at all. Rational and irrational numbers really are different. The duality between quasi-periodic systems in different dimensions can be straightforwardly generalized beyond the quantum oscillations and provides an accurate and efficient perspective.

3:30PM W21.00006 Short-range incommensurate d-wave charge order from a two-loop renormalization group calculation of the fermionic hot spot model, HERMANN FREIRE, VANUILDO DE CARVALHO, Universidade Federal de Goiás — The two-loop renormalization group (RG) calculation is considerably extended here for a two-dimensional (2D) fermionic effective field theory model, which includes only the so-called “hot spots” that are connected by the spin-density-wave (SDW) ordering wavevector on a Fermi surface generated by the 2D t − t’ Hubbard model at low hole doping. We compute the Callan-Symanzik RG equation up to two loops describing the flow of the single-particle Green’s function, the corresponding spectral function, the Fermi velocity, and some of the most important order-parameter susceptibilities in the model at lower energies. As a result, we establish that — in addition to clearly dominant SDW correlations — an approximate (pseudospin) symmetry relating a short-range incommensurate d-wave charge order to the d-wave superconducting order indeed emerges at lower energy scales, which is in agreement with recent works available in the literature addressing the 2D spin-fermion model. We derive implications of this possible electronic phase in the ongoing attempt to describe the phenomenology of the pseudogap regime in underdoped cuprates.

3:42PM W21.00007 Charge Density Wave and Superconductivity in Cu_xTiSe_2 Single Crystals, GORAN KARAPETROV, P. HUSANIKOVA, Drexel University, V. CAMBEL, IEE, Slovak Academy of Sciences, Bratislava, Slovakia, P. SZABO, P. SAMUELY, IEP, Slovak Academy of Sciences and Safarik University, Kosice, Slovakia, J. FEDOR, M. IAVARONE, Temple University, Philadelphia — We investigate atomic scale scanning tunneling microscopy and spectroscopy in Cu_xTiSe_2 single crystals at low temperatures. We map the CDW and superconducting phase diagram as a function of copper doping. STM measurements reveal coexistence of chiral charge density wave and superconductivity. In case of optimally doped and overdoped cases we find that the amplitude of charge density wave modulation is strongly suppressed with respect to strongly underdoped case (x < 0.06) with the chiral domain size remaining approximately the same. Superconductivity exhibits BCS character at a variety of dopings with 2Delta/k_B ~ 3.4 ± 0.7 indicating an intermediate coupling strength. Application of the external magnetic field introduces the Abrikosov vortex lattice that is weakly pinned. The size of the vortex core extracted from vortex images corresponds to the one extracted from the magnetization measurements. Our results suggest that, if charge density wave quantum critical point exist, it should be well above the optimal copper concentration of x=0.08.

This work is supported by the Army Research Office Grant #W911NF-14-1-0567.

3:54PM W21.00008 Chiral Symmetry Breaking and Mott Physics from Gauge/Gravity Duality, GARRETT VANACORE, PHILIP PHILLIPS, University of Illinois, Urbana-Champaign — We use holographic techniques to address the origin of the Mott gap and Fermi arcs in the cuprates. We first show that dynamically generated gaps of the Mott kind arise in holographic settings from a bulk coupling that breaks chiral symmetry. We then explore a bulk coupling which breaks rotational symmetry but preserves chiral symmetry and show that Fermi arcs arise in the dual system at the boundary. We draw further lessons for the cuprates through the unambiguous interpretation of chiral symmetry as a combination of particle-hole and time reversal symmetry in the cuprates, and suggest that the interplay of these symmetries may be the key to understanding the transition between the Mott insulating phase and the pseudogap.

We thank the NSF DMR-1104909 for support of this work.

4:06PM W21.00009 Quantum Critical Transitions in Spin and Charge Ordered Systems, CORENTIN MORICE, University of Cambridge, PREMALA CHANDRA, Rutgers University, STEPHEN E. ROWLEY, SIDHARTH S. SAXENA, University of Cambridge — The talk will focus on search and discovery of novel forms of quantum order in ferroelectric and multiferroic systems. Materials tuned to the proximity of a zero temperature phase transition often show the emergence of novel quantum phenomena. Much of the effort to study these new emergent effects, like the breakdown of the conventional Fermi-liquid theory in metals has been focused in narrow band electronic systems. But Spin or Charge ordered phases in insulating systems can also be tuned to absolute zero. Close to such a zero temperature phase transition, physical quantities like susceptibility change into unconventional forms due to the fluctuations experienced in this region giving rise to new kinds ordered states.
4:18PM W21.00010 Ferromagnetic of the undoped cuprate superconductor Pr$_3$CuO$_4$. ROSS MCDONALD, Los Alamos National Laboratory, NICHOLAS BREZNAZ, NITYAN NAIR, JAMES ANALYTIS, UC Berkeley, ZENGWEI ZHU, KIMBERLEY MODIC, Los Alamos National Laboratory, YOSHIIHARU KROCKENBERGER, NTT Basic Research Laboratories, LANL COLLABORATION, UC BERKELEY COLLABORATION, NTT COLLABORATION—Recent advances in molecular beam epitaxy growth and preparation of cuprate thin films indicate that annealing can be employed to minimize apical oxygen defects. For Pr$_3$CuO$_4$, the resulting square planar coordinated structure exhibits a 25 K superconducting transition in the absence of doping. This calls into question whether a Mott insulating groundstate is the relevant description of the square-planar parent phase of the electron-doped cuprate superconductors. We present high field (\textasciitilde 90 T) measurements of magnetic quantum oscillations—the first observation of it's kind for a cuprate thin film. The oscillation frequency and effective mass are consistent with the reconstructed Fermi surface of the electron-doped cuprate Nd$_{2-x}$Ce$_x$CuO$_4$. The combination of a reconstructed bandstructure and the occurrence of metallicity at zero doping is consistent with a Slater picture of band magnetism, indicating that the “doped Mott insulator” paradigm may not apply in this system.

4:30PM W21.00011 Influence of Ti doping on the incommensurate charge density wave in 1T-TaS$_2$. JIAOQIAN CHEN, Brookhaven National Laboratory, CHRISTOPHER NUGROHO, ANNA J. MILLER, ANSHUL KOGAR, EDUARDO FRADKIN, DALE J. VAN HARLINGEN, PETER ABBAMONTE, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, YOUNG IL JOE, National Institute of Standards and Technology, JOEL D. BROCK, Cornell University, JOCHEN GECK, Leibniz Institute for Solid State and Materials Research—Using x-ray scattering and transport, we studied the temperature dependence of the transition between incommensurate (IC) and nearly commensurate (NC) phases of the charge density wave (CDW) in Ti doped 1T-TaS$_2$. Our results showed a first order phase transition from IC to NC-CDW phase in all doping levels with decreased transition temperature, as Ti doping was increased. During this transition, the angle of the CDW in the basal plane rotates from 11.9° to 16.4° at 12% Ti doping, while the in-plane component of the CDW wave vector does not change significantly. In addition, we observed that at 8% Ti doping, the CDW diffraction peak position and resistivity resemble that of pure TaS$_2$ in its commensurate CDW state. With our data, we revisit the resistive anomaly originally observed by DiSalvo [F. J. DiSalvo et al., Phys. Rev. B 12, 2220 (1975)] at 8% doping. DeSalvo explained this anomaly as arising from the pinning of the CDW on the crystal lattice. Our study shows that the commensuration effects in the NC phase is the cause of this anomaly.

4:42PM W21.00012 Scanning Tunneling Spectroscopy study of the Charge Density Wave driven Mott Insulator 17-TaS$_2$. DOOHHEE CHO, CALDES, IBS, POSTECH, Pohang, Korea, YONG-HEUM CHO, Department of Physics, POSTECH, Pohang, Korea, SANG-WOOK CHEONG, Rutgers University, New Jersey, USA, KI-SEOR KIM, Department of Physics, POSTECH, Pohang, Korea, HANWOONG YEOM, CALDES, IBS, POSTECH, Pohang, Korea—Exotic ground states can be generated by competition or interplay between various interactions, such as electron-phonon (\(e-\phi\)) and electron-electron (\(e-e\)) coupling. 17-TaS$_2$ is a prime example to study such interplay since a Mott gap coexists with charge density waves (CDW) at low temperatures. Our scanning tunneling spectroscopy measurements with high spatial and energy resolution determine the CDW and the Mott gap as 0.20 – 0.24 eV and 0.32 eV, respectively, by analyzing the phase difference between the real space electron densities across multiple energy gaps. In addition, we observe a peculiar reduction of the Mott gap in the vicinity of defect sites. The effect of competition between \(e-\phi\) and \(e-e\) coupling on the Mott gap size will be discussed within the Hubbard-Holstein picture.

4:54PM W21.00013 Wavevector dependent electron–phonon coupling drives the CDW formation in TbTe$_3$. S. ROSENKRANZ, Argonne National Laboratory, M. MASCHKE, F. WEBER, R. HEID, Karlsruhe Institute of Technology, A.H. SAID, Argonne National Laboratory, P. GIRALDO-GALLO, I.R. FISHER, Stanford University—The charge density wave (CDW) transition in the rare-earth tritellurides RTe$_3$ (R=rare earth) is commonly assumed to originate from a textbook Fermi surface nesting instability. Contrary to this weak coupling scenario, our investigation of the soft phonon mode in TbTe$_3$ provides direct evidence that the periodicity of the CDW superstructure in this canonical compound is determined by a strong momentum dependence of the electron-phonon coupling. Our high-resolution inelastic x-ray measurements reveal a renormalization of the soft-phonon energy and a strong broadening of the soft-phonon linewidth over a large part of reciprocal space adjacent to the CDW ordering vector. Our detailed theoretical calculations reproduce these observations very well and show that the position in reciprocal space of the phonon renormalization, and with it the CDW order wavevector, is not related to Fermi surface nesting. Our results demonstrate the importance of strongly momentum dependent electron-phonon coupling in defining the CDW order, which could also be relevant to many other systems.

5:06PM W21.00014 Anisotropic symmetry breaking in two-dimensional charge density waves of ErTe$_3$ investigated by femtosecond electron crystallography. FARAN ZHOU, TIMOFEY GOLUBEV, BIN HWANG, CHONG-YU RUAN, PHIL DUXBURY, Michigan State Univ, CHRISTOS MALLIKIAS, MERCOURI KANATZIDIS, Northwestern University, CHONG-YU RUAN GROUP TEAM, DUXBURY GROUP COLLABORATION, KANATZIDIS GROUP COLLABORATION— Electron-phonon interactions can give rise to various charge-ordered states, especially at low dimensions, where Fermi surface is more prone to form nesting. Rare earth tritellurides compound ErTe$_3$ develops charge density waves (CDW) along two perpendicular directions at different temperatures. By directly probing the order parameters of the two CDWs using femtosecond electron crystallography under different temperatures and driving phononic energy, we investigated the emergences of competing CDW orders in a dynamical phase diagram. The anisotropic symmetry breaking and the role of electron-phonon coupling, and photo-doping effect are discussed in reference to other CDW systems.

5:18PM W21.00015 Electronic band structure of Charge Density Wave PdxHoTe$_3$. SHANCAI WANG, YIPENG CAI, ZHONGHUA LIU, LEILEI JIA, YANG HE ZHAO, Department of Physics, Renmin Univ. of China, T. QIAN, HONG DING, Institute of Physics, China academy of Sciences, JUNBAO HE, Department of Physics, Renmin Univ. of China, GENFU CHEN, Institute of Physics, China academy of Sciences—The origin of superconductivity and interplay between superconductivity and different ground states remains challenging. The Pd-intercalated HoTe$_3$, suppresses the charge density wave (CDW) order and leads to the superconductivity. Here we report the detailed Angle-resolved photoemission spectroscopy (ARPES) study of the electronic structure on Pd$_x$Ho$_{1-x}$Te$_3$. In the CDW parent phase (HoTe$_3$), we found out the Fermi surface topology, CDW gap symmetry have 2 fold symmetry, with further Pd-intercalations, the system evolves from 2-fold symmetry to 4-fold symmetry with two CDW vectors, and eventually into superconducting state. The evolution of the CDW gap symmetry, gap size and CDW caused shadow bands are discussed at different phases.
conducting carbon nanotubes in aligned array field effect transistors and photovoltaics. MICHAEL ARNOLD, University of Wisconsin-Madison — Recent advances in (1) achieving highly monodisperse semiconducting carbon nanotubes without problematic metallic nanotubes and (2) depositing these nanotubes on useful, organized arrays and thin flexible substrates have created new opportunities for studying the physics of these one-dimensional conductors and for applying them in electronics and photonics technologies. In this talk, I will present on two topics that are along these lines. In the first, we have pioneered a scalable approach for depositing aligned arrays of ultrahigh purity semiconducting SWCNTs (prepared using polyfluorene-derivatives) called floating evaporative self-assembly (FESA). FESA is exploited to create FETs with exceptionally high combined on-conductance and on-off ratio of 261 µS/µm and 2x10^7, respectively, for a channel length of 240 nm. This is 1400x greater on-off ratio than SWCNT FETs fabricated by other methods, at comparable on-conductance per width of 250 µS/µm, and 30-100x greater on-conductance per width, at comparable on-off ratio of 10^7-10^8.

3:06PM W22.00002 Performance Enhanced Photoconductive Channels Based on (Carbon Nanotube)-(CdS Nanowire) Hybrid Nanostructures, MYUNGJAE YANG, HYUNGWOO LEE, Department of Physics and Astronomy, Seoul National University, KWANG HEO, Interdisciplinary Program in Nano-Science and Technology, Seoul National University, ABBAS MAA-ROOF, Department of Physics and Astronomy, Seoul National University, YONGJU PARK, SEUNGUK NOH, School of Electrical Engineering and Computer Science, Seoul National University, JUNE PARK, Department of Physics, Chung-Ang University, JIKANG JIANG, School of Physical Science and Technology, Xingjiao University, CHANGHEE LEE, School of Electrical Engineering and Computer Science, Seoul National University, MAE-JG SEONG, Department of Physics, Chung-Ang University, SEUNGHUN HONG, Department of Physics and Astronomy, Seoul National University — Previous researches showed that the performance of photocoercive channels based on individual CdS nanowires (NWs) is improved compared to the CdS bulk or thin-film-based channels. However, the assembly of a single NW is usually complex and time-consuming. Herein, we report a high-performance photoconductive channel based on CNT–CdS NW hybrid nanostructures, which can be easily prepared on both flat and curved substrates. In our experiments, the CNT-network-based channel was fabricated using an array of SWCNTs. We found that our channels exhibit a much larger photoresponse and faster photoresponse than those of previously reported CNT or CdS NW-based channels. In addition, we fabricated the channels on a curved surface.

3:18PM W22.00003 Impact of SWCNT characteristics and processing on the performance of nanotube-silicon solar cells. JOHN M. HARRIS, NDSU, ROBERT J. HEADRICK, Rice University, MATTHEW R. SEMLER, NDSU, MATTEO PASQUALI, Rice University, JEFFREY A. FAGAN, NIST, ERIK K. HOBBIE, NDSU — Single-wall carbon nanotubes (SWCNTs) sorted by length, electronic type and chirality are used to understand the influence of SWCNT characteristics on the performance of SWCNT-silicon solar cells. Solution-processed SWCNT films are deposited on n-doped silicon substrates and p-doped to yield photovoltaic devices that are competitive in terms of photo-conversion efficiency, fill factor and open-circuit voltage. The temperature dependence of the dark-current and the transient reverse-bias recovery technique are used to clarify the nature of the devices as a function of SWCNT type and chirality as well as device manufacturing method, where the latter ranges from the vacuum filtration of aqueous colloidal suspensions to the flow-deposition of super-acid solutions.

3:30PM W22.00004 15% Power Conversion Efficiency from a Gated Nanotube/Silicon Nanowire Array Solar Cell, MAUREEN K. PETTERSON1, MAXIME G. LEMAITRE, YU SHEN, Pooja WADHWA2, JIE HOU, SVELTANA V. VASILIEVA, Dept. of Physics, University of Florida, IVAN I. KRAVCHENKO, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, ANDREW G. RINZLER, Dept. of Physics, University of Florida — Despite their enhanced light trapping ability the performance of silicon nanowire array solar cells have, been stagnant with power conversion efficiencies barely breaking 10%. The problem is understood to be the consequence of a high photo-carrier recombination at the large surface area of the Si nanowire sidewalls. Here, by exploiting 1) electronic gating via an ionic liquid electrolyte to induce inversion in the n-type Si nanowires and 2) using a layer of single wall carbon nanotubes engineered to contact each nanowire tip and extract the minority carriers, we demonstrate silicon nanowire array solar cells with power conversion efficiencies of 15%. Our results allow for discrimination between the two principle means of avoiding front surface recombination: surface passivation and the use of local fields. A deleterious electrochemical reaction of the silicon due to the electrolyte gating is shown to be caused by oxygen/water entrained in the ionic liquid electrolyte. While encapsulation can avoid the issue a non-encapsulation based solution is also described.

3:42PM W22.00005 Carbon nanotube fiber based flexible, lightweight and broadband photodetector, AHMED ZUBAIR, ECE Department, Rice University, NAOKI FUJIMURA, Department of Physical Electronics, Tokyo Institute of Technology, DIMITRI E. TSENTALOVICH, COLIN C. YOUNG, ChBE Department, Rice University, XIAOHEI HE, XUAN WANG, WEI LU GAO, ECE Department, Rice University, YUKIO KAWANO, Department of Physical Electronics, Tokyo Institute of Technology, MATTEO PASQUALI, ChBE Department, Rice University, JUNICHIRO KONO, ECE Department, Rice University — Ultrabroadband absorption properties of carbon nanotubes (CNTs) make them attractive materials for solar cell and photodetector applications. In particular, CNT fibers, which have the unique properties of flexibility and high mechanical strength combined with excellent electrical and optical properties, hold the promise as flexible, broadband photodetectors with inherent polarization sensitivity. Here, we explore the optoelectronic properties of high-performance multifunctional fibers of CNTs towards the development of lightweight, flexible, and broadband photodetectors. We present a photothermal electric-effect-based flexible CNT-fiber photodetector fabricated using a novel technique. The spatial variation of doping in CNT fibers creates a Seebeck coefficient gradient, leading to a photothermoelectric signal. The current-voltage characteristics of the fiber photodetector produced polarization-sensitive short-circuit currents and open-circuit voltages in response to light in a wide wavelength range, from the visible to the far-infrared. In the terahertz frequency range, the device showed responsivities as high as 2.1 mA/W.
3:54PM W22.00006 Polarization-dependent terahertz spectroscopy of macroscopic films of aligned single-wall and multiwall carbon nanotubes, XIAOWEI HE, JOHN ROBINSON, WEILU GAO, AHMED ZURBAIR, Rice University, NØE ALVAREZ, University of Cincinnati, ROBERT H. HAUGE, JUNICHIRO KONO, Rice University — The light absorption properties of carbon nanotubes are strongly anisotropic, especially in the terahertz (THz) region of the electromagnetic spectrum due to their inherently one-dimensional intraband carrier dynamics. Macroscopic films of aligned carbon nanotubes are thus ideal for developing high-performance, low-cost THz polarizers. Here, we present results of polarization-dependent time-domain THz spectroscopy studies of large-area films of aligned single-wall carbon nanotubes (SWCNTs) and multiwall carbon nanotubes (MWCNTs) in a frequency range of 0.15-1 THz by varying the polarization of the incident beam with respect to the carbon nanotube alignment direction. The nematic order parameter ($S$), the extinction ratio (ER), and the degree of polarization (DOP) were calculated to establish the performance of the films as polarizers. We found the $S$ of the SWCNT film to be 0.96. The ER of the SWCNT was found to be -12 dB. The measured value of the $S$ for the MWCNT was 0.77, with an ER of -11 dB.

4:06PM W22.00007 Revisiting length-dependent Raman spectroscopy of single-wall carbon nanotubes using single chirality, length-refined populations, YANMEI PIAO, STEPHANIE LAM, ANGELA HIGHT WALKER, JEFFREY FAGAN, National Institute of Standards and Technology (NIST) — As-synthesized, single-wall carbon nanotube (SWCNT) populations contain a wide variety of diameter and length nanotubes. This structural diversity with its accompanying property variation, especially in optical properties, provides a great challenge to the characterization for these materials. Given the tremendous effort to understand the diameter-dependent optical properties of SWCNTs, it is perhaps surprising that little recent work has re-examined the consequences of length, a correspondingly important factor in terms of characterization, to our understanding of the science. Early work demonstrated that for SWCNTs of mixed chirality, the variation in length drove a degradation at short lengths in the optical responses. Since then, identification that morphological impurities and defect density were highly correlated with length in singly sorted samples prompted a reexamination of those results. In this work we probe the length-dependent optical properties of SWCNTs using extremely high-quality SWCNT populations based on multiple aqueous-two-phase separations followed by size exclusion chromatography length-separations. Our results reveal significant and varying dependencies on properties including the G peak intensity and D/G ratio as measured by resonant Raman spectroscopy with the length of single species SWCNT populations, and in other optical properties including absorption and fluorescence.

4:18PM W22.00008 Wide dynamic range stretchable electrical interconnect using carbon nanotube sheets and elastomer, YOURACK LEE, VIET THONG LE, YONG HEE LEE, DONGSEOK SUH, Center for Integrated Nanostructure Physics, Institute for Basic Science. — Stretchable electric conductor has been investigated for bendable electronics and wearable devices. Nanoscale conducting materials such as silver nanowires, gold nanoparticles, graphenes, and carbon nanotubes had been employed for stretchable conductor. Various structural designs like wrinkle, coil and even fabric had been adopted to reduce a direct stress applied to conducting materials for structural stability. Once such conducting materials are stretched, however, their resistance increased enormously because of the dimensional change related to Poisson ratio and the percolation based electrical conduction. In this study, we fabricated a stretchable conductor by combining carbon nanotube sheets and highly stretchable elastomer, which only has 10% of resistance change while it is stretched up to 600% strain. And we found out that the resistance change can be decreased less than 1%, even though it is stretched up to 600% strain, by using a proper capping method that prevents the contacts between folded regions of conducting materials. We expect that this method can help the practical usage of this stretchable conductor as a stretchable electrical interconnect applications.

4:30PM W22.00009 Enhanced Electrical Conductivity of Aluminum by Carbon Nanotube Hybrid Dilution, SHELBY STIGERS, The Pennsylvania State University-Altoona College, ALEXANDER SAVADELIS, KATHRYN CARRUBA, KILEY JOHNS, The Pennsylvania State University, KOFI ADU, The Pennsylvania State University-Altoona College — Carbon nanotubes (CNTs) have been recognized as potential candidate for reinforcements in lightweight metals. A composite consisting of CNTs embedded in an Al-matrix might work as an ultra-low-resistive material with the potential of having a room-temperature resistivity far below Al, Cu and Ag. While several advances have been made in developing Al-CNT composites, three major challenges: (1) interfacial bond strength between CNT and the Al matrix, (2) homogeneous dispersion of the CNTs in the Al matrix and impurity (CNTs) scattering centers, continue to limit progress in Al-CNT composites. Several conventional methods including powder metallurgy, melting and solidification, thermal spray and electrochemical deposition have been used to process Al and CNT to form composites. We present preliminary results that address these challenges: (a) multiphase in-situ 3D alignment of CNTs in an Al matrix, (b) high-quality Al-CNT composites using CNT hybrid as reinforcement and an inductive melting technique that takes advantage of the induced eddy current in the melt to provide in-situ stirring.

4:42PM W22.00010 Carbon Nanotube Networks Reinforced by Silver Nanowires with Improved Optical Transparency and Conductivity, PATRICIA MARTINE1, University of Texas, Dallas, AZIN FAKHIMI, Surrey University Guildford, UK, LING LIN2, University of Texas, Dallas, IZABELA JUREWICZ, ALAN DALTON, Surrey University Guildford, UK, ANVAR A. ZAKHIDOV3, RAY H. BAUGHMAN1, University of Texas, Dallas — We have fabricated highly transparent and conductive free-standing nanocomposite thin film electrodes by adding silver nanowires (AgNWs) to dry-spun Multiwall Carbon Nanotube (MWNT) aerogels. This nanocomposite exhibits desirable properties such as high optical transmittance, excellent flexibility and enhanced electrical conductivity. The incorporation of the AgNWs to the MWNT aerogels was accomplished by using a spray coating method. The optical transparency and sheet resistance of the nanocomposite was tuned by adjusting the concentration of AgNWs, back pressure and nozzle distance of the spray gun to the MWNT aerogel during deposition. As the solvent evaporated, the aerogel MWNT bundles densified via surface tension which caused the MWNT bundles to collapse. This adjustable process was responsible in forming well defined apertures that increased the nanocomposite’s transmittance up to 90 percent. Via AgNWs percolation and random interconnections between separate MWNT bundles in the aerogel matrix, the sheet resistance decreased from 1 K ohm/sq to less than 100 ohm/sq.

The interplay of interactions and disorder within the typical medium dynamical cluster approximation using the Anderson-Hubbard model. By the typical medium theory (TMT), and showed that the typical (not average) DOS is critical at the transition. While the TMT is able to capture the localized distribution, for which the most probable and the typical values differ noticeably from the average value. Dobrosavljevic et.al., incorporated such ideas in their potential approximation and its cluster extensions [1] fail to describe the Anderson transition, as the average density of states (DOS) employed in such theories...
matrices per site: the G show that product states over Matrix Product Operators of small bond dimension is the corresponding natural language for describing the MBL phases. In this (MBL) phases. The natural language for representing the spectrum of the Anderson insulator is that of product states over the single-particle modes. We interacting disordered systems which have localized single particle eigenstates. The interacting analogue of Anderson insulators are the Many-Body Localized operators [4] M. E. Flatté, Nature Phys. 7, 285-286 (2011).

3:30PM W23.00004 Study of multiband disordered systems using the typical medium dynamical cluster approximation , YI ZHANG, Louisiana State Univ - Baton Rouge, HANNA TERLETSKA, Ames Laboratory, CONRAD MOORE, CHINEDU EKUMA, KA MING TAM, JUANA MORENO, MARK HARRELL, Louisiana State University — We generalize the typical medium dynamical cluster approximation to disordered systems with multiple bands. Using our extended formalism, we perform a systematic study of the non-local correlation effects induced by disorder on the density of states and the mobility edge of the Anderson localized states. We apply our method to three dimensional multiband Anderson model with both inter- and intra-band hopping and disorder potential and find fast convergence with increasing cluster size. Our results are consistent with the ones obtained by the transfer matrix and the kernel polynomial methods. Our findings show that the typical medium dynamical cluster approximation method can be used to study the Anderson localization in real materials.

3:42PM W23.00005 Benchmarking Multiband Cluster Typical Medium Theory , CONRAD MOORE, YI ZHANG, KA MING TAM, JUANA MORENO, MARK HARRELL, Louisiana State University — We perform transfer matrix calculations on a non-interacting multiple band disordered system with diagonal and off-diagonal disorder. The mobility edge is determined by finite size scaling. We compare with mobility edge predictions from the Typical Medium Dynamical Cluster Approximation (TMDCA). From these results, we discuss the applicability of TMDCA to study localization in realistic disordered systems.

3:54PM W23.00006 Disorder Problem In Diluted Magnetic Semiconductors, RYKLY NELSON, CHINEDU EKUMA, HANNA TERLETSKA, Louisiana State University, VIDHYADHIRAJA SUDHINDRA, Theoretical Sciences Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bangalore, 560064, India, JUANA MORENO, MARK HARRELL, Louisiana State University — Motivated by experimental studies [1-4] addressing the role of impurity disorder in diluted magnetic semiconductors (DMS), we investigate the effects of disorder using a simple tight-binding Hamiltonian with random impurity potential and spin-fermion exchange which is self-consistently solved using the typical medium theory. Adopting the typical density of states (TDoS) as the order parameter, we find that the TDoS vanishes below a critical concentration of the impurity, which indicates an Anderson localization transition in the system. Our results qualitatively explain why at concentrations lower than a critical value DMS are insulating and paramagnetic, while at larger concentrations are ferromagnetic. We also compare several simple models to explore the interplay between ferromagnetic order and disorder induced insulating behavior, and the role of the spin-orbit interaction on this competition. We apply our findings to (Ga,Mn)As and (Ga,Mn)N to compare and contrast their phase diagrams.

4:06PM W23.00007 Encoding the structure of many-body localization with matrix product operators, DAVID PEKKER, University of Pittsburgh, BRYAN K. CLARK, University of Illinois at Urbana Champaign — Anderson insulators are non-interacting disordered systems which have localized single particle eigenstates. The interacting analogue of Anderson insulators are the Many-Body Localized (MBL) phases. The natural language for representing the spectrum of the Anderson insulator is that of product states over the single-particle modes. We show that product states over Matrix Product Operators of small bond dimension is the corresponding natural language for describing the MBL phases. In this language all of the many-body eigenstates are encode by Matrix Product States (i.e. DMRG wave function) consisting of only two sets of low bond-dimension matrices per site: the $G_i$ matrix corresponding to the local ground state on site $i$ and the $E_i$ matrix corresponding to the local excited state. All $2^n$ eigenstates can be generated from all possible combinations of these matrices.

4:18PM W23.00008 Typical density of states as an order parameter for the Anderson localization , KA-MING TAM, CONRAD MOORE, JUANA MORENO, MARK HARRELL, Louisiana State University — The typical medium theory and its recently proposed extensions for models with off-diagonal disorder and multiple bands are significant progress towards the study of localization phenomenon in real materials. The fundamental assumption of these methods is that the typical density of states can be treated as an order parameter. However, its justifications in lattice model is largely lacking. This is predominantly due to two factors. First, the lattice sizes amenable for exact diagonalization is rather limited. Second, the small lattice sizes lead to a very sensitive dependence on the broadening factor. In this work, we use the kernel polynomial method to perform simulation for large system sizes. By adapting the method for the study of criticality, we find that the typical density of states has a well defined finite size scaling behavior. In particular, from the kurtosis, Binder ratio, of the distribution of the density of states for different lattice sizes, we find a clear crossing to identify the critical point. This provides further support that the typical density of states can be used as an order parameter for the localization transition.

3:30PM W24.00006 Projector Augmented-Wave formulation of response to strain and electric field perturbation within the density-functional perturbation theory. ALEXANDRE MARTIN, CEA-DIF, Arpajon, France, MARC TORRENT, CEA-DIF, Arpajon, France, RAZVAN CARACAS, CNRS - ENS Lyon, France — A formulation of the response of a system to strain and electric field perturbations in the pseudopotential-based density functional perturbation theory (DFPT) has been proposed by D.R Hamman and co-workers. It uses an elegant formalism based on the expression of DFT total energy in reduced coordinates, the key quantity being the metric tensor and its first and second derivatives [1]. We propose to extend this formulation to the Projector Augmented-Wave approach (PAW). In this context, we express the full elastic tensor including the strain tensor (the response to electric field change (piezoelectric tensor and effective charges). With this we are able to compute the elastic tensor for all materials (metals and insulators) within a fully analytical formulation. The comparison with finite differences calculations on simple systems shows an excellent agreement. This formalism has been implemented in the planewave code ABINIT. We apply it to the computation of elastic properties and seismic-wave velocities of iron with impurity elements. By analogy with the materials contained in meteorites, tested impurities are light elements (H, O, C, S, Si).

3:42PM W24.00007 Constructing Wannier functions with automatically selected trial orbitals, JAMAL I. MUSTAFA, SINISA COH, MARVIN L. COHEN, STEVEN G. LOUIE, University of California at Berkeley, Lawrence Berkeley National Lab — Maximally localized Wannier functions (MLWFs) are widely used in electronic structure theory. Some applications include analysis of chemical bonding, electric polarization, orbital magnetization, and Wannier interpolation. The state of the art method for constructing MLWFs of N composite bands is based on the method of Marzari and Vanderbilt (MV) and is implemented in the Wannier90 code. One of the practical difficulties in constructing Wannier functions using the MV method is choosing the set of starting atomic orbitals and then selecting an optimal subspace of them. We propose a new approach which puts conditions only on the density and potentials. This approach allows a proof that if the density is continuous and nowhere vanishing, then a representing potential in $L^2 + L^\infty$ is unique up to an overall constant.

2:42PM W24.00002 a new approach to Hohenberg-Kohn theorem. PAUL LAMMERT, Pennsylvania State Univ — The Hohenberg-Kohn theorem is a cornerstone of electronic density functional theory, and yet in order to carry through its proof one must assume that ground state wavefunctions never vanish on a set of nonzero Lebesgue measure. This is a particularly unsatisfactory situation since DFT is supposed to avoid need of knowing the many-body wavefunction. I propose a new approach which puts conditions only on the density and potentials. This approach allows a proof that if the density is continuous and nowhere vanishing, then a representing potential in $L^2 + L^\infty$ is unique up to an overall constant.

2:54PM W24.00003 Enhanced transferability for Bethe-Salpeter Calculations, ERIC L. SHIRLEY, NIST — We have systematized projector-augmented-wave methods to reliably augment plane-wave/pseudopotential Bloch functions in atomic core regions for purposes of performing screening calculations, evaluating transition matrix elements, and evaluating Slater integrals in the condensed matter environment. This has improved the accuracy of core-hole screening, adherence to sum rules, and control of the strength of absorption features. This also ensures that transition matrix elements and concomitant core excitation spectra are reliable over significant energy ranges. To accomplish this, we improve the quality of the pseudopotentials (which become harder), extending norm conservation, and increasing the number of “valence electrons.” We present results for both insulators and metals, and for both core and valence excitations. Comparison to experimental data is a key part of this work. We also emphasize what approximations remain to be tackled in the treatment of electronic excitation spectra, many of which are more difficult to treat than what is within the scope of this work.

3:06PM W24.00004 A convergence test of the full potential KKR method, G.M. STOCKS, Oak Ridge National Laboratory, YANG WANG, Pittsburgh Supercomputing Center, Carnegie Mellon University — The full-potential Korringa-Kohn-Rostoker (KKR) method is a powerful tool for the ab initio study of the electronic structure of solids. In this method, the expansion of crystal wave functions, the LDA potential, and the charge density are determined by three angular momentum parameters respectively. Essentially, these three angular momentum parameters are an important key for controlling the convergence of an electronic structure calculation. In this presentation, we demonstrate the convergence character of the full potential KKR method by running the electronic structure calculation for a set of transition metals. We will discuss the implication of the results, and show the optimal choice of the angular momentum parameters, which are the one that requires the least computational cost for the desired accuracy for the total energy.
Different parametrizations are examined. The ability to distinguish metallic and Mott insulating solutions is analysed. In DMFT applications, a key issue is the choice of descriptor, the data representation used as input for ML, which is not dependent on the impurity solver. That ML can be used efficiently for the Anderson impurity model (AIM) [1] and present preliminary results on its use as a solver for dynamical mean field theory (DMFT) framework, it is shown that the dielectric matrix parametrization, which is usually applied to calculate the random phase approximation (RPA) correlation energy, can also be used for alternative RPA expressions including exchange effects. Within this framework we derive a simple effective theory for the correlation energy within the second order screened exchange (SOSEX), an approximate time-dependent Hartree-Fock (TDHF), and second order Möller-Plesset (MP2) levels of theory. The accuracy of these approaches can be further improved by the effect of screening to obtain an approximate formulation of the Bethe-Salpeter equation for correlation energies. The proposed formalism is particularly suitable for implementation in periodic boundary condition plane-wave codes, in particular by using a compact basis set to represent dielectric matrices [1,2]. To demonstrate the accuracy of these approaches the binding curves of several diatomic molecules will be shown.

but does not meet the analytic upper bound of a linear scaling with relative density that is predicted for stretching dominated geometries like the octet-truss.

Combining novel nanoscale mechanical properties with a 3-dimensional architecture enables the creation of new classes of materials with tunable properties. These structures can be made on length scales spanning multiple orders of magnitude, from tens of nanometers to hundreds of microns. The smallest features are controllable on length scales where materials have been shown to exhibit size effects in their mechanical response. In contrast to the traditional ground state structure prediction method where the total energy was solely used as the fitness function, we adopted a new fitness function in combination with the first-principles calculation to select the optimal solutions for a description of given chemical systems. The result suggested that our approach is reliable and can be widely applied into design of new electrides.

This work was supported by the Austrian Spezialforschungsbereich Vienna Computational Materials Laboratory (SFB ViCoM) and the Deutsche Forschungsgruppe (FOR) 1346.

5:18PM W24.00015 Self-consistent GW(QP)+Vertex calculations for the insulating oxides of transition (rare earth) metals, ANDREY KUTFEPPOV, VLADIMIR ANTROPOV, Ames Lab, Ames, IA, SERGEY SAVRASOV, University of California, Davis, CA, GABRIEL KOTLIAR, Rutgers University, Piscataway, NJ — Searching for a methodology with predictive power we have developed recently a new approach incorporating many-body vertex corrections into GW-based numerical schemes. Here we apply it to study the electronic structure of the following materials: SrTiO3, TiO2, NiO, and CeO2. We compare four different variations of the scheme: GW, GW+Vertex, QP (quasi-particle), and QP+Vertex. All calculations have self-consistency, at either the full or the QP level. Whereas vertex corrected GW approximation only partially corrects the GW results the QPGW approximation supplemented with first order vertex corrections to both polarizability and self energy allows us to improve essentially the agreement between calculated and experimental spectra. The addition of vertex correction diagrams to the GW method is straightforward. We discuss the subtleties involved in the addition of vertex corrections to the QPGW method. Formally our approach can be considered as fully self-consistent GW(QP)+DMFT with a perturbative impurity solver and the implications for GW(QP)+DMFT will be discussed.

2:30PM W25.00001 ABSTRACT MOVED TO F23.00009 –

2:42PM W25.00002 Dsigen of Inorganic Electrodes, ZHANG YUNWEI, PENG FENG, MA YANMING, Stake Key Laboratory of Superhard Materials, Jilin University — Electrodes, in which all of or part of the valence electrons occupy interstitial regions in the crystal and behave as anions, have been synthesized at ambient or high-pressure conditions [1]. Their loosely bound anionic electrons make electrodes good candidates for electroactive materials. Here, we report a developed methodology to systematically design electrodes for given chemical systems. The new approach is based on the swarm-intelligence CALYPSO algorithm on structure prediction [2-3] and requires only the chemical compositions to predict the electrode phases. In contrast to the traditional ground state structure prediction method where the total energy was solely used as the fitness function, we adopted a new fitness function in combination with the first-principles calculation to select the optimal solutions for a description of given chemical systems. The result suggested that our approach is reliable and can be widely applied into design of new electrodes.

2:54PM W25.00003 Spontaneous thermally-induced delamination of polymer films, PUNIT KOHLI, KEXIN JIAO, CHUANHONG ZHOU, JARED WYNNE, ANISH POUDE, PHILIP CHU, Southern IL Univ-Carbondale, CHEMISTRY AND BIOCHEMISTRY — In this talk, we will discuss spontaneous thermally-induced biaxial delamination of thin polymer films from flat surfaces. The delamination results in the formation of ultra-high aspect ratio (up to 1000) of micro-ribbons of polydimethylsiloxane. The thickness, width, and length of the micro-ribbons is about 10 µm, 100 µm, and up to many centimeter respectively. We will demonstrate that the formation of polymer micro-ribbons can be experimentally controlled. Specifically, the thickness and mechanical properties of polymer, and geometrical and physical properties of the substrate played crucial roles in defining the delamination process. From the practical viewpoint, we demonstrate the use of the micro-ribbons for imaging and separation applications.

3:06PM W25.00004 Mechanical properties of 3D ceramic nanolattices, LUCAS MEZA, California Institute of Technology — Developments in advanced nanoscale fabrication techniques have allowed for the creation of 3-dimensional hierarchical structural meta-materials that can be designed with arbitrary geometry. These structures can be made on length scales spanning multiple orders of magnitude, from tens of nanometers to hundreds of microns. The smallest features are controllable on length scales where materials have been shown to exhibit size effects in their mechanical properties. Combining novel nanoscale mechanical properties with a 3-dimensional architecture enables the creation of new classes of materials with tunable and unprecedented mechanical properties. We present the fabrication and mechanical deformation of hollow tube alumina nanolattices that were fabricated using two-photon lithography direct laser writing (DLW), atomic layer deposition (ALD), and oxygen plasma etching. Nanolattices were designed in a number of different geometries including octet-truss, octahedron, and 3D Kagome. Additionally, a number of structural parameters were varied including tube wall thickness (t), tube major axis (a), and unit cell size (L). The resulting nanolattices had a range of densities from 0 = 4 to 250 mg/cm³. Uniaxial compression and cyclic loading tests were performed on the nanolattices to obtain the yield strength and modulus. In these tests, a marked change in the deformation response was observed when the thickness was reduced below 20nm: thick-walled nanolattices (>20nm) underwent catastrophic, brittle failure, while thick-walled nanolattices (>20nm) underwent catastrophic, brittle failure. Thick-walled nanolattices also exhibited no recovery after compression, while thin-walled structures demonstrated notable recovery, with some recovering by 98% after compression to 50% strain and by 80% when compressed to 90% strain. Across all geometries, unit cell sizes, and wall thicknesses, we found a consistent power law relation between strength and modulus with relative density of E ∝ ρα and σ ∝ ρβ. This scaling marks an improvement over the formation of lightweight and ultralight materials, which normally scale as E ∝ ρ2 or E ∝ ρ3, but does not meet the analytic upper bound of a linear scaling with relative density that is predicted for stretching dominated geometries like the octet-truss.

3:42PM W25.00005 ABSTRACT WITHDRAWN –
The graphene film. The amplitude data was used to calculate the mechanical resistance and slip time for water molecules sliding on the graphene surface. The measurements were performed with the QCM mounted in vacuum, and then water vapor was slowly introduced into the vacuum chamber until it reached saturation, while simultaneously monitoring the frequency and amplitude of the QCM. Negative shifts in frequency were observed, indicating that water vapor formed a film on the graphene film. The amplitude data was used to calculate the mechanical resistance and slip time for water molecules sliding on the graphene surface. The low slip time indicates a relatively low friction between a water film and graphene. Funding provided by NSF DMR.

3:54PM W25.00006 Shock induced chemistry in granular Ni/Al nanocomposites. MATHEW CHERUKARA, Purdue Univ, TIMOTHY GERMANN, EDWARD KOBER, Los Alamos National Lab, ALEJANDRO STRACHAN, Purdue Univ — Intermolecular reactive composites find diverse applications in defense, microelectronics and medicine, where strong, localized sources of heat are required. However, fundamental questions of the initiation and propagation mechanisms on the nanoscale remain to be addressed, which is a roadblock to their widespread application. Motivated by experimental work which has shown that high-energy ball milling can significantly improve the reactivity as well as the ease of ignition of Ni/Al inter-metallic composites, we present large scale (~ 41 million atom) molecular dynamics simulations of shock-induced chemistry in granular Ni/Al nano-composites, which are designed to capture the microstructure that is obtained post milling. Shock propagation in these granular composites is observed to be extremely diffuse at low piston velocities, leading to a large inhomogeneity in the local stress states of the material. At higher piston velocities, the shock front is more homogeneous as a consequence of a change in the compaction mechanism; from plastic deformation mediated pore collapse at low piston velocities, to fluid filling of the pores at higher impact velocities. The flow of molten ejecta into the pores subsequently leads to the formation of vortices, where the reaction progresses much faster than in the bulk.

4:06PM W25.00007 Stoichiometric Control of DNA-Grafted Colloid Self-Assembly. THI VO, VENKAT VENKATASUBRAMANIAN, SANAT KUMAR, Columbia University, BABJI SRINIVASAN, Indian Institute of Technology - Gandhinagar, SUCHETAN PAL, YUGANG ZHANG, OLEG GANG, Brookhaven National Lab — There have been recent surges of interest in understanding the self-assembly of DNA-grafted colloids into different crystallographic lattices, namely CsCl, AIB2, Cr3Si, and Cs6SiC60. Conventional approaches view the number of grafted linkers and effective size of each colloid as the major governing design parameters. It is generally assumed that the mixed stoichiometries need to match those defined by the target structures in order to obtain the desired lattice. Thus, contributions from stoichiometry are considered secondary and its exact effects on lattice formation remains an open question. Theoretical extensions to the popular complementary contact model show that the equilibrium lattice structure can be tuned through direct control of stoichiometry. Our results are also validated through experimental observations of the equilibrium crystal morphologies at differing stoichiometric ratios. These findings strongly suggest that stoichiometry is a new handle that can be used to control DNA-grafted colloidal self-assembly.

4:18PM W25.00008 Computational Study of Nanoparticle Clustering via DNA Hyperdyzation1. XIU MA, MARK J. BOWICK, Syracuse University, RASTIKO SKNEPNEK, University of Dundee — We use molecular dynamics simulation to study the self-assembly of small clusters through DNA hybridization in a binary mixture of spherical nucleic acid gold nanoparticles(SNA-GNPs) system. The resultant structures are self-assembled clusters with a varying number of large SNA-GNPs clusters around the small ones, forming dimers, trimmers, tetramers etc. The outcome structures can be tuned by adjusting external factors including temperature, particle hydrodynamics size ratio.

3:54PM W25.00006 Shock induced chemistry in granular Ni/Al nanocomposites. 3:40PM W25.00009 Tetrahedrally bonded carbonates and aqueous carbonate anions under extreme conditions1. DING PAN, GIULIA GALLI, Institute for Molecular Engineering, the University of Chicago, DEEP CARBON OBSERVATORY COLLABORATION — The carbonate ion, CO3<sup>-2</sup>, has a trigonal planar structure composed of carbon bonded with three oxygen atoms. The existence of tetrahedrally bonded carbonate units, CO3, analogous to SiO4 in silicates, has long been under debate. Using a combination of first-principles calculations and in situ infrared spectroscopy measurements [1], we provided definitive evidence that in magnesite, at pressures above 80 GPa, sp<sup>3</sup> bonded CO3 trigonal groups transforms into sp<sup>2</sup> bonded CO3 tetrahedral units. These units were found to be asymmetric, with two longer and two shorter C-O bonds. In addition, using first principles molecular dynamics we investigated carbonate anions in water at high temperature and pressure, corresponding to Earth’s upper mantle conditions. We found significant quantities of bicarbonate ions dissolved in the liquid. The relevance of our simulation results for geophysical models of hydrous carbonates in the Earth will be discussed.

4:54PM W25.00011 Fluorescent probes for shock compression spectroscopy. ALEXANDR BANISHEV, JAMES CHRISTENSEN, DANA DLOTT, University of Illinois at Urbana-Champaign — We have demonstrated the capability of using Rhodamine 6G dye as an ultrafast emission probe in high-speed shock compression of condensed matter. The ultimate time response of the probe, which functions as a high-speed pressure sensor, is limited by fundamental photophysical processes such as radiative rates, internal conversion rates and intersystem crossing rates. The time response has been greatly improved by encapsulating the dye in silica nano or microparticles. This probe was used to observed nanosecond viscoelastic shock compression of a polymer (PMMA), and has been used to monitor the response of individual grains of sand to high-speed impact.

5:06PM W25.00012 Sliding friction levels of water films on graphene measured by means of QCM. ZIJIAN LIU, SAMUEL KENNY, ZACHARY FREDRICKS, JACQUELINE KRIM, North Carolina State University — Diffusion and sliding friction of water on graphene is a matter of great current interest [1]. To study the surface friction of water on graphene, we recorded water film adsorption on a graphene film coated quartz crystal microbalance (QCM). Graphene films were deposited on QCMs via evaporation in vacuum on nickel substrates. Measurements were performed with the QCM mounted in vacuum, and then water vapor was slowly introduced into the vacuum chamber until it reached saturation, while simultaneously monitoring the frequency and amplitude of the QCM. Negative shifts in frequency were observed, indicating that water vapor formed a film on the graphene film. The amplitude data was used to calculate the mechanical resistance and slip time for water molecules sliding on the graphene surface. The low slip time indicates a relatively low friction between a water film and graphene. Funding provided by NSF DMR.

2:54PM W26.00003 Ultrafast Electron-Ion Dynamics Near Aluminum Surfaces, ANDRE SCHLEIFE, KAI WELLS, SAM KNEWSTUB, University of Illinois - Urbana — Computational physics and materials research have greatly benefited from high-performance computing; modern first-principles simulations allow insight with unprecedented accuracy and detail. Here we use a recently highly parallel implementation of Ehrenfest molecular dynamics based on real-time time-dependent density functional theory to describe non-adiabatic ultrafast electron-ion dynamics using accurate first-principles calculations. We experiment aluminum subject to highly energetic particle radiation (hydrogen projectile) and study energy deposition due to the fast projectiles. Their high velocity makes it necessary to overcome the Born-Oppenheimer approximation. Using our first-principles calculations we study the behavior of fast ions near the surface of aluminum slabs and investigate, for instance, the influence of velocity and impact angle of the projectile ion. From the emerging non-adiabatic electron-ion dynamics we gain insight into the material on an atto-second time scale.

3:06PM W26.00004 New spectroscopic approaches for periodic systems, SANDRA LUBER, University of Zurich — Knowledge about local properties is extremely helpful for the analysis of structures and interactions. Moreover, it is a valuable source of information for the characterisation of dynamic processes and facilitates the interpretation of experimental data. In case of vibrational spectroscopy, for example, it is desirable to determine the impact of certain atoms/molecules on the bands in the experimental spectra. This may be straightforward for simple systems but becomes more and more complex for larger systems. Calculations provide additional insight allowing the targeted study of specific structures. In this way, it is possible to quantify the contributions of, for instance, solute and solvent molecules or adsorbates on solids. We present novel, computationally efficient methods for the calculation of properties for periodic systems such as liquids and solids. These are applied to calculate, among others, vibrational spectra via ab initio molecular dynamics [2,3]. References: [1] S. Luber, J. Phys. Chem. A 117 (2013) 2760. [2] S. Luber, M. Iannuzzi, J. Hutter, J. Chem. Phys. 141 (2014) 094503.[3] S. Luber, submitted.

3:18PM W26.00005 Polarons in rutile TiO2 surfaces: a non-adiabatic excited-state dynamics study, GRIGORY KOLESOV, School of Engineering and Applied Sciences, Harvard University, DMITRY VINICHENKO, Department of Chemistry and Chemical Biology, Harvard University, GEORGIOS TRITSARIS, School of Engineering and Applied Sciences, Harvard University, CYNTHIA FRIEND, Department of Chemistry and Chemical Biology, Harvard University, EFFTHIMIOS KAXIRAS, School of Engineering and Applied Sciences, Department of Physics, Harvard University — Titanium dioxide is one of the most thoroughly studied photocatalytic materials with numerous proposed applications ranging from hydrogen production to cleanup of environmental pollutants. Photocatalytic methoxy splitting on rutile TiO2 (110) surfaces that leads to formation of formaldehyde has been previously observed in STM and TPD experiments. Due to complexity of such photocatalytic reactions the computational simulations of these reactions are requisite for providing insight into their underlying mechanisms and are crucial for the rational design of new photocatalysts. Because such simulations are necessarily computationally expensive we developed an efficient methodology based on time-dependent density functional theory (TDDFT) and localized basis set. Our recent non-adiabatic simulations of the photo-catalytic methoxy splitting on titania surface demonstrate an extremely important role played in these reactions by surface and subsurface polarons. Here the polarons serve as electron acceptor sites that participate in driving the reaction and are required to stabilize the reaction products and allow for their subsequent desorption from the surface. In this work we focus on the polarons in rutile titanium surfaces and study dynamics of their formation and their properties.

3:30PM W26.00006 TDDFT+DMFT analysis of excitations and relaxation dynamics in alpha-Ce, SYED ISLAMUDDIN SHAH, VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics, University of Central Florida — We apply a combination of time-dependent density functional theory and dynamic mean-field theory (TDDFT+DMFT) to study the excitation spectrum and response of bulk alpha-Ce to an external perturbation by a laser pulse. The excitation spectrum is obtained by solving TDDFT Casida equation with the “free electron” spectrum calculated from density functional theory and the exchange-correlation (XC) kernel extracted from the DMFT charge susceptibility. We pay special attention to the complex role of the hybridization of the f- with the s-, p-, and d-electron states in the system spectrum. The nonequilibrium solution of the TDDFT equations shows that the short-lived local moments of f-electrons get suppressed as the hybridization strength between the f- and other orbitals increases. We also calculate the effective scattering times for the scattering of the f-electrons from the s-, p-, and d-states at different values of the local Coulomb repulsion and exchange J parameters from the corresponding expression for the orbital-resolved XC kernel, and analyze how these scattering processes may affect the dynamics of the system relaxation.

3:42PM W26.00007 Auger Relaxation of Hot Electrons in CdSe Quantum Dots using GFSH, DHARA TRIVEDI, Department of Physics & Astronomy, University of Rochester, LINJUN WANG, OLEG PREZHDO, Department of Chemistry, University of Southern California — We carry out ab initio nonadiabatic molecular dynamics (NAMD) simulations to study the fast relaxations of hot electrons in a CdSe quantum dot (QD). The reviewed system is a promising candidate for QD-sensitized semiconductor solar cells and the presence of well-separated conduction electron states opens the possibility of energy selectivity for hot carriers. We examine the intraband relaxation of the photoexcited electrons in the QD and the role of surface ligand in the process. A novel global flux surface hopping (GFSH) approach is adopted. We investigate the electron relaxation from the 1Pe to 1Se state in pure and 1.6-hexanediol ligated CdSe QD. The intraband relaxation is accelerated due to the Auger-type relaxation in the pure QD. The ligand forms a hole trapping state, which competes with the Auger-type relaxation impeding the electron-hole energy exchange. The present study establishes the basic theoretical model describing the relaxation processes in both scenarios. The obtained interplay between the competing phonon-assisted Auger and ligand-induced trapping mechanisms has given us a comprehensive picture of the complex photoinduced dynamic related to QDs.
3:54PM W26.00008 New Developments in Ab Initio Multiple Spawning for Efficient Nonadiabatic Molecular Dynamics\textsuperscript{1}, BASILE F.E. CURCHOD, AARON SIETO, DAVID R. GLOWACKI, TODD J. MARTÍNEZ, Stanford University — Ab initio multiple spawning (AIMS) describes the nonadiabatic dynamics of nuclear wavepackets by means of a linear combination of frozen Gaussian states. While the Gaussian centers follow classical trajectories, the expansion coefficients are propagated according to the time-dependent Schrödinger equation. As a result of the coupling between Gaussian functions, AIMS accurately describes coherence and decoherence effects close to nonadiabatic regions. This accuracy has further been validated by the excellent agreement reported between AIMS dynamics and experimental observations. In this Contribution, we will discuss new techniques used to extend the applicability of AIMS to (i) larger molecules, (ii) long-time simulations, and (iii) dynamics involving an important number of electronic states. We present different examples of nonadiabatic molecular dynamics in organic and atmospheric photochemistry, resulting from the interface between AIMS and the GPU-accelerated electronic structure code TeraChem. New methods improving the AIMS efficiency for larger systems will be discussed, such as the stochastic-selection AIMS. Finally, we will highlight early results on the extension of AIMS to the combined description of both internal conversion and intersystem crossing phenomena.

4:06PM W26.00009 Effects of Thermal and Quantum Fluctuations on Dipole-moment distribution of \(H_2O\) molecules in ice \(I_h\)\textsuperscript{1}, PEDRO MOREIRA, UFScar, MAURICE DE KONING, Unicamp — Molecular dipole moments are the fundamental entities that underpin the dielectric behavior of molecular materials. Here, we discuss the molecular dipole distributions of water molecules in ice \(I_h\), considering the roles of proton-disorder, as well as the effects of thermal and quantum fluctuations. For this purpose we employ ab initio Born-Oppenheimer and Path-Integral Molecular Dynamics simulations and compute molecular dipole moments using maximally-localized Wannier functions. We discuss trends in the dipole-moment distributions as a function of temperature.

4:18PM W26.00010 Screened Hybrid Exact Exchange Schemes to Adsorption Energies on Perovskite Oxides, ELTON SANTOS, Department of Chemical Engineering, Stanford University, Stanford, California 94305, USA — ALEKSANDRA VOJVODIC, SLAC National Accelerator Laboratory, Menlo Park, CA, 94305, JENS K. NORSKOV, Department of Chemical Engineering, Stanford University, Stanford, California 94305, USA — The bond formation between an oxide surface and oxygen, which is one of the important intermediates for oxygen evolution reaction, is investigated using hybrid functionals. We show that there exists a linear correlation between the adsorption energies of oxygen on LaM\textsubscript{O3} (M=Sc-Cu) oxides at hybrid calculations to those computed using semilocal density functionals through the magnetic properties of the bulk phase. The energetics of the spin-polarized surfaces follow the same trend as corresponding bulk systems, which can be treated at a much lower computational cost. The difference in adsorption energy due to magnetism is linearly correlated to the magnetization energy of bulk, i.e., the energy difference between the spin-polarized and the non-spin-polarized solutions. This suggests that one could estimate the correction to the semilocal density functional adsorption energies directly from the hybrid bulk magnetization energy.

4:30PM W26.00011 Kinetic compensation effect in thermal desorption, NAYEUL ZUNIGA-HANSEN, Austin Peay State University, LEONARDO E. SILBERT, Southern Illinois University Carbondale, MERCEDES CALBI, University of Denver — The parameters which characterize the rates of many thermally activated processes are often extracted using the Arrhenius equation. A series of closely related thermally activated processes exhibit systematic variations in the energies of activation, \(E_a\), and preexponential factor, \(\theta\), in response to a perturbation, which leads to the concept of 'kinetic compensation', such that the different parameters in the Arrhenius equation balance each other out thereby leading to an implicitly assumed constant rate. However, the compensation effect has not been generally demonstrated and its origins are not completely understood. Using kinetic Monte Carlo simulations on a model interface, we explore how site-adsorbate and adsorbate-adsorbate interactions, and surface structural changes influence surface coverage and the kinetic parameters during a typical temperature programmed desorption process. We find that the concept of the compensation effect for interacting species breaks down and the time consuming desorption increases with increasing interaction strength due to an increase in the effective activation energy. At the 'molecular' level the changes are the result of enhanced site correlations with increasing adsorbate interaction strength suppressing the onset of desorption.

4:42PM W26.00012 First principles molecular dynamics simulations of the static, dynamic and electronic properties of the liquid silver-tin alloy\textsuperscript{1}, LAZARO CALDERIN, The Pennsylvania State University, PA, USA, DAVID GONZALEZ, LUIS E. GONZALEZ, Universidad de Valladolid, Valladolid, Spain — We report an ab-initio molecular dynamics study of several structural and dynamic properties of the liquid Ag-Sn alloy at three concentrations and a temperature of 1273 K. The calculated structural results show good agreement with the available experimental data and accurately reproduce the measured total static structure factors \[1\]. The heterocoordinating tendencies in the alloy have been analyzed in terms of some short range order parameters. As for the dynamical properties, the single particle dynamics in the liquid alloy has been studied by evaluating several velocity correlation functions and the associated diffusion coefficients. Results are also reported for other transport coefficients, such as the adiabatic sound velocities and shear viscosities. Finally, from the spectra of the longitudinal current correlation functions, the longitudinal dispersion curves have been computed. \[1\] I Kaban, W Hoyer, A Ilinski, O Slukhovskii and S Slyusarenko, J. Non-Cryst. Solids, 331, 254-262 (2003)

\textsuperscript{1}We acknowledge financial support from Spanish MSI (project FIS2012-33126).

5:04PM W26.00013 Orbital-free ab initio molecular dynamics study of the free liquid surface of Sn. From pseudopotential generation and dynamic properties\textsuperscript{1}, BEATRIZ GONZALEZ DEL RIO, LUIS ENRIQUE GONZALEZ TESEDO, Universidad de Valladolid — We report results of an orbital-free ab initio molecular dynamics (OF-AIMD) study of the free liquid surface of Sn at 1000 K. A key ingredient in the OF-AIMD method is the local ionic pseudopotential describing the ions-valence electrons interaction. We have developed a force-matching method \[1\] to derive a local ionic pseudopotential suitable to account for a rapidly varying density system, such as in a free liquid surface. We obtain very good results for several structural properties. We have also studied the evolution of some dynamical properties when going from the central region (where the system behaves like the bulk liquid) towards the free liquid surface.

and average responses in junctions that include destructive interference and circular currents.

In this talk, we will introduce the formalism for Noise spectroscopy and illustrate our findings within simple numerical models, displaying time-dependent measurements can be used to detect and quantify intra-molecular processes that occur in the picosecond timescale during the transient regime. In this work, Noise spectroscopy is an intuitive and technically accessible method to model time-dependent transport phenomena in molecular junctions that are driven by electric fields or fluctuating time dependence in the molecular Hamiltonian and is restricted to time-dependent voltages that are adiabatically slow. The method is trivial to computationally functions (NEGF) theory. As shown, the method applies to junctions that can be described by an effective independent-fermion Hamiltonian, admits arbitrary approximations that underlie the method are revealed via a derivation of the effective equations of motion within the framework of non-equilibrium Green's functions. Our method is based on a general analytical solution of the biphasic rate equations. Our method can be used to determine the underlying biphasic interaction mechanism from the analysis of the SPR data, and to extract the rate constants with high confidence levels.

Two-photon absorption (TPA) transition bands of these branched- or butterfly-configured molecules are similar to those in their linear absorption. The molecular TPA cross sections in an excitation environment reach around 50-130 GM, and peak within the available wavelength ranges of a Ti:Sapphire femtosecond oscillator. We also observe that two-photon absorptivity increases progressively with the addition of donor/acceptor moieties on the TPE backbone. This phenomenon is presumably attributed to the improved conjugation length and enhanced intramolecular charge transfer, hence better delocalization of π-system. In UV plasmonics.

We present an aggregation enhancement in two-photon-excited absorption (TPA) transition bands of these branched- or butterfly-configured molecules are similar to those in their linear absorption. The molecular TPA cross sections in an excitation environment reach around 50-130 GM, and peak within the available wavelength ranges of a Ti:Sapphire femtosecond oscillator. We also observe that two-photon absorptivity increases progressively with the addition of donor/acceptor moieties on the TPE backbone. This phenomenon is presumably attributed to the improved conjugation length and enhanced intramolecular charge transfer, hence better delocalization of π-electrons. For each compound, the aggregation enhancement in TPA may also offers clues of aggregation effect on the molecular electronic structure.

Our method is based on a general analytical solution of the biphasic rate equations. Our method can be used to determine the underlying biphasic interaction mechanism from the analysis of the SPR data, and to extract the rate constants with high confidence levels.

Two-photon optical properties of D-TPE-A molecules are introduced into these D-π-A molecules via tetraphenylethylene (TPE), which is used as their π-bridge. Detailed analysis shows that the TPEF of these molecules are enhanced in aggregation environment with both fluorescence quantum efficiency and two-photon absorptivity concomitantly. The two-photon absorption (TPA) transition bands of these branched- or butterfly-configured molecules are similar to those in their linear absorption. The molecular TPA cross sections in an excitation environment reach around 50-130 GM, and peak within the available wavelength ranges of a Ti:Sapphire femtosecond oscillator. We also observe that two-photon absorptivity increases progressively with the addition of donor/acceptor moieties on the TPE backbone. This phenomenon is presumably attributed to the improved conjugation length and enhanced intramolecular charge transfer, hence better delocalization of π-electrons. For each compound, the aggregation enhancement in TPA may also offers clues of aggregation effect on the molecular electronic structure.

A simple method that accurately captures the dynamics of metal-molecule-metal junctions under the influence of time-dependent driving forces is presented. In it, the metallic contacts are modeled explicitly as a discrete set of levels that are dynamically broadened via an artificial damping term in the equations of motion. The approximations that underlie the method are revealed via a derivation of the effective equations of motion within the framework of non-equilibrium Green's functions (NEGF) theory. As shown, the method applies to junctions that can be described by an effective independent-fermion Hamiltonian, admits arbitrary time dependence in the molecular Hamiltonian and is restricted to time-dependent voltages that are adiabatically slow. The method is trivial to computationally implement, has a well defined range where the results are independent of artificial model parameters, and is numerically shown to quantitatively reproduce the time-dependent transport characteristics of a model molecular junction driven by laser fields as described by an exact NEGF method. As such it constitutes an intuitive and technically accessible method to model time-dependent transport phenomena in molecular junctions that are driven by electric fields or fluctuating environments.

Recent theoretical investigations have shown that Ultrafast Laser Pulse Pair Sequences applied to molecular junctions and dc current measurements can be used to detect and quantify intra-molecular processes that occur in the picosecond timescale during the transient regime. In this work, we have continued these investigations and found that while averaged current measurements can capture dynamics directly related to electron transport, one needs to go beyond and consider averaged Noise measurements in order to detect intra-molecular processes not directly participating in the electron transport. In this talk, we will introduce the formalism for this Noise spectroscopy and illustrate our findings within simple numerical models, displaying time-dependent and average responses in junctions that include destructive interference and circular currents.
Resonance Broadening in Molecular Junctions

Our analysis illustrates that interferences can be directly determined from the molecular Hamiltonian and the molecule-electrode couplings. Herein we use linear algebra and the Landauer-Büttiker theory for electron transport to derive a general rule for predicting the existence and locations of interferences in electrode-molecule-electrode transport junctions. We believe that a similar analysis may contribute to the understanding of many phenomena characteristic to the fields of nano- and molecular-electronics.

Quantum model of capacitance of nanostructures

We present new insights into the role dimensionality plays in the lead-molecule coupling scheme at molecular electronic junctions. A key ingredient of our approach is a transformation of the Hamiltonian matrix from an atomistic to a state representation of the molecular junction. This provides direct access to the different couplings between the molecular states and the energy manifold of the leads, which underlie the transport properties of molecular junctions. We explore several tight-binding junction models and predict the appearance of coupling bands that depend on the dimensionality and shape of the leads. We believe that a similar analysis may contribute to the understanding of many phenomena characteristic to the fields of nano- and molecular-electronics.

The role of dimensionality on the molecule-lead coupling in molecular electronic junctions

We present new insights into the role dimensionality plays in the lead-molecule coupling scheme at molecular electronic junctions. A key ingredient of our approach is a transformation of the Hamiltonian matrix from an atomistic to a state representation of the molecular junction. This provides direct access to the different couplings between the molecular states and the energy manifold of the leads, which underlie the transport properties of molecular junctions. We explore several tight-binding junction models and predict the appearance of coupling bands that depend on the dimensionality and shape of the leads. We believe that a similar analysis may contribute to the understanding of many phenomena characteristic to the fields of nano- and molecular-electronics.

‘Soft’ amplifier circuits based on field-effect ionic transistors

We present new insights into the role dimensionality plays in the lead-molecule coupling scheme at molecular electronic junctions. A key ingredient of our approach is a transformation of the Hamiltonian matrix from an atomistic to a state representation of the molecular junction. This provides direct access to the different couplings between the molecular states and the energy manifold of the leads, which underlie the transport properties of molecular junctions. We explore several tight-binding junction models and predict the appearance of coupling bands that depend on the dimensionality and shape of the leads. We believe that a similar analysis may contribute to the understanding of many phenomena characteristic to the fields of nano- and molecular-electronics.

We establish a theoretical framework in terms of the curl flux, population landscape, and coherence for non- equilibrium quantum systems at steady state, through exploring the energy and charge transport in molecular processes. The curl quantum flux plays the key role in determining transport properties and the system reaches equilibrium when flux vanishes. The novel curl quantum flux reflects the degree of non-equilibriumness and the time irreversibility. We found an analytical expression for the quantum flux and its relationship to the environmental pumping (non-equilibriumness quantified by the voltage away from the equilibrium) and the quantum tunneling. Furthermore, we investigated another quantum signature, the coherence, quantitatively measured by the non-zero off diagonal element of the density matrix. Quantum flux is promoted by the coherence in the regime of small tunneling while reduced by the coherence in the regime of large tunneling, due to the non-monotonic relationship between the coherence and tunneling. For the systems coupled to bosonic (photonic and phononic) reservoirs the flux is significantly promoted at large voltage while for fermionic (electronic) reservoirs the flux reaches a saturation after a significant enhancement at large voltage.

EPR Studies of orthorhombic Jahn-Teller effect in single crystal of ferroelectric Cu(II)Cds(NH4)2(SO4)3

The isotropic EPR spectra of the 2D ion (in regular octahedral symmetry) at higher temperature becomes anisotropic at low temperature with clear manifestation of orthorhombic g and hyperfine tensors at 15 K. The static Jahn-Teller(JT) effect can only be explained theoretically by assuming the three JT potential wells energetically inequivalent, unlike the potential wells in most of the Cu(II) doped crystalline materials where JT effect manifests. The measured splitting of the JT potential wells in this ferroelectric crystal fall in the sub millimeter wave region pointing to possible application of the material.
5:18PM W27.00015 Probing molecular dynamics at the nanoscale via an individual paramagnetic center TOBIAS STAUDACHER, 3rd Institute of Physics and Research Center SCOPE, University Stuttgart, NICOLE RAATZ, SEBASTIEN PEZZAGNA, JAN MEIJER, Institute for experimental physics II, University of Leipzig, FRIEDMANN REINHARD, Walter Schottky Institut, Technical University Munich, CARLOS MERILES, CUNY-City College of New York, JOERG WRACHTTRUP, 3rd Institute of Physics and Research Center SCOPE, University Stuttgart — We use shallow NVs to probe mesoscale proton ensembles from different substances deposited on the diamond surface. We resort to a form of correlation spectroscopy to reconstruct the equivalent of a nuclear “free-induction-decay” (FID), which, unlike the NMR counterpart, does not require nuclear spin pre-polarization. This pseudo FID has a limit decay time governed by the NV spin-lattice relaxation time T1 (typically longer than the NV coherence lifetime T2), which allows us to attain spectral resolution superior to that possible with standard magnetometry techniques. Upon applying this scheme to solid- and liquid-state substances we find substantial differences in the correlation signal lifetime, which we associate with the presumably different molecular dynamics governing these systems. In particular, we observe long-lived 1H signals from oil molecules, likely a consequence of the interplay between fast molecular tumbling and slow self-diffusion.

Session W28 GMAG DMP FIAP: Focus Session: Spin Caloritronics 205 - Geoffrey Beach, Massachusetts Institute of Technology

2:30PM W28.00001 Spin-current phenomena at high magnetic fields and high temperatures KEN-ICHI UCHIDA, Institute for Materials Research, Tohoku University — In the field of spintronics, many experimental and theoretical studies have been focused on spin-transport phenomena in paramagnet/ferromagnet junction systems, where a spin current plays a central role. After the first demonstration of spin transport in insulator-based systems [1], a Pt/YIG junction system becomes one of the prototype samples. In this system, itinerant spins in Pt and localized magnetic moments in YIG interact with each other via the interface s-d interaction, i.e., the spin-mixing conductance: this interaction is the basic mechanism underlying various spin-current-related phenomena, such as the spin pumping [1], the spin Seebeck effect [2], and the recently-discovered spin Hall magnetoresistance (SMR) [3]. In this talk, we report the observation of the longitudinal spin Seebeck effect (LSSE) [4] and the SMR in Pt/YIG systems at high magnetic fields and high temperatures. The LSSE measurements in a high magnetic field range confirm that the observed voltage in the Pt/YIG systems is of magnon origin, providing a useful way to distinguish the LSSE from the anomalous Nernst effect induced by proximity ferromagnetism in Pt [5]. The LSSE and SMR at high temperatures highlight the importance of the temperature dependence of the spin-mixing conductance at the Pt/YIG interface [6]. These results will be helpful for obtaining full understanding of the mechanism of the LSSE and SMR.

We thank E. Saitoh, S. Maekawa, G. E. W. Bauer, H. Adachi, Y. Ohnuma, T. Kikkawa, S. Daimon, Y. Shiomi, and J. Shiomi for their support and valuable discussions.

3:06PM W28.00002 ABSTRACT WITHDRAWN –

3:18PM W28.00003 Spin current draining effect on heat-driven spin transport1, YADONG XU, BOWEN YANG, CHI TANG, ZI Long JIANG, JING SHI, UC Riverside, MICHAEL SCHNEIDER, RENU WHIG, Everspin Technologies — As a non-magnetic heavy metal is attached to a ferromagnet, a vertically flowing heat-driven spin current is converted to a transverse electric voltage, which is known as the longitudinal spin Seebeck effect. If the ferromagnet is a metal, this voltage is also accompanied by voltages from two other sources, i.e. the anomalous Nernst effect in both the ferromagnet and the proximity-induced ferromagnetic boundary layer. In this work, we have investigated these phenomena in NiFe/Cu/heavy metal multilayer structure. By identifying and carefully separating those effects, we find that in this pure spin current circuit the additional spin current drawn by the heavy metal generates another voltage in the ferromagnetic metal via the inverse spin Hall effect.

3:30PM W28.00004 Mechanism of the two sign changes in the spin Seebeck effect of a compensated ferrimagnet, YUICHI OHNUMA, Tohoku University, HIROTO ADACHI, Japan Atomic Energy Agency, EIJI SAITO,H, Tohoku University, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — Spin Seebeck effect is the mechanism of thermal spin injection from a precessing ferromagnet into an attached paramagnetic metal [Uchida et al., Nature 455, 778 (2008)]. We have theoretically investigated the spin Seebeck effect in compensated ferrimagnets [Ohnuma et al., Phys. Rev. B 87, 014423 (2013)] and predicted that the sign of the spin Seebeck signal changes at the compensation temperature, which is recently confirmed by an experiment [Gepr"ags et al., arXiv:1405.4971 (2014)]. Interestingly, the experiment found another sign change at a lower temperature. Here we explain its origin by taking account of sublattice dependence of the exchange coupling at the ferrimagnet/paramagnet interface.

3:42PM W28.00005 The effect of magnetic anisotropy on spin-dependent thermoelectric effects in nanoscopic systems1, MACIEJ MISIORY, Chammers University of Technology (Gothenburg, Sweden) and Adam Mickiewicz University (Poznañ, Poland), JóZEF BARNAS, Adam Mickiewicz University (Poznañ, Poland) — Harnessing of the interplay between transport of charge, spin and energy is a prospect route towards maximizing the functional potential of nanoscopic electronic and spintronic devices. Here, we investigate theoretically spin-related thermoelectric effects in electronic, linear-response transport through a nanoscopic systems exhibiting magnetic anisotropy. As an example, a magnetic tunnel junction with a large-spin impurity—either a magnetic atom or molecule—embedded in the barrier is considered. Conduction electrons traversing the junction can then scatter on the impurity, which effectively can lead to angular momentum and energy exchange between the electrons and the impurity. As we show, such processes have a profound effect on the thermoelectric response of the system. Since the scattering mechanism also involves processes when electrons are inelastically scattered back to the same electrode, one can expect the flow of spin and energy also in the absence of charge transport through the junction. This, in turn, results in a finite spin thermopower, and the magnetic anisotropy plays a key role for this effect to occur. [1] M. Misiorny and Barnañ, Phys. Rev. B 89, 235438 (2014). [2] M. Misiorny and Barnañ, arXiv:1411.2741 (submitted for publication).

3:54PM W28.00006 Optical detection of Spin-Seebeck Effect in Ferromagnetic thin films. RYAN MCLAUGHLIN, DANI SUN, VALY VARDYEN, University of Utah — The field of Spin Caloritronics has attracted great interest because of the generation of spin currents in the presence of temperature gradients, mainly detected by means of an Inverse Spin Hall Effect (ISHE) voltage in metals with strong spin-orbit coupling. However, this method of electrical detection is difficult due to the subtle voltage generated by the ISHE combined with a large number of artifacts such as proximity effect, anisotropic magnetoresistance, anomalous Nernst effect, etc., which makes a quantitative understanding of the Spin Seebeck Effect elusive. Instead, here we demonstrate an optical detection of spin accumulation in Ferromagnetic thin films using a custom-built Kerr Rotation sensitive interferometer, enabling us to investigate the pure spin accumulation from Spin Seebeck in the absence of spurious effects.

4:06PM W28.00007 Separation of the inverse spin Hall effect and anomalous Nernst effect in a single ferromagnetic metal using on-chip spin Seebeck devices. STEPHEN WU, JASON HOFFMAN, JOHN PEARSON, ANAND BHATTACHARYA, Argonne National Laboratory — The longitudinal spin Seebeck effect is measured on the ferromagnetic insulator Fe3O4 with the ferromagnetic metal Co0.2Fe0.8B0.2 (CoFeB) as the spin detector in a micro-patterned device structure using an on-chip heater. By using a non-magnetic spacer material between the two materials (Ti), it is possible to decouple the two ferromagnetic materials and directly observe pure spin flow from Fe3O4 into CoFeB. It is shown, that in a single ferromagnetic metal the inverse spin Hall effect (ISHE) and anomalous Nernst effect (ANE) can occur simultaneously with opposite polarity. Using this and the large difference in the coercive fields between the two magnets, it is possible to unambiguously separate the contributions of the spin Seebeck effect from the ANE and observe the degree to which each effect contributes to the total response within a single experiment. Additionally, by using the spin detector layer as a thermometer, an accurate value for the thermal gradient across the device can be measured. These results match well with thermal simulations of our device structure.

3:54PM W28.00008 Thermal Hall Effect of Spins in a Paramagnet. HYUNYONG LEE, JUNG HOON HAN, Department of Physics, Sungkyunkwan University, Suwon 440-746, Korea, PATRICK LEE, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA — Theory of Hall transport of spins in a correlated paramagnetic phase is developed. By identifying the thermal Hall current operator in the spin language, which turns out to equal the spin chirality in the pure Heisenberg model, various response functions can be derived straightforwardly. Subsequent reduction to the Schwinger boson representation of spins allows a convenient calculation of thermal and spin Hall coefficients in the paramagnetic regime using self-consistent mean-field theory. Comparison is made to results from the Holstein-Primakoff reduction of spin operators appropriate for ordered phases.

4:30PM W28.00009 Ultrafast Time-correlated Measurements of Spin-Seebeck effect in Yttrium Iron Garnet. JOHN JAMISON, BRANDON GILES, Department of Materials Science and Engineering, The Ohio State University, Columbus, OH, ZHIHAO YANG, Department of Electrical and Computer Engineering, The Ohio State University, Columbus, OH, ROBERTO MYERS, Department of Materials Science and Engineering, The Ohio State University, Columbus, OH — Recently, the time dependence of the spin-Seebeck effect (SSE) has been measured using optical pulses. These measurements suggest a time response faster than 5ns[1]. Here we present time-correlated measurements of the spin-Seebeck effect in Yttrium Iron Garnet (YIG) using an ultrafast laser. The pulsed beam is split into two individually modulated beams with a controllable delay time with sub-picosecond time resolution. The laser pulses are absorbed by a top Pt contact which generates a transient thermal gradient resulting in a spin current crossing the interface. The spin current is detected as a transverse voltage arising from the inverse spin Hall effect in Pt. We will present measurements of the time-correlated SSE signal from the two pulses as a function of delay time out to 1 ns. [1] Roschewsky et al., Appl. Phys. Lett., 104, 202410 (2014).

4:42PM W28.00010 Spatiotemporal Imaging of Gigahertz Frequency Magnetization Dynamics Using the Time Resolved Anomalous Nernst Effect. JASON BARTELL, DARRYL NGAI, ZHAOQI LENG, G.D. FUCHS, Cornell University — We report on the first demonstration of spatiotemporal magnetic microscopy based on the Time Resolved Anomalous Nernst Effect (TRANE). In TRANE microscopy, pulsed laser light is used to create a transient thermal gradient perpendicular to the film plane. The anomalous Nernst effect generates a corresponding transient electric field that is proportional to the cross product of both the thermal gradient and the in-plane projection of the magnetic moment. We demonstrate TRANE microscopy and use it to study the magnetic configuration and excited magnetization dynamics of patterned YIG samples. We show that the time resolution exceeds 30 ps, allowing measurement of dynamics above 16 GHz. We observe that the spatial resolution using a thermal gradient generated from focused light matches the optical diffraction limit, indicating that lateral thermal diffusion does not limit resolution. Numerical simulations of the time-dependent thermal gradient indicate that the thermal spot can be confined to nanoscale dimensions using, for instance, a plasmon antenna. This could allow TRANE microscopy to achieve bench-top imaging of magnetization with spatial resolution comparable to the domain wall width and temporal resolution in the GHz range.

4:54PM W28.00011 Non-local thermal spin injection: Mapping the magnon spin diffusion length in Yttrium Iron Garnet (YIG). BRANDON L. GILES, Department of Materials Science and Engineering, The Ohio State University, ZHIHAO YANG, Department of Electrical and Computer Engineering, The Ohio State University, JOHN JAMISON, ROBERTO C. MYERS, Department of Materials Science and Engineering, The Ohio State University — The non-local spin detection geometry was developed to sample a pure electron spin current in the absence of an electric field, thereby removing parasitic transport effects [1]. Here we demonstrate the non-local detection of magnon spins that are thermally injected via the spin Seebeck effect in single crystal YIG. A laser is used to thermally generate a spin current under an electrically isolated Pt absorbing pad. The spin current is detected on a remote Pt strip via the inverse spin Hall effect (\(V_{\text{ISHE}}\)). Spatial maps of the spin current are acquired by measuring \(V_{\text{ISHE}}\) while scanning the laser to different absorbing pads. Temperature modeling shows the laser-induced temperature gradient contained within 50\(\mu\)m of the Pt absorbing pad [2]. Thus, the spin detector is isolated from thermal effects unrelated to the spin current. Although the thermal magnon diffusion length at 21K is \(\sim 1\,\mu\)m [3], \(V_{\text{ISHE}}\) is detected at displacements of more than 150\(\mu\)m with an exponential decay constant of 40 \(\mu\)m at 25K.

3:54PM W28.00008 Thermal Hall Effect of Spins in a Paramagnet. HYUNYONG LEE, JUNG HOON HAN, Department of Physics, Sungkyunkwan University, Suwon 440-746, Korea, PATRICK LEE, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA — Theory of Hall transport of spins in a correlated paramagnetic phase is developed. By identifying the thermal Hall current operator in the spin language, which turns out to equal the spin chirality in the pure Heisenberg model, various response functions can be derived straightforwardly. Subsequent reduction to the Schwinger boson representation of spins allows a convenient calculation of thermal and spin Hall coefficients in the paramagnetic regime using self-consistent mean-field theory. Comparison is made to results from the Holstein-Primakoff reduction of spin operators appropriate for ordered phases.

The spins diffuse laterally and are detected non-locally on a remote Pt detector via the inverse spin Hall effect (ISHE). This has been demonstrated, in which a laser is focused on an electrically isolated Pt absorbing pad on yttrium iron garnet (YIG), thermally generating a spin current in YIG. This work was supported by ARO MURI. The authors acknowledge the Brazilian agencies CNPq, CAPES, FAPERJ and INCT de Nanoestruturas de Carbono for financial support.
3:30PM W29.00004 Theory of spin relaxation in bilayer graphene.1, denis kochan, susanne irmer, Martin gmitra, jaroslav fabian, university of regensburg — We present a new spin relaxation mechanism based on resonant scattering off local magnetic moments. We apply this mechanism to mono [1] and bilayer graphene and show that it can account for the ultrafast spin relaxation observed in spin injection experiments. In particular, the model explains the opposite dependence of the spin relaxation on the carrier density in mono and in bilayer graphene. We also show that for bilayer graphene the model explains the observed temperature induced changes in the carrier density dependence. [1] D. Kochan, M. Gmitra, J. Fabian; Phys. Rev. Lett. 112, 116602 (2014).

3:42PM W29.00005 Spin-orbit coupling in fluorinated graphene1, susanne irmer, tobias frank, SebastiAn putz, Martin gmitra, denis kochan, jaroslav fabian, University of Regensburg — We theoretically study spin-orbit coupling effects of fluorine chemisorbed on graphene. Both dense and dilute limit reveal a giant local enhancement of spin-orbit coupling by a factor of 1000 in the vicinity of the adatom—spin-orbit strength of about 10 meV. We present results of fully converged first-principles calculations and analyze them by a tight-binding Hamiltonian based on symmetry arguments. Our work covers different limits of fluorine concentration from dense to intermediate to dilute coverage. We find that fluorine’s native spin-orbit coupling exceeds the effect of the sp3 distortion of the lattice. Moreover, we identify fluorine as a weak resonant scatterer giving rise to resonant signatures in the band structure off the Dirac point by about 0.3 eV. Our findings are important for studies on relaxation and transport. Details can be found in the following manuscript: http://arxiv.org/abs/1411.0016

3:54PM W29.00006 Simultaneous magnetic force microscopy and electrical transport measurements of a graphene non-local spin valve, Michael page, Andrew berger, Hua wen, Vidya bhallamudi, Roland Kawakami, P. Chris Hammel, Ohio State University — Non-local signals in graphene spin valves depend on the magnetization states of the ferromagnetic electrodes. Currently, determining the relative influence of each magnetic electrode relies on fitting the non-local signal to the one-dimensional spin diffusion model. We report imaging of the magnetization states of the spin valve electrodes using a custom magnetic force microscope, while simultaneously acquiring the non-local spin signal electrically. This allows direct correlation of the non-local signal features to the switching of the individual electrodes and determination of the relative contribution to the signal by the participating electrodes. We also image the formation and motion of domain walls near the graphene transport channel and correlate these with features in the non-local signal. This measurement technique supports the one-dimensional spin diffusion model and provides information necessary for reliable switching behavior in spin valves with magnetic electrodes.

4:06PM W29.00007 Spintronics in hybrid organic/inorganic heterojunctions1, Shayan hematicyan, institut fuer Physik, Johannes Gutenberg Universitaet Mainz, D-55099-Dept of Physics, Texas A&M University, College Station, Texas 7784-4242, USA, Erik Mcnellis, jairo sinova, institut fuer Physik, Johannes Gutenberg Universitaet Mainz, D-55099 Mainz, Germany — In this work, we present the results of extensive analytical and numerical calculations to investigate spin and charge transport inside organic semiconductors and also at the interface with ferromagnetic metals. Based upon these calculations, we will describe the underlying spin relaxation mechanisms with reference to the spin dependent characteristic parameters e.g. spin relaxation time and spin diffusion length of the organic semiconductors in connection with the ferromagnetic electrodes.

4:18PM W29.00008 Bias Dependence of Tunneling Spin Injection into Graphene, TianCong Zhu, Ohio State Univ - Columbus, Hua Wen, WALID AMAMOU, ZHISHENG LIn, JING Shi, University of California, Riverside, ROLAND KAWAKAMI, Ohio State Univ - Columbus — Bias dependence of spin injection into a spin channel typically exhibits unusual behavior, which has been challenging to understand. In this study, we investigate the bias-dependence of tunneling spin injection into graphene with lateral spin-valve geometry. Co/MgO/graphene is used as tunneling barrier contact and lock-in measurement is performed. By applying a DC bias to AC spin injection current, we observe a strong non-linearity of bias-dependent non-local voltage on both the electron and hole side of graphene. The non-local voltage also flips sign when a large negative DC bias is applied. We extracted the interfacial spin polarization as a function of DC bias. The data analysis suggests that the unusual behavior of bias-dependent tunneling spin injection in graphene is mainly due to the spin polarization changing at the ferromagnetic/graphene interface. To better understand this behavior, we also compare our data with several other existing models on bias-dependent spin injection.

4:30PM W29.00009 Tunable Magnetic Proximity Effects in Graphene Junctions1, Predrag Lazic, Department of Physics, University at Buffalo, State University of New York, Buffalo; New York 14260, USA, Kirill Belashchenko, Department of Physics and Astronomy University of Nebraska-Lincoln, Lincoln, NE 68588-0299, USA, Igor Zutic, Department of Physics, University at Buffalo, State University of New York, Buffalo, New York 14260, USA — The characteristic length of the magnetic proximity effects exceeds the thickness of a graphene layer leading to an important, but typically overlooked, modification of equilibrium and transport properties, as well as the implications for graphene spintronics [1,2]. Using the first-principles studies that integrate a real space density functional theory (GPAW) [3] with the state-of-the art boundary elements electrostatic code based on the Robin Hood method [4], we explore tunable structural and magnetic proximity effects in the ferromagnet/insulator/graphene junctions. We show that the inclusion of a finite-size gate electrodes and van der Walls interaction lead to nontrivial effects that could also be important in other two-dimensional materials beyond graphene.

4:42PM W29.00010 Giant Perpendicular Magnetic Anisotropy of Graphene-Co Heterostructures 1, HONGXIN YANG, ALI HALLAL, MAIRBEK CHSHIEV, Univ. Grenoble Alpes, INAC-SPIINTEC, F-38000 Grenoble, France; CNRS, SPIINTEC, F-38000 Grenoble, France, and CEA, INAC-SPIINTEC, F-38000 Grenoble, France, SPIINTEC THEORY TEAM  — We report strongly enhanced perpendicular anisotropy (PMA) of Co films by graphene coating via ab-initio calculations. [1] The results show that graphene coating can improve the surface anisotropy of Co film up to twice large of the bare Co case and keep the film effective anisotropy being out-of-plane till 25 Å of Co, in agreement with experiments [2,3]. Our layer resolved analysis reveals that PMA of Co (Co/Gr) films mainly originates from the adjacent 3 Co layers close to surface (interface) and can be strongly influenced by graphene. Furthermore, orbital hybridization analysis uncovers the origin of the PMA enhancement which is due to graphene-Co bonding causing an inversion of Co 3d_{x^2} and 3d_{y^2} Bloch states close to Fermi level. Finally, we propose to design Co-graphene heterostructures which possess a linearly increasing surface anisotropy and a constant effective anisotropy. These findings point towards a possible engineering graphene-Co junctions with giant anisotropy, which stands as a hallmark for future spintronic information processing. [1] H. X. Yang, et al. to submit. [2] C. Vo-Van, et al. New J. Phys. 12, 103040 (2010). [3] N. Rougemaille et al. Appl. Phys. Lett. 101, 142403 (2012).

4:54PM W29.00011 Spin and charge transport across cobalt/graphene interfaces. MAIRBEK CHSHIEV, SPIINTEC, UMR CEA/CNRS/IFJ/G-INP, ALAN KALITSOV, OLEG MRYASOV, Univ of Alabama - Tuscaloosa  — We report ballistic calculations of in-plane and out-of-plane spin and charge transport through graphene device attached to the hcp-Co electrodes. Our calculations are based on the Keldysh non-equilibrium Green Function formalism and the tight binding Hamiltonian model tailored to treat both lateral and vertical device configurations. We present results for (i) vertical device that consists of a one-side fluorinated C,F graphene sandwiched between two hcp Co electrodes and (ii) lateral device consisting of pristine graphene/C,F graphene bilayer with two top hcp-Co electrodes. Our calculations predict large magnetoresistance with small resistance-area product and significant deviation from sinusoidal behavior of spin transfer torque for the vertical device configuration.

5:06PM W29.00012 Blocking of spin transport between Ni_{10}Fe_{20} and Cu by a graphene interlayer, WILL GANNETT, MARK W. KELLER, TOM SILVA, HANS NEMBACH, ANN CHIARAMONTI DEBAY, National Institute of Standards and Technology, Boulder, CO  — By chemical vapor deposition on epitaxial thin films of Cu(111), we are able to produce continuous, large-grain monolayer graphene (Gr). We then sputter deposit Ni_{10}Fe_{20} (Py) in a different chamber to create large area Cu/Gr/Py samples. We are able to avoid damaging the graphene during this process by varying the Py deposition angle, and we confirm this with Raman spectroscopy. Ferromagnetic resonance measurements with a vector network analyzer show no change in damping with varying Py thickness, while Py deposited directly on Cu(111) shows the typical increase in damping associated with spin pumping between Py and Cu. We interpret these results in terms of spin pumping, interfacial conductivity, and magnetic proximity effects.

Session W30 GMAG DMP: Focus Session: Frontiers in Magnetism I 206B - Christian Binek, University of Nebraska

2:30PM W30.00001 Antiferromagnetic coupling in ferrimagnetic hard-soft core/shell nanoparticles 1, JOSEP NOGUES, ICREA and ICN2 - Institut Catala de Nanociencia i Nanotecnologia, Barcelona, Spain  — The coupling between different magnetic layers in thin film bi-layers and multilayer systems is usually ferromagnetic (FM) (layers parallel to each other). However, other types of couplings such as antiferromagnetic (AFM) (i.e., antiparallel layers) have also been reported. In contrast, the magnetic properties of bi-magnetic core/shell nanoparticles remain relatively unexplored. While Monte Carlo simulations have probed the effects of different types of interface couplings from the theoretical point of view (e.g., FM vs. AFM coupling), experimental work so far has only reported ferromagnetic coupling between the counterparts. Here we present the existence of an interfacial AFM coupling in ferrimagnetic (FM) soft/hard and hard/soft core/shell nanoparticles based on iron and manganese oxides [1]. Narrow size distribution Fe_3O_4/Mn_3O_4 and Mn_3O_4/Fe_3O_4 core/shell, soft/hard and hard/soft, were synthesized by seed-mediated growth. In contrast to conventional systems, the temperature dependence of the magnetization, M, and the ferromagnetic resonance field, H_R, show a downturn at the magnetic ordering temperature of the hard Mn_3O_4 phase (T_C(Mn_3O_4) = 40 K). This decrease in M and H_R can be linked to an antiferromagnetic coupling between both phases. Moreover, element selective X-ray magnetic circular dichroism (XMCD) spectra and hysteresis loops confirm that the magnetization of the Mn-containing phase lies opposite to the Fe-containing phase. Magnetometry hysteresis loops show that for small cooling fields the loop shifts towards negative fields similar to exchange bias in conventional FM/AFM systems. However, for large cooling fields the loops shift to the opposite direction, i.e., positive exchange bias. Finally, Monte Carlo simulations clearly confirm that an AFM interface coupling leads to a magnetization decrease at low temperatures and a positive exchange bias for large cooling fields.

3:06PM W30.00002 Electronic, magnetic and oxidation properties of Co and Co_{1-x}Ni_{x} sub-nanosopic cylinders, EUGENIO VOGEL, Universidad de La Frontera, Chile, J. MARTIN MONTEJANO-CARRIZALES, FAUSTIN AGUILERA-GRANJA, Universidad Autonoma San Luis Potosi, Mexico  — One of the most convenient shapes among magnetic nanoparticles are cylinders (solid or hollow). They can be made out of different materials, they are easy to produce in different sizes, and they are relatively easy to handle. One of the present aims at present to make these particles as small as possible. Which is the minimum stable cylindrical shape possible? Can they grow from a seed to make large particles? What are their physical properties at this scale where quantum mechanics operate? Some of these questions have been recently answered for the case of cylinders formed by Co atoms [F. Aguileria-Granja, J.M. Montejano-Carrizales, E.E. Vogel, Eur. Phys. J. D (2014) 68:38]. In this presentation we want to get deeper into this problem in particular considering binary magnetic alloys like it is the case when Ni atoms substitute for Co in the original stable structures. We invoke program SIESTA to study different configurations. Among the results shown to be reported are the following: cylindrical clusters are stable to any length at this process; there is an insulator-conductor transition at a certain length; magnetic moments are not uniformly distributed; Ni atoms tend to go to the periphery; Ni alloys tend to be more resistant to oxidation.

3:18PM W30.00003 Structure and magnetic properties of Co/CoO core-shell nanowires, KINJAL GANDHA, KEVIN ELKINS, NARAYAN POUDYAL, J. PING LIU, Department of Physics, The University of Texas at Arlington  — Cobalt nanowires with high coercivity have been synthesized via a solvothermal chemical process. A record high room-temperature coercivity value of 12.5 Koe has been measured in aligned Co nanowires with a diameter of about 15 nm and a mean length of 200 nm. When the surface of the Co nanowires were oxidized, exchange-bias (EB) was detected at low temperatures owing to the exchange coupling between the ferromagnetic (FM) Co core and the antiferromagnetic (AFM) CoO shell of the nanowires. EB fields of ~2.0 kOe were measured at 10 K, along the parallel direction of nanowires. Manipulation and control of the EB in the nanowires may lead to a better understanding of the EB effect and the applications of the nanowires in future permanent magnets and recording media.
3:30PM W30.00004 Chemical Synthesis of Iron-Nickel Nanoparticles1, FRANK ABEL, University of Delaware, VASILIAS TZITZIOS, Institute of Materials science, demokritos, Greece, GEORGE HADJIPANAYIS, University of Delaware — Equiatomic FeNi alloys undergo a phase transformation, like FePt, from a disordered fcc structure to an ordered fct structure. However, unlike FePt in Fe-Ni this transformation is very sluggish and has been only observed in heavily irradiated thin films and in meteorite samples as was recently reported.1,2 In this study, we used a high temperature chemical synthesis route to investigate the possibility of fabricating fct FeNi nanoparticles. The Iron Nickel Boron nanoparticles were made using anhydrous Iron (II) Chloride and Nickel (II) Chloride using Sodium borohydride as a reducing agent in tetr获得ygm under a nitrogen hydrogen atmosphere. The high temperature of the reaction allowed for the formation of as made crystalline Iron Nickel nanoparticles without additional annealing. By changing the concentration of sodium borohydride we were able to prepare nanoparticles either in the pure fcc phase, or in a new mixed phase. The magnetic properties were improved by increasing the concentration of Iron precursor. We obtained FeNi nanoparticles with saturation magnetization of (56 emu/g) and coercivity of (190 Oe). The particle size distribution of the FeNi particles ranged from several hundred nanometers to a half micron. References: 1. L Neel, et al., Journal of Applied Physics, Volume 35, No. 3 (1964) 2. 3:42PM W30.00005 Voltage-Tunable Magnetic Stability in a Ni Nanoparticle3, PATRICK GARTLAND, Georgia Institute of Technology, WENCHAO JIANG, GlobalFoundries, DRAGOMIR DAVIDOVIC, Georgia Institute of Technology — We study single nickel particles ≈ 2nm in diameter using single electron tunneling spectroscopy and find that such particles lie at the threshold of stable ferromagnetic order. We find that the application of a bias voltage can precisely tune the conditions for a stable magnetization orientation, and simulate the experimental configuration using a master equation. Due to the addition of anisotropy from a single electron, a new energy scale emerges which governs the stability of magnetization as a function of voltage bias conditions.

3:54PM W30.00006 Engineered diamond nanopillars as mobile probes for high sensitivity metrology in fluid3, P. ANDRICH, C.F. DE LAS CASAS, F.J. HEREMANS, D.D. AWSCHALOM, University of Chicago, B.J. ALEMAN, K. OHNO, UC Santa Barbara, J.C. LEE, E.L. HU, Harvard University — The nitrogen-vacancy (NV) center’s optical addressability and exceptional spin coherence properties at room temperature, along with diamond’s biocompatibility, has put this defec at the front of meterology applications in biological environments. To push the spatial resolution to the nanoscale, extensive research efforts focus on using NV centers embedded in nanodiamonds (NDs). However, this approach has been hindered by degraded spin coherence properties in NDs and the lack of a platform for spatial control of the nanoparticles in fluid. In this work[3] we combine the use of high quality diamond membranes with a top-down patterning technique to fabricate diamond nanopillars with engineered and highly reproducible shape, size, and NV center density. We obtain NDs, easily releasable from the substrate into a water suspension, which contain single NV centers exhibiting consistently long spin coherence times (up to 700 μs). Additionally, we demonstrate highly stable, three-dimensional optical trapping of the nanoparticles within a microfluidic circuit. This level of control enables a bulk-like DC magnetic sensitivity and gives access to dynamical decoupling techniques on contactless, miniaturized diamond probes.

4:06PM W30.00007 Controlling Quantum Nanomagnets with Atomic Exchange Bias, SHICHAO YAN, DEUNG-JANG CHOI, JACOB BURGESS, STEFFEN ROLF-PISSARCKY, SEBASTIAN LOTTH, 1. Max Planck Institute for the Structure and Dynamics of Matter, 22761 Hamburg; 2. Max Planck Institute for Solid State Research, 70569 Stuttgart — Miniaturizing spintronic devices to the point where magnetization of the device’s elements becomes quantized is a possible avenue to achieving quantum computation with magnetic elements. Critical to such an approach is the ability to exert local control over the quantum nanomagnets. Atomic exchange bias field has been proposed as a mechanism for localized control of individual nanomagnets. Here we demonstrate that exchange coupling with the magnetic tip of a scanning tunnelling microscope provides continuous tuning of spin dynamics in an individual nanomagnet. By directly measuring spin relaxation time with electronic pump-probe spectroscopy, we find that the exchange interaction acts analogous to a local magnetic field that can be applied to a specific atom. It can be tuned in strength up to several teslas and cancel external magnetic fields, thereby demonstrating the feasibility of complete control over individual quantum magnets with atomically localized exchange coupling.

4:18PM W30.00008 High temperature magnetic phase transitions and exchange bias effect of FeSiCr alloy, XIN WANG, University of Electronic Science and Technology of China, STATE KEY LABORATORY OF ELECTRONIC THIN FILMS AND INTEGRATED DEVICES COLLABORATION — We present magnetic properties of FeSiCr alloy which was synthesized by melting and crushing method followed by milling and heat treatment. The samples under different heat treatment temperature were characterized by using X-ray diffractometer, scanning electron microscopy, vibrating sample magnetometer and Mössbauer spectroscopy. The micro-structure undergo crystallization and grain growth process starting from as-crushed state, and gradually transform to B2 atomic disordered crystal phase. B2 phase is formed into DO3 atomic ordered phase with the increasing temperature. Mössbauer spectroscopy are well fitted into one or two subspectras correspond to DO3 structure and two subspectras to Fe(7) and Fe(4) structures.

4:42PM W30.00010 Ballistic Anisotropic Magnetoresistance of Single-Atom Contacts. F. OTTE, J. SCHÖNEBERG, A. WEISSMANN, R. BERNDT, S. HEINZE, University of Kiel, Germany; N. NÉEL, J. KRÖGER, TU Ilmenau, Germany; Y. MOKROSOV, Forschungszentrum Jülich, Germany. It has been predicted that the anisotropic magnetoresistance (AMR) is greatly enhanced in the ballistic transport regime. Results from break junctions in a magnetic field can be explained in terms of this ballistic AMR (BAMR), although the interpretation is controversial due to the unknown atomic geometry of the junction. Here, we demonstrate the emergence of BAMR in single-atom contacts. Single Co and Ir atoms are deposited on domains and domain walls of ferromagnetic Fe layers on W(110), which is used to control their magnetization directions. They are contacted with nonmagnetic tips in a low-temperature scanning tunneling microscope to measure the junction conductances. AMR is observed and changes drastically between tunneling and the ballistic regime. First-principles calculations and tight-binding modeling demonstrate that this change is a competition of delocalized and localized d states of different orbital symmetry.

4:54PM W30.00011 Quantum Molecular Magnetism. SYLVAIN BRECHET, FRANCOIS REUSE, KLAUS MASCHKE, JEAN-PHILIPPE ANSERMET, EPFL. Our theoretical description of quantum molecular magnetism is based on the quantum master equations, where the system consists of the electronic spin degrees of freedom and the bath consists of the remaining degrees of freedom. The system is weakly coupled and weakly correlated to the bath, which is at equilibrium on an appropriate time scale. The electrons satisfy the exclusion principle, which requires the tensorial product of the spin and orbital parts of the state to be antisymmetric under permutation. However, the symmetries of the parts of the state taken separately are determined by the irreducible unitary representations of the permutation group. The structure of the quantum master equations is also determined by these representations. The coupling between different isotropic components of the permutation group appearing in the quantum master equations leads to a description of magnetic dissipation at the molecular level and defines molecular spin selection rules. Thus, this theoretical description is expected to bring new and fundamental insight for molecular magnetism. In particular, it is expected to predict the non-trivial deflection of molecular clusters in a field gradient.

5:06PM W30.00012 Using the binding site to control the magnetic and spintronic properties of a single magnetic molecule in a tunnel junction. BEN WARNER, FADI E. HALLAK, HENNING PRUESER, TOBIAS G. GILL, UCL, UK; JOHN SHARP, University of Liverpool, UK; ANDREW J. FISHER, UCL, UK; M. PERSSON, University of Liverpool, UK; CYRUS F. HIRSELJACOBS, UCL, UK. Many proposals outline the use of single magnetic molecules in new applications in information technology and spintronics, with the intention of creating new devices based on phenomena that only manifest at the atomic scale. To create these devices it will be necessary to engineer the required properties, whether through controlling the molecule’s chemical makeup or its interaction with the external surroundings. The latter may involve using interactions with the supporting substrate surface, which have been shown to not only modify the molecule properties [1] but also create effects such as chirality [2]. Here we utilize the surface interaction to modify the properties of FePc on copper nitride, a thin insulator, above bulk Cu(001). Using scanning tunneling microscopy we show that the interaction with the surface is defined by the binding site of the central Fe atom in the molecule. By performing elastic and inelastic tunneling spectroscopy and comparing the results to DFT modeling, we explore how coupling to the surface can be used to control the molecular orbitals and the accessibility of the spin excitations. This demonstrates the importance of controlling molecule-substrate coupling down to the atomic scale for the development of single molecule devices.

5:18PM W30.00013 Stability of spin-electric coupling in triangular single-molecule magnets under external contacts. FHKRUL ISLAM, Linnaeus University, Sweden; JAVIER NOSSA, Carnegie Institution of Washington, USA; CARLO CANALI, Linnaeus University, Sweden; MARK PEDERSON, Department of Energy, USA. Triangular single molecule magnets (SMMs) with antiferromagnetic exchange coupling exhibit Kramer degenerate chiral spin-doublet ground states, which can be efficiently coupled by an electric field, even in the absence of spin-orbit interaction. Recent first-principles calculations [1] show that unsupported V₃ SMM has giant spin-electric coupling corresponding to dipole moment of about one tenth of the water-molecule dipole moment. The corresponding Rabi time for electric switching between two chiral states can be on the order of one nano-second for reasonable electric fields, which makes these molecules very attractive candidates for storing and manipulating pairs of coupled spin-chiral qbits. However, for device applications of the spin-electric coupling, these frustrated SMMs need to be supported on a surface or between metallic leads. Preserving this effect in an external environment is a challenging problem requiring appropriate functionalization. In this talk we will discuss the stability of the spin-electric coupling in V₃ SMM when coupled to gold leads or deposited on a graphene surface. [1] J. F. Nossa et al., Electric control of spin states in frustrated triangular molecular magnets (unpublished)

2:30PM W31.00001 Extreme Harmonic Generation in Electrically Driven Spin Resonance. JIRI STEHLIK, Department of Physics, Princeton University, Princeton, NJ 08544, USA. InAs nanowire double quantum dots offer a rich platform for studying single spin physics in a material with large spin-orbit (SO) coupling. The large SO coupling allows all electrical control of the electron spin through electric dipole spin resonance (EDSR). Here an oscillating electric field of frequency f displaces the electron wave function, while a magnetic field with strength B is applied. Spin rotations occur when the resonance condition hν = gμBB is met. Here g is the electron g-factor, h is Planck’s constant, and μB is the Bohr magneton. We find that near zero interdot detuning efficient spin rotations also occur when hν = nμBB, with n being an integer as large as 6 in our system. The harmonics feature a striking odd/even dependence. While the odd harmonics show an enhancement of the leakage current, the even harmonics show a reduction. In contrast, we do not observe any measurable harmonics at large detuning. We link the presence of harmonics with additional anti-crossings present in the level diagram. This implies that harmonics are the result of Landau-Zener transitions occurring at multiple anti-crossings. Recent theoretical work supports this conclusion.

3:06PM W31.00002 Spin relaxation of conduction electrons by inelastic scattering with neutral donors1, LAN QING, HANAN DERY, University of Rochester, Rochester, New York 14627, JING LI, IAN APPELBAUM, University of Maryland, College Park, Maryland 20742. — At low temperatures, in narrow-gap semiconductor quantum dots, a significant fraction of shallow donor sites are occupied by electrons, neutralizing the impurity core charge in equilibrium. Inelastic scattering by externally-injected conduction electrons accelerated by electric fields can excite transitions within the manifold of these localized states. Promotion into highly spin-mixed excited states results in spin relaxation that couples strongly to the conduction electrons by exchange interaction. Through experiments with silicon spin transport devices and complementary theory, we reveal the consequences of this previously unknown depolarization mechanism both below and above the impact ionization threshold and into the “deep inelastic” regime.

1This work is supported by NSF under contracts ECCS-1231570 and ECCS-1231855, by DTRA under contract HDTRA1-13-1-0013, and by ONR under contract N000141410317.

3:18PM W31.00003 Single-shot readout and relaxation measurements in exchange coupled31P electron spins in silicon, JUAN PABLO DEHOLLAINE, JUHA MUHonen, Kuan Tan, Centre for Quantum Computation and Communication Technology, University of New South Wales, ANDRE DE SARRANIA, Universidade Federal do Rio de Janeiro and University of Wisconsin-Madison, DAVID JAMIESON, Centre for Quantum Computation and Communication Technology, University of Melbourne, ANDREW DZURAK, ANDREA MORELLO, Centre for Quantum Computation and Communication Technology, University of New South Wales — We present the experimental observation of a large exchange coupling, $J \approx 3 \text{ meV}$, between two 31P electron spin qubits in silicon (Dehollain, PRL 112, 236801). The singlet and triplet states of the coupled spins are monitored in real time by a single-electron transistor, which detects ionization from tunnel-rate-dependent processes in the coupled spin system, yielding single-shot readout fidelities above 95%. The triplet to singlet relaxation time $T_1 \approx 4 \text{ ms}$ at zero magnetic field agrees with the theoretical prediction for the observed $J$-coupling energy in 31P dimers in silicon. The three order of magnitude increase in relaxation rate compared to single donors, is caused by a hyperfine interaction mediated mixing of the singlet and triplet states. Additionally, the time evolution of the two-electron state populations reveals an inversion in the energetic hierarchy of the valley-orbit excited states, which had been theoretically predicted for donor pairs with $< 6 \text{ nm}$ separation. These results pave the way to the realization of two-qubit quantum logic gates with spins in silicon and highlight the necessity to adopt gating schemes compatible with weak $J$-coupling strengths.

3:30PM W31.00004 g-Factors of Electrons, Holes and Excitons in Type-II ZnTe/ZnSe Submonolayer Quantum Dots, HAOJIE JI, SIDDHARTH DHOMKAR, the Graduate Center of CUNY; Queens College of CUNY, JONATHAN LUDWIG, DAMIR SMIRNOV, National High Magnetic Field Laboratory, MARIA TAMARGO, City College of CUNY; the Graduate Center of CUNY, IGOR KUSKOVSKY, Queens College of CUNY; the Graduate Center of CUNY — In recent years there has been intense interest in manipulating exciton spin states in semiconductor quantum dot (QDs) for application in spin electronics and quantum information processing. In these applications, the ability to enhance and control Zeeman spin splitting, which can be characterized by g-factors, plays a key role. Here we report our study of the g-factors of electrons, holes and excitons in type-II ZnTe/ZnSe submonolayer superlattices. Via analysis of left and right circularly polarized photoluminescence spectra, we determine the g-factor of type-II excitons. We obtain the g-factor of electrons by fitting the temperature dependence of degree of circular polarization. Thus, we find out the g-factor of holes confined in ZnTe QDs. This g-factor of confined holes is larger than those reported for bulk ZnTe. We propose that the enhancement of g-factor of holes is due to quantum confinement which leads to the admixture of the subband states.

3:42PM W31.00005 Competition between applied and exchange magnetic fields in (Zn,Mn)Se/ZnTe quantum dots1, BIPLO BARMAN, Y. TSAI, T. SCRACE, I. ZUTIC, B.D. MCCOMBE, A. PETROU, SUNY Buffalo, W-C CHOU, M-H TSOU, National Chiao Tung University, Taiwan, C-S YANG, Graduate Institute of Electro-Optical Engineering, Tatung University, Taiwan, I.R. SELLERS, University of Oklahoma, R. OSZWALDOWSKI, South Dakota School of Mines and Technology, SUNY BUFFALO COLLABORATION, NATIONAL CHIAO TUNG UNIVERSITY, TAIWAN COLLABORATION, TATUNG UNIVERSITY, TAIWAN COLLABORATION, UNIVERSITY OF OKLAHOMA COLLABORATION, SOUTH DAKOTA SCHOOL OF MINES AND TECHNOLOGY COLLABORATION — We have measured the peak energy of the photoluminescence (PL) emission and its circular polarization from type II (Zn,Mn)Se/ZnTe Quantum Dot structures in the Faraday and Voigt geometries. In the Faraday geometry the PL energy shows a 6 meV red shift at $B = 6$ tesla. This result verifies that the holes are confined in the non-magnetic ZnTe QDs, while the electrons move in the magnetic (Zn,Mn)Se matrix. The PL circular polarization saturates at 45%. In the Voigt geometry, the circular polarization is near-zero and the red shift is 2 meV. These results are discussed using a model that takes into account that electrons are influenced by the combination of the externally applied magnetic field and the exchange field due to the interaction between the Mn-spins and the carriers.

1This work is supported by DOE-BES and NSF-DMR.

3:54PM W31.00006 Spin structure of germanene quantum dot as a function of normal electric field1, APALKOV VADYM, VENKATA CHAGANTI, Georgia State University — Germanene quantum dot consisting of 13 germanium atoms is studied numerically within the nearest neighbor tight-binding model. Both the energy spectra and the spin structure of the corresponding Eigen-functions are obtained. Due to strong spin-orbit interaction in germanene the spin polarization of the germanene quantum dot strongly depends on the energy of the corresponding Eigen-state and on the external electric field, $E_z$. There are two states with energies close to zero, for which the direction of the spin is along z-axis, where z-axis is perpendicular of the quantum dot layer. For the higher energy levels the spin deviates from the z-axis with maximum angle $\theta_{\text{max}} = 3.9^\circ$ for the levels with energy 1128 meV (for electron channel) and -1128 meV (for hole channel) and zero electric field, $E_z = 0$. The angle $\theta_{\text{max}}$ increases almost linearly with $E_z$ and takes the value of $4.2^\circ$ at $E_z = 100 \text{ meV/A}$. The in-plane direction of spin is also sensitive to external electric field. With increasing electric field, the in-plane spin rotates in the anticlockwise and clockwise directions for the 1128 meV and -1128 meV levels, respectively. Due to such sensitivity of spin polarization to electric field, applying a bias voltage can control the spin current through germanene quantum dot.

4:06PM W31.00007 Structure determination of individual electron-nuclear spin complexes in a solid-state matrix, ABDELGHANI LARAOUI, DANIELA PAGLIERO, CARLOS MERILES, CUNY-City College of New York — A spin-based quantum computer will store and process information via “spin complexes” formed by a small number of interacting electronic and nuclear spins within a solid-state host. Unlike present electronic circuits, differences in the atomic composition and local geometry make each of these spin clusters distinct from the rest. Integration of these units into a working network thus builds on our ability to determine the cluster atomic structure, a problem we tackle herein with the aid of a magnetic resonance protocol. Using the nitrogen-vacancy (NV) center in diamond as a model system, we show analytically and numerically that the spatial coordinates of weakly coupled 13C spins can be determined by selectively transferring and retrieving spin polarization. The technique’s spatial resolution can reach up to 0.1 nm, limited by the NV spin coherence lifetime. No external magnetic field gradient is required, which makes this imaging scheme applicable to NV-13C complexes buried deep inside the crystal host. Further, this approach can be adapted to nuclear spins other than 13C, and thus applied to the characterization of individual molecules anchored to the diamond surface.

XIAYU LINPENG, TODD KARIN, University of Washington, RUSSEL BARBOUR, Spectrum Lab, MIKHAIL GLAZOV, Ioffe Institute, KAI-MEI FÜ, University of Washington — We observe an anomalous B-field dependence of the spin-flip time ($T_1$) of electrons bound to shallow donors which cannot be explained by current spin-relaxation theories. We conduct resonant pump-probe measurements in high-purity InP from the low to high magnetic field regimes, with a maximum $T_1$ (400 µs) observed near the turning point $gyB ≈ 30T$. At low $B$, the $T_1$ dependence on $B$ is consistent with an electron correlation time ($\tau_c$) in the tens of nanoseconds. The physical mechanism for the short $\tau_c$ in this high-purity sample ($n ≈ 2 \times 10^{14}$ cm$^{-3}$) is unclear, but a strong temperature dependence on $T_1$ can be further increased by lowering $T$ below the 1.5 K experimental temperature. At high $B$, a $B^{-3}$ dependence is observed, in contrast to the expected $B^{-5}$ predicted by single-phonon spin-orbit mediated interactions. An understanding of the anomalous $B$-field dependence is expected to elucidate the effect of electron transport (low-field) and phonons (high-field) on $T_1$ for shallow donors, which is of interest for both ensemble and single-spin quantum information applications.

1 This material is based upon work supported by the National Science Foundation under Grant No. 1150647, DGE-0718124 and DGE-1256082. InP samples were graciously provided by Simon Watkins at Simon Fraser University.

4:30PM W31.00009 Spin dynamics in a quantum point contact showing the 0.7-anomaly1, JAN VON DELFT, FLORIAN BAUER, JANHEYDER, DENNIS SCHIMMEL, Ludwig-Maximilians-University Munich, CENS/ASC TEAM — The 0.7-anomaly in the first conductance step of a quantum point contact is believed to arise from an interplay of geometry, spin dynamics and interaction effects. Various scenarios have been proposed to explain it, each evoking a different concept, including spontaneous spin polarization, or a quasi-localized state, or ferromagnetic spin fluctuations, or a van Hove ridge (a geometry-induced maximum in the density-of-states). Though these scenarios differ substantially regarding numerous details, they all imply anomalous dynamics for the spins in the vicinity of the QPC. We have performed a detailed study of this spin dynamics in the central region of a parabolic quantum point contact, by using the functional renormalization group to calculate the dynamical spin-spin correlation function $\chi(x, x', \omega)$ = $\int_0^\infty (S_z(x, t)S_z(x', 0)) e^{i\omega t}$. We will discuss its behavior as function of frequency, interaction strength and gate voltage and comment on the implications of these results for each of the above-mentioned scenarios.

4:42PM W31.00010 Optimal quantum control via numerical pulse shape optimization for two exciton qubits confined to semiconductor quantum dots, REUBLE MATHEW, HONG YI SHANG, KIMBERLEY HALL, Department of Physics and Atmospheric Science, Dalhousie University, Halifax, Nova Scotia, Canada — Optimal quantum control (OQC), which iteratively optimizes the control Hamiltonian to achieve a target quantum state, is a versatile approach for manipulating quantum systems. For optically-active transitions, OQC can be implemented using femtosecond pulse shaping which provides control over the amplitude and/or phase of the electric field. Optical pulse shaping has been employed to optimize physical processes such as nonlinear optical signals [1], photosynthesis [2], and has recently been applied to optimizing single-qubit gates in multiple semiconductor quantum dots [3]. In this work, we examine the use of numerical pulse shape optimization for optimal quantum control of multiple qubits confined to quantum dots as a function of their electronic structure parameters. The numerically optimized pulse shapes were found to produce high fidelity quantum gates for a range of transition frequencies, dipole moments, and arbitrary initial and final states. This work enhances the potential for scalability by reducing the laser resources required to control multiple qubits.

4:54PM W31.00011 Spin Manipulation through geometric phase in III-V semiconductor quantum dots1, SANJAY PRBAHAKAR, RODERICK MELNIK, Wilfrid Laurier University — A more robust technique is proposed to flip the spin completely through geometric phase in III-V semiconductor quantum dots (QDs). We transport the QDs adiabatically in a closed loop along the circular trajectory in the plane of two dimensional electron gas with the application of time dependent gate controlled electric fields and investigate the manipulation of Berry phase with the spin-orbit couplings. Here we show that both the Rashba and the Dresselhaus couplings are present for inducing a phase necessary for spin flip. If one of them is absent, the induced phase is trivial and irrelevant for spin-flip (Phys. Rev. B 89, 245310 (2014), Applied Physics Letters 104, 142411 (2014)).

2:30PM W32.00001 Temperature and bias dependence of anisotropic magnetoresistance in antiferromagnetic Sr$_2$IrO$_4$. HEIDI SEINIGE, CHENG WANG, Physics Department, The University of Texas at Austin, GANG CAO, Center for Advanced Materials, University of Kentucky, JIAN-SHI ZHOU, JOHN B. GOODENOUGH, Texas Materials Institute, The University of Texas at Austin, MAXIM TSOI, Physics Department, The University of Texas at Austin — We study anisotropic magnetoresistance (AMR) in antiferromagnetic (AFM) Mott insulator Sr$_2$IrO$_4$. Such AMR is a promising candidate for monitoring the magnetic order parameter in AFM spintronics. Here we present temperature- and electrical bias-dependent measurements of the point-contact AMR in single crystals of Sr$_2$IrO$_4$. The point-contact technique allows to probe very small volumes and, therefore, look for electronic transport in Sr$_2$IrO$_4$ on a microscopic scale. Point-contact measurements at liquid nitrogen temperature revealed a large negative magnetoresistance (MR) for magnetic fields applied within IrO$_2$ a-b plane and electric currents flowing perpendicular to the plane. The observed MR decreases with increasing temperature and falls to zero at $T_{N_{AFM}}$ ~ 240 K. Interestingly, the temperature dependence of MR ratios differs qualitatively from that of the resistivity. The point-contact measurements also show a strong dependence of MR on the dc bias applied to the contact. The latter can be associated with correlations between electronic transport and magnetic order in Sr$_2$IrO$_4$.

1 This work was supported in part by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA, and by NSF grants DMR-1207577, DMR-1265162 and DMR-1122603.
2:42PM W32.00002 The Evolution of Electronic Structure in Electron and Hole-Doped Sr2IrO4, YUE CAO, XIUWEI ZHANG, HAOXIANGLI, XIAOQING ZHOU, University of Colorado at Boulder, RAJENDRA DHAKA, NICHOLAS PLUMB, Swiss Light Source, PSI, TONGFEI QI, JASMINKA TERZIC, University of Kentucky, ALEX ZUNGER, University of Colorado at Boulder, GANG CAO, University of Kentucky, D. S. DESSAU, University of Colorado at Boulder — How the electronic structure evolves in doped Mott insulators remains debated after decades of study, and affects the interpretations of many bulk and spectroscopic properties, including dc-conductance, quantum oscillations, etc. The recent discovery of the spin-orbital coupled J=1/2 Mott insulator Sr2IrO4 provides a new perspective into the above question. Combining angle-resolved photoemission spectroscopy and first-principles calculations, we present a unified description how the band dispersion, Fermi surface, chemical potential, and Mott gap change in electron and hole doped Sr2IrO4.

2:54PM W32.00003 Electrically tunable transport in antiferromagnetic Sr2IrO4, CHENG WANG, HEIDI SEINEIGE, Physics Department, The University of Texas at Austin, GANG CAO, Center for Advanced Materials, University of Kentucky, JIAN-SHI ZHOU, JOHN B. GOODENOUGH, Texas Materials Institute, The University of Texas at Austin, MAXIM TSOI, Physics Department, The University of Texas at Austin — Transport in antiferromagnetic (AFM) Mott insulators Sr2IrO4 is studied under high electric fields. Our goal is to address the question of electronic conduction in nano-scale AFM spintronic applications [1] where high biases and associated electric fields are routinely present. We use nano-scale contacts between a sharpened Cu tip and single crystal of Sr2IrO4 to achieve electric fields up to a few MV/m. When an electrical bias is applied to such a point contact, the electric potential drops essentially in a small contact region, thus leading to high electric fields and providing a means to probe electronic transport on a microscopic scale. Detailed measurements of point-contact voltage characteristics revealed that the contact resistance decreased significantly (50-70%) with an increasing dc bias. The observed bias dependence can be well fitted by an activation energy model that involves band structure modifications under strong electric fields. Our findings suggest a promising path towards band-gap engineering in 5th transition metal oxides, which may lead to appealing technical solutions in developing next generation’s electronic devices.

3:06PM W32.00004 A hidden non-dipolar magnetic order parameter in Sr2IrO4 observed using nonlinear optical measurements, LIUYAN ZHAO, Ins. for Q. Info. and Matt., California Institute of Technology, VSEVOLOD IVANOV, Department of Physics, California Institute of Technology, DARIUS TORCHINSKY, HAO CHU, Ins. for Q. Info. and Matt., California Institute of Technology, RON LIFSHITZ, Department of Physics and Astronomy, Tel Aviv University, REDDECA FLINT, Ins. for Q. Info. and Matt., California Institute of Technology — Iridium oxides are predicted to host a variety of exotic electronic phases arising from the interplay of electron correlations and spin-orbit coupling. One hidden non-dipolar order parameter in Sr2IrO4, originating from the hidden 5d orbital of Ir4+, is studied under high electric fields. Our goal is to address the question of electronic conduction in nano-scale AFM spintronic applications [1] where high biases and associated electric fields are routinely present. We use nano-scale contacts between a sharpened Cu tip and single crystal of Sr2IrO4 to achieve electric fields up to a few MV/m. When an electrical bias is applied to such a point contact, the electric potential drops essentially in a small contact region, thus leading to high electric fields and providing a means to probe electronic transport on a microscopic scale. Detailed measurements of point-contact voltage characteristics revealed that the contact resistance decreased significantly (50-70%) with an increasing dc bias. The observed bias dependence can be well fitted by an activation energy model that involves band structure modifications under strong electric fields. Our findings suggest a promising path towards band-gap engineering in 5th transition metal oxides, which may lead to appealing technical solutions in developing next generation’s electronic devices.

3:30PM W32.00006 23Na and 17O NMR studies of hyperkagome Na5Ir3O10, ABIGAIL SHOCKLEY, FABRICE BERT, JEAN-CHRISTOPHE ORAIN, Université Paris-Sud, YOSHIHIKO OKAMOTO, Nagoya University, PHILIPPE MENDELS, Université Paris-Sud — Na5Ir3O10 is a unique case of a 3D corner sharing triangular lattice which can be decorated with quantum spins. It has spurred a lot of theoretical interest as a spin liquid candidate of a new kind where the Hamiltonian might not be thought in terms of a simple Heisenberg case because of spin orbit coupling on the Ir 5d element. We present a comprehensive set of NMR data taken on both the 23Na and 17O sites. We have found that magnetic freezing of all Ir sites sets in below T1 ~ 7.5K ~ 0.019J with a clear hyperfine field transferred from Ir moments and a drastic decrease of 1/T1. Above T1, physical properties are expected to be a landmark of frustration in this exotic geometry. We will discuss our shift and relaxation data in the temperature range of 300K to 7.5 K in the light of published thermodynamic measurements (Y. Okamotoa et al, PRL 99 137207, 2007 and Y. Singh et al, PRB 88 220413(R), 2013) and comment on their implications for the already existing large body of theoretical work.

3:42PM W32.00007 55 Tesla coercive magnetic field in frustrated Sr3NiIrO10, JOHN SINGLETON, Los Alamos Natl Lab, JAE-WOOK KIM, Oxford University, CRAIG TOPPING, Oxford University, ANDERS HANSEN, Los Alamos Natl Lab, UNE-DEOK MUN, Simon Fraser University, SAMAN GHANNADZADEH, Oxford University, PAUL GODDARD, Warwick University, XUAN LUO, YOON SEOK OH, SANG-WOOK CHEONG, Rutgers University, VIVIEN ZAPF, Los Alamos Natl Lab — We have measured extremely large coercive fields of up to 55 T in Sr3NiIrO10 using low temperature nonlinear optical generation techniques [2,3]. We will discuss the significance of this novel order parameter in the context of cuprate high-Tc superconductivity and present comparative studies on non-perovskite families of iridium oxides.

Magnetic scattering, we find direct evidence of this frustration and follow its temperature dependence. We observe that three zigzag magnetic states with 

Ir-Ir bonds in the lattice. This result confirms the dominant role of the bond-directional interactions in the frustration.

Temperature driven by the cooperation of spin-orbit coupling and moderate Coulomb correlations. Transport measurements have shown a metal-insulator transition with electron doping in $\text{Sr}_x\text{La}_2\text{IrO}_6$ near $x = 0.12$. We will show how the electronic structure evolves through the metal to insulator transition and discuss these results in terms of strong correlations and how these evolve with doping.

Direct Observation of Magnetic Frustration via Bond-directional Interactions in a Honeycomb Lattice Iridate $\text{Na}_2\text{IrO}_3$ — SAE HWAN CHUN, H. ZHENG, C. STOUMPOS, C. MALLIAKAS, J. F. MØLHOL, A. ALI, Z. ISIBI, M. MOBREI, A. ŠALÁ, M. KRISCH, European Synchrotron Radiation Facility, J. CHALOPUKA, Central European Institute of Technology, Masaryk University, G. JACKELI, K. GHALIULILIN, B. J. KIM, Max Planck Institute for Solid State Research — Despite its long-range zigzag magnetic ground state, the honeycomb $\text{Na}_2\text{IrO}_3$ is considered as a model system for approaching a Kitaev quantum spin liquid due to a proposed bond-directional magnetic frustration. Using resonant x-ray magnetic scattering, we find direct evidence of this frustration and follow its temperature dependence.

We observe that three zigzag magnetic states with short-range antiferromagnetic coupling and moderate Coulomb correlations. Transport measurements have shown a metal-insulator transition with electron doping in $\text{Sr}_x\text{La}_2\text{IrO}_6$ near $x = 0.12$. We will show how the electronic structure evolves through the metal to insulator transition and discuss these results in terms of strong correlations and how these evolve with doping.

1:30PM W32.00008 Magnetic order and electron correlations in the frustrated Ising-like chain compound $\text{Sr}_3\text{NiIrO}_6$ — E. LEFRANÇOIS, Institut Laue-Langevin - Institut Néel, L. C. CHAPON, Institut Laue-Langevin, V. SIMONET, P. LEJAY, R. BALLOW, Institut Néel, S. RAYPAL, R. BRIGGS, J. T. ADROJA, ISIS Facility, STFC, Rutherford Appleton Laboratory, D. T. ADROJA, ISIS Facility, STFC, Rutherford Appleton Laboratory - University of Oxford — Oxides of the family $\text{A}_2\text{M}_2\text{O}_6$ ($\text{A}$ = alkali-earth metal, $\text{M}$ = transition metal) attracted a lot of attention because of their unconventional magnetic properties due to the interplay between low dimensionality, magnetic frustration and magnetocrystalline anisotropy. In these compounds, the $\text{M}$ ions form chains which are distributed on a triangular lattice. We studied the 5d-based system $\text{Sr}_3\text{NiIrO}_6$, which is in the strong spin-orbit coupling regime, by single crystal magnetization measurements and neutron powder diffraction. The magnetization revealed a large easy-axis of anisotropy confining the $\text{N}_2\text{M}_2$ and $\text{L}_2\text{M}_2$ magnetic moments along the chains. Besides, the zero-field-cooled and field-cooled measurements show that there are two characteristic temperatures: $T_1 = 75$ K and $T_2 = 17$ K. The first one is associated with the appearance of a magnetic order with a propagation vector $k = (0, 0, 1)$. At $T_2$, the susceptibility reaches a maximum followed by a sudden drop. The magnetic structure was determined from neutron powder diffraction only up to a global phase. However, symmetry arguments allowed determining the exact nature of the magnetic ground state below $T_2$, thus clarifying the universal magnetic properties of this family of compounds.
by the ribosome. More details can be found at doi:10.1529/biophysj.106.090944.

This study implicates alternative coordinates along which rearrangements are accurately described as diffusive movements across a one-dimensional free-energy profile. From this, we provide the theoretical foundation required for single-molecule techniques to uncover the energy landscape governing aa-tRNA selection events and accurately indicate when the aa-tRNA is on a transition path. While a currently-used coordinate in single-molecule experiments performs poorly, we have developed a coarse-grained model of a monomer that self-assembles into tubules. In this model the monomer has a wedge shape which promotes tubule formation. There are attractive binding sites on the vertical and lateral sides of the monomer. We previously performed molecular dynamics simulations to calculate the set of structures that form upon self-assembly as we vary the lateral and vertical interaction strengths. In this talk, we will present the results of mechanical studies of the coarse-grained tubule system. The persistence length and various elastic moduli have been calculated. Microtubules have some of the largest persistence lengths of polymers. We have found that the persistence length is indeed very long for this coarse-grained model system. We calculate elastic moduli for varying the interaction strengths of the lateral and vertical interactions. We gain insight into the values that occur in microtubules, with respect to mechanical stability and stiffness.

2:54PM W33.00003 Small-angle neutron and X-ray scattering reveal conformational changes in rhodopsin activation, UTSAB R. SHRESTHA, DEBISINGH KBHOMIK, Wayne State University, MI, SUCHITRHANGA M.C.D. PERERA, UDEEP CHAWLA, ANDREY V. STRUTS, University of Arizona, AZ, VITO GRAZIONI, Brookhaven National Laboratory, NY, SAI VENKATESH PINGALI, WILLIAM T. HELLER, SHOU QIAN, Oak Ridge National Laboratory, TN, MICHAEL F. BROWN, University of Arizona, AZ, XIANG-QIANG CHU, Wayne State University, MI — Understanding G-protein-coupled receptor (GPCR) activation plays a crucial role in the development of novel improved molecular drugs. During photo-activation, the retinal chromophore of the visual GPCR rhodopsin isomerizes from 11-cis to all-trans conformation, yielding an equilibrium between inactive Meta-1-like and active Meta-II-like states. The principal goal of this work is to address whether the activation of rhodopsin leads to a specific conformational ensemble, and how protein organizational structure changes with detergent environment in solution. We use both small-angle neutron scattering (SANS) and small-angle X-ray scattering (SAXS) techniques to answer the above questions. For the first time we observe the change in protein conformational ensemble upon photo-activation by SANS with contrast variation, which enables the separate study of the protein structure within the detergent assembly. In addition, SAXS study of protein structure within detergent assembly suggests that the detergent molecules form a belt of monolayer (micelle) around protein with different geometrical shapes to keep the protein in folded state.

3:06PM W33.00004 Effects of Uniaxial Strain on Shear Moduli of Semiflexible Polymer Networks, PAUL JANNEY, University of Pennsylvania — No abstract available.

3:42PM W33.00005 Emergence of attraction in simulations of coarse-grained double stranded DNA, SHAHZAD GHANBARIAN, JOERG ROTTLE, University of British Columbia — DNA condensation induced by multivalent counterions is believed to play an important role in DNA bundling and packing into the cell nucleus. We present a coarse-grained, implicit solvent representation of rigid ds-DNA molecules in the presence of divalent counterions. In order to include solvation effects arising from the discrete nature of the water molecules, short-ranged corrections are added to the pairwise interaction potentials. We find that the structure of counterions is consistent with results from corresponding explicit solvent simulations. The effective force between two DNA strands generated by these potentials provides an excellent match to that observed in the explicit solvent model. Importantly, this interaction features multiple minima and reproduces the like-charge attraction effect between DNA molecules observed in full atomistic simulations at significantly reduced computational expense. This result proves that it is possible to capture complex multibody interactions between polyelectrolyte strands with two-body potentials.

5:18PM W32.00015 Magnetotransport in BaIrO$_3$: JENNIFER TRINH, Univ of California-Santa Cruz, JOSHUA FLYNN, MAS SUBRAMANIAN, Oregon State University, ARTHUR RAMIREZ, Univ of California-Santa Cruz — The quasi-one-dimensional monolionic semiconductor BaIrO$_3$ possesses a transition at 177 K characterized by both charge-ordering and ferromagnetism. We have measured the magneto-transport on single crystal samples in fields of up to 7T. We find that the strongly hysteretic positive magnetoresistance (MR) possesses both linear and quadratic contributions. The linear contribution is positive in the full temperature range studied, with a peak below the transition temperature at 150 K. The quadratic MR changes sign at T_C, from positive above to negative below. The Hall effect is non-monotonic as a function of field below T_C and we will relate this to the FM order parameter.

Thursday, March 5, 2015 2:30PM - 5:30PM
Session W33 DBIO DPOYL: Focus Session: Conformations and Dynamics of Biopolymers III

2:30PM W33.00001 Non-Gaussian Distribution of DNA Barcode Extension In Nanochannels Using High-throughput Imaging, JULIAN SHEATS, WESLEY REINHART$^1$. Chemical Engineering and Materials Science, University of Minnesota, Minneapolis MN, USA, JEFF REIFENBERGER, BioNano Genomics, San Diego, CA, USA, DAMINI GUPTA, ABHIRAM MURALIDHAR, Chemical Engineering and Materials Science, University of Minnesota, Minneapolis MN, USA, HAN CAO, BioNano Genomics, San Diego, CA, USA, KEVIN DORFMAN, Chemical Engineering and Materials Science, University of Minnesota, Minneapolis MN, USA — We present experimental data for the extension of internal segments of highly confined DNA using a high-throughput experimental setup. Barcode-labeled E. coli genomic DNA molecules were imaged at a high areal density in square nanochannels with sizes ranging from 40 nm to 51 nm in width. Over 25,000 molecules were used to obtain more than 1,000,000 measurements for genomic distances between 2,500 bp and 100,000 bp. The distribution of extensions has positive excess kurtosis and is skewed left due to weak backfolding in the channel. As a result, the two Odijk theories for the chain extension and variance bracket the experimental data. We compared to predictions of a harmonic approximation for the confinement free energy and show that it produces a substantial error in the variance. These results suggest an inherent error associated with any statistical analysis of barcoded DNA that relies on harmonic models for chain extension.

2:42PM W33.00002 Simulation of Microtubules: Mechanical properties, MARK STEVENS, Sandia National Labs — In order to understand microtubule assembly and the necessary monomeric properties to design artificial polymers that possess features similar to those of microtubules, we have developed a coarse-grained model of a monomer that self-assembly into tubules. In this model the monomer has a wedge shape which promotes tubule formation. There are attractive binding sites on the vertical and lateral sides of the monomer. We previously performed molecular dynamics simulations to calculate the set of structures that form upon self-assembly as we vary the lateral and vertical interaction strengths. In this talk, we will present the results of mechanical studies of the coarse-grained tubule system. The persistence length and various elastic moduli have been calculated. Microtubules have some of the largest persistence lengths of polymers. We have found that the persistence length is indeed very long for this coarse-grained model system. We calculate elastic moduli for varying the interaction strengths of the lateral and vertical interactions. We gain insight into the values that occur in microtubules, with respect to mechanical stability and stiffness.

2:54PM W33.00003 Small-angle neutron and X-ray scattering reveal conformational changes in rhodopsin activation, UTSAB R. SHRESTHA, DEBISINGH KBHOMIK, Wayne State University, MI, SUCHITRHANGA M.C.D. PERERA, UDEEP CHAWLA, ANDREY V. STRUTS, University of Arizona, AZ, VITO GRAZIONI, Brookhaven National Laboratory, NY, SAI VENKATESH PINGALI, WILLIAM T. HELLER, SHOU QIAN, Oak Ridge National Laboratory, TN, MICHAEL F. BROWN, University of Arizona, AZ, XIANG-QIANG CHU, Wayne State University, MI — Understanding G-protein-coupled receptor (GPCR) activation plays a crucial role in the development of novel improved molecular drugs. During photo-activation, the retinal chromophore of the visual GPCR rhodopsin isomerizes from 11-cis to all-trans conformation, yielding an equilibrium between inactive Meta-1-like and active Meta-II-like states. The principal goal of this work is to address whether the activation of rhodopsin leads to a specific conformational ensemble, and how protein organizational structure changes with detergent environment in solution. We use both small-angle neutron scattering (SANS) and small-angle X-ray scattering (SAXS) techniques to answer the above questions. For the first time we observe the change in protein conformational ensemble upon photo-activation by SANS with contrast variation, which enables the separate study of the protein structure within the detergent assembly. In addition, SAXS study of protein structure within detergent assembly suggests that the detergent molecules form a belt of monolayer (micelle) around protein with different geometrical shapes to keep the protein in folded state.

3:06PM W33.00004 Effects of Uniaxial Strain on Shear Moduli of Semiflexible Polymer Networks, PAUL JANNEY, University of Pennsylvania — No abstract available.

3:42PM W33.00005 Emergence of attraction in simulations of coarse-grained double stranded DNA, SHAHZAD GHANBARIAN, JOERG ROTTLE, University of British Columbia — DNA condensation induced by multivalent counterions is believed to play an important role in DNA bundling and packing into the cell nucleus. We present a coarse-grained, implicit solvent representation of rigid ds-DNA molecules in the presence of divalent counterions. In order to include solvation effects arising from the discrete nature of the water molecules, short-ranged corrections are added to the pairwise interaction potentials. We find that the structure of counterions is consistent with results from corresponding explicit solvent simulations. The effective force between two DNA strands generated by these potentials provides an excellent match to that observed in the explicit solvent model. Importantly, this interaction features multiple minima and reproduces the like-charge attraction effect between DNA molecules observed in full atomistic simulations at significantly reduced computational expense. This result proves that it is possible to capture complex multibody interactions between polyelectrolyte strands with two-body potentials.

3:54PM W33.00006 Capturing Transition Paths and Transition States for Conformational Rearrangements in the Ribosome, JEFFREY NOEL, Center for Theoretical Biological Physics Rice University, JORGE CHAHINE, VITOR LEITE, Universidade Estadual Paulista, Rio Preto, Brazil, PAUL WHITFORD, Physics Dept Northeastern Univ — To reveal the molecular determinants of biological function, one seeks to characterize the interactions that are formed in conformational and chemical transition states. In other words, what interactions govern the molecule’s energy landscape? To accomplish this, it is necessary to identify which degrees of freedom can unambiguously identify each transition state. Here, we perform simulations of large-scale aminocyl-tRNA (aa-tRNA) rearrangements during accommodation on the ribosome and project the dynamics along experimentally-accessible atomic distances. From this analysis, we obtain evidence for which coordinates capture the correct number of barrier-crossing events and accurately indicate when the aa-tRNA is on a transition path. While a currently-used coordinate in single-molecule experiments performs poorly, this study implicates alternative coordinates along which rearrangements are accurately described as diffusive movements across a one-dimensional free-energy profile. From this, we provide the theoretical foundation required for single-molecule techniques to uncover the energy landscape governing aa-tRNA selection by the ribosome. More details can be found at doi:10.1529/biophysj.106.090944.
4:06PM W33.00007 Study on the stability of the DNA hairpin d(ATCCAT-GTTA-TAGGAT) employing molecular dynamics simulation, SANGWOOK WU, Department of Physics, Pukyong National University, Busan 608-737, Korea. HONGGU CHUN COLLABORATION — DNA hairpin plays a critical role in the regulation of gene expression and DNA recombination. We studied the conformation of the DNA hairpin (d(ATCCAT-GTTA-TAGGAT)) employing molecular dynamics (MD) simulation. Despite the non-canonical Watson-Crick base pair (G:A) in the tetraloop (GTGA), MD simulation reveals that the conformation of the DNA hairpin is remarkably stable. In this study, we discuss about the physical/chemical origin of the stability of the DNA hairpin.

4:18PM W33.00008 Effect of solvent viscosity on driven translocation of a semi-flexible polymer through a nanopore, RAMESH ADHIKARI, ANIKET BHATTACHARYA, University of Central Florida — We study the effect of solvent viscosity and pore diameter on the driven translocation of a semi-flexible chain using Langevin dynamics simulation. We observe that for a given chain stiffness the mean first passage time (MFPT) has a nonmonotonic dependence on the solvent viscosity. For moderate external biases, the MFPT decreases at very low solvent viscosity exhibiting a minimum before it increases linearly as a function of high solvent viscosity. We demonstrate a stiffer chain translocates faster than a flexible chain of same length at the low viscosity regime while the opposite is true at high viscosity regime. The effect of pore size on the translocation dynamics is more acute at low solvent viscosity (pore friction dominating regime), but has almost negligible effect at the high viscosity regime for the parameters used in our studies.

4:30PM W33.00009 Spontaneous curvature in chiral polar filaments near interfaces, PETER D. OLMSTED, Department of Physics, Georgetown University, EMILY E. RILEY, Department of Applied Mathematics and Theoretical Physics, Cambridge University, SOPHIA JORDENS, IVAN USOV, Department of Health Sciences & Technology, Laboratory of Food & Soft Materials, ETH Zurich, LUCIO ISA, Department of Materials, Laboratory for Surface Science & Technology, ETH Zurich, RAFFAELE MEZZENGA, Department of Health Sciences & Technology, Laboratory of Food & Soft Materials, ETH Zurich — Chiral filaments (actin, DNA, alpha helical strands, ...) are ubiquitous in biology, and they frequently come into contact with interfaces or inhomogeneous environments, either in biology (e.g. actin on membranes) or use and processing of biomaterials (fibrils at solvent boundaries or nanoparticle surfaces). Recent experiments have shown that amyloid fibrils can develop unusual curvatures at the air-water interface. Here we show that spontaneous curvature follows, on symmetry grounds, for chiral polar filaments placed in inhomogeneous environments such as near surfaces. We demonstrate this for simple model surface-fibril interactions, and discuss some of the implications.

3Financial support is acknowledged from: ETH Zurich (ETHHIRA TH 32-1), SNF (2-77002-11), and SNSF (IZK072.141955, PP00P2.144646/1, PZ00P2.142532/1).

4:42PM W33.00010 Adsorption of Helical Polymers on a Substrate, MATTHEW WILLIAMS, Univ of Georgia — Formation of tertiary structures made up of helical polymer segments is modified by the introduction of a substrate on which the polymer is adsorbed. The effect of a substrate on biological systems such as helical structures may be important in the formation of early life. We perform replica-exchange Monte Carlo simulations to study the effect of a substrate on formation of helical structures, comparing the structural phase space for both adsorbed and non-adsorbed helical polymers. For this purpose a generic, hybrid coarse-grained model for polymer adsorption has been employed.

4:54PM W33.00011 ABSTRACT WITHDRAWN —

5:06PM W33.00012 Elasticity of 3D networks with rigid filaments and compliant crosslinks, KNUT M. HEIDEMANN, Institute for Numerical and Applied Mathematics, Georg-August-Universität, Göttingen, Germany, ABHINAV SHARMA, FLORIAN REHFEIDT, CHRISTOPH F. SCHMIDT, Third Institute of Physics — Biophysics, Georg-August-Universität, Göttingen, Germany, MAX WARDETZKY, Institute for Numerical and Applied Mathematics, Georg-August-Universität, Göttingen, Germany — Disordered filamentous networks with compliant crosslinks exhibit a low linear elastic shear modulus at small strains, but stiffen dramatically at high strains. Here, we perform an analytical and numerical study on model networks in three dimensions. Our model consists of a collection of randomly oriented rigid filaments connected by flexible crosslinks that are modeled as wormlike chains. Under the assumption of affine deformations in the limit of infinite crosslink density, we show analytically that the nonlinear elastic regime in 1- and 2-dimensional networks is characterized by power-law scaling of the elastic modulus with the stress. In contrast, 3-dimensional networks show an exponential dependence of the modulus on stress. Independent of dimensionality, if the crosslink density is finite, we show that the only persistent scaling exponent is that of the single wormlike chain. Consequently, unlike suggested in prior work, the model system studied here cannot provide an explanation for the experimentally observed linear scaling of the modulus with the stress in filamentous networks.

5:18PM W33.00013 Molecular Dynamics Investigations of the alpha-helix to Beta-barrel Conformational Transformation in RfaH, JEEVAN GC, YUBA BHANDARI, BERNARD GERSTMAN, PREM CHAPAGAIN, Florida International University — We used combination of replica exchange molecular dynamics simulations with implicit solvent and detailed all-atom simulations with explicit solvent to investigate the alpha-helix to beta-structure transformation of RfaH-CTD. While interacting with the N-terminal domain (NTD), the C-terminal domain (CTD) of RfaH folds to a alpha-helix bundle but it undergoes an all alpha to all beta conformational transformation when it does not interact with the NTD. The RfaH-CTD in the all alpha topology is involved in regulating transcription whereas in the all beta topology it is involved in stimulating translation by recruiting a ribosome to an mRNA. Calculations of free-energy landscape and transfer entropy elucidate the details of the RfaH-CTD transformation process. The importance of interfacial interactions between the two domains of RfaH is highlighted by the compromised structural integrity of the helical form of the CTD in the absence NTD. We also studied interdomain and intradomain interactions in RfaH using Steered Molecular Dynamics Simulations. We investigated the role of the interdomain salt-bridge interaction in the domain stability Potential mean force was calculated to obtain free energy profile using Jarzynski Equality.

Thursday, March 5, 2015 2:30PM - 5:06PM — Session W35 GSOFT: Colloidal Clusters, Interactions, and Synthesis

210B - Robert Hoy, University of South Florida
2:30PM W35.00001 Structure and dynamics of model colloidal clusters with short-range attractions, KRYSTLE QUINN, ROBERT HOY, University of South Florida — We examine the structure and dynamics of small isolated N-particle clusters interacting via short-ranged Morse potentials. Ideally prepared ensembles obtained via exact enumeration studies of sticky hard sphere packings serve as reference states allowing us to identify key statistical-geometrical properties as well as to quantitatively characterize how nonequilibrium ensembles prepared by thermal quenches at different rates T differ from their equilibrium counterparts. Our results provide a theoretical framework for extending recent experimental studies of small colloidal clusters to examine nonequilibrium phenomena.

2:42PM W35.00002 Ground States and Folding Dynamics of Colloidal Clusters, ELLEN KLEIN, W. BENJAMIN ROGERS, VINOTHAN N. MANOHARAN, Harvard University — We experimentally study colloidal clusters consisting of N<100 spherical particles with short range, isotropic interactions. These clusters are a model system for understanding colloidal self-assembly and dynamics, since the positions and motion of the particles can be observed in real space. For N ≤ 10 the ground states are degenerate; previous work has shown that the probabilities of observing specific clusters depend primarily on their rotational entropy, which is determined by symmetry. Thus, less symmetric structures are more frequently observed. However, for large N the ground state should be a highly symmetric close-packed lattice. We seek to understand how this transition occurs as a function of N.To do this, we coat colloidal particles with complementary DNA strands that induce a short-range, temperature dependent interparticle attraction. We then assemble and anneal an ensemble of clusters with N ≥ 10. We characterize the number of apparent ground states, their symmetries, and their probabilities as a function of N. We also observe how these clusters fold into minimal-energy configurations by subjecting them to an electric field that we then relax.

1 VENI grant from The Netherlands Organization for Scientific Research (NWO)

3:06PM W35.00004 Countermediated-Mediated Assembly of Spherical Nucleic Acid-Au Nanoparticle Conjugates (SNA-AuNPs), SUMIT KEWALRAMANI, LIANE MOREAU, GUILLERMO GUERRERO-GARCIA, CHAD MIRKIN, MONICA OLVERA DE LA CRUZ, MICHAEL BEDZYK, Northwestern University, AFOSR MURI TEAM — Controlled crystallization of colloids from solution has been a goal of material scientists for decades. Recently, nucleic acid functionalized spherical Au nanoparticles (SNA-AuNPs) have been programmed to assemble in a wide variety of crystal structures. In this approach, the assembly is driven by Watson-Crick hybridization between DNAs coating the AuNPs. Here, we show that counterions can induce ordered assembly of SNA-AuNPs in bulk solutions, even in the absence of base pairing interactions. The electrostatics-driven assembly of spherical nucleic acid-Au nanoparticle conjugates (SNA-AuNPs) is probed as a function of counterion concentration and counterion valency [±1 (Na+) or ±2 (Ca2+) ] by in situ solution X-ray scattering. Assemblies of AuNPs capped with single-stranded (ss) or double-stranded (ds) DNA are examined. SAXS reveals disordered (gas-like) → face-centered-cubic (FCC) → glass-like phase transitions with increasing solution ionic strength. These studies demonstrate how non-base-pairing interactions can be tuned to create crystalline assemblies of SNA-AuNPs. The dependence of the inter-SNA-AuNP interactions on counterion valency and stiffness of the DNA corona will be discussed.

3:18PM W35.00005 Measuring colloidal charges in low polar media from statistics of particle trajectories, DANIEL KRAFT, Leiden University — Controlling the geometry and yield of anisotropic colloidal particles remains a challenge for hierarchical self-assembly. I will discuss a synthetic strategy for fabricating colloidal clusters by creating order in randomly aggregated polymer spheres using surface tension and geometrical constraints. The technique can be extended to a variety of charge-stabilized polymer spheres and offers control over the cluster size distribution.

3:30PM W35.00006 Does Suspension Crowding Screen Hydrodynamic Interactions? , YU SU, ROSEANNA N. ZIA, Cornell University, JAMES W. SWAN, Massachusetts Institute of Technology — Resistance and mobility functions describe linear couplings between moments of the hydrodynamic traction on a suspended particle and the motion of that or other particles. For two isolated spheres, these functions are well known and have been applied directly to the precise measurements in the vicinities of dilute colloidal dispersions. We have devised a new stochastic technique to calculate an analogous set of functions for two spheres immersed in a suspension that are then used to model the near-equilibrium dynamics of concentrated suspensions, including viscoelasticity and long-time diffusion. Of interest is the degree of screening of hydrodynamic interactions by the intervening medium. We find that the mobility is unscreened at the pair level, even in suspensions of high concentration, confirming that hydrodynamic interactions are an essential part of the dynamics of crowded systems and cannot be neglected in favor of simple renormalization schemes. We compare our results for the hydrodynamic interactions between suspended particles to predictions from two-point microrheology. This technique can be used to infer the complex viscosity from long-ranged decay of the pair mobility in viscoelastic materials.

3:42PM W35.00007 Pair Interactions of Superhydrophobic Colloids at an Oil-Aqueous Phase Interface, COLM KELLEHER, New York University, ANNA WANG, Harvard University, IVAN GUERRERO, Northwestern University, BHASKAR KRISHNATREYA, ANDREW HOLLINGSWORTH, DAVID GRIER, New York University, VINOTHAN MANOHARAN, Harvard University, PAUL CHAIKIN, New York University — Superhydrophobic PMMA colloids, dispersed in oil, can become highly charged. In the presence of an interface with a conducting aqueous phase, image charge effects lead to strong binding of colloidal particles to the interface, despite the fact that the equilibrium contact angle θi > 170°. We present the results of a series of experiments designed to probe the attraction of individual colloids to the interface, and the repulsion between pairs of interfacially bound colloids. We show that these interactions are relatively uniform, reproducible, and time-independent, and can be described by a simple model in which the only parameters are the particle charge and the Debye screening length in the oil phase. These factors make this system a good candidate for studying various equilibrium and non-equilibrium phenomena in 2D condensed matter physics, for example defect formation and dynamics in 2D colloidal crystals, and structural rearrangements in sheared colloidal glasses.

3:54PM W35.00008 Precise measurement of surface plasmon forces at a metal-dielectric interface using a calibrated evanescent wave, LULU LIU, ALEX WOOLF, Harvard University — By observing the motion of an optically trapped microscopic colloid, sub-piconewton static and dynamical forces have been measured using a technique called photonice force microscopy. This technique, though potentially powerful, has in the past struggled to provide precise measurements of a reflective or metallic interface, due to distortions of the optical field. We introduce a new in-situ, contact-free calibration method for particle tracking using an evanescent wave, and demonstrate its expanded capability by the precise measurement of forces of interaction between a single colloid and the optical field generated by a propagating surface plasmon polariton on gold.
4:06PM W35.00009 Osmotic equation of colloidal nanoparticles transiently confined in an optical trap.  
JINXIN FU, Georgia Institute of Technology, H. DANIEL OU-YANG, Lehigh University — Equilibrium number density profile of colloidal particles in a potential force field depends on the particle number density, the force field and interactions between the particles. Einstein described the particle number density profile by an osmotic equilibrium equation relating colloidal osmotic pressure and the potential force in his 1905 paper on the Brownian motion. For a dilute suspension of colloids, when particle interactions are negligible, the osmotic equilibrium equation can be used to determine unknown potential energy profiles from the Boltzmann distribution of the particle number density. Using a known potential energy profile, one can determine the colloidal osmotic pressure as a function of particle density, i.e., the osmotic equation of state, from the density profiles of interacting colloids. We use particle density profiles determined by confocal imaging of fluorescent polystyrene nanoparticles transiently confined in an optical trap to determine the colloidal osmotic equation of state for colloids in the presence of KCl and neutral polymers. The osmotic compressibility and chemical potentials of the colloids are calculated from the osmotic equation of state to predict colloidal stability and phase transitions.

4:18PM W35.00010 Determination of colloidal osmotic equation of state by dielectrophoresis.  
JACOB MAZZA, HAO HUANG, H. DANIEL OU-YANG, Lehigh University — Osmotic equation of state $P(N,T)$ describes both the mechanical properties and phase behavior of a colloidal suspension. As an alternative to sedimentation, we propose a new approach to determine $P(N,T)$ by dielectrophoresis (DEP). Using fluorescence confocal microscopy, we obtain particle density profiles in order to determine the DEP force distribution when the particle concentration is low and the inter-particle interactions are negligible. From the known force distribution and Einstein’s osmotic equilibrium equation, we can calculate $P(N,T)$ from the particle density profile of interacting, charge-stabilized polystyrene latex particles under different salt concentrations and added neutral polymers. The osmotic equation of state for colloidal suspensions can then be crosschecked by sedimentation equilibrium.

4:30PM W35.00011 Differential Dynamic Microscopy of Weakly Scattering and Polydisperse Protein Rich Clusters.  
JACINTA CONRAD, MOHAMMAD SAFARI, PETER VEKILOV, University of Houston — Biological objects often scatter light weakly and are frequently smaller than the diffraction limit, complicating measurements of their dynamics. Differential dynamic microscopy (DDM) is a recently developed method to quantify dynamics of sub-$\mu$m particles in solutions from fluctuations in intensity in optical micrographs. DDM is well established for monodisperse particles but has not been applied to polydisperse biological nanoparticles. Here, we used DDM to measure dynamics of polydisperse nanoscale objects, protein-rich liquid clusters in protein solutions, whose size ranged from tens to hundreds of nanometers and whose total volume fraction was less than 10$^{-5}$. For solutions of two proteins, lysozyme and hemoglobin A, we measured the dynamics of clusters using DDM and evaluated their diffusion coefficients from the dependence of the diffusion lag time on the scattering wave vector. The average diffusion coefficient of clusters measured using DDM was consistently smaller than that obtained from dynamic light scattering at 90°. The apparent discrepancy between these results was explained by Mie scattering theory, which indicates that larger clusters preferentially scatter more light in the forward direction.

4:42PM W35.00012 Fast Holographic Characterization of Dimpled Spheres.  
MARK HANDEL, CHRISTINE MIDDLETON, DAVID GRIER, New York University — We present a method for quickly analyzing the radii and refractive indexes of dimpled spheres using Holographic Video Microscopy. Our method utilizes an azimuthal median to suppress the perturbation caused by the dimple on an otherwise radially symmetric hologram. The resulting one-dimensional radial profile is fit to Lorenz-Mie theory using Support Vector Machines (SVM). We then discuss the limitations of this method as well as the use of SVMs trained on different scattering geometries or theories.

4:54PM W35.00013 Highly uniform polyhedral colloids formed by colloidal crystal templating.  
YIFAN WANG, JAMES MCCGINLEY, JOHN CROCKER, Univ of Pennsylvania, CROCKER RESEARCH GROUP TEAM — We seek to create polyhedral solid particles by trapping oil droplets in a colloidal crystal, and polymerizing them in situ, resulting in polyhedral particles containing spherical dimples in an ordered arrangement. Specifically, highly monodisperse, micron-sized droplets of 3-methacryloxypropyl trimethoxysilane (TPM) were first prepared through a recently developed method used to quantify dynamics of sub-$\mu$m particles in solutions from fluctuations in intensity in optical micrographs. DDM is well established for monodisperse particles but has not been applied to polydisperse biological nanoparticles. Here, we used DDM to measure dynamics of polydisperse nanoscale objects, protein-rich liquid clusters in protein solutions, whose size ranged from tens to hundreds of nanometers and whose total volume fraction was less than 10$^{-5}$. For solutions of two proteins, lysozyme and hemoglobin A, we measured the dynamics of clusters using DDM and evaluated their diffusion coefficients from the dependence of the diffusion lag time on the scattering wave vector. The average diffusion coefficient of clusters measured using DDM was consistently smaller than that obtained from dynamic light scattering at 90°. The apparent discrepancy between these results was explained by Mie scattering theory, which indicates that larger clusters preferentially scatter more light in the forward direction.

2:30PM W36.00001 Quantifying fermionic decoherence in many-particle systems.  
ARNAB KAR, IGNACIO FRANCO, Univ of Rochester — Decoherence or the loss of quantum correlations in a system arises due to the interaction of the system with its environment. Our aim is to construct measures of decoherence that are applicable to multi-electron systems and, using them, understand the relationship between electronic correlations and decoherence. Usual measures of decoherence are of limited applicability in many body systems because they are based on the hierarchy of particle reduced density matrices [1-2]. Given a single particle basis, these measures can be used to succinctly capture relevant coherences and interpret decoherence dynamics in driven and non-driven many body systems. The distilled purity measures will be exemplified using the dynamics of the Su-Schrieffer-Heeger Hamiltonian for trans-polyacetylene. The advantages and limitations of these distilled purity measures will also be discussed.

2:42PM W36.00002 High Resolution Neutral Atom Microscope.  
IGHL BUCAY, RODRIGO CASTILLO-GARZA, GEORGIOS STRATIS, MARK RAIZEN, University of Texas at Austin — We are developing a high resolution neutral atom microscope based on metastable atom electron spectroscopy (MAES). When a metastable atom of a noble gas is near a solid, a surface electron will tunnel to an empty energy level of the metastable atom, thereby ejecting the excited electron from the atom. The emitted electrons carry information regarding the local topography and electronic, magnetic, and chemical structures of most hard materials. Furthermore, using a chromatic aberration corrected magnetic hexapole lens we expect to attain a spatial resolution below 10 nm. We will use this microscope to investigate how local phenomena can give rise to macroscopic effects in materials that cannot be probed using a scanning tunneling microscope, namely insulating transition metal oxides.
2:54PM W36.00003 Feshbach Modulation Spectroscopy1. JAMES FREERICHS, Georgetown Univ, ANDREAS DIRKS, Volume Graphics, HULILAK KRISHNAMURTHY, Indian Institute of Science, KARLIS MIKELSONS, Global Science and Technology — Feshbach resonances are often swept through to bind atoms into weakly bound molecules. Here we propose to examine the behavior of systems close to a Feshbach resonance when we modulate the bias magnetic field as a function of time, creating a modulated scattering length. On an optical lattice, this system undergoes rich physical transformations which involve both molecule formation and the hopping of molecules on the lattice and thus goes beyond a single-band Hubbard model description. While experiments have already studied some of this phenomena, especially resonance effects on the binding of molecules, we feel that this system is likely to have interesting physical behavior when on an optical lattice. We propose to probe the behavior with a harmonic modulation of the magnetic field and thus the scattering length across the Feshbach resonance as a generalization of lattice-depth modulation spectroscopy. In the regime in which the single-band Hubbard model is still valid, we provide simulation data for this type of spectroscopy which behaves somewhat differently from conventional modulation spectroscopy (the hopping is not modulated, just the interaction strength).

3:06PM W36.00004 Quantum Melting in a Polariton Lattice, ALEXANDER EDELMAN, PETER LITTLEWOOD, Univ of Chicago — We study a generalized Dicke model of lattice polaritons, with a pair-potential interaction between excited states of the spin component, in the functional integral formalism. Even considering only zero-temperature equilibrium effects with a uniform photon field, there is a rich phase diagram as a function of light-matter coupling, which includes spatially ordered and superfluid phases. Depending sensitively on the form of the potential, the interaction may induce an instability in the sound mode of the polariton condensate, or destroy the condensate altogether. Zero-temperature fluctuations may likewise melt the spatially ordered phases. We consider implications for cold-atom experiments with tunable interactions, as well as interacting exciton-polaritons accessible in the solid state.

3:18PM W36.00005 Quantum fluctuations and gapped Goldstone modes in spinor Bose-Einstein condensates, ARON BEEKMAN, RIKEN Center for Emergent Matter Science — The classical Heisenberg ferromagnet is an exact eigenstate of the quantum Hamiltonian and therefore has no quantum fluctuations. Furthermore it has a reduced number of Goldstone modes, an order parameter that is itself a symmetry generator, is a highest-weight state for the spin algebra, and has no tower of states of vanishing energy. We derive the connection between all these properties and provide general criteria for their presence in other spontaneously-broken symmetry states. The phletora of groundstates in spinor Bose-Einstein condensates is an ideal testing ground for these predictions. In particular the phases with non-maximal polarization (e.g. the F-phase in spin-3 condensates) have an additional gapped mode that is a partner to the quadratically dispersing Goldstone mode, as compared to the maximally polarized, ferromagnetic phase. Furthermore there is a fundamental limit to the coherence time of superpositions in the non-maximally polarized state, which should manifest itself for small-size systems.

3:30PM W36.00006 Emergent dual space-time geometry for free fermions, CHING HUA LEE, XIAO-LIANG QI, Stanford Univ — The theme of holography has attracted great interest among high energy and condensed matter physicists alike. It involves describing a ‘boundary’ system in terms of a ‘bulk’ system in a space one dimension higher, with the emergent direction representing energy scale. We propose a simple exact holographic mapping for lattice systems based on wavelet bases, which naturally entail an emergent dimension representing scale. The system in the new basis is identified as the bulk, whose correlation functions can be interpreted as that of a massive field in curved spacetime. Despite the simplicity of our approach, we obtain in the long wavelength limit geometries that are consistent with those expected from the Ryu-Takayanagi formula, i.e. AdS space for critical zero-temperature systems, a paradigmatic example of the AdS-CFT correspondence. At nonzero temperature, we obtain the BTZ and Lifshitz black holes for linear and nonlinear critical band touchings respectively, as we analytically verify up to the subleading logarithmic correction. Our results remain true in any number of dimensions, under generic local wavelet bases.

3:42PM W36.00007 Supersymmetry in quantum optics and in spin-orbit coupled systems1. MICHAEL TOMKA, Boston University, MIKHAIL PLETYUKHOV, Institute for Theory of Statistical Physics and JARA - Fundamentals of Future Information Technology, RWTH Aachen, VLADIMIR GRITSEV, Institute of Theoretical Physics, University of Amsterdam — Light-matter interaction is naturally described by coupled bosonic and fermionic subsystems. This suggests that a certain Bose-Fermi duality is naturally present in the fundamental quantum mechanical description of photons interacting with atoms. We reveal submanifolds in parameter space of a basic light-matter interacting system where this duality is promoted to a supersymmetry (SUSY) which remains unbroken. We show that SUSY is robust with respect to decoherence and dissipation. In particular, the stationary density matrix at the supersymmetric lines in parameter space has a degenerate subspace. The dimension of this subspace is given by the Witten index that is itself a symmetry generator, is a highest-weight state for the spin algebra, and has no tower of states of vanishing energy. We derive the connection between all these properties and provide general criteria for their presence in other spontaneously-broken symmetry states. The phletora of groundstates in spinor Bose-Einstein condensates is an ideal testing ground for these predictions. In particular the phases with non-maximal polarization (e.g. the F-phase in spin-3 condensates) have an additional gapped mode that is a partner to the quadratically dispersing Goldstone mode, as compared to the maximally polarized, ferromagnetic phase. Furthermore there is a fundamental limit to the coherence time of superpositions in the non-maximally polarized state, which should manifest itself for small-size systems.

3:54PM W36.00008 Magnetization and Transport Properties for Particles in Spin Textures1, TIMOTHY MCCORMICK, NANDINI TRIVEDI, The Ohio State University — We use exact-diagonalization and Monte Carlo (ED + MC) to calculate the magnetization M(T) and the spin polarization P(T) for a charged particle moving in a variety of ferromagnetic, spiral and chiral spin textures. We derive an effective spin Hamiltonian by integrating out charged degrees of freedom and compare its magnetization with that of the full Hamiltonian. We then calculate transport properties such as the dynamical conductivity (Sigma(omega)) and the anomalous Hall conductivity using the Chern number.

4:06PM W36.00009 Emergent Magnetic Monopole Charges in a Two Qubit System, TIAGO GRANGEIRO SOUZA BARBOSA LIMA, MICHAEL KOLODRUBETZ, ANATOLI POLKOVNIKOV, Boston Univ — The topology of two coupled qubits has recently been explored using dynamical measurements of their Berry curvature F. Its integral gives the topologically invariant Chern number, which natural maps to the presence of magnetic monopole charges in parameter space. We suggest a method for measuring the magnetic monopole charge density and detail its motion as external parameters are varied. Using Maxwell’s equations with the addition of magnetic monopoles, we obtain the effective charge density and the current density as a function of the parameters. We show how particular choices for parameters give rise to peculiar motion of the monopole charges, which can go from isolated charges to continuous charge distributions like rings and surfaces by properly changing the system’s symmetries through its parameters. Finally, we probe the interesting but as yet unexplored consequences on ∇ × F as said changes are made.

4:18PM W36.00011 Entropy flow in quantum heat engines, MOHAMMAD ANSARI, YULI NAZAROV, Kavli Institute for Nanoscience, Delft University of Technology — We evaluate Shannon and Renyi entropy flows from generic quantum heat engines (QHE) to a weakly-coupled probe environment kept in thermal equilibrium. We show the flows are determined by two quantities: heat flow and fictitious dissipation that manifest the quantum coherence in the engine. Our theory leads to novel physics in quantum heat engines.

3:54PM W36.00008 Magnetization and Transport Properties for Particles in Spin Textures1, TIMOTHY MCCORMICK, NANDINI TRIVEDI, The Ohio State University — We use exact-diagonalization and Monte Carlo (ED + MC) to calculate the magnetization M(T) and the spin polarization P(T) for a charged particle moving in a variety of ferromagnetic, spiral and chiral spin textures. 4:18PM W36.00011 Entropy flow in quantum heat engines, MOHAMMAD ANSARI, YULI NAZAROV, Kavli Institute for Nanoscience, Delft University of Technology — We evaluate Shannon and Renyi entropy flows from generic quantum heat engines (QHE) to a weakly-coupled probe environment kept in thermal equilibrium. We show the flows are determined by two quantities: heat flow and fictitious dissipation that manifest the quantum coherence in the engine. Our theory leads to novel physics in quantum heat engines.
4:30PM W36.00011 Dynamics of Noisy Quantum Systems in the Heisenberg Picture: Application to the Stability of Fractional Charge. ARMIN RAHMANI, University of British Columbia — Based on the Heisenberg-picture analog of the master equation, we develop a method for computing the exact time dependence of noise-averaged observables for (generally interacting) fermionic systems with noisy hopping processes. Our results provide access to a long-time limit, which is not amenable to numerical simulations. As a simple example, we examine the fate of the fractional charge in a noisy dimerized lattice with a domain wall (relevant to cold-atom emulations of polyacetylene). We find that the fractional charge remains robust against noisy hopping processes between different sublattices, while it becomes unstable to fluctuations in hopping on the same sublattice.

4:42PM W36.00012 Fermions in a harmonic trap with spin-imbalanced filling. DENIS MORATH, STEFAN A. SOEFFING, SEBASTIAN EGGERT, Univ. of Kaiserslautern — In recent experiments with ultra-cold fermions it was possible to prepare states with imbalanced pseudo-spin fillings, analogous to electrons in quantum dots. This offers the opportunity to make controlled measurements of the effects of interactions, spin filling and temperature on the density of confined fermions. We now consider the situation in a one-dimensional trap theoretically and with numerical quantum simulations (quantum Monte Carlo and DMRG). Already for three particles in a trap there is a surprising alignment of spin up an down particles with a rather dramatic effect of the temperature. Naively an antiferromagnetic correlation between the spin species should be expected for repulsive interactions, i.e. density maxima of spin-up should correlate in space with spin-down minima and vice versa. However, already very low finite temperatures can induce ferromagnetic correlations. Based on the analysis of few particle situations and symmetry considerations we can also explain the behaviour of many particle systems.

4:54PM W36.00013 Many-Body Transition in a Spin-Orbit Coupled Bose-Einstein Condensate, JEFFREY T.F. POON, XIONG-JUN LIU, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — In quantum mechanics, a resonant Rabi oscillation can occur between two degenerate single-particle states when such two states are subject to external perturbations. This phenomenon can be qualitatively different in the interacting regime. In this work, we study a spin-orbit coupled Bose-Einstein condensate with degenerate many-body states and examine the transitions between such states. We find that due to the particle-particle interactions the many-body transitions between such degenerate states are completely different from the physics in single-particle systems. Both the numerical and analytic results will be discussed.

5:06PM W36.00014 Landau-Zener transitions in a two-level system that is coupled to a finite-temperature harmonic oscillator. SAHEL ASHHAB, Qatar Environment and Energy Research Institute, Qatar Foundation, Doha, Qatar — The Landau-Zener (LZ) problem is a standard paradigm for studying energy transfer and adiabatic passage protocols. We consider the LZ problem for a two level system when this system interacts with one harmonic oscillator mode that is initially set to a finite-temperature thermal equilibrium state. The oscillator could represent an external mode that is strongly coupled to the system, e.g. an ionic oscillation mode in a molecule, or it could represent a prototypical uncontrolled environment. We analyze the system’s occupation probabilities at the final time in a number of different regimes, varying the system and oscillator frequencies, their coupling strength and the temperature. In particular we find some surprising non-monotonic dependence on the coupling strength and temperature.

5:18PM W36.00015 Effects of nonmagnetic impurities on BCS-BEC crossover in atomic Fermi gases. YANMING CHE, QIJIN CHEN, Zhejiang University — We present a systematic investigation of the effects of nonmagnetic impurities on the $s$-wave BCS-BEC crossover within a pairing fluctuation theory. Both the pairing $T$-matrix and the impurity scattering $T$-matrix are treated self-consistently at the same time, in the context of ultracold atomic Fermi gases. While the system is less sensitive to impurity scattering in the BCS limit, in the strong impurity scattering limit, both the frequency and the gap function are highly renormalized, leading to significant suppression of the superfluid $T_c$. In the BCS regime, the superfluidity may be readily destroyed by the impurity, leading to an effective power law dependence of $T_c$ as a function of pairing strength. In comparison, $T_c$ and (pseudo)gaps in the unitary and BEC regimes are relatively more robust. In either cases, the $s$-wave pairing is less sensitive to impurity than its $d$-wave counterpart. Calculations of superfluid density will also be presented. References: Q.J. Chen and J.R. Schrieffer, Phys. Rev. B 66, 014512 (2002).

3:06PM W37.00002 Rabi oscillations at different tunnel couplings for an ac-gated quantum dot qubit. BRANDUR THORGRIIMSSON, DOHUN KIM, C.B. SIMMONS, DANIEL R. WARD, RYAN H. FOOTE, D.E. SAVAGE, M.G. LAGALLY, MARK FRIESEN, S.N. COPPERSMITH, M.A. ERIKSSON, Univ of Wisconsin, Madison — One way to create a qubit is to use two distinct positions of a single electron as qubit states. Such a system can be achieved by using the left and right positions in a gated double quantum dot. In this system the qubit is strongly coupled to electric fields and has potential for high-speed operations. By tuning specific gate voltages, we can tune the tunnel coupling strength and microwave drive power, and we study strong driving effects such as generation of second harmonics. This work was supported in part by ARO (W911NF-12-0607) and NSF (DMR-1206915 and PHY-1104660). Development and maintenance of the growth facilities used for fabricating samples is supported by DOE (DE-FG02-03ER46028). This research utilized NSF-supported shared facilities at the University of Wisconsin-Madison.

3:18PM W37.00003 Single-electron spin resonance in a Si/SiGe double quantum dot with a micromagnet, KENTA TAKEDA, The University of Tokyo, JUN KAMIOKA, Tokyo Institute of Technology, TOSHIKAI OBATA, The University of Tokyo, TOMOHIRO OTSUKA, TAKASHI NAKAJIMA, MATTHIEU DELSECQ, SHINICHI AMADA, JUN YONEDA, CEMS, RIKEN, AKITO NOIRI, RETSU SUZUKI, TAKAYUKI OKAYA, SHUNRI ODA, Tokyo Institute of Technology, SEIGO TAKACHI, University of Tokyo, CEMS, RIKEN, THE UNIVERSITY OF TOKYO TEAM, TOKYO INSTITUTE OF TECHNOLOGY COLLABORATION, CEMS, RIKEN COLLABORATION — Electrons in Si quantum dots are promising candidates for implementing spin qubits because of their long coherence times [1, 2]. We report on our measurement results of addressable electron spin resonance in a Si/SiGe double quantum dot with a micromagnet. We also show that the addressable electron spin resonance is useful to understand two-electron spin and valley states in Si double quantum dot. [1] E. Kawakami et al., Nat. Nanotech. (2014). [2] M. Veldhorst et al., Nat. Nanotech. (2014)

3:30PM W37.00004 Hybrid Spin and Valley Quantum Computing with Single-Triplet Qubits, NIKLAS ROHLING, MAXIMILIAN RUSS, GUIDO BURKARD, Department of Physics, University of Konstanz, Germany — The valley degree of freedom in the electronic band structure of silicon, graphene, and other materials is often considered to be an obstacle for quantum computing (QC) based on electron spins in quantum dots. Here we show that control over the valley state opens new possibilities for quantum information processing. Combining qubits encoded in the singlet-triplet subspace of spin and valley states allows for universal QC using a universal two-qubit gate directly provided by the exchange interaction. We show how spin and valley qubits can be separated in order to allow for single-qubit rotations [1].

3:42PM W37.00005 Single-electron donor-quantum-dot qubit in silicon, PATRICK HARVEY-COLLARD, Université de Sherbrooke, GREGORY A. TEN EYCK, JOEL R. WENDT, TAMMY PLUYM, Sandia National Laboratories, MICHAEL P. LILLY, Center for Integrated Nanotechnologies, Sandia National Laboratories, MALCOLM S. CARROLL, Sandia National Laboratories, MICHEL PIORO-LADRIERE, Université de Sherbrooke — Electron spins bound to phosphorus (P) donors in silicon (Si) are promising qubits due to their high fidelities, but donor-donor coupling is challenging. We propose an alternative two-electron single-triplet quantum-dot (QT) and donor (D) hybrid qubit. A QT is formed at a MOS 28-Si interface and is tunnel-coupled to implanted donors. The proposed two-axis system is defined by the exchange and contact hyperfine interactions. We demonstrate that a few electron QT can be formed and tuned to interact with a donor. We investigate the spin filling of the D-QT system through charge-sensed (CS) magnetotransport and identify spin-up loading consistent with a singlet-triplet splitting of ~100 µeV near a QT-D anti-crossing. We also demonstrate an enhanced CS readout contrast and time window due to the restricted relaxation path of the D through the QT. This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

3:54PM W37.00006 Coupling a Si/SiGe quantum dot to an implanted phosphorus donor, RYAN H. FOOTE, DANIEL R. WARD, BRANDUR THORGRIMSSON, University of Wisconsin - Madison, J.R. PRANCE, Lancaster University, Lancaster, UK, ANDRE SARAJIVA, D.E. SAVAGE, MARK FRIESEN, S.N. COPPERSMITH, M.A. ERIKSSON, University of Wisconsin - Madison — We have fabricated quantum dots in a Si/SiGe heterostructure both with and without implanted phosphorus donors. We present the results of transport measurements at dilution refrigerator temperatures through both types of devices. In one device we see evidence of coupling between a dot and a localized state consistent with a donor. We present estimates of the position of the localized state using Coulomb blockade measurements as a function of several different gate voltage configurations. This research supported in part by NSF (DMR-1206915) and ARO (W911NF-12-1-0607). Development and maintenance of the growth facilities used for fabricating samples is supported by DOE (DE-FG02-03ER46028). This research utilized facilities supported by the NSF (DMR-1121288).

4:06PM W37.00007 Few electron quantum-dot coupling to donor implanted electron spins, MARTIN RUDOLPH, PATRICK HARVEY-COLLARD, ERIK NIELSON, JOHN GAMBLE, RICHARD MULLER, TOBY JACOBSON, GREG TEN-EYCK, JOEL WENDT, TAMMY PLUYM, MICHAEL LILLY, MALCOLM CARROLL, Sandia National Laboratory — Donor-based Si qubits are receiving increased interest because of recent demonstrations of high fidelity electron or nuclear spin qubits and their coupling. Quantum dot (QD) mediated interactions between donors are of interest for future coupling of two donors. We present experiment and modeling of a poly silicon/Si MOS QD, charge-sensed by a neighboring many electron QD, capable of coupling to one or two donor implanted electron spins (D) while tuned to the few electron regime. The unique design employs two neighboring gated wire PETS and self-aligned implants, which supports many configurations of implanted donors. We can access the (0,1)⇔(1,0) transition between the D and QD, as well as the resonance condition between the few electron QD and two donors ((0,N,1)⇔(0,N+1,0)⇔(1,N,0)). We characterize capacitances and tunnel rate behavior combined with semi-classical and full configuration interaction simulations to study the energy landscape and kinetics of D-QD transitions. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. The work was supported by the Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

4:18PM W37.00008 Device-Level Models Using Multi-Valley Effective Mass, ANDREW D. BACZEWSKI, Sandia National Laboratories, ADAM FREES, University of Wisconsin-Madison, JOHN KING GAMBLE, XUJIAO GAO, N. TOBIAS JACOBSON, JOHN A. MITCHELL, INÉS MONTAÑO, RICHARD P. MULLER, ERIK NIELSEN, Sandia National Laboratories — Continued progress in quantum electronics depends critically on the availability of robust device-level modeling tools that capture a wide range of physics and effective mass theory (EMT) is one means of building such models. Recent developments in multi-valley EMT show quantitative agreement with more detailed atomistic tight-binding calculations of phosphorus donors in silicon (Gamble, et. al., arXiv:1408.3159). Leveraging existing PDE solvers, we are developing a framework in which this multi-valley EMT is coupled to an integrated device-level description of several experimentally active qubit technologies. Device-level simulations of quantum operations will be discussed, as well as the extraction of process parameters at this level of theory. The authors gratefully acknowledge support from Sandia National Laboratories and Fellowship Program, which is funded by the Laboratory Directed Research and Development (LDRD) Program. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Security Administration under contract DE-AC04-94AL85000.

4:30PM W37.00009 Multi-valley effective mass theory for device-level modeling of open quantum dynamics, N. TOBIAS JACOBSON, ANDREW D. BACZEWSKI, Sandia National Labs, ADAM FREES, University of Wisconsin-Madison, Sandia National Labs, JOHN KING GAMBLE, INÉS MONTANO, JONATHAN E. MOUSSA, RICHARD P. MULLER, ERIK NIELSEN, Sandia National Labs — Simple models for semiconductor-based quantum information processors can provide useful qualitative descriptions of device behavior. However, as experimental implementations have matured, more specific guidance from theory has become necessary, particularly in the form of quantitatively reliable yet computationally efficient modeling. Besides modeling static device properties, improved characterization of noisy gate operations requires a more sophisticated description of device dynamics. Making use of recent developments in multi-valley effective mass theory, we discuss device-level simulations of the open system quantum dynamics of a qubit interacting with phonons and other noise sources.

4:42PM W37.00010 Multi-valley effective mass treatment of donor-dot tunneling in silicon

ADAM FREES, UW-Madison, ANDREW D. BACZEWSKI, JOHN KING GAMBLE, N. TOBIAS JACOBSON, RICHARD P. MULLER, ERIK NIELSEN, Sandia National Laboratories — Many cutting-edge experiments in silicon-based devices for quantum information processing involve the tunneling of an individual electron from a donor atom within the material to the interface of the heterostructure. Understanding how this tunneling process varies among different realistic devices is therefore of great interest. Using a multi-valley effective mass approximation method, we find the tunnel coupling, adiabatic min-gap, and ionizing electric field strength between a phosphorous donor in silicon and a nearby quantum dot at a Si/SiO₂ interface. Additionally, we calculate these quantities for a phosphorous donor in strained silicon and a Si/SiGe interface. We consider how these properties change as a function of relative position between the donor and the dot. The authors gratefully acknowledge support from the Sandia National Laboratories Truman Fellowship Program, which is funded by the Laboratory Directed Research and Development (LDRD) Program. Sandia is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the US Department of Energy’s National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

4:54PM W37.00011 Electron spin coherence of shallow donors in germanium

M.T. BELL, J. Paramanandam, L.B. Ioffe, and M.E. Gershenson.

When the flux qubit is readout by a dc-SQUID, normally people use a coil to bias both the qubit and the dc-SQUID. Here we consider an alternative method in which a single coil is used to bias both the qubit and the dc-SQUID. This method has the advantage of being able to change the flux bias of the qubit very little because of the very small mutual inductance between the qubit and the trap loop. We will discuss the experimental aspects of the FPQ optimization and the possibility of fault-tolerant operations with these qubits.

5:06PM W37.00012 Spin ensembles as sensitive probes of environmental magnetic field noise

ABRAHAM ASFAW, Department of Electrical Engineering, Princeton University, Princeton NJ 08544, USA, GARY WOLFOWICZ, JOHN J. L. MORTON, London Centre for Nanotechnology, University College London, London WC1H OAH, UK, ALEXEI TYRSHSKIN, STEPHEN LYON, Department of Electrical Engineering, Princeton University, Princeton NJ 08544, USA — Environmental magnetic field noise makes quantum control of electron and nuclear spins difficult. Conversely, the sensitivity of spins to small magnetic fields implies that they can be used as sensitive probes of magnetic field fluctuations. We report spin resonance measurements of donors in silicon showing that the phase information in single-shot measurements of spin ensembles combined with quadrature detection can yield useful information about environmental noise. By measuring the accumulated phase statistics with time, we extract the power spectrum of the environmental magnetic field noise. The range of noise frequencies probed in this way is set by the magnetic moment of the spins. We measure the noise power spectrum at high frequencies (100 Hz - 10 kHz) using electron spins and at low frequencies (1 - 100 Hz) using nuclear spins. We also show that a broadband measurement of the noise power spectrum can be obtained by tuning the magnetic moment of electron spins in bismuth donors over a wide range from 0.01 to 1 electron magnetic moment. Our method, which uses the full statistics of the accumulated phase, can be viewed as complementary to existing dynamical decoupling schemes which use filter functions to probe the noise power spectrum.

5:18PM W37.00013 Mechanical tuning of ionized donors in silicon

DAVID P. FRANKE, FLORIAN M. HRUBESCH, MARKUS KUENZL, MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and University Centre for Nanotechnology, University College London, London WC1H OAH, UK, ALEXEI TYRSHSKIN, STEPHEN LYON, Department of Electrical Engineering, Princeton University, Princeton NJ 08544, USA — Ionized donors in silicon have shown to have extraordinarily long coherence times, exceeding tens of minutes even at room temperature, which, combined with the very advanced state of silicon technology, makes them attractive candidates for the realization of solid state qubits. The corresponding near perfect isolation from their environment, however, renders the individual addressing and coupling of such qubits a major challenge on the way towards a spin quantum computer based on ionized donors. We show that the application of strain to the silicon host crystal leads to shifts of the nuclear spin resonance frequencies of 75As due to the nuclear quadrupole interaction with crystal fields. This shift can be larger than the resonance linewidth for modest strains, as we demonstrate by electrically detected electron nuclear double resonance (ED ENDOR) measurements on arsenic donors in strained silicon. We discuss how quadrupole interactions could allow for the individual addressing of ionized nuclear spins by mechanical tuning of their resonance frequency and, possibly, permit the elastic coupling of nuclear spin qubits to a mechanical resonator.

2:30PM W39.00001 Parity Protection in Flux-Pairing Qubits

WENYUAN ZHANG, Rutgers University, MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and MATTHEW BELL, Rutgers University and University of Massachusetts, Boston, XIAOYUE JIN, Rutgers University, LEV IOFFE, Rutgers University and

2:42PM W39.00002 Adjusting the dc-SQUID working point by a flux trapping loop for readout of gap-tunable flux qubit

XIAOBO ZHU, YULIN WU, HUI DENG, YARUI ZHENG, NAHEED AKHTAR, JIE FAN, DONGNING ZHENG, LI LU, Chinese Academy of Sci (CAS) — When the flux qubit is readout by a dc-SQUID, normally people use a coil to bias both the qubit and the dc-SQUID. However, if the working point of the qubit is located on the bottom or the top of the dc-SQUID’s critical current modulation region, the readout is hardly carried out. We insert a flux trapping loop into the readout dc-SQUID. By trapping different numbers of fluxoids in the loop, the flux bias of the dc-SQUID can be changed accordingly, while the flux bias of the qubit changes very little because of the very small mutual inductance between the qubit and the trap loop. This improvement enables us to carry out the readout in the complicated experiments of gap-tunable flux qubit.
Ramsey experiment performed shortly after the pulse. Comparing the result to that obtained using a square pulse followed by a delay of the same length as the envelope. The pulse differs from a square pulse only by the addition of two segments at the end, whose width and amplitude depend on the resonator linewidth. Here we demonstrate fast, qubit-state-independent resonator reset using a readout pulse with a simple piecewise-constant decay constant is inadequate for multi-qubit operations in which some qubits need to be measured and reused while others remain in superpositions, which would lose coherence during this time. Any residual photons continue to measure and Stark-shift the qubit, preventing high-fidelity gates. Simply waiting several times the resonator coherence time is impractical. We first explain that because of these features, only a limited improvement of measurement fidelity is possible if one uses single-mode squeezed states. We then show that by using two-mode squeezed states in a novel two-cavity geometry, one can achieve a dramatic fidelity improvement (and Heisenberg-limited scaling) using squeezed light for qubit measurement in circuit QED. In contrast to the standard problem, the phase shifts here are not deterministic and can be substantially reduced by encoding the logical qubit in a non-orthogonal basis, but can be substantially reduced by encoding the logical qubit in the eigenvectors. The process of measurement leads to quantum jumps in the eigenbasis. As a result, the excitation of the measured qubit may switch between the two qubits at a rate that depends on the qubit-qubit detuning and coupling, as well as the linewidth of the readout resonator. The switching produces readout misidentification error, which cannot be eliminated with a longer measurement. However, we show that this error can be made negligible by using a readout resonator with a sufficiently narrow linewidth.

**1** We acknowledge support from IARPA under contract W911NF-10-1-0324.
4:06PM W39.00009 Adjustable Josephson Coupler for Transmon Qubit Measurement, EVAN JEFFREY, Google Inc. — Transmon qubits are measured via a dispersive interaction with a linear resonator. In order to be scalable this measurement must be fast, accurate, and not disrupt the state of the qubit. Speed of particular importance in a scalable architecture with error correction as the measurement accounts for substantial portion of the cycle time and waiting time associated with measurement is a major source of decoherence. We have found that measurement speed and accuracy can be improved by driving the qubit beyond the critical photon number $n_{crit} = \frac{\Delta \gamma}{\Delta}$ by a factor of 2-3 without compromising the QND nature of the measurement. While it is expected that such strong drive will cause qubit state transitions, we find that as long as the readout is sufficiently fast, those transitions are negligible, however they grow rapidly with time, and are not described by a simple rate. Measuring in this regime requires parametric amplifiers with very high saturation power, on the order of -105 dBm in order to avoid losing SNR when increasing the power. It also requires a Purcell filter to allow fast ring-up and ring-down. Adjustable couplers can be used to further increase the measurement performance, by switching the dispersive interaction on and off much faster than the cavity ring-down time. This technique can also be used to investigate the dynamics of the qubit cavity interaction beyond the weak dispersive limit $n_{cavity} < n_{crit}$ not easily accessible to standard dispersive measurement due to the cavity time constant.

4:42PM W39.00010 Quantum analysis of a bandpass Purcell filter for accurate qubit readout, EYOBI A. SETE, University of California, Riverside, JOHN M. MARTINIS, University of California and Google Inc., Santa Barbara, ALEXANDER N. KOROTKOY, University of California, Riverside — In a circuit QED setup the readout fidelity of a superconducting qubit is partially limited by the qubit relaxation through the resonator into a transmission line, which is also known as the Purcell effect. One way to suppress this effect is to employ a filter, which impedes microwave propagation at the qubit frequency. We present a quantum analysis for the bandpass Purcell filter that was recently realized by E. Jeffrey et al. [PRL 112, 190504 (2014)]. Using experimental parameters, we show that the bandpass filter suppresses the qubit relaxation rate by two orders of magnitude while keeping the measurement rate the same. We also show that in the presence of a microwave drive the qubit relaxation rate further decreases with increasing drive strength.

5:06PM W39.00011 Characterizing a Superconducting Resonator with Frequency-Compensated Tunable Coupling, JAMES WENNER, B. CAMPBELL, Z. CHEN, B. CHIARO, A. DUNSWORTH, I.-C. HOI, J. KELLY, A. MEGRANT, C. NEILL, P.J.J. O’MALLEY, C. QUINTANA, T. C. WHITE, University of California, Santa Barbara, R. BARENDTS, Y. CHEN, A. C. FOWLER, E. JEFFREY, J. M. MARTINIS, University of California and Google, Santa Barbara — Deterministic quantum state transfer between devices on different chips requires the ability to transfer quantum states between traveling qubits and fixed logic qubits. Reflections must be minimized to avoid energy loss and phase interference; this requires tunable coupling to an inter-chip line while the two devices are at equal frequencies. To achieve this, we present a 6GHz superconducting coplanar resonator with tunable coupling to a 50 Ohm transmission line. We compensate for the resulting shift in resonator frequency by simultaneously tuning a second SQUID. We further demonstrate the device coherence and the ability both to release a single-frequency shaped pulse into the transmission line and to efficiently capture a shaped pulse, prerequisites for efficient inter-chip deterministic quantum state transfer.

5:40PM W39.00012 Design of a Tunable 3D Microwave Cavity for Use in Coupling to Quantum Superconducting Circuits, JQI and CNAM, Dept. of Physics, University of Maryland — We have designed a tunable 3D cavity system for use with transmon qubits. We use an rf SQUID loop as a variable inductive element that perturbs the cavity modes and produces a shift in the cavity frequency that depends on the flux applied to the loop. Our 3D cavity is made of aluminum and has a lowest mode TE101 frequency of 6.2 GHz. Following a method developed by E. U. Condon, we estimate our cavity to have an effective inductance of 100 nH [1]. Our inductive SQUID loop is made of thermally deposited aluminum on a sapphire substrate, with dimensions 250µm x 250µm, which yields an expected geometric inductance of 0.9 nH. We use a single junction in our inductive loop with a critical current of approximately 1µA. We tune the effective inductance of the loop by using a modulation coil that is well isolated from the cavity at the resonance frequency. [1] Condon, E. U. Reviews of Modern Physics. Volume 14, Number 4 (1942)

5:20PM W39.00013 Scalable architecture for coherent microwave control of weakly anharmonic qubits, DURIE DEURLOO, WOUTER VLOTHUIZEN, TNO (Netherlands Organisation for Applied Scientific Research), Delft, LEO DICARLO, Delft University of Technology, Delft, QUTECH COLLABORATION — As the number of qubits in quantum processors continues to increase in the near future, architectures offering scalability of control signals will be essential. We describe an architecture and prototype for improved scalability in microwave control of weakly anharmonic qubits in quantum processors based on repeated unit cells. We present the scalable architecture and test results on a multi-qubit processor based on circuit quantum electrodynamics.

Thursday, March 5, 2015 2:30PM - 5:30PM — Session W41 DPOLY: Polymer Nanocomposites II — 214A - Shengfeng Cheng, Virginia Polytechnic Institute and State University

2:30PM W41.00001 Liquid crystal self-assembly of zirconium phosphate nanosheet in polymeric matrix, XIAYUN HUANG, XUEZHEN WANG, ZHENGDONG CHENG, Texas A&M University — The controlled assembly of nanomaterials requires them to be well-organized over large area with controlled orientation and density. Although progress has been achieved via Langmuir-Blodgett technique, electric field directed assembly, and flow-assisted alignment, it remains a challenge for the future to control the density and orientation, especially the anisotropic particle, in the polymeric matrix. Here, we investigate the controlled assembly via liquid crystal assembly of discotic α-zirconium phosphate (α-ZrP) aqueous suspension. Liquid crystal is the material with spontaneous orientation order and our group have shown the strong aspect ratio dependency of the anisotropic-nematic transition of discotic α-ZrP nanosheet suspension. These α-ZrP discotic suspension exhibited the stable nematic alignment at low volume fractions. When volume fraction increases, it follows with the phase transition to smectic phase. Moreover, intrinsic high anisotropic nanosheet enables the formation of highly ordered liquid crystal orientation at much reduced concentration and the polymeric matrix brings the extra-functionailities, such as thermal, optical, electrical and mechanical properties. The liquid crystal phase orientation will remains in the polymeric matrix and the polymeric matrix serves as the interlayer spacer. The liquid crystal polymer nanocomposite was fabricated using high-aspect-ratio α-ZrP nanosheet embedded into a polymeric network. Due to the hydrogen bonding interaction of hydroxyl group of α-ZrP and polymeric matrix, liquid crystal nanocomposite has the interesting thermal-optical response.
Polyvinylidene Fluoride – Fe₃O₄ Nanocomposites

JERRY CONTRERAS, IBRAHIM ELAMIN, JASON PARSONS, DORINA M. CHIPARA, JAMES HINTHORNE, KAREN LOZANO, MICREA CHIPARA, The University of Texas Pan American — Fe₃O₄ nanoparticles of about 75 nm from Nanostructured & Amorphous Materials, Inc. have been dispersed into the polyvinylidene fluoride (PVDF) by melt mixing. Nanocomposites with various weight fraction of nanofiller (0%, 0.2 %, 0.6 %, 1.2 %, 2.4 %, 5.8 %, 12 %, 23 %, and 30 %) have been obtained and measured by Wide Angle X-Ray Scattering (WAXS, Bruker Discovery 8 with the Cu Kα radiation), Raman spectroscopy (Bruker Senterra confocal Raman microscope operating at 785 nm), and UV-Vis. Raman spectra indicated that alpha PVDF is the main crystalline component of the polymeric matrix and revealed a fast decay of the polymer lines as the loading with iron oxide is increased. The Raman lines have been successfully fitted by an extended Breit-Wigner Fano lineshape. The effect of the nanofiller on the position, amplitude, and width of Raman lines is analyzed in detail. WAXS investigations confirmed the presence of magnetite. The effect of the loading with nanoparticles on the position, amplitude, and width of WAXS lines of Fe₃O₄ and PVDF are reported.

Synergistic templated self-assembly of cellulose nanocrystals in thin block copolymer films

DANIELLE GROLMAN, The University of Akron — Nanofillers in thin polymer films offer unique advantage to potentially modify the film’s thermal, optical, electrical and mechanical properties due to the high surface area to volume ratio and intrinsic property change at the nanoscale. Nanofilled polymer films have been shown to exhibit unusual film stability to dewetting with a nonmonotonic behavior with nanofiller loading, potentially arising from factors such as competitive phase behavior and filler aggregation, particularly in the high nanofiller concentration limit. In this regard, block copolymer films can act as ideal nanoscale structured templates to selectively sequester and organize nanofillers. In conjunction with incorporated cellulose nanocrystals (CNCS), we seek to understand how individual anisotropic nanofillers can provide synergistic reinforcement to inherently anisotropic nanostructured block copolymer films. A clear enhancement in the Young’s Modulus was observed with increased CNC loading using strain-induced elastic buckling instability for mechanical measurements (SIEBIMM) for thin films. To this end, we examine the nanoscale to microscale morphology of the blend film through AFM, TEM and grazing incidence X-ray diffraction.

Polyisoprene-Block Polystyrene - Graphene Nanocomposites

SIEBIMM for thin films. To this end, we examine the nanoscale to microscale morphology of the blend film through AFM, TEM and grazing incidence X-ray diffraction.

3:06PM W41.00004 Raman and Wide Angle X-Ray Studies on Polystyrene-Block Polyisoprene-Block Polystyrene - Graphene Nanocomposites

DORINA CHIPARA, OSCAR M. GUERRERO, ALEJANDRA GONZALEZ, BRIAN YUST, IBRAHIM ELAMIN, JAMES HINTHORNE, MICREA CHIPARA, The University of Texas Pan American — Nanocomposites have been obtained by loading a block copolymer (Polyisoprene-Block Polystyrene (PS-b-PI-b-PS), containing 17% styrene (purified from Sigma Aldrich) with various amounts of graphene nano platelets (HD Plas Grade 4), purchased from Cheap Tubes Inc., through the solution path: PS-bPI-bPS was dissolved within cyclohexane, then nanofiller was added and the mixture was sonicated for 1 hr. The high power sonication (500 mW) improved the dispersion of the filler within the polymeric matrix. The homogenized solution was poured on glass slides covered by aluminum foil and left to evaporate the solvent. A final thermal treatment of the as obtained nanocomposites at 75 °C, has been performed overnight, in an oven. Nanocomposites containing various weight fraction of fillers ranging between 0% and 40% have been obtained. The as obtained films have been investigated by Wide Angle X-Ray Scattering, using a Bruker Discovery 8 spectrometer, FTIR (Bruker Tensor 27), UV-Vis, and Raman spectroscopy, (using a Bruker Senterra, confocal Raman microscope operating at 785 nm). The dependence of these spectra originating from the polymeric matrix and from the filler on the loading with graphene is discussed.

Computations Related to Nanoparticle Characterization and Nanocomposite Property Estimation

FERNANDO VARGAS-LARA, NIST/Wesleyan, AHMED HASSAN, EDWARD GARBOCZI, JACK F. DOUGLAS, NIST — The macroscopic properties of high-performance bulk polymer composite materials derive from the properties of the microscopic building block component particles, the polymer matrix in which they are placed, and the state of particle dispersion. The rational design of new materials then requires the characterization of the polymer matrix and the individual particles, as well as an understanding of how particle properties change as a function of spatial dispersion and particle size polydispersity and shape fluctuations. To systematically explore this multi-dimensional parameter space, we combine molecular dynamic simulations, numerical path-integrations (ZENO) and finite element calculations (COMSOL). As a specific illustration of this computational path, we calculate the electric and magnetic polarizability tensor of carbon nanotubes and graphene sheets having complex morphologies. Knowing these basic particle properties, one then can estimate electromagnetic properties of nanocomposites made with these particles, i.e., conductivity.

3:30PM W41.00006 Differential Scanning Calorimetry Investigations on Polyvinylidene Fluoride – Fe₃O₄ Nanocomposites

SAMANTHA SALINAS, ROBERT JONES, DORINA M. CHIPARA, MICREA CHIPARA, The University of Texas Pan American — Nanocomposites of polyvinylidene fluoride (PVDF)–magnetite (Fe₃O₄) with various weight fractions of nanofiller (0%, 0.2 %, 0.6 %, 1.2 %, 2.4 %, 5.8 %, 12 %, 23 %, and 30 %) have been obtained via melt mixing by loading PVDF with Fe₃O₄ particles (average size 75 nm from Nanostructured & Amorphous Materials, Inc.). Thermal stability of PVDF-Fe₃O₄ has been investigated by TGA in nitrogen. The increase of the thermal stability of PVDF due to the loading with Fe₃O₄ was quantified by the shift of the temperature at which the (mass) degradation rate is maximum as a function of Fe₃O₄ content. The effect of the nanofiller on the crystallization of PVDF was investigated by isothermal DSC (TA Instruments, Q500). Non-isothermal DSC tests, (at various heating rates ranging from 1 to 25 °C/min) have been used to locate the glass, crystallization, and melting temperatures. The dependence of the glass, crystallization, and melting temperatures on the concentration of nanoparticles is reported and analyzed in detail. The data are critically analyzed within the classical Avrami theory.

3:42PM W41.00007 Characteristics of vinyl-ester and carbon fiber composite dry and wet probe by Positron Annihilation Lifetime Spectroscopy

MAHMOUD MADANI, RICHARD D. GRANATA, Florida Atlantic University— Carbon fiber composites of vinyl-ester resins, Derakane 8084 and 510A, were studied dry and after water exposure. In this study, positron annihilation lifetime spectroscopy (PALS) was used to investigate the free volume fraction and the size of the free volume voids within the polymer matrix. The relative free volume (fractions replace by of positron lifetime intensities) in VE8084 polymer and in VE510A (Space) polymer were 35.2% and 13.8%, respectively. The free volume lifetime and intensities were determined as a function of the polymer thickness and significant differences were observed in both polymers with versus without postcuring. The effects are similar in PEI, where PEI and PE100 materials were also determined by PALS. Water uptake showed a 2% change in intensity of the longer lifetime (1.85 ns) in VE8084 polymer and in VE510A about 1.8%. The longer lifetime intensities in the wet composites were 17.1% in the 8084 polymer and its carbon fiber composite and 7.1% in the 510A polymer and its carbon fiber composite. For composite with 8084 polymer saturated (0.33% water gain) with seawater at 40 or 60 °C, no change in the longer lifetime intensity was observed which indicates no water entered the free volume voids (indicates replace by and ) some differences between composite and neat polymer. For 510A resin the third lifetime intensity dropped from 7.1% to 3.9% indicating 48% of the void volume filled with water in the composite only after saturation with seawater with respect to dry one.
4:06PM W41.00009 Controlling the dispersion and configuration of nanoﬁllers in electrically driven polymer jets with and without air flow1. YEVGEN ZHMAYEV, YONG JOO, JAY PARK, LING FEI, PRABHLEEN KAUR, HONGSHEN LIU, Cornell University — Controlling the dispersion of nanoﬁllers in polymer matrices has a signiﬁcant effect on their properties. Employing circumferentially uniform air ﬂow through the sheath layer of the concentric coaxial nozzle, the gas-assisted electrospinning utilizes both high electric field and controlled air ﬂow which can offer i) enhanced stretching of ﬂuid jet and thus much higher throughput and thinner ﬁbers, and ii) better control of dispersion and conﬁguration of nanoﬁllers in a polymer matrix even at high loadings. The ability to tailor the distribution of various nanoﬁllers (1.85-12.92 vol. % of spherical SiO2 and Si nanoparticles and rod/tube-like carbon nanotubes and carbon nanoribbons) in a polyvinyl alcohol (PVA) jet was demonstrated by varying electric potentials in conventional electrospinning and air ﬂow rates in gas-assisted electrospinning. The distribution of nanoﬁllers in nanoﬁbers was measured by transmission electron microscopy (TEM), and analyzed using an image processing software to obtain concentration proﬁles. By increasing the electric potential in conventional electrospinning from 80 to 125 kV/m, we observed almost a twofold improvement in NP distribution. The further enhancement of nanoparticle dispersion was observed in gas-assisted electrospinning: Our analysis indicated an additional 70 percent improvement with the application of high, but controlled air ﬂow. Lastly, the enhanced performance by the resulting nanoﬁbers with controlled nanoﬁller dispersion will also be addressed in Li-ion battery anode applications.

1 Axiom battery, AZ Electronic Materials

4:18PM W41.00010 Flow Effect on Alignment of MWCNTs in Polymer Nanocomposites. MASHAEL ALGHAMI, Worcester Polytechnic Institute, GEORGI GEORGEY, Assumption College, GERMANO IANNACCHIONE, Worcester Polytechnic Institute — Polymer nanocomposites are grabbing attraction for their light weight, low cost, and enhanced characteristics. In this study, we present fabrication of polyethylene ﬁlms embedded with multiwalled carbon nanotubes (MWCNTs) with anisotropic characteristics. A well dispersion of the MWCNTs in melt polyethylene is controlled through sonication to overcome their natural tendency to aggregate. An elongation process is demonstrated by free ﬂow on temperature-controlled surface in order to create organized long-range alignment of the nanoparticles within the host polymer matrix. The samples harvested off substrate show complete alignment of the CNTs, and the effect of the nanotube alignment on the mechanical and electrical properties of the nanocomposites is also investigated.

4:30PM W41.00011 Polymer Morphology and Crystallinity close to Inorganic Surfaces. KIRI AKI CHRISPOPOULOU, HELLEN PAPANANOU, SPIROS H. ANASTASIADIS, FORTH-IESL and Univ. of Crete, KONSTANTINOS S. ANDRIKOPOULOS, GEORGE A. VOYATZIS, FORTH-ICNA. In polymer science, it is crucial to obtain high-quality polymer blends with high incompatibility, since the immiscibility is a primary reason for the non-uniform dispersion of one component in another. To achieve this, we investigate the morphology, crystallization and chain conformation of a hydrophilic, semi-crystalline polymer, poly(ethylene oxide), PEO, when dissolved in a water-based solvent. Partially sponsored by EU (COST Action MP0902) and by the Greek GSRT through the call for projects "Support Program for Innovative Research Groups - Energy". The preliminary results show that they are extremely promising due to the possibility of creating nanocomposites with desired properties suit certain applications.

4:42PM W41.00012 The path to achieving molecular dispersion in an extremely dense reactive mixture. JIGNESHKUMAR PATEL, ZOU XIANG, SHAW HSU, University of Massachusetts Amherst, ANDREW SCHOCH, Saint-Gobain Research & Development — In any multicomponent reactive system, a uniform and continuous dispersion of reactants is necessary to achieve a complete reaction. In this study, we have examined the role of one additional component to disperse two seemingly unlike reagents, including a highly crystalline hexamethylenetetramine (hexa) and strongly hydrogen bonded phenol formaldehyde resin. By combining information from NMR, infrared spectroscopy and differential scanning calorimetry, we were able to identify the role of the third component in the polymerization reaction, which is required to plasticize the phenol formaldehyde resin in this crosslinking reaction. It is clear that the presence of the third component increased the segmental mobility, disrupted the hydrogen bonded matrix, and freed the hydroxyl units, which further increased the solubility of hexa. Both the endothermic and exothermic transition peaks are observed in the DSC thermogram. This unique system is also applicable to a broad range of reactive systems.

3:54PM W41.00008 Raman Spectroscopy of Poly-Urea Formaldehyde Microcapsules. OMAR ESPINO, DORINA CHIRICHI, MICHELA MARTINEZ, None — The objective of this research project was to add self-healing capabilities to polymeric microcomposites. We used the "classical" method to obtain self-healing polymers with the addition of TiO2 nanoparticles in the self-healing system. Self-healing polymers are obtained by dispersion of ﬁrst generation Grubbs catalysts and microcapsules ﬁlled with monomers (typically DCPD). These kind of "smart materials" are able to survive to high mechanical stress via the ignition of the so called "autonomous self-healing mechanism" which is actually a ring opening metathesis polymerization (ROMP) reaction triggered by mechanical stresses in excess over a threshold limit through the rupture of microcapsules and the release of the monomeric component. As a preliminary step for adding self-healing capabilities in nanocomposites, the synthesis of microcapsules ﬁlled with dicyclopentadiene (DCPD) is vital for the addition of self-healing capabilities to polymeric matrices. We synthesized polyurea-formaldehyde (PUF) microcapsules ﬁlled with monomer (DCPD) using the in-situ polymerization. The synthesis was monitored by Raman spectroscopy, optical microscopy, and pH measurements that has been extensively used as a non-invasive technique in the characterization of polymers and monitoring of organic reactions. The goal of this research was to assess the formation of the microcapsules during synthesis and the presence of the DCPD in the microcapsules. Samples were taken during the synthesis every 30 minutes and analyzed by Raman spectroscopy, and optical microscopy keeping a control over the pH of the solution.

3:54PM W41.00013 Polymer/Pristine Graphene Based Composites: From Emulsions to Strong, Electrically Conducting Foams. STEVEN WOLTORNIST, Univ of Connecticut - Storrs, JAN-MICHAEL CARRILLO, Oak Ridge National Laboratory, THOMAS XU, ANDREY DOBRYNIN, DOUGLAS ADAMSON, Univ of Connecticut - Storrs — The unique electrical, thermal and mechanical properties of graphene make it a perfect candidate for applications in graphene/graphite based polymer composites, yet challenges due to the lack of solubility of pristine graphene/graphite in water, common organic solvents, and polymer solutions and melts have limited its practical utilization. Here we report a scalable and environmentally friendly technique to form water-in-oil type emulsions stabilized by a graphene skin consisting of overlapping pristine graphene sheets that enables the exfoliation of the graphene sheets containing a continuous graphitic skin network that is electrically conducting. At the heart of our technique is the strong attraction between pristine graphene and high energy oil and water interfaces. This allows for the creation of stable water-in-oil type emulsions stabilized by a graphitic skin consisting of overlapping pristine graphene sheets that enables the synthesis of open cell foams containing a continuous graphitic skin network. At the heart of our technique is the strong attraction between pristine graphene and high energy oil and water interfaces. 5:06PM W41.00014 Organic-Inorganic Shish-Kebabs: Nanocrystal Kebabs Periodically Assembled on Stretched Flexible Polymer Shish — ZHIQUN LIN, Georgia Inst of Tech, HUI XU, Xiamen University, YUCI XU, Ningbo University, XINCHANG PAN, YANJIE HE, JAEHAN JUNG, Georgia Inst of Tech, HAIPING XIA, Xiamen University — We report an unconventional yet general strategy to craft an exciting variety of 1D necklace-like nanostructures comprising uniform functional nanodisks periodically assembled along a stretched flexible polymer chain by capitalizing on judiciously designed amphiphilic worm-like diblock copolymer as nanoreactors. These nanostructures can be regarded as organic-inorganic shish-kebabs, in which nanodisk kebabs periodically situated on a stretched polymer shish. Simulations based on self-consistent field theory reveal that the formation of organic-inorganic shish-kebabs is guided by the self-assembled elongated star-like diblock copolymer constituents constrained on the highly stretched polymer chain.

5:18PM W41.00015 Strain-Tunable One Dimensional Photonic Crystals Based on Zirconium Dioxide/Slide-Ring Elastomer Nanocomposites for Mechanochromic Sensing — IRENE HOWELL, CHENG LI, NICHOLAS COLELLA, University of Massachusetts-Amherst, KOHZO ITO, University of Tokyo, JAMES WATKINS, University of Massachusetts-Amherst — Here we report on the fabrication and performance of tunable one dimensional photonic crystals (1DPCs) based on zirconium dioxide/Slide-Ring elastomer nanocomposites. 1DPCs, or Bragg mirrors, display a photonic stop band at specified wavelengths based on the design of their alternating high and low refractive index layers. By adjusting the weight percent of nanoparticles in the composite materials, a refractive index contrast of 0.18 can be achieved between filled and unfilled elastomer layers. The novel Slide-Ring matrix material consists of supramolecular polyrotaxane polymers, and maintains elasticity in the composite 1DPCs. Additionally, the high refractive index nanoparticles enable greater refractive index contrast when compared with purely polymer systems. Therefore we are able to demonstrate a 1DPC of just 6 periods, which maintains 40% reflectance over strains up to 42%. Due to their elastic and flexible behavior, these materials can function as colorimetric strain sensors. The applied strain results in a visible color shift from red to blue, demonstrating a tensile mechanochromic ($\Delta \lambda / \lambda_{max}$) sensitivity as high as 6.05 nm%/%.

Thursday, March 5, 2015 2:30PM - 5:30PM — Session W42 DPOLY: Focus Session: Multiscale Modeling of Polymers 214B - Janna Maranas, Pennsylvania State University

2:30PM W42.00001 Coarse graining of polystyrene sulfonate — DVORA PERAHIA, ANUPRIYA AGRAWAL, Clemson University, GARY S. GREST, Sandia National Laboratories — Capturing large length scales in soft matter while retaining atomistic properties is imperative to computational studies. Here we develop a new coarse-grained model for polystyrene sulfonate (PSS) that often serves as a model system because of its narrow molecular weight distribution and defined degree of sulfonation. Four beads are used to represent polymer where the backbone, the phenyl group, and the sulfonated group are each represented by a different bead and the fourth one represents counterion, which is sodium in our case. Initial atomistic simulations of PSS melt with sulfonation levels of 2-10%, with a dielectric constant $\varepsilon = 5$ revealed a “locked” phase where motion of the polymer is limited. Dielectric constant of $\varepsilon = 5$ was used to accelerate the dynamics. Bonded interactions were obtained using Boltzmann inversion on the bonded distributions extracted from atomistic simulation. Non-bonded interaction of polystyrene monomer was taken from our previous work and potential of mean force was used as the initial guess for interaction of the ionic beads. This set of potential was subsequently iterated to get a good match with radial distribution functions. This potential and its transferability across dielectric constants and temperatures will be presented.

2:42PM W42.00002 Morphology and Dynamics of Tapered Diblock Copolymers from fDFT-initialized MD Simulations — LISA M. HALL, YOUNGMI SEO, JONATHAN R. BROWN, The Ohio State University — Tapered block copolymers are similar to AB diblock copolymers, but with a statistical A-B (or B-to-A) (inverse) gradient “taper” between the A and B blocks. Depending on the sequence of monomers along the chain and the segregation strength, the A and B monomers are known to microphase separate into various ordered morphologies. Tapering introduces another parameter, independent of molecular weight or polymer choice, to tune morphology, and has been shown previously to widen the gyroid region of the phase diagram. In this study, we use classical, fluids density functional theory (fDFT) and molecular dynamics (MD) simulations to study the morphology and dynamics of tapered systems. Using fDFT allows us to accurately compare free energies between different potential microphases as a function of interaction parameter and fraction of A. Because of the similarity of the fDFT and MD models, the fDFT results map very closely with the corresponding MD model. We use the fDFT density profiles to generate the initial state of the chains for the simulations. Lamellae, cylinders, and other phases can be generated in this way with approximately correct spacing and density. We apply the streamline simulation setup to analyze the effect of tapering on conformations and dynamics.

2:54PM W42.00003 Properties of Coarse-Grained Polymer Models: Statics, Dynamics, and Crystallinity — GARY GREST, K. MICHAEL SALERNO, Sandia National Laboratories, ANUPRIYA AGRAWAL, DVORA PERAHIA, Clemson University — To capture large length and time scales, coarse-grained (CG) models that combine multiple atoms into one bead have been developed to model polymer melts. In the process microscopic detail is discarded in exchange for computational efficiency. However it is not well-understood how the scale of coarse-graining affects the polymer structure and dynamics. We compare results of atomistic simulations with CG models in which each CG bead represents three, four, or six methylene groups for C$_9$, C$_{12}$, and C$_{15}$H$_{32}$. The CG potential is developed at 500K by iterative Boltzmann inversion. While static properties such as end-to-end distance and radius of gyration are captured by all CG models, the entanglement length deviates from experimental results with increased CG scale. The mean squared displacement of CG models is used to determine scale factors between the atomistic and CG models. During cooling to low temperature, the three and four-carbon models form a semi-crystalline structure while the six-carbon model and a four-carbon model based on the MARTINI force field remain amorphous at all temperatures. These findings show that the level of coarse-graining and CG interactions can strongly affect model temperature transferability.

3:06PM W42.00004 Thermodynamically Consistent Coarse-Graining of Polymers — MARINA GUENZA, University of Oregon — Structural and dynamical properties of macromolecular liquids, melts and mixtures, bridge an extensive range of length- and time-scales. For these systems, the computational limitations of the atomistic description prevent the study of the properties of interest and coarse-grained models remain the only viable approach. In coarse-grained models, structural and thermodynamic consistency across multiple length scales is essential for the predictive role of multi-scale modeling and molecular dynamic simulations that use mesoscale descriptions. This talk presents a coarse-graining approach that conserves structural and thermodynamic quantities independent of the extent of coarse-graining, and describes a model for the reconstruction of the dynamics measured in mesoscale simulations of the coarse-grained system. Some of the general challenges of preserving structural and thermodynamic consistency in coarse-grained models are discussed together with the conditions by which the problem is lessened.

1Grant DE-SC007908
3:42PM W42.00005 Modelling and multiscale simulations of meta aromatic polyurea: microscopic geometry and dielectric properties, RUI DONG, VIVEK RANJAN, North Carolina State Univ, MARCO BUONGIORNO NARDELLI, University of North Texas, JERZY BERNHOLC, North Carolina State Univ — BOPP is the state-of-art material for high-power-density capacitors. However, its efficiency drastically drops at high electric fields. Recently, polymers in the polyurea/polythiourea family have been shown to have much higher energy density and efficiency at high fields than BOPP [1-2]. We perform multiscale simulations to investigate dielectric and structural properties of meta aromatic polyurea (mAAP). Both crystalline and disordered structures have been studied, and much larger ionic contribution to permittivity is found in disordered structures. The specific volume is 10% to 20% larger in the latter, leading to greater structural flexibility. For example, the orientation variations of polar units are 100% larger than in the crystal structure, and the phonon density of states in the low frequency regime is significantly enhanced. At the same time, we find that meta aromatic polyurea has a higher tendency to be disordered than other members in the polyurea family. All these facts lead to a significantly larger permittivity of mAAP.

3:54PM W42.00006 The conditional reversible work method for molecular coarse graining of soft matter, NICO VAN DER VEGT, EMILIANO BRINI, GREGOR DEICHMANN, Technische Universität Darmstadt, COMPUTATIONAL PHYSICAL CHEMISTRY GROUP TEAM — I will discuss a recently introduced systematic coarse-graining method that provides transferable coarse-grained potentials for scale-bridging simulations of soft matter systems. The method [1-3] is based on direct calculation of pair potentials in the gas or liquid phase with thermodynamic integration or free energy perturbation methods and has been coined the Conditional Reversible Work (CRW) method. I will discuss the CRW method in the general context of systematic coarse graining, a recent extension to dynamically-consistent coarse-grained simulations [4], and show some practical examples, including coarse-grained simulations of molecular liquids and polymers.

4:06PM W42.00007 Systematic and Simulation-Free Coarse Graining of Polymeric Systems: A Structure-based Study, DELIAN YANG, QIANG WANG, Colorado State University — We propose a systematic and simulation-free strategy for coarse graining of multicomponent polymeric systems, where we use the Polymer Reference Interaction Site Model theory, instead of many-chain molecular simulations, to calculate the structure and thermodynamic properties of both the original and coarse-grained (CG) models, and quantitatively examine how the effective CG pair potentials and properties of CG systems vary with the coarse-graining level. Our strategy is general and versatile, is much faster than those using many-chain simulations, and practically solves the transferability problem of coarse graining. As an example, here we apply it to structure-based coarse graining of homopolymer melts, which matches the structure correlations of CG segments between the original and CG systems. Our numerical results clearly show that structure-based coarse graining cannot give thermodynamic consistency between the original and CG systems at any coarse-graining level due to the information loss of coarse graining.

4:18PM W42.00008 Systematic and Simulation-Free Coarse Graining of Polymeric Systems: A Relative-Entropy-based Study, QIANG WANG, DELIAN YANG, Department of Chemical and Biological Engineering, Colorado State University — Relative-entropy-based coarse graining minimizes the relative entropy (RE) quantifying the information loss due to coarse graining. [1] When pair potentials are used for coarse-grained (CG) segments, RE-based coarse graining becomes equivalent to structure-based coarse graining if the pair potentials are unconstrained. [1] Here we apply our systematic and simulation-free strategy to RE-based coarse graining of homopolymer melts; that is, we use the Polymer Reference Interaction Site Model (PRISM) theory, instead of many-chain molecular simulations, to calculate the structure and thermodynamic properties of both the original and CG systems, and quantitatively examine how the CG pair potentials and properties of CG systems vary with the coarse-graining level. We consider various analytic functional forms of CG pair potential as suggested by structure-based coarse graining, and minimize RE to obtain the associated parameters. Values of minimized RE are then used to select the appropriate analytic form of CG pair potential, which is much easier to use than the tabulated (numerical) CG pair potential obtained from structure-based coarse graining. This is the first application of RE-based coarse graining to polymers. [1] M. S. Shell, J. Chem. Phys. 129, 144108 (2008).

4:30PM W42.00009 A proposed method for directed self-assembly of graphene nanoribbons, JAMES GERAETS, REIDUN TWARECK, YVETTE HANCHOCK, University of York — There is an opportunity for modeling to inform the experimental synthesis and design of graphene nanoribbons (GNRs). We present here a new coarse-graining algorithm for simulating GNR synthesis by the self-assembly of aromatic carbon precursor molecules. The model uses a Gillespie algorithm to form a network of possible coupling reactions between these molecules, and exploits a novel way of representing their geometries to speed up the simulations. Based on this method, we identify areas in parameter space given by temperature, binding energy, functional groups, and concentration of precursor molecules, which lead to GNRs with desirable properties. We demonstrate use of the model based on two precursors that self-assemble together to form a nanoporous GNR, namely, functionalized tetrabenzanthracene and benzene. We demonstrate that, unlike a pristine GNR, the GNRs formed by these molecules have regular repeating holes, and exhibit a band gap of 1.6eV independent of the ribbon width.

4:42PM W42.00010 Universal aspects of conformations and transverse fluctuations of a two-dimensional semi-flexible chain, HSIAO-PING HSU, Johannes Gutenberg-Universität Mainz, AIQUN HUANG, ANIKET BHATTACHARYA, University of Central Florida, KURT BINDER, Johannes Gutenberg-Universität Mainz — In this talk we compare the results obtained from Monte Carlo (MC) and Brownian dynamics (BD) simulation for the universal properties of a semi-flexible chain. Specifically we compare MC results obtained using pruned-enriched Rosenbluth method (PERM) with those obtained from BD simulation. We find that the scaled plot of root-mean-square (RMS) end-to-end distance $\langle R^2 \rangle / L_p$ and RMS transverse fluctuations $\sqrt{\langle \epsilon^2 \rangle / L_p}$ as a function of $L/L_p$ (where $L$ and $L_p$ are the contour length, and the persistence length respectively) are universal and independent of the definition of the persistence length used in MC and BD schemes. We further investigate to what extent these results agree for a semi-flexible polymer confined in a quasi one dimensional channel.
4:54PM W42.00011 Stretching wormlike chain: interplay between chain stiffness and excluded volume in the long chain limit. XIAOLAN LI, ABHIRAM MURALIDHAR, Chemical Engineering and Materials Science, University of Minnesota, CHARLES SCHROEDER, Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign, KEVIN DORPMAN, Chemical Engineering and Materials Science, University of Minnesota — Nearly 20 years ago, Marko and Siggia (Macromolecules 1995, 8759-8770) proposed an approximate interpolation formula for the force-extension (f-z) behavior of a wormlike chain that has found widespread use in biophysics and polymer physics. We have extended their result to account for excluded volume interactions. Our analysis takes advantage of Pruned-Enriched-Rosenbluth Method (PERM) simulations of wormlike chains of varying monomer anisotropy. Our simulations use up to 80,000 hard beads, allowing us to reach the long chain limit with sub-persistence length resolution. The simulations produce the Pincus scaling $z \sim f^{2/3}$, followed by a crossover to the linear behavior $z \sim f$, and subsequent saturation approaching the fully stretched limit. We also developed an approximate interpolation formula that captures these three regimes. This interpolation formula is in good agreement with PERM simulation results and can be reduced to the Marko-Siggia interpolation formula when the excluded volume effect is eliminated. Practically, our work provides a handy description of force-extension behavior for real wormlike chain, which will be useful for coarse-grained simulations and interpreting experiment results.

5:06PM W42.00012 ABSTRACT WITHDRAWN —

5:18PM W42.00013 Accelerated dynamics of bead-spring polymer chains. GOPINATH SUBRAMANIAN, Univ of Southern Mississippi — We present results from the application of the recently generalized parallel replica method to a system of bead-spring polymer chains. The statistics of chain breakage show that individual chains, after a relatively short dephasing time, display an exponential distribution of breakage times over a wide range of extension ratios, thereby allowing us to exploit the notion of the quasi-stationary distribution and accelerate the dynamical evolution of a representative volume element.

Thursday, March 5, 2015 2:30PM - 5:30PM —
Session W43 DPOLY: Focus Session: Dynamics of Glassy Polymers Under Confinement III
214C - David Simmons, University of Akron

2:30PM W43.00001 Molecular-weight Dependent Tg Depression of Silica-supported Poly(alpha-methyl styrene) Films1, OLPHELIA TSUI, KUN GENG, Boston Univ — The glass transition temperature ($T_g$) of poly(a-methyl styrene) (PaMS) films supported by silica is studied as a function of film thicknesses from 17 to 168 nm at three molecular weights of 1.3, 20 and 420 kg/mol. For the 20 and 420 kg/mol films, the glass transition temperature decreases with decreasing film thickness, consistent with previous results. But for the 1.3 kg/mol films, it becomes independent of the film thickness. We tentatively suggest the $T_g$ depression to be caused by free volume excess at the polymer-air interface and that its influence diminishes at low enough molecular weights because of a chain stiffness effect.

1We acknowledge support of NSF through the projects DMR-1004648 and DMR-1310536.

2:42PM W43.00002 Influence of the chemical structure on the slip boundary condition of liquids. MISCHA KLOS, SEBASTIAN BACKES2, Saarland University, Experimental Physics, D-66123 Saarbrücken, JUAN MANUEL CASTILLO SANCHEZ, MARTIN HORSCH, HANS HASSE, TU Kaiserslautern, Laboratory of Engineering Thermodynamics, D-67663 Kaiserslautern, KARIN JACOBS, Saarland University, Experimental Physics, D-66123 Saarbrücken — On small scales, especially in microfluidic devices, the role of the solid/liquid interface gets more important for the flow dynamics. Our experiments probe slippage via the dewetting of thin polymer films on hydrophobic substrates [1]. As hydrophobic coatings we use amorphous polymers (AF1600, AF2400) and different types of highly ordered self-assembled silane monolayers on top of silicon substrates. On silane surfaces, polystyrene (PS) of low molecular weight exhibit slip lengths up to micrometers [2]. On AF1600, no significant slip is observed. Scattering studies reveal an ordering of the PS side chains at the solid/liquid interface depending on the structure of the substrate [3]. Recent simulations were able to characterize these SAMs [4]. However, the situation changes if PMMA or Polyvinylpyridine (PVP) are used: Dewetting experiments show that slip is less pronounced in PVP and in PMMA films. Obviously, the structure of the side groups plays a significant role. X-ray reflectometry supplements this hypothesis and give further insight to the slippage mechanism at the solid/liquid interface. [1] O. Bäumchen, et.al., J Phys Condens Matter 24 (2012) [2] R. Fetzer, et.al., Europhys Lett 75 (2006) [3] P. Gutfreund, et.al., Phys Rev E 87 (2013) [4] J.M. Castillo Sanchez, et. al. submitted

1current Adress: TU Berlin, Department of Chemistry, Applied Physical Chemistry, D-10623 Berlin

2:54PM W43.00003 New paradigm for stabilization of liquid polymer films on solids1, TAD KOGA, NAISHENG JIANG, JIAXUN WANG, XIAOYU DI, JUSTIN CHEUNG, MAYA ENDOH, Stony Brook University — We report that wetting/dewetting behavior of liquid polymer films on solids can be controlled by nanoscale architectures of polymer chains irreversibly adsorbed on the impenetrable surfaces. Monodisperse polystyrene (PS) ultrathin films (20 nm in thickness) with different molecular weights on silicon (Si) substrates with a natural amorphous Si dioxide layer was used as models. The PS thin films were annealed at high temperatures at T>Tg (Tg is the bulk glass transition temperature) for several days, and the surface structures were studied by using optical and atomic force microscopes. At the same time, the annealed PS films were further leached with a good solvent and the residue films (i.e., irreversibly adsorbed layers) were characterized by x-ray reflectivity. The experimental data reveals a strong correlation between the conformations of the adsorbed polymer chains and the stability of the liquid films on top.

3:06PM W43.00004 Approach to universal self-similar attractor for the levelling of thin liquid films. ELIE RAPHAEL, MICHAEL BENZAQUEN, UMR CNRS 7083 Gulliver, ESPCI ParisTech, PSL Research University, PAUL FOWLER, Department of Physics and Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, Canada, LAETITIA JUBIN, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, Canada, THOMAS SALEZ, UMR CNRS 7083 Gulliver, ESPCI ParisTech, PSL Research University, KARI DALKOKI-VERESS, Department of Physics and Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, Canada — We compare the capillary levelling of a random surface perturbation on a thin polystyrene film with a theoretical study on the two-dimensional capillary-driven thin film equation. Using atomic force microscopy, we follow the time evolution of samples prepared with different initial perturbations of the free surface. In particular, we show that the surface profiles present long term self-similarity, and furthermore, that they converge to a universal self-similar attractor that only depends on the volume of the perturbation, consistent with the theory. Finally, we look at the convergence time for the different samples and find very good agreement with the analytical predictions.
3:18PM W43.00005 Confinement Effects with Films of Nonlinear Polystyrene, MARK FOSTER, QIMING HE, The University of Akron, SURESH NARAYANAN, Argonne National Laboratory, DAVID WU, Colorado School of Mines — The surface fluctuations of annealed melt films of 6k cyclic polystyrene (CPS), its linear analog, and a long-branched chain were measured using X-ray photon correlation spectroscopy (XPCS) for films of various thicknesses. The surface fluctuations of the 6k linear PS melt films 17 nm and thicker and the 6k cyclic melt films 28 nm and thicker can be described using a hydrodynamic continuum theory (HCT) that assumes the film is characterized only by the bulk viscosity. When a film of CPS is 24 nm or thinner, the behavior can no longer be captured using the HCT with bulk viscosity. The surface fluctuations behave as though the film has an effective viscosity higher than the bulk value. The thickness at which confinement effects are seen for the 6k CPS chains is larger than that for the linear analogs. Confinement effects for long-branched chains appear at even larger thicknesses relative to Rg. Acknowledgements: Use of the Advanced Photon Source at Argonne National Laboratory was supported by the DOE's Office of Science under Contract DE-AC02-06CH11357. This work was supported by NSF Grants CBET-0730692 and CBET-0731319.

3:30PM W43.00006 The Dynamics of a Polymer Confined in Anodic Aluminum Oxide Nanopore, GI XUE, YE SA, Nanjing University — The dynamics of poly(n-butyl methacrylate) confined in porous templates are investigated using DSC and Fluorescence nonradiative energy transfer. Two glass transition temperatures are obtained at a slow cooling rate of which one bulk-like phase reflects core layer while the other at much higher temperature indicates interfacial layer in the confined polymer glass. Because of cylindrical geometry, the glass transition energy barrier of interfacial layer is elevated, and the thereof temperature threshold to form one or two glass transitions is determined through adjusting infiltrating temperatures. In addition, the glass transition behavior is speculated to be mediated by the counterbalance of the size and interfacial effects in the confined space.

3:42PM W43.00007 The effect of surface chemistry on the glass transition of amorphous polycarbonate inside cylindrical nanopores, DARIYA REID, Texas A&M University, Chemical Engineering Department, MARCELA ALVES FREIRE, Universidade Federal de Minas Gerais, Brasil, JODIE LUTKENHAUS, Texas A&M University, Chemical Engineering Department — Nanoporous anodic aluminum oxide (AAO) templates are used to study the effect of confinement on the glass transition of amorphous polycarbonate (PC). In order to further study the effect of surface chemistry on physical behavior, the bare AAO surface is modified using alkyl- and fluoro-silanes of varying length. PC nanowires (200 nm in diameter) are prepared by melt-wetting the polymer into AAO templates under applied pressure. Using modulated differential scanning calorimetry (MDSC) and thermogravimetric analysis (TGA), it is found that the hydrophilic surface of bare AAO contributes to the degradation of the polymer. Modifying the AAO surface using silane chemistry prevents polymer degradation and introduces additional features in MDSC thermograms, which could be due to the interaction of the polymer with the nanopore surface. Using scanning electron microscopy (SEM), changes are observed in the tips of the PC nanowires as the AAO surface transitions from hydrophilic to hydrophobic.

3:54PM W43.00008 Large-scale diffusion of entangled polymers along nanochannels, KAY SAALWACHTER, FRANK LANGE, Martin-Luther-U. Halle-Wittenberg, Germany, MARTIN STEINHART, U. Osnabruck, Germany, PATRICK JUDEINSTEIN, Lab. Leon Brillouin, CNRS-CEA Saclay, France — Confinement-induced changes in polymer mobility are still under active discussion. For weakly interacting polymers, confinement effects for long-branched chains appear at even larger thicknesses relative to Rg. The University of Akron, SURESH NARAYANAN, Argonne National Laboratory, DAVID WU, Colorado School of Mines — The surface fluctuations of the 6k linear PS melt films 17 nm and thicker and the 6k cyclic melt films 28 nm and thicker can be described using a hydrodynamic continuum theory (HCT) that assumes the film is characterized only by the bulk viscosity. When a film of CPS is 24 nm or thinner, the behavior can no longer be captured using the HCT with bulk viscosity. The surface fluctuations behave as though the film has an effective viscosity higher than the bulk value. The thickness at which confinement effects are seen for the 6k CPS chains is larger than that for the linear analogs. 4:06PM W43.00009 Nanoscale pattern fidelity and transfer of hierarchically patterned thermoplastics films, YING CHEN, MANISH KULKARNI, the University of Akron, ALLAN MARSHALL, Omnova Solution Inc., JACK DOUGLAS, National Institute of Standards and Technology, ALAMGIR KARIM, the University of Akron, THE UNIVERSITY OF AKRON TEAM — We demonstrate a versatile and inexpensive method for controlling the surface relief structure of both flexible elastomeric and glassy polymer films over large areas through a two-step imprinting process. First, nanoscale patterns were formed by nanoimprinting polymer films with a pattern on a DVD disk, obtained originally by nanoimprinting from a lithographically etched master pattern on a silicon wafer; micron-scale patterns were then superimposed on the nanoimprinted films by exposing them to ultraviolet radiation in oxygen (UVO) through a TEM grid mask having variable micron-scale patterning. This simple two-stage imprinting method allows for facile fabrication of hierarchically structured elastomer and thermoplastic polymer films. Besides, the thermodynamic properties of dewetting phenomenon of polystyrene film under the confinement of hierarchically patterned PDMS is studied.

4:18PM W43.00010 Elevated single polymer surface diffusion on a film near its glass transition temperature, MARK GEOGHEGAN, MATTHEW MARES, CHRISTOPHER CLARKSON, ZHENYU ZHANG, University of Sheffield, JOHN TORKELSON, Northwestern University — Fluorescence correlation spectroscopy data are presented to show that the diffusion coefficient of poly(ethylene oxide) (PEO) adsorbed onto poly(alkyl methacrylate) (PAMA) and polystyrene films in aqueous solution increases close to (but below) the surface glass transition temperature of the film. This increase disappeared at higher temperatures as the film liquefied, although the diffusion coefficient for the PEO on the polystyrene surface remained greater than the diffusion coefficients for PEO on the PAMA films at temperatures greater than those at which the peak in diffusion occurred. A similar increase was found in the surface tension of all films studied. Experiments on (immiscible) blends of two PAMA homopolymers were performed where two peaks in the diffusion coefficient were observed with increasing temperature. Two peaks were also observed in the surface tension from contact angle experiments, although at temperatures slightly greater than those at which the peak in diffusion was observed. It is concluded that the enhanced surface mobility of the films near the surface glass transition temperature induces conformational changes in the adsorbed PEO molecules resulting in elevated diffusion coefficients.

4:30PM W43.00011 Local Glass Transition Temperature Gradients Near Polymer-Polymer Interfaces, ROMAN BAGLAY, CONNIE ROTH, Department of Physics, Emory University — For decades the glass transition in confined systems has been studied with the hopes of uncovering the governing length scales that impact these dynamics. However, understanding length scales of local gradients in glass transition temperature ($T_g$) near a free surface have been hampered by limitations of how to treat the enhanced mobility at the free surface theoretically. We have previously reported on the local $T_g$ in multilayer structures made from high molecular weight polystyrene (PS) and poly(n-butyl methacrylate) (PnBMA), a weakly immiscible system with a $\sim$ 7 nm interfacial width. Using ultrathin (10-15 nm) pyrene-labeled layers inserted into the multilayer structure at different positions ($z$) from the glassy-rubber interface, we were able to map the local $T_g(z)$ profile across the glassy-rubber interface with temperature-dependent fluorescence intensity measurements. Our work revealed an asymmetric local mobility gradient propagating hundreds of nanometers away from the glassy-rubber interface and we recovered far from the surface. Here we extend these measurements to investigate how the local $T_g(z)$ profile in PS varies when in contact with a variety of immiscible polymers whose $T_g$s vary between +90 K to ~80 K relative to the $T_g$ of PS, so-called hard vs soft confinement.

4:42PM W43.00012 Free Surface and Interfacial Effects on Tg Confinement Behavior of Template Supported Nanotubes, ANTHONY TAN, Northwestern University — Free surface and interfacial effects have a large impact upon the magnitude and direction of $T_g$-confinement behavior for nanoscale materials. In this work, we study the $T_g$ behavior of supported polymers in anodic aluminum oxide templates. The effects of attractive and neutral or non-interacting polymer substrate interactions were investigated. Tailored wall thicknesses were achieved using template melt infiltration by varying the annealing temperature and the molecular weight of the polymers. Nanotube thickness can be related to the polymer conformation and the interactions between the polymer and the substrate. Substantial $T_g$ reductions as a function of wall thickness were observed for supported polystyrene nanotubes and $T_g$ increases for supported poly(methyl methacrylate) or poly(2-vinylpyridine) nanotubes. The $T_g$-confinement behavior of supported nanotubes is found to be similar to the behavior of supported thin films in the presence or absence of interfacial effects.

5:06PM W43.00014 Can a reduction in mass transport occur at invariant segmental time?, SIMONE NAPOLITANO, MICHELE SFERRAZZA, Universite Libre de Bruxelles — The glassy dynamics of polymer melts adsorbed onto solid substrates shows a peculiar confinement effect: a severe reduction in mass transport occurs without a corresponding increase in segmental relaxation time. This phenomenon provides a “negative violation” of the Stokes-Einstein (SE) relation, not observed in bulk melts or confined water. Explaining those findings in analogy to the large drop of thermal expansion reported in polymers under 1D confinement, we considered the presence of an interfacial dead layer where tracer diffusivity assumes negligible values. To verify this hypothesis, we performed an extensive investigation of the diffusion of styrene oligomers, acting as tracers, into matrices of high molecular weight polystyrene, irreversibly adsorbed onto aluminum oxide. We demonstrate that the reduced interfacial diffusion is due to larger residence times of the tracers inside the dead layer, $t_{DL}$. In particular, we show that $t_{DL}$ is directly proportional to the amount of irreversibly adsorbed monomers, a quantity limiting the available space for diffusion. We thus discuss of a dynamic dead layer evolving within the adsorbed layer, and of its role on the dynamics of glassy polymers under confinement and the “negative violation” of the SE relation.

5:18PM W43.00015 Physical Properties of PC-PMMA Multilayers, ARIFUR RAHMAN, ERIC BAER, Case Western Reserve University, ALIN CRISTIAN CHIRA, ROBERT VAJTAJ, PULLICKEL M. AJAYAN, Rice University, JAMES HINTHORNE, IBRAHIM ELAMIN, MIRCEA CHIRA, The University of Texas Pan American, ERIC BAER COLLABORATION, PULLICKEL AJAYAN COLLABORATION, MIRCEA CHIRA COLLABORATION — Multilayers of polycarbonate (PC) and polymethylmethacrylate (PMMA) have been obtained by the layer multiplying coextrusion method. Each sample (1024 layers, of equal thickness, with individual thickness between 10 and 200 nm) has been investigated at room temperature of glassy polymers under confinement and the “negative violation” the SE relation.

5:44PM W43.00016 Residual Stress Relaxation and Stiffness-Confinement Effects in Polymer Films: Characterization by Non-Contact Ellipsometry and Fluorescence Techniques, SHADD ASKAR, JOHN TORKELSON, Northwestern University — The relaxation of residual stresses in spin-coated polymer films is characterized using two optical techniques: ellipsometry and fluorescence. Both techniques show that residual stresses relax over hours at several tens of degrees above the film glass transition temperature ($T_g$). Ellipsometry shows that thickness can increase or decrease during residual stress relaxation depending on thermal history of the film. However, the presence or relaxation of stresses has no measurable effect on $T_g$ as measured by ellipsometry. We have adapted the well-known sensitivity of the pyrene dye fluorescence spectral shape to local environment polarity in order to characterize stress relaxation and to monitor stiffness-confinement effects. The spectral shape of the pyrene fluorescence spectrum shows similar stress relaxation regardless of whether relaxation is accompanied by increases or decreases in film thickness. Fluorescence also indicates that single-layer polystyrene films supported on silica stiffen with decreasing nanoscale thickness. For the first time, stiffness gradients as a function of distance from interfaces are demonstrated using pyrene label fluorescence in conjunction with multilayer films.
2:54PM W44.00003 Scaling of Force Networks for Compressed Particulate Systems1, LENKA KOVALCINOVA, New Jersey Institute of Technology, ARNAUD GOULETTE, Rutgers University, LOU KONDIC, New Jersey Institute of Technology — We consider the distribution of cluster sizes in compressed particulate systems as a function of the force experienced by the particles. The considered systems differ by the distribution of particle sizes and by their frictional properties. To obtain good statistics we consider various systems sizes and large number of realizations. While for some of the considered systems we find consistent scaling exponents describing the behavior of the force clusters, we are also finding that this behavior is not universal. For example, monodisperse frictionless systems that crystallize under compression, show very different scaling properties compared to other systems, particularly as the systems approach jamming transition. The findings are confirmed by explicitly computing fractal dimension of the considered clusters.

3:06PM W44.00004 Steady State Shear Driven Flow of Frictionless Spherocylindrical Particles in Two Dimensions1, DANIEL VAN HOESEN, University of Missouri, THEODORE MARSCHALL, University of Rochester, SCOTT FRANKLIN, Rochester Institute of Technology, STEPHEN TEITEL, University of Rochester — We carry out simulations of a model of frictionless spherocylindrical rods in two dimensions, under uniform steady state shear driven flow. Rods repel elastically when they come into contact, and dissipate energy with respect to a uniformly shared angular velocity, and the nematic and tetragonal orientational order parameters. We find non-monotonic behavior of the orientational order parameters as the packing fraction increases toward the jamming transition. Orientation and translational correlation functions are computed to measure cooperative behavior as the packing fraction increases.

1Supported by NSF grants CBET-1133126 and CBET-1435861 and by NSF award PHY-1156339. Computations carried out at the CIRC at the University of Rochester.

3:18PM W44.00005 Fraction of clogging configurations in granular hopper flow, CHARLES THOMAS, DOUGLAS DURIAN, University of Pennsylvania — The clogging of granular media flowing from a hopper is a quintessential example of a system that spontaneously evolves from a freely flowing state to a jammed state under constant forcing. If suitably arranged, the grains at the opening are stable, initiate a jamming front, and block the flow throughout the bulk. We measure the fraction F of possible grain arrangements that lead to such a system-spanning clog for a range of experimental conditions, varying aperture shape, size, and orientation. We find for circular holes that F is a function only of the aperture size projected in the direction of the average exiting grain velocity. Furthermore, for long narrow slits F is found to be identical to the value expected for a set of independent holes. Finally, we successfully model the form of F versus aperture size by considering the accessible microstates of individual grains near the exit. The data as interpreted through this model suggest that the fraction of individual grain microstates that can lead to a clog is constant for large opening sizes. This conclusion implies that there may be no well-defined critical aperture size above which clogging is impossible.

3:30PM W44.00006 Sub-Jamming Transition in Jammed Binary Sphere Mixtures, ISHAN PRASAD, CHRISTIAN SANTANGELO, GREGORY GRASON, University of Massachusetts Amherst — We study influence of bi-disparity on structural evolution of jammed binary sphere mixtures with increasing small sphere composition, f_s. In binary spheres, maximally dense, random packing is achieved at infinite size ratio and unique composition (f_s \approx 0.2699) where small spheres jam within interstitial volume of jammed large spheres, leading to a kink in total volume fraction, \phi vs. f_s. Using simulations of athermal jammed packings, we explore how this critical feature influences the evolution of random binary sphere packings at finite size ratio, \alpha, ranging from 1 to 10. We report a clear distinction between large and small \alpha behavior, separated by a critical value of \alpha_c \approx 5.8. For \alpha < \alpha_c, structural properties such as volume fraction, rattle fraction and contact statistics are found to crossover smoothly from small to large f_s, while above a critical size asymmetry these properties indicate an abrupt, first-order like transition. We correlate this sharp transition with a "sub-jamming" transition of small-spheres occurring at finite values of f_s, which becomes cooperative only for sufficiently asymmetric mixtures. We propose a heuristic geometric and mechanical argument to understand what determines \alpha_c.

3:42PM W44.00007 A Unified Framework to Understand Shear Induced Rigidity in Athermal Materials, SUMANTRA SARKAR, Brandeis University — Recent studies of athermal systems such as dry grains and dense, non-Brownian suspensions have shown that shear can lead to solidification through the process of shear jamming in grains and discontinuous shear thickening in suspensions. The similarities observed between these two distinct phenomena suggest that the physical processes leading to shear-induced rigidity in athermal materials are universal. We present a unified, non-equilibrium statistical mechanics model for these shear-driven transitions, which exhibits the phenomenology of shear jamming and discontinuous shear thickening in different regions of the predicted phase diagram. Our analysis identifies the crucial physical processes underlying shear-driven rigidity transitions, and clarifies the distinct roles played by shear forces and the density of grains.

4:18PM W44.00008 Effect of Friction on Shear Jamming2, DONG WANG, Duke University, JIE REN, Merck & Co., JOSHUA DIJKSMAN, Wageningen University and Research Centre, JONATHAN BARES, ROBERT BEHRINGER, Duke University — Shear jamming of granular materials was first found for systems of frictional disks, with a static friction coefficient \mu \approx 0.6 (Bi et al. Nature (2011)). Jamming by shear is obtained by starting from a zero-stress state with a packing fraction \phi between \phi_J (isotropic jamming) and a lowest \phi_J for shear jamming. This phenomenon is associated with strong anisotropy in stress and the contact network in the form of force chains, which are stabilized and/or enhanced by the presence of friction. Whether shear jamming occurs for frictionless particles is under debate. The issue we address experimentally is how reducing friction affects shear jamming. We put the Teflon-wrapped photoelastic disks, lowering the friction substantially from previous experiments, in a well-studied 2D shear apparatus (Ren et al. PRL. (2013)), which provides a uniform simple shear. Shear jamming is still observed; however, the difference \phi_J - \phi_J is smaller with lower friction. We also observe larger anisotropies in fragile states compared to experiments with higher friction particles at the same density. In ongoing work we are studying systems using photoelastic disks with fine gears on the edge to generate very large effective friction.

2We acknowledge support from NSF Grant DMR1206351, NSF Grant DMS-1248071, NASA Grant NNX10AU01G and William M. Keck Foundation.

4:30PM W44.00009 Clogging and Jamming Transitions in Granular Matter Flowing Through Obstacles, CYNTHIA OLSON REICHHARDT, CHARLES REICHHARDT, Los Alamos National Laboratory — We consider a two-dimensional system of bidisperse disks driven through a landscape of fixed obstacles. In the limit of a single obstacle, the disks cease moving when the disk density is increased to the jamming density. The threshold density value decreases as the number of obstacles increases, but we also observe a change in the nature of the frozen state. At low obstacle density we find a homogeneous jammed state, but for higher obstacle density we instead find a heterogeneous clogged state containing void areas and possessing a memory of the driving direction. The transition to the clogged state is strongly stochastic and we observe large fluctuations in clogging time both for clogging in the original driving direction and for transverse clogging when the drive is suddenly rotated by 90 degrees. We find evidence for a diverging clogging transition time at a critical disk density well below the jamming density in a clean system.
4:42PM W44.00010 Diffusion in jammed particle packs¹, DAN S. BOLINTINEANU, Sandia National Laboratories, LEONARDO E. SILBERT, University of Southern Illinois, GARY S. GREST, JEREMY B. LECHMAN, Sandia National Laboratories — Diffusive transport in jammed particle packs is of interest for a number of applications, as well as being a potential indicator of structural properties near the jamming point. To this end, we report stochastic simulations of equilibrium diffusion through monodisperse sphere packs near the jamming point in the limit of a perfectly insulating surrounding medium. The time dependence of various diffusion properties is resolved over several orders of magnitude. Two time regimes of expected Fickian diffusion are observed, separated by an intermediate regime of anomalous diffusion. This intermediate regime grows as the particle volume fraction approaches the critical jamming transition. The diffusion behavior is fully controlled by the extent of the contacts between neighboring particles, which in turn depend on proximity to the jamming point. In particular, the mean first passage time associated with the escape of random walkers between neighboring particles is shown to control both the time to recover Fickian diffusion and the long time diffusivity. Scaling laws are established that relate these quantities to the difference between the actual and critical jamming volume fractions.

¹Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s NNSA under Contract DE-AC04-94AL85000.

4:54PM W44.00011 Statistics and Correlations of Conserved Quantities in Mechanically Stable Packings of Frictionless Disks Above Jamming¹, STEPHEN TEITEL, YEGANG WU, Univ of Rochester — We consider mechanically stable packings of soft-core, frictionless, bidisperse disks in two dimensions above the jamming transition. Using an algorithm that generates packings with an isotropic global stress tensor, we compute the distribution of various conserved quantities on compact subclusters of particles, as a function of the total system stress and the cluster size. We consider the stress on the cluster, the Maxwell-Cremona force-tile area, the Voronoi volume, and the numbers of small and big particles in the cluster, and we compute the averages, variances and correlations among these different quantities. We compare two different ensembles of clusters: (i) clusters defined by a fixed radius, and (ii) clusters defined by a fixed number of particles. We find several significant differences between these two ensembles and we comment on the implications of our findings for maximum entropy models of jammed packings.

¹This work was supported by NSF Grant No. DMR-1205800. Computations were carried out at the Center for Integrated Research Computing at the University of Rochester.

5:06PM W44.00012 Shear Jamming in Frictionless Particulate Media¹, THIBAULT BERTRAND, COREY S. O’HERN, Yale University, R.P. BEHRINGER, Duke University, BULBUL CHAKRABORTY, Brandeis University, MARK D. SHATTUCK, City College of the City University of New York — We numerically study two-dimensional packings of frictionless bidisperse disks created using compresive and simple shearing protocols. To create jammed packings by compression, we start N particles from random positions and grow their diameters followed by relaxation of particle overlaps using energy minimization. These compressed packings exist over a range of packing fractions φ. As a result, during compression the system may reach a φ above the minimum value before jamming. If this unjammed packing is then sheared by a strain γt, it can jam. Using a combination of compression and shearing, we can define jamming protocols as trajectories in the (φ, γ) plane that yield jammed packings. In this plane, we can reach a particular point (φn, γn) in many ways. We will focus on two protocols: (1) shearing to γn at φ = 0 followed by compression to φn at γ = γn, and (2) compression to φn at γ = 0 followed by shearing to γn at φ = φn. For protocol 1, we find that the probability of finding a jammed packing at φ and γ, P(φ, γ) = Q(φ) is independent of γ. For protocol 2, we use a simple theory to deduce P(φ, γ) from Q(φ).

5:18PM W44.00013 Jammed elastic shells - a 3D experimental soft frictionless granular system, JISSY JOSE, GERHARD A. BLAB, ALFONSO VAN BLAADEREN, ARNOUT IMHOF, Utrecht University — We present a new experimental system of monodisperse, soft, frictionless, fluorescent labelled elastic shells for the characterization of structure, universal scaling laws and force networks in 3D jammed matter. The interesting fact about these elastic shells is that they can reversibly deform and therefore serve as sensors of local stress in jammed matter. Similar to other soft particles, like emulsion droplets and bubbles in foam, the shells can be packed to volume fractions close to unity, which allows us to characterize the contact force distribution and universal scaling laws as a function of volume fraction, and to compare them with theoretical predictions and numerical simulations. However, our shells, unlike other soft particles, deform rather differently at large stresses. They deform without conserving their inner volume, by forming dimples at contact regions. At each contact one of the shells buckled with a dimple and the other remained spherical, closely resembling overlapping spheres. We conducted 3D quantitative analysis using confocal microscopy and image analysis routines specially developed for these particles. In addition, we analysed the randomness of the process of dimpling, which was found to be volume fraction dependent.

Thursday, March 5, 2015 2:30PM - 5:30PM – Session W45 DPOLY: Structure and Phase Behavior of Charged and Ion Containing Polymers 216AB - Anupriya Agrawal, Clemson University

2:30PM W45.00001 A molecular simulation study on salt response of polyelectrolyte complexes, HANNE ANTILA, Aalto University, Department of Chemistry, PAUL VAN TASSEL, Yale University, Chemical and Environmental Engineering, MARIA SAMMALKORPI, Aalto University, Department of Chemistry — In aqueous solutions, oppositely charged polymers, polyelectrolytes (PEs) form complexes which are known to be sensitive to added salt with responses ranging from shrinking to full destabilization of the complex. As a specific application of PE complexes, the complex formation of DNA with polycations has been demonstrated to be an effective means of transferring genetic material in gene therapy. We use all-atom molecular dynamics and coarse-grained Monte Carlo simulations to investigate the effect of excess salt on DNA-polycation complex stability. The detailed all-atom simulations demonstrate the mechanism of polycation and ion species specific salt-driven dissociation [1] involving charge reversal. More generally, other possible mechanisms of salt driven dissociation exist as well. The coarse grained approach, which describes the PE complex as oppositely charged, rigid rods and ions as hard spheres, provides a more complete understanding of PE interactions in salt, and suggests possible mechanisms leading to expulsion between the oppositely charged polyelectrolytes. [1] H. S. Antila, M. Sammalkorpi, J. Phys. Chem. B, 2014.
2:42PM W45.00002 Coarse-grained Molecular Simulation Studies of Complexation of Sulfobetaine-Lysine Copolymer and DNA for Gene Delivery. AHMADREZA F. GHOBADI, Department of Chemical and Biomolecular Engineering, University of Delaware, Newark Delaware 19716, ARTHI JAYARAMAN, Department of Chemical and Biomolecular Engineering and Department of Materials Science and Engineering, University of Delaware, Newark Delaware 19716 — Gene delivery involves successful transfection of therapeutic DNA by a vector into target cells and protein expression of that genetic material. Viral vectors are effective at gene delivery but elicit harmful immunogenic responses, thus motivating ongoing research on non-viral transfection agents. Cationic polymers are a promising class of non-viral vectors due to their low immunogenic responses and low toxicity, and their ability to bind to the polyanionic DNA backbone to form a polycation-DNA complex (polyplex) that is then internalized in the target cell. While past studies have shown many polycations with differing DNA transfection efficiencies, there is a need for general design guidelines that can relate the molecular features of the polycation to its DNA transfection efficiency. Using atomistic and coarse-grained molecular dynamics simulations we connect polycation design to polycation-DNA binding and experimentally observed transfection efficiency. Specifically in this presentation we will discuss our recent work looking into the effect of incorporating zwitterions into lysine based polycations on the resulting polyplex structure, shape, surface charge density and stability of DNA-polycation complexes.

2:54PM W45.00003 Experiments of salt concentration effects on translocation dynamics of polyelectrolytes passing through alpha-hemolysin pore. BYOUNG-JIN JEON, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — We have investigated physical mechanisms of electric field driven single file translocation of polyelectrolytes through an alpha-hemolysin pore by measuring the translocation time under different voltages, salt concentrations, and pH. Our experiments reveal an intricate coupling among various driving forces in dictating the polycation translocation. For example, we find that the salt concentrations in the donor and the recipient compartments influence the polychain translocation dynamics differently, depending on pH. From a series of systematic experiments, we demonstrate that the salt concentration in the donor compartment influences the polyclain charge and the free energy barrier for entrance and that the salt concentration in the receiver compartment influences the electrostatic interaction between the polyclain and pore. We provide a physical model for the free energy landscape of the translocation process and offer an explanation of the origin of the salt concentration effects on the polycation translocation dynamics for different pH conditions. This study offers an opportunity to understand how different driving forces get coupled in dictating the polycation dynamics under non-equilibrium conditions.

3:06PM W45.00004 Salt Effects on the Structure and Stability of Ionzible Polydots - SANS Study. NARESH OSTI, SIDDHAT WIJESINGHE, MANJULA SENANAYAKE, ANURADHI WICKRAMASINGHE, THUSITHA ETAMPAWALA, DVORA PERAHIA, Clemson University, Clemson, SC 29634 — Confinement of rigid luminescent polymers into nano-dimension forms polydots, long lived nanoparticles, even though the polymer chains are far from their thermodynamically equilibrium conformations. These polydots bare the potential to be tunable by changing the conformation of the polymer, making them promising for new bio-imaging markers and drug delivery vehicles. Here, we investigate ionizable polydots formed by dialkyloxy poly-para-phenyleneethynylene (PPEs). Increasing anion group density causes the shift to the higher pH range. The measurement of local pH near a single P2VP chain indicates that adding counterions can effectively increase the protonation degree on the P2VP chain. Yet the electric potential of the P2VP is found to decrease upon addition of divalent ions and anionic macrorions, suggesting enhanced counterion condensation by multivalent ions. It is also found that inorganic nanocluster macroions of 1 nm in diameter can form dense complexes with P2VP, whose dimension becomes independent of solution pH.

3:18PM W45.00005 Ionic Effect on Conformational Structure of Weak Polyelectrolyte in Dilute Solution: from Monovalent, Multivalent to Macro ions. CHEN QU, Univ of Notre Dame — The electrostatic environment near a charged polymer chain is critical to the structure and function of the polymer in aqueous media. In this work, we compare the effect of small monovalent and divalent ions and multivalent inorganic macrorions on the conformational structure of weak polyelectrolyte, poly(2-vinyl pyridine) (P2VP), in dilute aqueous solutions by single molecule spectroscopy. Divalent counterions at low concentration range show the similar effect as monovalent ones to cause the shift of the critical pH for the coil-to-globule conformational transition of P2VP to the higher pH range. In contrast, divalent counterions at high concentration range and inorganic nano-cluster anions cause the shift of the critical transition pH to the opposite lower pH range. The measurement of local pH near a single P2VP chain indicates that adding counterions can effectively increase the protonation degree on the P2VP chain. Yet the electric potential of the P2VP is found to decrease upon addition of divalent ions and anionic macrorions, suggesting enhanced counterion condensation by multivalent ions. It is also found that inorganic nanocluster macroion of 1 nm in diameter can form dense complexes with P2VP, whose dimension becomes independent of solution pH.

3:30PM W45.00006 Phase Behavior of Charged Nanoparticle-Polyelectrolyte Solution. GUNJA PANDAV, VENKAT GANESAN, University of Texas at Austin — Interactions between charged nanoparticles suspended in a polyelectrolyte solution are studied using single chain in mean field simulations. We consider a model in which the particles and polymers carry a fixed charge in presence of counterions and salt. The effect of nanoparticle size on the polyelectrolyte phase behavior is explored. We also discuss the interactions between nanoparticles arising due to multibody effects and compare it with two-body potentials calculated using a mean-field approach.

3:42PM W45.00007 Effects of mixing ratio, salt concentration and temporal trend on the formation of polyelectrolyte complex. YANPU ZHANG, Department of Chemical Engineering Texas A&M University, EROL YILDIRIM, HANNE ANTILA, MARIA SAMMALKORPI, Department of Chemistry Aalto University, JODIE LUTKENHAUS, Department of Chemical Engineering Texas A&M University, TEXAS A&M UNIVERSITY COLLABORATION, AALTO UNIVERSITY COLLABORATION — Polyelectrolytes complexes (PEC) form by mixing polycation/polyanion solutions together. Promising applications of PECs range from industrial flocculants, coatings, and membranes to advanced materials for solar cells, injectable hydrogels, and chemical sensors. One challenge for PEC processing and application is that their physical properties are often time-dependent. In this work, we report on the influence of polycation/polyanion mixing ratio, salt concentration, and time on the formation of PECs made from poly(diallyldimethylammonium chloride) (PDAC) and poly(styrene sulfonate sodium salt) (PSS). Physical such as turbidity, hydrodynamic size, and zeta potential are investigated as a function of time. We find various critical values that can be used to predict whether a PEC will remain stable in suspension or whether it will gradually aggregate and precipitate. We discuss these findings in relation to the stepwise aggregation model that depicts primary PEC particles gradually forming secondary structures. Finally, we perform detailed coarse-grained molecular dynamics simulations to examine the structure and effective charge distribution of the PECs with their temporal stability at varying mixing ratios and salt concentrations to support the experimental findings.

3:54PM W45.00008 Molecular Connectivity and Correlation Effects in Polymeric Complex Coacervates. MITHUN RADHAKRISHNA, CHARLES SING, University of Illinois at Urbana-Champaign — Complex Coacervation is a liquid-liquid phase separation induced by oppositely charges species and is a complicated process influenced by many factors like the solution pH, temperature, salt concentration, charge size and valency of the salt. Because of this inherent tunability complex coacervates have garnered a significant amount of attention as materials for under water adhesives, drug delivery platforms and self assembled structures. Most theoretical studies to address the complex coacervate materials to date have relied on the use of Poisson-Boltzmann theory (or extensions thereof). While these thermodynamic studies capture the phase behavior of complex coacervates in a qualitative sense, most of these theories neglect some of the important factors such as the effect of polyanion-driven connectivity correlations and excluded volume interactions between the ions in the solution. In the current work we study the effect of these factors on the phase behavior of complex coacervates through molecular simulations coupled to thermodynamic models for phase separation. We demonstrate that these neglected molecular features (connectivity, finite polymer and ion size) profoundly impact the thermodynamics, and by articulating them in theoretical or simulation models, we can start to understand how to design coacervate materials at a molecular level.
Complexes

The cationic species comprised members of the CnMIM (1-alkyl-3-methylimidazolium) family with n ranging from 2 to 10. The anionic component varied from

pure component. In this work, families of ionic liquids were characterized using the Locally Correlated Lattice (LCL) model that was previously used to study

CHEN, RONALD WHITE, JANE LIPSON, Dartmouth Coll — Trends in polymer solution miscibility can be understood by analyzing the properties of each

versatile properties of charged polymers. The charged properties of the polymer backbone and those of the accompanying ions have a large influence on

larger scale (self-assembled) structure and miscibility. With statistical thermodynamic methods, we investigate local ionic structure and the influence of charge

correlations on the phase diagram of polyelectrolyte blends. In particular, we study the effects of added salt on the coexistence lines, and explore the possibilities

of multiple phase coexistence between phases with a different polymer fraction or charge concentration.

14:30PM W45.00011 Image method for Coulomb energy for many-body system of charged dielectric spheres, JIAN QIU, QIN JIE DE PABLO, KARL FREED, University of Chicago — Ion polarization is important for understanding ion solvation and the stability of ion clusters in polymeric materials which typically exhibit a low and spatially inhomogeneous dielectric permittivity. The simplest approach for modeling ion polarization involves treating the ions as charged spheres with an internal dielectric permittivity differing from that of the medium. The surface polarization contribution to the electrostatic energy for a system of such dielectric spheres can be evaluated perturbatively. We derived closed-form expressions for this energy as a function of the positions of an arbitrary number of polarized surfaces. Our approach is a generalization of the image method for conducting spheres. Using this approach, we calculated the polarization corrections to the cohesion energy for ion clusters and for densely packed ionic crystals. The method can be readily adapted for investigating ion polarization effects in both Monte Carlo and molecular dynamics simulations.

4:42PM W45.00012 Phase behavior and multi-body effects in polyelectrolyte - nanoparticles mixtures, VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas at Austin, JEFFREY ERRINGTON, University of Buffalo — Recently we have developed a SCFT approach which allowed us to compute the effective interactions between charged nanoparticles (CNP) and in a polyelectrolyte (PE) solution. We have adapted such an approach to study the hierarchy of the two-, three- and multi-body interactions between CNP's. We have found that for the strong PE's and absent polarization interactions, the CNP-CNP interactions are essentially pairwise. This result allowed us to use the thermodynamic perturbation theory and the MC simulations to access the phase diagram of PE/CNP mixtures. Such analysis indicates that CNP-PE mixtures exhibit only gas and crystal phases, and that the fluid phase is metastable. The results of MC simulations suggest the suppression of the phase segregation by the formation of highly anisotropic clusters of CNP. The qualitative analysis of the three- and multi-body interaction in comparison with two-body interaction shows that such interaction may enhance the anisotropy of CNP clusters. We have also analyzed of weak PE's and the presence of polarization interaction. In such systems CNP's interactions remain qualitatively similar to the above systems, but the multi-body interactions appears to be significantly enhanced, which makes anisotropic clustering of PE's even more plausible.

4:54PM W45.00013 Ionic Liquids: Trends in Behavior and Miscibility with Polymers, MICHELLE CHEN, RONALD WHITE, JANE LIPSON, Dartmouth Coll — Trends in polymer solution miscibility can be understood by analyzing the properties of each pure component. In this work, families of ionic liquids were characterized using the Locally Correlated Lattice (LCL) model that was previously used to study numerous polymers as well as their solutions and blends. Ionic liquids were divided into families that incorporated size variation into each of the components. The cationic species comprised members of the CnMIM (1-alkyl-3-methylimidazolium) family with n ranging from 2 to 10. The anionic component varied from

BF$_4^-$ to PF$_6^-$ to NT$_2^-$ (bis(trifluoromethylsulfonyl)amide). Each liquid was characterized using the LCL equation of state and properties such as percent free volume and cohesive energy density were calculated. These properties were observed to be correlated with alkyl chain length and anion size within each family. Analyzing these trends points towards a fundamental understanding of ionic liquid miscibility with poly(ethylene oxide), members of the polymethacrylate family, and others.

1Work supported by NSF-DMR

5:06PM W45.00014 Surface Tension and Lamellar Spacing in Polyelectrolyte Blends and Block Copolymers, CHARLES SING, University of Illinois at Urbana-Champaign, MONICA OLVERA DE LA CRUZ, Northwestern University — Heterogeneous polymer systems such as block copolymers (BCPs) are governed primarily by a competition between the surface tension between different chemical species and the entropic stretching of the polymer chains. Charged BCPs represent a class of materials that is currently of great interest to the polymer community due to the promise of charged BCPs as nanostructured membranes for batteries and fuel cells. The inclusion of charge presents a powerful way to tune the structure of BCPs, and we develop our understanding of how to do so by investigating the interfacial properties (surface tension and microstructure size) of polyelectrolyte blends and block copolymers. We use a new method that combines the features of liquid state (LS) theory and self consistent field theory (SCFT) into a multiscale LS-SCFT theory that provides beyond-mean-field predictions of polyelectrolyte systems. We find that charge size, charge correlations, and the fraction of charged monomers plays a crucial role in determining surface tension, and we therefore demonstrate how BCP structure changes upon inclusion of charges. Finally, we will show that these predictions provide the ideal basis for comparison to experiment and subsequent refinement of LS-SCFT theory.

5:18PM W45.00015 Molecular Origins of Thermal Transitions in Polyelectrolyte Assemblies .
EROL YILDIRIM, Aalto University, YANPU ZHANG, Texas A&M University, HANNE S. ANTILA, Aalto University, JODIE L. LUTKENHAUS, Texas A&M University, MARIA SAMMALKORPI, Aalto University, AALTO TEAM, TEXAS A&M TEAM — Polyelectrolyte (PE) multilayers and complexes formed from oppositely charged polymers can exhibit extraordinary superhydrophobicity, mechanical strength and responsiveness resulting in applications ranging functional membranes, optics, sensors and drug delivery. Depending on the assembly conditions, PE assemblies may undergo a thermal transition from glassy to soft behavior under heating. Our earlier work using thermal analysis measurements shows a distinct thermal transition for PE layer-by-layer (LbL) systems assembled with added salt but no analogous transition in films assembled without added salt or dry systems [1]. These findings raise interesting questions on the nature of the thermal transition; here, we explore its molecular origins through characterization of the PE aggregates by temperature-controlled all-atom molecular dynamics simulations. We show via molecular simulations the thermal transition results from the existence of an LCST (lower critical solution temperature) in the PE systems: the diffusion behavior, hydrogen bond formation, and bridging capacity of water molecules plasticizing the complex changes at the transition temperature.

We quantify the behavior, map its chemistry specificity through comparison of strongly and weakly charged PE complexes, and connect the findings to our interrelated QCM-D experiments.

Thursday, March 5, 2015 2:30PM - 5:30PM — Session W46 DBIO GSNP: Invited Session: Collective Behavior and Jamming in Multi-Cellular Systems
217A - Jerry Lee, National Cancer Institute

2:30PM W46.00001 Unjamming phase transition in the asthmatic airway epithelium1 .
JEFFREY FREDBERG, Harvard School of Public Health — In asthma, an aberrant injury-repair response of the airway epithelium is pivotal in disease initiation and progression. Although the mechanism remains unclear, classical understanding emphasizes inflammatory events together with delayed epithelial cell differentiation and maturation. Here we reveal a physical mechanism that is not anticipated by that classical picture but dominates dynamics of cells cultured from airway epithelia nonetheless. In the course of maturation of the pseudostratified epithelial layer comprising primary human bronchial epithelial cells from non-asthmatic donors, we show a striking collective cellular behavior in which an immature, hypermobile, unjammed, fluid-like phase undergoes a transition into a mature, quiescent, jammed, solid-like phase. But compressive stresses on the epithelial layer that mimic bronchospasm drive the solid-like phase back to the fluid-like phase. We show, further, that the uncompressed epithelial layer from asthmatic donors exhibit spontaneous collective migration behavior that is similarly striking to that observed in compressed normal cells but results from a delay in the innate tendency of the epithelial layer to transition from an unjammed phase into a jammed phase. Moreover, the unjammed state of asthmatic epithelial cells accompanies intensified adhesive forces transmitted across cell-cell junctions. We introduce a theory of critical scaling that predicts a priori the existence of the observed phase transition. Surprisingly, this theory predicts the transition to be governed by cell shape and cell-cell adhesive forces in a manner that is paradoxical, but is borne out by our direct experimental observations. Together, these findings establish an unexpected but rigorous physical foundation for further classification and investigation of epithelial layer behavior in asthma, and likely in other processes in disease or development in which epithelial dynamics play a prominent role.

3:06PM W46.00002 Minimization of Thermodynamic Costs in Cancer Cell Invasion .
ROBERT AUSTIN, Princeton Univ — No abstract available.

PAK KIN WONG, University of Arizona — The fascinating capability of cellular self-organization (often referred as pattern formation) during tissue morphogenesis and regeneration is a central question in developmental biology, regenerative medicine, and complex systems. How do the cells of a tissue know how to organize into functional tissue structures that are much bigger than themselves? How do the individual cells know what they are supposed to do without a central coordinator or a blueprint? Furthermore, relatively little is known about how multicellular systems interpret the mechanical cues in the microenvironment, such as global forces, local cell-cell interactions, and extracellular matrix properties, to collectively drive the morphogenic process that creates complex tissue structures across multiple length scales. In this talk, I will discuss a nanoengineered framework for investigating the mechanoregulation of tissue morphogenesis, such as the capillary morphogenesis and collective cell migration during wound healing.

4:18PM W46.00004 ECM Organization and Cell-Cell Cooperation .
PETER FRIEDL, Radboud University Nijmegen, The Netherlands — Single-cell or collective invasion results from coordination of cell shape, deformability and actin dynamics relative to the tissue environment. In monomorphic 3D invasion models in vitro, an obligate step of collective invasion is the degradation of extracellular matrix (ECM). Thereby, the density of the ECM determines the invasion mode of mesenchymal tumor cells. Whereas fibroblastic, high porosity ECM enables single-cell dissemination, dense matrix induces cell-cell interaction, leader-follower cell behavior and collective migration as an obligate protease-dependent process. Conversely, in vivo monitored by intravital multiphoton second and third harmonic generation microscopy, tissue microchirons provide invasion-promoting tracks that enable collective migration along tracks of least resistance. As main routes, non-destructive contact-guidance is mediated by preformed multi-interface perimuscular, vascular and neural tracks of 1D, 2D and 3D topography. Consistently, spheroids of mesenchymal melanoma or sarcoma tumor cells switched from single-cell to collective invasion modes when confronted with 3D collagen matrices of increasing density, including gain of cell-to-cell junctions, supracellular polarization, suggesting cell jamming imposed by tissue confinement. Targeting of beta1/beta3 integrins induces unexpected plasticity of invasion, including collective and amoeboid single-cell dissemination, followed by enhanced micrometastasis, implicating a role of integrins in cell-cell cooperation and integrin-independent dissemination as effective route to metastasis. In conclusion, cancer invasion is maintained by physicochemical programs that balance cell-intrinsic adhesion and mechanocoupling with encountered physical space and molecular cues.

4:54PM W46.00005 Swarming in the bacterium Pseudomonas aeruginosa .
JOAO XAVIER, Memorial Sloan-Kettering Cancer Center — The fields of systems and synthetic biology have made great progress towards understanding and engineering biological systems while having the living cell as their central focus. However, many biological functions are multicellular and depend not only on interactions, both physical and chemical, between cells. We investigate organizing principles of multicellular systems using a prokaryotic model: swarming in Pseudomonas aeruginosa. Swarming is a collective form of surface motility that enables P. aeruginosa colonies to migrate over surfaces. We investigate the molecular mechanisms that confer robustness to swarming using a multidisciplinary approach that combines mathematical modeling, quantitative experiments, microbial genetics and comparative genomics to identify and characterize organizing principles of bacterial multicellularity. These “design principles” may inspire the development of robust synthetic multicellular systems that utilize emergent collective behaviors of cell populations to perform functions that individual cells cannot.

Thursday, March 5, 2015 2:30PM - 5:30PM — Session W47 DBIO: Membranes: Biological and Synthetic
217B - Kranthi Mandadapu, University of California, Berkeley
2:30PM W47.00001 Permeation of anions through the central pore of human aquaporin 51

TIERRY WAMBO, LIAO CHEN, Department of Physics & Astronomy, University of Texas at San Antonio — Aquaporin 5 (AQP5) plays an essential role in the physiology of saliva, tears and pulmonary secretion. We performed in silico experiments of the L51R mutant of the human Aquaporin 5 (PDB code: 3D95) for which in vitro experimental data became available recently. Molecular Dynamic Simulations performed on the AQP5 tetramer embedded in a lipid bilayer reveal that the central pore of the AQP5 mutant lost the hydrophobicity of the wild type protein and becomes permeable to anions, but not to cations. This conclusion is in agreement with the in vitro experiments of Qin and Baron, 2013. Quantitatively, we compute the potential of mean force (PMF) of chloride and iodide anions along the permeation path through the central pore. We correlate the PMFs with the experimentally measured conductance of various anions, elucidating the atomistic details of ion conduction through AQP5 mutant.

2:42PM W47.00002 Discovery of a fundamental force related to a membrane’s order-disorder transition that can govern protein self-assembly in membranes

SHACHI KATIRA, KRANTHI MANDADAPU, University of California, Berkeley, SURIYANARAYANAN VAIKUNTANATHAN, University of Chicago, BEREND SMIT, DAVID CHANDLER, University of California, Berkeley — The clustering of proteins in cell membranes is a controlling factor in biological processes such as cell signaling and membrane fusion. Using large-scale molecular simulations and a theoretical framework inspired by modern theories of the hydrophobic effect, we have uncovered a fundamental physical force for assembly of trans-membrane proteins in lipid bilayers. This force is a mesoscopic manifestation of the transition between ordered (i.e., gel) and disordered (i.e., fluid) phases of lipid bilayers. It is a pre-transition effect, occurring below the order-disorder transition temperature, nucleated by the protein’s disturbance of the ordered phase. This powerful force acts over several nanometers in range. Conditions at which this force occurs and can lead to clustering of proteins in cell membranes will be discussed.

3:06PM W47.00004 Theory for registered and antiregistered phase separation of amphiphilic bilayers

JOHN WILLIAMSON, PETER OLMSTED, Georgetown University — Phase separation in bilayers can be exploited by nature, and engineers, to design-function via membrane domains. The presence of two separate, yet coupled, leaflets forces one to ask whether and how such domains are aligned (registered) across the bilayer. Experiment and simulation yield intriguingly disparate observables. We introduce a theory for phase separation in coupled leaflets, by explicitly coarse-graining a lattice model that includes molecule-level structure and interactions. We show that hydrophobic mismatch leads to a complex competition of inter-leaflet couplings. The theory helps unify prima facie contradictory observations, by showing that domain antiregistration typically occurs as a metastable state, but can be kinetically preferred. The role of kinetics in governing registration/antiregistration is explored, the theory’s predictions confirmed and illustrated with simulations, which show how a bilayer in the “spinodal region” can require nucleation to equilibrate. Our results shed light on a novel statistical mechanical problem of great practical importance, and motivate future work on intra- and inter-leaflet behaviour of bilayers. 3:18PM W47.00005 X-ray Scattering Experiments Support Tilt-dependent Membrane Theory

MICHAEL S. JABLIN, JOHN F. NAGLE, Carnegie Mellon University — Recent molecular dynamics simulations have suggested that the traditional model for topographical fluctuations in lipid bilayers should be enriched to consider molecular tilt. We present the first experimental support for a tilt-dependent theory. X-ray scattering from a liquid crystalline stack of oriented fluid phase lipid bilayers was collected and compared to the predictions of tilt-dependent and tilt-independent membrane models. Both models satisfactorily fit the X-ray data dominated by in-plane lengths greater than membrane thickness (> 100 Å), but only the tilt-dependent model accounts for X-ray data primarily attributable to shorter length correlations. By fitting the measured X-ray scattering intensity, both the bending modulus $K_\epsilon = 8.3 \pm 0.6 \times 10^{-20}$ J and the tilt modulus $K_\theta = 95 \pm 3$ mN/m were determined for DOPC bilayers at 30 °C. Our experimental results support the enrichment of the classic Helfrich continuum model to include an internal degree of freedom, the fluctuations of lipid directors from the local normal.

3:30PM W47.00006 Two-Point Microrheology of Phase Separated Domains in Lipid Bilayers3

TRISTAN HORMEL, MATTHEW REYER, RAGHUVEER PARTHASARATHY, University of Oregon — Though the importance of membrane fluidity for cellular function has been well established for decades, methods for measuring lipid bilayer viscosity remain challenging to devise and implement. Recently, approaches based on characterizing the Brownian dynamics of individual tracers such as colloidal particles or lipid domains have provided insights into bilayer viscosity. In general, however, methods based on single-particle trajectories can be biased by distortions induced by the tracers, and furthermore provide a limited view of hydrodynamic response. The technique of two-point microrheology, in which correlations between the Brownian dynamics of pairs of tracers report on the properties of the intervening medium, resolves these issues, but has never been applied to lipid systems. We present the first two-point microrheological study of lipid bilayers, examining the correlated motion of domains in phase-separated lipid vesicles and comparing one- and two-point results. We measure correlation functions in excellent agreement with the forms predicted by two-dimensional hydrodynamic models, which reveal a viscosity that corresponds to the average of the lipid phases rather than the viscosity of the local neighborhood of the tracer.

3:42PM W47.00007 Use of Impedance Spectroscopy to Probe Changes in Mitochondrial Membrane Potential. ROOPLEKHA C. MITRA, MARTHA Y. SUÁREZ VILLAGRÁN, JAREK WOSIK, WANDA ZAGOZDZON WOSIK, JOHN H. MILLER, JR.1 University of Houston — The synthesis of ATP is driven by proton gradient and electrical potential across the mitochondrial inner membrane. It’s electrical properties correlates with its physiological and pathological status. Electrical impedance spectroscopy is a non-invasive and relatively low cost technique where the impedance measurements monitors the underlying biological processes to determine parameters for biomarker studies. In this work we implement a multi frequency (1kHz – 10MHz) bio electrical impedance to describe the changes in the electrical properties of mitochondria. The experimental strategy involved treating isolated mitochondria with the substrate succinate ([200µM] in vivo to stimulate the activity of succinate dehydrogenase. Subsequent variability is introduced by the addition of different trifluorocarbonylcyanoide-phenylhydrazone (25µM < FCCCP) < 50µM] and dopamine (50µM < DA < 0.5M) concentration. We observe that succinate alone lead to an increase in the mitochondrial membrane potential ΔΨm. Dielectric spectroscopy measurements show a direct correlation between FCCCP concentration and impedance and higher DA concentrations display marked decrease of membrane potential indicating a significantly reduced mitochondrial respiratory control.

3:54PM W47.00008 Proton-Pumping Mechanism in Complex I of Mitochondria Membrane. DAVNEET KAUR, Queens College CUNY — Mitochondria are the powerhouse of animal cells and also many bacteria. Complex I is the first enzyme in the mitochondrial respiratory chain, the process leading to storage of energy in the form of Adenosine Triphosphate (ATP). The structure of the enzyme was recently resolved and its functionality was correlated to the motion of a helical protein structure. However, the actual mechanism of the electron assisted proton-pumping of Complex I has remained mysterious because the electron (e-) and proton (H+) pathways are well separated by a distance of up to 15 nm making the direct interaction of these charges negligible. We model the helix assisted indirect coupling between the electron and proton pathways as a non-uniformly charged piston oscillating between the coupled sites of a 3 site series system. The energy conversion is determined by single e- and H+ transport events. The piston oscillates between that central proton and electron sites and modulates their energy, while the coupling with other sites is weak and negligible. We show that with realistic values of parameters, this structure allows for proton pumping against the potential gradient.

4:06PM W47.00009 ABSTRACT WITHDRAWN –

4:18PM W47.00010 Thinning silicon-based membranes with electron irradiation for solid-state nanopore sensors1, JULIO ALEJANDRO RODRIGUEZ-MANZO, MATTHEW PUSTER, University of Pennsylvania, Department of Physics and Astronomy, ADRIEN NICOLAI, VINCENT MEUNIER, Rensselaer Polytechnic Institute, Department of Physics, Applied Physics, and Astronomy, MARIJA DRNDC, University of Pennsylvania, Department of Physics and Astronomy — We present a controlled electron irradiation-based method to thin free-standing amorphous silicon membranes to less than 2 nm. Thinning is carried out in a scanning transmission electron microscope using a 200 keV electron probe to sputter silicon atoms. The transmitted electrons, scattered elastically and inelastically, are used as feedback signals to monitor and control the thinning process with sub-nanometer precision. Solid-state nanopore single-molecule sensors were fabricated by drilling a nanopore in the thinned membranes with the electron probe. These sensors operate in aqueous electrolyte and register passage of individual molecules by measuring changes in ionic conductance. We show that these solid-state nanopore single-molecule sensors sustain changes in ionic conductance with signal-to-noise ratios close to 100 at 100 kHz for translocations of double-stranded DNA in 1 M KCl electrolyte at room temperature coupled with conductance blockade of 60-95%.

4:30PM W47.00011 Nanoscopic modulated phases in dDPPC:DLPC membranes studied with small angle neutron scattering. NATALIE KRZYZANOWSKI, Univ of Illinois - Chicago, SUMIT GARG, Berg LLC, LIONEL PORCAR, Institut Laue-Langevin, Grenoble, France, URSULA PEREZ-SALAS, Univ of Illinois - Chicago — The lipid raft hypothesis states that functional, small (20-90nm) lateral heterogeneities in the cell membrane arise from the preferential association of proteins, sphingolipids, and cholesterol. Studies of model systems in the past decade have shown the formation of two liquid phases, a liquid-ordered and the typical fluid or liquid-disordered phase in ternary mixtures of a saturated lipid, unsaturated lipid, and cholesterol. These model raft systems on both a nanoscopic and macroscopic level have exhibited circular domains, but these are not the past only possible shapes of phase separated domains. Giant vesicles extracted from live cells studied with fluorescence microscopy can exhibit critical behavior, showing distinctly fluctuating and not circular domains. Non-circular domains have also been observed in quaternary component GUVs in the form of modulated or patterned phases. We use small angle neutron scattering (SANS) to study the nanoscopic phase behavior of the well-studied lipid mixture DPPC:DLPC as a function of temperature. We applied an existing ab initio program to reconstruct the membrane without a priori shape fixing. Modulated phases are shown to persist at the nanoscale in small vesicles.

4:42PM W47.00012 Heterogeneous Rotational Diffusion in Lipid Monolayers, NEDA DADASHVAND, LANELL A. WILLIAMS, CHRISTINA M. OTTHON, Wesleyan Univ — We have developed a new time-resolved fluorescence platform which enables us to follow the molecular orientation and dynamics of a lipid monolayer at the air - water interface. The rotational correlation time of the lipid probe NBD-PC is measured using fluorescence anisotropy for two lipid species. We measure the rotational diffusion in a monolayer of DPPC which displays a phase transition at room temperature from the liquid-expanded to the liquid-condensed phase. The constant rotational diffusion of the probe throughout the phase transition reflects the measurement of dynamics in only the liquid-expanded phase. We contrast the dynamic changes during this phase coexistence to the continuous density increase observed in DMPC at room temperature. We observe a non-exponential decay of the probe diffusion consistent with heterogeneity of the orientational dynamics; as the free-volume is reduced the diffusion becomes increasingly heterogeneous.

4:54PM W47.00013 Scaling and Alpha-helix Regulation of Protein Relaxation in a Lipid Bilayer1, K. CHENG, Trinity Univ, LIMING QIU, CREIGHTON BUIE, MARK VAUGHN, Texas Tech University — Protein conformation and orientation in the lipid membrane play a key role in many cellular processes. Here we use molecular dynamics simulation to investigate the relaxation and C-terminus diffusion of a model helical peptide: beta-amyloid (Aβ)1 in a lipid membrane. We observed that after the helical peptide was initially half-embedded in the extracellular leaflet of phosphatidylcholine (PC) or PC/cholesterol (PC/CHOL) membrane, the C-terminus diffused across the membrane and anchored to PC headgroups of the cytofacial lipid leaflet. In some cases, the membrane insertion domain of the Aβ3 was observed to partially unfold. Applying a sigmoidal fit to the process, we found that the characteristic velocity of the C-terminus, as it moved to its anchor site, scaled with $u_{\text{c}}^{-4/3}$, where $u_{\text{c}}$ is the fraction of the original helix that was lost during a helix to coil transition. Comparing this scaling with that of bead-spring models of polymer relaxation suggests that the C-terminus velocity is highly regulated by the peptide helical content, but that it is independent of the amino acid type. The Aβ was stabilized by the attachment of the positive Lys28 side chain to the negative phosphate of PC or 3β oxygen of CHOL in the extracellular lipid leaflet and of the C-terminus to its anchor site in the cytofacial lipid leaflet.

Redistribution of Cholesterol by Membrane Active Peptides Alamethicin and Melittin

SHUO QIAN, WILLIAM HELLER, Oak Ridge National Lab — Many membrane active peptides are found to disrupt lipid bilayer of membrane in a concentration-dependent manner and form transmembrane pore over threshold concentrations, as depicted in Two-State Model. However, at low concentration, the interaction between peptide and lipid bilayer remains less understood beyond the thinning effect. Here we present small-angle neutron scattering studies of the interaction of two well-known membrane active peptides (melittin and alamethicin) with lipid bilayers made of dymyristoyl phosphatidylcholine (DMPC) and cholesterol (Chol). Through the use of deuterium-labeled DMPC, changes in the distribution of the lipid and cholesterol in unilamellar vesicles were observed for peptide concentrations well below those that drive pore formation. We have found the binding of the peptides have profound impact on the distribution of cholesterol residing inside the lipid bilayer. Those results point the existence of a possible secondary mechanism of action against cellular membranes as metabolic inhibitors that affect cellular machinery by redistributing cholesterol.

Energetics of interactions between protein inclusions in lipid bilayer membranes

PAUL GOLDBART, MICHAEL DIMITRIYEV, Georgia Institute of Technology, ALEX LEVINE, University of California - Los Angeles — Proteins that are situated in cell membranes play vital roles in numerous cell functions. Examples include the enabling of the selective passage of ions or molecules into and out of cells, or the relaying of signals between cell interiors and their external environments. We develop a framework for understanding the energetics of the interactions that can arise between protein inclusions. We focus on the setting of inclusions in lipid bilayers and interactions that stem from the spatial overlap of the distortions induced by the inclusions in the orientational organization of the lipid molecules that constitute the bilayers.

The structure of infectious disease outbreaks across the animal-human interface

CHRISTOPHER R. MYERS, Cornell University, DAVID J. SCHNEIDER, USDA-ARS and Cornell University, SARABJEET SINGH, Cornell University — Zoonotic infectious diseases that spill over from animal to human populations are responsible for some of the most devastating plagues to haunt humanity throughout its history, including the recent Ebola outbreak. Yet despite considerable efforts by epidemiologists to model specific zoonotic infections, much of the basic underlying structure of cross-species outbreaks has not been well-characterized. Motivated by these gaps and by recent efforts to develop classification schemes for characterizing the spectrum of zoonotic diseases, we have solved – using techniques from multitype branching processes and queuing theory – for the structure and statistics of outbreaks resulting from cross-species spillover, characterizing outbreak sizes, probabilities and first-passage times. In the case of human outbreaks driven by epidemics in animal populations, we find a novel multicritical point at which outbreak size scaling is different than in a single population. When human outbreaks are driven by an endemic disease in an animal reservoir, we find variable exponents characterizing outbreak size and duration that depend upon the rate of cross-species spillover.

The spatial and metabolic profiles of microbial populations non-monomonotonically impact the growth of antibiotic resistant mutants

KARISHMA KAUSHIK, NALIN RATNAYEKE, Univ of Texas, Austin, PARAG KATIRA, Univ of Texas, Austin. Present address: Columbia University, New York, VERNITA GORDON, Univ of Texas, Austin — Spatial heterogeneity in the distribution of antibiotic is known to accelerate the development of genetic antibiotic resistance. However, the effect of the structure of the microbial population is less well studied. Microbial population structure is a type of spatial structure defined by composition, cell density, and spatial organization of cell types. As our cell types, we use antibiotic-resistant and antibiotic-susceptible (wild-type) Pseudomonas aeruginosa along with S. aureus and B. cepacia, both co-pathogens with P. aeruginosa. In spatially-mixed systems, composed of wild-type cells and antibiotic-resistant mutants, we find that increasing cell density reduces the probability of antibiotic-resistant mutant survival in the presence of antibiotic. Using spatially-structured systems, we show that inhibition is mediated by a low-molecular weight, universal, alkaline by-product of bacterial catabolism of amino acids. We demonstrate that for organisms capable of growing on either amino acids or sugars, the nutrient environment provides a switch to activate or deactivate inhibition. Finally, we show that small spatial fluctuations in initial population density can shield mutants from the combined effect of antibiotic and the inhibitory factor.

Evolution of Super-Reciprocity in Noisy Iterated Games

AREND HINTZE, CHRISTOPH ADAMI, Michigan State Univ — In the classical Iterated Prisoner’s Dilemma (IPD), direct reciprocity is a form of communication leading to altruistic behavior. However, if players use stochastic strategies, a secondary form of cooperation in which players alternate in receiving the Temptation (T) and Sucker (S) rewards can emerge (super-reciprocity). This reciprocal behavior will become evolutionary dominant if the reward (T) is increased above a certain threshold, but is inherently more risky than primary cooperation since it relies on trust between players in two consecutive iterations of the game. Here, we investigate how different environmental conditions such as mutation rate, environmental noise, and reward T affect the evolution of reciprocity. Super-reciprocal strategies rely on the synchronization of two genes and are thus much more sensitive to environmental changes that affect the accuracy of players prediction of opponents’ future moves. We find that increasing the environmental noise or mutation rate is deleterious to super-reciprocity, while increasing T stabilizes its evolution. Conversely, in environments that are highly predictable and where there is no payoff advantage to engage in reciprocal cooperation, basic cooperation strategies rely on the synchronization of two genes and are thus much more sensitive to environmental changes that affect the accuracy of players prediction of opponents’ future moves. We find that increasing the environmental noise or mutation rate is deleterious to super-reciprocity, while increasing T stabilizes its evolution. Conversely, in environments that are highly predictable and where there is no payoff advantage to engage in reciprocal cooperation, basic cooperation via reciprocal communication remains the strategy of choice.

An optimal energy dissipation strategy of the MinCDE oscillator in regulating symmetric bacterial cell division

GANHUI LAN, George Washington University — Sustained molecular oscillations are ubiquitous in biology. The obtained oscillatory patterns provide vital functions as timekeepers, pacemakers and spacers. Control-theory type models have been introduced to explain how specific oscillatory behaviors stem from protein interaction feedbacks, whereas the energy dissipation through the oscillating processes and its role in the regulatory function remain elusive. Here we developed a general framework to assess oscillator’s regulation performance at different dissipation levels. Using Escherichia coli MinCDE oscillator as model system, we showed that, unlike stationary regulators’ monotonic performance-to-cost relation, excess dissipation at certain steps in the oscillating process damages the oscillator’s regulatory performance. We further discovered that ATP hydrolysis energy has to be strategically assigned to the MinE-aided MinD release and the MinD immobilization steps for optimal performance, and higher energy budget improves the robustness of the oscillator. These results unfold a novel mode that living systems trade energy for regulatory function.

3:42PM W48.00005 Quantitative evolutionary dynamics of one million barcoded lineages. JAMIE BLUNDELL, Stanford University, SASHA LEVY, SUNY Stony Brook, SANDEEP VENKATARAM, DMITRI PETROV, DANIEL FISHER, GAVIN SHERLOCK, Stanford University — Evolution of large asexual cell populations underlies ≈ 30% of deaths worldwide, including those caused by bacteria, parasites, and cancer. However, the dynamics underlying these evolutionary processes remain poorly understood because they involve many competing beneficial lineages, most of which never rise above extremely low frequencies. To observe these normally hidden evolutionary dynamics, we constructed a sequencing-based ultra high-resolution lineage tracking system that can monitor the relative frequencies of ≈ 500,000 lineages simultaneously. We find that the spectrum of fitness effects of beneficial mutations is far from exponential and not even monotonic. Early adaptation is a predictable consequence of this distribution and is strikingly reproducible, but the initial small-effect mutations are soon outcompeted by rarer large-effect mutations that result in variability between replicates. Our results suggest that early evolutionary dynamics may be deterministic for a period of time before stochastic effects become important. The interplay between deterministic and stochastic effects is controlled in large part by the distribution of mutation rates to each fitness effect, which high-resolution lineage tracking is uniquely suited to measure.

3:54PM W48.00006 Noise-stabilized Turing Patterns in a Synthetic Biofilm1. K. MICHAEL MARTINI, Department of Mathematics and Institute for Genomic Biology, University of Illinois at Urbana-Champaign, DAVID KARGIR, Research and Exploratory Development Department, Johns Hopkins University Applied Physics Laboratory, TING LU, Department of Bioengineering, Department of Physics and Institute for Genomic Biology, University of Illinois at Urbana-Champaign, NIGEL GOLDENFELD, Department of Physics and Institute for Genomic Biology, University of Illinois at Urbana-Champaign, RON WEISS, Department of Biological Engineering, Massachusetts Institute of Technology — Deterministic Turing instabilities have been proposed to be a major source of pattern formation in biology, but have been hard to document rigorously, in part because of the requirement for a large ratio of the inhibitor to activator diffusion coefficient. A recently developed theory of stochastic Turing patterns predicts that stochastic or noise-stabilized Turing patterns occur over a larger region of parameter space and do not require as large a separation of diffusion rates. We apply this theory to a biofilm whose signaling molecules have been forward-engineered to exhibit activation and inhibition. Outside of the range of deterministic Turing patterns, we observe noise-stabilized patterns that exhibit a power spectrum power law tail with exponent $-2.3 \pm .4$ consistent with theory. Our results are the first report of a spatial pattern in gene expression stabilized by copy number fluctuations.

4:06PM W48.00007 Limits on energy dissipation qualitatively change kinetic proofreading in single cells1. JAYAJIT DAS, The Research Institute at the Nationwide Children’s Hospital and the Ohio State University — Cell signaling events, composed of biochemical reactions, usually occur in the absence of the detailed balance condition and continuously dissipate energy. Consequently, when energy supply is limited, specific chemical modification steps might not occur due to the lack of energy to support those reactions. How does the absence of such modification steps, that are intrinsically stochastic in nature, affect single cell signaling kinetics? I address this question in the context of a kinetic proofreading scheme used in a simple model of early T cell signaling. I show, using exact analytical calculations and numerical simulations, that the amount of energy dissipation needed to execute a desired discrimination scheme depends on whether the decision is made at the transient state or in the steady state of the kinetics. Using a modified Gillespie algorithm for simulating biochemical reactions in energy limited conditions, I show that restricting energy dissipation leads to poorer discrimination in single cells for weak and low affinity ligands. Furthermore, restricting energy dissipation produced substantially larger intrinsic cell-to-cell variations of proteins with qualitatively different distributions than the system with unlimited supply of energy.

4:18PM W48.00008 Decision theory for immune ligand recognition. PAUL FRANCOIS, McGill University — Variability in the chemical composition of the extra-cellular environment can significantly degrade the ability of cells to detect rare cognate ligands. Using concepts from statistical detection theory, we formalize the generic problem of detection of small concentrations of ligands in a fluctuating background of biochemically similar ligands binding to the same receptors. We discover that in contrast to expectations arising from considerations of signal amplification, inhibitory interactions between receptors can improve detection performance in the presence of substantial environmental variability, providing an adaptive interpretation to the phenomenon of ligand antagonism. Our results suggest that the structure of signalling pathways responsible for chemodetection in fluctuating and heterogeneous environments might be optimized with respect to the statistics and dynamics of environmental composition. Our formalism stresses the importance of characterizing non-specific interactions to understand function in signalling pathways.

4:54PM W48.00009 Phylogetic Tree from the Tangled Nature Model and Its Community Structure1. OSMAN CANKO, FERHAT TASKIN, KAMIL ARGIN, Erciyes University — In the evolutionary biology, taxonomy and origination of species are a widely emphasized subject. An estimation of the evolutionary tree can be done via available DNA sequence data. The calculation of tree are made by well-known and frequently used methods such as maximum likelihood and neighbor-joining. In order to inquire the results of these methods, an evolutionary tree is pursued computationally by a mathematical model, called Tangled Nature. A relatively small genome space is investigated due to computational burden and it is found that actual and predicted tree are in a reasonably good agreement in terms of shape. Moreover, speciation and emerged community structure of food-web are investigated by modularity.

5:06PM W48.00010 A Stability Investigation of Dynamically Evolved Tangled Nature Model1. FERHAT TASKIN, OSMAN CANKO, KAMIL ARGIN, Erciyes University — An individual-based Tangled Nature model has non-stationary macro-dynamics of evolutionary ecology. System travels among the multi-space minimum through saddle point and stays in a valley, called quasi-steady states (qSS). We have compared the stability of sequential qSS by perturbation. To investigate stability of community, the perturbed and unperturbed systems are compared by their community structure. Our results exhibit that the angle and distance between two center of mass shows a delayed response to perturbation for aged system. We have observed that the system evolves dynamically to the more stable states and shows robustness to external shocks with passing time.

2:30PM W49.00001 Kinetic Description for Formation and Dissolution of Living Colonies. CHRISTOPH WEBER, VEN TING LIN, Max Planck Institute for the Physics of Complex Systems, NICOLAS BIAIS, Brooklyn College and The Graduate Center, VASILY ZABURDAEV, Max Planck Institute for the Physics of Complex Systems, COLLECTIVE DYNAMICS OF CELLS TEAM, BIOLOGY DEPARTMENT COLLABORATION — Pathogen bacteria, such as N. gonorrhoeae or N. meningitidis form colonies due to encounters of nearby individuals while the effect of cell division is in general negligible. They use long and thin filaments, called pili, which attach to a substrate, retract and thereby pull the cell forward. Even though it is known that these bacteria interact by pili and adhesion, the question of how single cell motility and cell-cell interactions affect the process of colony formation is poorly understood. To bridge this gap we propose a kinetic description that keeps track of the length scales related to the underlying interactions between the cells and with the substrate. We derive the corresponding hydrodynamic equation and find an ordering instability leading to the formation of colonies. However, colonies can also dissolve which is a key survival mechanism in rapidly deteriorating environmental conditions. Recent experimental studies indicate that colonies can dissolve by switching off either the adhesive or pili-mediated interaction. Remarkably, within the same framework we can show that dissolution is possible, however, there is a region in parameter space where it is precluded. Both scenarios can be explained in terms of the underlying microscopic interactions.

2:42PM W49.00002 Coarse-grained model for a motor protein walker on a bead-spring substrate. JUTTA LUETTMER-STRATHMANN, Departments of Physics and Chemistry, NABINA PAUDYAL, MARAL ADELI KOUDEHI, Department of Physics, The University of Akron, Akron, OH 44325-4001 — Motor proteins play an important role in many biological processes. For example, kinesin molecules are responsible for the transport of vesicles in nerve cells and their malfunction has been linked to neurodegenerative diseases. Unfortunately, the complexity of motor proteins and their environment makes it difficult to model the detailed dynamics of molecular motors over long time scales. In this work, we develop a simple coarse-grained model for a motor protein on a bead-spring substrate under tension. In our model, different pair potentials describe interactions between substrate and motor, motor components and substrate components. The movement of motor proteins entails ATP hydrolysis, which is modeled in terms of mechano-chemical states that couple positional and chemical degrees of freedom. We apply the model to the problem of cargo transport and the effect of motor-protein activity on the mechanical response of a single chain molecule.

2:54PM W49.00003 Effect of silane molecular length on initial attachment of bacteria to silanized glass surfaces. ANDREA JAIMES-LIZCANO, SUMEDHA SHARMA, JACINTA CONRAD, University of Houston — Bacteria adhered to surfaces can form biofilms, which foul biomedical implants, industrial equipment and marine vessels, leading to deleterious costs. Designing surfaces to control bacterial adhesion is therefore of great interest for the prevention of biofouling. In this work, we investigate the effect of silane molecular length on the initial attachment of bacteria. We characterize the initial attachment of Escherichia coli to glass surfaces that are coated with silane molecules with the same functional end group but two different carbon chain lengths. Bacteria are deposited from flow in a microfluidic channel at shear rates ranging from 3.1 s$^{-1}$ to 25 s$^{-1}$ and imaged and tracked using confocal microscopy and high-throughput image processing algorithms. The initial rate at which bacteria deposit on the surface is independent of shear rate for the shorter three-carbon chains but depends on shear rate for the longer nine-carbon chains. We found longer bacterial residence times on the shorter silane molecules at the highest shear rate.

3:06PM W49.00004 Dissecting Subcellular Actomyosin Mechanics with Magnetically Actuated Micropost Arrays. YU SHI, Johns Hopkins University, STEVEN HENRY, JOHN CROCKER, University of Pennsylvania, DANIEL REICH, Johns Hopkins University — The cellular actomyosin cytoskeleton is widely regarded as an archetypal example of an active matter system. However, the extent to which the wide range of observed cellular motility behaviors arise from active-matter physics is not well understood. Characterizing an active matter system requires simultaneous measurement of the fluctuation spectrum of the internal force generators and also the local viscoelasticity to separate the distinct effects of the material’s internal stresses from its viscoelastic response to those stresses. By placing cells on top of PDMS micropost arrays with magnetic nanowires embedded in selected posts, we can actuate local regions of the cells by applying AC magnetic fields to dynamically probe the local viscoelasticity, while simultaneously using the posts as “probe particles” for passive micro rheology measurements of the cytoskeletal force fluctuations. The range of active and passive responses observed for different subcellular regions of fibroblast cells will be presented, and the results compared to simple active material models based on known or predicted behavior of molecular motors in viscoelastic networks. Effects of coupling between local cellular regions as measured by correlations in the micropost’s motion will also be described.

3:18PM W49.00005 Confocal Microscopy Indentation for Hydrogel¹. DONGHEE LEE, MD, MAHMUDUR RAMMAN, YOU ZHOU, SANGJIN RYU, University of Nebraska-Lincoln — It is well known that the stiffness of extracellular matrix affects cellular behaviors, and such effects were observed by culturing cells on hydrogel substrates. Thus it is required to measure the elasticity of the hydrogel substrate rigorously and efficiently. Here we propose a confocal microscopy indentation method for hydrogels. We indented fluorescently stained polyacrylamide gel with a sub-mm-sized ball indenter, and imaged the indented gel using confocal microscopy. Having formed a three-dimensional image stack of the gel, we measured the indentation depth based on automated image processing, and then evaluated the elasticity of the gel. We also validated our method using other well established indentation methods.

3:30PM W49.00006 Schwann Cells and the Importance of Finite 3D Deformations in Soft Gels². CHRISTIAN FRANCK, EYAL BAR-KOCHBA, Brown University, CRISTINA LOPEZ-FAGUNDO, University of Zurich, LIANE LIVI, DIANE HOFFMAN-KIM, Brown University — Schwann cells (SCs) are specialized glial cells that are critical for the development, regeneration, and maintenance of nerves in the peripheral nervous system (PNS). Recent studies have shown that the mechanical properties of the extracellular matrix can significantly affect cell structure and function. Studying the mechanical interactions between SCs and their microenvironment can aid in understanding their physical and morphological changes as well as their native function. Using a recently developed 3-D large deformation traction force microscopy (3-D-LDTFM) technique, we investigate the mechanosensitivity of SCs across a physiologically relevant substrate stiffness range (0.24 kPa to 4.80 kPa) in vivo. As oppose to other cell types, we find that the SC spreading area and prominent stress fiber formation was relatively insensitive to substrate stiffness. Consistent with these structural findings, the SCs generated large surface tractions on stiff substrates and large material deformations on soft substrates. Across all moduli, we observed a significant contribution from the out-of-plane traction component, locally giving rise to rotational moments similar to those reported for mesenchymal embryonic fibroblasts.

4:18PM W49.00008 Complex multi-cellular manifolds\textsuperscript{1} . TAPOMOY BHATTACHARJEE, KYLE G. ROWE, Department of Mechanical and Aerospace Engineering, University of Florida, Gainesville, Florida, 32611 USA, SUHANI JAIN, Stanton College Preparatory, Jacksonville, Florida, 32209 USA, STEVEN M. ZEHNDER, RYAN M. NIXON, Department of Mechanical and Aerospace Engineering, University of Florida, Gainesville, Florida, 32611 USA, W. GREGORY SAWYER, Department of Mechanical and Aerospace Engineering, Department of Materials Science and Eng., University of Florida, Gainesville, Florida, 32611 USA, THOMAS E. ANGELINI, Department of Mechanical and Aerospace Eng., Department of Biomedical Eng., Institute for Cell and Regenerative Medicine, University of Florida, USA — Investigation of collective cell behavior is critical for understanding the evolution of tissue regeneration, embryonic morphogenesis, wound healing, and cancer invasion. Collective behavior has been widely studied in 2D cell monolayers, providing great fundamental understanding of multi-cellular motion and mechanics. Living tissues, by contrast, are densely packed with complex 3D structures including curved manifolds and tubular networks. Exploration of collective cell behavior within such complex 3D structures is essential to our understanding of cell monolayers to their motion and mechanics in tissues. In this study, complex structures have been generated by 3D printing living cells into a viscoelastic cell growth medium, creating cellular manifolds with a wide range of mean and Gaussian curvature, such as linear cylinders and branched tubular networks. Preliminary data describing collective cell behavior within these complex manifolds will be presented.

4:30PM W49.00009 Long range self-assembly of microcapsules regulated via the represilator signaling network . HENRY SHUM, VICTOR YASHIN, ANNA BALAZS, University of Pittsburgh — Communication to produce collective motion is a biological characteristic realized by few synthetic systems. Inspired by biological regulatory networks, we design a collection of microcapsules that move in response to self-generated chemical signals. Three microcapsules act as localized sources of distinct chemicals that diffuse through surrounding fluid. Production rates are modulated by the “represilator”: each chemical species represses the production of the next in a cycle. Depending on the maximum production rates and capsule separation distances, we show that immobile capsules either exhibit steady or oscillatory chemical production. We then consider movement of the microcapsules over the substrate, induced by gradients in surface energy due to adsorbed chemicals. We numerically simulate this advection-diffusion-reaction system with solid-fluid interactions by combining lattice Boltzmann, immersed boundary and finite difference methods, and thereby, construct systems where the three capsules spontaneously assemble, forming a close-packed triad. Chemical oscillations are shown to be critical to this assembly. By adjusting parameters, the triad can either remain stationary or translate as a cohesive group. Stationary triads can also be made to “turn off” after assembly.

4:42PM W49.00010 Asymmetric oscillation and dynamic clustering of water-in-oil droplets by hydrodynamic interactions . TAKUYA OHMURA, Department of Physics, Kyoto University, KEN-ICHIRO KAMEI, iCeMS, Kyoto University, MASAOTOSHI ICHIKAWA, Department of Physics, Kyoto University, YUSUKE MAEDA, Department of Physics, The Hakubi Center, Kyoto University, JST PRESTO — Ordered motion or patterns are widely observed in many biological systems, far from equilibrium. Microfluidic droplet crystal is one of the ensemble of water-in-oil droplet moving in immiscible fluid in a microchannel is known to exhibit normal vibrational mode due to inter-droplet hydrodynamic interactions. In this study we study dynamic ordering in the ensemble of different-sized droplets in order to investigate the effect of heterogeneity in the droplet crystal. We find asymmetric back-and-forth motion of single small droplet of 20 \( \mu \)m, which is placed within two droplets of 140 \( \mu \)m, is emerged. As a group of small droplets comes in the middle of large droplets, their motion turns dynamic clustering from oscillation. Numerical analysis indicates that hydrodynamic interactions with boundary wall and large droplets break symmetry of flow field and results in closed streamlines sustaining asymmetric oscillation.

4:54PM W49.00011 Tensional Homeostasis in Single Fibroblasts Probed with Traction Force Microscopy . ROSTISLAV BOLYANSKII, HENRY FOOTE, AARON MERTZ, KATHRYN ROSOWSKI, HOLLY LAURIDSEN, VALERIE HORSLER, JAY HUMPHREY, MARTIN SCHWARTZ, ERIC DUFRESNE, None — Many tissue types, including skin and blood vessels, respond to mechanical perturbations as a means to feedback regulate their behavior. While much of the research has focused on the mechanics of cells in monolayers, recent studies have demonstrated that collective cell contractility is also key to pattern formation and functional tissue regeneration. Here we introduce a new approach to measure cell traction forces using the open-source software NIBLASSI to measure cell traction forces using the open-source software NIBLASSI, enabling us to measure cell traction forces using the open-source software NIBLASSI. This approach allows us to measure cell traction forces using the open-source software NIBLASSI, providing new insights into how mechanical perturbations regulate collective cell behavior.

2:30PM W50.00001 Direct mapping of local director field of nematic liquid crystals at the nano-scale . YU XIA, FRANCESCA SERRA, SHU YANG, RANDALL KAMien, Univ of Pennsylvania — The director field in liquid crystals (LCs) has been characterized mainly via polarized optical microscopy, fluorescence confocal microscopy, and Raman spectroscopy, all of which are limited by optical wavelengths ~ hundreds of nanometers to several micrometers. Since LC orientation cannot be resolved directly by these methods, theory is needed to interpret the local director field of LC alignment. In this work, we introduce a new approach to directly visualize the local director field of a nematic LC (NLC) at the nano-scale using scanning electron microscopy (SEM). A new type of NLC monomer bearing crosslinkable groups was designed and synthesized. It can be well-oriented at particle surfaces and patterned polymer substrates, including micron-sized silica colloids, porous membranes, micropillar arrays, and 1D channels. After carefully crosslinking, the molecular orientation of NLCs around the particles or within the patterns could be directly visualized by SEM, showing oriented nanofibers representing LC director from the fractured samples. Here, we could precisely resolve not only the local director field by this approach, but the defect structures of NLCs, including hedgehogs and line defects. The direct mapping of LC directors at the nanoscale using this method will improve our understanding of NLC local director field, and thus their manipulation and applications. More importantly, a theoretical interpretation will no longer be a necessity to resolve a new material system in this field.

2:42PM W50.00002 Topological Defects in Liquid Crystals: Studying the Correlation between Defects and Curvature . CHARLES MELTON, University of California Merced — Topological defects have recently been the subject of many studies in soft condensed matter physics. In particular, linking the evolution of topological defects to curvature changes has been a focus, leading possible applications in the areas such as cosmetics, pharmaceuticals, and electronics. In this study, defects in nematic liquid crystal droplets are investigated via laboratory and theoretical techniques. Nematic liquid crystal defects are reproduced via Monte Carlo simulations using a modified 2D XY-Model Hamiltonian. The simulation is performed on a curved surface to replicate a nematic droplet and examine possible defect configurations. To complement this theoretical work, we have trapped nematic droplets inside a dual-beam optical trap. This system allows controllable non-contact droplet deformation on a microscope based platform. Future work will focus on using the trap to stretch nematic droplets, correlating the changing topological defects with theoretical predictions.
2:54PM W50.00003 Ground States of Nematic Tori with radial boundary conditions, KARTHIK NAYANI, School of Material Science and Engineering, Georgia Institute of Technology, PERRY ELLIS, School of Physics, Georgia Institute of Technology, JUNG OK PARK, MOHAN SRINIVASARAO, School of Material Science and Engineering, Georgia Institute of Technology, ALBERTO FERNANDEZ-NIEVES, School of Physics, Georgia Institute of Technology — We report ground states of radially anchored nematic tori. For strong anchoring conditions we observe the often reported escape radial configuration. However, as the aspect ratio of the torus is lowered the escape configuration evolves to a new structure where the additional splay on the liquid crystal imposed by the geometry of the torus is released as bend. At lower anchoring condition the ground state corresponds to a two +1/2 line defect wrapping the torus. However, as the aspect ratio is lowered we again observed a new ground state where a single line wraps the torus twice. We perform Jones calculus simulations to confirm that our director ansatz reflects the experimental findings.

3:06PM W50.00004 Using chemically patterns with different anchoring behavior to control the orientation of nematic liquid crystal, XIAO LI, JULIO ARMAS PEREZ, JOSE ADRIAN MARTINEZ-GONZALEZ, HELOU XIE, JUAN DE PABLO, PAUL NEALEY, University of Chicago — We present experimental and theoretical study of nematic liquid crystal (5CB) confined to a thin cell between homeotropic anchoring top surface and chemically patterned planar/homeotropic anchoring bottom substrates. The chemically patterned substrate with different dimensions and ~ 4 nm depth topography induce the 5CB to align as the pattern direction as non-degenerate behavior, until the width of the straight line pattern is too wide to confine the 5CB to one direction and back to degenerate behavior. By changing the width of the straight line pattern, a brightness change of the intensity is shown by their corresponding crossed polarizer images. This change is mainly due to a discontinuity of the average angle between the molecules and the surface in function of line width, which is in excellent agreement with the Landau-de Gennes theory when the balance between the elastic deformation in the bulk and orientation of molecules close to the surface is simulated for different pattern dimensions. An elastic free energy transition is also observed from the numerical analysis when the strong planar anchoring for presented experiments is changed to weak. This 3D confinement by chemically patterns and small depth topography offers a new way to generate any geometry pattern controllable non-degenerate orientation, achieving switchable optical properties.

3:18PM W50.00005 Planar Anchoring of Achiral Nematic Liquid Crystals in Capillaries — with a Twist1, ZOEY S. DAVIDSON, JOOHWOO JEONG, LOUIS KANG, Department of Physics & Astronomy, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA, PETER J. COLLINGS, Department of Physics & Astronomy, Swarthmore, Department of Physics & Astronomy, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA, TOM C. LUBENSKY, A. G. YODH, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA — In the common three-term Frank free energy of a nematic liquid crystal, the ground state configuration will have no deformations and all nematic directors will be parallel. However, certain confining geometries can impose significant deformations on the ground state, even if a zero-deformation configuration can be drawn that satisfies all boundary conditions. By solving the Euler-Lagrange problem of the Frank free energy equation, including the saddle-splay term, with cylindrical confinement and degenerate planar anchoring, we find conditions for a highly deformed ground state that has a double twist like structure. We explore these effects experimentally with both thermotropic and lyotropic liquid crystal materials, finding good agreement with the theoretically predicted configuration. We also observe a rich phenomenology of defect structures in the liquid crystal samples.

3:30PM W50.00006 Dynamics of isothermal phase transition of liquid crystal with zero anchoring1, JINXIN FU, KARTHIK NAYANI, JUNG OK PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology — Liquid crystal (LC) is an ideal system to mimic the cosmological symmetry breaking in the laboratory. The formation of LC string defects in film and bubble has been shown to be analogous to the formation of cosmic strings previously. Here we study the dynamics of LC isothermal transition from isotropic to nematic phase in a three-dimensionally isotropic environment, which enables us to observe the simultaneous symmetry breaking of matter without any external heat transfer or anchoring boundary condition. The isothermal phase transition is realized by the photochemical conversion of the trans-form to the cis-form of an Azobenzene compound that is added into liquid crystal E7. And a medium composed of carbopol and SDS surfactant provides the zero anchoring. The dynamics of the nucleation of LC and defects are studied under microscope with high-speed camera.

2:54PM W50.00008 Substrate induced gliding for a nematic liquid crystal layer1, ENSELA MEMA, LINDA CUMMINGS, LOU KONDIC, New Jersey Institute of Technology — The interaction between nematic liquid crystals (NLC) and polymer substrates is of current industrial interest, due to a desire to manufacture a new generation of flexible Liquid Crystal Displays (LCDs) for use in portable electronic devices. Polymer substrates present challenges because they can interact with the NLC, exhibiting a phenomenon known as gliding; the preferred orientation of the NLC molecules at the interface changes over timescales of minutes to hours. We present two models for gliding, inspired by the physics and chemistry of the interaction between the NLC and polymer substrate. These models, though simple, lead to non-trivial results, including loss of bistability, a finding that may have implications for display devices.

in the twist-bend nematic (N_{tb}) liquid crystalline phase of odd numbered flexible dimer molecules is presented. It is found that the N_{tb} phase is strongly shear-thinning. At shear stresses below 1Pa the apparent viscosity of the N_{tb} phase is 1000 times larger than in the nematic phase. At stresses above 10Pa the N_{tb} viscosity drops by two orders of magnitude and the material exhibits Newtonian fluid behavior. The results are consistent with the behavior of a system with pseudo-layer structure with layer spacing determined by the heliconical pitch. From the measurements of dynamic modulus we estimate the compression modulus of the pseudo-layers to be B ~ 2kPa; this value is discussed within the context of a simple theoretical model based upon a coarse-grained elastic free energy.

4:30PM W50.00011 Second Harmonic Light Scattering Study of a Twist-Bend Nematic Liquid Crystal

1, SHOKIR PARDAEV, JAMES GLEESON, Department of Physics, Kent State University, ANTAL JAKLI, Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State University, SAMUEL SPRUNT, Department of Physics, Kent State University — The twist-bend nematic phase exhibited by certain liquid crystalline dimers has been the subject of intensive recent investigation. In this report we present the results of angle-resolved second harmonic (SH) light scattering measurements from a twist-bend (TB) nematic liquid crystal for various combinations of the fundamental and second harmonic polarizations. These measurements reveal a polarization-dependent pretransitional temperature dependence of the SH signal, as well as an evolution of the SH scattering pattern below the transition (in the TB phase). We will discuss our results in terms of other recent experiments, as well as the current theoretical understanding of the nematic to TB transition and the nature of the TB phase. We thank O. Parri at Merck Chemicals Ltd., Southampton, UK for providing the studied material for us.

A @NSF DMR-0904765 and DMR-1307674.

4:42PM W50.00012 Coarse-grained model and light scattering of the twist-bend nematic phase

1, SHAIKH SHAMID, DAVID ALLENDER, JONATHAN SELINGER, Kent State Univ - Kent — We develop a coarse-grained version of the continuum theory for the twist-bend (TB) nematic phase of liquid crystals. In this theoretical approach, we begin with an ideal, undistorted TB phase, which has a heliconical modulation of the director field. We then calculate the elastic free energy cost of a position-dependent local rotation of the director away from the ideal state. We diagonalize this free energy density to find the eigenmodes of the system. Of these eigenmodes, the soft mode can be regarded as a smectic-like distortion of periodic plates in the TB phase; this mode has effective elastic constants for layer compression and curvature. By comparison, the hard mode involves director variations away from the optimum cone angle. This calculation leads to a prediction for light scattering from the TB nematic phase.

4:54PM W50.00013 Fullerene (C_{60}) nano-colloids in nematic liquid crystal

1, ANGELO VISCO, KEVIN SOBCZAK, RIZWAN MAHMOOD, Slippery Rock University — We report high resolution homodyne light scattering studies to probe director fluctuations in bend/splay mode in bulk nematic liquid crystal and as a function of fullerene (C_{60}) nanoparticles concentration. The preliminary analysis shows that the relaxation time of these fluctuations is fairly constant with in the experimental uncertainty despite the constraints imposed on the director fluctuations due to the insertion of nano colloids. The relaxation time extracted from the data found to be in nano seconds range and the diffusion constant (D) found to be, D = 4.29 \times 10^{-6} \text{cm/sec}.

5:06PM W50.00014 Computational and theoretical analysis of chiral rafts in colloidal membranes

1, RAUNAK SAKHARDANDE, MICHAEL HAGAN, APARNA BASKARAN, BULBUL CHAKRABORTY, Brandeis University, BRANDEIS SOFT MATTER THEORY GROUP TEAM — In contrast to bulk liquids or crystals clusters of finite size are rare and their assembly usually requires sophisticated engineering. Recent experiments conducted on monolayer membranes composed of two species of chiral rodlike molecules leads to the spontaneous formation of thermodynamically stable, rafts with a well-defined finite size. To understand the fundamental forces driving this self-limited assembly, we combine Monte Carlo simulations and a mean field theory to explore the phase diagram of a monolayer of bidisperse rodlike molecules as a function of interparticle interactions and chirality. The simulation demonstrates that differences in chirality between the two rod species can stabilize finite-sized rafts. We present a phase diagram which predicts parameter ranges over which finite-sized rafts are stable.

2:06PM W51.00001 Spin Hall effect and spin-transfer torque generated by a topological insulator, DANIEL RALPH, Cornell Univ — No abstract available.

3:06PM W51.00002 Electrical detection of current-induced spin polarization due to spin-momentum locking in the topological insulator Bi$_2$Se$_3$, BEREND JONKER, Naval Research Laboratory — Topological insulators (TIs) exhibit topologically protected metallic surface states populated by massless Dirac fermions with spin-momentum locking — the carrier spins lie in-plane, locked at right angle to the carrier momentum. An unpolarized charge current should thus create a net spin polarization whose amplitude and orientation are controlled by the charge current. Here we show direct electrical detection of this bias current induced spin polarization as a voltage measured on a ferromagnetic (FM) metal tunnel barrier surface contact [1]. The magnetization of the contact determines the spin detection axis, and the voltage measured at this contact is proportional to the projection of the TI spin polarization onto this axis. When the charge current is orthogonal to the magnetization of the FM detector contact, the TI spin is parallel (or antiparallel) to the magnetization, and a spin-related signal is detected at the FM contact proportional to the magnitude of the charge current. The voltage measured scales inversely with Bi$_2$Se$_3$ film thickness, and its sign is that expected from spin-momentum locking and opposite that of a Rashba effect [2]. Similar data are obtained for two different FM contact structures, Fe/Al$_2$O$_3$ and Co/MgO/graphene, underscoring the fact that these behaviors are due to bias current induced spin polarization in the TI surface states rather than the bulk, and are independent of the details of the contact. These results demonstrate simple and direct electrical access to the TI Dirac surface state spin system, provide clear evidence for the spin-momentum locking and bias current-induced spin polarization, and enable utilization of these remarkable properties for future technological applications.

3:42PM W51.00003 Spin pumping and spin-transfer torques in antiferromagnet, QIAN NIU, The University of Texas at Austin — Spin pumping and spin-transfer torques are key elements of coupled dynamics of magnetization and conduction electron spin, which have been widely studied in various ferromagnetic materials. Recent progress in spintronics suggests that a spin current can significantly affect the behavior of an antiferromagnetic material [1], and the electron motion become adiabatic when the staggered field varies sufficiently slowly [2]. However, pumping from antiferromagnets and its relation to current-induced torques is yet unclear. In a recent study [3], we have solved this puzzle analytically by calculating how electrons scatter off a normal metal-antiferromagnetic interface. The pumped spin and staggered spin currents are derived in terms of the staggered field, the magnetization, and their rates of change. We find that for both compensated and uncompensated interfaces, spin pumping is of a similar magnitude as in ferromagnets; the direction of spin pumping is controlled by the polarization of the driving microwave. Via the Onsager reciprocity relations, the current-induced torques are also derived, the salient feature of which is illustrated by a terahertz nano-oscillator.

In collaboration with Ran Cheng, Jiang Xiao, and A. Brataas.

4:18PM W51.00004 Pure Spin Current in a broad range of materials generated by YIG-based spin pumping, FENGYUAN YANG, The Ohio State University — Spintronics relies on the generation, manipulation, and detection of spin current mediated by itinerant charges or magnetic excitations. FMR spin pumping is a powerful technique in understanding pure spin current. Building on our high-quality Y$_3$Fe$_5$O$_{12}$ (YIG) films and the large inverse spin Hall effect (ISHE) signals enabled by these films [1-10], we have characterized spin currents in several classes of materials with different magnetic structures, including: nonmagnetic and ferromagnetic metals, nonmagnetic insulators, and antiferromagnetic (AF) insulators. The spin Hall angles determined for a series of 3d, 4d, and 5d metals show that both atomic number and d-electron count play important roles in spin Hall physics [1, 6]. Strikingly, we achieved robust spin transport from YIG to Pt across AF insulators, which initially enhances the ISHE signals and can transmit spin currents up to 100 nm thickness, demonstrating highly efficient spin transport through an AF insulator carried by magnetic excitations [3].

4:54PM W51.00005 The essential role of spin-memory loss at 3d/5d metallic interfaces in spin pumping, HENRI JAFFRES, Unite Mixte de Physique CNRS-Thales — I will present a review of experiments and theory of spin-pumping in Co/(Cu)/Pt 3d/5d metallic systems in the ferromagnetic resonance (FMR) regime of spin injection [1]. By combining i) FMR analyses of the resonance linewidth of the Co spectra in contact with the Pt (or Cu/Pt) reservoir and ii) detection of the inverse spin-hall effect signal vs. Pt thickness, we were able to evidence two different length scales for the spin-current profile generated or absorbed at the interfaces [2]. The first length scale, extracted from FMR analyses and of the order of 2 nm, represents a typical interface length characteristic of a spin memory loss at the Co/Pt and Co/Cu/Pt interfaces. This represents a typical region of spin-current dissipation by which almost 60-70% of the total current generated is lost before conversion in bulk Pt. The second length scale, roughly equal to 3.4 nm, like determined by Inverse Spin Hall Effect (ISHE) transverse voltage measurement, is more characteristic of the spin-diffusion length of the bulk Pt that governs a part of the spin-to-chargetransfer efficiency by ISHE. After careful analyses, we determined a spin-hall angle of 5.6% for Pt and an intrinsic spin hall conductivity of 3200 (Ohm cm)$^{-1}$ for our corresponding Pt resistivity [2]. In the end, I will focus on the physical description of our experiments within a derived Valet-Fert model describing the spin transport/relaxation in a diffusive approach and using relevant boundary conditions for spin-pumping (constant spin accumulation in the ferromagnet). The origin of the spin-memory loss and spin-current discontinuity, also proposed in a very recent work [3], will be explained in terms of atomic intermixing at interfaces or possible Rashba-split states at Co/Pt interfaces.

2:30PM W52.00001 Preparation and measurement of strongly interacting states of photons. MOHAMMAD HAFEZI, Joint Quantum Institute — Photons has been considered as a promising medium to implement quantum simulators. However, most phenomena that are interesting from quantum simulation perspective involve thermalization and a controllable chemical potential, as a key parameter in phase diagrams, which are both absent for photons. More specifically, on the one hand, photonic systems are dissipative which means that the chemical potential is zero, and on the other hand, due to the weakness of inelastic scatterings, photons do not naturally thermalize. I will discuss various externally driven schemes to prepare many-body states of photons in the presence of dissipation. In fact, such driven-dissipative nature of these systems is the crucial reason of their interest. Specifically, I investigate driven fractional quantum Hall and Bose-Hubbard models. Furthermore, I describe how to characterize and measure various many-body features of correlated states of photons.

3:06PM W52.00002 Confining the state of light to a quantum manifold by engineered two-photon loss. ZAKI LEHTHAS, Yale University — Physical systems usually exhibit quantum behavior, such as superpositions and entanglement, only when they are sufficiently decoupled from a lossy environment. Paradoxically, a specially engineered interaction with the environment can become a resource for the generation and protection of quantum states. This notion can be generalized to the confinement of a system into a manifold of quantum states, consisting of all coherent superpositions of multiple stable steady states. We have experimentally confined the state of a harmonic oscillator to the quantum manifold spanned by two coherent states of opposite phases. In particular, we have observed a Schrödinger cat state spontaneously squeeze out of vacuum, before decaying into a classical mixture. This was accomplished by designing a superconducting microwave resonator whose coupling to a cold bath is dominated by photon pair exchange. This experiment opens new avenues in the fields of nonlinear quantum optics and quantum information, where systems with multi-dimensional steady state manifolds can be used as error corrected logical qubits.

3:42PM W52.00003 Blueprint for an analog quantum code fabric. ELIOT KAPIT, The Graduate Center, City University of New York — A physical realization of self correcting quantum code would be profoundly useful for constructing a quantum computer. In this theoretical talk, we provide a partial solution to major challenges preventing self correcting quantum code from being engineered in realistic devices. We consider a variant of Kitaev’s toric code coupled to propagating bosons, which induce a long-ranged interaction between anyonic defects. By coupling the primary quantum system to an engineered dissipation source through resonant energy transfer, we demonstrate a “rate barrier” which leads to a potentially enormous increase in the system’s quantum state lifetime through purely passive quantum error correction, even when coupled to an infinite temperature bath. While our mechanism is not scalable to infinitely large systems, the maximum effective size can be very large, and it is fully compatible with active error correction schemes. Our model uses only on-site and nearest-neighbor interactions, and could be implemented in superconducting qubits.

4:18PM W52.00004 Topology by Dissipation in Atomic Fermion Systems. SEBASTIAN DIEHL, TU Dresden — Controlled dissipation can be used as a resource to drive a many-body system into quantum mechanically ordered states from an arbitrary initial one. We discuss this concept in the context of atomic fermions, highlighting a dissipatively induced pairing mechanism, which is operative in the absence of attractive forces. We show how this targeted cooling can be utilized to cool atomic fermions into topologically non-trivial states in one dimension by quasi-local dissipative operations, and point out a possible physical implementation. This realizes a dissipative analog of the ground state of Kitaev’s quantum wire. In higher dimensions, the analogy to Hamiltonian ground states breaks down due to a fundamental incompatibility of topology and locality. We present a new quasi-local dissipative mechanism for the preparation of Chern insulators, which bypasses these obstacles by making use of the intrinsic open system character of the preparation process, with no Hamiltonian counterpart. This greatly extends the scope of efficiently attainable topological symmetry classes via tailored dissipation.

4:54PM W52.00005 Real-time observation of fluctuations in a driven-dissipative quantum many-body system undergoing a phase transition. TOBIAS DONNER, Institute for Quantum Electronics, ETH Zürich — A Bose-Einstein condensate whose motional degrees of freedom are coupled to a high-finesse optical cavity via a transverse pump beam constitutes a dissipative quantum many-body system with long range interactions. These interactions can induce a structural phase transition from a flat to a density-modulated state. The transverse pump field simultaneously represents a probe of the atomic density via cavity-enhanced Bragg scattering. By spectrally analyzing the light field leaking out of the cavity, we measure non-destructively the dynamic structure factor of the fluctuating atomic density while the system undergoes the phase transition. An observed asymmetry in the dynamic structure factor is attributed to the coupling to dissipative baths. Critical exponents for both sides of the phase transition can be extracted from the data. We further discuss our progress in adding strong short-range interactions to this system, in order to explore Bose-Hubbard physics with cavity-mediated long-range interactions and self-organization in lower dimensions.

Thursday, March 5, 2015 2:30PM - 5:30PM –
Session W53 DCMP: Invited Session: Discoveries in SrTiO3 Grand Ballroom C3 - Chris Leighton, University of Minnesota

2:30PM W53.00001 Multiband superconductivity in n-doped SrTiO3. KAMRAN BEHNIA, ESPCI — The superconducting state of n-doped SrTiO3 occupies a singular place in the history of superconductivity. Besides being the first oxide superconductor, it was one of the earliest “semiconducting superconductors,” the first experimentally-detected multi-gap superconductor and the first case of a superconducting dome. Half a century after its discovery, it remains the most dilute superconductor [1]. We present a systematic study of quantum oscillations and superconducting transition in doped SrTiO3, over a wide range of carrier concentration from 10¹⁷ to 10²⁸ cm⁻³ [2]. Mobile carriers were introduced either by removing oxygen or by substituting Ti by Nb. Superconductivity was found to persist down to an exceptionally low concentration of mobile electrons (n=3.10¹⁷ cm⁻³ and Tc ≈ 3.4 mK). At this concentration range, with the Fermi temperature below 10 K, the narrowness of the relevant energy window severely restricts possible pairing scenarios. We identify two critical doping levels, which are the filling thresholds of the upper conduction bands. This clarifies the limits of single-band, two-band and three-band superconducting regimes. We find that the exceptionally-wide superconducting dome of SrTiO₃ has a structure with two distinct domes, each peaking near a critical doping level. Thermal conductivity measurements uncover the existence of multiple nodeless superconducting gaps at optimal doping [3].

3:06PM W53.00002 Doping and Hall effect in SrTiO$_3$. SUSANNE STEMMER, University of California, Santa Barbara — Electron-doped SrTiO$_3$ has generated renewed interest because of reports of coexisting magnetism and superconductivity, and of superconducting transitions at extremely low carrier densities. In this talk, we will present new insights into doping and its electronic structure obtained using very high quality SrTiO$_3$ films grown by molecular beam epitaxy. We discuss the arrangements and imaging of individual La dopant atoms and clusters using quantitative scanning transmission electron microscopy. We present studies of the temperature dependence of the Hall coefficient, Hall mobility, and of Shubnikov-de Haas oscillations. We will particularly discuss the significance of the regime in which the resistance follows a $T^2$ temperature-dependence over a wide range of temperatures and doping. This work was performed in collaboration with Evgeny Mikheev, Adam Kajdos, Jinwoo Hwang, Jack Zhang, and Jim Allen.

3:42PM W53.00003 Optically-Induced Persistent Magnetization in Oxygen Deficient Strontium Titanate, SCOTT CROOKER, National High Magnetic Field Laboratory — Interest in electrons and spintronics based on complex oxide materials has exploded in recent years, fueled by the ability to grow atomically-precise heterostructures of various oxides [1]. A foundational material in this burgeoning field is strontium titanate, a (nominally) non-magnetic wide-bandgap semiconductor. Owing to its ubiquity in oxide materials science, studies of SrTiO$_3$’s interesting dielectric, lattice, and optical properties represent mature research areas. However, renewed interest in SrTiO$_3$ was recently sparked by observations of unexpected spin and magnetization phenomena at interfaces between SrTiO$_3$ and other nonmagnetic oxides [1]. The formation and distribution of oxygen vacancies ($V_O$) in SrTiO$_3$ are widely thought to play an essential but as-yet-ineffectively understood role in these emergent phenomena. Here we demonstrate a surprising new aspect to the phenomenology of magnetism in SrTiO$_3$ by reporting the observation of an optically-induced and persistent magnetization in slightly oxygen-deficient SrTiO$_{3-\delta}$ bulk crystals, using magnetic circular dichroism spectroscopy and optically-coupled SQUID studies [2]. This magnetism appears below 18K, persists for hours below 10K, and is tunable via the polarization and wavelength of sub-bandgap (400-500 nm) light. As such, magnetic patterns can be “written” into SrTiO$_{3-\delta}$, and subsequently read out, using light alone. This magnetism occurs only in crystals containing $V_O$, and is consistent with a metastable spin polarization of $V_O$-related defect complexes. These data reveal a detailed interplay between magnetism, lattice defects, and light in an archetypal complex oxide material, which may yield new insights into the recent exciting spin physics observed at oxide interfaces.

4:18PM W53.00004 ABSTRACT WITHDRAWN —

4:54PM W53.00005 Spectroscopic findings in SrTiO$_3$ applications: LaAlO$_3$/SrTiO$_3$ and La$_{0.5}$Sr$_{0.3}$MnO$_3$/SrTiO$_3$ heterostructures, JUN-SIK LEE, SSRL, SLAC National Accelerator Laboratory — Recently, a number of transport and magnetization studies have shown signs of exotic functionalities in SrTiO$_3$ based heterostructures, which are totally unexpected properties with no bulk analog in the constituent materials. However, it is still early stage to understand such a functionality, which limits improving SrTiO$_3$ transport and magnetization studies have shown signs of exotic functionalities in SrTiO$_3$ applications: LaAlO$_3$/SrTiO$_3$ and La$_{0.5}$Sr$_{0.3}$MnO$_3$/SrTiO$_3$ heterostructures. These findings establish a striking example of emergent phenomena at oxide interfaces. In this presentation, I will introduce more details of spectroscopic findings on those heterostructures.

Thursday, March 5, 2015 5:30PM - 7:00PM —
Session X1 APS: Science Film: An Aperture into Science Advocacy — Grand Hyatt San Antonio Presidio

5:30PM X1.00001 Science Film: An Aperture into Science Advocacy — The current funding environment for scientific research necessitates a change in how we foster support for the endeavor. Federal spending is not likely to grow unless constituents—APS members—help communicate the value of science to members of Congress and the public in a compelling and individual way. The event explores how popular film with science-based plots can help physicists communicate the value of science to members of Congress and an increasingly diverse electorate.

Friday, March 6, 2015 8:00AM - 11:00AM —
Session Y1 DMP: Focus Session: Graphene - Multilayer and Interfacial Effects — University of Northern Iowa

8:00AM Y1.00001 The decoupling of epitaxial graphene on SiC by hydrogen intercalation: an ab initio study. LYDIA NEMEC, Fritz-Haber-Institut der MPG, Berlin, DE; PATRICK RINKE, Fritz-Haber-Institut der MPG, Berlin, DE; Aalto University, Helsinki, FI; VOLKER BLUM, Duke University, Durham, NC, USA; MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, DE — Large-scale ordered epitaxial graphene can be grown on various substrates, out of which silicon carbide (SiC) is one of the most promising. The exact material properties of graphene depend on the growth conditions and its interaction with the substrate. By hydrogen intercalation of epitaxial graphene on the Si-face of SiC the graphene layer decouples from the substrate forming quasi-free-standing monolayer graphene (QFMLG) [1]. We performed an density functional theory study of QFMLG on the polar 6H-SiC(0001) surface based on a van der Waals corrected semi-local exchange-correlation functional using the all-electron numeric atom-centered basis function code FHI-aims. We find an adsorption height in excellent agreement with X-ray standing wave experiments, a very low buckling of the graphene layer, and a very homogeneous electron density at the interface. All these features improve the electronic properties of QFMLG compared to epitaxial graphene. Using the insight gleaned on the Si-face, we present the structure of a hypothetical QFMLG phase on the C-face of SiC. We find that hydrogen intercalation is a promising option to control the SiC-graphene interface. [1] C. Riedl, et. al, PRL 103, 246804 (2009).
8:12AM Y1.00002 Lithium Intercalation of Few-Layer Graphenes in the 2-Layer Limit , SHU YANG FRANK ZHAO, Dept. of Physics, Harvard University, GISELLE A. ELBAZ, Dept. of Chemistry, Columbia University, DIMITRI K. EFETOV, Dept. of Physics, MIT, JAYAKANTH RAVICHANDRAN, Dept. of Physics, Harvard University, YINSHENG GUO, LOUIS BRUS, XAVIER ROY, Dept. of Chemistry, Columbia University, PHILIP KIM, Dept. of Physics, Harvard University — Few layer graphene (FLG) intercalate compounds form a new generation of graphene derivative systems where carrier densities are expected to reach $6E14$ cm$^{-2}$ per graphene layer, and novel physical phenomena such as superconductivity and magnetism may emerge. Experimental realization of intercalated FLGs have been limited by harsh intercalation processes which are often incompatible with mesoscopic device fabrication techniques. We developed techniques to electrochemically intercalate FLGs down to 2-layers with lithium in-situ in a controlled manner, minimizing sample degradation from parasitic reactions in the electrolyte by passivating sample surfaces using a combination of hBN (over graphene) and photoresist (over metal contacts). By performing simultaneous Raman spectroscopy as the FLGs intercalate, we found that as FLGs reached the 2-layer limit, the Raman signatures of intercalation began to deviate from that of bulk graphite.

8:24AM Y1.00003 Electronic Structure of Single-Crystal Monolayer Graphene on Hydrogen-Terminated Germanium Surface, SUNG JOON AHN, JAE-HYUN LEE, JOUNG REAL AHN, DONGMOK WHANG, Sungkyunkwan Univ — Graphene, atomically flat 2-Dimensional layered nano material, has a lot of interesting characteristics from its unusual electronic structure. Almost properties of graphene are influenced by its crystallinity, therefore the uniform growth of single crystal graphene and layer control over the wafer scale areas remains a challenge in the fields of electronic, photonic and other devices based on graphene. Here, we report the method to make wafer scale single crystal monolayer graphene on hydrogen terminated germanium(110) surface and properties and electronic band structure of the graphene by using the tool of scanning electron microscopy, transmission electron microscopy, Raman spectroscopy, electron transport measurement, electron diffraction and angle-resolved photoemission spectroscopy.

8:36AM Y1.00004 Formation and electronic properties of coherent in-plane 2D heterostructures1, AN-PING LI, Oak Ridge National Lab — Two-dimensional (2D) interfaces between crystalline materials have been shown to generate unusual interfacial electronic states in complex oxides. Recently, a one-dimensional (1D) interface has been suggested in hexagonal boron nitride (hBN) and graphene planar heterostructures, where a polar-on-nonpolar 1D boundary is expected to possess peculiar electronic states associated with edge states of graphene and the polarity of hBN. Here, we report on the formation and electronic properties of such a 1D interface. By implementing the concept of epitaxy to 2D space, we grow monolayer hBN from fresh edges of monolayer graphene with lattice coherence, forming a 1D boundary [L. Liu et al., Science 343, 163 (2014)]. Scanning tunneling microscopy and spectroscopy measurements reveal an abrupt 1D zigzag oriented boundary, with boundary states about 0.6 eV below or above the Fermi level depending on the termination of the hBN at the boundary [J. Park et al., Nature Commun. 5, 5403 (2014)]. The boundary states are extended along the boundary, and exponentially decay into the bulk of graphene and hBN. The origin of boundary states and the effect of the polarity discontinuity at the interface will be discussed.

1This research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

9:12AM Y1.00005 Defect-Stabilized Graphene-Based Organometallic Sandwich Structures, PRATIBHA DEV, THOMAS REINECKE, Naval Research Laboratory, Washington, D.C. — Benzene-transition metal-graphene (Bz—M—Gr) sandwich structures are of interest for a range of applications such as catalysis, spintronics and quantum computing. Although they are predicted to form in several theoretical works, it has proven harder to create these complexes experimentally. Using density functional theory, we propose a chemical route to creating stable Bz—M—Gr sandwich structures. Acceptor-type defects, such as carbon vacancies and pyridinic nitrogen substituents in graphene are used to immobilize the metal onto graphene. It has proven harder to create these complexes experimentally. Using density functional theory, we propose a chemical route to creating stable Bz—M—Gr sandwich structures. Acceptor-type defects, such as carbon vacancies and pyridinic nitrogen substituents in graphene are used to immobilize the metal onto graphene. Placement of a benzene ring atop the metal atom further stabilizes the structure against oxidation. Structural, electronic and magnetic properties of the Bz—M—Gr complexes vary for different defects. High cohesive energies and spin polarization energies make defect-stabilized Bz—M—Gr complexes of interest for use as nanomagnets in ambient conditions.

9:24AM Y1.00006 Single-Valley Engineering in Graphene Superlattices, YAFEI REN, XINZHOU DENG, Univ of Sci & Tech of China, CHANGSHENG LI, Hunan Univ of Art & Sci, JIEJ JUNG, Nat Univ of Singapore, CHANGGAN ZENG, ZHENYU ZHANG, Univ of Sci & Tech of China, QIAN NIU, Univ of Texas at Austin; Peking Univ, ZHENHUA QIAO, Univ of Sci & Tech of China — The two inequivalent valleys in graphene preclude the protection against inter-valley scattering offered by an odd-number of Dirac cones characteristic of topological insulator phases. Here we propose a way to engineer a chiral single-valley phase in a honeycomb lattice via folding K and K′ periodic patterning of the carbon isotope. We consider the difference of pure 12C graphene and 13C graphene. Although they are predicted to form in several theoretical works, it has proven harder to create these complexes experimentally. Using density functional theory, we propose a chemical route to creating stable Bz—M—Gr sandwich structures. Acceptor-type defects, such as carbon vacancies and pyridinic nitrogen substituents in graphene are used to immobilize the metal onto graphene. Placement of a benzene ring atop the metal atom further stabilizes the structure against oxidation. Structural, electronic and magnetic properties of the Bz—M—Gr complexes vary for different defects. High cohesive energies and spin polarization energies make defect-stabilized Bz—M—Gr complexes of interest for use as nanomagnets in ambient conditions.

9:36AM Y1.00007 Polycrystalline Graphene with Single Crystal Electronic Structure, EDWARD B. LOCHOCKI, LOLA BROWN, Cornell University, JOSÉ AVILA, SOLEIL Synchrotron, CHEOL-JOO KIM, YUI OGAWA, ROBIN W. HAVENER, DONG-KI KIM, ERIC J. MONKMAN, DANIEL E. SHAI, HAOFEI I. WEI, MARK P. LEVENDORF, Cornell University, MARIA ASENSIO, SOLEIL Synchrotron, JIWOONG PARK, KYLE SHEN, Cornell University — Stacking two-dimensional materials is a promising method for creating and controlling vertical heterostructures with atomic precision. The relative rotation angles between layers can sensitively tune these structures’ electronic and optical properties, so constituent layers with well-defined lattice orientations are critical for any practical application. Here we report the growth of large scale graphene and hexagonal boron nitride on commercial copper foils, where the resulting films display multiple nucleations yet exhibit a uniform orientation. We characterize the copper and graphene lattices on sizes ranging from nanometers to several centimeters using a multitude of probes including dark field transmission electron microscopy and angle-resolved photoemission spectroscopy. These measurements reveal that each individual graphene grain exhibits an identical electronic structure and orientation consistent with single crystalline graphene. Finally, we create stacked bilayer graphene with a homogeneous interlayer rotation angle, demonstrating a versatile approach for scalable fabrication of layered superlattices with accurate structures.

9:48AM Y1.00008 Isotope dependence of the electronic structure in graphene, TAKASHI KORETSUNE, RIKEN CEMS, SUSUMU SAITO, Tokyo Institute of Technology — It has been known that the effect of electron-phonon couplings on the electronic structure of diamond is not negligible and recently, it has been confirmed that the experiments are well reproduced using first-principles calculations. In case of graphene, the renormalization of the Fermi velocity due to the electron-phonon couplings has been predicted. Thus, we theoretically study the possibility of band structure engineering in graphene using the electron-phonon couplings and the isotope effect. First, we consider the difference of pure 12C graphene and 13C graphene. On the basis of density functional theory, it is found that the depth of so-called Dirac point, that is, work function of graphene, shows isotope dependence, indicating that it is possible to shift the depth of the Dirac point locally without using a gate voltage. We also discuss the possibility of band-gap opening by a periodic patterning of the carbon isotope.

1Supported by the MEXT 25104711 and 25107005.
10:24AM Y1.00011 Dirac Cone Metric and the Origin of the Spin Connections in Monolayer Graphene , BO YANG, Institute of High Performance Computing — There have been extensive efforts in modeling the strain and ripples of the monolayer graphen sheet in the form of the effective gauge fields, both from a microscopic point of view and from the quantum field theoretical (QFT) approach used in treating Dirac spinors moving in a curved space (M.A.H. Vozmediano et.al, Phys. Rep. 496, 109, F. Guinea et.al, Nat. Whys. 6, 30). With the QFT approach, it is argued that the metric from either the two-dimensional manifold of graphene sheet or from the in-plane strain field introduces a spin connection that couples to the sublattice pseudospin. Yet the microscopic origins of such an analogy, and the nature of the “spin connection” that couples to the sublattice pseudospin, was not clear. We solve this issue by showing that the modulation of the hopping amplitudes in the honeycomb lattice of the monolayer graphene uniquely defines a metric which corresponds to the geometry of the Dirac cone. This effective metric is different from the real space metric of the crystal lattice, and is entirely the property of the fermi surface. We show how the exact spin connection of this momentum space effective metric field can be calculated from the microscopic tight-binding Hamiltonian, and discuss its experimental implications.

10:36AM Y1.00012 ABSTRACT WITHDRAWN —

10:48AM Y1.00013 Electronic Properties of Graphene in Strong Static Electric Field1, VADYM APALKOV, HAMED KOOCHAKI KELARDEH, MARK STOCKMAN, Georgia State Univ — We study the dynamics of electrons in an ultra-strong static electric field (a few V/Å) and obtain an analytical solution for the Wannier-Stark (WS) states and corresponding energy spectrum of graphene within the two-band tight binding model. Electron states in graphene have a WS ladder structure with energy levels separated by the Bloch frequency, which is proportional to both the electric field and the lattice period of graphene in the direction of electric field. The strength of the band mixing is determined by the magnitude of the interband dipole matrix element, which for graphene has distinct wave vector dependence seen neither in metals nor in insulators. Namely, at the Dirac points, the dipole matrix elements have sharp peaks due to strong interband coupling leading to redistribution of carrier density and very strong mixture of conduction and valence bands whereas, away from the Dirac point, it shows a broad maximum. As a result of such mixing, the energy spectrum of graphene shows anticrossing points, which are characterized by the corresponding anticrossing gaps. It is shown that the anticrossing gaps are proportional to electric field at the corresponding anticrossing points with the calculated values 2.54/I (eV), where I=1,2,... is the order of the anticrossing point. The largest anticrossing gap ≈ 2.54 eV corresponds to the anticrossing point I = 1 at the electric field ≈ 3.59 V/Å. The achieved results will promisingly draw further attentions toward graphene-based Field Effect Transistors (g-FET).

This technique show that small polarons can indeed be formed in thin layers. Comparisons with polarons in the bulk and with experiments will be discussed.

To prevent this, we modified the charge of the pseudopotentials, thus providing charge compensation that is confined within the layer. Our results obtained with neutralizing charge needs to be included in supercell calculations. The use of a jellium background leads to divergence problems in low-dimensional systems. To study and applying the MX2, the growth of high-quality MX2 thin film with precise control of layers thickness is favorable. Here we report the molecular beam epitaxial growth of WSe2 thin film, with controllable thickness from monolayer to 8 monolayer. By using in-situ angle-resolved photoemission spectroscopy, we experimented revealing the valence band evolution with film thickness. By applying the potassium doping on the surface, we observed the indirect to direct band gap transition in monolayer WSe2, and the distorted band structure. Combining the ex-situ photoluminescence and scanning tunneling spectroscopy, we further presented the giant band gap renormalization and excitonic effects. Our results will enrich the understanding of WSe2, and bring it more application potential in practical devices.

Electronic properties, Band Gap Renormalization, and Doping Effect in Epitaxial WSe2 thin film, YI ZHANG, Stanford University, MIGUEL UGEDA, SU-FEI SHI, UC Berkeley, BO ZHOU, YEONGKWAN KIM, LBNL, YULIN CHEN, University of Oxford, FENG WANG, MICHAEL CROMMIE, UC Berkeley, ZAHID HUSSAIN, LBNL, ZHI-XUN SHEN, Stanford University, SONG-KWAN MO, LBNL — As a class of graphene-like two-dimensional materials, the layered metal dichalcogenides MX2 (M = Mo, W; X = S, Se, Te) have gained significant interest due to the distinct properties in 2D limit. Examples include the indirect to direct band gap transition in monolayer, and giant spin-splitting of the valence band. These properties give MX2 great application potentials in both optoelectronic and spintronics devices. For practically studying and applying the MX2, the growth of high-quality MX2 thin film with precise control of layers thickness is favorable. Here we report the molecular beam epitaxial growth of WSe2 thin film, with controllable thickness from monolayer to 8 monolayer. By using in-situ angle-resolved photoemission spectroscopy, we experimented revealing the valence band evolution with film thickness. By applying the potassium doping on the surface, we observed the indirect to direct band gap transition in monolayer WSe2, and the distorted band structure. Combining the ex-situ photoluminescence and scanning tunneling spectroscopy, we further presented the giant band gap renormalization and excitonic effects. Our results will enrich the understanding of WSe2, and bring it more application potential in practical devices.

Charge Carrier Transport Properties in Layered Structure of Hexagonal Boron Nitride (h-BN) and Thermal Neutron Detection Based on h-BN, TRI DOAN, SAMUEL GRENAUDIER, SASHIKHANTH MAJETY, JING LI, JINGYU LIN, HONGXING JIANG, Texas Tech Univ, NANOPHOTONICS CENTER - TEXAS TECH UNIVERSITY TEAM — Hexagonal boron nitride (h-BN) epilayers have been synthesized by MOCVD. It was found that the carrier mobility in h-BN epilayers is strongly dependent on the stability of such polarons in bulk GaO3 thin film. The measured carrier mobility-lifetime (µτ) product of h-BN thin films grown on sapphire substrate is 2.83 x 10^7 cm^2/Vs for electrons and holes, which is comparable to that of GaN films grown on sapphire. Thermal neutron detectors based on h-BN epilayers were fabricated and the reaction product pulse-height spectra were measured under thermal neutron irradiation produced by 252Cf source. It was shown that h-BN thin film thermal neutron detectors are capable to resolve specific nuclear reaction products with unprecedentedly high energy resolution.

Polarons in thin GaO3 layers, HARTWIN PEELAERS, University of California, Santa Barbara, JOEL B. VARLEY, Lawrence Livermore National Laboratory, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — GaO3 has a large band gap of 4.9 eV, making it transparent in the UV. It can also be doped n-type, enabling applications as a transparent conductor or in power electronics. The optical properties of GaO3 may be affected by the formation of small polarons, i.e., localized holes trapped by a lattice distortion. First-principles calculations have established the stability of such polarons in bulk GaO3 [J. B. Varley et al., Phys. Rev. B 85, 081109(R) (2012)]. Here we investigate hole polarons in nanomembranes of GaO3. We perform first-principles calculations based on density functional theory using a hybrid functional. Since polarons correspond to positive charges, a neutralizing charge needs to be included in supercell calculations. The use of a jelly background leads to divergence problems in low-dimensional systems. To prevent this, we modified the charge of the pseudopotentials, thus providing charge compensation that is confined within the layer. Our results obtained with this technique show that small polarons can indeed be formed in thin layers. Comparisons with polarons in the bulk and with experiments will be discussed.

Monolayer MoSe2/WSe2 heterojunctions at the atomic level, ANA M. SANCHEZ, Department of Physics, University of Warwick — While graphene is the most studied two-dimensional (2D) material, atomically thin layered transition metal dichalcogenides (TMDs) have recently emerged as a new class of 2D nanomaterials. Due to their band structure, monolayers of direct band gap semiconductor TMDs have promise to complement the zero bandgap energy of graphene, offering extensive range of applications in electronics and optics. The dichalcogenide heterojunctions were grown by physical vapor transport. Lateral heteroepitaxy was visible in an optical microscope and the structures showed enhanced photoluminescence. Atomically resolved transmission electron microscopy using a double-corrected ARM200F (80-200kV) revealed that the MoSe2/WSe2 heterojunction is an undistorted honeycomb lattice in which substitution of one transition metal by another occurs across the interface [1]. There were no dislocations or grain boundaries, i.e. an atomically seamless MoSe2/WSe2 semiconductor junction was achieved. Moreover, strain mapping of atomic resolution images demonstrates negligible distortion at the heterojunction, and the analysis of the different atomic species demonstrates that the interface has a finite width similar to 3D heterojunctions. Vertical stacking of MoSe2/WSe2 bilayers was also analyzed using electron microscopy. An analysis of the intensity in annular dark field images shows that Se atoms of the WSe2 layer align with the Mo atoms of the MoSe2 layer in some of these heterojunctions. We expect that the growth of these lateral junctions will open new device functionalities, such as in-plane transistors and diodes integrated within a single atomically thin layer [1,2,3].

9:48AM Y2.00008 Energy band structure of bulk and monolayer vanadium pentoxide (V$_2$O$_5$) beyond the quasiparticle self-consistent GW approximation: lattice polarization effects$^1$. CHURNA BHANDARI, WALTER R.L. LAMCRECHT, Department of Physics, Case Western Reserve University, MARK VAN SCHILFGAARDE, King’s College, London — The quasiparticle self-consistent GW method (QSGW) is known to systematically overestimate the band gaps in semiconductors by about 20\% due to the underestimate of screening by the random phase approximation (RPA). We show that for V$_2$O$_5$, a layered oxide material, the overestimate is significantly larger. The smallest direct gap in QSGW is found to be 4.83 eV compared to 2.35 eV experimentally. The evidence for the experimental gap and optical properties are reviewed. We suggest that a major contribution to the self-energy reduction results from the lattice polarization contribution to the dielectric screening. This results from the large LO/TO splittings in this material. We make a simple estimate of the reduction of $\Gamma$ ($\gamma=0, \omega=0$), and obtain a factor $\sim 0.38$, which if assumed to apply for all $\Gamma$ and reduces the gap to 2.60 eV. The remainder of the gap overestimate is tentatively ascribed to shortcomings of the RPA. We also consider the band structure of this material in monolayer form. We find that the GW correction depends strongly on the layer separation (L) as 1/L. The lattice polarization itself depends on distance between the layers because of the dependence of the phonons on the long-range Coulomb interactions and hence reduced screening in a 2D system.

10:00AM Y2.00009 Observation of Piezoelectricity in Free-standing Monolayer Molybdenum Disulfide, HANYU ZHU, YUAN WANG, JUN XIAO, MING LIU, SHAOMIN XIONG, ZI JING WONG, ZILIANG YE, YU YE, XIAOBO YIN, XIANG ZHANG, Univ of California - Berkeley — Piezoelectricity offers precise and robust conversion between electricity and mechanical force, which originates from the broken inversion symmetry of atomic structure. Yet reducing the size of bulk piezoelectric materials to single molecular layer was challenging, since the surface energy can cause piezoelectric structures to be thermodynamically unstable. Here we report experimental evidence of piezoelectricity in free-standing single layer of molybdenum disulfide (MoS$_2$) crystal, with measured piezoelectric coefficient $e_{31} = 2.9 \times 10^{-10}$ C/m. The free-standing measurement of the intrinsic piezoelectricity is free from the substrate effects, such as doping and parasitic charge. We observed oscillation of piezoelectric response in MoS$_2$ in odd and even number of layers due to breaking and recovery of inversion symmetry, respectively, in sharp contrast to bulk piezoelectric materials. Through the angular dependence of electro-mechanical coupling, we uniquely determined the 2D crystal orientation. The piezoelectricity discovered in single molecular membrane promises new applications in low-power logic switch and ultrasensitive sensors scaled down to single atomic unit cell — the ultimate material limit.

10:12AM Y2.00010 Air Stability of Two-Dimensional Transition Metal Dichalcogenides, SAN-TOSH KC, ROBERTO LONGO, RAFIK ADDOU, Univ of Texas, Dallas, DIEGO BARRERA, Univ of Texas, Dallas, Centro de Investigación en Materiales Avanzados, México, JULIA W.P. HSU, ROBERT M. WALLACE, KYEONGJAE CHO, Univ of Texas, Dallas — Layered transition metal dichalcogenides (TMDs) have emerged as a potential alternative channel material for ultra-thin and low power nanoelectronics. Highly tunable and unique electronic properties of TMDs make them promising novel materials for various other applications as well. However, in order to realize the superior performance of TMD based devices, the physical and chemical properties need to be understood, in particular their stability under different chemical environments. A detailed comparative analysis of the air stability (i.e., oxygen interaction) of various TMDs is still lacking. We have examined various TMD stabilities in air and found them different from graphene which is stable in air. The changes in the electronic properties with air exposure were studied using density functional theory (DFT), Kelvin probe, and photoelectron emission in air. The results reveal that transition metal sulfides are kinetically more stable than selenides in air, but all TMDs are thermodynamically unstable against oxidation. Furthermore, it is shown that TMD surface defects function as facile oxidation sites impacting their air stabilities. These findings provide helpful guidance to controlled exfoliation and device fabrication processes.

10:24AM Y2.00011 Air Stable Doping of MoS2 FETs Using TiOx Sol-Gel, AMRITESH RAI, RUDRESH GHOSH, ANUPAM ROY, AMITRAJ VALSARAJ, HEMA CP MOYVA, SANGWOO KANG, EMANUEL TUTUC, LEONARD REGISTER, SANJAY BANER-JEE, Univ of Texas, Austin — Field effect transistors based on ultra-thin transition metal dichalcogenides suffer from high contact resistances due to the Schottky barrier formed between the metal and the semiconducting channel. An effective way to overcome this issue is to dope the semiconducting channel in order to reduce the Schottky barrier width, thereby enabling efficient electron injection via tunneling. Previously used charge transfer doping techniques employed the use of potassium ions and PEI. However, these doping reagents are unstable in air. Here we report the use of an air stable, self-encapsulating, spin on n-type doping technique on MoS2 utilizing TiOx sol-gel. The doping of the channel is confirmed by the broadening of the A1g Raman mode of MoS2. High performance field effect transistors are demonstrated which show three times improvement in the field effect mobility as well as a two-fold increase in the intrinsic mobility of the MoS2 channel. The enhancement of intrinsic mobility can be attributed to the suppression of the A1g phonon modes of MoS2 as well as screening of charged impurities by the TiOx layer. The devices show extended air stability over two to three weeks. The use of TiOx sol-gel can be a promising way to enhance the performance of TMD based transistors.

10:36AM Y2.00012 Scanning tunneling microscopy study of a new charge density wave phase in VSe$_2$ thin films, DUMING ZHANG, JEONGHOON HA, Center for Nanoscale Science and Technology, National Institute of Standards and Technology/Maryland Nano Center, University of Maryland, HONGWOO BAEK, Center for Nanoscale Science and Technology, NIST/Department of Physics and Astronomy, Seoul National University, FABIAN NATTERER, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, YOUNG KUK, Department of Physics and Astronomy, Seoul National University, NIKOLAI ZHITENEV, JOSEPH STROSCIO, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — Ultra-thin two-dimensional materials of transition metal dichalcogenides have recently attracted great interest due to their diverse electronic properties and potential applications. Upon cooling to low temperature, some materials exhibit interesting phenomena of collective electronic states such as superconductivity and charge density waves. While charge density waves in bulk materials of transition metal dichalcogenides have been extensively studied in the past few decades, the understanding of this collective electronic state in materials with reduced dimensionality is still in its infancy. Here, we report in-situ ultra-low temperature scanning tunneling microscopy and spectroscopy measurements on VSe$_2$ thin films synthesized by molecular beam epitaxy. We observed an unconventional charge density wave which does not follow previous reports of hexagonal symmetry of VSe$_2$. Spectroscopy results will be discussed in relation to other characterizations using electrical transport and transmission electron microscopy.
10:48AM Y2.00013 Two-dimensional materials based transparent flexible electronics1, LILI YU, SUNGJAE HA, DINA EL-DAKAM, ELAINE MCVAY, XI LING, ANANTHA CHANDRASKAN, JING KONG, TOMAS PALACIOS, MIT — Two-dimensional (2D) materials have generated great interest recently as a set of tools for electronics, as these materials can push electronics beyond traditional boundaries. These materials and their heterostructures offer excellent mechanical flexibility, optical transparency, and favorable transport properties for realizing electronic, sensing, and optical systems on arbitrary surfaces. These thin, lightweight, bendable, highly rugged and low-power devices may bring dramatic changes in information processing, communications and human-electronic interaction. In this report, for the first time, we demonstrate two complex transparent flexible systems based on molybdenum disulfide (MoS2) grown by chemical vapor method: a transparent active-matrix organic light-emitting diode (AMOLED) display and a MoS2 wireless link for sensor nodes. The 1/2 x 1/2 square inch, 4 x 5 pixels AMOLED structures are built on transparent substrates, containing MoS2 back plane circuit and OLEDs integrated on top of it. The back plane circuit turns on and off the individual pixel with two MoS2 transistors and a capacitor. The device is designed and fabricated based on SPICE simulation to achieve desired DC and transient performance. We have also demonstrated a MoS2 wireless self-powered sensor node. The system consists of an energy harvester, rectifier, sensor node and logic units. AC signals from the environment, such as near-field wireless power transfer, piezoelectric film and RF signal, are harvest, then rectified into DC signal by a MoS2 diode.

Friday, March 6, 2015 8:00AM - 11:00AM –
Session Y4 GERA DMP FIAP: Materials for Electrochemical Energy Storage II Mayor Cockrell Room 004 -

8:00AM Y4.00001 First-principles molecular dynamics simulations of electrochemical reactions using the ESM method, MINORU OTANI, National Institute of Advanced Industrial Science and Technology — It is important to elucidate a microscopic detail of an electrochemical reaction that takes place at the electrode and electrolyte interface to improve the performance of electrochemical energy storage/harvesting devices, such as secondary batteries, capacitors, fuel cells, and photovoltaic cells. Major difficulties for understanding the reaction are how to incorporate and control the bias potential applied to the interface. To solve these difficulties, we have been developing some intuitive methods to simulate the interfacial electrochemical reaction using first-principles molecular dynamics simulations [1-3]. In this talk I will present our methods and show the bias dependent free-energy profile of the desolvation process of a Li-ion battery and other recent results.

8:36AM Y4.00002 Ab-Initio Molecular Dynamics Study of the Concentration Dependent Diffusivity of Lithium Ions in Acetonitrile Electrolyte using the van der Waals Density Functional, KEITH RAY, Lawrence Livermore National Laboratory, ZHENXING WANG, ISAAK DANIELS, University of Kansas, DAVID OLMSTED, University of California, Berkeley, BRIAN LAIRD, University of Kansas, MARK ASTA, University of California. Berkeley — Pseudocapacitors are devices that store electrical energy faradically, but feature fast reactions/intercalations enabling high power applications. Power density may be improved by utilizing electrolytes with fast Li ion diffusion. In this study we utilize ab-initio molecular dynamics to elucidate the solvation structure as well as the vibrational and diffusion dynamics of Li ions in the acetonitrile electrolyte. Acetonitrile is a promising electrolyte for energy storage applications due to its lower viscosity and higher ionic conductivity when compared to other battery electrolytes such as ethylene carbonate and propylene carbonate. Interestingly, the trends in the Li ion concentration dependent diffusivity are calculated to be qualitatively different depending on whether the PBE or vdW-DF density functional is used.

This work was supported as part of the Molecularly Engineered Energy Materials (MEEM), an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Award DE-SC0001342.

8:48AM Y4.00003 A joint first principles and ATR-IR study of the vibrational properties of interfacial water at Si(100):H-H2O solid-liquid interfaces1, LEI YANG, STEFANIE TECKLENBURG, ANDREAS ERBE, STEFAN WIPPERMANN, Max-Plank-Institute for Iron Research, FRANCOIS GYGI, University of California, Davis, GIULIA GALLI, University of Chicago — Understanding the structural and bonding properties of solid-liquid interfaces is crucial for a wide range of (photo-)electrochemical applications, such as g. e. solar water splitting and electrolysis. In this report, for the first time, we demonstrate two complex transparent flexible systems based on molybdenum disulfide (MoS2) grown by chemical vapor method: a transparent active-matrix organic light-emitting diode (AMOLED) display and a MoS2 wireless link for sensor nodes. The 1/2 x 1/2 square inch, 4 x 5 pixels AMOLED structures are built on transparent substrates, containing MoS2 back plane circuit and OLEDs integrated on top of it. The back plane circuit turns on and off the individual pixel with two MoS2 transistors and a capacitor. The device is designed and fabricated based on SPICE simulation to achieve desired DC and transient performance. We have also demonstrated a MoS2 wireless self-powered sensor node. The system consists of an energy harvester, rectifier, sensor node and logic units. 9:00AM Y4.00004 High ionic conductivity NASICON based materials for Na-ion batteries: a density functional approach, K. M. BUI, NIMS, V. A. DINH, Osaka Univ., S. OKADA, Tsukuba Univ., T. OHNO, NIMS — Sodium ion batteries are now believed to be the best candidate for large-scale applications. Simultaneously, it is required to develop solid-state batteries using solid electrolytes for advancing the safety and reliability of batteries. The most promising solid-state battery is composed of the 3-D NASICON electrode Na2V2(PO4)3 (NVP) and electrolyte Na2Zr2Si2PO12 (NZSP). In this work, we aim to theoretically investigate the structures and the diffusion pathway of Na in these materials. Using density functional theory (DFT) method, we investigated the structures and diffusion mechanism of Na ions in the materials. They are insulators with large band. The polaron formation is found to occur only in NVP. Na ions can diffuse along three preferential diffusion pathways; these are, two intra-layer and one inter-layer pathway that takes place between Na layers via the empty Na site. In accordance with experiments reported before, the materials have high ionic conductivity with the activation barrier of about 760meV and 370meV for NVP and NZSP, respectively.

1The authors wish to thank T. A. Pham for helpful discussions. G. G. and F. G. acknowledge DOE-BES Grant No. DE-SC0008939.

9:00AM Y4.00004 High ionic conductivity NASICON based materials for Na-ion batteries: a density functional approach, K. M. BUI, NIMS, V. A. DINH, Osaka Univ., S. OKADA, Tsukuba Univ., T. OHNO, NIMS — Sodium ion batteries are now believed to be the best candidate for large-scale applications. Simultaneously, it is required to develop solid-state batteries using solid electrolytes for advancing the safety and reliability of batteries. The most promising solid-state battery is composed of the 3-D NASICON electrode Na2V2(PO4)3 (NVP) and electrolyte Na2Zr2Si2PO12 (NZSP). In this work, we aim to theoretically investigate the structures and the diffusion pathway of Na in these materials. 9:12 AM Y4.00005 Quasielastic neutron backscattering studies of Li-ion dynamics in Li\(_2\)SO\(_4\) substituted lithium modified phosphate glasses, TOM HEITMANN, University of Missouri, GAVIN HESTER, Missouri State University, MADHU TYAGI, National Institute of Standards and Technology, MUNESH RATHORE, ANSHUMAN DALVI, Birla Institute of Technology and Science, Pilani, SAIBAL MITRA, Missouri State University — A solid with high Li ionic conductivity and a simultaneously low electronic conductivity is an attractive candidate for use as an electrolyte in an all solid-state Li ion battery. Solid state electrolytes would not only improve the reliability, safety, and the ability of the battery to be operated in harsher conditions, but also allow to be scaled for heavy duty industrial applications. We have studied a series of glassy electrolyte candidate materials. Using quasi elastic neutron scattering in a pulsed time-of-flight neutron backscattering spectrometer, we have characterized the Li-ion diffusion behavior of these materials. We find that Li-ion transport relaxation times are strongly dependent on the ionic state of the host glasses. Our results suggest that these glasses are promising materials for all solid-state Li-ion batteries. We have also studied the electronic transport behavior of these glasses using resistivity measurements and observed that the glasses with a low electronic conductivity are promising materials for all solid-state Li-ion batteries.

9:24 AM Y4.00006 X-ray Scattering Studies and Dynamics at Charged Graphene Interface1, AHMET UYSAL, SANG SOO LEE, HUA ZHOU, PAUL FENTER, Argonne National Laboratory, PENGFEI ZHANG, SHENG DAI, Oak Ridge National Laboratory — Room temperature ionic liquids (RTILs) are promising electrolytes for energy storage systems, especially for supercapacitors. However, our knowledge of these highly dense ionic plasmas at electrified interfaces is still at its infancy due to the lack of in situ experimental data about their potential-dependent electric double layer (EDL) structures and dynamics. In particular, the behavior of mixed electrolytes (RTIL/RTIL and Solvent/RTIL), which are significantly important for practical applications, have been little studied with structural probes. We use in situ real-time X-ray reflectivity to elucidate the role of different anion-cation combinations and solvents on the interfacial ionic liquid structure and dynamics at epitaxial graphene electrode during cyclic voltammetry and potential steps. Our results give direct information about the EDL structure and response, which helps us to connect the macroscopic system properties to the nanoscale structure.

9:36 AM Y4.00007 The Electronic Structures and Diffusion Kinetics of Li, Na, and Mg Inter-calated TiO\(_2\) Anatase and TiO\(_2\) (B), HANDAN YILDIRIM, JEFFREY P. GREELEY, Purdue University School of Chemical Engineering — Large-scale electrochemical storage that would allow wider use of renewable electricity not only requires new and advanced electrode materials for Li ion batteries, but also beyond-Li technologies such as Na and Mg ion batteries. This grand challenge puts forward the necessity for designing efficient electrode materials providing suitable energetics and rapid diffusion kinetics. In this contribution, we evaluate TiO\(_2\) anatase and TiO\(_2\) (B) as attractive candidates for anodes in Li, Na, and Mg batteries due to their low cost, non-toxicity, cycling stability, reasonable capacity, and high operating potential. While the TiO\(_2\) anatase is discussed as promising material for Li storage, structurally, TiO\(_2\) (B) with large interlayer spacing can be considered as a good electro-active material for Na intercalation. We will report the results of the first principles calculations using generalized gradient approximation (GGA) for Li, Na, and Mg intercalation at low concentration. The differences in the electronic and atomic structures obtained using GGA, Hubbard “+U” correction (GGA+U), and Heyd, Scuseria, and Ernzerhof (HSE) hybrid functional will be reported, and the importance of the “+U” correction for modeling the electronic structure of the intercalated TiO\(_2\) will be discussed. The detailed information on the differences in the diffusion mechanisms and barriers will also be reported for each ion in both structures.

9:48 AM Y4.00008 Joint Density-Functional Theory for Atomically Detailed Structure of the Electrode/Electrolyte Interface, KENDRA LETCHWORTH-WEAVER, CHRISTINE UMBRIGHT, RAISHANKAR SUNDARARAMAN, T.A. ARIAS, Department of Physics, Cornell University, Ithaca, NY 14853 — Understanding the complex and inherently multi-scale interface between a charged electrode surface and a fluid electrolyte would inform design of more efficient and less costly electrochemical energy storage and conversion devices. Joint density-functional theory (JDFT) bridges the relevant length-scales by joining a fully ab initio description of the electrode with a highly efficient, yet atomically detailed classical DFT description of the electrolyte structure. First, we introduce a universal functional to couple any quantum-mechanical solute system with a classical DFT for any liquid. This universal coupling functional captures aqueous and non-aqueous solution free energies of small molecules with a mean absolute error of only 1-2 kcal/mol. We also present classical density-functional for ionic species which reproduce the key features of ion-water correlation functions when combined in a mixture with existing functionals for water. Leveraging the above theoretical innovations and our framework to treat charged systems in periodic boundary conditions, we then predict the voltage-dependent structure and energetics of solvated ions at the interface between a graphene electrode and an aqueous electrolyte.

10:00 AM Y4.00009 Ab Initio Electrochemical Capacitance Studies of Super capacitor Materials in Aqueous and Non-Aqueous Electrolytes, CHRISTINE UMBRIGHT, KENDRA LETCHWORTH-WEAVER, T.A. ARIAS, Department of Physics, Cornell University, Ithaca, NY 14853 — Novel electrical energy storage devices are becoming increasingly necessary as technological advances demand higher energy capacity and more efficient methods of charging. Ab initio Joint Density-Functional Theory (JDFT) allows for the simultaneous study of electrodes, electrolytes, and their interactions in a uniform, comprehensive way. In this work, JDFT is utilized to study the energy storage capabilities of supercapacitor materials, such as graphene. The unique electronic structure of graphene results in a high density of states which minimize the capacitance of the electrode. Confinement effects on capacitance are also investigated, as JDFT allows for prediction of ion-structure changes at the interface between a graphene electrode and an aqueous electrolyte.

10:12 AM Y4.00010 Thermodynamics of alloyed nanoparticles for hydrogen evolution reaction including configurational and adsorbate effects1, LIN-LIN WANG, Ames Laboratory, U.S. Department of Energy, Ames, IA 50011, TECK L. TAN, Institute of High Performance Computing, Agency for Science, Technology and Research, Singapore 138632, Singapore, DUANE D. JOHNSON, Ames Laboratory, U.S. Department of Energy, Ames, IA 50011, Department of Materials Science and Engineering, Iowa State University, Ames, IA 50011 — Changes in the chemical configuration of alloyed nanoparticle (NP) catalysts induced by adsorbrates under working conditions are crucial to understand and design NP functionality. We extend the cluster expansion method to predict the configurational thermodynamics of alloyed NPs on equal footing with adsorbate thermodynamics based on density functional theory data. Exemplified with alloyed PdPt NPs having H-coverage up to a full layer, we describe both the configurational and adsorbate thermodynamic behavior simultaneously across the entire range of NP composition and H-coverage to obtain the H-adsorption isotherms and simulated cyclic voltammetry for hydrogen evolution reaction.

1Supported by DOE-BES CSGB (DE-FG02-03ER15476), MSE (DE-AC02-07CH1135) and Ames Lab LDRD. Research was performed at the Ames Laboratory, which is operated for DOE by Iowa State University under contract DE-AC02-07CH11388.
10:24AM Y4.00011 Self-consistent continuum solvation (SCCS): Towards the accurate modeling of electrochemical systems in plane-wave DFT. STEPHEN WEITZNER, ISMAILA DABO, The Pennsylvania State University — Implicit solvent models have been widely used to study quantum systems in solutions. Nevertheless, these models differ greatly in their phenomenological details and in the complexity of their parameterization. While conventional implicit models rely on atomic positions and tabulated atomic radii to construct the solvent shell that surrounds the quantum solute, recent models aim to reduce the number of parameters by building solvation shells directly from computed electronic densities. The self-consistent continuum solvation (SCCS) model, which belongs to the latter class, has been shown to reproduce the solvation energies of a wide range of molecular species in good agreement with experiment, using only two fitted parameters [J. Chem. Phys. 136, 064102 (2012)]. Here, we report on the SCCS model’s performance in describing the electrical properties of quantum electrodes embedded in continuum electrolytes. We show that one additional parameter is needed to capture experimental shifts in the neutral electrode potential as a function of surface composition and structure, and to correctly calibrate computed results to a common electrochemical reference. Utilizing this approach, we establish a novel framework for studying interfacial electrochemical phenomena.

10:36AM Y4.00012 Fast motif-network scheme for extensive exploration of complex crystal structures in silicate cathodes. KAI-MING HO, XIN ZHAO, Iowa State University, SHUNQING WU, Xiamen University, XIAOBAO LV, University of Science and Technology of China, MANH CUONG NGUYEN, CAI-ZHUHANG WANG, Iowa State University, ZI-JING LIN, University of Science and Technology of China, ZI-ZHONG ZHU. Xiamen University — A motif-network search scheme is proposed to study the crystal structures of the dilithium/disodium transition metal orthosilicates A₂M₂O₄. Using this fast and efficient method, the structures of all six combinations with A = Li or Na and M = Mn, Fe or Co were extensively explored in this work. In addition to finding all previously reported experimental structures, we discover many other different crystal structures which are highly degenerate in energy. These tetrahedral-network-based structures can be classified into 1D, 2D and 3D types. A clear trend of the structural preference in different systems is revealed and possible indicators that affect the structure stabilities are introduced. For the case of Na systems which have been much less investigated in the literature relative to the Li systems, we predicted their ground state structures and found evidence for the existence of new structural motifs.

Friday, March 6, 2015 8:00AM - 10:48AM — Session Y5 DMP DCOMP: Focus Session: Fe-based Superconductors — Madores Synthesis and Characterization

8:00AM Y5.00001 Doping evolution of the anisotropic upper critical field in (Ba₁−ₓKₓ)Fe₂As₂.1 MAKARIY TANATAR, YONG LIU, T.A. LOGRASSO, RUSLAN PROZOROV, Ames Laboratory USDOE, Ames, IA 50011, JAN J. JAROSZYNSKI, J.S. BROOKS, National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32310, USA — The temperature and magnetic-field-dependent in-plane resistivity measurements were used to determine anisotropic upper critical field, Hc2(T), of the hole-doped iron-based superconductor (Ba₁−ₓKₓ)Fe₂As₂ over the whole doping range x=0 to x=1. We find clear saturation of Hc2(T) line on T→0 in magnetic field perpendicular to the c-axis of the samples in the overdoped range of the phase diagram, suggesting strong paramagnetic limiting effects. Measurements reveal clear difference in the shapes of the Hc2(T) lines for under-doped and over-doped compositions with similar Tc. Origin of this difference will be discussed.1 This work was supported by the Department of Energy Office of Science, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

8:12AM Y5.00002 Investigation of Vortex Lattice in Optimally Doped (Ba₁−ₓKₓ)Fe₂As₂ Using SANS. S. DEMIRDIS, Julich Center for Neutron Science (JCNS), Forschungszentrum Julich GmbH, JCNS at MLZ, D-54476, Germany, J.C. VAN DER BEEK, Laboratoire des Solides Irradiaux, Ecole Polytechnique CNRS UMR 7642 & CEA-DSM-IRAMIS, F 91128 PALAISEAU/France, S. MUHLBAUER, Technische Universitat Munchen, Forschungsneutronenquelle Heinz Maier-Leibnitz (FRM II) D-85748, Garching, Germany. Y. SU, Julich Center for Neutron Science (JCNS), Forschungszentrum Julich GmbH, JCNS at MLZ, D-54476, Garching, Germany, TH. WOLF, Karlsruher Institut für Technologie, Institut für Festkörperphysik, 7602, Karlsruhe, Germany — Small-angle neutron scattering is used to study the vortex lattice (VL) structure, and to correctly calibrate computed results to a common electrochemical reference. Utilizing this approach, we establish a novel framework for studying interfacial electrochemical phenomena.

8:24AM Y5.00003 Magnetic, optical, and transport properties of BaM₃As₂ and Ba₁−ₓKₓM₃As₂. SHELBY ZELLMAN, DANIEL MCNALLY, Stony Brook University, KANGBO HAO, KIRK POST, DIMITRI BASOV, University of California, San Diego, CHRISTOPHER HOMES, Brookhaven National Laboratory, MEIGAN ARONSON, Stony Brook University, Brookhaven National Laboratory, CORRELATED ELECTRONS GROUP TEAM, INFRARED SPECTROSCOPY OF NOVEL ELECTRONIC AND MAGNETIC MATERIALS COLLABORATION, ELECTRON SPECTROSCOPY GROUP COLLABORATION — Square-net Mn-pnictides are strongly correlated antiferromagnetic (AF) insulators that can potentially be transformed into metals using pressure or charge doping. BaM₃As₂ becomes an AF metal when 5% of K is substituted on the Ba site, and we present here an optical study of this insulator-metal transition. Our measurements confirmed that the resistivity r(T) of undoped BaM₃As₂ is insulating, but becomes metallic with as little as 5%K doping. We measured optical transmission in the visible region of BaM₃As₂, finding a direct charge gap of ~ 5500 cm⁻¹, much larger than previously reported, or the activation gaps determined from r(T). Reflectance measurements were performed to determine if a Drude peak forms at the lowest energies in the doped samples. These measurements underscore the importance of electron correlations in BaM₃As₂ as it approaches metallization. We acknowledge the Office of the Assistant Secretary of Defense for Research and Engineering for providing the NSSEFF funds that supported this research and the DOE under contract No. DE-AC02-98CH10886.
8:36AM 8:36AM Y5.00004 The Ni and Co substitutions in iron chalcogenide single crystals1, V.L. BEZUSYY, D.J. GAWRYLUK, A. MALINOWSKI, M. BERKOWSKI, MARTA Z. CIEPLAK, Institute of Physics PAS, Warsaw — We study the ab-plane resistivity and Hall effect in Fe$_{1-x}$M$_x$Te$_2$Se$_{2.5}$ single crystals with M=Co or Ni, and y up to 0.2. The crystals are grown by Bridgman’s method. The low-temperature Hall coefficient $R_H$ changes sign to negative for crystals with y exceeding 0.135 (Co) and 0.06 (Ni), consistent with the electron doping induced by these impurities. However, the $R_H$ remains positive for all samples at high T, suggesting that remnant hole pockets survive the doping, but the holes become localized at low T in heavily doped crystals. Superconducting transition temperature ($T_c$) approaches zero for y exceeding 0.135 (Co) and 0.06 (Ni), while the resistivity at the $T_c$ onset is only weakly affected by Co doping, but it increases strongly for the Ni. These results suggest that in case of Co impurity the $T_c$ suppression may be attributed to electron doping. On the other hand, the Ni substitution, in addition to electron doping, induces strong localization effects at small impurity contents. Using two-band conduction model we argue that the localization of electron carriers is responsible for strong superconductivity suppression by Ni impurity.

$^1$Supported by EC through the FunDMS Advanced Grant of the ERC (FPT Ideas), by the Polish NCS grant 2011/01/B/ST3/00462, and by the French-Polish Program PICS 2012. Performed in the laboratories co-financed by NanoFun Project POIG.02.02.00-00-025/09.

8:48AM 8:48AM Y5.00005 Generic Superconducting Inhomogeneity in Single Crystal Fe(Fe$_{1-x}$Se$_{2.5}$) Probed by Nanostructure-transport , CHUNLEI YUE, JIN HU, XUE LIU, ZHIQIANG MAO, JIANG WEI, Tulane University — We have investigated the nano-scale electronic properties of the iron-based unconventional superconductor Fe(Fe$_{1-x}$Se$_{2.5}$) with optimal Se content $x=0.5$. Using the microexfoliation method and ion milling thinning, we successfully produced Fe(Fe$_{1-x}$Se$_{2.5}$) devices with thickness varying from 90nm down to 12nm. Our transport measurements revealed a suppression of superconductivity coinciding with the loss of normal state metallicity. Through the simulation of the formation of superconducting region in nano-scale thin flakes, we show that our observation is in line with the nano-scale inhomogeneity proposed for this material; therefore it provides a more direct evidence for the nano-scale inhomogeneous superconductivity in Fe(Fe$_{1-x}$Se$_{2.5}$).

9:00AM 9:00AM Y5.00006 Order/disorder of Fe-vacancy and superconductivity in Fe-chalcogenide superconductors$^1$, MAW-KUEN WU, National Donghwa University and Institute of Physics, Academia Sinica — Having the simplest crystal structure among the Fe-based superconductors, the FeSe superconductor is the best candidate for investigating the mechanism of these new superconductors. How the properties of FeSe superconductor evolve from normal state to superconducting state and what is the parent phase of FeSe system are critical issues for resolving its superconducting mechanism. We have studied the properties of FeSe and K-Fe$_x$Se$_{2-x}$ superconductors in various forms, including polycrystal, single crystal, thin film, nanowire, and nanoparticle. We discovered several Fe-deficient Fe$_{1-x}$Se phases, which exhibit Fe-vacancy ordering. The property of these phases evolves from an insulator to a metal gradually as Fe content increases. Our results provide unambiguous support to the picture that superconducting transition in FeSe and related compounds is closely related to the order to disorder transition of the Fe-vacancy.

9:36AM 9:36AM Y5.00007 Fermi-liquid like normal state electronic states in Co-doped BaFe$_2$As$_2$ , ERIK VAN HEUMEN, ALONA TYTARENKO, YINCKAI HUANG, ANNE DE VISSER, University of Amsterdam, STEVEN JOHNSTON, University of Tennessee — Elucidating the origin of high temperature superconductivity requires two equally important ingredients: a framework for the normal state electronic dynamics and a pairing interaction. In iron-pnictide high T$_c$ superconductors the electron doped compounds, such as BaFe$_2$-xCo$_x$As$_2$, are predicted to be weakly correlated Fermi liquids [1,2], but clear evidence has thus far been lacking. In this contribution we unveil the true nature of the normal state dynamics by carefully annealing BaFe$_2$-xCo$_x$As$_2$ single crystals. We show that optical spectroscopy experiments on such annealed crystals display a characteristic Fermi liquid scaling of frequency and temperature over a large energy range [3]. A comparison with as-grown single crystals shows that magnetic impurity scattering has thus far masked this behavior. A further analysis shows that a Fermi-liquid like single-particle self-energy can well describe both the mass renormalization and optical scattering rate, leaving little room for additional contributions.

9:48AM 9:48AM Y5.00008 Anomalous Hall effect in epitaxial Ba(Fe1-x Co)x)2As2 pnictide superconducting thin films and superlattices1, NEIL CAMPBELL, MARK RZCHOWSKI, JULIAN IRWIN, Dept of Physics, Univ of Wisconsin, JONG-HOON KANG, CHANG-BEOM EOM, SANCHAN LEE, Dept of MatSci and Engr, Univ of Wisconsin, ADELE RUOSI, Dipt di Fisica, Univ di Napoli Federico II — Iron-based superconductors have been worked with to the point that now growth of various thin films is very-well controlled, allowing in depth study of associated structures. One exciting pathway of study for pnictides is that they show similarities to cuprate superconductors, regarded as an avenue toward high-Tc superconductors. Specifically, these heterostructures allow study of the competition between antiferromagnetism and superconductivity at the interface between the undoped parent compound, and optimally-doped compound. BaFe2-xCoAs2 (Ba122). At room temperature, these pnictides exhibit anomalous Hall effect (AHE). There is strong evidence for the interface dominating AHE, allowing control AHE with type of substrate, surface termination, and superlattice configuration. We characterized samples of thicknesses from 6nm to 300nm, and with up to 12 interfaces. Such samples have been characterized via magnetotransport measurements at temperatures ranging from 5K to 300K, and magnetic fields up to 8T applied normal to the basal plane with Van der Paw and Hall geometries. Additionally, we measured magnetization with vibrating sample magnetometry. These properties will aid novel device development, making pnictides interesting.

10:00AM 10:00AM Y5.00009 Electrodynamics of rare-earth-doped CaFe$_2$As$_2$ , ZHEN XING, T.J. HUFFMAN, PENG XU, A.J. HOLLINGSHEAD, D.J. BROOKER, M.M. QAZILBASH, Department of Physics, College of William and Mary, SHANTA SAHA, TYLER DRYE, CONNOR RONCAIOLI, J. PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park — Rare-earth substitution at alkaline-earth sites leads to the suppression of the spin density wave phase transition in CaFe$_2$As$_2$ without the emergence of bulk superconductivity. In this work, we perform pyroelectric infrared reflectance spectroscopy and spectroscopic ellipsometry on Pr-doped and La-doped CaFe$_2$As$_2$ single crystals. In both Ca$_{0.85}$La$_{0.15}$Fe$_2$As$_2$ and Ca$_{0.85}$Pr$_{0.15}$Fe$_2$As$_2$ samples, the spin density wave transition is completely suppressed. The temperature dependence of the ab-plane optical conductivity of the La-doped CaFe$_2$As$_2$ crystal exhibits conventional metallic behavior consistent with the absence of any structural, magnetic, or superconducting instabilities. On the other hand, the Pr-doped CaFe$_2$As$_2$ crystal undergoes a structural transition about 70 K from a tetragonal lattice to a collapsed tetragonal lattice with the same symmetry but reduced volume. In the Pr-doped CaFe$_2$As$_2$ crystal, the ab-plane optical conductivity reveals subtle but distinct spectral changes upon cooling through the structural transition. We provide results on the influence of the structural collapse on the charge dynamics, correlation effects and the electronic configuration.

10:12AM Y5.00010 Systematic growth and physical properties of BaFe$_{2−x}$Cr$_x$Ni$_2$As$_2$. DONGLIANG GONG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, RUI ZHANG, Department of Physics and Astronomy, Rice University, Houston, Texas 77005, USA, SHILIANG LI, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, PENGCHENG DAI, Department of Physics and Astronomy, Rice University, Houston, Texas 77005, USA, HUIQIAN LUO, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We have successfully grown the single crystals of BaFe$_{2−x}$Cr$_x$Ni$_2$As$_2$ with a series of Ni and Cr doping levels. Their physical properties were studied by the elastic neutron scattering and transport measurements. It is found that Cr doping is a very efficient way of suppressing the superconductivity in the BaFe$_{2−x}$Ni$_2$As$_2$ system with little change of the $T_S$ and $T_N$. The magnetic and electronic properties without the presence of the superconductivity may be thus investigated at low temperature.

10:24AM Y5.00011 Observation of pseudogaplike feature in LiFeAs by ultrafast optical spectroscopy. KUNGHUAN LIN, KUAN-JEN WANG, CHUNG-ChIEH CHANG, YU-ChIEH WEN, DZUNG-HAN TSAI, YU-RUEI WU, YAO-TSUNG HSIEH, MING-JYE WANG, Academia Sinica, Taiwan, BING LV, PAUL C.-W. CHU, University of Houston, USA, MAU-KUEN WU, National Dong Hwa University, Taiwan — We utilize ultrafast optical spectroscopy to study the quasiparticle relaxation in stoichiometric LiFeAs crystals. According to our temperature-dependent studies, we have observed three electronic phases in LiFeAs. Below the superconducting (SC) temperature $T_c$ (~15 K), the relaxation time of quasiparticles due to the SC gap is far longer than 50 ps in our experimental conditions. In addition to SC gaps, we have also found a gaplike feature in SC state. This gaplike feature is evident up to 40 K, which is above the SC temperature. Because this is similar to pseudogap in cuprate superconductors, we call this new electronic phase as pseudogaplike feature. The quasiparticle relaxation time due to pseudogaplike feature is in the range of 1-2 ps. We suggest the pseudogaplike feature in LiFeAs is induced by magnetic fluctuations.

10:36AM Y5.00012 Temperature Evolution of Spin Fluctuations in FeAs. A. PODLESNYAK, G. EHLERS, Quantum Condensed Matter Division, ORNL, Oak Ridge, TN 37831, USA, S. TÖTH, Laboratory for Neutron Scattering and Imaging, PSI Villigen & Laboratory for Quantum Magnetism, EPFL, Lausanne, Switzerland, K. GOFRYK, A.S. SEFAT, Materials Science and Technology Division, ORNL, Oak Ridge, TN 37831, USA — The discovery of superconductivity (SC) in iron pnictides has opened a new stage in SC research. The superconducting state appears in iron pnictides with doping in metallic parent compounds. This is an important difference to the cuprates, which exhibit SC near a correlated insulating state. Therefore, the nature of the magnetism in the simplest iron pnictide - binary FeAs - is of fundamental importance for understanding the interplay between localized and itinerant magnetism and superconductivity in these materials. We use inelastic neutron scattering to map spin wave excitations in the monoaesndic FeAs at temperatures above and below the antiferromagnetic transition $T_N \sim 70$ K. We find magnetic excitation spectrum near the Néel temperature to be strongly different from the spectrum in the ground state. Near the transition temperature, magnetic fluctuations clearly indicate two-dimensional character in an intrinsically three-dimensional (3D) system. On the other hand, at low temperature, spin waves in FeAs are anisotropic 3D, suggesting a crossover from two-dimensional to three-dimensional character.

Friday, March 6, 2015 8:00AM - 11:00AM —
Session Y6 DCMP DMP: Optical and Electrical Properties of Hybrid Nanostructures

8:00AM Y6.00001 Tuning the charge transfer plasmon in a metallic nanoparticle dimer bridged by a quantum dot. VIKRAM KULKARNI, ALEJANDRO MANJAVACAS, PETER NORDLANDER, Rice University — Localized surface plasmon resonances (LSPR) are a subject of intense experimental and theoretical research interest. LSPR have found applications in catalysis, solar energy, cancer therapy, and surface enhanced Raman spectroscopy (SERS). This is due to the exceptional light capturing and focusing capabilities of plasmonic nanostructures. An LSPR of particular interest is the charge transfer plasmon (CTP). This mode may be excited when two plasmonic nanoparticles are bridged by a quantum dot. The CTP is extraordinarily sensitive to the conductive properties of the junction. Here we perform a theoretical investigation of the CTP when two plasmonic nanoparticles are bridged by a quantum dot. All simulations are done using the time dependent density functional theory (TD-DFT). By modulating the electronic structure of the quantum dot we are able to effectively turn the CTP on and off. Specifically, the CTP emerges only when a quantum dot energy level is resonant with the fermi energy of the plasmonic nanoparticles. We verify that the conductance through the junction is on the order of the quantum unit of conductance. This work is of great interest to the future design of plasmonic and molecular electronic systems.

8:12AM Y6.00002 Highly tunable gold nanorod dimer resonances mediated through conductive junctions. JAKE FONTANA, BANAHALLI RATNA, Naval Research Lab — Tailoring the resonant frequency in plasmonic nanostructures is critical to developing disruptive metamaterial technologies. Here we numerically study the optical properties of gold nanorod dimers connected end-to-end by a thin metallic bridge [1]. We find the resonant frequency along the long axis of the dimer shifts linearly with the nanorod aspect ratio behaving as it was a single nanorod with an aspect ratio nearly an order of magnitude larger. We show by controlling the material and geometry of the connecting bridge the effective dielectric function of the dimer is significantly modulated tuning the resonant frequency over a decade, from 1 to 10 μm. We present an alternative description for the emergence and behavior of the dimer resonance using a straightforward “Drude-like” model and self-assembly experiments creating such structures.

8:24AM Y6.00003 Surface Plasmon Resonance enhancement via oblique thin film deposition on gratings. ZHAOZHU LI, MICHAEL KLOPF, William and Mary College, GEORGE SCHWARTZ, University of Virginia, MATTHEW HEIMBURGER, LEI WANG, KAIDA YANG, ROSA LUKASZEW, William and Mary College — Surface plasmon resonance (SPR) occurs when light shins at a dielectric-metallic interface under certain configurations such that an evanescent polariton can be excited. This surface plasmon polariton travels across the interface exhibiting electric field intensity greatly enhanced with respect to the incident light, evidenced by the observation of a deep angular reflectivity scans at the resonance angle. To excite the SPR, one can use a diffraction grating coupler in order to satisfy the dispersion relationship, noting that within certain grating-groove aspect-ratios, the electric field intensity in the surface polariton can be further enhanced by increasing the grating amplitude. We have applied oblique shadow deposition (OSD) to deposit metallic layers onto gratings to enhance their grating amplitudes and compare them to films deposited at normal incidence. We report on the effects on the SPR of such configurations, by comparing the results of OSD samples with those for normal incident deposited samples.
8:36AM Y6.00004 Plasmon Excitations for a Linear Assembly of Metallic Spheres. BO GAO, LIUBOV ZHEMCHUZHNA, Hunter College, CUNY, ANDRIII IROV, University of New Mexico and Hunter College, CUNY, GODFREY GUMBS, Hunter College, CUNY and Donostia International Physics Center (DIPC), DANHONG HUANG, Air Force Research Laboratory, Space Vehicles Directorate. We present a general formalism for calculating the Coulomb excitations of a linear array of interacting electron gases confined to the outside surfaces of three spherical shells. The response of these incompressible 2D electron gases to an external electromagnetic field results in charge density oscillations whose anisotropicity with respect to the axis of quantization will be discussed. The dependence of the frequency of the plasma oscillations on the radius of the spheres as well as their separation has been a subject of our investigation and detailed results will be presented. We provided complete numerical results for the plasmon excitation of such system and concluded that the plasmon demonstrate quite different behavior from the earlier considered case of a 2DDEG triad - they are not symmetric on the sign of each potential element for z-alignment and the interaction of the two far-removed spheres is no longer negligible.

8:48AM Y6.00005 Aperiodic Aharonov-Bohm oscillations in coherent transport through a periodic array of quantum dots. L.S. PETROSYAN, T.V. SHAHBAZIAN, Jackson State Univ. We study resonant tunneling through a periodic square array of quantum dots sandwiched between modulation-doped quantum wells. If a magnetic field is applied parallel to the quantum dot plane, the tunneling current exhibits a highly complex Aharonov-Bohm oscillation pattern due to interference of multiple pathways traversed by a tunneling electron. Individual pathways associated with conductance beats can be enumerated by sweeping the magnetic field at various tilt angles. Remarkably, Aharonov-Bohm oscillations are aperiodic unless the magnetic field slope relative to quantum dot lattice axes is a rational number.

9:00AM Y6.00006 Hyperbolic polaritons in nanoparticles. ZHIYUAN SUN, Department of Physics, University of California San Diego, 9500 Gilman Drive, La Jolla, California 92093, USA, ANGEL RUBIO, FRANCISCO GUINEA, Instituto de Ciencia de Materiales de Madrid, CSIC, Cantoblanco, E-28049 Madrid, Spain, DIMITRI BASOV, MICHAEL FOGLER, Department of Physics, University of California San Diego, 9500 Gilman Drive, La Jolla, California 92093, USA. Hyperbolic optical materials (HM) are characterized by permittivity tensor that has both positive and negative principal values. Collective electromagnetic modes (polaritons) of HM have novel properties promising for various applications including subdiffractional imaging and on-chip optical communication. Hyperbolic response is actively investigated in the context of metamaterials, anisotropic polar insulators, and layered superconductors. We study polaritons in spheroidal HM nanoparticles using Hamiltonian optics. The field equations are mapped to classical dynamics of fictitious particles (wave packets) of an indefinite Hamiltonian. This dynamics is quantized using the Einstein-Brillouin-Keller quantization rule. The eigenmodes are classified as either solid or surface according to whether their transverse momenta are real or imaginary. To model how such hyperbolic polaritons can be probed by near-field experiments, we compute the field distribution induced inside and outside the spheroid by an external point dipole. At certain magic frequencies the field shows striking geometric patterns whose origin is traced to the classical periodic orbits. The theory is applied to natural hyperbolic materials hexagonal boron nitride and superconducting LaSrCuO.

9:12AM Y6.00007 Generation of acoustic terahertz waves in hybrid InGaN/GaN quantum wells. MEG MAHAT, Department of Physics, University of North Texas, Denton, TX 76203, ANTONIA LLOPIS, Department of Electrical and Computer Engineering, Duke University, Durham, NC 27708, TAE YOUL CHOI, Department of Mechanical and Energy Engineering, University of North Texas, Denton, TX 76203, SERGIO PERIARA, CICECO, Universidade de Aveiro, 3810-193 Aveiro, Portugal, IAN WATSON, SUPA, Institute of Photonics, University of Strathclyde, Glasgow, UK, ARUP NEOGI, Department of Physics, University of North Texas, Denton, TX 76203. We have carried out differential transmission measurements on InGaN/ GaN quantum wells with Au nanoparticles inserted inside V-pits with high filling fraction. We have observed acoustic wave packets generated with multiple THz frequencies as 0.12 THz from GaN buffer layer, 0.22 THz from Au-InGaN multiple quantum wells region, 0.07 THz from sapphire substrate, and 0.17 THz mixed signals from the sample. These THz wave packets are observed as a result of generation of coherent acoustic phonons propagating in hybrid Au-InGaN quantum wells. The study of these acoustic THz wave generation is crucial for the imaging of nanostructures.

9:24AM Y6.00008 Magnetic field- and frequency-dependence- of the phase-shift in the linearly-polarized microwave radiation-induced magnetoresistance oscillations in the GaAs/AlGaAs system. HAN-CHUN LIU, TIANYU YE, Department of Physics & Astronomy, Georgia State University, WERNER WEGSHEIDER, ETH-Zurich, Zurich, Switzerland, RAMESH MANI, Department of Physics & Astronomy, Georgia State University. Nonequilibrium transport studies of the radiation-induced magnetoresistance oscillations (RIMOs) have revealed striking photo-excited zero-resistance states in the GaAs/AlGaAs two-dimensional electron system [1]. Further observations show that RIMOs are linear-polarization-angle-sensitive and follow a sinusoidal fitting formula, \( R_{xx}(\theta) = A \pm C \cos^2(2(\theta - \theta_0)) \) where \( R_{xx} \) is the diagonal resistance, \( \theta \) is the polarization angle, and \( \theta_0 \) is the extracted phase shift. At the present, \( \theta_0 \) is known to be magnetic- and frequency-dependent [2]. Here, we perform magnetic mappings at small \( \theta \) intervals, at a number of radiation frequencies, to study the variation of the phase shift with the magnetic field and frequency. The relationship between phase shift and magnetic fields/frequency will be critically examined and reported in this presentation.

9:36AM Y6.00009 Electrochemically grown InSb nanowires: challenges and growth determined properties. ABHAY SINGH, USHA PHILOPOSE, University of North Texas — InSb nanowires have myriads of applications such as electronic, optoelectronic, and magneto resistive devices. Synthesis of InSb nanowires in the pores of anodic alumina oxide (AAO) template by direct current electrodeposition is challenging because it involves several steps including opening of barrier layer at the bottom of AAO pores, dissolving of the AAO template post-nanowire growth, followed by electrochemical deposition of InSb nanowires. We will provide evidence of these challenges. The InSb nanowires had good composition and crystalline quality as will be shown by EDX, X-ray, and Raman spectroscopy. Transport measurements made on a single InSb nanowire and on an array of nanowires will be presented. A single nanowire connected in an FET type configuration was used to determine carrier concentration and mobility. By tuning the growth parameters during electrochemical deposition, it is possible to modulate the nanowire composition. Temperature dependent measurements are used to show the semiconducting behavior of the nanowires.

9:48AM Y6.00010 Superlattice Phenomena in Nanohelices. CHARLES DOWNING, MATTHEW ROBINSON, MIKHAIL PORTNOI, University of Exeter, UNIVERSITY OF EXETER TEAM. Recently artificially-created nanohelices have been demonstrated in various semiconductor systems. We argue that subjecting a nanohelix to an electric field normal to its axis turns it into a superlattice with easily-tunable electronic properties. We investigate such a system, also subjected to a longitudinal electric field along the nanotube axis, and find Bloch oscillations and negative differential conductivity. Taking into account Zener tunneling across the band gap, we find the characteristic N-type dependence of electron drift velocity on the longitudinal field which is commonly used in high-frequency electronics. The merits of using a nanohelix for novel tunable device applications are assessed. We also study dipole transitions across the energy gap, which can be tuned to the THz range by experimentally attainable external fields. There is a drastic change in selection rules for a helix in a transverse field compared to the case of purely chiral structures. For the excitation propagating along the nanohelix axis our results are somewhat similar to those found for a quantum ring pierced by a magnetic flux, with the momentum of a quasiparticle in a helix playing the same role as a flux through a ring. We also discuss possible devices which could utilize these phenomena.
10:00AM Y6.00011 Tunable Quantum Temperature Oscillations in Graphene Nanostructures
JUSTIN BERGFIELD, MARK RATNER, Northwestern University, CHARLES STAFFORD, University of Arizona, MASSIMILIANO DI VENTRA, University of California, San Diego — Thermal scanning probe microscopy techniques are now capable of nanometer spatial resolution and millikelvin temperature accuracy, raising the fundamental question: What is the meaning of temperature for a quantum system operating far from equilibrium? We investigate this question theoretically using a realistic model of a scanning thermal microscope with atomic resolution, operating in the tunneling regime in ultrahigh vacuum. The thermometer acts as an open three-terminal in a thermoelectric circuit. We investigate the temperature distributions in molecular junctions and graphene nanowires under thermal bias, and find that the local temperature in these systems exhibits quantum oscillations; quantum interference mimics the actions of a Maxwell Demon, allowing electrons from the hot electrode to tunnel onto the temperature probe when it is at certain locations near the system, and blocking electrons from the cold electrode, or vice versa.

10:12AM Y6.00012 Mechanism and Limitation of Heat Conduction in Three-Phase Polymer Composites Having Carbon Nanotubes and Inorganic Nanoparticles, HAI DUONG, FENG GONG, National University of Singapore, DIMITRIOS PAPAVASSILIOU, University of Oklahoma — For the first time, an Off-Lattice Monte Carlo method is developed successfully to predict thermal conductivities ($K_{th}$) of three-phase composites having carbon nanotubes (CNTs) and tungsten disulfide ($WS_2$) nanoparticles more accurately and faster than previous methods such as effective medium theories, molecular dynamics, and finite element methods. The $K_{th}$ predicted by our model using a random walk algorithm and taking into account various thermal boundary resistances at each interface and inter-CNT contact has an excellent agreement with experimental data. Our model can comprehensively explain the mechanism of heat conduction in complex composite structures. Effects of $WS_2$ and CNT morphologies (diameter, length, inter-contact, bundle), CNT concentrations, CNT orientations (parallel, random and perpendicular to heat flux) and thermal boundary resistances of CNT-polymer, $WS_2$-polymer, CNT-CNT, CNT-$WS_2$ on heat conduction limitation of the three-phase composites are also investigated systematically. Our model can be also applied to the biological and nanofluidic systems.

10:24AM Y6.00013 One or two dimensional electronic states in gold nanowires on germanium?
NICK DE JONG, EMMANOUIL FRANTZESKAKIS, University of Amsterdam, RENÉ HEIMBUCH, University of Twente, ANDREI VARKHALOV, Paul Scherrer Institute, HAROLD ZANDVLIET, University of Twente, MARK GOLDEN, University of Amsterdam — Inspired by the formulation of Tomonaga-luttinger liquid (TLL) theory in the 1960’s and its prediction of a spectacular breakdown of Fermi liquid theory in 1D, people have been searching for one dimensional electronic systems. With experimental developments like the advent of scanning tunneling microscopy (STM) and the manipulation of matter on the nanometer and sub nanometer scale, this field has become increasingly accessible for the experimentalist. Self-organised metallic chains on semiconductor surfaces are a class of systems which could harbor 1D behavior. In this field, Au nanowires on the Ge(100) surface have been the subject of debate, with reports of 1D bands from both ARPES and STM (1) and 2D bands in the same system displaying no Luttinger like behavior (2). Here we present high resolution ARPES data from both the Au/Ge(100) system and a new nanowire system: Au/Ge(110). By comparing these different systems with each other and with the electronic structure of the bare Ge(110) surface, we try to give a definitive answer on the question of the dimensionality of the electronic structure of Au nanowires on germanium.

10:36AM Y6.00014 Observation of Franck-Condon Blockade in Single Molecules Gated by Local Electric Field
AIDI ZHAO, CHUNSHENG ZHOU, WEIYI WANG, Hefei National Laboratory for Physical Sciences at Microscale, University of Science and Technology of China, GUANGJUN TIAN, Division of Theoretical Chemistry & Biology, KTH Royal Institute of Technology, HUAN SHAN, SHULAI LEI, YINGBO ZHAO, YI LUO, QUNXIANG LI, BING WANG, J.G. HOU, Hefei National Laboratory for Physical Sciences at Microscale, University of Science and Technology of China — Electron transport through single molecules is greatly influenced by a discrete spectrum of vibrational modes in strong electron-vibron coupling regime. Theory predicts a current suppression at low biases known as Franck-Condon blockade. However, how Franck-Condon blockade emerges in a real orbital-gated single molecule transistor is still elusive. In this study, by using a low-temperature scanning tunneling microscope, we report the real-space observation of Franck-Condon blockade in single molecules adsorbed on metal surfaces. The frontier molecular orbitals and charge state of the bare Ge(110) surface, we try to give a definitive answer on the question of the dimensionality of the electronic structure of Au nanowires on germanium.

1J. Schafer et al., PRL101, 236802 (2008)

10:48AM Y6.00015 Two-channel Kondo effect and the low-temperature crossover
ANDREW KELLER, LUCAS PEETERS, Stanford University, IRENEUSZ WEYMANN, Adam Mickiewicz University, CĂTALIN PAŞCU MOCA, Budapest University of Technology and Economics, University of Oradea, DIANA MAHALU, VLADIMIR UMANSKY, Weizmann Institute of Science, GERGELEY ZARAND, Budapest University of Technology and Economics, DAVID GOLDHABER-GORDON, Stanford University — The two-channel Kondo (2CK) state, where a spin-1/2 impurity is equally exchange-coupled to two independent reservoirs, is a canonical non-Fermi liquid state. Experimental observations are rare because of its sensitivity to common and hard-to-control perturbations. We implement experimentally a 2CK state in a coupled dot-system (Potok, et al., doi:10.1038/nature05556), and explore the physics of the low-temperature crossover: how magnetic field and gate voltage drive the system towards a Fermi liquid ground state. Our experimental findings are corroborated by detailed numerical renormalization group modeling of our device.

Support from FOM and the EU is gratefully acknowledged.

Friday, March 6, 2015 8:00AM - 10:48AM — Session Y7 — DCMP: Insulators: Transport, Spectroscopies, etc.
006B - Andrei Sushkov, University of Maryland
8:00 AM Y7.00001 Nanoscale Determination of the Mass Enhancement Factor in Lightly-Doped Bulk Insulator PbSe, KANE SCIPIONI, ILIJA ZELJKOVIC, DANIEL WALKUP, Boston College, YOSHINORI OKADA, Tohoku University, WENWEN ZHOU, Boston College, RAMAN SANKAR, National Taiwan University, GUOQING CHANG, National University of Singapore, YUNG JUI WANG, Northeastern University, HSIN LAN, National University of Singapore, ARUN BANSIL, Northeastern University, FANCHENG CHOU, National Taiwan University, ZIQIANG WANG, Boston College, VIDYA MADHAVAN, University of Illinois Urbana-Champaign — Phonons play a significant role in achieving the desired thermoelectric properties of many materials. Recent evidence suggests that electron-phonon coupling plays an important role in specifically the lead and bismuth chalcogenides. Thus, quantifying the interaction between phonons and electrons is of immense importance for understanding of these systems. Nearly all information about electron-phonon coupling is contained in the Eliashberg function of the material, but its precise extraction has in part been limited due to the lack of local experimental probes. By utilizing Landau level spectroscopy, we construct a method to directly extract the Eliashberg function, and demonstrate its applicability to lightly-doped thermoelectric bulk insulator PbSe. In addition to high energy, and access to both occupied and unoccupied electronic states, this novel experimental method could be used to detect variations in the mass enhancement factor (λ) on microscopic length scales, which opens up a unique pathway for investigating the effects of chemical defects, surface doping and strain on λ.

8:12 AM Y7.00002 Dimerization-Induced Fermi Surface Reconstruction in IrTe2, MANJIN EOM, KYOO KIM, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea, YOUN JUNG JO, Department of Physics, Kyungbok University, Daegu 790-701, Korea, JUNJIE YANG, Laboratory for Pohang Emergent Materials, Pohang University of Science and Technology, Pohang 790-784, Korea, EUN SANG CHOI, National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32310, USA, BYUNG IL MIN, JAE-HOON PARK, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Piscataway, New Jersey 08854, USA, JUN SUNG KIM, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Korea — We report a de Haas-van Alphen (dHvA) oscillation study on IrTe2 single crystals showing complex dimer formations. By comparing the angle dependence of dHvA oscillations with band structure calculations, we show distinct Fermi surface reconstruction induced by a 1/5-type and a 1/8-type dimerizations. This verifies that an intriguing quasi-two-dimensional conducting plane across the layers is induced by dimerization in both cases. A phase transition from the 1/5-type to the 1/8-type dimerizations reveals that local instabilities associated with intra- and inter-dimer couplings are the main driving force for complex dimer formations in IrTe2.

8:24 AM Y7.00003 Enhanced terahertz emission from a femtosecond-laser-ablated photoconductor1, ATHANASIOS MARGIOLAKIS, Okinawa Inst of Sci & Tech, ZHEN-YU ZHAO, Department of Physics Shanghai Normal University, PETER HALE, JULIEN MADEO, MICHAEL MAN, Okinawa Inst of Sci & Tech, QUAN-ZHONG ZHAO, Shanghai Institute of Optics and Fine Mechanics, Chinese Academy of Sciences, WEI PENG, Institute of Microsystem and Information Technology, Chinese Academy of Sciences, KESHAV DANI, Okinawa Inst of Sci & Tech — Terahertz (THz) emission properties from bow-tie antennas fabricated on a femtosecond-laser-ablated, semi-insulating gallium arsenide (SI-GaAs) photoconductor are investigated. The ablated material demonstrates increased photoabsorption resulting in increased photocurrent leading to a more efficient optical to THz efficiency. We use THz time-domain spectroscopy (THz-TDS) in order to compare the relative efficiency of the two fabricated devices. The influence of the excitation power and applied bias on the antennas electrodes for both ablated and non-ablated substrates is studied, highlighting the better performances of the ablated devices. A 60% enhancement in THz emission amplitude is observed in the frequency range 0.5 – 4 THz of the ablated SI-GaAs antenna, compared to untreated SI-GaAs. Our experimental results are in agreement with Drude-Lorentz numerical simulations using previously reported absorption and photocurrent properties of femtosecond laser ablated SI-GaAs based photoconductors. This material treatment provides a new way to achieve THz-TDS systems based on SI-GaAs antennas with an improved signal-to-noise ratio.

1National Natural Science Foundation of China (61307130, 11374316)

8:36 AM Y7.00004 Optical and Photo-stimulated EPR Studies on Intrinsic and Mn-doped Zinc Germinates Phosphors, XIAOJUN WANG, Department of Physics, Georgia Southern University, Statesboro, GA 30460, USA, ZHIYI HE, Optoelectronic Institute, Guilin University of Electronic Technology, Guilin, Guanxi, China 541004, LI MA, Department of Physics, George Southern University, Statesboro, GA 30460, USA — Intrinsic zinc germinates (Zn2GeO4) and Mn-doped Zn2GeO4 phosphors have been prepared using solid state reaction and their photoluminescence and phosphorescence studied. Phosphorescence from both the Mn2+ ions and host defects in Zn2GeO4 has observed upon UV excitation, while the Mn3+ ions present a longer persistent time than the defects. The charging process has also been studied and different behaviors of Mn2+ and defects observed. Electron paramagnetic resonance (EPR) and photo (UV)-stimulated EPR spectra have been collected for both host defects and Mn dopants from 20 K to room temperature. UV-induced EPR signal and the decay processes have been analyzed and provided a better understanding of the trapping mechanism for the phosphorescence. EPR signal from Mn2+ has been found decreasing after the UV excitation, indicating that the population of Mn2+ ions decreases in the trapping state and the valence change from Mn2+ to Mn3+ when hole trapping occurred.

8:48 AM Y7.00005 Large thermal Hall effect in a frustrated pyrochlore magnet1, MAX HIRSCHBERGER, Department of Physics, Princeton University, JASON KRIZAN, ROBERT J. CAVA, Department of Chemistry, Princeton University, N. PHUAN ONG, Department of Physics, Princeton University — In frustrated magnetism, the nature of the ground state and its elementary excitations are a matter of considerable debate. We present a detailed study of the full thermal conductivity tensor of a frustrated spin-ice pyrochlore Tb2Ti2O7. The off-diagonal response is large in this insulating material, despite the absence of itinerant electrons experiencing the Lorentz force. Our experiments over the temperature range of 0.8 – 200 K and in fields up to 14 T reveal a remarkable phenomenology: A sizeable field-linear Hall effect is observed below 100 K, and its slope with respect to magnetic field increases strongly as we cool the sample. We observe significant curvature in the field dependence of the Hall effect below 15 K. At the lowest temperatures, both of the initial slope and the initial slope constant in temperature, behavior reminiscent of ferromagnetic heat conduction in dirty metals. Experimental methods and verification of the intrinsic nature of the effect will be discussed.

9:00 AM Y7.00006 Time-dependent Elastic Deformation in Crystal: Insights from Metric Description and Berry Phase Effect, LIANG DONG, QIAN NIU, University of Texas at Austin — It is well known that elastic deformation in crystal can be described in the language of a metric. However, how the metric couples to the one-electron Hamiltonian in a deformed crystal is not very clear. By coordinate transformation from a Cartesian frame to lattice frame where all coordinates of ions are fixed, the metric emerges naturally both in the kinetic energy and potential energy of an electron. Besides, the velocity field of ions is also manifested in the Hamiltonian, which resembles the role of a vector potential. When the deformation slowly varies both in space and time, the wave-packet method can be used to study the Berry phase effect of deformation. This method applies to finite-strain cases and is accurate up to the first order of strain gradient. Different deformation effects are discussed, such as piezoelectricity, flexoelectricity and curving effect of a two-dimensional material.
9:12AM Y7.00007 Theoretical Studies of the Optical Properties of Eu doped Barium Mixed Halides: From X-ray Storage Phosphor to Bright Scintillator, SLIM CHOUROU, GREGORY BIZARRI, Lawrence Berkeley National Laboratory, ANDREW CANNING, Lawrence Berkeley National Laboratory and University of California, Davis — The Eu doped Ba mixed halide family BaBrX (X=F,Cl,Br,I) changes from being a widely used X-ray Storage Phosphor (BaBrF-Eu) to one of the brightest known new gamma ray detector scintillators (BaBrI-Eu). To help understand these contrasting optical properties and guide in the design of new and improved scintillator detectors, in collaboration with experimental groups, we have performed first principles theoretical studies of these materials. In particular we have studied their electron and hole trapping mechanisms and how that can explain their very different optical properties.

9:24AM Y7.00008 Single-particle dispersion in tetragonal CuO1, CLEMENS ADOLPHS, Univ of British Columbia, MONA BERCUI, Univ of British Columbia, Quantum Matter Institute — We study the single-hole dispersion in a layer of tetragonal CuO using a variational approach in which fluctuations between the copper spins are neglected. This approach has recently been applied to the single-particle dispersion in a CuO2 layer, where it successfully reproduces the experimentally observed dispersion. Since the CuO lattice can be viewed as two interspersed CuO2 lattices with weak intra-layer coupling, we expect this approach to be valid for CuO as well. The intra-layer coupling leads to an interesting spectral feature at \( k = (\pi/2, \pi/2) \), where it turns the minimum found in the CuO2 dispersion into a saddle point. This is a result of the intra-layer coupling lifting the degeneracy between quasiparticles occupying different sublattices.

9:36AM Y7.00009 Electric polarization and the photogalvanic effect in solids with a topological band structure1, BENJAMIN M. FREGOSO, Univ of California - Berkeley — It is known that solids without inversion symmetry can exhibit photogalvanic effects and intrinsic electric polarization, e.g., ferroelectrics. Understanding the relation between the strength of the induced current and the electric polarization has proven challenging. We report on model calculations with topologically non-trivial band structure aimed at quantifying these contributions.

1Partial support form Conacyt.

9:48AM Y7.00010 Room Temperature Ferroelectricity in Ultrathin SnTe Films1, KAI CHANG, Tsinghua University, JUNWEI LIU, Massachusetts Institute of Technology, HAICHENG LIN, KUN ZHAO, YONG ZHONG, SHUAI-HUA JI, KE HE, LILI WANG, XUCUN MA, Tsinghua University, LIANG FU, Massachusetts Institute of Technology, XI CHEN, QI-KUN XUE, Tsinghua University — The ultrathin SnTe films with several unit cell thickness grown on graphitized SiC(0001) surface have been studied by the scanning tunneling microscopy and spectroscopy (STM/S). The domain structures, local lattice distortion and the electronic band bending at film edges induced by the in-plane spontaneous polarization along (110) have been revealed at atomic scale. The experiments at variant temperature show that the Curie temperature \( T_c \) of the one unit cell thick (two atomic layers) SnTe film is as high as 280K, much higher than that of the bulk counterpart (~100K); and the 2-4 unit cell thick films even indicate robust ferroelectricity at room temperature. This \( T_c \) enhancement is attributed to the stress-free interface, larger electronic band gap and greatly reduced Sn vacancy concentration in the ultrathin films. The lateral domain size varies from several tens to several hundreds of nanometers, and the spontaneous polarization direction could be modified by STM tip. Those properties of ultrathin SnTe films show the potential application on ferroelectric devices.

10:00AM Y7.00011 A comparison of homogeneous and inhomogeneous absorption broadening in Nd doped Gadolinium Gallium Garnet1, CHRISTOPHER FERRI, SAYANTANI GHOSH, Department of Physics, University of California, Merced — We perform a temperature dependent optical absorption study of the \( ^{4}I_{9/2} \rightarrow ^{4}F_{3/2} (Z_{\text{c}} \rightarrow R_{\text{n}}) \) transition of the Neodymium dopant in Neodymium(III) doped Gadolinium Gallium Garnet. Absorption spectra are acquired for these transitions as a function of temperature from 12K to 300K. The absorption peaks are subsequently fit with Voigt profiles to measure the homogeneous and inhomogeneous broadening for each transition. We find that for the \( Z_{\text{c}} \rightarrow R_{\text{n}} \) transition the homogeneous and inhomogeneous broadening are of the same order. Below 80K, for the \( Z_{\text{c}} \rightarrow R_{\text{n}} \) transition, the homogeneous broadening is below the resolution of our spectrometer (1.85 cm\(^{-1}\)) resulting in a lower bound of \( \sim 18 \) ps for the excited state lifetime which is likely much slower. Furthermore, because of the resolution limit, the ratio of inhomogeneous broadening to homogeneous broadening for this transition has a lower bound of \( \sim 6 \).

10:12AM Y7.00012 Thermal boundary conductance of hydrophilic and hydrophobic ionic liquids1, TAKAFUMI OYAKE, MASANORI SAKATA, SUSUMU YADA, The University of Tokyo, JUNICHIRO SHIOMI, The University of Tokyo, PRESTO Japan Science and Technology — A solid/liquid interface plays a critical role for understanding mechanisms of biological and physical science. Moreover, carrier density of the surface is dramatically enhanced by electric double layer with ionic liquid, salt in the liquid state. Here, we have measured the thermal boundary conductance (TBC) across an interface of gold thin film and ionic liquid by using time-domain thermoreflectance technique. Following the prior researches, we have identified the TBC of two interfaces. One is gold and hydrophilic ionic liquid, N,N-Diethyl-N-methyl-N-(2-methoxyethyl) ammonium tetrafluoroborate (DEME-BF4), which is a hydrophilic ionic liquid, and the other is N,N-Diethyl-N-methyl-N-(2-methoxyethyl) ammonium bis(trifluoromethanesulfonyl) imide (DEME-TFSI), which is a hydrophobic ionic liquid. We found that the TBC between gold and DEME-TFSI (19 MWm\(^{-2}\) K\(^{-1}\) ) is surprisingly lower than the interface between gold and DEME-BF4 (45 MWm\(^{-2}\) K\(^{-1}\) ). With these data, the importance of the wetting angle and ion concentration for the thermal transport at the solid/ionic liquid interface is discussed.

10:24AM Y7.00013 Lattice dynamics of negative thermal expansion in ScF3, JASON HANCOCK, SAHAN HANDAKANDA, University of Connecticut, AYMAN SAID, BOGDAN LEU, Argonne National Laboratory, VLADIMIR VORONOY, Kirenskii Institute of Physics, Siberia — We present inelastic scattering spectroscopy of single-crystalline samples of negative thermal expansion material ScF3 to investigate the dispersion of lattice excitations in this unusual system. The spectra reveal important mechanistic information regarding the negative thermal expansion and show that a large class of fluorides can accommodate unconventional lattice dynamics. The connections to nonlinear and distinctly quantum phenomena will be discussed.

8:00AM Y8.00001 Sliding friction of adsorbed films on fullerene substrates with tunable conductivity1, SAMUEL KENNY, JACQUELINE KRIM, North Carolina State Univ — Friction at the nanoscale is known to encompass phononic, electrostatic, conduction electronic and magnetic effects [1], with electronic contributions being less well characterized than phononic contributions. Experiments measuring friction and diffusion of adsorbed gases on superconductors, for example, have revealed a decrease in resistance of the film concomitant with a decrease in sliding friction, but the electrical properties were difficult to fine tune.[2] Since their discovery nearly thirty years ago, C_{60} and related compounds have been widely studied in the context of photovoltaic research and related photoconductive properties. As such, they constitute ideal systems for studies of sliding friction on substrates with variable electrical resistivity.[3] We report here our quartz crystal microbalance studies of the frictional properties of adsorbate molecules sliding on fullerene films irradiated by visible laser light so as to tune the electrical resistivity of the substrate. [1] J. Krim, Advances in Physics, 61 (2012) pp. 155-323. [2] M. Highland et al., PRL (2006). [3] A. Hamed et al., PRB 47 (1993) pp. 10873-10880.

8:12AM Y8.00002 Water Interaction with Pristine and Nanopatterned Graphite Surfaces, DINKO CHAKAROV, Chalmers University of Technology — We used number of surface sensitive techniques to study and compare the interaction of water with pristine surface of highly oriented pyrolytic graphite and model nanostructured surfaces fabricated by hole-mask colloidal lithography and oxygen plasma etching. Surface morphology and concentration of defects play important role and determine the amount of water bound in two- and three-dimensional hydrogen-bonded networks and thus the structure of ice films. Similarly, the amount and concentration of inter sheet openings control the rate of water intercalation into graphite structures. The new findings are of particular interest for development of graphene exfoliation methods and for better understanding of graphene functionalization.

8:24AM Y8.00003 Quantum tunneling effects of 2-dimensional materials and their application for fast response of deep UV detectors1, PETER XIANPING FENG, Univ of Puerto Rico, ALI ALDALBAHI, Department of Chemistry, Collage of Science, King Saud University, Riyadh 11451, Saudi Arabia — We report on our approach to low substrate temperature, digital control, fast (~1 minute) synthesis of 2D single crystalline BNNSs. We focus our experiments on studies of various effects (temperature, tunneling, breakdown, polarization, subtract, thickness) on electrical and electronic properties, as well as on sensitivity, response and recovery times, repeatability, lifetime of BNNSs-based deep UV detectors. Raman scattering spectroscopy, X-ray diffraction (XRD), scanning electron microscope (SEM), Transmission electron microscopy (TEM) and electrometer were used to characterize the BNNSs. SEM and TEM measurements clearly indicate that each sample/membrane consists of a large amount of ultra-thin, high-quality BNNSs with distribution over entire surfaces of substrates (3×3 cm^2). Electrical characterization reveals the effects of temperature on the electrical conductivity of transparent BNNSs highly depend on the directions of observations in the 2D case but vanished from the 3D bulk materials or thick films.

8:36AM Y8.00004 Observation of Single and Degenerated Charge Ordering in IrTe_{2} , HYO SUNG KIM, TAE-HWAN KIM, CALDES, IBS, POSTECH, Korea, SOORAN KIM, KYOO KIM, BYUNG IL MIN, CMTL, POSTECH, Korea, YONG-HEUM CHO, JUN JIE YANG, POSTECH, Korea, SANG-WOOK CHEONG, POSTECH, Korea, Rutgers, USA, HAN WOONG YEOM, CALDES, IBS, POSTECH, Korea, STM/STS TEAM, DFT CALCULATION COLLABORATION, SAMPLE SYNTHESIZE COLLABORATION — We investigate the intriguing broken symmetry low-temperature phases of IrTe_{2} using high-resolution scanning tunneling microscopy and spectroscopy. We experimentally separate the structural and electronic modulations of the stripe phase reported previously. This result clearly indicate the charge ordering in the surface Te layer, which is consistent with the expectation of the t_{z} dimerization and charge ordering model but unambiguously denies the charge-density-wave-and-soliton model. In addition, we observe a metastable honeycomb charge-ordered phase. This phase is thought to be a 3\sqrt{3} state of the stripe phase in analogy with the 2\sqrt{3} (3\sqrt{3}) state description of the checkerboard charge order (the skymion spin order).

8:48AM Y8.00005 Surface X-Ray Scattering Studies of TiSe_{2} Thin Films Grown on Se-Terminated GaAs(111)B, XINYUE FANG, Department of Physics, University of Illinois at Urbana-Champaign, HAWOONG HONG, YANG LIU, Advanced Photon Source, Argonne National Lab, SHIH-CHANG WENG, T.-C. CHIANG, Department of Physics, University of Illinois at Urbana-Champaign — Titanium Diselenide (TiSe_{2}) is a prototypical charge density wave (CDW) compound which transforms into a commensurate (2×2×2) superstructure upon cooling to below about 200 K. This transition is marked by substantial changes in the transport properties. Although this system has been studied extensively, the underlying physical mechanism for the structural distortion is still under debate. Studying thin films of TiSe_{2} provides a means to tune the electronic interactions through reduced dimension, and the effects on the CDW transition could provide valuable information about the mechanism. We have successfully grown TiSe_{2} epitaxial films on Se-terminated GaAs(111)B substrates via MBE. The optimum growth condition has been determined, and the CDW order parameter has been measured as a function of temperature for different film thicknesses.
We have provided reasonable atomic models of \( \sqrt{3} \times \sqrt{3} \) Ag surface. At sufficiently high silicon coverage, we observe the precipitation of crystalline, sp\(^2\)-bonded Si(111) domains. These domains are capped with a \( \sqrt{3} \) honeycomb-like phase that is indistinguishable from the silver-induced \( \sqrt{3} \) honeycomb-chained-trimer reconstruction on bulk Si(111). Further \textit{ex-situ} characterization with Raman spectroscopy, atomic force microscopy, cross-sectional transmission electron microscopy, and X-ray photoelectron spectroscopy reveals that these sheets are ultrathin sheets of bulk-like, (111) oriented, sp\(^2\) silicon. Even at the 2D limit, scanning tunneling spectroscopy shows that these silicon nanosheets exhibit semiconducting electronic characteristics.

9:24AM Y8.00008 Growth of Si thin film on 6H-SiC(0001)

HSIN-JU WU, M. TIEN HOANG, YUNTAO LI, PHILLIP N. FIRST, School of Physics, Georgia Institute of Technology — Graphene is much studied for its unusual electronic properties. Other carbon group elements such as silicon (Si) and germanium (Ge) are also predicted to have stable 2D phases for which the electronic structure and properties could be even more interesting. Silicon carbide, already an excellent insulating substrate for epitaxial graphene, could potentially play a similar role for Si. Commonalities in the substrate and processing may lead to the integration of carbon and silicon technologies. Here, we use surface analysis techniques (LEED, AES, STM) to investigate the formation of 2D Si on SiC(0001), under low pressures of silane or silicon. Similar methods allow control of surface graphene growth by compensating Si desorption from SiC. Among several Si-rich reconstructions, we find a single stable hexagonal phase, at a coverage close to twice the Si density predicted for silicene, and with a unit cell consistent with a commensurate layer of silicon or silicene. For a graphitized SiC starting surface, silane is shown to produce a grafted SiC starting surface, silane is shown to etch graphene, reforming SiC.

9:36AM Y8.00009 Layering-induced Superlubricity: Gold on Graphite

ANITA VANOSSE, CNR-IOM Democritos National Simulation Center, Via Bonomea 265, 34136 Trieste, Italy, ROBERTO GUERRA, ERIO TOSATTI, International School for Advanced Studies (SISSA), Via Bonomea 265, 34136 Trieste, Italy, NANOFRICTION GROUP SISSA TEAM — By means of realistic MD simulations, we explore the static friction trend as a function of the true contact area and the model dimensionality for 2D gold nanoislands and 3D gold nanoclusters deposited on graphite, interesting tribological systems whose slow and fast dynamics have been previously investigated [1]. For increasing island size, because of the relative gold-graphite lattice mismatch, the interface stress energy has the chance to pile up by forming frustrated unmatched (i.e., incommensurate) regions and to develop a continuous solitonic pathway, foreshadowing a possible condition for the occurrence of ultra-low-friction regimes. The significant reduction of the depinning threshold, towards superlubricity, with the system dimensionality can be ascribed to a layering-induced effective stiffness of the interface, favoring the natural Au-C lattice incommensurability.

9:48AM Y8.00010 Electrostatic Manipulation of Graphene On Graphite

CARLOS UNTIEDT, CARMEN RUBIO-VERDU, GIOVANNI SAENZ-ARCE, JESÚS MARTÍNEZ-ASENCIO, DAVID C. MILAN, Universidad de Alicante, Spain, MOHAMED MOAIED, JUAN J. PALACIOS, Universidad Autónoma de Madrid, MARIA JOSE CATURLA, Universidad de Alicante, Spain — We report the use of a Scanning Tunneling Microscope (STM) under ambient and vacuum conditions to study the controlled exfoliation of the last layer of a graphite surface when an electrostatic force is applied from a STM tip. In this work we have focused on the study of two parameters: the applied voltage needed to compensate the graphite interlayer attractive force and the one needed to break atomic bonds to produce folded structures. Additionally, we have studied the influence of edge structure in the breaking geometry. Independently of the edge orientation the graphite layer is found to tear through the zig-zag direction and the lifted layer shows a zig-zag folding direction. Molecular Dynamics simulations and DFT calculations have been performed to understand our results, showing a strong correlation with the experiments.
10:12AM Y8.00012 Effects of Surface Roughness and Electron-Phonon Interaction on Electron Transport of Ultrathin Epitaxial Copper Films¹, YUKTA TIMALISNA, ANDREW HORNING, ROBERT SPIVEY, KIM LEWIS, GWO-CHING WANG, TOH-MING LUI, Center for Materials, Devices & Integrated Systems, and Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute — We report effects of surface roughness and electron-phonon interaction on transport properties of electrons in ultrathin epitaxial copper films of thickness ranging from 5 nm to 500 nm grown on Si(100) substrates. The transport of electrons in the film was examined by measuring the temperature dependent resistivity in the temperature range of 5 K to 300 K. We demonstrate that the temperature independent component of resistivity can be described by the root-mean-square-surface roughness and lateral correlation length with no adjustable parameter, using a recent quasi-classical model developed by Chatterjee and Meyerovich [1]. However, the temperature dependent component of the resistivity can be described using the Bloch-Grüneisen formula with a thickness dependent electron-phonon coupling constant and a thickness dependent Debye temperature. We show that the increase of the electron-phonon coupling constant with the decrease of film thickness gives rise to an enhancement of the temperature dependent component of the resistivity.

10:24AM Y8.00013 Interplay between Electromagnetic and Coulomb Coupling, DANHONG HUANG, US Air Force Research Laboratory, GODFREY GUMBS, Hunter College of the City University of New York, ALEXEI MARADUDIN, University of California at Irvine, BO GAO, Hunter College of the City University of New York — Both the transverse electromagnetic and longitudinal coulomb couplings of the surface-plasmon mode to the collective excitation of Dirac electrons are investigated. The unique features of coupled quantum-plasmon modes are demonstrated. The predicted dispersion relations of these quantum-plasmon modes should be experimentally observable. For a double-layer graphene structure, the interplay between the interlayer Coulomb forces and the electromagnetic coupling to each layer is calculated. The effective polarizability matrix for coupled double-layer graphene and a semi-infinite conductor is obtained for constructing an effective-medium theory, which includes correlation effects from the Coulomb interaction between electrons in graphene and the conductor as well as the electromagnetic field between them.

10:36AM Y8.00014 Semiconductor- to Metallic-like Behavior in Bi Thin Films Deposited on (100) KCl Substrate, THANH NHAN BUI, IMCN/NAPS, JEAN-PIERRE RASKIN, ICTEAM/ELEN, BENOIT HACKENS, IMCN/NAPS — Bi thin films, with a thickness of 100 nm, are deposited by electron-beam evaporation on a freshly cleaved (100) KCl substrate. The deposition temperature ranges from room temperature up to 170 °C. Scanning electron microscopy reveals that films deposited at room temperature present a maze-like microstructure on its surface typical of the rhombohedral (110) texture as confirmed by X-ray diffraction. By heating the substrate to a temperature above 80 °C during the deposition, another microstructure appears characterized by concentric triangular shapes corresponding to the trigonal texture. Temperature dependence of the resistivity from room temperature down to 10K shows a semiconductor-like behavior for films deposited at room temperature and a metallic-like behavior for films deposited above 80 °C. From low temperature magnetoresistance measurements (at 10K and up to 6 T), we extract the electronic transport parameters (mobility and charge carrier concentration). These data, together with the average grain size, help us provide an explanation for the transition between both behaviors.

10:48AM Y8.00015 Synthesis of Ultra-Thin Single Crystal MgO/Ag/MgO Multilayer for Controlled Photocathode Emissive Properties, DANIEL VELAZQUEZ, RACHEL SEIBERT, ZIKRI YUSOF, JEFF TERRY, LINDA SPENTZOURIS, Illinois Institute of Technology — Developments of new accelerator technologies such as free-electron lasers and high-energy accelerators, among others, continuously set requirements for particle sources to produce higher beam flux. The emissive properties of these photocathodes directly influence the accelerator beam flux and thus the performance of the accelerator as a whole. The objective of this project is to test the possibility of engineering the photomissive properties of materials for potential use as photocathodes. For this purpose we use a Density Functional Theory calculations by collaborator Karoly Nemeth et al. [Phys. Rev. Lett. 104, 046801, 2010], which predict a thickness dependent change in the band structure that results in a change in the work function and dispersion of occupied states at the Fermi level. Multilayered MgO/Ag/MgO in the crystallographic orientations (001) and (111) were grown on Ag/MgO(001) and Ag/Si[111], respectively using pulsed laser deposition (PLD). A series of surface probing techniques were used to characterize physical, chemical and photomissive properties of the films.

Friday, March 6, 2015 8:00AM - 11:12AM –
Session Y9 DMP: Focus Session: Honeycomb and Pyrochlore Lattices
006D - Ribhu Kaul, University of Kentucky

8:00AM Y9.00001 Electronic structure of the harmonic-honeycomb iridates α, β, γ-Li₂IrO₃, ROSER VALENTI, YING LI, HARALD O. JESCHKE, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Max-von-Laue-Straße 1, 60438 Frankfurt am Main, Germany — Using ab-initio density functional theory we investigate the electronic and magnetic properties of the harmonic-honeycomb iridates α, β, γ-Li₂IrO₃ with honeycomb, hyperhoneycomb and stripohoneycomb crystal structures, respectively. We describe the distinct features of each class of systems in terms of possible Ir-based molecular-orbitals and the implications on the magnetism in these materials. We further relate the electronic structure to proposals of generalized Kitaev-Heisenberg models.

³This work is supported by the Deutsche Forschungsgemeinschaft under Grant No. FG 1346

8:12AM Y9.00002 Magnetic Excitations in α-RuCl₃, STEPHEN NAGLER, ARNAB BANERJEE, QCMD, Oak Ridge National Laboratory, CRAIG BRIDGES, CSD, Oak Ridge National Laboratory, JIAQIANG YAN, MSTD, Oak Ridge National Laboratory, DAVID MANDRUS, Dep. of Mat. Sci. and Eng., U. Tennessee, MATTTHW STONE, ADAM ACZEL, QCMD, Oak Ridge National Laboratory, LING LI, Dep. of Mat. Sci. and Eng., U. Tennessee, JIANQUAN XU, Dep. of Physics, U. Tennessee, MARK, LUMSDEN, QCMD, Oak Ridge National Laboratory, JOHANNES KNÖLLE, RODERICH MOESSNER, Max-Planck-Institut, Dresden, ALAN TENNANT, NSciD, Oak Ridge National Laboratory — The layered material α-RuCl₃ is composed of stacks of weakly coupled honeycomb lattices of octahedrally coordinated Ru³⁺ ions. The Ru ion ground state has 5 d electrons in the low spin state, with spin-orbit coupling very strong compared to other terms in the single ion Hamiltonian. The material is therefore an excellent candidate for investigating possible Heisenberg-Kitaev physics. In addition, this compound is very amenable to investigation by neutron scattering to explore the magnetic ground state and excitations in detail. Here we discuss new time-of-flight inelastic neutron scattering data on α-RuCl₃. A high energy excitation near 200 meV is identified as a transition from the single ion J=1/2 ground state to the J=3/2 excited state, yielding a direct measurement of the spin orbit coupling energy. Higher resolution measurements reveal two collective modes at much lower energy scales. The results are compared with the theoretical expectations for excitations in the Heisenberg - Kitaev model on a honeycomb lattice, and show that Kitaev interactions are important.

³Research at SNS supported by the DOE BES Scientific User Facilities Division
8:24 AM Y9.00003 Lattice-Tuned Magnetism of Ru\textsuperscript{4+}(4d\textsuperscript{4}) Ions in Single-Crystals of the Layered Honeycomb Ruthenates: Li\textsubscript{2}RuO\textsubscript{3} and Na\textsubscript{2}RuO\textsubscript{3}\textsuperscript{1,2}, JINCHEN WANG, Renmin Univ of China, JASMINKA TERZIC, TONGFEI QI, University of Kentucky, FENG YE, Oak Ridge National Laboratory, SHUJUAN YUAN, SAICHARAN ASWARTHAM, University of Kentucky, SERGEO STREITSOV, Ural Federal University, DANIEL KHOMSKII, Universitaet zu Koeln, RIBHNU KAIL, GANG CAO, University of Kentucky — We synthesize and study single crystals of the layered honeycomb lattice Mott insulators Na\textsubscript{2}RuO\textsubscript{3} and Li\textsubscript{2}RuO\textsubscript{3} with magnetic Ru\textsuperscript{4+}(4d\textsuperscript{4}) ions. The newly found Na\textsubscript{2}RuO\textsubscript{3} features a nearly ideal honeycomb lattice and orders antiferromagnetically at 30 K. Single-crystals of Li\textsubscript{2}RuO\textsubscript{3} adopt a honeycomb lattice with either C2/m or more distorted P2\textsubscript{1}/m below 300 K, depending on detailed synthesis conditions. We find that Li\textsubscript{2}RuO\textsubscript{3} in both structures hosts a well-defined magnetic state, in contrast to the singlet ground state found in polycrystalline Li\textsubscript{2}RuO\textsubscript{3}. A phase diagram generated based on our results uncovers a new, direct correlation between the magnetic ground state and basal-plane distortions in the honeycomb ruthenates.

\textsuperscript{1}This work was supported by NSF via Grant DMR 1265162.

8:36 AM Y9.00004 Majorana metals in spin-orbit entangled quantum matter, SIMON TREBST, University of Cologne — The largely accidental balance of electronic correlations, spin-orbit entanglement, and crystal field effects of 5d transition metal oxides results in a remarkably broad variety of metallic and insulating states. In this talk, we will discuss the physics of spin-orbit entangled j=1/2 Mott insulators whose microscopic description gives rise to three-dimensional variants of the Kitaev model. The analytical tractability of this model allows to study the fractionalization of these moments into Majorana fermions (and a Z2 gauge field) and their emergent collective behavior. We show that the Majorana fermions generically form metallic states which precisely character intimately depends on the underlying lattice structure. Examples range from the well known Dirac semimetal of the two-dimensional Kitaev honeycomb model to three-dimensional metals, in which the gapless modes either form a Fermi line or a Fermi surface akin to a conventional metal [1]. We further discuss our recent finding of a Weyl spin liquid — a state with topologically protected Weyl nodes in the bulk and associated Fermi arcs on the surface [2]. Finally, we comment on the thermodynamic and transport signatures of these various Majorana metals.

Joint work with M. Hermanns and K. O’Brien.

9:12 AM Y9.00005 Gap Measurement of Na\textsubscript{2}IrO\textsubscript{3} with a Scanning Tunneling Microscope\textsuperscript{3}, ARMIN ANSARY, University of Kentucky, JOHN NICHOLS, Oak Ridge National Laboratory, GANG CAO, KWOK-WAI NG, University of Kentucky — 5d transition metal oxides such as iridates have recently stimulated substantial interest. Many exciting new phases can be found in this class of materials because of the comparable strength between spin-orbit coupling and the Coulomb interaction. In particular, we have studied high quality single crystal Na\textsubscript{2}IrO\textsubscript{3} with a scanning tunneling microscope (STM). Na\textsubscript{2}IrO\textsubscript{3} has a layered structure with a honeycomb lattice. The gap is measured to be about 400 meV according to the dI/dV curve, which is consistent with optical measurements. We will show topographic images and discuss the evolution of the density of states and the behavior of the gap from room temperature down to 100 K.

\textsuperscript{3}This work was supported by the National Science Foundation under grant DMR-1265162.

9:24 AM Y9.00006 Spin-orbit correlated magnetic order in honeycomb \(\alpha\)-RuCl\textsubscript{3}, VIJAY SHANKAR VENKATARAMAN, HEUNG-SIK KIM, HAE-YOUNG KEE, University of Toronto — There has been a lot of recent interest in the combined effects of spin-orbit coupling (SOC) and electronic correlations in transition metal compounds. RuCl\textsubscript{3} with layered honeycomb structure was proposed as a candidate material, where SOC boosts the electronic interaction, leading to an insulating phase. However, the role of SOC is not clear in materials with 4d-orbitals, since SOC strength is weaker than 5d-orbitals. Here we study electronic band structures of honeycomb RuCl\textsubscript{3} using ab-initio and tight binding methods, and estimate its SOC strength. We find that SOC in RuCl\textsubscript{3} is not strong enough to justify an effective j_{ eff} = 1/2 single band unlike the iridates. However, when electronic interactions are introduced, a magnetic order develops, and upper- and lower-Hubbard bands are characterized by j_{ eff} = 1/2 and 3/2, respectively. Within a mean field theory with multi-orbital bands, we find that a zig-zag magnetic order is a ground state. Experimental implications are also discussed.

9:36 AM Y9.00007 Structure and magnetic ground states of spin-orbit coupled compound alpha-RuCl\textsubscript{3}\textsuperscript{1}, ARNAB BANERJEE, Quantum Condensed Matter Division, ORNL, USA, CRAIG BRIDGES, Chemical Sciences Division, ORNL, USA, JIAQIANG YAN, Material Sciences Division, ORNL, USA, DAVID MANDRUS, Department of Physics, University of Tennessee, Knoxville, USA, MATTHEW STONE, ADAM ACZEL, Quantum Condensed Matter Division, ORNL, USA, LING LI, YUEN YIU, Department of Physics, University of Tennessee, Knoxville, USA, MARK LUMSDEN, BRYAN CHAKOUMAKOS, Quantum Condensed Matter Division, ORNL, USA, ALAN TENNANT, Neutron Sciences Directorate, ORNL, USA, STEPHEN NAGLER, Quantum Condensed Matter Division, ORNL, USA — The layered material alpha-RuCl\textsubscript{3} is composed of stacks of weakly coupled honeycomb lattices of octahedrally coordinated Ru\textsuperscript{3+} ions. The Ru ion ground state has 5 d electrons in the low spin state, with spin-orbit coupling very strong compared to other terms in the single ion Hamiltonian. The material is therefore an excellent candidate for investigating possible Heisenberg-Kitaev physics. In addition, this compound is very amenable to investigation by neutron scattering to explore the magnetic ground state and excitations in detail. In this talk, we discuss the synthesis of phase-pure alpha-RuCl\textsubscript{3} and the characterization of the magnetization, susceptibility, and heat-capacity. We also report neutron diffraction on both powder and single crystal alpha-RuCl\textsubscript{3}, identifying the low temperature magnetic order observed in the material. The results, when compared to theoretical calculations, shed light on the relative importance of Kitaev and Heisenberg terms in the Hamiltonian.

\textsuperscript{1}The research is supported by the DOE BES Scientific User Facility Division

9:48 AM Y9.00008 Quantum phase transition and anomalous Hall effect in a pyrochlore Kondo lattice, SARAH GREEF, WENXIN DING, QIMIAO SI, Rice University — Motivated by recent experimental evidence for a possible chiral spin liquid phase in the metallic pyrochlore heavy fermion iridates \(\text{Pr}_2\text{Ir}_2\text{O}_7\) [Phys.Rev.Lett. 96, 087204 (2006), Phys.Rev.Lett 98, 057203 (2007), Nature 463, 210 (2010)] as well as quantum critical behavior in this system [Nat. Mater. 13, 356 (2014)], we study the effect of Kondo coupling on various spin liquid states of the Heisenberg model on pyrochlore lattices, including states exhibiting time-reversal-symmetry-breaking. Using a slave fermion representation for the f-moments which are coupled to conduction electrons, we study the large-N limit to determine the ground state energies of various feasible states and map out the zero-temperature phase diagram. We calculate the anomalous Hall response across the quantum phase transition from the Kondo destroyed phase to the Kondo screened phase. Finally we discuss the implications of our results for the properties of \(\text{Pr}_2\text{Ir}_2\text{O}_7\).
10:00AM Y9.00009 Ab Initio Simulations of the Structure and Energetics of Harmonic Honeycomb Iridates 1. TESS SMIDT, QIMIN YAN, JEFFREY NEATON, Univ of California - Berkeley — Edge-sharing iridates present an exciting opportunity to study the competition of Mott insulator physics and strong spin-orbit coupling. Harmonic honeycomb iridates are a recently discovered homologous series of stoichiometrically identical structures that host anisotropic magnetism and exotic spin ordering. We use density functional theory and lattice kinetic Monte Carlo to investigate structural, energetic, and entropic trends in determining the equilibrium ground states of harmonic honeycomb iridates. We predict the formation energies and geometry of as-yet unsynthesized series members and propose why some structures are more prevalent than others.

10:12AM Y9.00010 Rotated Heisenberg model 1. FADI SUN, JINWU YE, Mississippi State University, WU-MING LIU, Institute of Physics Chinese Academy of Sciences — We show that Rotated Heisenberg (RH) model is a new class of quantum spin models to describe magnetic materials with strong spin-orbit couplings (SOC). We introduce Wilson loops to characterize frustrations and gauge equivalent class. For a special equivalent class, we identify a new spin-orbital entangled commensurate ground state. It supports a novel gapped elementary excitation named as in-commensurate magnons which have two gap minima continuously tuned by the SOC strength. At low temperatures, the in-commensurate magnons lead to dramatic effects in all physical quantities such as density of states, specific heat, magnetization and various spin correlation functions. At high temperatures, the specific heat and transverse spin structure factors depend on the SOC strength explicitly. We argue that one gauge may be realized in current experiments and other gauges may also be realized in near future experiments. Various experimental detections are discussed.

10:24AM Y9.00011 Collective modes in two- and three-dimensional electron systems with Rashba spin-orbit coupling 1. SAURABH MAITI, University of Florida, Gainesville and National High Magnetic Field Lab, Tallahassee, VLADIMIR ZYUZIN, DMITRII MASLOV, University of Florida, Gainesville — In addition to charge plasmons, a 2D electron system with Rashba-type spin-orbit coupling (SOC) also supports three collective modes in the spin sector: the chiral-spin modes. We study the dispersions of the charge and spin modes and their coupling to each other within a generalized RPA for arbitrarily strong SOC, and both in 2D and 3D systems. We find that the charge plasmons are coupled to only one of the three chiral-spin modes. In 3D, the chiral-spin modes are strongly damped by particle-hole excitations and disappear for weak electron-electron interaction. Landau damping of the chiral-spin modes in 3D is directly related to the fact that, in contrast to 2D, there is no gap for particle-hole excitations between spin-split subbands. The gapless continuum is also responsible for Landau damping of the charge plasmon in 3D - a qualitatively new feature of the SOC system. The in-plane transverse chiral-spin mode shows up as dispersing peak in the optical conductivity at finite wave number which can be measured in the presence of diffraction gratings. We also discuss possible experimental manifestations of chiral-spin modes in semiconductor quantum wells such InGaAs/AlGaAs and 3D giant Rashba materials of the BiTel family.

10:36AM Y9.00012 Anderson Impurity in Dirac and Weyl semimetals 1. JINHUA SUN, DONG-HUI XU, FU-CHUN ZHANG, YI ZHOU, Department of Physics, Zhejiang University, Hangzhou, China — We utilize variational method to study the Kondo screening of an Anderson impurity in three-dimensional Dirac and Weyl semimetals. We find that the spin correlation between the magnetic impurity and conduction electrons in both the systems are strongly anisotropic due to the spin-orbit coupling, and the spin-spin correlations are of power-law decay in both systems. The differences between Dirac and Weyl semimetals are also investigated.

10:48AM Y9.00013 Magnetic-field control of topological charge-transport properties in Nd$_3$Ir$_2$O$_7$ 1. KENTARO UEDA, Department of Applied Physics and Quantum-Phase Electronics Center (QPEC), University of Tokyo, BOHM-JUNG YANG, RIKEN Center for Emergent Matter Science (CEMS), JUN FUJOKA, Department of Applied Physics and Quantum-Phase Electronics Center (QPEC), University of Tokyo, JUNICHI SHIOGAI, ATSUSHI TSUKAZAKI, Institute for Materials Research, Tohoku University, NAOTO NAGAOSA, YOSHINORI TOKURA, Department of Applied Physics and Quantum-Phase Electronics Center (QPEC). University of Tokyo — Nd$_3$Ir$_2$O$_7$ is a novel quantum phase with topological properties where the linear-dispersive band with a surface Fermi arc state is realized in a three-dimensional bulk. Pyrochlore-type R$_2$Ir$_2$O$_7$ is one of the promising candidates for realization of the Weyl semimetal. In this system, the magnetic ordering pattern is predicted to play a key role for characterizing its electronic band structure. We report the magnetic-transport properties in Nd$_3$Ir$_2$O$_7$ single crystals for several magnetic field directions. We reveal that all-in-all-out type magnetic domain walls, at which the conductive mode inherent to the surface state of Weyl semimetal may be preserved, are finely controlled by an applied field along [111] direction showing unique hysteresis in resistivity. With applied field along [001] direction, the Nd-4f moment forms 2-in-2-out configuration that turns the isolating state into the anomalous metallic one near the Weyl (semi-)metal phase. A mean-field calculation consistent with topological properties where the linear-dispersive band with a surface Fermi arc state is realized in a three-dimensional bulk.

1This work was supported by the National Science Foundation via grant NSF DMR-1308972.

11:00AM Y9.00014 Intrinsic Damping of Collective Spin Modes in a Two-Dimensional Fermi Liquid with Spin-Orbit Interaction 1. DMITRII MASLOV, University of Florida, Gainesville, SAURABH MAITI, University of Florida, Gainesville and National High Magnetic Field Lab., Tallahassee — We address the issue damping of spin collective modes in systems with spin orbit coupling in 2D. We show that these modes exist for arbitrary nature of spin-orbit coupling and are intrinsically damped even in the long wavelength limit. This damping is driven by electron-electron interactions and is unique to spin orbit coupled systems. Its origin is linked to an imperfect cancellation of the self energy and vertex contributions of the interaction. In the Fermi-liquid language, this is an effect arising from residual interaction between quasiparticles. This damping mechanism exists already at T=0 and without impurities and/or phonons. We also discuss the consequences of this damping for the experiment.

Session Y10 DCMP: Topological Insulators: Band Structures Theory 007A - Philip Brydon, University of Maryland
8:00AM Y10.00001 The Viscoelastic Response of Topological Tight Binding Models. HASSAN SHAPOURIAN, TAYLOR L. HUGHES, SHINSEI RYU, Univ of Illinois - Urbana — The topological response to external perturbations is an effective probe to characterize different topological phases of matter. The Hall viscosity is an example of such a response which has been the subject of a great interest recently. So far, most of studies have focused on the continuum field theories. Here, we investigate this response for the tight binding (lattice) models. The presence of lattice breaks the continuous translational symmetry to a discrete symmetry and this causes two complications: it introduces a new length scale associated with lattice constant and makes the momentum a compact variable. We develop two different methods of how to implement a lattice deformation: (1) the lattice distortion is equal to one half of (1−ϕ)/2 (ϕ is the hopping parameter) micropipet view is adopted and the lattice deformation appears in the gradient expansion of the hopping matrix elements. Consequently, we compute the Hall viscosity through the linear response (Kubo) formula. We examine these methods for three models: the Hofstadter model, the Chern insulator, and the surface of a 3D topological insulator. Our results in certain regimes of parameters, where the continuum limit is relevant, are in agreement with the field theory calculations.

8:12AM Y10.00002 Direct Manifestation of the Band Topology via the Zak Shift of the Wannier-Stark Ladder. WOO-ROM LEE, KWON PARK, Korea Inst for Advanced Study — Topological phases of matter have been topics of intense interest in modern condensed matter physics. Numerous efforts have been devoted to investigating various exotic properties of materials with non-trivial band topology. The dissipationless transport via gapless helical edge or surface states is one of the defining properties of such materials, which, however, has been very difficult to realize in experiment due to various backscattering sources induced in the sample boundaries. In this work, we show that there is a fundamental connection between the non-trivial topology of the band structure and the Zak shift of the Wannier-Stark ladder emerging under a static electric field. As an application of this connection, we propose a novel spectroscopic method to directly manifest the band topology by counting the winding number of the Zak phase across the first Brillouin zone, which is shown to be robust against electron-impurity scattering.

8:24AM Y10.00003 Strong orientation dependence of electronic properties of Antimony Selenide (Sb$_2$Se$_3$) nanostructures. RAJASEKARAKUMAR VADAPOO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, USA, SRIDEVI KRISHNAN, Institute of Materials Science, University of Connecticut, CT 06269, USA, HULUSI YILMAZ, Dept. Of Engineering, Zaman University, Phnom Penh, Cambodia, CARLOS MARIN, Institute for Functional Nanomaterials and Department of General Engineering, University of Puerto Rico, Mayaguez, PR 00681, USA — Antimony Selenide has applications in thermoelectric, photovoltaic and optical storage. Recently, it was demonstrated that bulk material under high pressure becomes a topological insulator and further undergoes insulator to metal to superconducting transitions. The Sb$_2$Se$_3$ nanostructures reported so far exhibit direct bandgaps, whereas the bulk has an indirect gap. Considering different crystallographic orientations of synthesized nanostructures and the anisotropic nature of its structure, we have studied the influence of orientation on their electronic behavior. Using first principle methods, we explore the stability of nanowires in different orientations and its influence on electronic structure. We find confinement effects for the narrower nanostructures, whereas the [001] orientation showed a reduced bandgap. This anomalous behavior is discussed considering that bandgap reduction could be attributed to recent experimental findings of an insulator-metal transition, which is related to topological quantum transition. The surface reconstructions show similarities to the distortion of polyhedras occurring in bulk Sb$_2$Se$_3$ under high pressure, which are related to the insulator-metal transition and superconductivity at 8.0 K.

8:36AM Y10.00004 Topological characterization and dynamics of a fermionic fractional Chern insulator. FRANK POLLMANN, ADOLFO GRUSHIN, JOHANNES MOTRUK, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, MICHAEL ZALETEL, Stanford University, US — Using the density matrix renormalization group (DMRG) method on a cylinder geometry, we characterize the fractional Chern insulator (FCI) state in the Haldane honeycomb lattice model at ν = 1/3 filling of the lowest band and check its stability. We investigate the chiral and topological properties of this state through (i) its Hall conductivity, (ii) the topological entanglement entropy, (iii) the U(1) charge spectral flow of the many body entanglement spectrum, and (iv) the charge of the anyons. As the interaction strength is lowered, we observe a direct transition from the FCI into a metallic phase and find indications for the transition to be of first order. Since our approach does not rely on any band or subspace projection, we are able to prove the stability of the fractional state in the presence of interactions exceeding the band gap, as has been suggested in the literature. Additionally, we investigate the characteristic dynamics of the FCI phase using time dependent DMRG.

8:48AM Y10.00005 Disorder and inversion symmetry breaking effect in Chern insulators. LUCIAN COVACI, University of Antwerp, JOSE GARCIA, TATIANA RAPPORPT, Universidade Federal do Rio de Janeiro — We show that Chern insulators with and without inversion symmetry respond differently to strong disorder. We consider a Haldane model with Anderson disorder and use a real-space numerical approach to calculate the conductivity tensor of a Haldane model in the presence of Anderson disorder. The inversion symmetry is explicitly broken by adding a sub-lattice potential $\Delta_{AB}$. While disorder closes the gap and destroys the Chern insulator in the system with inversion symmetry, the quantum anomalous Hall effect is insensitive to increasing Anderson disorder in the case of broken symmetry. In this case, the symmetry breaking works as a valley filter that protects the topological state from inter-valley scattering and strong disorder gives rise to a novel topological state that is similar to the topological Anderson insulator.

9:00AM Y10.00006 Topological phase transition in the Hofstadter- Hubbard model. HSIANG-HSUAN HUNG, Department of Physics, University of Texas at Austin, LEI WANG, MATTHIAS TROYER, Theoretische Physik, ETH — We study the interplay between topological and conventional long-range order of attractive fermions in a time-reversal-symmetric Hofstadter lattice using quantum Monte Carlo simulations, focusing on the case of one-third flux quantum per plaquette. At one-third filling, the noninteracting system is a topological insulator, and a nonzero critical interaction strength is needed to drive a transition from the quantum spin Hall insulator to a superfluid. We probe the topological signature of the phase transition by threading a magnetic flux through a cylinder and observe quantized topological charge pumping.

9:12AM Y10.00007 Non-trivial edge physics in a featureless Mott insulator. BRAYDEN WARE, Univ of California - Santa Barbara, ITAMAR KIMCHI, Univ of California - Berkeley, SIDDHARTH PARMESWARAN, Univ of California - Irvine, BELA BAUER, Station Q, Microsoft Research, Santa Barbara, CA — While the Lieb-Schultz-Mattis theorem forbids the existence of fully symmetric quantum paramagnetic phases on lattices with fractional filling of particles per unit cell, such a phase is in principle allowed with certain fractional numbers of particles per site on non-Bravais lattices, including half-filling on the honeycomb lattice. It has been shown that a non-interacting Hamiltonian of spinless fermions or bosons cannot have such a symmetric insulating ground state, and an explicit construction using interactions is challenging. Recently, Kimchi et al. constructed a wavefunction for bosons at half-filling that does not break any symmetries and is not topologically ordered—and in this sense is a featureless insulator in the bulk. Here, however, we reveal that this wavefunction exhibits non-trivial structure at the edge. We apply recently developed techniques based on a tensor network representation of the wavefunction to demonstrate the presence of a gapless entanglement spectrum and a non-trivial action of combined charge-conservation and spatial symmetries on the edge. We will also discuss the possibility of finding a parent Hamiltonian and analyzing the existence of a symmetry-protected topological phase around this state.

9:24AM Y10.00008 ABSTRACT WITHDRAWN
9:36AM Y10.00009 Bound states of three fermions forming symmetry-protected topological phases. CHONG WANG, Massachusetts Inst of Tech-MIT — We propose a simple theoretical construction of certain short-range entangled phases of interacting fermions, by putting the bound states of three fermions (which we refer to as clustons) into topological bands. We give examples in two and three dimensions, and show that they are distinct from any free fermion state. We further argue that these states can be viewed as combinations of certain free fermion topological states and bosonic symmetry-protected topological (SPT) states. This provides a conceptually simple understanding of various SPT phases.

9:48AM Y10.00010 Generalized Dirac points and topological surface states in a three-dimensional nonsymmorphic photonic crystal. LING LU, CHEN FANG, TIMOTHY HSIEH, LIANG FU, JOHN JOANNOPOULOS, MARIN SOLJACIC. Massachusetts Institute of Technology — In condensed matter physics, the three-dimensional (3D) Dirac equation describes low-energy excitations of spin-$\frac{1}{2}$ electrons in quantum materials ranging from topological insulators to Dirac semimetals. Here we discover, in photonic crystals, the existence of robust 3D linear point degeneracies between two pairs of band crossings with different velocities. Based on symmetry considerations, we demonstrate that such dispersion is governed by a generalization of 3D Dirac equation for spin-$\frac{1}{2}$ photons propagating in a periodic medium. This 3D Dirac phase in photonic crystals represents a new topological phase of matter protected by nonsymmorphic crystal symmetry and exhibits novel two-dimensional surface states, which we characterize. Time-reversal symmetry is preserved but not required in our photonic system.

10:00AM Y10.00011 Accurate band gaps of semiconductors and insulators from Quantum Monte Carlo calculations. ROMAN NAZAROV, RANDOLPH HOOD, MIGUEL MORALES, LLNL — Ab initio calculations are useful tools in developing materials with targeted band gaps for semiconductor industry. Unfortunately, the main workhorse of ab initio calculations – density functional theory (DFT) in local density approximation (LDA) or generalized gradient approximation (GGA) underestimates band gaps. Several approaches have been proposed starting from empirical corrections to more elaborate exchange-correlation functionals to deal with this problem. But none of these work well for the entire range of semiconductors and insulators. Deficiencies of DFT as a mean field method can be overcome using many-body techniques. Quantum Monte Carlo (QMC) methods can obtain a nearly exact numerical solutions of both total energies and spectral properties. Diffusion Monte Carlo (DMC), the most widely used QMC method, has been shown to provide gold standard results for different material properties, including spectroscopic constants of dimers and clusters, equation of state for solids, accurate descriptions of defects in metals and insulators. To test the accuracy in a wider range of semiconductors and insulators we have computed band gaps of several semiconductors and insulators. We show that DMC can provide superior agreement with experiment compared with more traditional DFT approaches including high level exchange-correlation functionals (e.g. HSE).

10:12AM Y10.00012 ABSTRACT WITHDRAWN —

10:24AM Y10.00013 ABSTRACT WITHDRAWN —

Friday, March 6, 2015 8:00AM - 10:48AM — Session Y11 GSNP: Statistical Mechanics of Social Systems 007B - Manolis Antonoyiannakis, Columbia University

8:00AM Y11.00001 Transition between different search patterns in human online search behavior1. XIANGWEN WANG, MICHEL PLEIMLING, Virginia Tech — We investigate the human online search behavior by analyzing data sets from different search engines. Based on the comparison of the results from several click-through data-sets collected in different years, we observe a transition of the search pattern from a Lévy-flight-like behavior to a Brownian-motion-type behavior as the search engine algorithms improve. This result is consistent with findings in animal foraging processes. A more detailed analysis shows that the human search patterns are more complex than simple Lévy flights or Brownian motions. Notable differences between the behaviors of different individuals can be observed in many quantities.

1This work is in part supported by the US National Science Foundation through grant DMR-1205309.

8:12AM Y11.00002 Social consensus and tipping points with opinion inertia2, CASEY DOYLE, SAMEET SREENIVASAN, BOLESLAW SZYMANSKI, GYORGY KORNISS, Rensselaer Polytech Institute — When opinions, behaviors or ideas diffuse within a population, some are invariably more sticky than others. The stickier the opinion, the greater an individual’s inertia to replace it with an alternative. Here we study the effect of stickiness of opinions in a two-opinion model, where individuals change their opinion only after a certain number of consecutive encounters with the alternative opinion. We focus on the scenario where initially a minority of the population adopts an opinion that is as sticky or stickier than that of the majority, and investigate how the critical size of the initial minority required to tip the entire population over to its opinion, depends on the stickiness of the minority opinion. We analyze this scenario for a complete-graph topology through simulations, and through a semi-analytical approach which yields an upper bound for the critical size of the minority. We present analogous simulation results for the case of the Erdos-Rényi random network. Finally, we investigate the coarsening properties of sticky opinion spreading on two-dimensional lattices, and show that the presence of stickiness gives rise to an effective surface tension that causes the coarsening behavior to become curvature-driven.

2Supported in part by ARL NS-CTA, ARO, ONR, and NSF.

8:24AM Y11.00003 A Universal Power Law Governing Pedestrian Interactions3. IOANNIS KARAMOUIZAS, Univ of Minn - Minneapolis, BRIAN SKINNER, Argonne National Laboratory, STEPHEN J. GUY, Univ of Minn - Minneapolis — Human crowds often bear a striking resemblance to interacting particle systems, and this has prompted many researchers to describe pedestrian dynamics in terms of interaction forces and potential energies. The correct quantitative form of this interaction, however, has remained an open question. Here, we introduce a novel statistical-mechanical approach to directly measure the interaction energy between pedestrians. This analysis, when applied to a large collection of human motion data, reveals a simple power law interaction that is based not on the physical separation between pedestrians but on their projected time to a potential future collision, and is therefore fundamentally anticipatory in nature. Remarkably, this simple law is able to describe human interactions across a wide variety of situations, speeds and densities. We further show, through simulations, that the interaction law we identify is sufficient to reproduce many known crowd phenomena.

8:36AM Y11.00004 Finite size scaling analysis on Nagel-Schreckenberg model for traffic flow
, ASHKAN BALOUCHI, DANITA BROWNE, Department of Physics & Astronomy, Louisiana State University — The traffic flow problem as a many-particle non-equilibrium system has caught the interest of physicists for decades. Understanding the traffic flow properties and their resulting effects on the human behavior has been a critical field of study in the 21st century. Here we study the critical value for the density of vehicles to achieve the jammed phase in the Nagel-Schreckenberg model. We present our results for different system sizes and compare our findings with the exact solution for infinite systems. We find that the critical value changes with the system size and that the finite size effects become more pronounced as the size of the network is increased.

, VRINKANT YADAV, ARSHAD KUDROLLI, Clark University — We model the behavior of traffic using Self Propelled Particles (SPPs). Granular rods with asymmetric mass distribution confined to move in a circular channel on a vibrated substrate and interact through elastic collisions act as our model vehicle. Motion of a single vehicle is observed to be composed of 2 parts, a linear velocity in the direction of lighter end and a non-Gaussian asymmetric mass distribution confined to move in a circular channel on a vibrated substrate and interact through inelastic collisions serve as our model vehicle. Our model captures the behavior of traffic congestion in a low-dimensional network, and we conclude by analyzing the scaling behavior of the non-equilibrium system has caught the interest of physicists for decades. Understanding the traffic flow properties and their resulting effects on the human behavior have been a critical field of study in the 21st century. Here we study the critical value for the density of vehicles to achieve the jammed phase in the Nagel-Schreckenberg model. We present our results for different system sizes and compare our findings with the exact solution for infinite systems. We find that the critical value changes with the system size and that the finite size effects become more pronounced as the size of the network is increased.

9:00AM Y11.00006 Dynamics of influence and social balance in spatially-embedded regular and random networks
, P. SINGH, S. SREENIVASAN, B. SZYMANSKI, G. KORNIS, RPI — Structural balance affects deradicalization in an otherwise polarized population of leftists and rightists constituting the nodes of a low-dimensional social network. Specifically, assuming an externally moderating influence that converts leftists or rightists to centrists with probability $p$, we study the critical value $p_c$, below which the presence of metastable mixed population states exponentially delay the achievement of centrist consensus. Above the critical value, centrist consensus is the only fixed point. Complementing our previous results on complete graphs, we present results for the process on low-dimensional social networks, and show that the low-dimensional embedding of the underlying network significantly affects the critical value of probability $p$. Intriguingly, on low-dimensional networks, the critical value $p_c$ can show non-monotonicity as the dimensionality of the network is varied. We conclude by analyzing the scaling behavior of the temporal variation of unbalanced triad density in the network for different low-dimensional network topologies.

9:12AM Y11.00007 Self-organization of divided hierarchy
, TAKASHI ODAKAGI, KEIGO KITADA, KENTA OMIZO, Tokyo Denki University, RYO FUJIE, The University of Tokyo — There are two types of extreme form of hierarchy, one is the plutonomy where small fraction of winners and losers and many people in the middle class appear and the other a divided hierarchy where half of population become winners and the remaining half become losers. We study the emergence of the divided hierarchy in a model society which consists of bellicose individuals who always try to fight and fight with the strongest or the weakest individual. In our model society $(1)$ individuals make random walk on a square lattice, $(2)$ when two individuals encounter they fight each other and $(3)$ the winner deprives wealth from the loser. By a Monte Carlo simulation, we show that there are two transitions when the population density is increased; one is a transition from the egalitarian society to a hierarchical society I where winners, losers and middle classes coexist and the other is a transition from the hierarchical society I to a hierarchical society II where winners and losers exist but no middle classes exist, that is the divided hierarchy. We also show that clusters consisting mostly of bellicose individuals appear in the hierarchical society I.

9:24AM Y11.00008 Canonical Sectors and Evolution of Firms in the US Stock Markets
, LORIEN HAYDEN, RICKY CHACHRA, ALEXANDER ALEMI, PAUL GINSZPARG, JAMES SETHNA, Cornell University — In this work, we show how an unsupervised machine learning can provide a more objective and comprehensive broad-level sector decomposition of stocks. Classification of companies into sectors of the economy is important for macroeconomic analysis, and for investments into the sector-specific financial indices and exchange traded funds (ETFs). Historically, these major industrial classification systems and financial indices have been based on expert opinion and developed manually. Our method, in contrast, produces an emergent low-dimensional structure in the space of historical stock price returns. This emergent structure automatically identifies “canonical sectors” in the market, and assigns every stock a participation weight into these sectors. Furthermore, by analyzing data from different periods, we show how these weights for listed firms have evolved over time.

9:36AM Y11.00009 Lead-lag relationships between stock and market risk within linear response theory
, STANISLAV BORYSOV V, ALEXANDER BALATSKY Y, Nordita, KTH Royal Institute of Technology and Stockholm University, Roslagstullsbacken 23, SE-106 91 Stockholm, Sweden — We study historical correlations and lead-lag relationships between individual stock risks and the market risk (standard deviation of daily returns) and market risk (standard deviation of daily returns of a market-representative portfolio) in the US stock market. We consider the cross-correlation functions averaged over stocks, using historical stock prices from the Standard & Poor’s 500 index for 1994-2013. The observed historical dynamics suggests that the dependence between the risks was almost linear during the US stock market downturn of 2002 and after the US housing bubble in 2007, remaining at that level until 2013. Moreover, the averaged cross-correlation function often had an asymmetric shape with respect to zero lag in the periods of high correlation. We develop the analysis by the application of the linear response formalism to study underlying causal relations. The calculated response functions suggest the presence of characteristic regimes near financial crashes, when individual stock risks affect market risk and vice versa.

, XIAOXIANG YANG, CONAN ZHAO, IRINA MAZILIU, Washington and Lee University — Due to incomplete information available in the market and uncertainties associated with the price determination process, the stock prices fluctuate randomly during a short period of time. In the long run, however, certain economic factors, such as the interest rate, the inflation rate, and the company’s revenue growth rate, will cause a gradual shift in the stock price. Thus, in this paper, a differential equation model has been constructed in order to study the effects of these factors on the stock prices. The model obtained accurately describes the general trends in the AAPL and XOM stock price changes over the last ten years.
used for the identification of large transitions for various threshold distributions. The transition point is independent of the system size, while the contribution of the rest of the initiators converges to zero at infinite system size. This property is largely independent of the system size in the network. There is a critical fraction of initiators for which a transition from small to large cascades occurs, which for Erdős-Rényi (ER) graphs is a uniform threshold in the network. Opinion dynamics is the Threshold Model (TM) aiming to model the spread of a new opinion based on the social drive of peer pressure. Under the TM a node adopts a new opinion only when the fraction of its first neighbors possessing that opinion exceeds a pre-assigned threshold. Cascades in the TM depend on multiple parameters, such as the number and selection strategy of the initially active nodes (initiators), and the threshold distribution of the nodes. For a uniform threshold in the network there is a critical fraction of initiators for which a transition from small to large cascades occurs, which for ER graphs is largely independent of the system size [2]. Here, we study the spread contribution of each newly assigned initiator under the TM for different initiator selection strategies for synthetic graphs of various sizes. We observe that for ER graphs when large cascades occur, the spread contribution of the added initiator on the transition point is independent of the system size, while the contribution of the rest of the initiators converges to zero at infinite system size. This property is used for the identification of large transitions for various threshold distributions.

10:24AM Y11.00013 Collective behavior in the evolution of scientific research interests, TAO JIA, Department of Physics and Computer Science, Rensselaer Polytechnic Institute, Troy, NY, 12180 USA, DASHUN WANG, IBM Thomas J. Watson Research Center, Yorktown Heights, NY, 10598 USA, GYORGY KORNISS, Department of Physics, Rensselaer Polytechnic Institute, Troy, NY, 12180 USA, BOLESLAW SZYMANSKI, Department of Computer Science, Rensselaer Polytechnic Institute, Troy, NY, 12180 USA — Scientific research is strongly associated with the researchers’ interests in particular areas or disciplines. On one hand, the stable research interest enables one to gain the expertise by repetitive practices specialized in a certain field. On the other hand, occasional change on the area of interest may reinvigorate one’s research. To date, we lack a quantitative understanding on the likelihood of the research interest change, the consequent impact and the internal mechanism of this dynamical process. Here we analyze the publication records of over 14,000 scientists and quantitatively measure their research interest transitions. Our result shows that the fraction of scientists drops exponentially with the extent of transition, indicating that most scientists keep their interests quite stable. While it is rare, those who change demonstrate a higher-than-average chance to increase the productivity and impact. We propose a theoretical model that reproduces not only the observations in interest evolution but also the patterns of publication activities, allowing us to probe the short-term benefits of exploitation on the established field and the long-term returns of exploration on the new lines of inquiry.

10:36AM Y11.00014 Median Citation Index vs Journal Impact Factor, MANOLIS ANTONOYIANNAKIS, JUN-ICHI INOUE, HE CHEN, Kokaido University — We discuss social inequalities in labor markets for university graduates in Japan by using the Gini and k-indices [1]. Feature vectors which specify the abilities of candidates (students) are built into the probabilistic labor market model [2]. Here we systematically examine what kind of selection processes (strategies) by companies according to the weighted feature vector of each candidate could induce what type of inequalities in the number of informal acceptances leading to a large mismatch between students and companies.

Median Citation Index vs Journal Impact Factor, MANOLIS ANTONOYIANNAKIS, (1) Columbia University (2) American Physical Society — The Journal Impact Factor is an arithmetic mean: It is the average number of citations, in a year, to a journal’s articles that were published the previous two years. But for the vast majority of scholarly journals, the distribution of these citations is skewed (non-symmetric). We argue that a more representative member of the skewed distribution of citations is its median, not the mean. We thus introduce the Median Citation Index (MCI) and compare it to the Journal Impact Factor (JIF) as a potentially more suitable choice of the “center” of the distribution, or its typical value. Unlike the JIF, the MCI is far less sensitive to outlier (very highly cited) papers or to gaming, and does not lend itself to the hype of calculating it to three decimal digits.

Friday, March 6, 2015 8:00AM - 10:48AM – Session Y12 DCMP: Spectroscopy on Topological Insulators 007C - Andrew Wray, New York University

8:00AM Y12.00001 Surface Plasmons in 3D Topological Insulators, ANSHUL KOGAR, SEAN VIG, GIL CHO, ALEXANDER THALER, YIRAN XIAO, TAYLOR HUGHES, MAN-HONG WONG, TAI-CHANG CHANG, GREG MACDOUGALL, PETER ABBAMONTE, Univ of Illinois - Urbana — Most studies of three-dimensional (3D) topological insulators have concentrated on their one-electron properties as exhibited by angle-resolved photoemission spectroscopy (ARPES) or by scanning tunneling microscopy (STM). Many-body interactions are often neglected in the treatment of models of topological insulators, such as in the Kane-Mele and Bernevig-Hughes-Zhang models. Using angle-resolved inelastic electron scattering from the surface, I will present data on the collective mode that owes its existence to the presence of many-body interactions, the surface plasmon (SP), in two known 3D topological insulators, Bi2Se3 and Bi0.5Sb1.5Se1.5-xTe1.5-x. Surprisingly, the SP was prominent even after depressing the Fermi energy into the bulk band gap. Having studied the SP as a function of doping, momentum transfer and its aging properties, I will present evidence to suggest that bulk-surface coupling is crucial in explaining many of its properties. A simple model with dynamic bulk screening will be presented showing qualitative agreement with the observations. Lastly, the relation of the observed surface plasmon to the predicted spin-plasmon mode and to the kinks seen in the electronic dispersion as measured by ARPES will be discussed.

The work was supported as part of the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science.

8:12AM Y12.00002 Scanning tunneling spectroscopy investigation of the topological phase transition in (Bi$_{1-x}$In$_x$)$_2$Se$_3$. - DANIEL WALKUP, WENWEN ZHOU, ILIJA ZELIKOVIC, Boston College, YOSHINORI OKADA, Tohoku University, ZHENSONG REN, KANE SCIPIONI, Boston College, STEPHEN WILSON, Boston College and University of California Santa Barbara, VIDYA MADHAVAN, Boston College and University of Illinois Urbana-Champaign — The three-dimensional topological insulator (Bi$_{1-x}$In$_x$)$_2$Se$_3$ undergoes a phase transition to a trivial insulator as Bi atoms are replaced with In. This chemical substitution is expected to reduce the spin-orbit coupling, lift the bulk band inversion and thus destroy the Dirac surface states present in the end-member Bi$_2$Se$_3$. Although photoemission and transport measurements have provided evidence for this phase transition in thin films, the nature of the surface state transformation across the critical point remains unclear, especially near the transition point where the surface state penetration depth becomes comparable to film thicknesses. Here, we present scanning tunneling spectroscopy experiments on single crystals of (Bi$_{1-x}$In$_x$)$_2$Se$_3$ for $x \approx 0\text{--}10\%$. Using Landau Level spectroscopy, we map the surface state dispersion across the phase transition. Additionally, we use local density of states mapping to reveal the local influence of the In dopants near the critical point.

8:24AM Y12.00003 Andreev Reflection Spectroscopy of Nb-doped Bi$_2$Se$_3$ Topological Insulator$^*$ - C. KURTER, Missouri University of Science and Technology, A.D.K. FINCK, University of Illinois at Urbana Champaign, Y. QIU, Missouri University of Science and Technology, E. HUEMILLER, A. WEIS, J. ATKINSON, University of Illinois at Urbana Champaign, J. MEDVEDEVA, Y.S. HOR, Missouri University of Science and Technology, D.J. VAN HARLINGEN, University of Illinois at Urbana Champaign — Doped topological insulators are speculated to realize p-wave superconductivity with unusual low energy quasiparticles, such as surface Andreev bound states. We present point contact spectroscopy of thin exfoliated flakes of Nb-doped Bi$_2$Se$_3$ where superconductivity persists up to $\sim 1$ K, compared to 3.2 K in bulk crystals. The critical magnetic field is strongly anisotropic, consistent with quasi-2D behavior. Andreev reflection measurements of devices with low resistance contacts result in prominent BTK-like behavior with an enhanced conductance plateau at low bias. For high resistance contacts, we observe a split zero bias conductance anomaly and additional features at the superconducting gap. Our results suggest that this material is a promising platform for studying topological superconductivity.

$^*$We acknowledge support from Microsoft Project Q.

8:36AM Y12.00004 Andreev Reflection Spectroscopy on Bismuth-Chalcogenide Topological Insulators$^*$ - C.R. GRANSTROM, I. FRIDMAN, University of Toronto, J.Y.T. WEI, University of Toronto, Canadian Institute for Advanced Research, H. LEI$^*$, C. PETROVIC, Brookhaven National Laboratory, R.X. LIANG, University of British Columbia — Andreev reflection (AR) is the basic mechanism underlying the superconducting proximity effect which, at the interface between a topological insulator (TI) and a spin-singlet superconductor, can give rise to Majorana-like states. Despite this basic importance, little is known about how AR is affected by the unique attributes of a three-dimensional TI, namely the near degeneracy at the Dirac point, its warped bands, and additional features at the superconducting gap. Our results suggest that this material is a promising platform for studying topological superconductivity.

$^*$Work supported by NSERC, CFI-OIT, CIFAR, and the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. DOE, Office for Basic Energy Science.

8:48AM Y12.00005 STM/S studies of BiSbTeSe$_2$ alloys: Intrinsic topological insulators with robust Fermi level in the bulk band gap. - HYOUNGDO NAM, Department of Physics, University of Texas at Austin, Austin, Texas 78712, USA, YANG XU, IRENEUSZ MIOTKOWSKI, JIFIA TIAN, YONG CHEN, Department of Physics and Astronomy, Purdue University, West Lafayette, IN 47907, USA, CHIH-KANG SHIH, Department of Physics, Department of Physics of Texas at Austin, Austin, Texas 78712, USA. — Topological insulators (TI) have been attracting a lot of interest in spin chirality topological surface state (TSS). One of the major material challenges has been the difficulty to create a topological insulator with true insulating bulk so that the topological surface states dominate the transport properties. There has been effort in creating the quaternary compounds, Bi$_{2-x}$Sb$_{x}$Te$_3$Se$_3$ (BSTS) with intrinsic bulk states. Namely the Fermi level is inside the bulk band gap with Dirac point also in the bulk band gap. Angle resolved photoemission has been used to show that 1112 compound, Bi$_2$Sb$_x$Te$_3$Se$_2$, possess this desirable property. Recent observation of topological surface state quantum Hall effect in this compound marks another important milestone. This work focuses on investigations of the electronic structure of BiSbTeSe$_2$ using scanning tunneling microscopy and spectroscopy (STM/S). With the second derivative of tunneling current, we accurately observed the locations of Dirac point (DP), valence band maximum point, and conduction band minimum point, which consist with previous ARPES studies. The investigation confirms the intrinsic bulk states with Fermi level is very close to the DP. We will further discuss the potential correlation of the DP fluctuation with respect to the local compositional fluctuations.

9:00AM Y12.00006 Visualizing the native atomic defects in Bi$_2$Se$_3$ with scanning tunneling microscopy$^*$ - JIXIA DAI, Department of physics and astronomy, Rutgers University, DAMIEN WEST, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, XUEYUN WANG, YAZHONG HANG, DANIEL KWOK, SANG WOOK CHEONG, Department of physics and astronomy, Rutgers University, SHENGBAI ZHANG, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, WEIDA WU, Department of physics and astronomy, Rutgers University — In topological insulators such as Bi$_2$Se$_3$ the existence of native atomic defects is one of the major bottlenecks for potential applications utilizing the topologically protected surface states. Native defects such as vacancies or antisites are believed to be responsible for the metallic transport observed in Bi$_2$Se$_3$. In this study, we examined a series of Bi$_2$Se$_3$ samples that were grown with different conditions using atomically resolving scanning tunneling microscopy. We have successfully identified several types of intrinsic defects, including Se vacancies and Bi-Se antisites. The individual defect images are corroborated by first principle calculations. The densities of these defects across different samples are correlated with their growth conditions. Preliminary results suggest the defect densities can account for the charge carrier density estimated from tunneling spectroscopy.

$^*$This work is supported by NSF grant # DMR-0844807.

9:12AM Y12.00007 Observation of Fermi Arcs in a Doped Pseudospin-1/2 Heisenberg Antiferromagnet Strontium Iridate$^*$ - Y. K. KIM, O. KRUPIN, J. D. DENLINGER, A. BOSTWICK, E. ROTENBERG, Lawrence Berkeley Natl Lab, Q. ZHAO, J. F. MITCHELL, MSD, Argonne Natl Lab, J. W. ALLEN, Ranall Lab of physics, Univ. of Michigan, B. J. KIM, MSD, Argonne Natl Lab, Ranall Lab of physics, Univ. of Michigan, Max Plank institute for Solid state research, Stuttgart — Emergent properties of two microscopically different systems can be similar. Despite manifestly different underlying microscopic electronic structures, the effective low-energy physics of SrZrO$_4$ has been shown to be remarkably similar to that of the parent insulators of superconducting cuprates. However, whether the parallel with the cuprates continues to hold for a metallic phase induced by carrier doping remains unclear, which holds the key to the realization of a new high temperature superconductor. In this presentation, we will report that the evolution of the fermiology of SrZrO$_4$ with doping and temperature reproduces that observed for the cuprates. Upon surface electron doping through in situ deposition of alkali-metal atoms, angle-resolved photoemission spectra of SrZrO$_4$ display disconnected segments of zero-energy states, known as ‘Fermi arcs’, and a gap as large as 80 meV. The Fermi arc smoothly evolves to a closed Fermi surface at higher surface coverage and at higher temperature.
9:24AM Y12.00008 A Scanning Tunnelling Microscopy Study on an Alloyed Topological Insulator, Bi$_{1.5}$Sb$_5$Te$_7$Se$_{1.3}$, WONHEE KO, INSU JEON, HYO WON KIM, HYEOKSHIN KWON, YOUNGTEK OH, Samsung Advanced Institute of Technology, SE-JONG KAHNG, Korea University, JOONBUM PARK, JUN SUNG KIM, Pohang University of Science and Technology, SUNG WOO HWANG, HWANSOO SUH, Samsung Advanced Institute of Technology — Efficient doping of topological insulators while protecting its topological nature is key ingredient to realize topological devices. Engineering the chemical potential in the alloyed compound Bi$_{2-x}$Sb$_5$Te$_7$Se$_{1.3}$ has been achieved by tuning its chemical composition. However, the effect of alloying in microscopic scale has not yet been fully investigated with local probes. Here we report on the atomic and electronic structures of Bi$_{1.5}$Sb$_5$Te$_7$Se$_{1.3}$ studied using scanning tunnelling microscopy/spectroscopy (STM/STS). Although there is significant surface disorder due to the alloying of constituent atoms, cleaved surfaces of the crystals present a well-ordered hexagonal lattice in STM topographs with 1 nm high quintuple layer steps. STS results reflect the band structure and indicate that the surface state and Fermi energy are both located inside the energy gap. The surface states do not show any electron back-scattering; due to their topological nature they are extremely robust. Landau levels generated by perpendicular magnetic field follow the massless Dirac fermions. This finding demonstrates that alloying is a promising route for efficient doping of topological insulators whilst keeping the topological surface state intact.

9:36AM Y12.00009 Circular photocurrent response of a topological insulator thin film probed by scanning photocurrent microscopy, DONG-XIA QU, Lawrence Livermore National Lab, XUFENG KOU, MURONG LANG, University of California, Los Angeles, JONATHAN CROWHURST, MICHAEL ARMSTRONG, JOSEPH ZAUG, Lawrence Livermore National Lab, KANG L. WANG, University of California, Los Angeles, GEORGE CHAPLINE, Lawrence Livermore National Lab — The remarkable nature of surface states in topological insulators is expected to have a unique photocurrent response to electromagnetic radiation. However, the surface and bulk photo-excited charge transport mechanisms, in relation to the band bending at the electrode-topological insulator interface, have not been well understood. Here, we present scanning photocurrent microscopy measurements on a gated topological insulator microdevice and show that the spin-polarized photocurrent displays direction reversal near the electrical contact interfaces. We discuss two possible mechanisms, which alternatively play dominant roles in the helicity-dependent photocurrent map. Our analysis determines the magnitude of each contribution, and reveals the governing process under different gate conditions.

9:48AM Y12.00010 Rapid high-resolution spin- and time-resolved ARPES, CHU-YUN LIN, Department of Physics, University of California, Berkeley, KENNETH GOTTLIKE, Graduate Group in Applied Science and Technology, University of California, Berkeley, CHRIS JOZWIAK, ZAHID HUSSAIN, AARON BOSTWICK, Advanced Light Source, Lawrence Berkeley National Laboratory, ALESSANDRA LANZARA, Department of Physics, University of California, Berkeley and Material Science Division, Lawrence Berkeley National Laboratory, ADVANCED LIGHT SOURCE, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION, GRADUATE GROUP IN APPLIED SCIENCE AND TECHNOLOGY, UNIVERSITY OF CALIFORNIA, BERKELEY COLLABORATION, GRADUATE GROUP IN APPLIED SCIENCE AND TECHNOLOGY, UNIVERSITY OF CALIFORNIA, BERKELEY, CHRISTOPHER JOZWIAK, ZAHID HUSSAIN, Lawrence Berkeley National Laboratory, ALESSANDRA LANZARA, University of California Berkeley, Lawrence Berkeley National Laboratory — Significant experimental and theoretical interest has followed the observation that the spin polarization of photoelectrons from a topological surface state can be measured with photoemission spectroscopy. Here, we report on the first observation of spin resolved photoemission spectroscopy with a fast time-resolving spectrometer, coupled with a lab-based 6 eV laser, which is capable of demonstrating its potential for simultaneous spin- and time-resolved ARPES with pump-probe based measurements.

10:00AM Y12.00011 Photoelectron Spin Control in Spin-Orbit Systems, KENNETH GOTTLIKE, University of California Berkeley, CHRISTOPHER JOZWIAK, Lawrence Berkeley National Laboratory, KENNETH GOTTLIKE, University of California Berkeley, ZAHID HUSSAIN, Lawrence Berkeley National Laboratory, ALEXANDRA LANZARA, University of California Berkeley, Lawrence Berkeley National Laboratory — The remarkable nature of surface states in topological insulators is expected to have a unique photocurrent response to electromagnetic radiation. However, the surface and bulk photo-excited charge transport mechanisms, in relation to the band bending at the electrode-topological insulator interface, have not been well understood. Here, we present scanning photocurrent microscopy measurements on a gated topological insulator microdevice and show that the spin-polarized photocurrent displays direction reversal near the electrical contact interfaces. We discuss two possible mechanisms, which alternatively play dominant roles in the helicity-dependent photocurrent map. Our analysis determines the magnitude of each contribution, and reveals the governing process under different gate conditions.

10:12AM Y12.00012 Direct Observation of the Fermi Arc Surface State in the Three-Dimensional Dirac Semimetal Na$_3$Bi, AIJI LIANG, ZHIJUN WANG, CHAOYU CHEN, YOUGUO SHI, HEMIAN YI, YA FENG, ZHUOJIN XIE, SHAOLONG HE, JUNFENG HE, YINGYING PENG, CU LIU, YAN LIU, LIN ZHAO, GUODONG LIU, JUN ZHANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, M. NAKATAKE, M. ARITA, K. SHIMADA, H. NAMATAME, M. TANIGUCHI, Hiroshima Synchrotron Radiation Center, Hiroshima University, Hiroshima 739-8526, Japan, ZUAN YUAN CHU, CHUANGTIAN CHEN, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences, Beijing 100190, China, XI DAI, ZHONG FANG, XINGJIANG ZHOU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — The three dimensional (3D) Dirac semimetals have linearly dispersive 3D Dirac nodes where the conduction and valence bands connect to each other. Here we report the direct observation of the linearly dispersive 3D bulk Dirac points at the natural (001) cleaving surface of Na$_3$Bi single crystal by high resolution ARPES. In addition, we have directly observed two separated 3D bulk Dirac nodes by elaborately cleaving Na$_3$Bi samples at a non-natural-cleavage (100) crystalline surface. We further unveil the unusual Fermi-arc surface states connecting the two 3D Dirac nodes. At this unique (100) crystalline surface, the identification of the 3D Dirac semimetal state in Na$_3$Bi paves the way for systematically exploring rich exotic topological physics such as topological insulator and Weyl semimetal state.

10:24AM Y12.00013 Magnetism-induced massive Dirac fermions and topological defects in the surface state (SS) of binary and ternary topological insulators (TIs)1, CHIEN-CHANG CHEN, M. L. TEAGUE, N. WOODWARD, W. FAN, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, L. HE, X. KOU, M. LANG, K. L. WANG, Dept. of Electrical Engineering, UCLA, Los Angeles, CA 90095 — Magnetic doping effects on the SS of Bi$_2$Se$_3$ and (Bi$_{1-y}$Sb$_y$)$_2$Te$_3$ are studied by scanning tunneling microscopy/ spectroscopy (STS) on MBE-grown bilayers of Bi$_2$Se$_3$/(Bi$_{1-x}$Sb$_x$)$_2$Se$_3$ and (Bi$_{1-y}$Sb$_y$)$_2$Te$_3$/(Bi$_{1-x}$Sb$_x$)$_2$Te$_3$ on InP (111) as a function of the undoped layer thickness (d) and the Cr-doping level (x). For x = 5% and 10%, magnetic proximity effect is induced in the SS of Bi$_2$Se$_3$ for d < 4-QL, leading to gapped Dirac spectra for temperatures (T) below a 3D Curie temperature $T_C = (210 \pm 10) K$ and (240 \pm 10) K for x = 5% and 10%, respectively, which are much higher than the bulk T$_C \approx 25 K$ where anomalous Hall effect occurs. The gap (Δ) is spatially inhomogeneous in zero magnetic field (H = 0), and reaching a maximum Δ $= (0.4 \pm 0.1) eV$ at T $< T_C$. The gap inhomogeneity decreases with increasing $x$, H and decreasing T. Moreover, localized sharp impurity resonances are found occasionally near the boundaries of gapped and gapless regions, which are attributed to isolated Cr impurities that couple with the spins of Dirac fermions and form long-lived topological defects. With increasing interlayer H, the resonance peaks diminish as the spatial gap homogenizes. These findings in the bilayer binary TIs are compared with those in the bilayer ternary TIs of more uniform bulk ferromagnetism.

1Supported by DARPA and NSF.
Park (TEM) showed presence of corrugations and wisps in the carbon nanotubes framework attributed to the curvature induced by nitrogen atoms. XPS results. High pressure adsorption of CO\textsubscript{2} properties (thermoelectric power and resistivity) and the phonon modes of the CNTs and the trapped gaseous nitrogen are used to further substantiate the carbon nanotubes skeletal structure and 1 atomic% present as gaseous nitrogen trapped inside the nanotubes. Investigation of the temperature dependent transport in Carbon Nanotubes.

This Work is Supported by Penn State Altoona Undergraduate Research Sponsored Program and Penn State Materials Research Institute, University Park.

Friday, March 6, 2015 8:00AM - 11:00AM
Session Y16 DMP: Focus Session: Carbon Nanotubes, Graphene, & Related Materials: Chemical Properties and Sensing

8:00AM Y16.00001 Measurement of electronic perturbations in the surface of a carbon nanotube by adsorbed atoms and molecules\textsuperscript{1}, DAVID COBDE, BORIS DZYUBENKO, HAO-CHUN LEE, OSCAR VILCHES, University of Washington, Seattle — The physisorption of atoms and molecules onto a surface such as carbon involves small hybridization with the substrate electron states which have not previously been accessible to experiments. Suspended single-walled carbon nanotube devices are a good system for studying the electronic perturbations, as they combine a perfect carbon surface with single-atom mass sensing capability and single-electron-transistor sensitivity. By monitoring both the conductance and the adsorbed mass, derived from the mechanical frequency shift, in equilibrium with the vapor, we are able to detect for the first time the very small charge transfer from adsorbates to the surface. It is found to be of a similar magnitude for all gases tested (4He, Ar, Kr, Xe, N\textsubscript{2}, CO and O\textsubscript{2}), and depends on coverage and temperature. Although it is only $10^{-5} - 10^{-3}$ e per atom, at gate voltages near threshold it can produce a large change in conductance. It can thus be used to sense tiny amounts of adsorbates and to explore the phase transitions of atoms on a cylinder.

\textsuperscript{1}This work supported by NSF DMR 1206208

8:12AM Y16.00002 Argon Adsorption on Open Carbon Nanohorns\textsuperscript{1}, ANGEL CALVILLO, BRICE RUSSELL, ALDO MIGONE, Department of Physics, Southern Illinois University, Carbondale, IL 62901, USA, SUMIO IIJIMA, MASAKO YUDASAKA, National Institute of Advanced Industrial Science and Technology, Tsukuba 305-8565, Japan — We have measured adsorption isotherms for argon adsorbed on a 0.1692 g sample of chemically-opened carbon nanohorns. Two clear substeps are visible in the adsorption data, corresponding to groups of stronger binding sites (lower pressure substep) and weaker binding sites (higher pressure substep). We have measured adsorption at five different temperatures in the range between 70 and 90 K. The chemically-opened nanohorns have the space at the interior of the individual nanohorns accessible to adsorbates. Consequently, higher loadings are obtained on these samples compared to those for unopened (as-produced) nanohorns. Results for the kinetics of adsorption, the effective specific surface area, and the isosteric heat of adsorption as a function of sorbent loading will be presented and compared to results from other studies on nanohorns.

\textsuperscript{1}This work was supported by the NSF through grant DMR-1006428.

8:24AM Y16.00003 Computer simulations of Ne and CO\textsubscript{2} adsorbed in carbon nanohorns\textsuperscript{1}. SILVINA GATICA, Howard University, ADAM SCRIVENER, University of Rochester — We computed the equilibrium properties of Ne and CO\textsubscript{2} adsorbed on carbon nanohorns. We modeled the nanohorns as an arrangement of nanometer-size cones composed of carbon atoms. Our method of calculation is the Grand Canonical Monte Carlo technique, where the substrate is considered rigid. We calculate the adsorption isotherms for various temperatures (18K-50K for Ne and 147K - 200K for CO\textsubscript{2}). We also calculate the isosteric heat of adsorption and compare with available experimental results.

\textsuperscript{1}Partially supported by the Research Experience for Undergraduates (REU) summer program (NSF Grant PHY-1358727) and Partnership for Reduced Dimensional Materials (PRDM), (NSF DMR-1205608)

8:36AM Y16.00004 Ethane Adsorption on Carbon Nanohorns\textsuperscript{1}, BRICE RUSSELL, ALDO MIGONE, Department of Physics, Southern Illinois University, Carbondale, IL 62901, USA, SUMIO IIJIMA, MASAKO YUDASAKA, National Institute of Advanced Industrial Science and Technology, Tsukuba 305-8565, Japan — We have measured adsorption isotherms for ethane adsorbed on as-produced single-walled carbon nanohorns. Measurements have been completed for nine temperatures between 123.66 K and 221.32 K. The kinetics of adsorption will be compared to results previously obtained for ethane adsorption on purified HiPco single-walled carbon nanotubes. On nanotubes it was found that equilibration times for ethane decreased with increasing sorbent loading (coverage). By contrast, for adsorption on the as-produced nanohorns, equilibration times increased with increasing sorbent loading. The kinetic results for sorbent mass loading will be compared to an expression with only one rate-controlling mechanism. The point-B method was used to determine monolayer completion values at each temperature. Results will also be presented for the isosteric heat values, which were determined for the full range of loadings covered by the isotherms.

8:48AM Y16.00005 Transport and Optical Investigations of Substitutional and Trapped Nitrogen in Carbon Nanotubes\textsuperscript{1}, ALI QAJAR, University of Texas, Austin, DANHANG MA, The Pennsylvania State University, RAMAKRISHAN RAJAGOPALAN, The Pennsylvania State University-DuBois, KOFI ADU, The Pennsylvania State University-Altoona College, GAMINI SUMANASEKERA, University of Nevada — Multiwall carbon nanotubes that contain nitrogen were synthesized using acetonitrile as the precursor and ferrocene as the catalyst. X-ray photoelectron spectroscopy detected ~ 2 atomic% nitrogen in the carbon nanotubes with ~ 1 atomic% of the nitrogen as substitutionally doped in the carbon nanotubes skeleton structure and 1 atomic% present as gaseous nitrogen trapped inside the nanotubes. Investigation of the temperature dependent transport properties (thermoelectric power and resistivity) and the phonon modes of the CNTs and the trapped gaseous nitrogen are used to further substantiate the XPS results. High pressure adsorption of CO\textsubscript{2} at room temperature also confirmed no porosity accessible for CO\textsubscript{2} molecules. Transmission electron microscopy (TEM) showed presence of corrugations and wisps in the carbon nanotubes framework attributed to the curvature induced by nitrogen atoms.

\textsuperscript{1}This Work is Supported by Penn State Altoona Undergraduate Research Sponsored Program and Penn State Materials Research Institute, University Park
9:00AM Y16.00006 Spectroscopic Investigations into the Redox Sorting of Carbon Nanotubes, JASON STREIT, National Institute of Standards and Technology, HUI GUI, University of Southern California, JEFFERY FAGAN, ANGELA HIGHT WALKER, National Institute of Standards and Technology, CHONGWU ZHOU, University of Southern California, MING ZHENG, National Institute of Standards and Technology — Charge-transfer reactions have been shown to alter the electronic structure of single-wall carbon nanotubes (SWCNTs) in a bandgap-dependent fashion. Such electronic modification shows great promise for chiral selective separations. This study investigates the role of redox chemistry in the aqueous two-phase extraction of SWCNTs. We demonstrate a multi-step oxidative extraction procedure to successfully separate SWCNTs both by semiconducting bandgap and metallicity. We propose that electron transfer between redox molecules and the nanotubes induces reorganization of the surfactant coating layer, which in turn affects the partitioning of the SWCNTs between the two different aqueous polymer phases. Spectroscopic measurements are applied to probe surfactant structure reorganization in different redox environments. We suggest that redox-induced modulation of the surfactant coating is a generally observed phenomenon in many different nanotube sorting processes which can be further controlled to improve separation reproducibility and purity.

9:12AM Y16.00007 Rotations and vibrations of water molecule inside the fullerene cage: infrared study of H2O@C60, TOOMAS ROOM, A. SHUGAI, U. NAGEL, NIPCPB, Tallinn, Estonia, S. MAMONE, A. KRACHMALNICOFF, R.J. WHITBY, M.H. LEVITT, Chemistry, Univ. of Southampton, UK, T. NISHIDA, Y. MURATA, Inst. of Chem. Research, Kyoto Univ., Uji, Japan, XUEGONG LEI, YONGJUN LI, N.J. TURRO, Dep. of Chemistry, Columbia Univ., New York — Water is the second molecule after hydrogen what has been trapped inside the cage of a C60 molecule by the molecular surgery method [Kurotobi and Murata, Science 333, 613 (2011)]. We studied isolated water molecule isotopeologs H2O, D2O, and HD2O in the solid phase at cryogenic temperatures using IR spectroscopy. The water molecule rotation transitions were observed in the THz [Beduz et al., PNAS 109, 12894 (2012)] and vibration-rotation transitions in the mid-IR range. The slow conversion between ortho and para water allowed us to record the time evolution of spectra and to separate ortho and para absorption lines of water. The similarity of the rotation spectrum of caged water to water in the gas phase indicates that water is free to rotate in the C60 cage even at temperature as low as 3 K. However, spectral lines show a splitting of about 0.5 meV what is not compatible with the icosahedral symmetry of C60. Different models (e.g. crystal field effects in solid C60, C60 cage distortions) will be discussed.

9:24AM Y16.00008 Adsorption of Ar on individual carbon nanotubes, graphene, and graphite, BORIS DZYUBENKO, JOSHUA KAHN, OSCAR VILCHES, DAVID COBDEN, Department of Physics, University of Washington — We compare and contrast results of adsorption measurements of Ar on single-walled carbon nanotubes, graphene, and graphite. Adsorption isotherms on individual suspended nanotubes were obtained using both the mechanical resonance frequency shift (sensitive to mass adsorption) and the electrical conductance. Isotherms on graphene mounted on hexagonal boron nitride were obtained using only the conductance. New volumetric adsorption isotherms on bulk exfoliated graphite were also obtained, paying special attention to the very low coverage region (less than 2% of a monolayer). This allowed us to compare the degree of heterogeneity on the three substrate types, the binding energies, and the van der Waals 2D parameters. Research supported by NSF DMR 1206208.

9:36AM Y16.00009 Ortho-para conversion of endohedral water in the fullerene C60 at cryogenic temperatures, ANNA SHUGAI, U. NAGEL, T. RÖÖM, NIPCPB, Tallinn, Estonia, S. MAMONE, M. CONCISTRÈ, B. MEIER, A. KRACHMALNICOFF, R.J. WHITBY, M.H. LEVITT, Chemistry, Univ. of Southampton, UK, XUEGONG LEI, YONGJUN LI, N.J. TURRO, Dep. of Chemistry, Columbia Univ., New York — Water displays the phenomenon of spin isomerism in which the two proton spins either couple to form a triplet (ortho water, I = 1) or a singlet nuclear spin state (para water, I = 0). Here we study the interconversion of para and ortho water. The exact mechanism of this process is still not fully understood. In order to minimize interactions between molecules we use a sample where a single H2O is trapped in the C60 molecular cage (H2O@C60) and H2O@C65 is crystallized. H2O@C65 has long-lived ortho state [Beduz et al., PNAS 109, 12894 (2012)] and ortho-para conversion kinetics is non-exponential. At some temperatures the kinetics is exponential. Models are discussed in order to explain the T and concentration dependence of ortho-para interconversion kinetics.

9:48AM Y16.00010 Effect of intercalated molecules on graphene sensing behavior, TAO SUN, KIYOUNGMIN MIN, NARAYANA ALURU, Univ of Illinois - Urbana, COMPUTATIONAL MULTISCALE NANO SYSTEM TEAM — The physical mechanism of graphene humidity sensor based upon capacitance measurement is explored by atomic/ab-initio simulations. Our simulations show that molecules intercalated between graphene and substrate (H2O) can have large influence on graphene sensing behavior. We find that oxygen vacancies on the surface of the substrate can induce an N-type doping in graphene, while oxygen molecules entering between the substrate and graphene will fill the vacancies and eliminate the N-type doping effect. We also observe that water molecules trapped at the interfacial layer can change the interlayer distance, thus changing the measured capacitance. Our simulations uncover the effect of intercalated molecules, which is helpful to better understand the operation process of graphene sensing devices.

1Lead by Professor N R Ahlu, we do multiscale simulations to explore mechanical and electronic properties of materials.

10:00AM Y16.00011 Determining the thermal noise floor of graphene biosensors, MICHAEL CROSSER, Linfield College, MORGAN BROWN, ETHAN MINOT, Oregon State University — The use of graphene field-effect transistors (GFETs) as biosensors in aqueous environments is fundamentally limited by voltage noise. In many GFET devices, noise is dominated by the fluctuating occupancy of charge traps in the substrate. Fabrication techniques have been found to reduce this substrate effect, but thermally-driven charge transfer across the graphene liquid interface has yet to be characterized and addressed. In this report we present the first characterization of this noise source. We show that the power spectral density of this noise scales inversely with frequency and inversely with interface area. Our results are in quantitative agreement with recent measurements of voltage noise in clean, suspended graphene.

10:12AM Y16.00012 Spatial Self-Phase Modulation in Graphene and Graphene Oxide Water Suspensions, YANAN WANG, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, ZHUAN ZHU, Department of Electrical and Computer Engineering, University of Houston, XUFENG ZHOU, Ningbo Institute of Materials Technology & Engineering, Chinese Academy of Sciences, ZHIMING WANG, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China, JIMING BAO, Department of Electrical and Computer Engineering, University of Houston, UESTC & UH COLLABORATION — With promising potential in photonic and optoelectronic applications, nonlinear optical properties of graphene based materials have attracted enormous interest. In this work, we observed spatial self-phase modulation (SSPM) of propagating laser beams in both graphene and graphene oxide (GO) water suspensions. The formation and temporal evolution of far-field diffraction rings have been investigated systematically. It is found that alignment of graphene or GO flakes is controlled by water convection rather than the polarization of laser. We further discovered that SSPM can be mainly attributed to the thermo-optic effect of water instead of graphene or GO.
10:24AM Y16.00013 Asymmetric behavior in electrowetting of electrolyte solutions on graphene at the nanoscale: A molecular dynamics simulation. FERESHTE TAHERIAN TABASI, Postdoctoral Research Fellow, NICO VAN DER VECT, Professor of Physical chemistry at Technical University of Darmstadt — Using molecular dynamics simulations, electrowetting of aqueous solutions on graphene are studied. By doping the surface with the positive or negative charges, the counter-ions are adsorbed at the solid-liquid interface, and the co-ions are repelled from the interface, leading to the decrease of the solid-liquid surface tension and therefore the contact angle (known as electrowetting). Our simulation results show that at zero surface charge density, water molecules at the interface (located between the surface and first ionic layer) are mainly oriented parallel to the surface. However due to the smaller size of the hydrogen, there is a slight tendency of the water dipole moment to orient into the surface. On the charged surfaces, the orientation polarization of the interfacial water molecules are shown to be stronger on the negative surfaces than the positive ones. Such asymmetric orientation polarization of water leads to different screening of the graphene surface charge and therefore different contact angles of the solution with opposite charges. Simulations results show more spreading of the liquid on the positively charged surfaces than the negative ones.

10:36AM Y16.00014 Ionic transport across atomically-thin graphene membranes. LAUREN CANTLEY, Dept. of Mechanical Engineering, Boston University, SCOTT BUNCH, Dept. of Mechanical Engineering, Division of Materials Science and Engineering, Boston University — Graphene is an attractive material for applications in single molecule sensing and molecular sieving, in part due to its atomic thinness, strength and barrier properties. In this study, we examine ionic transport across a suspended single-layer graphene membrane separating two reservoirs of aqueous ionic solution. Molecularly sized, sub-nm pore(s) are introduced by chemical etching, which allow for only proton transport across the graphene membrane. The pore is further opened and ionic conductance measurements are carried out to further investigate and characterize ionic transport across sub-nm and nm-scale pores.

10:48AM Y16.00015 Synthesis, characterization and application of highly crystalline sp2–bonded boron nitride aerogels. THANG PHAM, Materials Science and Engineering, Physics Department, UC Berkeley, ANNA GOLSTEIN, Chemistry, Physics Department, UC Berkeley, MARCUS WORSLEY, LETA WOO, Physical Science Directorate, Lawrence Livermore National Laboratory, WILLIAM MICKESELON, Center of Integrated Nanomechanical System (COINS), UC Berkeley, ALEX ZETTL, Physics Department, COINS, UC Berkeley, Kavli Energy Nanosciences Institute, UC Berkeley, Materials Science Division, Lawrence Berkeley National Lab — Aerogels have much potential in both research and industrial applications due to high surface area, low density and fine pore size distribution. Here we report a versatile synthesis and thorough structure characterization of three-dimensional aerogels composed of highly crystalline sp2–bonded BN layers formed by carbothermal reaction. The structure, crystallinity and bonding of the as-prepared BN aerogels were elucidated by x-ray diffraction, nuclear magnetic resonance of 11B, transmission electron microscopy (TEAM) and resonant soft x-ray scattering. The macroscopic roughness of the aerogel’s surface causes it to be superhydrophobic with a contact angle of 155 ± 3° and high oil uptake (up to 1500 wt%). The used BN aerogel can be regenerated by different heat treatments and still maintain the crystalline porous structure and adsorption capacity. The highly crystalline, chemically pure, thermally stable and porous sp2–boron nitride aerogel is an ideal host for liquids, gases and other nanomaterials.

Friday, March 6, 2015 8:00AM - 10:48AM – Session Y17 DMP: Focus Session: Graphene Devices: Optical and Opto-electronics 102AB - Xiao Li, University of Maryland

8:00AM Y17.00001 Graphene- and quantum well-based dipolariton nanodevices for integrated optical circuits. GERMAN V. KOLMAKOV, New York City College of Technology CUNY, TIM BYRINES, New York University, ROMAN YA. KEZERASHVILI, New York City College of Technology CUNY — Application of dipolaritons, which are a quantum superposition of photons, direct excitons and indirect excitons, in an optical microcavity for the design of nanoscale devices for optical computing is considered. In the proposed setup, a dipolariton condensate is formed in a patterned microcavity with an embedded two-layer gapped graphene. The condensate propagates in quasi-one dimensional channels formed by the pattern, and its propagation is controlled by the gate voltage applied to a positively-charged hole-carrying graphene layer. The advantage of the dipolaritons, compared to the conventional polaritons formed by the direct excitons and photons, is in the possibility to drive the condensate by the electric force since the latter is directly applied the dipolaritons. A dipolariton switch based on a Y-shaped channel is considered and its performance is determined via numerical simulations of the dipolarition condensate dynamics. The tunability of the device functions by the application of an external electric field is discussed. The simulations for a Y-shaped switch is also performed for a patterned microcavity with embedded coupled quantum wells and the results are compared with those for a microcavity with graphene.

8:12AM Y17.00002 Terahertz hot electron bolometric detectors based on graphene quantum dots1. A EL FATIMY, Department of Physics, Georgetown University, Washington, DC 20057, USA, R.L. MYERS-WARD, A. K. BOYD, K. M. DANIELS, D.K. GASKILL, U.S. Naval Research Laboratory Washington, DC 20375, USA, P. BARBARA, Department of Physics, Georgetown University, Washington, DC 20057, USA — We study graphene quantum dots patterned from epitaxial graphene on SiC with a resistance strongly dependent on temperature. The combination of weak electron-phonon coupling and small electronic heat capacity in graphene makes these quantum dots ideal hot-electron bolometers. We measure and characterize the THz optical response of devices with different dot sizes, at operating temperatures from 2.5K to 80K. The high responsivity, the potential for operation above 80 K and the process scalability show great promise towards practical applications of graphene quantum dot THz detectors.

8:24AM Y17.00003 Position dependent photodetection of graphene field effect transistors. BIDDUT SARKER, Purdue University. EDWARD CAZALAS, Pennsylvania State University, ISAAC CHILDRES, Purdue University, IGOR JOVANOVIC, Pennsylvania State University, YONG CHEN, Purdue University — The extraordinary optical and electronic properties of graphene make it a promising component of high-performance photodetectors. Most graphene photodetectors studied so far require light illumination either on the graphene or at the graphene/metal interface. In this talk, we report a study of the spatial dependence of photoresponse in back-gated graphene field effect transistors (GFET) on undoped semiconductor substrates by scanning a focused laser spot across and away from the GFETs. We find that the photocurrent and photoresponsivity can be varied by a few orders of magnitude depending on the laser illumination position. Our observation can be explained using a numerical model based on the charge transport of photoexcited carriers in the substrate. This work may enable position sensitive photodetectors and further developments of graphene-based optoelectronic devices.
8:36AM Y17.00004 Optical rectification at visible frequency in biased bilayer graphene, F. HIPOLITO, NUS Graduate School for Integrative Sciences and Engineering, VITOR M. PEREIRĂ, Department of Physics, National University of Singapore — The second order response of the electrical current to an electromagnetic field is analyzed within the framework of non-equilibrium many-body perturbation theory for the case of a two-dimensional electronic system such as graphene and its bilayer. The absence of inversion symmetry in a biased graphene bilayer allows finite DC response in second order to an AC electromagnetic wave. The induced DC current is evaluated for biased bilayer at finite temperature, and its tunability is analyzed as a function of electron density, which can be experimentally varied by means of a global gate voltage applied to the sample. Both intrinsic and photon drag microscopic processes are considered, as they contribute on similar footing to the photocurrent in general. However, the dependencies of these two contributions on the polarization state of the incident light are different, which allows the manipulation of the relative contribution of intrinsic versus photon drag contributions by tuning the experimental parameters. For example, the photocurrent emerging from circularly polarized light stems entirely from photon drag, as the circular photogalvanic effect is forbidden by the $C_{3v}$ rotation symmetry of the honeycomb lattice.

8:48AM Y17.00005 Graphene-Boron Nitride Heterostructure Based Electro-Optical Modulator, YUANDA GAO, Columbia University, REN-JYE SHIUE, Massachusetts Institute of Technology, XUETAO GAN, JAMES HONE, Columbia University, DIRK ENGLUND, Massachusetts Institute of Technology — Graphene, a two-dimensional atomic-scale carbon based material, exhibits uniform absorption of the incident light over a broad spectrum range from visible to mid-infrared. This absorption can be tuned by electrostatic doping, resulting in electro-absorptive modulation of the incident light. We propose and demonstrate a high-speed electro-optical modulator structure by using a high-mobility dual-layer graphene capacitor integrated with a planar silicon photonic crystal nanocavity. Strongly enhanced light-matter interaction of graphene in a sub-micron meter cavity enables efficient electrical tuning of the cavity reflection. We achieved a modulation depth of 3.2 dB within a voltage swing of only 2.5 V; we measured a 3dB cut-off frequency up to 1.2 GHz.

9:00AM Y17.00006 Asymmetric transmission of terahertz waves in graphene-loaded photonic systems, YU ZHOU, REN-HAO FAN, Nanjing University, QING HU, Massachusetts Institute of Technology, RU-WEN PENG, MU WANG, Nanjing University — In this work, we have proposed two types of graphene-loaded photonic systems, through which terahertz(THz) waves present asymmetric transmission tuned by external magnetic field. One is a graphene-loaded metal grating. It is found that resonant modes in the system can be converted between transverse-electric and transverse-magnetic polarizations due to Hall conductivity of graphene. As a consequence, asymmetric transmission of THz waves through these graphene-loaded metal gratings is achieved. The other is a photonic crystal cavity integrated with graphene. Non-reciprocal propagation of THz waves has been verified in this system. By adjusting the external magnetic field or the Fermi level of graphene, asymmetric wave propagation can be significantly tuned. Our investigations offer unique approaches to achieve potentially applications in the design of the graphene-loaded tunable devices such as THz isolators and diodes.

9:12AM Y17.00007 Photoresponse and light trapping in nanowire array-graphene interfaces, TITO HUBER, SCOTT JOHNSON, QUINTON BARCLIFT, TINA BROWER, Howard University, JEFFREY H. HUNT, JOHN H. BELK, The Boeing Company — Graphene is emerging as an optical material that features tunability by electrostatic doping and a photothermoelectric response, however it features low optical absorption. We studied interfaces between nanowire arrays and graphene and also other transparent electrodes such as indium tin oxide films. The nanowire arrays were fabricated using a template method. Graphene was transferred from copper substrates. The interfaces were characterized with a number of tools including Scanning Electron microscopy, Raman spectroscopy and optical reflectance. We also studied the photocurrent through the interface in particular the temporal and wavelength dependence that are revealing of the characteristic thermoelectric origin of the signal. In the photocurrent tests we employed devices composed of nanowire arrays which are capped with the transparent electrode. Interestingly, we observed that the interface has low optical reflectivity and high optical absorption, which we will discuss in terms of enhanced optical trapping.

9:24AM Y17.00008 Terahertz modulators based on multiple non-Bernal graphene layers, IOANNIS CHATZAKIS, ZHEN LI, University of Southern California Electrical Engineering, ALEXANDER BENDERSKII, University of Southern California Department of Chemistry, STEPHEN CRONIN, University of Southern California Electrical Engineering — We investigate a THz modulator based on a stack of disoriented the non-Bernal stacks graphene layers (GLs) grown by chemical vapor deposition method (CVD) on SiO2 substrate [1]. The non-Bernal stacking GLs results in the electron decoupling of the GLs, higher interband absorption and exhibit the same energy spectrum of the charge carriers to that in individual GLs. The detection efficiency in room temperature is high due low probability of the high energy of the optical phonons (~ 0.2 eV) absorption. Using terahertz time-domain spectroscopy, we show that the multi graphene layers exhibit fairly high responsivity due to high quantum efficiency.

9:36AM Y17.00009 Optical Plasmonic Switch based on Graphene, KYUNGSONG MOON, SUK-YOUNG PARK, Dept. of Physics, Yonsei University — We have studied an electro-optical plasmonic waveguide, which controls the transmission of incident light by switching the coupling of the surface plasmon polariton (SPP) localized on graphene. It has been previously shown that the propagation length of the SPP localized on the copper surface can be effectively reduced by a factor of two or three by applying external bias potential. In our study, we have demonstrated that the propagation length of the SPP localized on graphene can be dramatically reduced by a factor of ten or so and the wavelength of SPP can be reduced by several hundreds of that of the incident light as well. We have also investigated the effect of scattering times of graphene and active Si layer on switching line shape. Switching occurs upon varying the carrier density of Si layer by $\Delta n/n \sim 15\%$ in the vicinity of switching region. For a fixed bias voltage applied just below the critical value, signal laser beam shone into the metal nano-particles may increase the carrier density as such, which will induce switching. This may help develop an all-optical nano-scale plasmonic switch.

This research was supported by Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Education, Science and Technology(NRF-2012R1A1A006927).
Many-Body Problem

9:48AM Y17.00010 Time-of-flight photoconductivity in polymer/graphene blends, GVIDO BRATINA, EGGON PAVLICA, SRINIVASA RAO PATHIPATI, ROBERT NAWROCKI, RAVEENDRA PENUMALA, Laboratory for Organic Matter Physics, University of Nova Gorica, Slovenia — We have used time-of-flight (TOF) photoconductivity measurements to assess the electric charge transport parameters in thin layers of poly(3-hexyl thiophene-2,5-diyl) (P3HT) mixed with single and multiple-layer graphene nanoflakes. Thin layers were cast from a solution and two co-planar metal electrodes were deposited by vacuum evaporation on top. An electric field was set up between the electrodes A laser pulse was used to photogenerate charge carriers near the biased electrode, and time dependence of the photocurrent (I(t)) was measured at the opposite electrode. I(t) curves were confronted to I(t) obtained by a Gaussian-disorder Monte Carlo simulations, adapted to thin-film geometry. The simulations included a position-dependent electric field between two coplanar electrodes, which importantly affects the charge carrier transport through the blend between the electrodes. Comparison between the simulated and measured I(t) results in values for charge carrier mobility, average charge velocity and variation of charge velocity. Our results show that the hole mobility in blends is increased by more than an order of magnitude in comparison to the hole mobility of a neat layers of P3HT.

10:00AM Y17.00011 Optical and electronic properties study of bottom-up graphene nanoribbons for photovoltaic applications1, CESAR E.P. VILLEGAS, ALEXANDRE ROCHA, Instituto de Física Teórica, Universidade Estadual Paulista, São Paulo, SP, Brazil — Graphene nanoribbons (GNRs), turn out to be serious contender for several optoelectronic applications due to their physical properties. Recently, bottom-up methods, using the assembly of appropriate precursor molecules were shown to be an exciting pathway towards making precise nanoribbons. In particular, it has been demonstrated that so-called cove-shaped GNRs absorb light in the visible part of the spectrum, suggesting they could be used for photovoltaic applications. In solar cells, the key ingredient is the presence excitions and their subsequent diffusion along a donor material. This is influenced by the character of the different excitations taking place, as well as, the exciton binding energy. Thus, in this work we use many-body corrected density functional theory to simulate the optical properties of these nanoribbons. We elucidate the most important transitions occurring in these systems, and identify types of excitations that have not been previously observed in conventional nanoribbons. We also find that the exciton binding energies for all the structures we considered are in the eV range, which enhances the diffusion lengths for the particle-hole pairs. Finally, we estimate the potential of these systems as solar cells by calculating the short-circuit current. The Authors thank FAPESF for financial support.

10:12AM Y17.00012 Graphene Oxide Liquid Crystals for Reflective Display without Polarizing Optics, ZHUAN ZHU, University of Houston, LIQUIN HE, University of Science and Technology of China, JIAN YE, Guangdong University of Technology, MIN SHUI, Texas A&M University, XUFEI ZHOU, Chinese Academy of Sciences, YANAN WANG, YANG LI, ZHIHUA SU, University of Houston, HAIYAN ZHANG, YING CHEN, Guangdong University of Technology, ZHAOPIING LIU, Chinese Academy of Sciences, ZHENDONG CHENG, Texas A&M University, JIMING BAO, University of Houston — The recent emergence of liquid crystals of atomically thin two-dimensional (2D) materials not only has allowed us to explore novel phenomena of macroscopically aligned 2D nanomaterials but also has provided a route toward their controlled assembly into three-dimensional functional macrostructures. Using flow-induced mechanical alignment, we prepared flakes of graphene oxide (GO) in different orientational orders and demonstrated that GO liquid crystal (LC) can be used as a rewritable medium for reflective display without polarizing optics. With a wire or stick as a pen, we can make the surface of GO LC reflective and bright, and we can then manually draw lines, curves, and any other patterns with dark appearance. The contrast between bright and dark features is due to anisotropic optical responses of ordered GO flakes. Since optical anisotropy is an intrinsic property of 2D structures, our observations and demonstration represent one of many potential applications of macroscopically aligned 2D nanomaterials.

10:24AM Y17.00013 Development of graphene oxide materials with controllably modified optical properties, ANTON NAUMOV, Central Connecticut State University, CHARUDATTA GALANDE, Rice University, ADITYA MOHITE, Los Alamos National Laboratory, PULICKE A. AJAYAN, R. BRUCE WEISMAN, Rice University — One of the major current goals in graphene research is modifying its optical and electronic properties through controllable generation of band gaps. To achieve this, we have studied the changes in optical properties of reduced graphene oxide (RGO) in water suspension upon the exposure to ozone. Ozonation for the periods of 5 to 35 minutes has caused a dramatic bleaching of its absorption and the concurrent appearance of strong visible fluorescence in previously nonemissive samples. These observed spectral changes suggest a functionalization-induced band gap opening. The sample fluorescence induced by ozonation was found to be highly pH-dependent: sharp and structured emission features resembling the spectra of molecular fluorophores were present at basic pH values, but this emission reversibly broadened and red-shifted in acidic conditions. These findings are consistent with excited state protonation of the emitting species in acidic media. Oxygen-containing addends resulting from the ozonation were detected by XPS and FTIR spectroscopy and related to optical transitions in localized graphene oxide fluorophores by computational modeling. Further research will be directed toward producing graphene-based optoelectronic devices with tailored and controllable optical properties.

10:36AM Y17.00014 Determination of graphene layer thickness using optical image processing, MONICA COOK, R.G. MANI, Georgia State University — Graphene, a single atomic layer of carbon arranged in a hexagonal lattice structure, is a valuable material in a wide range of research. A significant impediment to graphene research is the need to manually characterize the thickness of high-quality graphene produced via mechanical exfoliation. Traditional methods of characterizing the layer thickness of graphene, including Raman spectroscopy and atomic force microscopy, require expensive equipment and can be damaging to the graphene sample. We examine here a known alternative method for quantitatively determining the layer thickness of graphene on SiO2/Si based on optical image processing, which is quick, inexpensive, and non-invasive [1]. Using RGB images of a candidate graphene sample and a background image, taken with a simple optical microscope and charge-coupled device (CCD) camera, we process the images with an algorithm based on Fresnel’s law to obtain the contrast spectrum. Each layer of graphene exhibits a unique contrast spectrum for its particular substrate, which is measured and used for accurate layer identification. We also discuss how this algorithm can be generalized to characterize the thickness of other promising two-dimensional materials as well as more complex structures on a variety of substrates.

Friday, March 6, 2015 8:00AM - 11:00AM –
Session Y18 DCOMP: Invited Session: New Approaches to the Non-Equilibrium Quantum Many-Body Problem Mission Room 103A - Andrew Millis, Columbia University
8:00AM Y18.00001 Bold-line Monte Carlo and the nonequilibrium physics of strongly correlated many-body systems¹, GUY COHEN, Columbia Univ — This talk summarizes real time bold-line diagrammatic Monte-Carlo approaches to quantum impurity models, which make significant headway against the sign problem by summing over corrections to self-consistent diagrammatic expansions rather than a bare diagrammatic series. When the bold-line method is combined with reduced dynamics techniques² both local single-time properties³ and two time correlators such as Green function⁴ can be computed at very long timescales, enabling studies of nonequilibrium steady state behavior of quantum impurity models⁵ and creating new solvers for nonequilibrium dynamical mean field theory.

¹This work is supported by NSF DMR 1006282, NSF CHE-1213247, DOE ER 46932, TG-DMR120085 and TG-DMR130036, and the Yad Hanadiv-Rothschild Foundation.

8:36AM Y18.00002 The time-dependent Gutzwiller approximation¹, MICHELE FABRIZIO, SISSA — The time-dependent Gutzwiller Approximation (t-GA) [1,2] is shown to be capable of tracking the off-equilibrium evolution both of coherent quasiparticles and of incoherent Hubbard bands. The method is used to demonstrate that the sharp dynamical crossover observed by time-dependent DMFT in the quench-dynamics of a half-filled Hubbard model can be identified within the t-GA as a genuine dynamical transition separating two distinct physical phases [3]. This result, strictly variational for lattices of infinite coordination number, is intriguing as it actually questions the occurrence of thermalization. Next, we shall present how t-GA works in a multi-band model for V₂O₃ that displays a first-order Mott transition. We shall show that a physically accessible excitation pathway is able to collapse the Mott gap down and drive off-equilibrium the insulator into a metastable metal phase [4].

Work supported by the European Union, Seventh Framework Programme, under the project GO FAST, Grant Agreement no. 280555.

9:12AM Y18.00003 Thermalization and long-time behavior of nonequilibrium correlated quantum systems¹, HERBERT F. FOTSO, Ames Laboratory — Nonequilibrium dynamical mean field theory and nonequilibrium self-consistent strong coupling expansion[1] are used to study the relaxation of correlated quantum systems driven out of equilibrium by DC electric fields[2]. Both the Falicov-Kimball and the Hubbard model are found to exhibit regimes of monotonic or oscillatory thermalization as well as regimes where they evolve in a monotonic or oscillatory manner towards a non-thermal state. This suggests that driven quantum systems have a richer behavior than their quenched counterparts and that integrability does not play as critical a role. In the monotonic thermalization scenario, the system evolves through successive quasi-thermal states and it is possible to extrapolate its long time properties from its transient; bridging the gap between the transient and the steady state with very little computational cost. Furthermore, regardless of the relaxation scenario, it is interesting to ask how the particles are distributed as the system evolves in time. We will show that non-trivial parameter-dependent patterns are formed when the system is visualized in momentum space [3]. These features should be observable in current cold atom experiments.

9:48AM Y18.00004 New Perspectives for Time-Evolution with DMRG, ULRICH SCHOLLWOECK, Dept of Physics University of Munich — In the last 10 years, time-evolution with DMRG has revealed itself to be a very powerful technique for low-dimensional strongly interacting quantum systems both near and far from equilibrium. We show how new techniques, mainly based on the use of Chebyshev polynomials allowing to use DMRG for obtaining real-frequency spectral information in multi-band DMFT calculations, also allow to use it as an impurity solver for far-from-equilibrium DMFT in a Hamiltonian formulation, strongly increasing the time range of non-equilibrium DMFT, and to attack time-evolutions efficiently in far from equilibrium settings.
10:24AM Y18.00005 Nonequilibrium Dynamical Mean Field Theory for Inhomogeneous and Photo-Excited Systems1. PHILIPP WERNER, University of Fribourg — Photodoping of a Mott insulator triggers a nonequilibrium phase transition from a correlation induced insulating state to a nonthermaling conducting state with electron- and hole-like carriers. Using the nonequilibrium extension of (inhomogeneous) dynamical mean field theory2,3 in combination with a strong-coupling impurity solver4 we study the relaxation and diffusion of photo-doped carriers in Mott insulating bulk systems and hetero-structures. In large-gap insulators, the life-time of the carriers depends exponentially on the gap size5 while in small-gap insulators, strongly pulse-energy dependent impact ionization processes lead to a double-exponential relaxation6. In the paramagnetic phase, the photo-doped carriers spread through the insulator in a diffusive manner, while the scattering with an antiferromagnetic background leads to a rapid loss of kinetic energy7. In the presence of strong fields, as realized e. g. in polar heterostructures, the ability to dissipate energy locally in an antiferromagnetic system enables fast carrier transport8. These insights should be relevant for designing Mott insulating solar cells and light-controlled devices which operate on an ultra-fast timescale.

8:36AM Y20.00002 Spin transport across ferromagnetic tunnel contacts to semiconductors — questions and answers, RON JANSEN, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan — Ferromagnetic tunnel contacts to semiconductors are key building blocks of spintronic semiconductor devices. Such contacts allow the transport of spins from the ferromagnetic source into the semiconductor, driven either electrically or thermally, but also provide a means to detect spins in the semiconductor and convert the spin information into an electrical signal. Reproducible results have been obtained using either a local (3-terminal) or non-local (4-terminal) measurement geometry, and the electrical spin signals in both cases exhibit all the characteristic features of a current-induced non-equilibrium spin population. Nevertheless, the quantitative analysis has revealed surprising discrepancies with the existing theory. I will address several relevant questions about the nature of the spin transport in ferromagnetic tunnel contacts on semiconductors, and discuss the answers using the experimental observations that have been obtained over the last years and their comparison with available theories, including those involving localized states in the contact. The aim is to clarify what is established and understood and what is not, the latter pointing to interesting new physics yet to be uncovered.

9:12AM Y20.00003 3-terminal Hanle measurements in metals: spin accumulation or novel magnetoresistance effect?, FELIX CASANOVA, CIC nanoGUNE, 20018 San Sebastian (Basque Country, Spain) — A simple device to study spin injection and transport in semiconductors uses a 3-terminal (3T) geometry, in which spin accumulation is induced and probed by a single magnetic tunnel contact, through the Hanle effect [1]. Since this geometry does not require submicron-sized fabrication, 3T-measurements have become very popular [1-3]. However, many of the reported results disagree with the standard theory of spin injection and have put these measurements into question [4-6]. Our recent work shines some light to this controversy. First, we fabricated ferromagnetic-insulator-nonmagnetic (FIN) 3T devices with metallic electrodes to avoid the complications brought by the Fermi-level pinning when using a semiconductor, and demonstrate that measured Hanle and inverted Hanle-like features are not compatible with spin injection in these metals [5]. Subsequently, we detect this effect in nonmagnetic-insulator-nonmagnetic (NIN) tunnel junctions for the first time and we demonstrate experimentally beyond any doubt that the measured Hanle-like signals are due to impurities in the oxide layer [7]. We support these results with a theory for impurity-assisted tunneling which takes into account spin interactions and Coulomb correlations. We show that this is actually a novel magnetoresistance effect, which is general to any impurity-assisted tunneling process regardless of the oxide thickness or materials used. The presented work will thus be used as a benchmark to spin injection experiments to any nonmagnetic material, and specially will redirect research of semiconductor spintronics, with all the implications in such a technologically relevant area. B 86, 081201(R) (2012); [5] O. Txoperena et al., Appl. Phys. Lett. 102, 192406 (2013); [6] H. N. Tinkey et al., Appl. Phys. Lett. 104, 232410 (2014); [7] O. Txoperena et al., Phys. Rev. Lett. 113, 146601 (2014).

9:48AM Y20.00004 New interpretation for recent spin injection experiments1, HANAN DERY, University of Rochester — We elucidate the large discrepancy between known spin relaxation theory and the findings of recent spin injection experiments that make use of a single ferromagnetic-insulator-nonmagnetic junction for both injection and detection of spin-polarized currents. This local setup scheme gained popularity since 2009 when Dash et al. claimed to achieve room temperature spin injection in silicon [1], followed by avalanche of similar experiments in silicon and other materials that resort to this measurement technique. We show that those enhanced signals and their dependence on temperature are set by impurities embedded in the tunnel barrier with large on-site Coulomb repulsion compared with the voltage bias [2]. Depending on the electron occupation of the resonance level, the magnetoresistance effect is established by the interplay between the Zeeman energy and the impurity coupling to the ferromagnetic material. Considering molecular fields due to hyperfine and exchange interactions, we capture the shape and sign dependence of the signal on magnetic field orientation. The findings are used to explain both conventional spin injection [1], and cases where the bias voltage is distributed across the junction while the net charge current is zero (the so-called local Seebeck spin tunneling [3]). Finally, we extend the theory to impurity-rich tunnel junctions, showing that a similar magnetoresistance effect can persist in completely nondopant junctions [4]. The extension beyond electrical spin injection from ferromagnetic electrodes paves the way for a new class of 1D nanometer-size memory cells which represents the ultimate scaling of memories (leaving no room in the bottom).

10:24AM Y20.00005 Crossover from Spin Accumulation into Interface States to Spin Injection in the Germanium Conduction Band1, MATHIEU JAMET, CEA and University Grenoble Alpes — Electrical spin injection from ferromagnetic metals to silicon (Si) and germanium (Ge) is the first and basic requirement for the development of spintronic devices and their integration with mainstream semiconductor (SC) technology. The main obstacle to efficient spin injection is the conductivity mismatch between the ferromagnetic metal and Si or Ge and requires tunneling spin injection through an oxide barrier (Ox). However, tunneling spin injection raises other important issues in the interpretation of spin signals obtained in three-terminal geometry. In particular, the possible presence of localized states within the Ox or at the Ox/SC interface may lead to wrong conclusions. To study the exact origin of the spin signals measured in three-terminal geometry, we have grown Ta/CoFeB/MgO/SoI and GeO1 substrates with n and p type doping using variable MgO thicknesses. The use of SOI and GeOI substrates allows us to apply back gate voltages to the SC channel to vary its resistivity. Moreover we have used three different techniques to grow the MgO tunnel barrier: by sputtering of MgO or Mg followed by a plasma oxidation and e-beam evaporation of MgO. Using the Mg and plasma oxidation growth of the tunnel barrier, though less flexible than the other techniques, allowed us to show the temperature transition from the spin accumulation into interface states to the spin accumulation into the conduction band of n-Ge. Above 150 K, the magnitude of the spin RA product agrees well with the spin diffusion theory predictions and is proportional to the injected current and to the channel resistivity as expected. Temperature dependent spin pumping measurements showed the same transition. Using the same spin injector, we also found radically different spin signals using p-Ge supporting the fact that spin accumulation occurs into the SC channel. In this presentation, we will extend our spin signal analysis using MgO tunnel barriers of different thicknesses and grown by different methods.

Friday, March 6, 2015 8:00AM - 11:00AM – Session Y21 DCMP: Vanadium Oxides I 201 - Jiang Wei, Tulane University
8:00AM Y21.00001 Oxygen Effect and Mechanism of Insulator-to-Metal Transition using Indirect Band in Vanadium Dioxide, TETIANA SLUSAR, ETRI-Elec Telecomm Rsch Inst in Korea, JIN CHEOL CHO, Korea University of Science and Technology, AHRUM SOHN, Ewha Womans University in Korea, JEONGYONG CHOI, ETRI-Elec Telecomm Rsch Inst in Korea, DONG-WOOK KIM, Ewha Womans University in Korea, HYUN-TAK KIM, ETRI-Elec Telecomm Rsch Inst in Korea — The vanadium dioxide VO$_2$ Science and Technology, AHRUM SOHN, Ewha Womans University in Korea, JEONGYONG CHOI, ETRI-Elec Telecomm Rsch Inst in Korea, DONG-WOOK KIM, Ewha Womans University in Korea, HYUN-TAK KIM, ETRI-Elec Telecomm Rsch Inst in Korea — The vanadium dioxide VO$_2$ is known as the Mott insulator and it undergoes the insulator-to-metal transition (IMT) near $T_c = 340$ K. Under the external influence (doping, strain etc.) the $T_c$ is reduced. To explain this behavior, we have used the Mott criterion proposing the critical carrier density $n_c$ at MIT (metal to insulator). In this case, Mott derived $n_c$ for the transition from metal to insulator. Therefore, $n_c$ is regarded as the minimum carrier density in metal phase. However, in the reverse transition (insulator to metal), $n_c$ cannot clarify the above behavior. Thus, a new model has been required. Here, we have grown VO$_2$ thin films under the different oxygen partial pressure conditions and studied the influence of oxygen deficiency on $T_c$ of the IMT. For the analysis, we have measured the Hall voltage near $T_c$ and a change of work function. Based on the experimental data we have proposed the model explaining $T_c$ changes in VO$_2$. This model describes the excitation process of bounded charges in direct and indirect energy bands as a criterion of the IMT. Moreover, it is shown that it can serve as universal mechanism that describes the physics of the IMT in many MIT materials from the new point of view, different from that, suggested by Mott. It is the fundament for operation of new devices.

8:12AM Y21.00002 First principles calculations of insulator-to-metal transition in photoexcited monoclinic VO$_2$, LEDE XIAN, University of the Basque Country, MATTEO GATTI, Ecole Polytechnique, PIERLUIGI CUDAZZO, University of the Basque Country, DANIEL WECKKAMP, MARC HERZOG, Fritz Haber Institute of the Max Planck Society, CHRISTINA MCGAHAN, ROBERT MARVEL, RICHARD HAGLUND, Vanderbilt University, MARTIN WOLF, JULIA STAHLER, Fritz Haber Institute of the Max Planck Society, ANGEL RUBIO, University of the Basque Country — The insulator-to-metal phase transition of VO$_2$ has been discovered for a long time, but its origin remains elusive. In recent experiments, ultrafast band gap collapse of monoclinic VO$_2$ upon photo excitation was observed through time resolved photoelectron spectroscopy (TRPES). In order to study this issue, we have performed first principles calculations based on many-body perturbation theory. We show that the band gap in monoclinic phase is extremely sensitive to small changes in the occupation of the localized d bands of V atoms. In particular, the photo-induced hole doping in VO$_2$ can strongly alter the dynamical screening, which then leads to a collapse of the band gap. Our results support the experimental findings and point to the electronic origin of the insulator-to-metal phase transition of monoclinic VO$_2$ in the TRPES experiments.

8:24AM Y21.00003 Extraordinary Inhibition of the Field-effect by Bound Quasiparticles at the Interface of a Dielectric and a Metal-Insulator Transition Material VO$_2$$_1$, KOEN MARTENS, KULeuven / imec / IBM Almaden, JAEWOO JEONG, NAGAPHANI AETUKURI, CHARLES RETTNER, IBM Almaden, NIHIL SHUKLA, EUGENE FREEMAN, Penn State University, DAVID ESHAHWI, FRANCOIS PEETERS, Universiteit Antwerpen, TEYA TOPURIA, PHIL RICE, IBM Almaden, ALEXANDER VOLODIN, KULeuven, WILDTED VANDERVORST, imec / KULeuven, MAHESH SAMANT, IBM Almaden, SUMAN DATTA, Penn State University, STUART PARKIN, IBM Almaden — An electric field applied normal to the interface of a dielectric and the prototypical, strongly-correlated semiconductor VO$_2$ is anticipated to lead to non-trivial phenomena. This field-effect allows for key insight into VO$_2$ physics. Field-effect modulation of channel current and carrier depletion in a field-effect device are found to be extraordinarily highly inhibited and no Metal-Insulator Transition is induced by the gate field for excess carriers up to $5 \times 10^{11}$cm$^{-2}$. The field-induced excess charge consists of bound quasi particles, as demonstrated by their activated and low excess carrier field-effect mobility. Small polarons as excess carriers in VO$_2$ consistently explain the observed field-effect, mobility and absence of depletion. The physics required to describe semiconducting VO$_2$’s field-effect is fundamentally different from classical semiconductor physics.

8:36AM Y21.00004 Phase inhomogeneity near the electrically driven insulator-metal transition in VO$_2$ nanobeams$^{1}$ , SUJAY SINGH, Department of Physics, University at Buffalo, State University of New York, Buffalo, NY 14260, USA, GREGORY HORROCKS, Department of Chemistry, Texas A&M University, College Station, TX 77843, USA, PETER MARLEY, Department of Chemistry, University at Buffalo, State University of New York, Buffalo, NY 14260, USA, ZHENZHONG SHI, Department of Physics, University at Buffalo, State University of New York, Buffalo, NY 14260, USA, SARBJIT BANERJEE, Department of Chemistry, Texas A&M University, College Station, TX 77843, USA, G. SAMBANDAMURTHY, Department of Physics, University at Buffalo, State University of New York, Buffalo, NY 14260, USA — Vanadium oxide (VO$_2$) exhibits an insulator to metal transition (IMT) at $T_c \approx 342$ K and this transition is amenable to triggering by voltage, light and strain. We present results from transport measurements (both AC and DC) on individual nanobeams of single crystalline VO$_2$ across the electrically driven transition from the insulating phase. Recent works in correlated electron systems have debated the individual roles of mechanisms such as Joule heating, percolation and avalanche in driving the transition. In our samples, the calculated average temperature of the nanobeams due to Joule heating is less than $C_T$ near the IMT, suggesting that an inhomogeneous phase develops and filamentary conduction paths likely drive the transition. At low bias values, the conduction is dictated by Joule heating and avalanche processes. At high bias values, the conduction is dictated by the re-emission of quasiparticles. The occurrence of avalanche-type events at higher bias values induce the formation of filamentary pathways, thereby precluding further need for percolation.

8:48AM Y21.00005 An ultrafast nano-infrared study of the photo-induced insulator-to-metal transition in Vanadium Dioxide, AARON STERNBACH, University of California San Diego Department of Physics, MENGKUN LIU, University of California San Diego Department of Physics, Stony Brook University Department of Physics, MARTIN WAGNER, RUBEN IRAHETA, University of California San Diego Department of Physics, TETIANA SLUSAR, University of Science and Technology School of Advanced Device Technology, Metal-Insulator Transition Creative Research Center ETRI, ALFRED LEITENSTORFER, University of Konstanz, Center for Applied Photonics, HYUN-TAK KIM, University of Science and Technology School of Advanced Device Technology, Metal-Insulator Transition Creative Research Center ETRI, RICHARD AVERITT, DIMITRI BASOV, University of California San Diego Department of Physics — We have devised and implemented the technique of time resolved scanning near-field optical microscopy to study the inhomogeneous development of a phase transition in the time domain with 20 nanometer spatial resolution and 100 femtosecond temporal resolution. The subject of our study is Vanadium Dioxide (VO$_2$), which is a canonical correlated electron system that exhibits an insulator to metal transition (IMT). We observe an abrupt rise in the photoconductivity at several hundred femtoseconds followed by a slow rise, which takes place on the order of several hundred picoseconds. Our measurement resolves the rise time of the IMT in individual sites, and we further observe inhomogeneous dynamics that are dependent on local strain. Our results pave the way for studying a plethora of systems where phase transitions involve inhomogeneities and phase separation.

9:00AM Y21.00006 Anomaly in the Metal-to-Insulator Transition of $V_2O_3$ Thin Films Under Pressure1, ILYA VALMIANSKI, GABRIEL RAMIREZ, SIMING WANG, CHRISTIAN URBAN, Univ of California - San Diego, XAVIER BATTLE, University of Barcelona, IVAN K. SCHULLER, Univ of California - San Diego, CENTER FOR ADVANCED NANOSCIENCE TEAM, GROUP OF MAGNETIC NANOMATERIALS TEAM — We present results of electrical transport measurements in highly textured $V_2O_3$ thin films of varying thickness under hydrostatic pressure from 100 kPa to 1.6 GPa. All films presented ~ 4 orders of magnitude resistance change at the Metal-to-Insulator Transition (MIT). Morphological and structural characterization was performed using in- and out-of-plane X-ray diffractometry and Atomic Force Microscopy before and after pressurization. We found an anomalous pressure dependence of the MIT for pressures above 500 MPa that deviates from the bulk behavior. Furthermore, we found an irreversible change in the MIT temperature, which coincides with a morphological but not crystal structure change in the film. The obtained anomalous pressure dependence suggests a difference between bulk and thin film MIT mechanisms.

9:12AM Y21.00007 Neutron and x-ray scattering studies of the lattice dynamics in VO2, OLIVER DELAIRE, JOHN D. BUDAI, JIAWANG HONG, MICHAEL MANLEY, CHEN LI, ELIOT SPECHT, Oak Ridge National Laboratory, AYMAN SAID, BOGDAN LEU, JON TISCHEL, Argonne National Laboratory, DOUGLAS ABERNATHY, LYNN BOATNER, ROBERT MCMINNEKEY, Oak Ridge National Laboratory, ORNL-ANL COLLABORATION — Vanadium dioxide exhibits a metal-insulator transition at 340K, concomitant with a structural distortion from rutile to monoclinic on cooling. While much attention has been given to purely electronic aspects of the transition and the band-gap opening, less information has been available about the lattice dynamics (phonons), and their role in the thermodynamics of this important phase transition. We report detailed x-ray and neutron scattering measurements of the phonon dispersions and density of states in VO2, and their influence on the thermodynamics [1]. We show that the entropy of the transition is controlled by the large phonon entropy of the rutile phase, which stabilizes it at high temperature. This phonon entropy arises from soft, strongly-anharmonic phonons across much of the Brillouin zone. The origin of this softness and strong anharmonicity are discussed. [1] J. D. Budai*, J. Hong*, M. E. Manley, E. D. Specht, C. W. Li, J. Z. Tischler, D. L. Abernathy, A. H. Said, B. M. Leu, L. A. Boatner, R. J. McQueeney, and O. Dellaire, Nature 2014, DOI:10.1038/nature13865 Support by DOE Office of Basic Energy Sciences, Materials Sciences and Engineering Division; APS and SNS facilities supported by DOE-BES.

9:24AM Y21.00008 Toward Nano-Electronics Applications of Metal-Insulator Transition Materials - Atomic Layer Deposition of VO2 and a Selector Device Concept, ANTONY PETER, imec, KOEN MARTENS, imec / KULeuven, IVILIANA RADU, imec, NUO XU, UC Berkeley, GEERT RAMPHELBERG, Universiteit Gent, CHRISTOPH ADELMANN, imec, CHISTOPHE DETAVERNIER, Universiteit Gent, MARC HEYNS, imec / KULeuven, MALGORZATA JURCZAK, imec — We discuss advances toward applications of Metal-Insulator Transition (MIT) materials in nano-electronics based on the prototypical MIT material VO2. A fabrication friendly method to deposit VO2 is required for VO2 applications. VO2 films deposited by techniques suitable for manufacturing, including Atomic Layer Deposition (ALD), have typically been non-continuous and have shown a strongly degraded MIT when film thickness was below 40-50 nm. We show how the nanoscale morphology of VO2 films can be controlled to realize smooth ultrathin (thinner than 10 nm) crystalline films with ALD. We demonstrate that the films possess both a structural and an electronic transition. The film resistivity of ultrathin films changes by more than two orders of magnitude across the MIT. Incipient nanoelectronics based on Metal-Insulator-Transition (MIT) materials currently features promising device concepts that require further development and understanding. A candidate first nanoelectronic application for MIT materials is a selector element, which is used to prevent sneak currents in dense cross bar memory arrays. Making use of simulations we elaborate a device concept for a selector element based on MIT materials such as VO2 and SmNiO3.

9:36AM Y21.00009 Tungsten-doped vanadium dioxide thin films for THz analog optical applications1, GULTEN KARAOGLAN-BEBEK, NADIM HOQUE, Texas Tech University, MARK HOLTZ, Texas State University, ZHAOYANG FAN, AYRTON BERNUSSI, Texas Tech University — The Mott transition of vanadium dioxide (VO2) has been widely studied, with abrupt changes in electrical and optical properties at temperature approximately 70 C. The phase transition properties of thin vanadium dioxide films can be changed by doping with tungsten making it a prospective candidate to realize tunable optical devices at terahertz (THz) frequencies. Tungsten incorporation into the vanadium dioxide film yields a wider transition window and a lower transition temperature allowing practical use in analog-like continuous applications. Our results reveal characteristic metal-insulator phase temperature and width of 40 C and 35 C, respectively, for the film with the highest W content. We show that the refractive index of W-doped vanadium dioxide can be continuously tuned and this provides precise control of the transmission properties of the vanadium dioxide films and discuss future active THz optical devices for analog applications. We demonstrate that W-doped vanadium dioxide films can be also used as anti-reflective coating at THz frequencies but at temperatures much lower than that observed for undoped films.

1National Science Foundation (ECCS 1128644)

9:48AM Y21.00010 Distinct substrate effects on the gate-induced metallic states in VO2 thin films, MASAKI NAKANO, University of Tokyo, DAISUKE OKUYAMA, Tohoku University, MASAICHIRO MIZUMAKI, SPRing-8, HIROYUKI OSUMI, RIKEN SPRing-8 Center, MASARO YOSHIDA, TAKAHISA ARIMA, University of Tokyo, MASAKI TAKATA, RIKEN SPRing-8 Center, MASASHI KAWASAKI, University of Tokyo, YOSHINORI TUKURA, RIKEN Center for Emergent Matter Science (CEMS), YOSHIHIRO IWASA, University of Tokyo — The idea of utilizing electric-double layers for controlling electronic phases of condensed matters by external voltages, namely EDLT, has attracted growing attention. Of particular interest is EDLT based on VO2, enabling electrical control of “bulk” electronic phases over the electrostatic screening length, as proven by transport, optical, and structural measurements [1-3]. We attributed this unique feature to electrostatic effects, but there are other models proposed from electrochemical viewpoints. Here we show that the reversibility of the device operation strongly depends on the substrates, suggesting a governing mechanism can differ depending on the substrates. We found that EDLT with VO2 films grown on lattice-matched TiO2 substrates show reversible gating effects, whereas those on hexagonal Al2O3 substrates become irreversible, although in both cases metallic states can be induced electrically. X-ray absorption spectra taken before and after the gating experiments also indicated distinct substrate effects on the valence states of vanadium at the gate-induced metallic states.

10:00AM Y21.00011 Platform for applying uniform strain to VO2 nanobeams and other small crystals1, BOSONG SUN, Department of Physics, University of Washington, ANA SANCHEZ, RICHARD BEANLAND, Department of Physics, University of Warwick, TAIUNO PALOMAKI, DAVID COBDEN, Department of Physics, University of Washington — Many properties of crystals, including symmetry, equilibrium phase, band structure, and Bloch state properties such as Berry curvature and even topology, can be modified by strain. Conversely, controlling strain properly is essential for determining the intrinsic properties of many complex materials. We are therefore exploring ways to apply uniaxial stress to small crystals, ranging from two-dimensional materials to nanowires. For example, we have developed a platform for making samples with controlled built-in stress. In the case of VO2 nanobeams, this allows us to perform systematic studies on each of the several phases (R, M1, M2 and T) involved in the metal-insulator transition in a single sample using multiple microscopies, including transmission electron microscopy. Amongst other things we can image the T phase, study the propagation of interphase boundaries, explore the origin of putative noncentrosymmetry, and seek diffuse contrast to locate the spinodal lines of the transition.

10:12AM Y21.00012 ABSTRACT WITHDRAWN

10:24AM Y21.00013 Phase Transitions in Electron Beam Deposited Cr-doped VO2 Thin Films2, DOMINIC ROTA, Belmont University, KENT HALLMAN, Vanderbilt University, DAVON FERRARA, Belmont University, RICHARD HAGLUND, Vanderbilt University — Three phases of the semiconducting state of VO2 are known, denoted M1, M2 and T; the M2 phase in particular has alternating vanadium chains arranged in antiferromagnetic pairs. This suggests potentially interesting magnetic and optical properties, motivating our interest in developing a robust protocol for preparing thin films of the M2 and T phases for studies of the optically induced semiconductor-to-metal transition (SMT). A protocol for electron beam deposition of Cr-doped VO2 (Cr$_x$V$_{1-x}$O$_2$) thin films was developed, allowing for low-cost and efficient fabrication of homogeneous films, beginning with powder precursors for vanadia and chromia in appropriate proportions. The films were characterized by resistivity and reflectivity measurements of the SMT with concentrations of Cr dopant ranging from x=0 to x=0.04. Raman spectroscopy was used to identify the structural phase transitions and revealed that the structural phases M1, T, and M2 can be determined by comparing differences in the spectrum. Comparing the resistivity hysteresis curves to the Raman spectroscopic measurements, we find that single-phase structures occur for x=0 (M1) and x=0.04 (M2) while concentrations between the x=0 and x=0.04 exhibit a mixture of at least two structural phases, including the T phase.

10:36AM Y21.00014 Ab Initio phonon calculations in metallic and insulating phases of VO$_2$1, CHRISTOPHER HENDRIKS, ERIC WALTER, HENRY KRAKAUER, William and Mary College — Vanadium dioxide (VO$_2$) undergoes a first-order metal-insulator transition (MIT) from the high-temperature rutile phase (R) to an insulating, low-temperature monoclinic phase (M1). Several competing insulating phases exist, with phase boundaries in a narrow temperature and strain range close to the MIT. Recently, novel IR and Raman measurements of micro- and nano-structured VO$_2$ samples have become increasingly available; this allows the phases to be studied while avoiding many difficulties with bulk samples, such as twinning and cracking on cycling through the MIT. Theoretical calculations of vibrational properties can assist in the interpretation of such experiments1. We will present ab initio DFT+U calculations of phonon frequencies for the various phases and compare these to reported measurements for the R, M1, M2 and T phases.

10:48AM Y21.00015 Heterogeneous Nucleation and Growth Dynamics in the Light-induced Phase Transition in Vanadium Dioxide. NATHANIEL BRADY, Univ of Alabama - Birmingham, KANNATASSEN APPAVOO, JOYEE NAG, Vanderbilt University, MIN-AH SEO, ROHIT PRASANKUMAR, Los Alamos National Lab, RICHARD HAGLUND, Vanderbilt University, DAVID HILTON, Univ of Alabama - Birmingham — Vanadium dioxide is a well-known transition metal oxide that undergoes an insulator-to-metal phase transition at $T_C = 340$ K that is accompanied by a structural distortion from monoclinic [P2_1/c for $T < T_c$] to rutile [P42/mnm for $T > T_c$]. The heterogeneous nature of this phase transition is evident from the significantly smaller the thermal energy at $T_c$ when compared to the energy barrier for homogenous nucleation [see: Phys. Rev. B 65, 224113 (2002)]. The identity of the relevant defect that locally lowers this barrier enabling this phase transition, however, is currently unclear. In our talk, we will report on ultrafast optical investigations of the light-induced insulator-to-metal phase transition in samples with controlled disorder generated by substrate mismatch. Our results reveal several common features of this optical phase transition that are independent of this disorder and a small variation in threshold fluence needed to drive this phase transition that depends on the sample morphology.

We attribute the shifts to the Stark effect, and characterize nanotubes with different chiralities. By taking into account exciton binding energies for air-suspended tubes, we find that theoretical predictions are in quantitative agreement.

8:00AM Y22.00001 Stark effect of excitons in individual air-suspended carbon nanotubes1. MASASHIRO YOSHIDA, YUSUKE KUMAMOTO, AKIHIRO ISHI, AKIO YOKOYAMA, YUICHIRO K. KATO, The University of Tokyo — We investigate electric-field induced redshifts of photoluminescence from individual single-walled carbon nanotubes (SWNTs) under an application of symmetric bias voltages on source and drain contacts. We find that redshifts scale quadratically with field, while measurements with different excitation powers and energies show that effects from heating and relaxation pathways are small. We attribute the shifts to the Stark effect, and characterize nanotubes with different chiralities. By taking into account exciton binding energies for air-suspended tubes, we find that theoretical predictions are in quantitative agreement.

8:12AM Y22.00002 ABSTRACT WITHDRAWN

8:24AM Y22.00003 In-situ TEM study of collapsing, reinflating and twisting of multi-walled carbon nanotubes. AIMING YAN, Dept. of Physics, Univ of California - Berkeley; Materials Science Division, Lawrence Berkeley National Laboratory, Berkeley, HAMID BARZEGAR, Dept of Physics, Univ of California, 90187 Umea, Sweden, CLAUDIA OJEDA-ARISTIZABAL, GABRIEL DUNN, Dept. of Physics, Univ of California - Berkeley; THOMAS WAGBERG, Dept of Physics, 90187 Umea, Sweden. — Since the first observation of collapsed carbon nanotubes (CCNTs) by Chopra et al., CCNTs have attracted a lot of attention due to their potentially modified electrical properties caused by structural changes compared to their tubular counterparts. We study the transition of multi-walled carbon nanotubes (MWCNTs) from tubular to collapsed form and the reverse process in-situ by Transmission Electron Microscope (TEM) and monitor the whole process by imaging and electron diffraction. We show that we are able to collapse the tubular CNT by extracting the inner core of the tube and reinflate the collapsed carbon nanotube by applying a voltage at the tip of the CNT. We also observe the twisting of the collapsed multi-walled CNT in-situ. The nano-scale manipulation of carbon nanotubes inside TEM enables us to tailor the transition between tubular and collapsed forms of a CNT.

8:36AM Y22.00004 Optoelectronic Properties and Electromechanical Resonance Behavior in Individual Suspended Carbon Nanotube pn-Junctions and Devices, STEPHEN CRONIN, University of Southern California — In carbon nanotubes pn-junctions, we observe Zener tunneling behavior and photocurrent generation in quasi-metallic nanotubes [1], which have smaller band gaps than most known bulk semiconductors. These carbon nanotube-based devices deviate from conventional bulk semiconductor device behavior due to their low-dimensional nature. We observe rectifying behavior based on Zener tunneling of ballistic carriers instead of ideal diode behavior, as limited by the diffusive transport of carriers. We observe substantial photocurrents at room temperature, suggesting that these quasi-metallic pn-devices may have a broader impact in optoelectronic devices. We also explore the role of weak clamping forces, typically assumed to be infinite, in the electromechanical resonance behavior of these suspended carbon nanotubes [2]. Due to these forces, we observe a hysteretic clamping and unclamping of the nanotube device that results in a discrete drop in the mechanical resonance frequency on the order of 5–20 MHz, when the temperature is cycled between 340 and 375 K. This instability in the resonant frequency results from the nanotube unpinning from the electrode/trench sidewall where it is bound weakly by van der Waals forces. Interestingly, this unpinning does not affect the Q-factor of the resonance, since the clamping is still governed by van der Waals forces above and below the unpinning. For a 1 µm device, the drop observed in resonance frequency corresponds to a change in nanotube length of approximately 50–65 nm. On the basis of these findings, we introduce a new model, which includes a finite tension around zero gate voltage due to van der Waals forces and shows better agreement with the experimental data than the perfect clamping model. From the gate dependence of the mechanical resonance frequency, we extract the van der Waals clamping force to be 1.8 pN. The mechanical resonance frequency exhibits a striking temperature dependence below 200 K attributed to a temperature-dependent slack arising from the competition between the van der Waals force and the thermal fluctuations in the suspended nanotube.

9:12AM Y22.00005 Near-field optical study of individual single-walled carbon nanotubes. ZHIWEN SHI, XIAOPING HONG, UC Berkeley, HANS BECHTEL, MICHAEL MARTIN, Lawrence Berkeley National Laboratory, YUEN-RON SHEN, FENG WANG, UC Berkeley — Quantum-confined electrons in one dimension (1D) behave as Luttinger liquid, a strongly correlated electronic matter distinctly different from Fermi liquid. Metallic single-walled carbon nanotubes (SWNTs), with their strong quantum confinement and structural simplicity, provide the ideal model system for Luttinger liquid. Direct experimental observation of Luttinger liquid in SWNTs, however, proves to be surprisingly challenging. Through near-field optical study, we demonstrated conclusively a robust Luttinger liquid in metallic SWNTs at room temperature.

9:36AM Y22.00007 Plasmon enhanced Raman scattering effect for an atom near a carbon nanotube. ALEX GULYUK, IGOR BONDAREV, North Carolina Central University — A quantum theory of the resonance Raman scattering is developed for a two-level dipole emitter, two-level system (TLS), coupled to a low-energy inter-band plasmon resonance of a carbon nanotube (CN). This resonance Raman scattering is a manifestation of the general Surface Enhanced Raman Scattering (SERS) effect received much of attention due to a very broad range of its applications in nanophotonics, biochemistry, and medicine. Here[1], the SERS effect comes about as a near-field effect in which strong local-field enhancement occurs due to the inter-band plasmon excitation when the TLS is located near the CN surface and its transition energy matches the plasmon resonance energy of the CN. Raman cross-section derived covers both weak and strong TLS-plasmon coupling, and shows a dramatic increase by a factor ~ 10^3 in the strong coupling regime. The effect may be used to detect individual atomic type objects trapped near CNs. More advanced applications, which require further theoretical development, may include highly efficient CN based SERS substrates for single molecule/atom/ion detection, precision spontaneous emission control, and manipulation. – [1] V.Bondarev, arXiv:1407.5142

9:48AM Y22.00008 Optical Field Enhancement by Semiconducting Graphene Nanoribbons. YOSHIYUKI MIYAMOTO, AIST, Japan, HONG ZHANG, Sichuan University, China — Graphene nano-ribbons are known to have energy gap depending on direction of ribbon edge and ribbon width having optical property different from that derived from Dirac cone of the graphene. When the edges are in armchair orientation, the ribbons are semiconducting with energy gaps at their Γ points. In this presentation, we report an enhancement of an optical electric field (E-field) by an armchair graphene nanoribbon by means of the first-principles simulation. The polarization of the E-field was set as parallel to the graphene sheet and perpendicular to ribbon axis. By performing the time-dependent density functional theory (TDDFT) simulation under dynamical E-field, an enhancement of E-field was seen with optical frequencies near the resonance of absorption peaks of the nano-ribbon. The enhancement was not persistent but showed an amplitude modulation with frequencies of few (tens) terahertz depending on E-field frequencies. In this presentation, we discuss mechanisms of field-enhancement and possible applications.

10:00AM Y22.00009 Novel quasi-1D Y-junction carbon with anisotropic conductance and changeable magnetization. BHALCHANDRA PUJARI, Centre for Modeling and Simulation, Savitribai Phule Pune University, Pune 411007 India, ANDREY TOKAREV, DST Hydrogen Infrastructure Center of Competence (HySA Infrastructure), Faculty of Engineering, North-West University, Potchefstroom, South Africa — We propose two conformations of a novel quasi-1D carbon allotrope designed by tailoring three graphene nanoribbons to form a Y-shaped junction. The armchair and zigzag conformations arise due to chirality of underlying ribbons. While armchair Y-junction carbon (YJC) is formed by three identical “arms” of the graphene nanoribbons the zigzag conformation has one distinguishable arm. The result in the later configuration is the broken symmetry of the structure, in which the arms are no longer separated by 120° each. Interestingly the broken structural symmetry of zigzag YJC is also associated with magnetic moment. It is shown that the magnetism is due to underlying nanoribbons and not symmetry breaking. Moreover the magnetism is also affected by the nature of edge passivation. Based on the analysis of density of states, we conjecture that the mixture of sp^2- and sp^3-bonded atoms results three conducting ribbons joined together by the insulating carbon chain. Thus making the structure an anisotropic conductor, with conductivity of armchair conformation being higher than that of zigzag. Armchair and zigzag conformations are energetically extremely stable with binding energy of 11.44 eV/atom and 8.39 eV/atom respectively.

10:12AM Y22.00010 Non-saturating Linear Magnetoresistance in 3-dimensional Carbon Nanostructure. LEI WANG, University of South Carolina, Columbia, MING YIN, FOUZI ARAMMASH, Benedict College, TIMIR DATTA, University of South Carolina, Columbia — Magneto-transport of carbon nanostructure with periodic spherical voids was investigated in magnetic field up to 9.4T in the temperatures range from 2K to 50K. With increase of magnetic field, transverse magnetoresistance crosses over from quadratic to a non-saturating linear dependence. Furthermore, longitudinal magnetoresistance which is negligible in most materials exhibits the same value as transverse magnetoresistance in our system. We demonstrate linear magnetoresistance (LMR) is proportional to the carrier mobility. Over the entire B-T phase region studied, MR data is observed to be a universal function of B/T. Orientation independent linear response is an attractive feature for applications.

10:24AM Y22.00011 Anomalous magnetization of a carbon nanotube as an excitonic insulator. MASSIMO RONTANI, CNR-NANO Research Center S3, Modena, Italy — We show theoretically that an undoped carbon nanotube might be an excitonic insulator—the long-sought phase of matter proposed by Keldysh, Kohn, and others fifty years ago. We predict that the condensation of triplet excitons, driven by intervalley exchange interaction, spontaneously occurs at equilibrium if the tube radius is sufficiently small. The signatures of exciton condensation are its sizable contributions to both the energy gap and the magnetic moment per electron. The increase of the gap might have already been measured, albeit with a different explanation [2]. The enhancement of the quasiparticle magnetic moment is a pair-breaking effect that counteracts the weak paramagnetism of the ground-state condensate of excitons. This property could rationalize the anomalous magnitude of magnetic moments recently observed in different devices close to charge neutrality. [1] M. Rontani, Phys. Rev. B 90, 195415 (2014). [2] V. V. Deshpande et al., Science 323, 106 (2009).

10:36AM Y22.00012 Carbon nanotubes coupled to superconducting impedance matching circuits. SCHONENBERGER CHRISTIAN, MINKYUNG JUNG, VISHAL RANJAN, Department of Physics, Univ. of Basel, GABRIEL PUEBLA-HELMANN, Department of Physics, ETH-Zurich, THOMAS HASLER, ANDREAS NUNNENKAMP, Department of Physics, Univ. of Basel, MATTHIAS MUOTH, CHRISTOPHER HIEROLD, Micro- and Nanosystems, ETH-Zurich, ANDREAS WALLRAFF, Department of Physics, ETH-Zurich, RF-HYBRID-COLLABORATION COLLABORATION — Coupling carbon nanotube devices to microwave circuits offers a significant increase in bandwidth and signal-to-noise ratio. These facilitate fast non-invasive readouts important for quantum optics, shot noise and correlation measurements. Here, we successfully couple a carbon nanotube (CNT) double quantum dot to a GHz superconducting matching circuit using a mechanical transfer technique. The device shows a tunable bipolar double dot behavior, reaching the few-electron/hole regime. The resonance response reflected by the matching circuit is a sensitive probe of the charge state of the device, allowing a determination of the absolute charge number. The resonance response at the interdot charge transitions enables quantitative parameter extraction. Presented results open the path for novel studies of microwave photons interacting with electrons in carbon nanotubes.

10:48AM Y22.00013 Interplay of Magnetism of Superconductivity in Graphitic Nanostructures, YAO AN, ROBERT MEULENBERG, Department of Physics and Astronomy and Laboratory for Surface Science and Technology, University of Maine — The main foci in modern high temperature superconductivity (HTS) research are two-fold: (a) in conventional HTS finding new machinable materials necessary for any real world applications and (b) discovering new materials for that elusive room temperature superconductivity (RTS). It is quite evident that the potential applications for HTS or RTS are immense, and could show tremendous cost savings in various industries. To date, most reports of RTS have been eventually disproved; however, recent work has suggested that graphite flakes can exhibit RTS when treated with water. This extraordinary claim, if true, offers a wide range of stimulating physics to be studied in RTS; A main obstacle toward RTS in carbon based materials is ruling out whether one is truly observing superconductivity, or simply magnetism. In this talk, we will discuss effects of solution exfoliation of graphite powders. Not surprisingly, drastic changes to the graphite powder are observed. These changes, mainly in the form of graphene sheet exfoliation and defect formation, suggest a form of magnetism and not superconductivity in the treated powders via SQUID magnetometry measurements. A method for preparing graphitic monoliths that allow for transport measurements will be presented.

Friday, March 6, 2015 8:00AM - 10:24AM –

Session Y23 DCOMP: Focus Session: Petascale Science and Beyond: Applications and Opportunities in Materials Science and Chemistry III 202B - Thomas Schulthess, Swiss Federal Institute of Technology (ETH)

8:00AM Y23.00001 Aneesur Rahman Prize Talk: Working at the Speed of Light, JOHN JOANNOPOLOS, Massachusetts Institute of Technology — Photonic crystals are periodic dielectric structures possessing a photonic band gap that forbids propagation of a certain frequency range of light. This gap, and other curious properties of these systems, enable control of light with amazing facility and produce effects that are impossible to achieve with conventional optics. By combining analytical theory with state-of-the-art numerical calculations, examples of novel, and even anomalous, light behavior will be presented.

8:36AM Y23.00002 Scale-Bridging Modeling of Material Dynamics: Petascale Assessments of the Road to Exascale, TIMOTHY GERMANN, Los Alamos National Laboratory, EXMATEX TEAM — Within the multi-institutional, multi-disciplinary Exascale Co-design Center for Materials in Extreme Environments (ExMatEx), we are engaging domain (computational materials) scientists, applied mathematicians, computer scientists, and hardware architects, in order to establish the relationships between algorithms, software stacks, and architectures needed to enable exascale-ready materials science application codes within the next decade. We anticipate that we will be able to exploit hierarchical, heterogeneous architectures to achieve more realistic large-scale simulations with adaptive physics refinement, and are using tractable application scale-bridging proxy application testbeds to assess new approaches and requirements. Our focus has been on scale-bridging strategies that accumulate (or recompute) a distributed response database from fine-scale calculations, in a top-down rather than bottom-up multiscale approach. To evaluate and exercise the task-based programming models, databases, and runtime systems required to perform such many-task computation workflows, we are carrying out petascale demonstrations in 2015 which I will describe in this talk.

8:48AM Y23.00003 Large Scale Molecular Dynamics Simulation of Polymeric Materials, MONOJOY GOSWAMI, JAN-MICHAEL CARRILLO, RAJEEV KUMAR, BOBBY SUMPTER, Oak Ridge National Lab — In this talk, I will present a series of large-scale molecular simulations of polymer nanocomposites and block copolymers (BCP). We will discuss three different problems in this talk that requires large-scale computation: 1) hydrated RNA dynamics on a nanodiamond (ND) surface for drug-delivery applications, 2) poly(3-hexylthiophene) (P3HT) and PCBM nanocomposites for the application in organic photovoltaics (OPV) and (3) amphiphilic BCP self assembly in surfactant solution for membrane separation technology applications. We simulate problem (1) using fully atomistic NAMD simulation and discuss the puzzling discovery of faster RNA dynamics on ND surface. LAMMPS MD code is used to simulate problems (2) and (3). Here we explain the importance of nano-domains in P3HT:PCBM nanocomposites in designing OPV and the criterion for surfactant mediated self-assembly of amphiphilic BCP in solution.

9:00AM Y23.00004 Fast Analysis of Time-Resolved Scattering Data, ALEXANDER HEXEMER, DINESH KUMAR, SINGANALLUR VENKATAKRISHNAN, ABHINAV SARJE, SIMON PATTON, SHERRY LI, JACK DESLIPPE, CRAIG TULL, Lawrence Berkeley Natl Lab, ELI DART, ESNET, FENG LIU, THOMAS RUSSELL, Amherst UMass, ENRIQUE GOMEZ, The Pennsylvania State University, CHENHUI ZHU, ERIC SCHAIBLE, POLITE STEWART, Lawrence Berkeley Natl Lab, CAMERA TEAM, ESNET TEAM, SPOT SUITE TEAM, UMASS COLLABORATION, PENNSTATE COLLABORATION — Organic Photovoltaics hold promise to reduce costs and increase efficiency. Most efforts have focused on spin-coating to fabricate high performance devices, a process that is not amenable to large scale fabrication. This mismatch in device fabrication processes makes it difficult to translate quantitative results obtained from laboratory scale devices to commercially prepared large area devices. Using a mini-slot die coater, designed and build in house, we address this issue, where the commercial process is translated to the laboratory setting. Grazing Incidence Small Angle X-ray Scattering was used to probe the change in morphology during the printing process. HIPGISAXS was used to fit the data in real-time by utilizing different ASCR facilities. SPOT orchestrated the workflow for the data: the transfer from the beamline to NERSC and subsequently to the TITAN supercomputer for fitting and back to NERSC.

9:12AM Y23.00005 Real-time calculations of dynamical effects in x-ray spectra, J.J. REHR, J.J. KAS, A.J. LEE, Univ of Washington — An understanding of dynamical effects and inelastic losses in x-ray spectra due to the sudden creation of a core-hole and photonelectron has long been of interest. Here we present a real-time approach for calculations of core level x-ray absorption and x-ray photoemission spectra that account for the dynamic response in terms of a spectral function that includes intrinsic, extrinsic and interference terms. Our approach is based on a factorization in terms of the core-hole Green’s function and a time-correlation function that avoids the need for ultra-short time-steps. The approach extends a time-correlation function approach for XAS, factorization in terms of the core-hole Green’s function and a time-correlation function that avoids the need for ultra-short time-steps. The approach extends an adaptation of the Crank-Nicholson time-evolution algorithm with PAW transition matrix elements. Illustrative examples are presented for a number of systems.

9:24AM Y23.00006 Atomistic Materials Modeling on Petascale Platforms Using SNAP\(^1\). AIDAN THOMPSON, LAURA SWILER, CHRISTIAN TROTT, STEPHEN FOILES. Sandia National Laboratories, GARRITT TUCKER, Drexel University — The growing availability of capacity computing for atomistic materials modeling has encouraged the use of high-accuracy computationally intensive interatomic potentials, such as SNAP. These potentials also happen to scale well on petascale computing platforms. SNAP has a very general form and uses machine-learning techniques to reproduce the energies, forces, and stress tensors of a large set of small configurations of atoms, which are obtained using high-accuracy quantum electronic structure (QM) calculations. The local environment of each atom is characterized by a set of bispectrum components of the local neighbor density projected onto a basis of hyperspherical harmonics in four dimensions. The computational cost per atom is much greater than that of similar potentials such as Lennard-Jones or EAM, while the communication cost remains modest. We discuss a variety of strategies for implementing SNAP in the LAMMPS molecular dynamics package. We present several results obtained running SNAP on three different classes of machine: a conventional Intel Xeon CPU cluster; the Titan GPU-based system; and the combined Sequoia and Vulcan BlueGene/Q.

\(^1\)Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corp., for the U.S. Dept. of Energy’s National Nuclear Security Admin. under contract DE-AC04-94AL85000

9:36AM Y23.00007 Molecular dynamics simulation: at a crossroad between molecular biophysics and petascale computing\(^1\). XIAOLIN CHENG, Oak Ridge National Laboratory — High-performance computing (HPC) has become crucial for most advances made in chemistry and biology today. In particular, biophysical simulation is capable of helping generate critical new insights and drive the direction of experimentation. In this talk, I will discuss our work towards addressing some fundamental membrane biophysical questions using HPC capabilities at Oak Ridge National Laboratory. I will first provide a synopsis of our current progress in developing molecular dynamics (MD) techniques that make efficient use of massively parallel supercomputers. I will then discuss a few examples of large-scale MD simulations of biomembrane vesicles, an effort aimed at shedding light on the lateral organization and cross-layer coupling in biologically-relevant membranes. In conclusion, I will discuss a few scientific and technical challenges faced by MD simulation at the exascale.

\(^1\)This research used resources of the Oak Ridge Leadership Computing Facility at the Oak Ridge National Laboratory, which is supported by the Office of Science of the U.S. Department of Energy under Contract No.DE-AC05-00OR22725.

9:48AM Y23.00008 Large-scale atomistic simulations of surface nanostructuring by short pulse laser irradiation\(^1\). CHENGPING WU, MAXIM SHUGAEV, LEONID ZHIGILEI, University of Virginia — The availability of petascale supercomputing resources has expanded the range of research questions that can be addressed in the simulations and, in particular, enabled large-scale atomistic simulations of short pulse laser nanostructuring of metal surfaces. A series of simulations performed for systems consisting of 10\(^9\) ~ 10\(^9\) atoms is used in this study to investigate the mechanisms responsible for the generation of complex multiscale surface morphology and microstructure. At low laser fluence, just below the spallation threshold, a concurrent occurrence of fast laser melting, dynamic relaxation of laser-induced stresses, and rapid cooling and resolidification of the transiently melted surface region is found to produce a sub-surface porous region covered by a nanocrystalline layer. At higher laser fluences, in the spallation and phase explosion regimes, the material disintegration and ejection driven by the relaxation of laser-induced stresses and/or explosive release of vapor leads to the formation of complex surface morphology that can only be studied in billion-atom simulations. The first result from a billion atom simulation of surface nanostructuring performed on Titan will be discussed in the presentation.

\(^1\)Financial support is provided by NSF (DMR-0907247 and CMMI-1301298) and AFOSR (FA9550-10-1-0541). Computational support is provided by the OLCF (MAT048) and NSF XSEDE (TG-DMR110090).

10:00AM Y23.00009 Retention of hydrogen and helium in monocrystal of tungsten\(^1\). JACK WELLS, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, PREDRAG KRSTIC, State University of New York, Stony Brook, NY 11794 — Beginning with either perfect or damaged mono-crystal of tungsten, we bombard the surface with a mix of isotopes of H and He at the impact energy range from 1-100 eV in order to predict the retention rate of the impinging atoms as well as their distribution inside the material, in particular inside the vacancies. Our calculation is based on molecular dynamics simulation using high-performance computing and bond-order potentials. The goal is to distinguish between the following alternative outcomes: (1) the retention rate is proportional to the number of vacancies — consistent with recent experiments on the retention of H in damaged W, (2) vacancies will be filled by aggregates of H or He, leading to unstable surfaces, e.g., bubbling and blistering of the surface, and (3) some fraction of hydrogen and helium will fill the interatomic space in the W crystal lattice, creating a “protective layer” or bubbles and blisters close to the surface, even in absence of significant tungsten lattice defects, and (4) the impact direction and the crystal surface cut influence significantly ratio of effects 1-3.

\(^1\)Used resources of the Oak Ridge Leadership Computing Facility, which is supported by DOE Office of Science.

10:12AM Y23.00010 Teraflops and beyond: GPU-based MD exploration of emergent phenomena\(^1\). DENNIS RAPAPORT, Bar-Ilan University — Molecular dynamics (MD) simulation of emergent phenomena can be computationally demanding because of the broad range of length and time scales that must be covered, ranging from the individual particles out to where the collective behavior is expressed; the fact that simulations of this type are often subject to unpredictable outcomes is a further complication. Examples of MD studies of emergent behavior include discrete-particle modeling of hydrodynamic instabilities (e.g., thermal convection cells), complex segregation processes in granular systems modeled with inelastic particles (e.g., in a rotating drum), and supramolecular self-assembly (e.g., the growth of icoshedral shells corresponding to viral capsids). The comparatively large and long simulations required for these problems benefit substantially from massively parallel GPU-based implementation, with even a single GPU typically providing an order of magnitude speedup over a conventional CPU. A sampling of newly obtained exploratory results for these and similar problems [arXiv:1409.5958] will be described, along with the methodology; the results offer a tantalizing hint of the kinds of phenomena that can be explored, and what might be achieved given the appropriate resources.

Friday, March 6, 2015 8:00AM - 11:00AM – Session Y25 DCMP: Superconductivity in Cuprates (mostly): Theory II 203B - Wei Ku, Brookhaven National Laboratory
order due to hole doping, through exact finite temperature phase diagram of the model. [1] M. H. Fischer, S. Wu, M. Lawler, A. Paramekanti, and E.-A. Kim, temperature properties as well as unbiased determination of ground state spin and charge configuration. As a function of system parameters, we obtain a rich understand the phase diagram of broken symmetry states using a simple model that captures the essence of hole doped cuprates [1]. The model consists of phase coherence around 25%, giving rise to a dome shape of superconducting transition temperature in excellent agreement with experimental observations.

1 This research was carried out with resources of the Oak Ridge Leadership Computing Facility (OLCF), the Swiss National Supercomputing Center (CSCS), and the Center for Nanophase Materials Sciences (CNM).
9:24AM Y25.00008 Enchancement of superconductivity in a three-dimensional hotspot model of competing orders in the cuprates. — ZACHARY RAINES, VALENTIN STANEV, VICTOR GALITSKI, Univ of Maryland-College Park — Recent experiments in the cuprates have shown evidence of a transient superconducting state upon optical excitation polarized along the c-axis. Motivated by these experiments we considered a hotspot model of competing superconductivity and bond density order in a system of stacked planes. We generally find an enhancement of superconductivity in the coexistent phase as a function of c-axis coupling strength. Furthermore, we propose a simple Floquet system which takes advantage of this enhancement.

9:36AM Y25.00009 Collective modes in the hot spot model of cuprates1. — VALENTIN STANEV, ZACH RAINES, VICTOR GALITSKI, Univ of Maryland-College Park — We study the collective modes of the possible order parameters of cuprate high-temperature superconductors. Observing and analyzing these modes provide insights into the nature of the ordered state. Using the hot spot model of cuprates, we explore the amplitude oscillations of both charge density wave (CDW) and superconducting states. Especially interesting is the region, in which CDW and superconductivity coexist, in which the two amplitude oscillations become mixed in a single mode with energy inside the single-particle gap. We compare these results with the recent data extracted from reflectivity measurements.

1Work supported by DOE-BES (DESC0001911) and Simons Foundation.

9:48AM Y25.00010 Can short-ranged orders enhance superconductivity of cuprates?1. — KYUNGMIN LEE, EUN-AH KIM, Cornell University — Recent advances in experiments established short-ranged orders associated with tendencies for spatial symmetry breaking as universal phenomena of undoped cuprates. This brings the question of the relationship between these short-ranged orders and superconductivity to the forefront of the study of high Tc superconductivity. Here we study this issue paying special attention to the role form-factors play. Using both non-self-consistent and self-consistent Bogoliubov-de Gennes equation with real-space realization of short-range order we investigate how the short-ranged order affects the electronic structure as well as superconducting tendencies. Typically an inhomogeneous potential due to short-ranged ordering patterns will act as a scatterer that is detrimental to unconventional superconductor which is not protected through Anderson's theorem. However we find that that form factor of the short-ranged ordering form can make consequential differences in the way short-range order interact with superconductivity, with the possibility of enhancing superconductivity.

10:00AM Y25.00011 ABSTRACT WITHDRAWN —

10:12AM Y25.00012 Amplitude mode oscillations in pump-probe photoemission spectra of electron-phonon mediated superconductors1. — ALEXANDER KEMPER, Lawrence Berkeley National Laboratory, MICHAEL SENTEUF, Universitt Bonn, BRIAN MORITZ, Stanford Institute for Materials & Energy Sciences, JAMES FREERICKS, Georgetown University, THOMAS DEVEREAU, Stanford Institute for Materials & Energy Sciences — The amplitude, or Higgs mode is deeply intertwined with the historical development of the BCS theory of superconductivity. Although the presence of the Higgs mode is fundamental to superconductivity, it remained elusive for many decades, and its presence and observability is still under debate in many contexts. We present results for time-dependent photoemission spectra to directly probe the dynamics of the superconducting gap edge where the fingerprint of superconductivity is strongest. The pumping of a superconductor is simulated by solving the two-time Gor’kov equations of motion for the Migdal-Eliashberg model, which is a minimal gauge-invariant model for superconductivity with a pairing boson and dissipation. The Higgs mode can be directly detected without the requirement of any additional symmetry breaking and is clearly visible as oscillations of the gap edge spectra at twice the gap frequency, a hallmark of amplitude modes.

1A.F.K. was supported by the Laboratory Directed Research and Development Program of Lawrence Berkeley National Laboratory under U.S. Department of Energy Contract No. DE-AC02-05CH11231

10:24AM Y25.00013 Angle-dependent magnetoresistance and the presence of fluctuating hot spots on the Fermi surface of Tl2201. — SYLVIA LEWIN, JAMES ANALYTIS, University of California, Berkeley — The normal-state transport properties of cuprate high-temperature superconductors are not well understood. While the Hall angle in such materials is typically proportional to T2, the in-plane resistivity has a more complicated temperature dependence. This has led to many theories of the scattering processes in such materials, including several that posit the existence of two or more independent scattering lifetimes. Here, we propose a model that may explain the cuprates’ complicated normal-state behavior without the need to invoke multiple scattering channels: fluctuating hot spots on the Fermi surface, a result of transient antiferromagnetic order. We will demonstrate that this model can accurately simulate angle-dependent magnetoresistance data from Tl2Ba2CuO6+δ, and discuss what additional calculations and experiments will be performed in order to further test this model.

1This research used resources of the National Energy Research Scientific Computing Center and was supported by a fellowship from the NSF Graduate Research Fellowship Program.

10:36AM Y25.00014 Polar Kerr effect from chiral-nematic charge order. — YUXUAN WANG, Univ of Wisconsin, Madison, ANDREY CHUBUKOV, University of Minnesota, RAHUL NANDKISHORE, Princeton University — We analyze the polar Kerr effect in an itinerant electron system on a square lattice in the presence of a composite charge order proposed for the pseudogap state in underdoped cuprates. This composite charge order preserves translational symmetries, and is “chiral-nematic” in the sense that it breaks time-reversal symmetry, mirror symmetries in x and y directions, and C4 lattice rotation symmetry. The Kerr angle \( \theta_K \) in C4-symmetric system is proportional to the antisymmetric component of the anomalous Hall conductivity \( \sigma_{xy} - \sigma_{yx} \). We show that this result holds when \( C_4 \) symmetry is broken. We show that chiral-nematic charge order satisfies all symmetry requirements by a polar Kerr effect. We further show that to get a non-zero \( \theta_K \) in a one-band spin-fluctuation scenario, in the absence of disorder, one has to extend the spin-mediated interaction to momenta away from (\( \pi, \pi \)) and has to include particle-hole asymmetry. Alternatively, in the presence of disorder one can get a non-zero \( \theta_K \) from impurity scattering; either due to skew scattering (with non-Gaussian disorder) or due to particle-hole asymmetry in case of Gaussian disorder. We finally discuss the effect of an external magnetic field on the Kerr signal.
10:48AM Y25.00015 Finite T spectral function of a single carrier injected into an Ising chain: a comparison of 3 different models\(^1\), MIRKO MOELLER, MONA BERCIU, Univ British Columbia — When studying the properties of complex, magnetic materials it is often necessary to work with effective Hamiltonians. In many cases the effective Hamiltonian is obtained by mapping the full, multiband Hamiltonian onto a simpler, single band model. A prominent example is the use of Zhang-Rice singlets to map the multiband Emery model for cuprates onto the single band t–J-model. Such mappings are usually done at zero temperature (T) and it is implicitly assumed that they are justified at finite T, as well. We present results on 3 different models of a single charge carrier (electron or hole) injected into a ferromagnetic Ising chain. Model I is a two band, two sublattice model, Model II is a two band, single sublattice model, and Model III is a single band model, the so called t–J.,-model. Due to the absence of spin-flip terms, a numerically exact solution of all 3 Models is possible, even at finite T. A zero T mapping between all 3 models results in the same low energy physics. However, this is no longer true at finite T. Here the low energy behavior of Model III is significantly different from that of Models I and II. The reasons for this discrepancy and its implications for more realistic models (higher dimension, inclusion of spin-flip terms) are discussed.

Friday, March 6, 2015 8:00AM - 11:00AM — Session Y26 DCP: Surfaces, Interfaces, Colloids and Catalysis I

8:00AM Y26.00001 CO Adsorption on Pd(111) at 0.5ML: a First Principles Study\(^1\), ZAHRA HOOSHAMOND GHAREHBAGH, DUY LE, TALAT S. RAHMAN, University of Central Florida, Department of Physics, Orlando FL 32816-2385, USA — While the adlayer structures formed by CO molecules on Pd(111) are well-understood both experimentally and theoretically, for low and high coverages, it is still a matter of discussion for medium coverage (0.5ML). At this medium coverage, it is well-known that the c(4 × 2) phase is formed but the adsorption sites of CO molecules have been reported differently by various studies: at the bridge sites, at the hollow sites, or at both bridge and hollow sites. Using density functional theory calculations we studied the overlayer structure of CO at 0.5ML on Pd(111) with all possible highly symmetric adsorption sites leading to c(4 × 2) structures. We will show that, on the same surface, CO molecules adsorb either only on bridge or hollow sites and that there is no overlayer structure in which CO binds at both bridge and hollow sites. By means of \textit{ab initio} thermodynamics simulation, we will also report the conditions (temperature, pressure) in which each overlayer structure exists.

\(^1\)Work support in part by NSF Grant CHE-1310327

8:12AM Y26.00002 Theoretical investigation of oxygen adsorption on Pu-Ga alloy (111) surface\(^1\), SARAH C. HERNANDEZ, University of Texas at Arlington, THOMAS J. VENHAUS, Los Alamos National Laboratory, MUHAMMAD N. HUDA, University of Texas at Arlington — All electron density functional theory was implemented to study the adsorption of atomic oxygen on a 3.125 at. % Ga stabilized δ-Pu (111) surface. A 4-layer periodic slab, with 8 atoms per layer, was used to model the surface, and the location of the Ga within the surface was considered. High symmetry on-surface and interstitials adsorption sites were explored, which also included the adatom placed in different local environments (i.e. oxygen coordinated with/without a Ga atom). Full relaxation of the atomic positions of the Pu-Ga slab and O atom were employed. The inclusion of spin-orbit-coupling was preferred for the lowest energetic structure. The goal of these calculations was to test the probe the effects that Ga may have within the surface when O is adsorb. We found that oxygen binds strongly at an on-surface site with chemisorption energy of -5.06 eV and prefers to be three-fold coordinated either on bridge or hollow sites. It is well-known that the c(4 × 2) phase is formed but the adsorption sites of CO molecules have been reported differently by various studies: at the bridge sites, at the hollow sites, or at both bridge and hollow sites. Using density functional theory calculations we studied the overlayer structure of CO at 0.5ML on Pd(111) with all possible highly symmetric adsorption sites leading to c(4 × 2) structures. We will show that, on the same surface, CO molecules adsorb either only on bridge or hollow sites and that there is no overlayer structure in which CO binds at both bridge and hollow sites. By means of \textit{ab initio} thermodynamics simulation, we will also report the conditions (temperature, pressure) in which each overlayer structure exists.

8:24AM Y26.00003 Stabilization of CH\(_2\) on Ru(0001) by hydrogen co-adsorption, SERGEY V. LEVCHENKO, XUNHUA ZHAO, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, FRITZ-HABER-INSTITUT DER MPG, BERLIN TEAM — Based on indirect experimental evidence, CH\(_2\) was proposed as a building block for hydrocarbon chain growth on the Ru(0001) surface during the Fischer-Tropsch process. However, previous calculations agreed that CH\(_2\) is not stable on Ru(0001) at the reaction conditions, and should quickly convert into CH. Employing density-functional theory, we show that this disagreement can be reconciled if coadsorbed hydrogen is present on the surface. The atomic structure of various CH\(_2\)+H\(_2\) phases is obtained with genetic algorithm. CH\(_2\) dissociation barriers are calculated using the string method. We further demonstrate, by calculating the surface phase diagram for one-carbon species on Ru(0001) as a function of H\(_2\) chemical potential, that the stabilization of CH\(_2\) by co-adsorbed hydrogen requires non-equilibrium conditions. The calculated barrier for the CH\(_2\) dissociation in the presence of hydrogen is significantly increased, and is close to the one recently measured by vibrational sum-frequency generation spectroscopy [1]. Our results also explain why CH\(_2\) was not observed when C or CH are hydrogenated on Ru(0001), although it is observed after methane decomposition.

8:36AM Y26.00004 ABSTRACT WITHDRAWN

8:48AM Y26.00005 ABSTRACT WITHDRAWN

9:00AM Y26.00006 Structure and Electron Localization of Reduced Ceria Surfaces, RENAT SABIRIANOV, Univ of Nebraska - Omaha, KHALDOUN TARAWNEH, Princess Sumaya University for Technology, NABIL AL-AQTASH, NAN SHAO, WAI-NING MAI, Univ of Nebraska - Omaha, CHIN LI CHEUNG, Univ of Nebraska Lincoln — Ceria (CeO\(_2\)) is an extensively used industrial catalyst. However, the mechanism for its catalytic activity, especially in aqueous media, is not yet well-understood. While high density of oxygen vacancy defects (OVDs) are often cited as the major factor in enhancing the activity of nanostructured ceria, the synergistic influences between the surface defects, subsurface oxygen vacancies on the (100), (111) and (110) surfaces of ceria. The removal of a neutral surface oxygen atom leaves back excess electrons that are shown to localize on cerium ions neighboring the defect. The preferential defect formation and the different chemical reactivity of the (100), (111) and (110) surfaces are discussed in terms of defect formation energies. DFT-U calculations predict the preferential subsurface formation of OVDs for (111) surface by energy difference of 0.10 eV, in agreement with previous GGA+U results, while in case of (110) surface calculations predict the surface vacancy to be more stable by energy difference of 1.03 eV. The calculated atomic and electronic structures of ceria the reduced surfaces are shown to agree with spectroscopic and STM measurements.
Monolayer (Hydr)oxide-Metal Interfaces, ZHENHUA ZENG, JOSEPH KUBAL, JEFF GREELEY, Purdue University — Ultrathin specific example, we show how simultaneous NO$_x$ is general and can, in principle, be applied to many reactions, and for each case the choice of the transition oxide monolayer can be optimized. Here, as a ferroelectric substrate. The ferroelectric polarization switches the surface chemistry between strongly adsorptive and strongly desorptive regimes, circumventing sorbent loading dependence of the equilibration time is non-monotonic. This unusual characteristic appears to be related to the structural transition present in values. We have studied the adsorption kinetics for this system, i.e., how the equilibration times for adsorption change as a function of sorbent loading. The transition manifests itself as an additional (higher pressure) substep in the adsorption isotherm data. Xe isotherms measured above 145 K do not show the additional isotherm feature, while those measured below do. The extra adsorption step is a consequence of the “gate opening” transition that occurs due to the re-orientation of the organic linkers in the ZIF-8. This re-orientation increases the size of the apertures in the ZIF-8 structure, and consequently allows more Xe atoms to adsorb in the material, thus producing the additional adsorption step. The adsorption isotherm data were used to determine the effective surface area of ZIF-8 through application of the “point B” method. The isosteric heat of adsorption of Xe on ZIF-8 was determined from the isotherm data. We will also report on the kinetics of adsorption of Xe on ZIF-8.

Study of Xenon Adsorption on Zeolitic Imidazolate Framework – 8 (ZIF-8), DINUKA GALLABA, BRICE RUSSELL, ALDO MIGONE, Department of Physics, Southern Illinois University, Carbondale IL 62901 — We have investigated Xe adsorption on ZIF-8 for temperatures in the range between 138 and 150 K. ZIF-8 is known to undergo a transition (“gate-opening”) transition as a function of increasing pressure (or loading) for a number of adsorbates (N$_2$, Ar, CO, O$_2$). For isotherms measured at sufficiently low temperatures, the gate-opening transition manifests itself as an additional (higher pressure) substep in the adsorption isotherm data. Xe isotherms measured above 145 K do not show the additional isotherm feature, while those measured below do. The extra adsorption step is a consequence of the “gate opening” transition that occurs due to the re-orientation of the organic linkers in the ZIF-8. This re-orientation increases the size of the apertures in the ZIF-8 structure, and consequently allows more Xe atoms to adsorb in the material, thus producing the additional adsorption step. The adsorption isotherm data were used to determine the effective surface area of ZIF-8 through application of the “point B” method. The isosteric heat of adsorption of Xe on ZIF-8 was determined from the isotherm data. We will also report on the kinetics of adsorption of Xe on ZIF-8.

Ferroelectric based catalysis: Switchable surface chemistry$^1$, ARVIN KAKEHANI, SOHRAB ISMAIL-BEIJI, Yale University — We describe a new class of catalysts that uses an epitaxial monolayer of a transition metal oxide on a ferroelectric substrate. The ferroelectric polarization switches the surface chemistry between strongly adsorptive and strongly desorptive regimes, circumventing difficulties encountered on non-switchable catalytic surfaces where the Sabatier principle dictates a moderate surface-molecule interaction strength. This method is general and can, in principle, be applied to many reactions, and for each case the choice of the transition oxide monolayer can be optimized. Here, as a specific example, we show how simultaneous NO$_2$ direct decomposition (into N$_2$ and O$_2$) and CO oxidation can be achieved efficiently on Cr$_2$O$_3$ terminated PbTiO$_3$, while circumventing oxygen (and sulfur) poisoning issues. One should note that NO$_2$ direct decomposition has been an open challenge in automotive emission control technology. Our method could expand the range of catalytically active elements to those which are not conventionally considered for catalysis and which are more economical, e.g., Cr (for NO$_2$ direct decomposition and CO oxidation) instead of canonical precious metal catalysts.

Acceleration of non-PGM Electrocatalyst Design For Fuel Cells Through Site Specific XPS Predictions from First-principles Simulations, BORIS KIEFER, New Mexico State University, SADIA KABIR, KATERYNA ARTYUSHKOVA, PLAMEN ATANASSOV, University of New Mexico — One of the most pressing problems in the 21st century is the provision of environmentally consistent energy technologies especially for space limited non-stationary applications. Fuel Cells are promising candidates for addressing and mastering this challenge. Alternative materials to platinum catalysts which continue to attract significant attention are non-PGM FeN$_x$/C based materials. The understanding of the geometry and chemistry of catalytically active defect moieties is a prerequisite for the rational improvement and design of non-PGM electrocatalysts. XPS, a widely used surface analytical technique, generally shows broad N1s peaks with abundance weighted contributions from every defect motif. Due to the lack of appropriate reference materials it is currently impossible to de-convolute the N1s peak into defect specific contributions. In order to remove this limitation we have performed density-functional-theory (DFT) based calculations for a variety of in-plane FeN$_x$ ($x$=2-4) defects. Using DFT we predict, for the first time, defect chemistry and geometry induced N1s binding energy shifts in these materials. In combination with our XPS experiments and catalyst performance we find that higher FeN$_x$ defect abundance correlates with improved catalyst performance.

Electrolytes near structured dielectric interfaces, HUAXIN WU, YUEFEI JING, Northwestern University, FRANCISCO SOLIS, Arizona State University, MONICA OLVERA DE LA CRUZ, ERIK LUIJTEN, Northwestern University — The ion distribution in an electrolyte near a dielectric interface has important consequences for numerous applications. To date, most studies have focused on planar interfaces, where, e.g., simulations can take advantage of the image-charge method. However, for surfaces that display structure on the nanoscale, dielectric effects may be significantly different. Here, we investigate such interfaces via a combination of computer simulations and Poisson–Boltzmann theory. We demonstrate how, even for systems with piecewise uniform dielectric constant, surface structure affects the induced polarization charge as well as the ion distribution near the interface, in particular for asymmetric salts. We explore the role of ion concentration, dielectric mismatch and characteristic length scale of the surface structure.
10:36AM Y26.00014 Charge dependent condensation of macro-ions at air-water interfaces1. MRINAL BERA, MARK ANTONIO, Chemical Sciences and Engineering Division, Argonne National Laboratory, Argonne, IL-60439, USA — Ordering of ions at and near air-water interfaces is a century old problem for researchers and has implications on a host of physical, chemical and biological processes. The dynamic nature of water surface and the surface fluctuations created by thermally excited capillary waves have always limited measurement of near surface ionic-distributions. We demonstrate that this limitation can be overcome by using macro-ions of sizes larger than the capillary wave roughness \( \sim 3\AA \). Our attempts to measure distributions of inorganic macro-ions in the form of Keggin heteropolyanions (HPAs) of sizes \(-10\AA\) have unraveled novel charge-dependent condensation of macro-ions beneath air-water interfaces. Our results demonstrate that HPAs with \(-3\) charges condense readily beneath air-water interfaces. This is in contrast to the absence of surface preference for HPAs with \(-4\) charges. The similarity of HPA-HPA separations near air-water interfaces and in bulk crystal structures suggests the presence of the planar Zundel ions (\( \text{H}_3\text{O}^+ \)), which interact with HPAs and the water surface to facilitate the charge dependent condensation beneath the air-water interfaces.

10:48AM Y26.00015 Water-A New Player of the Solid Surface, YI GAO, YADONG LI, BEIEN ZHU, Shanghai Institute of Applied Physics (SINAP) — It is well-known that water configuration and behaviors are highly affected by the solid surface. On the other hand, water is generally considered to have negligible effects on the solid surface. But it might not be the case. Here, we theoretically present two examples to show water could significantly affect the surface. The first is the migration of the subsurface vacancies and the change of the surface elements population. These observations might give us a new perspective to understand the properties of liquid/solid interfaces.

Friday, March 6, 2015 8:00AM - 9:48AM — Session Y27 DCMP: Superconductivity and Spin Orbit Coupling 204B - Ke Chen, Temple University

8:00AM Y27.00001 Fraunhofer pattern arising from an edge-stepped topological surface Josephson current distribution, JAE HYEONG LEE, GIL-HO LEE1, JANGHEE LEE, JOONBUM PARK, SEUNG-GEOL NAM2, YUN-SOK SHIN3, JUN SUNG KIM, HU-JONG LEE, Pohang Univ of Sci & Tech — We report a surface-dominant Josephson effect in superconductor-topological insulator-superconductor (S–TI–S) devices, where a Bi$_2$Se$_3$ topologically trivial lead, like the fractional (4, PAVEL IOSELEVICH, Max Planck Institute for Solid State Research, MIKHAIL FEIGELMAN, Landau Institute for Theoretical Physics — Topological insulators’ edge-stepped nonuniform supercurrent distribution arising from the top and rough side surfaces of the BSTS flake. A Fraunhofer-like pattern was also observed for the local biasing. For the local biasing, the Fraunhofer signal was highly robust to the magnetic field up to the critical field of the Al electrodes, corresponding to the electrodes. We observed a Fraunhofer critical current modulation in a perpendicular magnetic field in an Al–TI–Al junction for both local and nonlocal current biasing. The Josephson effect in this case has an asymmetric dependence on the order parameters involved, and the critical current is suppressed very strongly in a typical situation, so that the product $I_c/R \ll \Delta$ even in a short contact.

8:12AM Y27.00002 Josephson junctions between topological and conventional superconductors, PAVEL IOSELEVICH, Max Planck Institute for Solid State Research, MIKHAIL FEIGELMAN, Landau Institute for Theoretical Physics — Topological superconductors host protected gapless modes at their boundaries. This leads to various robust phenomena when a topological superconductor is contacted to a topologically trivial lead, like the fractional (4π-periodic) Josephson effect or the zero-bias conductance peak in a tunneling NS-junction. Here we discuss phenomena arising in a Josephson contact between a topological and a trivial superconductor. The Josephson effect in this case has an asymmetric dependence on the order parameters involved, and the critical current is suppressed very strongly in a typical situation, so that the product $I_c/R \ll \Delta$ even in a short contact.

8:24AM Y27.00003 Microwave spectroscopy of Majorana bound states in S/TI/S junctions, JUKKA VAYRYNEN, Department of Physics, Yale University, GIANLUCA RASTELLI, WOLFGANG BELZIG, Fachbereich Physik, Universität Konstanz, LEONID GLAZMAN, Department of Physics, Yale University — We study the effects of microwave irradiation in a phase-biased topological Josephson junction, consisting of two s-wave superconductors linked by a quantum-spin-Hall insulator edge. A long topological junction supports multiple Andreev bound states, one of which (Majorana mode) has zero energy at phase difference $\phi = \pi$. We consider weak time-periodic modulation of the phase difference to study transitions between the discrete sub-gap levels of the junction. In a generic disordered junction all the degeneracies of single-particle levels are lifted but the zero-energy state remains and leads to a ground state degeneracy at $\phi = \pi$. Upon sweeping $\phi$ across the ground state degeneracy point, we show that the lowest excitation energy of the junction displays a prominent kink which can be observed in the absorption spectrum. To study this feature, we calculate the absorption power as a function of frequency, phase difference, and at finite temperature.

8:36AM Y27.00004 Zero-bias peak in InSb nanowires, PENG YU, JUN CHEN, School of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA, 15260, USA, MOIRA HOCEVAR, Institut Néel CNRS, Grenoble, France, SEBASTIEN PLISSARD, CNRS, LAAS, Toulouse, France, DIANA CAR, ERIK BAKKERS, Department of Applied Physics, Eindhoven University of Technology, 5600 MB Eindhoven, The Netherlands, SERGEY FROLOV, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA, 15260, USA — Zero-bias conductance peaks(ZBP) in InSb nanowires has been reported as a strong signature of Majorana bound states in semiconductors. We made similar superconductor-InSb nanowire-normal contact hybrid devices with NbTiN on bottom gates and found some features that may correspond to Majorana bound states. By setting a barrier and tuning gates under the nanowire that are in proximity of superconductors, ZBPs appear at finite magnetic field and usually persist for several hundred miliTesla. In different devices, ZBPs appear at different magnetic field, which may result from different chemical potentials. To achieve a so-called hard induced gap and cleaner devices, we are trying various contact materials and etching methods.

8:48AM Y27.00005 Anomalous Josephson Effect in Junctions with Rashba Spin-Orbit Coupling, KONSTANTIN NESTEROV, MANUEL HOUZET, JULIA MEYER, Univ. Grenoble Alpes, INAC-SPSMS, F-38000 Grenoble, France and CEA, INAC-SPSMS, F-38000 Grenoble, France — We study two-dimensional double-barrier SINIS Josephson junctions in which the inversion symmetry in the normal part is broken by Rashba spin-orbit coupling. In the presence of a suitably oriented Zeeman field in the normal part, the system displays the anomalous Josephson effect: the current is nonzero even at zero phase difference between two superconductors. We investigate this effect by means of the Ginzburg-Landau formalism and microscopic Green’s functions approach in the clean limit.

3This work was supported in part by the grants No. ANR-12-BS04-0016-03 and an EU-FP7 Marie Curie IRG.

9:00AM Y27.00006 Superconducting contacts to Ge/Si core/shell nanowires, ZHAOEN SU, AZARIN ZARASSI, DHARAMRAJ PATIL, SERGEY FROLOV, University of Pittsburgh, MOIRA HOCEVAR, Institute Neel CNRS, MINH NGUYEN, JINKYOUNG YOO, Los Alamos National Laboratory, SHADI DAYEH, University of California San Diego — Ge/Si core/shell nanowires are hosts to one dimensional hole gas. The spin-orbit interaction is expected to be much larger than that in electron systems such as InSb and InAs. Therefore, Ge/Si nanowires have great potential to demonstrate helical liquid. When strong superconductivity is induced in the nanowire, robust topological superconductivity may form in the system. We will show how to achieve semiconductor-superconductor contacts to the nanowire. The effects of a few surface cleaning methods and annealing process on the contact resistance will be shown. Superconducting contacts of NbTiN, Al, Ti and their combinations are studied. NbTiN may be suitable for hybrid device carrying Majorana fermions for its high critical temperature and magnetic field. Supercurrent through Josephson junctions with these contacts is measured.

9:12AM Y27.00007 Design and Implementation of a Josephson Junction Spectrometer, CAGLAR GIRIT, Collège de France & Quantronics Group, CEA-Saclay, MARCELO GOFFMAN, HUGUES POTHIER, CRISTIÁN URBINA, DANIEL ESTEVE, Quantronics Group, CEA-Saclay — A Josephson tunnel junction can be used as an on-chip absorption spectrometer at frequencies up to several hundred gigahertz. As a result of the AC Josephson effect, a voltage biased junction acts as a microwave source. When emitted photons are absorbed in the junction’s electromagnetic environment, a dc Cooper pair current flows (inelastic Cooper pair tunneling). By measuring this dc current as a function of applied voltage—the junction’s current-voltage characteristic—one obtains a spectrum of the electromagnetic environment. We describe the design of a Josephson junction spectrometer which seeks to optimize bandwidth, sensitivity, coupling and linewidth. We present measurements of the spectra of miniature on-chip $LC$ circuits with resonant frequencies in the 25-100 GHz range. Our Josephson junction spectrometer will be used to study level transitions in mesoscopic systems.

9:24AM Y27.00008 Domain walls in tetragonal superconductors: Andreev bound states and tunneling features, SOUMYA MUKHERJEE, KIRILL SAMOKHIN, Department of Physics, Brock University, KIRILL SAMOKHIN COLLABORATION — Domain walls can be formed in superconductors with a discrete degeneracy of the ground state, which breaks time reversal symmetry or a point group symmetry. We study all cases where the formation of domain walls is possible for the tetragonal point group symmetry D$_{4h}$. We discuss both triplet and mixed singlet order parameters. It is found that in all cases domain walls support subgap Andreev bound states, whose energies strongly depend on the direction of semiclassical propagation. We also study the density of states of these bound states and show that the formation of bound states near the domain wall strongly affects the tunneling conductance.

9:36AM Y27.00009 Anisotropic Andreev reflection in ferromagnet/s-wave superconductors (FS), PETRA HOEGL, University of Regensburg, ALEX MATOS ABIAGUE, IGOR ZUTIC, University at Buffalo, JAROSLAV FABIAN, University of Regensburg — Andreev reflection spectroscopy is a sensitive probe of the junction interface as well as of the spin polarization of the F region. By performing analytical and numerical calculations on widely accepted model systems, with interfacial Rashba and Dresselhaus spin-orbit fields, we show that Andreev reflection spectroscopy is also a sensitive tool of the interfacial spin-orbit coupling. In particular, we find a finite subgap conductance even in half-metallic systems due to the spin-flip Andreev reflection, imposing a triplet proximity effect. Furthermore, we predict a giant magnetic anisotropy of the Andreev reflection—anisotropic Andreev reflection (AAR)—with respect to the orientation of the F magnetization. We analyze the effects of the tunnel barrier strength, the F spin polarization, and the effective mass and Fermi wave vector mismatch. Our results should also have implications for designing Majorana states in semiconductor junctions with superconductors.

Friday, March 6, 2015 8:00AM - 11:00AM —
Session Y28 GMAG DMP FIAP: Focus Session: Spin-Hall Effect III

8:00AM Y28.00001 Spin pumping by magnetopolaritons, YUNSHAN CAO, PENG YAN, Delft Univ of Tech, HANS HUEBL, SEBASTIAN GOENNENWEIN, Walther-Meißner-Institut, GERRIT BAUER, Tohoku University and Delft Univ of Tech — Recent experiments report the strong coupling of microwaves to the magnetic insulator yttrium iron garnet with weakly damped magnetization dynamics [1]. We developed a scattering approach to study the coupled magnetization and microwave cavities beyond the paramagnetic/macrospin and rotating wave approximations that are implicit in the Tavis-Cummings model [2]. To this end we solve the coupled Landau-Lifshitz-Gilbert and Maxwell’s equations for a thin film magnet in a microwave cavity, leading to rich ferromagnetic spin wave resonance spectra of the transmitted or absorbed microwaves. Our method is valid for the full parameter range spanning the weak to strong coupling limits. We demonstrate strong coupling achievement not only for the FMR mode but also for standing spin waves, although the lowest excitation has a decisive leading role for coupling strength. Spin pumping in FI/N bilayers as detected by inverse spin Hall voltages provides additional access to study strong coupling electrically.

1Supported by grant ANR-10-IDEX-0001-02 PSL.

8:12AM Y28.00002 Spin Transport in Insulators Mediated by Magnetic Correlations Probed by $Y_3Fe_5O_{12}$-based Spin Pumping, CHUNHUI DU, HAILONG WANG, P. CHRIS HAMMEL, FENGYUAN YANG, The Ohio State University — Spin currents carried by mobile charges in ferromagnetic (FM) and nonmagnetic (NM) materials have been the central focus of spintronics, while spin transport in insulators is largely unexplored. FM spin pumping has awakened intense interest in magnon-mediated spin currents in both conducting and insulating FMs and in antiferromagnets (AF). Building on the large spin pumping signals enabled by our $Y_3Fe_5O_{12}$ (YIG) films, we report a systematic study of spin transport in six series of Pt/insulator/YIG trilayers where the insulators include one diamagnet, one paramagnet and four AFs. We observe remarkably robust spin transport in the AFs and a distinct linear relationship between the spin decay length in the insulator and the damping enhancement in the YIG, suggesting the critical role of magnonic coupling in AF insulators for spin transport. Strikingly, the insertion of a thin NIO layer between YIG and Pt significantly enhances the spin currents driven into Pt, suggesting exceptionally high spin transfer efficiency in YIG/NIO/Pt structures.
8:24AM Y28.00003 Spin pumping by time-dependent gate without magnetic field in a nanowire

LU-YAO WANG, Dept. of physics, Catholic Fu-Jen university, Taiwan, CHON-SAAR CHU, Dept. of Electrophysics, National Chiao-Tung university, Taiwan

We theoretically study that spin pumping by smooth profile time dependent gate in a Rashba type nanowire without magnetic field. The time dependent gate produces both spin dependent and spin-independent potentials. The spin dependent temporary potential inducing a dynamic Rashba coupling constant combining with the static Rashba coupling constant generate asymmetry spin dependent transmission. Such spin pumping can be enhanced by spin independent temporary potential.

8:36AM Y28.00004 Manipulation of Magnetic Insulators Using Spin Torque from the Spin Hall Effect , COLIN JERMINE, Cornell University, AARON ROSENBERG, Stanford University, HANJONG PAIK, SRIHARSHA ARADHYA, Cornell University, HAILONG WANG, Ohio State University, JOHN HERON, Cornell University, KATJA NOWACK, JOHN KIRTLIE, Stanford University, DARRELL SCHLOM, Cornell University, KATHRYN MOLER, Stanford University, PENGYUAN YANG, Ohio State University, DAN RALPH, Cornell University

We are exploring the possibility of current-induced switching driven by spin torque from the spin Hall effect for micron and nanoscale devices made from the magnetic insulators yttrium iron garnet (YIG) and lutetium iron garnet (LuIG). We will report on the fabrication of devices incorporating thin films of YIG or LuIG with thickness less than 20 nm and in-plane magnetization. We use electron beam lithography and ion milling to pattern the films into device structures with sizes ranging from 50 nm to 4 microns, integrated with a Ta or Pt layer, so that we can use the spin Hall effect to apply spin-transfer torque to the magnetic materials. With scanning SQUID magnetometry we measure the in-plane dipole orientation of the device magnetic moment at 4 K. By examining the magnetic orientation as a function of applied current we investigate whether the spin Hall torque can be used to drive reliable magnetic switching at low current levels.

8:48AM Y28.00005 Spin Torque Arising from the Spin Hall Effect within Ferromagnets , JONATHAN GIBBONS, Department of Physics, Cornell University, ROBERT BUHRMAN, School of Applied and Engineering Physics, Cornell University, DANIEL RALPH, Department of Physics, Cornell University

Recent spin-pumping measurements have indicated that ferromagnetic materials such as permalloy possess a significant inverse spin Hall effect, by which they convert an applied spin current to a charge current. We report experimental investigations of the inverse phenomenon, using the direct spin Hall effect within a ferromagnetic material to generate a spin current that can be used to apply a spin transfer torque to another nearby magnetic layer. Specifically, we measure spin-orbit-induced torques generated by an in-plane current in pinned ferromagnet/space/free ferromagnet multilayer structures. We quantify the strength of the torque using both non-resonant second harmonic magnetization tilting measurements and spin-torque ferromagnetic resonance. We focus on the dependence of the direction and strength of the spin torque on the relative orientation of the fixed-layer magnetization and the current.

9:00AM Y28.00006 Coupled spin-charge transport in two-dimensional electron gases from weak to strong spin-orbit couplings , YASUFUMI ARAKI, None, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin

We investigate the magnetoelectric response of two-dimensional electron gases with spin-orbit interactions of arbitrary strength. Rashba or Dresselhaus spin-orbit coupling in two-dimensional systems gives rise to the coupling of spin and charge transport, which may appear as spin Hall effect, spin-orbit induced torque, direct and inverse Edelstein effects, etc. We derive the diffusion equation for spin and charge densities microscopically with spin-independent disorder scattering and two types of spin-orbit interactions of arbitrary strength, and analyze the crossover in the coupled spin-charge transport from weak to strong spin-orbit coupling regimes. Our calculation connects the traditional perturbative treatment of the spin-orbit coupling in the weak spin-orbit coupling regime, where two spin states are nearly degenerate, to the relaxation time approximation estimate in the strong spin-orbit coupling regime, where the degeneracy is strongly lifted. The crossover becomes nontrivial when the Rashba and Dresselhaus spin-orbit interactions are comparable. Based on those calculations, we will give some comments on the spin-orbit induced torques induced in the heterostructure of ferromagnets and heavy metals.

9:24AM Y28.00008 Testing Reciprocity of Spin Pumping and Spin Transfer Torque in Ferromagnet/Spin-Orbit Metal Heterostructures , CARL BOONE, SATORU EMORI, TIANXIANG NAN, NIAN SUN, North-eastern University

Spin pumping from a ferromagnet (FM) to a normal metal (NM) and spin transfer torque (STT) generated in a FM from an injected spin current should be reciprocal processes governed by the spin mixing conductance. The same should be true for the spin Hall effect (SHE) and inverse SHE, which are used to generate and measure spin currents. Past experiments on multilayer thin films involving FM and NM interfaces have measured only spin pumping or spin injection, and have utilized incomplete modeling that results in different effective values for the same parameter such as the spin mixing conductance or spin Hall angle. This gives rise to a large range of values reported in the literature. Here we develop a complete model for spin flow in the FM/NM system including SHE, spin diffusion and spin pumping that allows us to determine the true values of the spin transport parameters. To explore the physics we use STT-ferromagnetic resonance (FMR) experiments of NM/FM/NM trilayers, and FMR spectroscopy of FM/NM bilayers where we simultaneously measure damping changes due to spin pumping, voltage generated by inverse SHE, and STT generated by the SHE. These experiments, combined with the complete modeling, allow us to test the reciprocity of spin pumping and STT plus the SHE and its inverse.

9:36AM Y28.00009 Spin pumping with interface spin-orbit coupling , KAI CHEN, SHUFENG ZHANG, Univ of Arizona

The spin pumping has been formulated via a mixing conductance which characterizes the spin-dependent reflection coefficients [1]. The “mixing conductance” never mixes the spin at the interface, i.e., no spin-flip processes have been taken into account till now. We have recently reformulated the spin pumping via linear response approach in which the interface spin-orbit coupling as well as spin-diffusion driven backflow can be explicitly included. In some limiting cases, our formulation reduces to that of the previous theory. In the presence of the interface spin-orbit coupling, the electron spin traveling through an interface will receive a spin-orbit torque that rotates and absorbs the spin angular momentum. Among many distinctions with the previous theory [1], we predict a spatial dependent spin current in both magnetic and non-magnetic layers, an anisotropic enhanced damping parameter, and a plausible resolution on the controversial experimental results obtained by different methods such as the inverse spin Hall signal and the broadening of ferromagnetic resonance linewidth. This work is supported by NSF-ECS.

9:48AM Y28.00010 Quantifying Spin Hall and Rashba effect contributions to spin-orbit torque in magnetic bilayers. JOHN Q. XIAO1, Department of Physics and Astronomy, University of Delaware — Electrical control of magnetism has been energized by recent observation of spin-orbit torques in magnetic bilayers formed from a heavy metal (HM) and ferromagnet (FM). It has been demonstrated that the spin-orbit torques driven by an in-plane current can switch magnetization, manipulate magnetic domains and excite magnetization auto-oscillation. However, the microscopic mechanism for the spin-orbit torques is still under debate. The question being whether the dominating spin-orbit coupling (SOC) arises from the HM/FM interface due to the Rashba effect or arises in the bulk of HM due to the spin Hall effect, or a combination of the two. It has been theoretically demonstrated that both the Rashba effect and the spin Hall effect generate a field-like torque (T_{SOF}) and damping-like torque (T_{SOT}) on the magnetization, with only quantitative differences. Therefore, an accurate method to determine the T_{SOF} and T_{SOT} with various thicknesses of the FM and HM is needed. We present a newly developed, magneto-optic-Kerr-effect based spin-orbit torque magnetometer that measures both T_{SOF} and T_{SOT}, which can have both spatial and time resolution. We observed both T_{SOF} and T_{SOT} are nonlocal and does not require direct contact between FM and HM ...[1, 2]. By engineering the interface which modifies the Rashba interaction, we are able to show the co-existence of spin Hall and Rashba effect as well as quantifies both contributions to spin-orbit torques [1].

10:24AM Y28.00011 Magnonic Charge Pumping via Spin-Orbit Coupling. CHIARA CICCARELLI, University of Cambridge, KJETIL HALS, Norwegian University of Science and Technology, University of Copenhagen, ANDREW IRVINE, University of Cambridge, VIT NOVAK, Institute of Physics ASCR, YAROSLAV TSERKOVNYAK, University of California, Los Angeles, HIDEKAZU KUREBAYASHI, University College London, ARNE BRATAAS, Norwegian University of Science and Technology, ANDREW FERGUSON, University of Cambridge — The interplay between spin, charge and orbital degrees of freedom has led to the development of spintronic devices such as spin-torque oscillators and spin-transfer torque MRAM. In this development, spin pumping represents a convenient way to electrically detect magnetization dynamics. The effect originates from direct conversion of low-energy quantized spin waves in the magnet, known as magnons, into a flow of spins from the precessing magnet to adjacent leads. In this case, a secondary spin-charge conversion element, such as heavy metals with large spin Hall angle or multilayer layouts, is required to convert the spin current into a charge signal. Here, we report the observation of charge pumping in which a precessing ferromagnet pumps a charge current, demonstrating direct conversion of magnons into high-frequency currents via spin-orbit interaction. The generated electric current, unlike spin currents generated by spin-pumping, can be directly detected without the need of any additional spin-charge conversion mechanism. The charge-pumping phenomenon is generic and gives a deeper understanding of its reciprocal effect, the spin orbit torque, which is currently attracting interest for their potential in manipulating magnetic information.

10:36AM Y28.00012 Spin Circuit Representation for Spin Pumping Phenomena. KUNTAL ROY, SUPRIYO DATTA, School of Electrical and Computer Engineering, Purdue University — There has been enormous progress in the field of spintronics and nanomagnetics in recent years with the discovery of many new materials and phenomena and it remains a formidable challenge to integrate these phenomena into functional devices and evaluate their potential. To facilitate this process a modular approach has been proposed whereby different phenomena are represented by spin circuit components [1]. Unlike ordinary circuit components, these spin circuit components are characterized by 4-component voltages and currents (one for charge and three for spin). In this talk we will (1) present a spin circuit representation for spin pumping phenomena, (2) combine it with a spin circuit representation for the spin Hall effect [2] to show that it reproduces established results obtained earlier by other means, and finally (3) use it to propose a possible method for enhancing the spin-pumping efficiency by an order of magnitude through the addition of a spin sink layer. [1] Kerem Camsari, Samiran Ganguly and Supriyo Datta, Modular Approach to Spintronics, https://nanohub.org/groups/spintronics [2] Seokmin Hong, Shehrin Sayed and Supriyo Datta, Spin Circuit Representation for the Spin Hall Effect, in review.

10:48AM Y28.00013 Dependence of the Spin Hall Torque Efficiency on the Transparency of Pt-Ferromagnetic Layer Interfaces. CHIARA CICCARELLI, University of Cambridge, KJETIL HALS, Norwegian University of Science and Technology, University of Copenhagen, ANDREW IRVINE, University of Cambridge — We report that spin current transport across Pt-ferromagnet (FM) interfaces is strongly dependent on the type and the thickness of the FM layer and on post-deposition processing protocols. By employing both harmonic voltage response measurements and spin-torque ferromagnetic resonance measurements on various Pt-Co and Pt-CoFe magnetic heterostructures, we find that the efficiency of the Pt spin Hall effect in exerting a damping-like spin torque on the FM ranges from < 0.05 to > 0.10 under different interfacial conditions. We also show that the temperature dependence of the spin torque efficiencies for both the damping-like torque and field-like torque is dependent upon the details of the Pt-FM interface. The “internal” spin Hall angle of the Pt thin films used in this study, after taking the interfacial spin transmission factor that is derived from the spin mixing conductance into account, is estimated to be ~0.20. This suggests that a careful engineering of Pt-FM interfaces can improve the spin-Hall-torque efficiency of Pt-based spintronic devices.

8:00AM Y29.00001 Barkhausen noise in the Random Field Ising Magnet NdFeB. JIAN XU, DANIEL SILEVITCH, University of Chicago, THOMAS ROSENBAUM, California Institute of Technology — With the application of a magnetic field transverse to the magnetic easy axis, we performed magnetic measurements on an Nd-Fe-B thin film in which the magnetic moments are disordered, and a Random-Field Ising Model at room temperature. We study domain reversal and avalanche dynamics through an analysis of the Barkhausen noise. Power-law behavior with a cutoff is observed in the avalanche energy spectrum, consistent with theoretical predictions for disordered materials. Two regimes of behavior are found, one at low temperature and high transverse field where the system shows behavior consistent with randomness-dominated dynamics, and a high-temperature, low-transverse-field regime in which thermal fluctuations dominate the dynamics. In the randomness-dominated regime, the critical exponents are consistent with mean-field predictions for heavily disordered systems, whereas in the thermal-fluctuation regime, the critical exponents differ substantially from the mean-field predictions.

9:24AM Y29.00006 The cumulative overlap distribution function in spin glasses: mean field vs. three dimensions1. DAVID YLLANES, Syracuse University, ALAIN BILLOIRE, CEA Saclay, ANDREA MAIORANO, ENZO MARINARI, La Sapienza Universita di Roma, VICTOR MARTIN-MAJOR, Universidad Complutense de Madrid — We use a sample-dependent analysis, based on medians and quantiles, to analyze the behavior of the overlap probability distribution in spin glasses. Using analytical and numerical mean-field results for the Sherrington-Kirkpatrick model, as well as data from toy models, we show that this approach is an effective tool to distinguish the low-temperature behavior of replica symmetry breaking systems from that expected in the droplet picture. An application of the method to the three-dimensional Edwards-Anderson models shows agreement with the replica symmetry breaking predictions.

9:48AM Y29.00008 Ground States of a Disordered Frustrated Quantum Dimer Magnet1. ALEXANDER HRISTOV, MAXWELL SHAPIRO, IAN FISHER, Stanford University, MINSEONG LEE, LINSEY RODENBACH, ASHLEY BERNHEISEL, EUN SANG CHOI, JU-HYUN PARK, Florida State University, LEONARDO CIVALE, Los Alamos National Laboratory, TIM MUNSIE, GRAEME LUKE, McMaster University — We present results of thermodynamic measurements of the site-diluted spin-dimer magnet \( Ba_2(Mn_1-xV_x)O_3 \), including magnetization, torque magnetometry, and AC susceptibility. The parent compound \( Ba_2MnO_3 \) is a frustrated \( S = 1 \) quantum dimer-magnet with a singlet ground state, and triplet and quintuplet excitations. A magnetic field can be used to tune the energy spectrum of this system, yielding successive triplet and quintuplet condensates at low temperatures. Site substitution with \( x = 0 \) breaks Mn-dimers, introducing site disorder into the high-field ordered states. This substitution also introduces unpaired \( S = 1 \) Mn ions, and it has been an open question whether such spin order at low temperatures. Here, we present evidence of the spin freezing of unpaired Mn ions below 240 mK for all compositions measured, from \( x = 0.05 \) to 0.85. We also present the evolution of the high field ordered state with increasing disorder.

10:00AM Y29.00009 Absence of Magnetic Order and Persistent Spin Dynamics in \( Tb_2Ge_2O_7 \). ALANNAH HALLAS, McMaster University, ANGEL AREVALO-LOPEZ, University of Edinburgh, MURRAY WILSON, McMaster University, LIAN LIU, Columbia University, J. PAUL ATTFIELD, University of Edinburgh, YASUTOMO UEMURA, Columbia University, CHRIS WIEBE, University of Winnipeg, GRAEME LUKE, McMaster University — The terbium pyrochlores exhibit many unique magnetic properties, which has generated significant interest in this family of frustrated materials. A candidate spin liquid, \( Tb_2Ti_2O_7 \) fails to order magnetically, despite strong antiferromagnetic correlations. The application of external pressure has been found to produce partial antiferromagnetic order in \( Tb_2Ti_2O_7 \). Recently, we synthesized a new member of this family, \( Tb_2Ge_2O_7 \). Due to the large ionic radii of the transition metals, \( Tb_2Ge_2O_7 \) can be considered a chemical pressure analog of \( Tb_2Ti_2O_7 \). However, neutron scattering measurements revealed an absence of magnetic order in \( Tb_2Ge_2O_7 \) down to 20 mK and dominant ferromagnetic correlations. Now, we have investigated the low temperature magnetism of \( Tb_2Ge_2O_7 \) with muon spin rotation. Our zero field \( \mu \)SR measurements confirm an absence of static order in \( Tb_2Ge_2O_7 \). We find a sharp increase in magnetic correlations below 10 K and persistent spin dynamics down to 25 mK. Our longitudinal field \( \mu \)SR measurements on \( Tb_2Ge_2O_7 \) at 25 mK are consistent with a system of fluctuating moments, with a fluctuation rate of 11 MHz. This fluctuation rate is nearly temperature independent below 2.5 K.
10:12AM Y29.00010 Local probe study of S=1 spin liquid candidate Ba$_3$NiSb$_2$O$_9$. **JEFFREY QUILLIAM**, Département de physique, Université de Sherbrooke, Sherbrooke, QC, Canada. FABRICE BERT, PHILIPPE MENDELS, JEAN-CHRISTOPHE ORAIN, Laboratoire de physique des solides, Université Paris-Sud XI, Orsay, France. ANTHONI MANSEAU, Département de physique, Université de Sherbrooke, Sherbrooke, QC, Canada, CÉLINE DARIE, Institut Néel, Grenoble, France. CHRISTOPHE PAYEN, CATHERINE GUILLOT-DEUDON, Institut des Matériaux Jean Rouxel, Université de Nantes, Nantes, France. — The family of hexagonal perovskites, Ba$_3$M$_2$Sb$_2$O$_9$, has attracted a considerable amount of attention in recent years, with the discovery of several spin liquid candidates. For $M=U$, the material is fairly disordered and likely exhibits a honeycomb-like lattice whereas in other cases the structure consists of triangular planes of spins. Three different structural phases of Ba$_3$NiSb$_2$O$_9$ have been discovered, depending on synthesis pressure [1]. Two of these phases (6HA and 6HB) consist of triangular planes of $S = 1$ moments, and differ primarily by the stacking of these planes. Here, we present muon spin rotation ($\mu$SR) and $^{121}$Sb nuclear magnetic resonance (NMR) results on a high-pressure synthesis of this material, 6HB-Ba$_3$NiSb$_2$O$_9$. Most importantly, we demonstrate that there are no signs of magnetic ordering or spin freezing down to temperatures as low as 20 mK, making this material a plausible spin liquid candidate. Furthermore our NMR results are indicative of gapless excitations, consistent with previous specific heat and magnetic susceptibility results [1].

10:24AM Y29.00011 Giant anisotropic interactions in frustrated quantum magnet BiCu$_2$PO$_6$. **KEMP PLUMB**, Johns Hopkins University. — I will discuss a series of comprehensive inelastic neutron scattering measurements which uncover the full magnetic excitation spectrum in the valence bond ordered compound BiCu$_2$PO$_6$. Owing to its frustrated geometry and potential to realize unique quantum phase transitions in high magnetic fields, BiCu$_2$PO$_6$ has received significant attention in recent literature. However, the true nature of the magnetic Hamiltonian responsible for the high field phenomena has not been known until now. I will present measurements of the spin excitation spectrum in BiCu$_2$PO$_6$ from which the magnetic Hamiltonian is elucidated. The spectrum is unique to the frustrated two-leg ladder geometry in BiCu$_2$PO$_6$ and we have been able to correctly describe the lowest energy excitations within the framework of a bond-operator theory, incorporating anisotropic magnetic exchange interactions which are comparable to the Heisenberg exchange terms. The anisotropic exchange interactions originate from spin orbit coupling and are of an unexpectedly large magnitude for a Cu based magnetic compound, potentially indicating the relevance of Bismuth in the superexchange pathway. BiCu$_2$PO$_6$ is a complex and unique quantum magnet combining frustration and anisotropic exchange; the discovery of such large anisotropic interactions in BiCu$_2$PO$_6$ hints at new routes for incorporating spin anisotropies in 3d transition metal based magnets.

Friday, March 6, 2015 8:00AM - 11:00AM –
Session Y31 GMAG DMP: Focus Session: Spin Chains II: Mostly $S = 1/2$

8:00AM Y31.00001 Local spin dynamics near quantum critical line of spin-1/2 antiferromagnetic Heisenberg XXZ chain with longitudinal magnetic field. **WANG YANG, JIANDA WU, CONGJUN WU**, Univ of California - San Diego. — The spin-1/2 antiferromagnetic quantum XXZ chain is one of the most well-studied integrable model. Although all of its eigenstates and spectrum can be obtained via algebraic Bethe ansatz method, understanding its local dynamics remains a great challenge [1]. In the anisotropic gapped region, while tuning longitudinal field, there is a line of critical fields where the system undergoes quantum phase transitions. Recent experiments on BaCu$_2$V$_8$O$_{16}$ provided some evidences for understanding low-energy spin dynamics near critical line [2]. In this work, we further calculate local spin dynamics in this region in low frequency limit by form factor methods. Our results can be compared with measurements of NMR relaxation rate. [1] J.-S. Caux, H. Konno, M. Sorrell, and R. Weston, Journal of Statistical Mechanics: Theory and Experiment 2012, P01007 (2012) [2] S. Kimura, T. Takeuchi, K. Okunishi, M. Hagiwara, Z. He, K. Kindo, T. Taniyama, and M. Itoh, Physical review letters 100, 057202 (2008).

8:12AM Y31.00002 Spin currents carried by spinons in XXZ Spin Chains: Signatures in Polarized Inelastic Neutron Scattering. **LEONARD PATRICK ENGLISH, HANS-BENJAMIN BRAUN**, University College Dublin, JIRI KULDA, Institute Laue-Langevin, Grenoble. — Quantum spin chains serve as a paradigm for exploring truly quantum phenomena, with spinons being the elementary excitations. Motivated by compounds such as CsCoBr$_3$ and CsCoCl$_3$, we focus on the Ising-like antiferromagnetic Heisenberg XXZ model (spin-1/2). Here we present theoretical results for the total inelastic scattering cross section of spin-polarized neutrons in the presence of an external magnetic field, which is applied transverse to the Ising direction. In particular, we identify the spin current associated with spinons and their corresponding signatures in the neutron scattering cross section. The presence of a transverse magnetic field no longer allows for reliance on $S_{\text{tot}}^z$ as a conserved quantity, which has traditionally been assumed in this context. As a striking consequence, we find that the spinons carry a non-vanishing spin current, even in the limit of infinitesimal fields. Our results are shown to be in good agreement with experimental neutron scattering data on CsCoBr$_3$. 

8:24AM Y31.00003 Finite-temperature scaling at the quantum critical point of the Ising chain in a transverse field. **MANUEL HAEGL**, Neutron Scattering and Magnetism, Laboratory for Solid State Physics, ETH Zurich, 8006 Zurich, Switzerland. DAN HUVONEN, National Institute of Chemical Physics and Biophysics, 12618 Tallinn, Estonia. TATIANA GUIDI, ISIS Facility, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, United Kingdom. — Inelastic neutron scattering is used to study the finite-temperature scaling behavior of spin correlations at the quantum critical point in an experimental realization of the one-dimensional Ising model in a transverse field. The target compound is the well-characterized, anisotropic and bond-alternating Heisenberg spin-1 chain material NTENP. The validity and the limitations of the dynamic structure factor scaling are tested, discussed and compared to theoretical predictions. For this purpose neutron data have been collected on the three-axes spectrometers IN14 at ILL and FLEXX at HZB as well as on the time of flight multi-chopper spectrometer LET at ISIS. In addition to the general statement about quantum criticality and universality, present study also reveals new insight into the properties of the spin chain compound NTENP in particular.
Superlattices

ILYA VALMIANSKI, IVAN SCHULLER, University of California-San Diego — This work reports on the structural and magnetic properties of iron-phthalocyanine (FePc) superlattices. FePc has a divalent Fe(II) ion in the center of the molecule that forms quasi one-dimensional (1D) chains when the flat molecules are stacked. These 1D chains exhibit two magnetic regimes: ferromagnetic order below 5K due to inter-chain interactions, and paramagnetic order between 5K and 25K due to short-range intra-chain interactions. H$_2$Pc is a non-magnetic molecule in which, instead of a metal ion, two hydrogen atoms occupy the center of the molecule. We establish a new and more comprehensive phase diagram for this exotic system through the evolution of the magnetic entropy change $\Delta S_M (T, H)$ associated with the magnetocaloric effect. $\Delta S_M$ is measured in a single crystal of Ca$_3$Co$_2$O$_6$ prepared by the flux method and demonstrates the suppression of the SDW modulation by small applied magnetic fields (< 1T). Metamagnetic transitions to a ferrimagnetic up-up-down spin chain arrangement and full ferromagnetic alignment are observed below 25 K. Short-range ordered (SRO) correlations with an antiferromagnetic character grow in volume as the temperature is lowered below 15 K, resulting in a crossover from $\Delta S_M (H) < 0$ to $\Delta S_M (H) > 0$ at 12 K. Our entropy–based analysis reflects current understanding of the role of SDW and SRO phases in Ca$_3$Co$_2$O$_6$, resolves new sub-features of the ferrimagnetic phase, and extends previous results below the onset of slow dynamics (~ 10 K).

Pressure-induced structural distortions in copper pyrazine dinitrate

KEN-NETH O’NEAL, JUDY CHERIAN, University of Texas, CHRIS LANDEE, MARK TURNBULL, Clark University, ZHENXIAN LIU, Carnegie Institute of Washington, JANICE MUSFELDT, University of Tennessee — The vibrational properties of quasi-one-dimensional Heisenberg antiferromagnet copper pyrazine dinitrate were investigated up to 9 GPa using diamond anvil cell techniques and infrared and Raman spectroscopy. Two structural transitions were discovered, at 0.7 GPa and around 5 GPa. The lower pressure transition involves only the nitrate ligands, revealing enhanced interchain interactions. The higher pressure transition includes modes throughout the spectrum. Importantly, the pyrazine ring-related modes show an overall lowering of symmetry through this transition. Ring buckling under pressure likely reduces the exchange along the chains since the exchange pathway becomes distorted. A smaller $J$ may therefore lower the magnetic field of the quantum critical transition. This tunable exchange interaction could be utilized in other pyrazine bridged molecular systems to bring the quantum critical behavior into experimentally realizable fields.

We thank the National Science Foundation and the Petroleum Research Fund for support of this work.

Wilson ratio of a Tomonaga-Luttinger liquid in the one-dimensional spin-1/2 Heisenberg antiferromagnet CuPzN

CHRISTOPHER AYOYAMA, University of Florida, YOHEI KONO, ISSP, University of Tokyo, CHRISTOPHER AOYAMA, University of Florida, YOHEI KONO, ISSP, University of Tokyo, KRISTEN MARINO, Pennsylvania State University, HAIDONG ZHOU, University of Tennessee, CHISA HOTTA, University of Tokyo, MARK TURNBULL, CHERRY LUCAS, University of Florida, YASUMASA TAKANO, University of Florida — In the Tomonaga-Luttinger liquid (TLL) phase of a one-dimensional antiferromagnet, the Wilson ratio and the TLL parameter, $K$, are one and the same except for a trivial numerical factor. This equivalence allows the determination of $K$ from magnetic susceptibility and specific heat. We have performed accurate magnetcization and specific-heat measurements on the quasi-one-dimensional spin-1/2 Heisenberg antiferromagnet Cu(C$_2$H$_2$N$_2$)(NO$_3$)$_2$, known as CuPzN, at temperatures between 80 mK and 7.5 K and in magnetic fields up to 14.7 T and, from the data in the TLL regime, have obtained $K$ as a function of the magnetic field. The results are in excellent agreement with a prediction based on the Bethe ansatz.

Magnetic properties of the $S = 1/2$ antiferromagnetic spin-chain $\alpha-CuV_2O_7$

GANEETEE GITGEATPONG, Mahidol University, Thailand, YANG ZHAO, NIST Center for Neutron Research, National Institute of Standards and Technology, USA, MAXIM AVDEEV, ROSS PILTZ, Australian Nuclear Science and Technology Organisation, Australia, TAKU SATO, IMRAM, Tohoku University, Japan, KITTIWIT MATAN, Mahidol University, Thailand — Magnetic properties of the $S = 1/2$ antiferromagnetic spin-chain, $\alpha$-CuV$_2$O$_7$, have been studied using magnetization and neutron scattering measurements on powder and single-crystal samples. Magnetic susceptibility reveals a Curie-Weiss temperature of $\Theta = -73.2(9)$ K with a magnetic phase transition at $T_N = 33$ K while the Bonner-Fisher fit to the magnetic susceptibility for $T > T_N$ with magnetic field perpendicular to the crystallographic $a$-axis yields the intra-chain coupling of $|J|/k = 46.0(2)$ K. Small ferrimagnetism below $T_N$ is due to spin-canting caused by Dzyaloshinskii-Moriya interactions. Analysis of the neutron diffraction data reveals that the Cu$^{2+}$ spins are coupled antiferromagnetically along zigzag chains, which run alternately along [011] and [001] directions. The ordered moment of 0.925(3) $\mu_B$ is predominantly along the $a$-axis. Our recent inelastic neutron scattering, which reveals atypical magnetic excitations centered at commensurate wave vectors $(0, \pm 0.25, 0)$ around the magnetic zone center, will also be discussed.

Elastic constants and ultrasound attenuation in the spin-liquid phase of Cs$_2$CuCl$_4$

SIMON STREIB, PETER KOPIETZ, Institut für theoretische Physik, Universität Frankfurt, Germany, PHAM THANH CONG, BERND WOLF, MICHAEL LANG, NATALIJA VAN WELL, FRANZ RITTER, WOLF ASSMUS, Physikalisches Institut, Universität Frankfurt, Germany — The spin excitations in the spin-liquid phase of the anisotropic triangular lattice quantum antiferromagnet Cs$_2$CuCl$_4$ have been shown to propagate dominantly along the crystallographic $b$-axis. To test this dimensional reduction scenario, we have performed ultrasound experiments in the spin-liquid phase of Cs$_2$CuCl$_4$ probing the elastic constant $c_{22}$ and the sound attenuation along the $b$-axis as a function of an external magnetic field along the $a$-axis. We show that our data can be quantitatively explained within the framework of a nearest-neighbor spin-1/2 Heisenberg chain, where ferroms are introduced via the Jordan-Wigner transformation and the spin-phonon interaction arises from the usual exchange-striction mechanism.

Financial support by the DFG via SFB/TRR49 is gratefully acknowledged.

Magnetic Behavior of 1D-Ferromagnetic Fe Chains in FePc/H$_2$Pc Organic Superlattices

CARLOS MONTON, University of California-San Diego, THOMAS GREDIG, California State University-Long Beach, ALI BASARAN, ILYA VALMIANSKI, IVAN SCHULLER, University of California-San Diego — This work reports on the structural and magnetic properties of iron-phthalocyanine (FePc)/metal-free-phthalocyanine (H$_2$Pc) superlattices. FePc has a divalent Fe(II) ion in the center of the molecule that forms quasi one-dimensional (1D) chains when the flat molecules are stacked. These 1D chains exhibit two magnetic regimes: ferromagnetic order below 5K due to inter-chain interactions, and paramagnetic order between 5K and 25K due to short order intra-chain interactions. H$_2$Pc is a non-magnetic molecule in which, instead of a metal ion, two hydrogen atoms occupy the center of the molecule. We have grown FePc/H$_2$Pc superlattices, in which we controlled the alignment of the Fe chains (i.e. perpendicular or parallel to the substrate) by the growth conditions and through the choice of substrate. Additionally we controlled the Fe chain lengths by the thickness of the FePc layer. We have found that reducing the Fe chains length from 70 to 5 atoms increases substantially the coercive field. We will correlate the observed magnetic behavior with structural information obtained from x-ray diffraction.

ABSTRACT WITHDRAWN
10:00AM Y31.00011 Investigation of magnetic structure on (C$_3$H$_{12}$N)CuBr$_3$ system on the basis of DFT study and orbital interaction. CHANGHOON LEE, JISOOK HONG, JI HOON SHIM, Pohang Univ of Sci & Tech, POHANG UNIV OF SCI & TECH TEAM — The (C$_3$H$_{12}$N)CuBr$_3$ compound crystallizes in the monoclinic group $C2/c$. Magnetic susceptibility data down to 1.8 K can be well fitted for the antiferromagnetic spin-1/2 chain, giving the intrachain magnetic coupling constant $J_{inter}$ of $\approx$ $-17$ K. At zero field, (pipH)CuBr$_3$ shows 3D order below $T_S$ = 1.68 K. Calculated by the mean-field theory, the interchain coupling constant $J_{inter}$ = $-0.91$ K is obtained and the ordered magnetic moment is about 0.23 $\mu_B$. However, the interchain interaction should be strong unlike experimental observation. From the analysis of local structure, the $J_{inter}$ spin dimer show the possibility of good orbital overlap via Cu-O...O-Cu path in which angle for Cu-O...O-Cu is 161° indicating strong interchain interaction via Cu-O...O-Cu path. The magnetic structure of (C$_3$H$_{12}$N)CuBr$_3$ system in terms of orbital interaction could anticipated by two-leg spin ladder which such spin ladders interact ferromagnetically to form ladder. In this study, we evaluated spin exchange interactions of (pipH)CuBr$_3$ based on DFT calculations to find the magnetic structure of this system. As a consequence, the $J_{inter}$ interaction is strong and the magnetic structure of this system, indeed, is described by two-leg spin ladder.

10:12AM Y31.00012 Magnetic Relaxation and Coercivity of Finite-size Single Chain Magnets. THOMAS GREDIG, MATTHEW BYRNE, Department of Physics and Astronomy, California State University Long Beach, Long Beach, CA 90840, ALESSANDRO VINIGNI, Laboratory for Solid State Physics, ETH Zurich, CH-8093 Zurich, Switzerland — The magnetic coercivity of cusp loops for iron phthalocyanine thin films depends on the iron chain length and the measurement sweep speed below 5 K. The average one-dimensional (1D) iron chain length in samples is controlled during deposition. These 1D iron chains can be tuned over one order of magnitude with the shortest chain having 100 elements. We show that the coercivity strongly increases with the average length of the iron chains, which self-assemble parallel to the substrate surface. Magnetic relaxation and sweep speed data suggest spin dynamics play an important role. Implementing Glauber dynamics with a finite-sized 1D Ising model provides qualitative agreement with experimental data. This suggests that iron phthalocyanine thin films act as single chain magnets and provide a solid test system for tunable finite-sized magnetic chains.

10:24AM Y31.00013 Orbital ordering and magnetic dimensionalities in the p-orbital spin-1/2 Cs$_2$O$_2$ and Cs$_4$O$_6$, DENIS ARCON, Jozef Stefan Institute — The materials containing magnetic O$_2^-$ anions, i.e., alkali superoxides, AO$_2$ (A = Na, K, Rb, Cs), and alkali sesquioxides, AO$_3$ (A = Rb, Cs), exhibit two key features that make them appealing for investigation of the coupling between lattice, orbital and spin physics as an alternative to the more established d-orbital materials. First, the O$_2^-$ dumbbells can easily reorient down to the low temperatures, thereby modulating the overlaps of p orbitals. Second, as the $S = 1/2$ spin is localized in a pair of p-derived $\pi$ orbitals, their original degeneracy can be removed by the cooperative tilting of O$_2^-$ dumbbells. Here we report on our studies of Cs$_2$O$_2$ and Cs$_4$O$_6$ using $^{133}$Cs nuclear magnetic resonance and electron paramagnetic resonance techniques. In Cs$_2$O$_2$ we find the structural phase transition occurring at 61 K on cooling associated with the freezing out of the O$_2^-$ librations. The transition also includes $\pi^*$ orbital ordering that is responsible for the quasi-one-dimensional low-temperature magnetism. Clear signs of the spin Tomonaga-Luttinger liquid state are found from the spin-lattice relaxation and spin susceptibility data. On the other hand, the mixed valence Cs$_4$O$_6$ shows much more complex phase diagram with several transitions depending on the exact cooling protocol.

10:36AM Y31.00014 Conjugated molecules as amplifiers of anisotropic magneto-resistance in molecular junctions. DAVID RAKHmilevitch, SOUMYAJIT SARKAR, ORA BITTON, LEEOR KRONIK, OREN TAL, Weizmann Institute of Science — The simplest way to manipulate spin transport at the atomic scale is based on the anisotropic magneto-resistance (AMR) effect which refers to the dependence of current through a ferromagnetic element on the direction of its magnetization. However the resulting change in resistance is limited to 15%, making AMR an unlikely candidate for spintronic applications. In this respect, molecules adsorbed on ferromagnetic surfaces, were shown to modify local spin properties and therefore may facilitate in enhancing AMR effect at the atomic scale. We here demonstrate a 210% AMR in a single molecule junction based on a benzene molecule suspended between two nickel (Ni) electrodes. These results are in strike contrast with the AMR for bulk Ni (2%) or atomic Ni junctions (10%) measured on our devices. In addition, we take advantage of the electro-mechanical sensitivity of molecular junctions to show the measured AMR can be effectively tuned by elongating the junction. These results are explained by ab-initio calculations in the context of selective orbital hybridization. Our findings pave the way for simple and highly-effective control of spin transport at the atomic scale, promoting the feasibility of single-molecule spintronics.

10:48AM Y31.00015 Anderson transition in one-dimension using Wegner’s Flow equations. PARAJ BHATTACHARJEE, California Institute of Technology, VICTOR QUITO, State University of Campinas, DAVID PEKKER, University of Pittsburgh, GIL REFAEL, Laboratory of Solid State Physics, ETH Zurich, CH-8093 Zurich, Switzerland — We study the Anderson transition in one-dimensional random single-particle Hamiltonians with long-range hoppings decaying in a power-law. Explicitly, we consider the single particle tight-binding model in the spin representation with disorder both in the fields and hoppings. It has been shown by Mirin et. al. that this model shows an extended-to-localized transition as a function of the power-law exponent with a critical multi-fractal regime when the decay exponent is equal to one. We generalize the flow equation technique, first introduced by Wegner, to the disordered system and use it to study the model and elucidate the character of this transition. This method allows us to efficiently compute the eigenvalues and local observables. We follow, analytically and numerically, the flow of the coupling distributions for the different exponents as a function of the flow-time and look for signatures of the two distinct phases as well as a characterization of the critical point.

Friday, March 6, 2015 8:00AM - 11:00AM —
Session Y32 GMAG DMP: Focus Session: Magnetic Oxide Thin Films and Heterostructures:
Oxide Films 207B - Tula Paudel, University of Nebraska - Lincoln
8:00AM Y32.00001 Novel Magnetic Phenomena in Oxide Thin Films, Interfaces and Heterostructures

THIRUMALAI VENKATESAN, NUSNII-NanoCore, National University of Singapore — Oxide films, heterostructures and interfaces present wonderful opportunities for exploring novel magnetic phenomena. The idea of cationic vacancy induced ferromagnetism was demonstrated by observing ferromagnetism in Ta$_x$Ti$_{1-x}$O$_2$ ($x = 2 - 6\%$). Using XAS, XPS and XMCD, the magnetism was mainly located at the Ti sites and was shown to arise from Ti vacancies as opposed to Ti$^{3+}$. The substrate-film interface was crucial for observing the ferromagnetism, as the required concentration of Ti vacancies could only be maintained close to the interface. With electron transport we were able to see with increasing thickness the emerging role of Kondo scattering (mediated by Ti$^{3+}$) and at larger thickness impurity scattering. The polar LaAlO$_3$/non-polar SrTiO$_3$ interface exhibits a mixture of magnetic phases most likely arising from cationic defects and selective electron occupancy in Ti $t_{2g}$ levels. Using XMCD ferromagnetism was seen at these interfaces even at room temperature. Unlike LaAlO$_3$, polar LaMnO$_3$ is an insulator exhibiting orbital order that has a smaller band gap than SrTiO$_3$. It is a traditional antiferromagnetic material, but when grown on SrTiO$_3$, polar LaMnO$_3$ exhibits ferromagnetism for film thicknesses exceeding 5 unit cells. This is discussed in terms of electronic reconstruction with polar charge transfer to the LaMnO$_3$ side of the interface and also to the surface of the overlayer. Novel magnetic coupling effects are seen in perovskite ferromagnets separated by a polar oxide layer such as LaAlO$_3$ or NdGaO$_3$, whereas non-polar oxides do not show the same effect. The coupling between the ferromagnetic layers oscillates in sign between FM and AFM, depending on the barrier thickness. Such coupling is totally unexpected in the absence of any itinerary electrons, with insulating barriers that are too thick for tunneling. The novel magnetic coupling is shown to be mediated by spin-orbit coupling and also magnetic excitation of defect levels in the polar oxide planes.

8:36AM Y32.00002 Odd-parity magnetoresistance in pyrochlore iridate thin films with broken time-reversal symmetry

TAKAHIRO FUJITA, YUSUKE KOZUKA, MASAKI UCHIDA, Univ of Tokyo, ATSUMI TSUKAZAKI, Tohoku University, TAKA-HISA ARIMÁ, MASASHI KAWASAKI, Univ of Tokyo, DEPARTMENT OF APPLIED PHYSICS AND QUANTUM-PHASE ELECTRONICS CENTER TEAM, INSTITUTE FOR MATERIALS RESEARCH TEAM, PRESTO, JAPAN SCIENCE AND TECHNOLOGY AGENCY (JST) TEAM, DEPARTMENT OF ADVANCED MATERIALS SCIENCE TEAM, RIKEN CENTER FOR EMERGENT MATTER SCIENCE TEAM — Weyl Semimetal phase has a three dimensional Dirac-like band structure, which has been recently predicted to be materialized in lanthanides iridate pyrochlore (La$_2$Ir$_2$O$_7$), accompanied with all-in-all-out spin ordering. Nevertheless, obtaining high quality La$_2$Ir$_2$O$_7$ single crystal has been extremely challenging even in bulk. Here, we report on fabrication and magnetotransport property of Eu$_2$Ir$_2$O$_7$ single crystalline thin films. Our films show clear metal insulator transition at around 100 K. We reveal that one of the two degenerate all-in-all-out domain structures, which are interchangeable with time-reversal operation, can be selectively formed by the polarity of the cooling magnetic field. This domain is robustly sustained against sweep magnetic field of 9 T at 2 K, as evidenced by an unusual odd field dependent term in the magnetoresistance and an anomalous term in the Hall resistance. Our findings pave the way for exploring novel quantum transport predicted at their surfaces/interfaces or magnetic domain walls of the pyrochlore iridates.

8:48AM Y32.00003 The intrinsic magnetic structure and ordering of multiferoic h-LuFeO$_3$ Films

WILLIAM RATCLIFF, STEVEN DISSELER, JULIE BORCHERS, NIST, CHARLES BROOKS, JULIA MUNDY, Cornell University, JAMES CLARKSON, University of California, Berkeley, GREGORY STIEHL, Cornell University, PETER SCHIFFER, University of Illinois at Urbana-Champaign, DAVID MULLER, DARRELL SCHLOM, Cornell University, JARRETT TSYMBAI, PETER DOWBEN, University of Nebraska-Lincoln, Nebraska Center for Materials and Nanoscience, WENBIN WANG, Fudan University, JIAN WANG, Canadian Light Source, EVGENY TSIBIMAL, PETER DOWBEN, University of Nebraska-Lincoln, Nebraska Center for Materials and Nanoscience — We have studied the unoccupied electronic band structure of the hexagonal ferrites h-LuFeO$_3$ and h-YbFeO$_3$ using the absorption spectroscopy obtained with linearly polarized soft X-ray synchrotron radiation. The shapes of the spectra have been analyzed in terms of the splitting of atomic energy levels in various crystal fields corresponding to the local symmetry of the different atomic sites. Significant hybridization between O-2p and various iron and rare earth orbitals (such as Fe-3d, Lu/Yb-5d and Yb-4f) is observed. The photoemission damping is weak in the valence band of LuFeO$_3$, but when grown on SrTiO$_3$, LuFeO$_3$ exhibits ferromagnetism for film thicknesses exceeding 5 unit cells. This is discussed in terms of electronic reconstruction with polar charge transfer to the LaMnO$_3$ side of the interface and also to the surface of the overlayer. Novel magnetic coupling effects are seen in perovskite ferromagnets separated by a polar oxide layer such as LaAlO$_3$ or NdGaO$_3$, whereas non-polar oxides do not show the same effect. The coupling between the ferromagnetic layers oscillates in sign between FM and AFM, depending on the barrier thickness. Such coupling is totally unexpected in the absence of any itinerary electrons, with insulating barriers that are too thick for tunneling. The novel magnetic coupling is shown to be mediated by spin-orbit coupling and also magnetic excitation of defect levels in the polar oxide planes.

9:00AM Y32.00004 X-ray absorption spectroscopy study on h-LuFeO$_3$ and h-YbFeO$_3$ single crystal thin films

XIAOSHAN XU, University of Nebraska-Lincoln, Nebraska Center for Materials and Nanoscience, SHI CAO, TULA PAUDEL, KISHAN SINHA, XUANYUAN JIANG, University of Nebraska-Lincoln, Nebraska Center for Materials and Nanoscience, WENBIN WANG, Fudan University, JIAN WANG, Canadian Light Source, EVGENY TSYMBAL, PETER DOWBEN, University of Nebraska-Lincoln, Nebraska Center for Materials and Nanoscience — We have studied the unoccupied electronic band structure of the hexagonal ferrites h-LuFeO$_3$ and h-YbFeO$_3$ using the absorption spectroscopy obtained with linearly polarized soft X-ray synchrotron radiation. The shapes of the spectra have been analyzed in terms of the splitting of atomic energy levels in various crystal fields corresponding to the local symmetry of the different atomic sites. Significant hybridization between O-2p and various iron and rare earth orbitals (such as Fe-3d, Lu/Yb-5d and Yb-4f) is observed. The spectral weight contributions to the electronic states near the edge of the conduction band are found to consist of Fe-3d, Lu/Yb-5d, and Yb-4f as relatively narrow bands, as well as a wide O-2p band covering much of the measured energy range. The results are consistent with the density functional theory calculation including onsite-Coulomb repulsion corrections in terms of Hubbard U.

9:12AM Y32.00005 Time-resolved x-ray diffraction study of photoinduced strains in h-LuFeO$_3$ single crystal thin film

KISHAN SINHA, XUANYUAN JIANG, Department of Physics and Astronomy, University of Nebraska, Lincoln, Nebraska 68588, USA, XIAO WANG, Department of Physics, Bryn Mawr College, Bryn Mawr, Pennsylvania 19010, USA, ANTHONY DICHIARA, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, XUEMEI CHENG, Department of Physics, Bryn Mawr College, Bryn Mawr, Pennsylvania 19010, USA, YUELIN LI, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, XIAOSHAN XU, Department of Physics and Astronomy, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, Nebraska 68588, USA — We have studied the structural response of epitaxially stabilized h-LuFeO$_3$ (0001) thin film to above-band-gap optical excitation (pump) using time-resolved x-ray diffraction (probe) at picosecond time scale. The shift in (004) Bragg peak induced by a 390 nm excitation (30 ps duration) has been studied as a function of pump fluence and pump-probe time delay. The out-of-plane photoinduced lattice strain ($\Delta c/c$) exhibits a non-linear relation with fluence. The relaxation time is on the order of 1 ns. These observations suggest a relaxation mechanism that may be mediated by combined effects of charge recombination and phonon relaxation.
9:24AM Y32.00006 Local control of antiferromagnetic domains in Cr₂O₃[1]. S. ADENWALLA, UDAY SINGH, W. ECHTENKAMP, CH. BINEK, Univ of Nebraska - Lincoln — We have used a Cr₂O₃/Pd/(Co/Pd), exchange biased heterostructure to measure the spatial distribution of anti-ferromagnetic (AFM) domains in magnetoelectric AFM Cr₂O₃. The AFM Cr₂O₃ possesses a residual roughness insensitive surface magnetization below its Néel temperature (Tₙₑₑ 307K). This surface magnetization couples to the ferromagnetic material (Co/Pd) and results in exchange bias. Cooling the Cr₂O₃ from above its Néel temperature in different magnetization states of the ferromagnet results in the formation of AFM domains in Cr₂O₃. The AFM domains in the Cr₂O₃ were mapped by a spatial map of the exchange bias of the ferromagnet for the sample cooled in various remnant conditions of Co/Pd and zero-field cooled Cr₂O₃. The exchange bias, which is high above room temperature, is greatly reduced below the Néel temperature, resulting in a single AFM domain, and then, subsequently writing a reversed AFM domain using the heat from a 6 mW focused laser beam. Scanning the laser beam allows for the writing of any domain pattern with a spatial resolution of 5 μm, limited only by the focusing optics.

9:36AM Y32.00007 The role of spin fluctuations in the conductivity of CrO₂[1], KATE HEFFERNAN, D. TALBAYEV, Tulane University, XUEYU ZHANG, A. GUPTA, University of Alabama — Chromium dioxide is a half-metallic ferromagnet with Tₘ = 390K. Below Tₘ, the conductivity of CrO₂ grows by two orders of magnitude and is temperature independent below about 30 K. It is believed that electron scattering by spin fluctuations is responsible for the strong temperature dependence of the conductivity. We performed time-resolved THz spectroscopy (TRTS) and time-resolved magneto-optical Kerr effect (TRMOKE) to study the role of spin fluctuations in electron conduction. A thin film CrO₂ sample was excited by an optical pump pulse. The induced conductivity changes were measured by TRTS and the induced spin response by TRMOKE. A fast and a slow component were observed in both responses. The fast component dominates the TRTS response, while the slow dominates the TRMOKE which we attribute to the spin demagnetization in CrO₂. Since the slow component contributes only a small fraction of the total conductivity change in TRTS, we conclude that spin fluctuations may not play the dominant role in the pump-induced conductivity change. We also observed that the film transmits less THz light after the pump excitation, which corresponds to it becoming more conductive. We will discuss the relationship of our observations to the electronic and optical properties of CrO₂.

9:48AM Y32.00008 Ferromagnetic boundary magnetization properties of epitaxial Cr(2-x)AlₓO₃ thin films. LORENZO FALLARINO, CIC nanoGUNE Consolider, CHRISTIAN BINEK, University of Nebraska - Lincoln, ANDREAS BERGER, CIC nanoGUNE Consolider — The existence of an equilibrium net magnetization at (0001) surfaces is enabled by symmetry constraints for the magnetoelectric antiferromagnet Cr₂O₃. The occurrence of this boundary magnetization (BM) is furthermore roughness insensitive [1]. The BM is hereby fully coupled to the bulk antiferromagnetic order parameter and can be reversed together with it by a combination of E and H fields in bulk materials [2], or solely by magnetic means for single crystal (0001) oriented thin chromia films [3]. In order to understand whether the BM can be extended to alloys containing different oxide materials, we investigated the effect of Al₂O₃ doping onto the structural and magnetic properties of Cr₂O₃. We grew, using a hybrid growth procedure, 100 nm thick high-quality epitaxial Cr(2-x)AlₓO₃(0001) thin films in the concentration range between x = 0 to x = 0.6, preserving the original corundum crystal structure and symmetry. Using SQUID magnetometry, we showed that the critical temperature Tₓ of the NC phase can be tuned by alloying with Al₂O₃ using the BM as a probe to study the magnetic transition. Furthermore, we were able to evaluate the critical exponent and the absolute BM values for different samples. Both properties are consistent with the expected values, corroborating the BM nature of the observed magnetic signals. References: [1] K. D. Belashchenko, Phys. Rev. Lett. 105, 147204 (2010); [2] X. He et al., Nat. Mater. 9,579 (2010); [3] L. Fallarino et al., Appl. Phys. Lett. 104, 022403 (2014)

10:00AM Y32.00009 Electronic and magnetic properties of (1 1 1)-oriented CoCr₂O₄ epitaxial thin film[1], XIAORAN LIU, MICHAEL KAREEV, YANWEI CAO, Department of Physics, University of Arkansas, JIAN LIU, Department of Physics, University of California, Berkeley, SRIMANTA MIDDEY, DEREK MEYERS, Department of Physics, University of Arkansas, JOHN FREELAND, Advanced Photon Source, Argonne National Laboratory, JAK CHAKHALIAN, Department of Physics, University of Arkansas, DEPARTMENT OF PHYSICS, UNIVERSITY OF CALIFORNIA; BERKELEY COLLABORATION, MATERIALS SCIENCE DIVISION, LAWRENCE BERKELEY NATIONAL LABORATORY. — We report on the fabrication of high quality (1 1 1)-oriented ferrimagnetic normal spinel CoCr₂O₄ epitaxial thin films on single crystal Al₂O₃ substrates. The structural, electronic and magnetic properties were characterized by in-situ reflection high energy electron diffraction, atomic force microscopy, X-ray diffraction, X-ray photoemission spectroscopy, SQUID magnetometry and element resolved resonant X-ray magnetic scattering. The comprehensive characterization reveals that no disorder in the cation distribution or multivalency issue is present in the samples. As a result, Kagomé and triangular layers are naturally formed via this specific growth approach. These findings offer a pathway to fabricate two dimensional Kagomé heterostructures with novel quantum many-body phenomena by means of geometrical design.

1J.C. was supported by the DOD-ARO under Grant No. 0402-17291. Work at the Advanced Photon Source, Argonne is supported by the U.S. DOE under Grant No. DEAC02 06CH11357.

10:12AM Y32.00010 Fe₃O₄ thin films: from worse to better than the bulk, L.H. TJENG, X.H. LIU, C.F. CHANG, A.D. RATA, A. KOMAREK, Max Planck Institute for Chemical Physics of Solids, Dresden — Magnetite Fe₃O₄ is one of the most investigated materials from the class of transition metal oxides. It shows a first-order anomaly in the temperature dependence of the electrical conductivity at Tᵥ = 125 K, the famous Verwey transition. However, thin films of Fe₃O₄ show always a lower Tᵥ compared to the bulk material. The transition in films is also much broader than in the bulk. In order to find out the reason, we have performed a systematic investigation of the transport properties in dependence of the oxygen pressure, thickness, and the choice of the substrate. The findings point us the way how to grow films that have very sharp transitions with even higher Tᵥ than the bulk material.

10:24AM Y32.00011 Structural and magnetic properties of epitaxial delafossite CuFeO₂ thin films grown by pulsed laser deposition[1], TESS SENTY, TOYANATH JOSHI, ROBBYN TRAPPEN, JINLING ZHOU, SONG CHEN, UIUC, CHICAGO, IL. — Delafossite CuFeO₂ is a metallic two-dimensional layered compound modeled after the layered graphite structure, which has a magnetic moment at the Cu site and an antiferromagnetic structure. In this work, we report on the growth and low temperature characterization of epitaxial thin films of CuFeO₂ using a pulsed laser deposition system. The films were grown on SrTiO₃(001) substrates at 400°C. The structural quality of the films was confirmed by x-ray diffraction, showing a (00l) orientation, and by atomic force microscopy. The magnetic properties were measured using a SQUID magnetometer, and the magnetic moment was found to be consistent with the theoretical value of 1.8μB per Cu ion. The electrical transport properties were measured using a physical property measurement system, and the Seebeck coefficient was measured to be positive, indicating a p-type semiconductor behavior. The thermal conductivity was measured using a differential scanning calorimeter, and the thermal conductivity was found to be low, consistent with the expected behavior for a two-dimensional material. The films were also found to be metallic, with a high electrical conductivity of 10⁵ S/m at 10 K. Overall, these results demonstrate the potential of CuFeO₂ thin films for applications in low temperature electronics and magnetism.

Semiconductor Research Corporation program, sponsored by MARCO and DARPA. The PMA strongly depends on the thickness of the ferromagnetic layers and the interfacial oxidation level of the bilayers. We will also discuss electric field controlled magnetic properties in these systems. This work was supported in part by NSF (ECCS-1310338) and by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation Corporation, sponsored by DARPA.

1. Yubo Cui, Wilhelms Geerts, Fidele Twagirayezu, Department of Physics, Texas State University, San Marcos, TX 78666, Stefan Zollner, Department of Physics, New Mexico State University, Las Cruces, NM 88003 — Recently several electronic devices have achieved significant enhancements that have been attributed to an oxidized NiFe layer. A study on lateral spin valves, was found to have an increased magnetoresistance after leaving it exposed to air. The enhancements were attributed to the partly oxidation of a NiFe layer. Even more recently the turn on voltages of Hematite based water splitting devices was lowered to record low of .61 V with the addition of an amorphous NiFeOx layer. We investigated the optical properties of Ni80Fe20-oxide thin films that were deposited by reactive RF sputtering on quartz and Si/SiO2 substrates. Deposition was performed in an AJA Magnetron System using an Ar gas flow of 8 sccm and an oxygen gas flow of 2 sccm for different substrate temperatures (24-600 degrees Celsius). The optical properties in the visible spectrum and the film thickness were measured using a Woollam M2000 variable angle spectroscopic ellipsometer. Additional measurements were performed with a Woollam IR-VASE from 1.7 to 30 micrometer. The measurement results show the existence of a phonon peak around 382 cm\(^{-1}\) slightly red-shifted from the 390 cm\(^{-1}\) phonon peak of single crystalline NiO. XRD spectra did only reveal X-ray peaks of the rocksalt structure.

8:00AM Y34.00001 Advanced 3D Ni(OH)\(_2\)/CNT Gel Composite Electrodes for Supercapacitors\(^1\)
Hanlin Cheng, Hai Minh Duong, National University of Singapore — In order to enhance the performance of supercapacitors, advanced 3D Porous CNT/Ni(OH)\(_2\) gel composite electrodes are developed in this work. Compared with previously reported graphene gel supercapacitors, our electrodes using 1D CNTs have smaller diffusion resistance due to a shorter ion transport path. The developed 3D xerogel composite electrodes demonstrate the success of a careful engineered guest/host materials interface. Initially, the CNT gels are coated on the nickel foam to form a 3D scaffold, which serves as a microscopic electrical conductive network. Then Ni(OH)\(_2\) are incorporated using a traditional electrodeposition method. In this work, two types of the 3D CNT-coated nickel foams are investigated. The gels can be used directly as hydrogels or dried in air to form xerogels. Both hydrogels and xerogels present 3D tangled CNT networks. It shows that the hydrogel composite electrodes with unraveled CNTs, though presenting high capacitances of 1400 F/g at low discharge rate, possess lower capacitances at higher discharge rate and a poor cycling performance of less than 23% retention. In contrast, the xerogel composite electrodes can overcome these limitations in terms of a satisfied discharge performance of 1200 F/g and a good cycling retention more than 85% due to a stronger Ni(OH)\(_2\)/CNT interface. The CNT bundles in the xerogel electrodes formed during the drying process can give a flat surface with small curvature, which facilitate the Ni(OH)\(_2\) nucleation and growth.

8:12AM Y34.00002 Energetic and solvation effects at photoanode-catalyst interfaces: IrO\(_2\)/WO\(_3\)\(^1\)
Yuan Ping, Joint Center for Artificial Photosynthesis, California Institute of Technology and Lawrence Berkeley National Laboratory, William Goddard III, Joint Center for Artificial Photosynthesis, California Institute of Technology. GIULIA GALLI. The University of Chicago — One key challenge in building photo-electrochemical cells to split water is to engineer interfaces between photo-electrodes and catalysts that are stable in harsh pH conditions and permit optimal charge transfer. Iridium oxide is the only known catalyst for oxygen evolution stable in acidic conditions and hence a good candidate to be interfaced with photo-anodes. Using ab initio calculations, we investigated the structural and electronic properties of tungsten trioxide surfaces interfaced with an iridium dioxide thin film. We built a microscopic model of the interface that exhibits a formation energy lower than the surface energy of the most stable IrO\(_2\) surface, in spite of a large lattice mismatch, and we found no impurity states pinning the Fermi level. Both within Density Functional and many body perturbation theory (GW), we found that the two oxides form undesirable Ohmic contacts, when an IrO\(_2\) thin film fully covers WO\(_3\). However, our calculations predicted that if the morphology of the catalyst allows for partial exposure of the two oxides to water, then Schottky barriers may be formed, which favor charge transfer and hence water splitting. This work suggests ways to optimize light-absorber-catalyst interfaces for optimal charge transport.

8:24AM Y34.00003 Connecting the dynamic response of electrodes to their electronic structure \(^1\)
Anton Van Der Ven, Materials Department, University of California Santa Barbara — The electrodes of Li-ion batteries exhibit a wide range of intriguing electronic, thermodynamic and kinetic properties. Most electrode materials undergo a series of phase transformations as a result of drastic changes in Li concentration during each charge and discharge cycle. The mechanisms of these phase transformations remain poorly understood but usually involve a coupling between ionic diffusion, structural changes and interface migration. While phase transformations affect electrodes at the particle level, their mechanisms are ultimately determined by the electronic structure and crystallography of the electrode chemistry. Describing these phase transformations phenomenologically starting from first principles requires suitable coarse-graining strategies and a reliance on statistical mechanical approaches to account for the important role of temperature and entropy. This talk will describe how first-principles statistical mechanical approaches have provided insights about the mechanisms of kinetic processes in a variety of transition metal oxides and sulfides with widely differing crystal structures.
Effects of the dielectric response of solvent molecules filling, DFT+ECs incorporating organic electrolytes, aqueous electrolyte-based asymmetric supercapacitors (ASCs) have been attracting intensive attention recently. In this work, we present an incisive spectroscopic technique for directly probing redox orbits based on bulk electron momentum density measurements via high-resolution X-ray Compton scattering. Application of our method to spinel LiMn2O4 (a lithium ion battery cathode material) is discussed. The orbital involved in lithium insertion and extraction process is mainly the oxygen 2p orbit. Moreover, the manganese 3d states are shown to experience spatial delocalization involving 0.16 electrons per Mn site during the battery operation. Our analysis provides a clear understanding of the fundamental redox process involved in the working of the lithium ion battery. Work supported in part by the US DOE.

Electronic Structure at Electrode/Electrolyte Interfaces in Magnesium based Batteries. JANAKIRAMAN BALACHANDRAN, DONALD SIEGEL, University of Michigan, Ann Arbor — Magnesium is a promising multivalent element for use in next generation electrochemical energy storage systems. However, a wide range of challenges such as low coulombic efficiency, low/varying capacity and cyclability need to be resolved in order to realize Mg based batteries. Many of these issues can be related to interfacial phenomena between the Mg anode and common electrolytes. Ab-initio based computational models of these interfaces can provide insights on the interfacial interactions that can be difficult to probe experimentally. In this work we present ab-initio computations of common electrolyte solvents (THF, DME) in contact with two model electrode surfaces namely — (i) an “SEI-free” electrode based on Mg metal and, (ii) a “passivated” electrode consisting of MgO. We perform GW calculations to predict the reorganization of the molecular orbitals (HOMO/LUMO) upon contact with these surfaces and their alignment with respect to the Fermi energy of the electrodes. These computations are in turn compared with more efficient GGA (PBE) & Hybrid (HSE) functional calculations. The results obtained from these computations enable us to qualitatively describe the stability of these solvent molecules at electrode-electrolyte interfaces.

Mg intercalation mechanism at the Mo6S8 cathode surface proposed by first-principles methods1. LIWEN WAN, DAVID PRENDERGAST, Joint Center for Energy Storage Research, The Molecular Foundry, Lawrence Berkeley National Laboratory — In recent years, great attention has been paid to the development of divalent Mg-ion batteries, which can potentially double the energy density and volumetric capacity compared to monovalent Li-ion batteries. The prototype Mg-ion battery, comprising Mg(anode)/Mg2(AlCl3-BuEt)2/THF(electrolyte)/Mo6S8(cathode), was established in 2000 by Aurbach et al. Despite the remarkable success of this prototype system, we still lack a clear understanding of the fundamental Mg intercalation/deposition mechanism at the electrolyte/electrode interfaces that perhaps results in the observed sluggish Mg transport process. Our previous work has shown that Mg-ions are strongly coordinated in the bulk electrolyte by a combination of counterion, Cl−, and organic aprotic solvent, THF. In this work, we use first-principles methods to study Mg intercalation behavior at the Mo6S8 cathode surface with the presence of solvent molecules. It is found that the image charge, formed on this metallic cathode surface, can effectively weaken the solvent-surface interactions and facilitate Mg intercalation. A detailed Mg intercalation mechanism is proposed and the unique role of Mo6S8 as the cathode material is emphasized.

Asymmetric Supercapacitors with Dominant Pseudocapacitance in Neutral Aqueous Electrolyte. YUANBING MAO, QIANG LI, University of Texas-Pan American — Electrochemical capacitors (ECs) are promising power sources for portable electronics and hybrid electric vehicles. To solve the poor ionic conductivity, intrinsic inflammability and toxicity issues of current ECs incorporating organic electrolytes, aqueous electrolyte-based asymmetric supercapacitors (ASCs) have been attracting intensive attention recently. In this presentation, prototype MnO2-NFs/KCl//CNTs supercapacitor cells in neutral aqueous electrolyte allow rapid charge/discharge kinetics, fast ionic response, and evident pseudocapacitive dominance due to the unique MnO2-NF architecture and novel ASC design. For the first time, the respective contributions of the pseudocapacitance and EDL capacitance to the overall electrochemical performance of ASCs were differentiated with a proof of pseudocapacitive dominance \( \eta_{pseudocap}/\eta_{EC} = 2.5 \). To sum, this study provides a brilliant proof-of-concept design of novel supercapacitors with pseudocapacitive dominance to achieve ultimate energy storage applications with both high energy and power density.

Impact of strong electronic correlations on the phase stability of oxide and phosphate intercalation materials. ERIC ISAACS, CHRIS MARIANETTI, Department of Applied Physics and Applied Mathematics, Columbia University — Li intercalation in certain battery cathode materials such as Li1FePO4 (LFP) occurs via a two-phase (phase separated) process, which significantly impacts the voltage profile and charge/discharge kinetics. The phase separation in LFP is not predicted by density functional theory (DFT), but it is captured by DFT plus Hubbard U (DFT+U) suggesting the significant role of electronic correlations in determining its thermodynamic properties [F. Zhou et al., Phys. Rev. B 69, 201101 (2004)]. In order to understand the impact of such correlations on the phase stability of transition metal oxide and phosphate intercalation materials, here we investigate the formation energies of phase separating LFP, phase stable Li2CoO2, and phase stable Sr2La1-x52TiO2 within DFT+U. We present the relationship between different formation energy contributions and the on-site Coulomb energy. Furthermore, we illustrate how band filling, p-d hybridization, magnetism, and charge and orbital ordering can impact the phase stability of such systems.

10:24AM Y34.00011 Structure and interface properties of the electrolyte material Li$_4$P$_2$S$_6$\(^1\)
ZACHARY D. HOOD, Oak Ridge National Lab., CAMERON KATES\(^2\), N. A. W. HOLZWARTH, Wake Forest U. — Li$_4$P$_2$S$_6$ has been identified in several high temperature preparations of lithium thiophosphate electrolytes as a synthesis or decomposition product. Its characteristic P−P bond may be partly responsible for its relative stability. Early structural analyses\(^3\) found the P sites to be disordered. Our previous simulations\(^4\) found a related low energy structure with ordered P sites. We report here a re-examination of the simulation results and new X-ray measurements which indicate that the lowest energy structure of Li$_4$P$_2$S$_6$ is different from that determined in previous analysis. Ionic conductivity and thermal stability are also reported. In addition to examining the bulk electrolyte, we have simulated idealized interfaces of Li$_4$P$_2$S$_6$ and lithium metal representing an electrolyte/anode system.

10:36AM Y34.00012 Modeling solid electrolyte/electrode interface stability using first principles calculations\(^1\)
NICHOLAS LEPLEY, N. A. W. HOLZWARTH, Wake Forest University — The formation of a stable interface between electrode and electrolyte materials is a necessary property for batteries in general and for Li-ion batteries in particular. We present a framework for understanding and predicting the electrochemical stability of electrode/electrolyte interfaces based on density functional theory calculations. Within this framework, we have extended our previous work\(^2\) to include quantitative results for the solid-solid interface energy of the Li$_4$PS$_4$/Li, Li$_3$PO$_4$/Li, Li$_2$S/Li, Li$_2$O/Li, and Li$_2$PS$_4$/Li$_2$S interfaces. We show that under local equilibrium conditions the interface energy appears to be a good indicator of the stability of the interface. While the results we present are focused on the interface between Li-ion solid electrolytes and Li metal we expect the method to be applicable to other interface systems.

8:00AM Y35.00001 Deconstruction of excitations in atomtronic systems using phase reference\(^1\)
MARK EDWARDS, BRENNAN COHELEACH, Georgia Southern University, CHARLES CLARK, Joint Quantum Institute — Laboratory atomtronic systems consisting of a Bose–Einstein–condensed gas with strong horizontal confinement and arbitrary planar potential, such as a ring–plus–disk, are now possible. Perturbing the ring part (e.g., by stirring) can produce excitations such as vortices and solitons. Each excitation uniquely modifies the local condensate phase and these modifications can be probed by overlapping the ring with the unperturbed disk via condensate release. The resulting interference pattern contains signatures of the excitations present at release time. Using the Gross–Pitaevskii equation, we studied whether this interference pattern can be used to determine what excitations were present at release time. We created individual excitations in a ring–plus–disk condensate, released it to see the interference pattern and created a compendium of these patterns. We also studied whether the individual patterns can be superposed and tested the deconstruction procedure by analyzing the interference of a strongly stirred ring by comparing the deconstruction with the condensate state at release time.

8:12AM Y35.00002 Thermal and quantum fluctuation effects in rotational hysteresis of ring Bose–Einstein condensates\(^1\)
C.W. CLARK, Y.-H. WANG, Joint Quantum Institute, C. HELLER, M. EDWARDS, Georgia Southern University — In a recent experiment\(^2\) a ring Bose–Einstein condensate (BEC) with zero circulation (with winding number $m = 0$) and stirred by a barrier jumped to an $m = 1$ state when stirred faster than a certain critical speed, $\Omega_c^1$. Conversely an $m = 1$ condensate dropped to $m = 0$ when stirred below a critical speed, $\Omega^1_c$, which was lower than $\Omega_c^1$. The hysteresis loop areas, $\Omega^1_c - \Omega^1_c$, disagreed significantly with the predictions of the zero–temperature Gross–Pitaevskii equation. We report the results of simulating this experiment with both the Zaremba–Nikuni–Griffin (ZNG) theory and the Truncated Wigner Approximation (TWA).

8:24AM Y35.00003 Unusual vortex matter in rotating Bose–Einstein condensates with SU(2) broken symmetry\(^1\)
PEDER GALTELAND, Department of Physics, Norwegian University of Science and Technology, EGOR BABAEEV, Department of Theoretical Physics, The Royal Institute of Technology, ASLE SUDBO, Department of Physics, Norwegian University of Science and Technology — We consider a Ginzburg–Landau model of a rotating two-component Bose–Einstein condensate with SU(2) broken symmetry through the use of numerical Monte Carlo techniques. We include the full spectrum of thermal amplitude- and phase-fluctuations. The model exhibits an unusual state of global phase coherence with no accompanying vortex line lattice. This state is not a counterpart in single-component condensates. The conditions for such a state are experimentally realizable in, e.g., homonuclear mixes of atomic gases in separate hyperfine states, tuned to the SU(2) point with Feshbach resonance techniques.

8:36AM Y35.00004 Vortex annihilation and inverse cascades in two dimensional superfluid turbulence, ANDREW LUCAS, PAUL M. CHESLER, Harvard Univ — The dynamics of a dilute mixture of vortices and antivortices in a turbulent two-dimensional superfluid at finite temperature is well described by first order Hall-Vinen-Iordanskii equations, or dissipative point vortex dynamics. These equations are governed by a single dimensionless parameter: the ratio of the strength of drag forces to Magnus forces on vortices. When this parameter is small, we demonstrate using numerical simulations that the resulting superfluid enjoys an inverse energy cascade where small scale stirring leads to large scale vortex clustering. We argue analytically and numerically that the vortex annihilation rate in a laminar flow may be parametrically smaller than the rate in a turbulent flow with an inverse cascade. This suggests a new way to detect inverse cascades in experiments on two-dimensional superfluid turbulence using cold atomic gases, where traditional probes of turbulence such as the energy spectrum are not currently accessible.

8:48AM Y35.00005 Excitation spectrum of a tightly confined spin-2 Bose gas, MATJAZ PAYRITS, RYAN BARNETT, Imperial Coll — We introduce an effective low-energy action for a spin-2 Bose gas in a tight trap in the presence of a quadratic Zeeman field. We derive the excitation spectrum by expanding the action to second order in deviations from the ground state configuration and subjecting it to a functional integral analysis. This is a generalization of standard Bogoliubov theory as it allows for the study of excitations about fragmented states, occurring ubiquitously in spinor Bose gas systems. It is found that the excitations generally consist of mean-field-like states uniformly integrated over rotations about the direction of the magnetic field (or all of SU(3) in the absence of a magnetic field). This parallels the general observation that states breaking fewer symmetries tend to be lower in energy. Though unstable in the thermodynamic limit, these states are stabilized for finite particle numbers, potentially allowing for a convenient means of studying fragmentation experimentally. For the nematic region of the spin-2 phase diagram, we also show that the quadratic Zeeman dependence of the spectrum smoothly approaches the previously obtained discontinuous mean-field dependence.

9:00AM Y35.00006 Probing the Collective Modes of Spherical Shell-Shaped Condensates with Quench Numerics, FRANCES YANG, Smith College, KUEI SUN, The University of Texas at Dallas, KARMELA PADAVIC, SMITHA VISHVESWARA, University of Illinois at Urbana-Champaign, COURTNEY LANNERT, Smith College and the University of Massachusetts at Amherst — We explore the collective modes of Bose-Einstein condensates by numerical solution of the Gross-Pitaevskii equation with an external “bubble trap” potential and the limits of a thin-shell condensate and a filled-spherical condensate.

9:12AM Y35.00007 Microscopic theory of BEC phase transition in a critical region, VITALY KOCHAROVSKY, Texas A&M University, VLADIMIR KOCHAROVSKY, Inst. of Applied Physics of the Russian Academy of Science and Univ. of Nizhny Novgorod, Russia — A microscopic theory, which should connect the asymptotics of the ordered and disordered phases across a critical region, has not been found so far even for anyone of the numerous phase transitions. Here we present such microscopic theory for a phase transition in an interacting Bose gas [Phys. Lett. A 378, n. 49 (2014)]. It allows one to describe formation of a condensate phase from a disordered phase across an entire critical region continuously. We find an exact Hamiltonian for Bose-Einstein condensation (BEC) in a mesoscopic system and derive the exact fundamental equations for the condensate wave function and Green’s functions, which are valid both inside and outside critical region. These equations are governed by a single dimensionless parameter: the ratio of the strength of drag forces to Magnus forces on vortices. We introduce an effective low-energy action for a spin-2 Bose gas in a tight trap in the presence of a quadratic Zeeman field.

9:24AM Y35.00008 Moving solitons in a one-dimensional fermionic superfluid - an exact solution, DMITRY EIFMINK, University of Maryland, VICTOR GALITSKI, Joint Quantum Institute, University of Maryland — A fully analytical theory of a traveling soliton in a one-dimensional fermionic superfluid is developed within the framework of time-dependent self-consistent Bogoliubov-de Gennes equations, which are solved exactly. The soliton manifests itself in a kink-like profile of the superconducting order parameter and hosts a pair of Andreev bound states. They adjust to soliton’s motion and play an important role in its stabilization. A phase jump across the soliton and its energy decrease with soliton’s velocity and vanish at the critical velocity, corresponding to the Landau criterion, where the soliton starts emitting quasiparticles and becomes unstable. The “inertial” and “gravitational” masses of the soliton are calculated and the former is shown to be orders of magnitude larger than the latter. This results in a slow motion of the soliton in a harmonic trap.

9:36AM Y35.00009 3D dimeron as a stable topological object, SHIJIE YANG, YONGKAI LIU, Beijing Normal University — Searching for novel topological objects is always an intriguing task for scientists in various fields. We study a new three-dimensional (3D) topological structure called 3D dimeron in the trapped two-component Bose-Einstein condensates. The 3D dimeron differs to the conventional 3D skyrmion for the condensates hosting two interlocked vortex-rings. We demonstrate that the vortex-rings are connected by a singular string and the complexity constitutes a vortex-molecule. The stability is investigated through numerically evolving the Gross-Pitaevskii equations, giving a coherent Rabi coupling between the two components. Alternatively, we find that the stable 3D dimeron can be naturally generated from a vortex-free Gaussian wave packet via incorporating a synthetic non-Abelian gauge potential into the condensates.

9:48AM Y35.00010 Black–hole lasing action in laboratory Bose–Einstein condensates, YIHSIEH WANG, TED JACOBSON, University of Maryland, MARK EDWARDS, Georgia Southern University, CHARLES W. CLARK, Joint Quantum Institute — A recent experiment infers the the production of Hawking radiation in an analogue black-hole laser, which consists of a Bose-Einstein condensate of about 5,000 $^{87}$Rb atoms in a trap with a translating potential step. In the co-moving reference frame the flow velocity of the condensate exceeds the sound speed in a region confined between two sonic points, the analogue black and white hole horizons. We report simulations of that experiment based on the zero-temperature Gross-Pitaevskii (GP) equation that are consistent with the reported experimental results. The simulations show exponential growth of oscillatory modes trapped between the horizons, with a power spectrum consistent with expectations from the Bogoliubov dispersion relation, which saturates after an initial period. Quantum Hawking radiation occurs spontaneously in the vacuum, but in the presence of a coherent state of phonons it takes on a classical form captured by the zero-temperature GP equation. The growth of the trapped modes results from repeated super-radiant scattering from the black hole horizon, associated with emission of Hawking radiation to the exterior that is not well-resolved in the simulation.

10:00AM Y35.00011 The fate of a gray soliton in a quenched Bose-Einstein condensate. OLEK-SANDR GAMAYUN, Lancaster Univ. YULIA BEZVERSHENKO, Bogolyubov Institute for Theoretical Physics, VADIM CHEIANOV. Leiden University — We investigate the destiny of a gray soliton in a repulsive one-dimensional Bose-Einstein condensate undergoing a sudden quench of the non-linearity parameter. The outcome of the quench is found to depend dramatically on the ratio $\eta$ of the final and initial values of the speed of sound. For integer $\eta$ the soliton splits into exactly $2\eta - 1$ solitons. For non-integer $\eta$ the soliton decays into multiple solitons and Bogoliubov modes. The case of integer $\eta$ is analyzed in detail. The parameters of solitons in the out-state are found explicitly. Our approach exploits the inverse scattering method and can be easily used for the similar quenches in any classical integrable system.

10:12AM Y36.00002 Emission spectrum of atoms in a harmonic trap. POOJA SINGH, YURI ROSTOVTSIV, University of North Texas — We consider an excited atom in a harmonic trap. The evolution of quantum atomic states is theoretically studied under adiabatic approximation. The emission spectra for trapped atoms are calculated. We have show interference effects as well as trapping effect in a trap that has a size larger than the wavelength of radiation.

10:24AM Y35.00013 Conservation of helicity in superfluids. HRIDEISH KEDIA, DUSTIN KLECKNER, University of Chicago, DAVIDE PROMENT, University of East Anglia, WILLIAM T.M. IRVIN, University of Chicago — Helicity arises as a special conserved quantity in ideal fluids, in addition to energy, momentum and angular momentum. As a measure of the knottedness of vortex lines, Helicity provides an important tool for studying a wide variety of physical systems such as plasmas and turbulent fluids. Superfluids flow without resistance just like ideal (Euler) fluids, making it natural to ask whether their knottedness is similarly preserved. We address the conservation of helicity in superfluids theoretically and examine its consequences in numerical simulations.

Friday, March 6, 2015 8:00AM - 11:00AM — Session Y36 DAMOP: New Developments in Atomic, Molecular, and Optical Physics 211 - Nathan Gemelke, Pennsylvania State University

8:00AM Y36.00001 ABSTRACT WITHDRAWN —

8:12AM Y36.00002 Emission spectrum of atoms in a harmonic trap. POOJA SINGH, YURI ROSTOVTSIV, University of North Texas — We consider an excited atom in a harmonic trap. The evolution of quantum atomic states is theoretically studied under adiabatic approximation. The emission spectra for trapped atoms are calculated. We have show interference effects as well as trapping effect in a trap that has a size larger than the wavelength of radiation.

8:24AM Y35.00003 When is the mode-summation method of calculating van der Waals force valid? ARVIND NARAYANASWAMY, Columbia University — Most calculations of van der Waals forces and Casimir forces can be categorized as variations of two “proto methods”: (1) Lifshitz theory, and (2) mode summation method. In the Lifshitz theory, by which I include the subsequent generalization by Dzyaloshinskii, Lifshitz, and Pitaevskii [Adv. Phys. 10, 165 (1961); See also Zheng and Narayanaswamy, Phys. Rev. A 83, 042504 (2011)] the dispersion force is expressed in terms of the (dyadic) Green’s function of the vector Helmholtz equation. In the mode summation method [see Casimir, Proc. Kon. Ned. Akad. Wetensch. 51, 793 (1948); Van Kampen, Nijboer, and Schram, Phys. Lett. A 26, 307 (1968)], the free energy of a configuration of objects is expressed in terms of the sum of the free energies of each of the possible electromagnetic modes. The derivative of this free energy with respect to variation of relative positions between the objects yields the force between two objects. However, we raised questions about the validity of the mode summation method when calculating van der Waals forces in dissipative media [see Narayanaswamy and Zheng, Phys. Rev. A 88, 012502 (2013) and Ninham, Parsegian, and Weiss, J. Stat. Phys. 2, 323 (1970)]. In this talk, I want to start a discussion about the validity of the mode summation method.

8:36AM Y36.00004 Landau-Zener transitions mediated by an environment in the open-multistate model. SAVANNAH GARSON, Osaka Prefecture University, AMRO DODIN, LENA SIMINE, DVIRA SEGAL, University of Toronto — We study Landau-Zener transitions between two linearly driven states with the addition of a shared discretized continuum. The continuum allows for population decay from the initial state as well as indirect transitions. The probability of nonadiabatic transition in this model preserves the standard Landau-Zener functional form apart from a shift in the usual exponential factor, reflecting population transfer into the continuum. We provide an intuitive explanation for this behavior assuming individual, independent transitions between pairs of states. In contrast, the ground state survival probability at long time shows a novel, non-monotonic, functional form with an oscillatory behavior in the sweep rate at low sweep rate values. We envision our system as a simplified model regarding memory preservation in a quantum dot as the dot interacts with the surrounding environment.

8:48AM Y36.00005 ABSTRACT WITHDRAWN —

9:00AM Y36.00006 Near field heat transfer in superlattices1. RAUL ESQUIVEL-SIRVENT, Instituto de Fisica, UNAM — I present a theoretical calculation of the near field heat transfer between super lattices made of alternative layers of both metallic and semiconductor materials. The calculation of the near field transfer requires the knowledge of the reflectivities, that are obtained by calculating the surface impedance of the super lattice. Depending on the periodicity of the lattice and the dielectric function of the materials the near field heat transfer can be modulated or engineered. Additional control on the heat transfer is achieved by introducing defects in the superlattice. The results are extended to include photonic hypercrystals that effectively behave like a hyperbolic metamaterial even in the near field (1), where the tuning of the heat transfer is modified by (1) E. E. Narimanov, Phys. Rev. X 4, 041014 (2014).

9:12AM Y36.00007 ABSTRACT WITHDRAWN —
9:24AM Y36.00008 Neutral Atom Nanolithography Using a Pulsed Magnetic Lens1, ERIK ANCIAX, RODRIGO CASTILLO-GARZA, JAMIE CARDNER, MARK RAIZEN, UT Austin — We present the status of a method of neutral atom lithography that achieves sub-10nm resolution. This method is based on the nanoscale imaging of a beam of metastable atoms with an aberration-corrected hexapole lens. The lens creates a magnetic field gradient that increases with the distance from the center of the lens so as to focus divergent low field seeking atoms toward a single focal spot past the lens. The scheme takes advantage of the narrow velocity distribution of a pulsed supersonic beam as well as an optical pumping and cooling scheme that modifies the magnetic state of the atoms and further reduces its velocity dispersion. This method can be used not only to pattern but to spectroscopically probe surfaces with spatial resolution below 10nm.

9:36AM Y36.00009 Proposal of a new type of optical parametric amplifier for efficient X-ray generation, WAYNE HUANG, Texas A&M University, ROGER BACH, HERMAN BATELAAN, University of Nebraska-Lincoln, MARLAN SCULLY, Texas A&M University — With an optical parametric amplifier (OPA), one can transfer energy from the pump light to the seeded light via sum parametric resonance (also called parametric down conversion). In this process, coherent light with frequency lower than the pump is generated. Using infrared as pump, one can obtain light in the mid/far-infrared regime. In contrast to OPA, the quantum amplification by super-radiant emission of radiation (QASER) suggests that energy transfer can occur when the pump frequency is equal to the difference of the seeded frequencies [1]. Thus, coherent light with frequency much higher than the pump can be generated. The physical mechanism behind QASER is called difference parametric resonance. We propose to build a new type of optical parametric amplifier based on this concept and transfer energy from infrared to X-ray. In this presentation, I would like to capture the main idea of QASER by discussing the difference parametric resonance in a coupled oscillating system. A perturbation analysis is given to provide insight into the mechanism as well as the conditions for experimental realization. We will also briefly discuss realizations of difference parametric resonance in electronic, mechanical, and acoustic systems. [1] M. O. Scully et al., Phys. Rev X 3, 041001 (2013).

48AM Y36.00010 Measured Atomic Ground State Polarizabilities of 35 Metallic Elements1, JOHN INDERGAARD, LEI MA, BAIQIAN ZHANG, ILIA LARKIN, Georgia Inst of Tech, RAMIRO MORO, Cameron University, Oklahoma, WALTER DE HEER, Georgia Inst of Tech — Advanced pulsed cryogenic molecular beam electric deflection methods utilizing a position-sensitive mass spectrometer and 7.87 eV ionizing radiation were used to measure the polarizabilities of more than half of the metallic elements in the periodic table for the first time. These measurements increase the total number of experimentally obtained atomic polarizabilities from 23 to 57. Concurrent Stern-Gerlach deflection measurements verified the ground state condition of the measured atoms. Generating higher temperature beams allowed for the comparison of relative populations of the ground and excited states in order to extract the true temperature of the atomic beam, which followed the nominal temperature closely over a wide temperature range. Comparison of newly measured polarizabilities with state-of-the-art calculations exposes significant systematic and isolated discrepancies throughout the periodic table.

10:00AM Y36.00011 Complex time contours in tunnel ionization and low-energy structures1, EMILIO PISANTY, MISHA IVANOV, Imperial College London — In tunnel ionization, a strong low-frequency laser field removes an electron from an atom by setting up a slowly-varying potential energy barrier that the electron can tunnel through. During its subsequent oscillations in the laser field, the electron can revisit the neighborhood of the remaining ion one or more times. Frequently, this is a soft recollision which affects the momentum distribution, although more substantial effects can happen. We use the Analytical R-Matrix theory to investigate the effect of these soft recollisions, focusing on low drift momenta, where the laser-induced trajectory has a turning point near the nucleus. Our framework provides a complex-valued trajectory perspective on the electron propagation, from first principles. We show that the presence of the Coulomb interaction, which is responsible for the soft recollisions, forbids certain common choices of contour within the complex time plane, and we describe an algorithm for safely circumventing the associated branch cuts. We find quantum analogues to the classical turning points near the ion, and we investigate their relation to the recently-discovered low-energy and very-low-energy structures in above-threshold ionization.

1We acknowledge funding from CONACYT (Mexico) and the MC-ITN CORINF network.

10:12AM Y36.00012 Fast spectrophotometry with compressive sensing, DAVID STARLING, IAN STORER, Penn State University — Spectrophotometers and spectrometers have numerous applications in the physical sciences and engineering, resulting in a plethora of designs and requirements. A good spectrophotometer balances the need for high photometric precision, high spectral resolution, high durability and low cost. One way to address these design objectives is to take advantage of modern scanning and detection techniques. A common imaging method that has improved signal acquisition speed and sensitivity in limited signal scenarios is the single pixel camera. Such cameras utilize the sparsity of a signal to sample below the Nyquist rate via a process known as compressive sensing. Here, we show that a single pixel camera using compressive sensing algorithms and a digital micromirror device can replace the common scanning mechanisms found in virtually all spectrophotometers, providing a very low cost solution and improving data acquisition time. We evaluate this single pixel spectrophotometer by studying a variety of samples tested against commercial products. We conclude with an analysis of flame spectra and possible improvements for future designs.

10:24AM Y36.00013 Red Shifted Absorbance of A-site Substituted Bismuth Titanate Pyrochlore: Characterization and Stability Analysis from First Principles1, CEDRIC MAYFIELD, MUHAMMAD HUDA, Department of Physics, University of Texas at Arlington — Transition metal inclusion has enhanced photocatalytic activity of bismuth titanate (Bi2Ti2O7) up to an impurity threshold concentration. Beyond the threshold, spectral absorbance is continually red shifted but increased photocurrent is not reciprocated. We investigated, from first principles, the origin of decreased photocurrent in modified Bi2Ti2O7 (BTO) by calculating the electronic structures of a representative set of doping configurations and by performing a phase stability analysis of the doping. We report our theoretical/computational strategy of analyzing free energy space and show an explicit dependence of pure phase synthesis on changes in free energy. Also, we present a probability distribution of the doping configurations based on formation enthalpy to better understand the nature of doping in BTO. We found that transition metal substitutions are favorable at the A-sites due to unchanging coordination with O ions.

10:36AM Y36.00014 Dopant concentration dependent optical and X-Ray induced photoluminescence in Eu$^{3+}$ doped La$_2$Zr$_2$O$_7$ 1, MADHAB POKHREL, Univ of Texas, Pan American, MIKHAIL BRIK, University of Tartu, YUANBING MAO, Univ of Texas, Pan American — Herein, we will be presenting the dopant (Eu) concentration dependent high density La$_2$Zr$_2$O$_7$ nanoparticles for optical and X-ray scintillation applications by use of X-ray diffraction, Raman, FTIR, scanning electron microscopy (SEM), transmission electron microscopy (TEM), and X-ray excited photoluminescence (PL). Several theoretical methods have been used in order to investigate the structural, electronic, optical, elastic, dynamic properties of Eu doped La$_2$Zr$_2$O$_7$. It is observed that Eu: La$_2$Zr$_2$O$_7$ shows an intense red luminescence under 258, 322, 394 and 465 nm excitation. The optical intensity of Eu: La$_2$Zr$_2$O$_7$ depends on the dopant concentration of Eu$^{3+}$. Following high energy excitation with X-rays, Eu: La$_2$Zr$_2$O$_7$ shows an atypical Eu PL response (scintillation) with a red emission. The intense color emission of Eu obtained under 258 nm excitation, the X-ray induced luminescence property along with reportedly high density of La$_2$Zr$_2$O$_7$, makes these nanomaterials attractive for optical and X-ray applications.

10:48AM Y36.00015 Semi-Classical and Quantum-Field Descriptions for the Non-Linear Electromagnetic Response of Many-Electron Systems1, VERNE JACOBS, Naval Research Laboratory — Semi-classical and quantum-field descriptions for the non-linear electromagnetic response relevant to resonant pump-probe optical phenomena in quantized many-electron systems are formulated within a general reduced-density-matrix framework. Time-domain (equation-of-motion) and frequency-domain (resolvent-operator) formulations are developed in a unified and self-consistent manner. A preliminary semi-classical perturbation treatment of the electromagnetic interaction is adopted, in which the electromagnetic field is described as a classical field satisfying the Maxwell equations. It is emphasized that the development of a quantized-field approach will be essential for a fully self-consistent quantum-mechanical formulation. Compact Liouville-space operator expressions are obtained for the general (n'th order) non-linear electromagnetic-response tensors describing moving many-electron atomic systems. The tetradic matrix elements of the Liouville-space self-energy operators are evaluated for environmental collisional and radiative interactions.

Friday, March 6, 2015 8:00AM - 11:00AM
Session Y39 GQI: Superconducting Cavities and Resonators 213AB - Jose Aumentado, NIST

8:00AM Y39.00001 Microwave mode structure of superconducting metamaterial resonators, HAOZHI WANG, FRANCISCO ROUXINOL, MATTHEW LAHAYE, BRITTON PLOURDE, Syracuse University — Arrays of lumped circuit elements can be used to form metamaterial resonant structures that exhibit novel behavior compared to resonators made from conventional distributed transmission lines. By engineering the parameters and configurations of the lumped elements composing the unit cell of such a metamaterial resonator, one can generate spectra with wide stop-bands as well as pass-bands with dense microwave modes. If the metamaterials are fabricated from superconducting traces, the losses can be low enough to allow for these dense modes to be resolved and potentially coupled to quantum systems, such as superconducting qubits. We will present our low-temperature measurements of a variety of superconducting metamaterial resonators and we will compare these with numerical simulations of the microwave properties.

8:12AM Y39.00002 Lattice waveguide QED: many-body interactions by dissipation, BAPTISTE ROYER, KEVIN LALUMIÈRE, ARNE GRIMSMO, ALEXANDRE BLAIS, Département de Physique, Université de Sherbrooke, Sherbrooke, Québec, Canada — In waveguide QED, superconducting qubits acting as artificial atoms are coupled to a 1D superconducting transmission line playing the role of common bath for the qubits. By controlling their effective separation, it is possible to engineer various types of dissipation-induced interactions between the qubits. In this talk, we consider the situation where multiple superconducting qubits are coupled to a lattice of superconducting transmission lines. Depending on the choice of lattice, the qubits exhibit a rich variety of interactions. We present a Markovian master equation framework to describe these systems, and discuss results obtained for simple lattices.

8:24AM Y39.00003 Universal Control of an Oscillator with Dispersive Coupling to a Qubit, STEFAN I. KRASTANOV, CHAO SHEN, VICTOR Y. ALBERT, REINIER W. HEERES, BRIAN M. VLASTAKIS, ROBERT J. SCHOELKOPF, LIANG JIANG, Yale University — We investigate quantum control of an oscillator mode that dispersively couples to an ancillary qubit. In the strong dispersive regime we can drive the qubit conditioned on the selected number states of the oscillator, which enables selective number-dependent arbitrary phase (SNAP) operation and universal control of the oscillator. Based on our proof of universal control, we provide explicit constructions for arbitrary state preparation and arbitrary unitary operation of the oscillator. Moreover, we present an efficient procedure to prepare the number state $|n⟩$ using only $O(\sqrt{n})$ operations. We also compare our scheme with known quantum control protocols for coupled qubit-oscillator systems. We point out that this universal control scheme of the oscillator can be readily implemented using superconducting circuits.

8:36AM Y39.00004 A Quasi-3D, Purcell-Filtered Hardware Module for Quantum Information, C. AXLINE, M. REAGOR, K. SHAIN, P. REINHOLD, T. BRECHT, E. HOLLAND, C. WANG, R. HEERES, L. FRUNZIO, R.J. SCHOELKOPF, Department of Applied Physics, Yale University — The advent of 3D circuit quantum electrodynamics has provided an ultra-low-loss environment for superconducting qubits, boosting qubit coherences over 100 microseconds and linear resonator lifetimes above 10 milliseconds. Planar devices, however, allow lithographic control of parameters and suggest greater scalability. We have developed a single-chip, seamless-cavity architecture that answers the call[1] for a modular computational element, comprising 3D transmon, fast, Purcell-filtered readout, and long-lived storage cavity. This design incorporates advantages of both 2D and 3D architectures. It also serves as a novel testbed for qubit loss mechanisms, as resonator and qubit modes have similar material participations. Initial results—T1 and T2 comparable to the best 3D transmons—shift blame away from the metal-substrate interfaces widely considered to be the limiting loss channel in current-generation transmons, and further experiments using this system will probe these losses more carefully. We propose several modifications and extensions to these modules to miniaturize the design and to build more sophisticated quantum systems. [1] M. H. Devoret and R. J. Schoelkopf, Science 8 March 2013: 339 (6124), 1169-1174.

8:48AM Y39.00005 Cavity state manipulation using a dispersively coupled qubit. REINIER HEERES, BRIAN VLASTAKIS, ERIC HOLLAND, STEFAN KRASTANOV, VICTOR V. ALBERT, CHAO SHEN, LIANG JIANG, ROBERT SCHOELKOPF, Yale University — The large available Hilbert space and high coherence of cavity resonators makes them an interesting resource in quantum information processing. For example, several schemes exist to encode a logical qubit in such a harmonic oscillator in a way that would be protected against certain kinds of errors. Here we demonstrate a method to manipulate a cavity state using a far off-resonantly coupled qubit, using only linear controls and a gate we call the Selective Number Arbitrary Phase (SNAP) gate. This gate allows to impart an arbitrary phase on each Fock-state component of the cavity. We show how we can use these tools to correct for the effects of Kerr-evolution as well as how to create a single-photon Fock state. Our scheme can be generalized to arbitrary cavity state creation and even allows to construct arbitrary unitary operators to give universal control of the oscillator.

9:00AM Y39.00006 Quantum dynamics of an electromagnetic mode that cannot contain N photons. EMMANUEL FLURIN, LANDRY BRETHEAU, PHILIPPE CAMPAGNE, FRANCOIS MALLET, BENJAMIN HUARD, Laboratoire Pierre Aigrain, QELEC TEAM — Electromagnetic modes are instrumental for realizing quantum physics experiments and building quantum machines. In this experiment, we demonstrate a new way to manipulate these modes by effectively controlling their phase space. By preventing access to a single energy level, the dynamics of the field is dramatically changed. Here, it was possible to keep the mode from containing a number of photons N, which was arbitrarily chosen between 2 and 5. Under this constraint, and starting in its ground state, a resonantly driven mode is confined to levels 0 to N-1. The level occupation is then found to oscillate in time, similarly to an N-level system. Performing a direct Wigner tomography of the field reveals its non-classical features. In particular, at half period in the evolution, it resembles a “Schrödinger cat state.” This fine control of the field in its phase space enables innovative applications in quantum information and metrology.

9:12AM Y39.00007 Exploration of sapphire whispering gallery mode resonator crystals for use as a quantum computing memory. ADAM SIROIS, Univ of Colorado - Boulder, MANUEL CASTELLANOS-BELTRAN, NIST-Boulder, DANIEL CREEDON, Univ. of W. Australia, RAYMOND SIMMONDS, JOHN TEUFEL, NIST-Boulder, MICHAEL TOBAR, Univ. of W. Australia, JOSE AUGMENTADO, NIST-Boulder — Sapphire whispering gallery mode (WG) resonators are a known to support multiple, high-quality factor modes in a compact volume at microwave frequencies. In this talk we demonstrate the ability to parametrically couple whispering gallery modes by use of a Josephson-junction-based coupling element. In this manner we implement a ‘storage and retrieval’ protocol which may be useful for storing several complex microwave quantum states in small volumes.

9:24AM Y39.00008 Fabrication of transmon qubits embedded in superconducting whispering gallery mode resonators. K. SERNIAK, Z.K. MINEV, I.M. POP, L. FRUNZIO, R.J. SCHOELKOPF, M.H. DEVORET, Department of Applied Physics, Yale University — Superconducting whispering gallery mode resonators (WGMs) can confine up to 98% of two high quality modes in lossless vacuum [APL 103, 142604]. We have fabricated new WGMR-based devices using standard lithography techniques and in which transmon qubits were integrated. The advantages of this transmon-resonator configuration are i) the possibility to perform a targeted study of thin-film quality factor across different methods and steps of fabrication and ii) precise control of the Hamiltonian parameters.

3 Work supported by: IARPA, ARO, and ONR.

9:36AM Y39.00009 Coherences of transmon qubits embedded in superconducting whispering gallery mode resonators. Z.K. MINEV, K. SERNIAK, IOAN POP, Z. LEGHTAS, K. SLIWA, L. FRUNZIO, R. SCHOELKOPF, MICHEL DEVORET, Department of Applied Physics, Yale University — We describe the design and measurement of a planar uperconducting two-resonator one-qubit device. The two resonators are realized in a hardware-efficient way by the differential modes of a superconducting whispering gallery mode resonator [APL 103, 142604]. This device forms an integrated basis for a quantum memory [New J. Phys. 16, 045014 2014].

9:48AM Y39.00010 Engineering non-linear resonator mode interactions in circuit QED by continuous driving: Introduction. WOLFGANG PFAFF, MATTHEW REAGOR, REINIER HEERES, NISSIM OFEK, KEVIN CHOU, JACOB BLUMOFF, ZAKI LEGHTAS, STEVEN TOUZARD, KATRINA SLIWA, ERIC HOLLAND, STEFAN KRASTANOV, LUIGI FRUNZIO, MICHEL DEVORET, LIANG JIANG, ROBERT SCHOELKOPF, Yale Univ — High-Q microwave resonators show great promise for storing and manipulating quantum states in circuit QED. Using resonator modes as such a resource in quantum information processing applications requires the ability to manipulate the state of a resonator efficiently. Further, one must engineer appropriate coupling channels without spoiling the coherence properties of the resonator. We present an architecture that combines millisecond lifetimes for photonic quantum states stored in a linear resonator with fast measurement provided by a low-Q readout resonator. We demonstrate experimentally how a continuous drive on a transmon can be utilized to generate highly non-classical photonic states inside the high-Q resonator via effective non-linear resonator mode interactions. Our approach opens new avenues for using modes of long-lived linear resonators in the circuit QED platform for quantum information processing tasks.

10:00AM Y39.00011 Engineering non-linear resonator mode interactions in circuit QED by continuous driving: Manipulation of a photonic quantum memory. MATTHEW REAGOR, WOLFGANG PFAFF, REINIER HEERES, NISSIM OFEK, KEVIN CHOU, JACOB BLUMOFF, ZAKI LEGHTAS, STEVEN TOUZARD, KATRINA SLIWA, ERIC HOLLAND, VICTOR V. ALBERT, LUIGI FRUNZIO, MICHEL H. DEVORET, LIANG JIANG, ROBERT J. SCHOELKOPF, Departments of Applied Physics and Physics, Yale University — Recent advances in circuit QED have shown great potential for using microwave resonators as quantum memories. In particular, it is possible to encode the state of a quantum bit in non-classical photonic states inside a high-Q linear resonator. An outstanding challenge is to perform controlled operations on such a photonic state. We demonstrate experimentally how a continuous drive on a transmon qubit coupled to a high-Q storage resonator can be used to induce non-linear dynamics of the resonator. Tailoring the drive properties allows us to cancel or enhance non-linearities in the system such that we can manipulate the state stored in the cavity. This approach can be used to either counteract undesirable evolution due to the bare Hamiltonian of the system or, ultimately, to perform logical operations on the state encoded in the cavity field. Our method provides a promising pathway towards performing universal control for quantum states stored in high-coherence resonators in the circuit QED platform.
10:12AM Y39.00012 Demonstrating real-time feedback that enhances the performance of measurement sequence with cat states in a cavity , N. OFEK, A. PETRENKO, Y. LIU, B. VLASTAKIS, Yale University, L. SUN, Yale University, Tsinghua University, Beijing, China, Z. LEGHTAS, R. HEERES, K.M. SLIWA, Yale University, M. MIRRAHIMI, Yale University; INRIA Paris-Rocquencourt, L. JIANG, M.H. DEVORET, R.J. SCHOELKOFF, Yale University — Real-time feedback offers not just the convenience of streamlined data acquisition, but is an essential element in any quantum computational architecture that requires branching based on measurement outcomes. State-preparation, mitigating the effects of qubit decoherence, and recording the trajectories of quantum systems are just a few of the many potential applications of real-time feedback. Photon number parity measurements of cat states in superconducting resonators are a particularly useful platform for demonstrating the clear advantages of having sophisticated feedback schemes to enhance the performance a proposed error-correction protocol [Leghtas et.al. PRL 2013]. In a cQED architecture, where a transmon qubit is coupled to two superconducting cavities, we present a field-programmable gate array (FPGA) device capable of making decisions and calculations with latency times far shorter than the lifetimes of any of the system’s constituents. This level of performance opens the door to realizing many complex, previously unfeasible, experiments in superconducting qubit systems.

10:24AM Y39.00013 Utilizing photon number parity measurements to demonstrate quantum computation with cat-states in a cavity , A. PETRENKO, N. OFEK, B. VLASTAKIS, Yale University, L. SUN, Yale University, Tsinghua University, Beijing, China, Z. LEGHTAS, R. HEERES, K.M. SLIWA, Yale University, M. MIRRAHIMI, Yale University; INRIA Paris-Rocquencourt, L. JIANG, M.H. DEVORET, R.J. SCHOELKOFF, Yale University — Realizing a working quantum computer requires overcoming the many challenges that come with coupling large numbers of qubits to perform logical operations. These include improving coherence times, achieving high gate fidelities, and correcting for the inevitable errors that will occur throughout the duration of an algorithm. While impressive progress has been made in all of these areas, the difficulty of combining these ingredients to demonstrate an error-protected logical qubit, comprised of many physical qubits, still remains formidable. With its large Hilbert space, superior coherence properties, and single dominant error channel (single photon loss), a superconducting 3D resonator acting as a resource for a quantum memory offers a hardware-efficient alternative to multi-qubit codes [Leghtas et al. PRL 2013]. Here we build upon recent work on cat-state encoding [Vlastakis et. al. Science 2013] and photon-parity jumps [Sun et al. 2014] by exploring the effects of sequential measurements on a cavity state. Employing a transmon qubit dispersively coupled to two superconducting resonators in a cQED architecture, we explore further the application of parity measurements to characterizing such a hybrid qubit/cat state architecture. In so doing, we demonstrate the promise of integrating cat states as central constituents of future quantum codes.

10:36AM Y39.00014 Continuous generation and stabilization of Schrödinger cat states in a quantum circuit , A. ROY, Z. LEGHTAS, A.D. STONE, M.H. DEVORET, Department of Applied Physics, Yale University, M. MIRRAHIMI, Department of Applied Physics, Yale University and INRIA Paris Rocquencourt — While dissipation is widely considered as being harmful for quantum coherence, it can, when properly engineered, lead to the stabilization of non-trivial pure quantum states. Deterministic generation of non-classical states like Schrödinger cat states is one of the key ingredients in performing universal quantum computation. We theoretically propose a scheme, adapted to superconducting quantum circuits, for continuous generation and stabilization of these states in a cavity using dissipation engineering. We first generate these states inside a high-Q cavity by engineering its dissipation with a bath that only exchanges photons in pairs. We then stabilize these transient states against single-photon decay using a second engineered bath. The single-photon stabilization is autonomous, and exploits the photon-number-dependent frequency-s splitting due to Kerr interactions in the strongly dispersive regime of circuit QED. We present analytical and numerical results demonstrating the robustness of the scheme and its amenability to immediate experimental implementation.

Work supported by ARO

10:48AM Y39.00015 Deterministic amplification for cat-state engineering in circuit-QED , JAEWOO JOO, ATI and Physics Department, Univ of Surrey, DANIEL OI, Physics Department, University of Strathclyde, MATTHEW ELLIOTT, ERAN GNROSSAR, ATI and Physics Department, Univ of Surrey, TIMOTHY SPILLER, York Centre for Quantum Technologies, Department of Physics, University of York — We propose a novel implementation scheme of amplifying the size of Schrödinger cat states in superconducting circuits. While the amplification method in quantum optics is normally probabilistic, our scheme can be performed deterministically in circuit-QED. Using adiabatic methods and optimal control, we demonstrate that the amplification operation can be built deterministically in a system of a transmon qubit strongly coupled with a cavity. This amplification tool will in particular open the potential of continuous-variable nonclassical states toward practical quantum technologies, for example stabilization of cat-type states and continuous-variable teleportation.

Friday, March 6, 2015 8:00AM - 11:00AM —
Session Y41 DPOLY: Focus Session: Biopolymers I: Biohybrids, Biointerfaces, and Modeling
214A - Bradley D. Olsen, Massachusetts Institute of Technology

8:00AM Y41.00001 Multiscale modelling of polymers at soft-bio interface , PAOLA CARBONE
The University of Manchester — The behaviour of polymers at a liquid/liquid interface has become increasingly technologically important in recent years. For example, many of the self-assembly processes involving macromolecules occur at such interfaces and one of the most common chemical processes used to produce polymer nanoparticles—the solvent displacement method— involves the diffusion of the polymer chains from a good solvent, where the polymer initially dissolves, to a non-solvent where the nanoparticles are formed. Finally, polymer-based drug nanocarriers (either nanoparticles or micelles) are becoming increasingly popular in drug delivery and their behaviour at fluid interfaces (such as a lipid/water boundary) should be properly understood in order to predict their biological activity. Here we show how using a multiscale approach it is possible to gain a detailed picture of the thermodynamic stability of homo- and co-polymers at fluid interfaces spanning from universal rules valid to any polymer systems at high dilution to the specific cases of amphiphilic linear and branched polymers.

School of Chemical Engineering and Analytical Science

8:36AM Y41.00002 Self-Assembly of DNA–Graft Copolymer Nanoparticles , ZONGHUI WEI, Northwestern University, YONG REN, JOHN-MICHAEL WILLIFORD, HAI-QUAN MAO, Johns Hopkins University, ERIK LJUJTEN, Northwestern University, NORTHWESTERN UNIVERSITY COLLABORATION, JOHNS HOPKINS UNIVERSITY COLLABORATION — Self-assembled DNA–copolymer nanoparticles are promising gene delivery systems due to their high biocompatibility. Notably, such nanoparticles can exhibit a variety of morphologies. Previously, we demonstrated that the nanoparticle shape can be tuned through variation of solvent polarity in a solution of DNA and block copolymers. Moreover, we confirmed that this shape can influence transfection efficiency [1]. In terms of ease of manufacturing as well as tunability of the system, it is important to explore the possibility of employing other types of condensing agents. Here, we report on the use of polyelectrolytes with grafted PEG side chains, which offer facile synthesis and an additional control parameter in the form of grafting density. Via a combination of experiments and molecular dynamics simulations we demonstrate that a high degree of shape control of the micellar nanoparticles can indeed be achieved through variation of the density and length of the grafted side chains. [1] Jiang, X.; Qu, W.; Pan, D.; Ren, Y.; Williford, J. M.; Cui, H. G.; Lujten, E.; Mao, H. Q. Advanced Materials 25, 227–232 (2013).
8:48AM Y41.00003 Monodisperse dendrimeric phytoglycogen nanoparticles in water act as hard sphere colloidal dispersions. JOHN DUTCHER, ERZSI PAPP-SZABO, CARLEY MIKI, University of Guelph — Phytoglycogen is a highly branched polysaccharide that is very similar to the energy storage molecule glycogen. We have isolated monodisperse phytoglycogen nanoparticles from corn and these particles are attractive for applications in the cosmetic, food, and beverage, and biomedical industries. Many of these promising applications are due to the special interaction between the nanoparticles and water, which results in: (1) high solubility; (2) low viscosity and high stability in aqueous dispersions; and (3) a remarkable capacity to sequester and retain water. We have used cone-and-plate and concentric cylinder rheometry to measure the dependence of the zero shear viscosity of aqueous dispersions of phytoglycogen on the phytoglycogen concentration. We find that the nanoparticles behave like hard spheres in water, with the viscosity diverging for volume fractions very close to that corresponding to randomly packed hard spheres. This simple system provides an ideal platform for detailed testing of theories of colloidal glasses and jamming.

9:00AM Y41.00004 Tracing lipids and their association with keratin in the adhesive gecko setae by NMR Spectroscopy. DHARAMDEEP JAIN, ALYSSA.Y. STARK, PETER H. NIEWIAROWSKI, TOSHIKAZU MIYOSHI, ALI DHINOJWALA, University of Akron — Numerous examples exist in nature where the coexistence of lipids and keratin is prominent. Examples include cell membranes, epidermis, avian feathers, wool, insect cuticle and the adhesive hairy features known as “setae” on the gecko toe. Until recently the setae were only considered to be composed of keratinous material. Given the prevalence of lipid-keratin associations in nature however, it is perhaps not surprising that phospholipids were found in the setae, and interestingly, in the form of a footprint after a gecko moves along a surface. However, the organization and the molecular-level behavior of lipids and keratin in the setae is still not known. Here, we demonstrate the use of NMR spectroscopy to detect lipids and understand their association with keratin in the molts termed as “sheds” from the toe pad and the non-adhesive regions of the epidermal skin. Our results show a distribution of similar lipids in both the skin and toe shed but with different dynamics at a molecular level. The study can help us understand the system better both biologically and for the design of better synthetics, but our findings may also have a larger impact on the recurring observations of lipids in many popular biomaterials and biological systems.

9:12AM Y41.00005 ABSTRACT WITHDRAWN

9:24AM Y41.00006 Deposition and Grafting of Collapsed Elastin-Like Co-Polypeptides on Silicon. ROBIN MAYS, North Carolina State University, JULIE ALBERT, Tulane University, SARAH MACEWAN, Duke University, MICHAEL DICKY, North Carolina State University, ASHUTOSH CHILKOTI, Duke University, JAN GENZER, North Carolina State University — Protein-based polymers offer the potential for responsive, bio-compatible, well-defined (molecular weight and sequence) systems. Elastin-like peptides (ELPs) are well suited for solution-based biomedical applications, including drug delivery and biomolecular purification. In order to use ELPs for stimuli-responsive surfaces, a detailed understanding of deposition conditions and behavior is instrumental. We crafted diblock ELPs with lower critical solution temperature (LCST) behavior on silicon surfaces. We synthesized 33kDa ELPs through genetic expression in bacteria with recombinant DNA technology. The diblock copolypeptides we used have a hydrophobic block (VPGVG) and a hydrophilic block (VPVSG), with each block having a different LCST. These diblock ELPs form micelles in solution when heated above the transition temperature of the hydrophobic block. We can graft either fully solvated ELPs or micellar ELP structures to an EDC/NHS activated surface. Our findings indicate a surprising stability of ELP aggregation on surfaces. We investigated the effects of time, temperature, and grafting block on the morphology, thickness, and water contact angle of our surfaces. Using atomic force microscopy, we studied the morphology of the deposited ELPs both in air and water.

9:36AM Y41.00007 Nanostructure Formation in Fusion Protein Block Copolymers Containing A Globular Protein Block. BRADLEY OLSEN, GUOKUI QIN, MATTHEW GLASSMAN, CHRISTOPHER LAM, DONGSOOK CHANG, MIT, ERIC SCHIABLE, ALEXANDER HEXEMER, Lawrence Berkeley Lab — Fusion proteins provide an elegant method for the synthesis of precisely defined block copolymers, where the use of molecular biology techniques enables monodisperse synthesis, precise control over block length and arrangement, and the incorporation of complex folded chain shapes and biofunctional structures. Here, we show that a block copolymer that contains a globular protein block and a coil-like protein block can self-assemble into a nanostructured material despite the chemical similarity between the two halves of the molecule. Using model polymers composed of the red fluorescent protein mCherry and an elastin-like polypeptide (ELP), the phase behavior of a simple linear fusion is shown to resemble that of protein-polymer conjugates. Molecular biology also enables the preparation of well-controlled double tail fused structures, and the self-assembly of these molecules shows that the chain topology of the fusion protein has a large impact on its self-assembly. At the same molar mass and composition, the double tailed structures self-assemble at a lower concentration and exhibit a greater number of order-order transitions than their single tailed counterparts. In addition, the double tailed fusions retained a higher fraction of functional protein in the final material.

9:48AM Y41.00008 Tailoring selectivity and flux in interior functionalized peptide nanotubes through self-assembly. SINAN KETEN, LUIS RUIZ, Northwestern University — Self-assembly of cyclic peptide nanotubes (CPNs) in polymer thin films has opened up the possibility to create separation membranes with tunable nanotubes that can differentiate molecules at the sub-nanometer level. Recent studies have demonstrated that the interior chemistry of the CPNs can be tailored by inserting functional groups in the nanopore lumen (mCPNs) (Hourani et al. JACS, 2011). Through theory and multi-scale MD simulations, here we explain how the stacking ordering of binary mixtures of functional CPs can be prescribed using the entropic elasticity of conjugated polymers (Ruiz & Keten, Soft Matter, 2014). The linear self-similar coarsening growth mechanism, kinetic trapping and its effects on stacking sequences will be demonstrated (Ruiz & Keten, J. Phys. Chem. Lett., 2014). Building on these insights, we present a new approach to addressing the challenge of boosting water flux and ion selectivity simultaneously, specifically by inserting two different types of functional microgroups in the lumen, and by controlling CP stacking order. Simulations elucidate how functional groups inspired from biological amino acids influence the transport of water and ions through mCPNs. We find mixing functional groups to tune partial charge distributions and pore size can be used to boost flux and selectivity (Ruiz & Keten, Nanoscale, 2014). Our computational thought experiments lay the foundation for bioinspired principles to discover artificial nanochannels for separation applications.

10:00AM Y41.00009 Coarse-grained modelling of RNA. PETR SULC, The Rockefeller University, FLAVIO ROMANO, THOMAS OULDRIDGE, JONATHAN DOYE, ARD LOUIS, University of Oxford — We present a new, nucleotide-level model for RNA, oRNA, based on the coarse-graining methodology recently developed for the oxDNA model of DNA. The model is designed to reproduce structural, mechanical and thermodynamic properties of RNA, and the coarse-graining level aims to retain the relevant physics for RNA hybridization and the structure of single- and double-stranded RNA. In order to explore its strengths and weaknesses, we test the model in a range of nanotechnological and biological settings. Applications explored include the folding thermodynamics of a pseudoknot, the formation of a kissing loop complex, the unzipping of a hairpin motif, and the thermodynamics and kinetics of RNA strand-displacement reaction. We argue that the model can be used for efficient simulations of the structure of systems with thousands of base pairs, and for the assembly of systems of up to hundreds of base pairs. The source code implementing the model is released for public use at dna.physics.ox.ac.uk.

The work presented here is funded by the National Science Foundation (DMREF award CBET-1234305).
10:12AM Y41.00010 Rationally Designed Random Heteropolymer Surfactants for the Encapsulation and Stabilization of Proteins in Organic Solvents, BRIAN PANGANIBAN, University of California, Berkeley, BAOFLI QIAO, Northwestern University, MONA OBADIA, Université Claude Bernard Lyon 1, MONICA OLVERA DE LA CRUZ, DOMINIC DROCKENMULLER, Université Claude Bernard Lyon 1, TING XU, University of California, Berkeley — Stabilizing proteins in organic solvents can provide opportunities to overcome challenges in many areas, such as biosynthetic catalysis of hydrophobic substrates and biomimetic materials. Reverse micelles have been used to encapsulate proteins in organic solvents; however, currently-used small molecule surfactants are inefficient in both stabilizing native protein conformation and allowing for the retention of inherent protein functionality for extended periods of time. These surfactants are often quite dynamic and cannot completely suppress organic solvent penetration, resulting in protein denaturation. To address this pitfall, we report a new class of random heteropolymer surfactants that anchor to the protein surface through multiple non-covalent, complimentary interactions. These newly designed polymeric surfactants can effectively increase the retention of activity of several proteins in organic solvent in comparison to both a small molecule surfactant and an amphiphilic diblock copolymer. The modularity of this design process has the potential to be translated to a variety of proteins that can provide an enhanced platform for applications that include molecular recognition, catalysis, nanoscale assemblies, and medical therapeutics.

Friday, March 6, 2015 8:00AM - 11:00AM — Session Y42 DPOLY: Theory and Modeling of Diblock Copolymers and Blends 214B • Charles S. Ingalls, University of Illinois at Urbana-Champaign

8:00AM Y42.00001 Ordering in Mixed Polymer Brushes1, AMALIE L. FRISCHKNECHT, CHESTER K. SIMOCKO, DALE L. HUBER, Sandia National Laboratories — Mixed polymer brushes, consisting of two different homopolymers grafted to a substrate, microphase separate into phases reminiscent of those of diblock copolymer thin films. However, mixed polymer brushes typically display less long range order than diblock copolymers. One reason for the lack of long-range order is variations in the grafting densities of the two polymers, which result in quenched disorder in the system. Here we use self-consistent field theory (SCFT) to explore whether mixed brushes consisting of AB and AC diblock copolymers grafted to the surface can order better than homopolymer mixed brushes. In particular, we consider the case when A is a random copolymer of B and C, and thus has equivalent interaction strengths with both B and C blocks. Large cell SCFT calculations are performed for systems with Gaussian-correlated grafting density distributions. The theory predicts that mixed diblock brushes with a random copolymer block grafted to the surface are more ordered than the equivalent homopolymer brushes. The dependence of these results on polymer volume fractions and interaction parameters, as well as equivalent comparison with experiments, will be discussed.

1Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a Lockheed-Martin Company, for the U.S. Department of Energy under Contract No. DE-AC04-94AL85000.

8:12AM Y42.00002 Transferable potentials for coarse-grained simulations of block copolymer biomimetic membranes1, MALGORZATA KOWALIK, IAN SINES, JANNA K. MARANAS, MANISH KUMAR, Department of Chemical Engineering, The Pennsylvania State University, University Park, PA 16802 — We present a framework of minimal model transferable coarse-grained potentials for use in molecular dynamics simulations of amphiphilic block copolymer biomimetic membranes. Testing two, three, and five-bead models of polyethylene oxide polyethylene (PEO-PED) polymer membranes, we show that values for membrane thickness and area per polymer chain obtained using the two-bead model for use in molecular dynamics simulations of amphiphilic block copolymer biomimetic membranes. We demonstrate that cross interactions can be represented using combining rules with the use of a scaling factor which is correlated with the difference in hydrophobicities of the interacting hydrophobic/hydrophilic monomers. In this way it becomes possible to rapidly simulate and screen new combinations of block copolymers with minimal potential development effort.

8:24AM Y42.00003 Molecular Dynamics Simulations of Microphase Separating Tapered Diblock Copolymers, YOUNGMI SEO, JONATHAN R. BROWN, LISA M. HALL, The Ohio State University — Tapered AB copolymers consist of pure A and B blocks separated by a middle block whose composition is a statistical linear gradient from pure A to pure B (or from B to A for an inverse taper). These systems microphase separate into ordered structures similar to typical AB diblock copolymers. Prior experiments and theory suggest that one can use taper length as an adjustable parameter (beyond those available in the diblock system) to control interfacial and phase behavior, and that tapers potentially make the bicontinuous double gyroid phase more accessible at high molecular weight. Using a simple coarse-grained model, we perform molecular dynamics (MD) simulations to determine the interfacial profiles and other features of the structure and dynamics as a function of taper length. We reproduce the results from self-consistent field theory (SCFT); specifically, tapering increases miscibility, widens the interfacial region, shortens domain spacing, and makes network phases more preferable. The significantly smaller lamellar spacing for inverse tapers is explained in terms of polymer chain folding or snaking across the interface. The dynamic analysis shows the diffusion and relaxation behavior are closely related to the chain conformations and interfacial behavior. The effect of tapering on penetrant diffusion through one of the microphases will also be discussed.

8:36AM Y42.00004 Dynamic and Topological Properties of Lamellar Phases, VAIYANATHAN SETHURAMAN, VENKAT GANESAN, Department of Chemical Engineering, University of Texas at Austin, Austin, Texas 78712, USA — We investigate the local dynamical and global topological properties of a diblock copolymer system in its lamellar phase. Explicitly, we investigate the heterogeneity in the dynamics and non-Gaussian parameter (α) of different segments in the ordered phase as a function of its distance from the interface for a chain length of N = 100. At short time scales, weak heterogeneities are observed for low degree of compositional segregation and the heterogeneities increased for increased interactions between unlike monomers. Monomers near the interface also showed higher α values compared to those away from the interface. We also investigate the entanglements of ordered lamellar phases using molecular dynamics simulations which reveal a reduction in the average entanglement length for increasing γ/N. We use consistent field theory calculations to probe the number of topological constraints near the interface. Such calculations showed an increase in the number of constraints near the interface, thus corroborating the results obtained from molecular dynamics simulations.
J. Chem. Phys. recently-developed dynamical self-consistent mean-field theory on polymer blends and diblock copolymer melts and without compromising on neglecting compositional fluctuations, as is the case with self-consistent mean field theory. The assumption that the fluctuations in the incompressibility field are of a Gaussian nature allows one to use standard MC techniques. We compare the simulation results with predictions from theories that include fluctuations, such as a theory developed by Fredrickson and Helfand (FH) and the recently published renormalized one-loop calculations. Once the incorporation of the ultra-violet divergence is taken care of in an accurate way, the simulation results can be nicely mapped onto the theoretical predictions near the transition region, even for moderate simulation resolutions. [1]: Stasiak and Matsen, Macromolecules 46, 8037 (2013)

9:00AM Y42.00006 Accurate fluctuation-corrected phase diagrams of high-molecular-weight block-copolymer melts, KRIS DELANEY, GLENN FREDRICKSON, UC Santa Barbara — We describe a theoretical framework for accurately computing fluctuation-corrected phase diagrams of block polymer melts. The method is based on complex Langevin sampling of a UV regularized field-theoretic model, with Helmholtz free energies computed using thermodynamic integration. UV regularization ensures that the free energies thus computed do not have an arbitrary; they can be compared to incommensurate phases, permitting for the first time the explicit computational determination of order-order transitions within a mean-field approximation. The method allows one to study field-theoretic fluctuations without using renormalization-group techniques and is applicable to block copolymers that cannot be accurately treated with perturbation theory on the one-loop level. We note that our method uses no uncontrolled approximations beyond the initial definition of a coarse-grained molecular model for the polymer melt. The method can be applied straightforwardly to melts and solutions containing multiple species with diverse polymer architectures.

9:12AM Y42.00007 Morphology of Tapered and Ion-containing Diblock Copolymers from Fluids Functional Density Theory, JONATHAN R. BROWN, LISA M. HALL, The Ohio State University — We use classical, fluids density functional theory (fDFT) to study microphase separation in block copolymer systems. We focus on systems where local monomer scale ordering may be more important than for typical diblock copolymers, so fDFT allows us to generate more accurate density profiles and free energies at constant pressure. Specifically, we study the effect of tapering, or adding a gradient region (taper) between the pure A and B blocks of an AB diblock; the taper changes in composition smoothly from A to B. This additional control parameter allows one to increase the miscibility of the two blocks and the effective segregation strength \( \chi_N \) of the system. In contrast to our prior SCFT study, we capture the effect of the depletion of monomer density near the A-B interface, which changes as a function of taper length and interfacial width. Further, these methods can also be applied to ion containing systems, in which case monomer scale packing around ions is also important; we will show the fDFT predicted microphase morphology of block ionomers.

9:24AM Y42.00008 Survey of experimental data from diblock copolymer melts: Do experiments and simulations agree?, PAVANI MEDAPURAM, DAVID MORSE, Univ of Minnesota - Twin Cities — Recent simulations by our group have established that a variety of different simplified simulation models of symmetric diblock copolymers exhibit universal behavior that is now well characterized. In this talk, we report our progress in analyzing published experimental data for a variety of nearly symmetric diblock copolymers using methods closely analogous to those used to analyze simulation results. We will discuss the extent to which experiments on a wide variety of systems are consistent with the results of simulations, and with one another.

9:36AM Y42.00009 Finite Size Effects and Commensurability in Lattice Simulations of Symmetric Diblock Copolymers, AKASH ARORA, FRANK S. BATES, KEVIN D. DORFMAN, Chemical Engineering and Materials Science, University of Minnesota, Minneapolis MN, USA — Monte Carlo (MC) simulations have been used widely to study the fluctuation driven weakly first-order transition in symmetric diblock copolymers. However, the predicted value of the order-disorder transition (ODT) often differs from the true value (thermodynamic limit) because of the finite size of the simulation box. In order to locate the true ODT, we have studied finite size effects in lattice MC simulations of lamella forming symmetric diblock copolymers. The straightforward application of finite size scaling (FSS) is questionable due to incommensurability between the ordered structure domain spacing and the periodicity of the lattice. To address this issue, we estimate the preferred domain spacing by simulating multiple system sizes to find nearly commensurate systems. Furthermore, we apply FSS to these nearly commensurate systems to predict the ODT in the thermodynamic limit.

9:48AM Y42.00010 Dynamical self-consistent field theory of the evolution of instabilities in polymer blends and diblock copolymer melts, DOUGLAS GRZETIC, ROBERT WICKHAM, Univ of Guelph — We demonstrate our recently-developed dynamical self-consistent mean-field theory [J. Chem. Phys. 140, 244907 (2014)] in a polymeric context, by studying the early-time spinodal decomposition of a symmetric binary polymer blend and the dynamics of the order-order transition between the LAM and HEX phases in an asymmetric diblock copolymer melt. A Brownian dynamics description of a dense system of Rouse chains interacting pair-wise via a modified, species-dependent Lennard-Jones potential is reformulated, through a novel dynamical mean-field approximation, as that of a single chain interacting with a self-consistently determined dynamical mean field. A large ensemble of single chain Brownian dynamics simulations, run in parallel, efficiently determines the space- and time-dependent density that is used to weight the Lennard-Jones interaction in the mean-field calculation. Our theory gives access to chain conformation statistics, maintains a connection to microscopic time-scales and scales favorably with chain-length via a fast Rouse transform. We examine the performance of our method, and discuss our results for the growth of unstable modes in the blend and in the diblock copolymer melt.

10:00AM Y42.00011 Free energies and commensurability effects in simulations of three-dimensional ordered phases of diblock copolymers, TAHER GHASIMAKBARI, DAVID MORSE, University of Minnesota — We present an approach to the calculation of precise phase boundaries in simulations of diblock copolymer melts that is based on the calculation of free energies by thermodynamic integration. Results of simulations of three dimensionally periodic structures are extremely sensitive to commensurability effects, i.e., to the relationship between the dimensions of the (generally small) periodic simulation cell and the (generally unknown) preferred dimensions of a particular ordered phase. We avoid this by measuring the free energy for each ordered phase of interest using several different simulation sizes to estimate free energies as functions of unit cell size and thereby estimate the optimal cell size and corresponding free energy.

10:12AM Y42.00012 Estimation of \( \chi \) parameter from molecular simulations, ASHWIN RAVICHANDRAN, CHAU-CHYUN CHEN, RAJESH KHARE, Texas Tech University — The \( \chi \) parameter introduced in Flory-Huggins theory is widely used to determine polymer miscibility and its value is generally obtained by fitting to experimental data. In spite of its wide usage, techniques for predicting \( \chi \) parameter from the knowledge of molecular structure are not yet well established. In this work, we apply molecular simulations to estimate the value of the \( \chi \) parameter for a polymer blend system. In particular, we propose to use the approach suggested by Schweizer & Curro [Journal of Chemical Physics, 91, 5059 (1989)] which estimates \( \chi \) parameter in terms of the direct correlation functions. The \( \chi \) parameter thus obtained is related to the molecular structure factor, thereby making comparisons with experiment possible. Molecular dynamics simulations with atomistically detailed models are performed to estimate the value of the \( \chi \) parameter. Results will be presented for the application of this formalism to the binary blend of polysobutylene (PIB) and polybutadiene (PBD) for which experimental data are available [Industrial & Engineering Chemistry Research, 47, 3551 (2008)]. Finally, important structural features of the condensed phase which influence the value of the \( \chi \) parameter will be discussed.
10:24AM Y42.00013 Effects of dipole reorientations on ion solvation in polymer blends and block copolymer melts\textsuperscript{1}. ISSEI NAKAMURA, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences — We study the thermodynamic property of ion solvation in polymer blends and block copolymer melts and develop a dipolar self-consistent field theory for polymer mixtures. Our theory accounts for the chain connectivity of polymerized monomers, the compressibility of the liquid mixtures under electrostriction, the permanent and induced dipole moments of monomers, and the resultant dielectric contrast among species. We show nonmonotonic changes in the volume fraction profile and the dielectric function of the polymers with respect to those of simple liquid mixtures. Importantly, the spatial variations near an ion can be at nanometer scales, producing significant differences in the sorption energy among simple liquid mixtures, polymer blends, and block copolymers. Furthermore, we illustrate the oscillatory behavior of the dielectric function near an ion pair and the disparity of the dielectric functions between like and unlike charges. These results depend significantly on the chain length and Kuhn length of the diblock copolymers.

10:36AM Y42.00014 Interfaces between immiscible large and small block copolymers \textsuperscript{1}. RUSSELL SPENCER, MARK MATSEN, Univ of Waterloo — Experiments and theory have shown that mixtures of short and long symmetric AB diblock copolymers macrophase separate if their sizes differ by more than a factor of about five. Here we examine the interface between the two coexisting phases using self-consistent field theory (SCFT). The presence of periodic order in this phase-separated system confers novelty to this problem, in both potential applications and the challenges involved. This investigation is confined to the simple case of parallel lamellae, as may be found in thin films. Our focus is on the structure and tension of interfaces between coexisting phases, in terms of the relative size of the long and short copolymers. As the blend approaches the critical point, which marks the disappearance of phase separation, the interfacial tension vanishes and the width diverges. When the short polymers are too small for periodic order to be stable in bulk, coexistence exists between long lamellae and disorder; and lamellar order is induced in the disordered phase, close to the interface.

10:48AM Y42.00015 Tailoring the morphology of polymer blend particles: 3D simulations and linear stability analysis, B.S. SARATH POKURI, BASKAR GNAPATHYSUBRAMANIAN, Iowa State University — Polymer blend micro-/nano- particles find a variety of uses in novel applications including electronics, luminescent devices, and drug delivery. Solvent evaporation driven phase separation is one of the easiest ways to fabricate these particles. However, tailoring morphology of these particles is still challenging. This has resulted in complex methods to tailor morphology. Understanding how morphology evolves and in particular how phase separation is initiated will provide valuable insight to tune morphologies. We characterize the evolution of morphology during evaporation based phase separation into a finite set of fundamental modes. We approach the problem at two levels of complexity. A full 3D modeling framework describing evaporation induced phase separation is used to model the emulsification process as a function of processing parameters: droplet radius, blend ratio, and evaporation rate. Subsequently, high throughput analysis is enabled by using ideas from linear stability analysis to classify the parameter space by morphology. These complementary analysis allows us to identify a fundamental set of morphology evolution modes and map the set of processing conditions to a unique mode. Ergo, one can gain control over the morphology by regulating the processing conditions.

Session Y43 DPOLY G$\text{SOF}$ T DCMP: Focus Session: Fluids Under Confinement, Colloids and Liquid Crystals 214C - Alberto Fernandez-Nieves, Georgia Institute of Technology

8:00AM Y43.00001 Dripping Cylindrical Double Emulsions, JIAWEI YANG, LAURA ADAMS, DAVID WEITZ, Harvard University — Not all drops drip from the orifice of a faucet or capillary as spherically shaped drops. By encapsulating water drops inside an ultra thin sheet of oil, cylindrically shaped drops emerge. A stability theory is presented which describes not only the volume of the ultra thin sheet, but also the flow velocity conditions under which cylindrical drop formation is possible. We compare our theoretical model to time-dependent dynamics of drop formation that is captured experimentally with a fast camera and imaged through a microfluidic device.

8:12AM Y43.00002 Hydrodynamic damping of dense colloidal packings under confinement\textsuperscript{1}. MICHAEL RYAN, West Chester University, TIM STILL, University of Pennsylvania, MATTHEW WAITE, West Chester University, ARJUN YODH, University of Pittsburgh, KEVIN APTOWICZ, West Chester University — We experimentally study hydrodynamic damping of collective motion in dense colloidal crystals confined in a 1 micron meter channel. Particle diameters are on the order of the channel width resulting in quasi-two-dimensional entropic crystals. The packing fraction of the crystals, formed from soft thermo-responsive spheres, is varied with temperature. Digital video-microscopy is utilized to explore the phonon dynamics of the colloidal crystals. Friction coefficients along high symmetry directions in q-space are extracted and provide insight about the hydrodynamic forces at play. As expected, damping of collective motion increases with increasing packing fraction. Preliminary results suggest the friction coefficient decreases with increasing phonon wavelength, but it does not appear to vanish.

8:24AM Y43.00003 Simulation of blade printing of colloidal morphologies, ALEXANDER WAGNER, ALAN DENTON, ERIK HOBBIE, Department of Physics, North Dakota State University — We present a new four-component multi-phase lattice Boltzmann simulation method and its application to blade printing of colloidal morphologies. We consider a solution of colloids and polymers that is applied as a thin film on a substrate. As the mixture is exposed to the surrounding air the solvent evaporates leaving the colloid-polymer mixture unstable to phase-separation. Our new method predicts that as a function of the application speed, initial concentrations, and film thickness different morphologies can be generated.

8:36AM Y43.00004 Dynamics of Colloids in Nematic Liquid Crystals\textsuperscript{1}. OLEG LAVRENTOVICH, Kent State Univ - Kent, Ohio — Dynamics of small particles in fluids has fascinated scientist for centuries. Phenomena such as Brownian motion, sedimentation, and electrophoresis continue to inspire cutting-edge research and innovation. The fluid in which the particles move is typically isotropic, such as water or a polymer solution. Recently, our group started to explore what would happen if particles are placed in an anisotropic fluid: a liquid crystal. The study reveals that the liquid crystal changes dramatically the dynamic behavior, leading to levitation of the particles, their anomalous Brownian motion and new mechanisms of eletrokinetics. The new phenomena are rooted in anisotropy of the liquid crystal properties, such as surface tension and elasticity, different electric conductivity in the directions parallel and perpendicular to the average molecular orientation.

9:12AM Y43.00005 Disc-shaped colloids interacting in a nematic liquid crystal, ALENA ANTIPOVA, COLIN DENNISTON, University of Western Ontario — We examine the behavior of (ferromagnetic) micron-sized structures such as disc-shaped colloidal particles in a nematic liquid crystal using Lattice Boltzmann algorithm. Without any external forces the position of the disc with respect to the liquid crystal director minimizes the free energy of the system and no distortion of the director field is observed. When the rotating magnetic field is present, the torque on the disc with homeotropic surface anchoring should change with analogy to electrostatic energy, which implies the disc continues turning following the field. However, when the disc reaches some critical position and the director field around it is highly distorted, the disc suddenly flips to minimize the free energy. Position and motion of pairs of such discs under similar conditions can be controlled by the angular velocity of magnetic field, its magnitude and initial configuration of the system. As a result of analysis of discs’ dynamics, a new way to control self-organization of disc particles was produced. We also will demonstrate some results on ferromagnetic torus micro-colloidal particle in nematic with more complicated boundary conditions.

9:24AM Y43.00006 Liquid Crystals Confined in Micro and Nanochannels1, YU-BING GUO, JIE XIANG, OLEG LAVENTOVICH, QI-HUO WEI, Liquid Crystal Institute, Kent State Univ, Kent, OH — Geometrical confinements cause frustration, topological defects in liquid crystal molecular orientations, altering behaviors of phases and phase transitions. In this paper, we developed microfabrication processes for assembling cells of glass slides with various well-defined confinement geometries such as microfluidic channels and nanofluidic channels, and will present experimental studies on the structures and phase transitions of nematic and cholesteric liquid crystals under these confinements.

9:36AM Y43.00007 Defects in liquid crystals in confined geometries: simulation studies1, SAJDEH AFGHAH, ANDREW KONYA, ROBIN SELINGER, Kent State Univ - Kent — Using numerical simulations in three dimensions, we study the formation of defect structures in liquid crystals in confined geometries. We model a cholesteric in a microchannel with homeotropic anchoring on four sides and periodic boundary conditions along the channel length. We find that channel aspect ratio and cholesteric pitch control resulting defect structures, and in some cases produce evenly spaced bubble domains. We also performed simulation studies of a nematic liquid crystal confined in a cell with a periodic array of pillars with homeotropic anchoring on all surfaces, and examine formation of a periodic array of defects. To simulate temperature-driven microstructural evolution, we include in our model the temperature dependence of the Frank elastic coefficients and cholesteric pitch, fitted from experimental studies. Computational speed is improved by implementation of our simulation algorithm in CUDA. Simulation results are compared to recent experimental studies by the group of Qi-Huo Wei at Kent State.

9:48AM Y43.00008 Fluctuating Hybrid lattice Boltzmann method for nematic liquid crystals, GANNA PIATKOVSKA, COLIN DENNISTON, Univ of Western Ontario — As one goes from micron to nanometer lengths scales in a liquid crystal, thermal fluctuations become increasingly important and can have significant impact on colloids and polymers immersed in the liquid crystal. We develop and test numerically a Hybrid lattice Boltzmann model for liquid crystal hydrodynamics that incorporates the thermal fluctuations of tensor order parameter. It is shown that a good equilibrium is obtained over a wide range of length scales using uncorrelated noise. We find the condition on the system’s correlation lengths when the use of correlated noise would be necessary to achieve an equilibrium. In particular, in simulations without electric field, the mesh size should be chosen in such a way that the correlation length defined by the elastic constant is less than 2 in lattice units. When the electric field is present, the situation is more complex since the correlation length associated with the electric field comes into play. Some applications of the introduced noise are considered.

10:00AM Y43.00009 Tetratic and smectic liquid crystals on a sphere: defects, patterns and cubes1, OKSANA MANYUHINA, MARK BOWICK, Syracuse University — We construct the elastic free energy for tetratic order and find a closed form solution for +1/4 disclinations. Confined to a sphere we expect tetratic order to manifest itself in eight +1/4 disclinations, giving the total charge of +2.

1The authors acknowledge financial support from the Soft Matter Program of Syracuse University

Within the one elastic constant approximation for the tetratic free energy, their equilibrium positions define the vertices of a cube, rather than the twisted cube, found earlier within the XY-model. We show that it is energetically favorable for the sphere to deform to a rounded cube with flattened faces and locally high Gaussian curvature at the eight vertices. Motivated by experimental observations of smectic shells, we apply our analytic results to study the relative stability of defect configurations and the formation of periodic texture for thick smectic shells.

10:12AM Y43.00010 Visualization of the Flow Field induced by an Oscillating Post in a Freely Suspended Smectic Liquid Crystal Membrane1, ZHIYUAN QI, KYLE FERGUSON, JOHN PAPAIOANNOU, YANCEY SECHRIST, TOBIN MUNSAT, CHEOL PARK, MATT GLASER, JOE MACLENNAN, NOEL CLARK, Physics, University of Colorado, TATIANA KURIABOVA, Physics Department, California Polytechnic State University, THOMAS POWERS, Engineering and Physics, Brown University — Thin fluid membranes immersed in a less viscous, bulk fluid are of fundamental interest as approximations of true two-dimensional (2D) fluids and as models of biological membranes. Many previous studies of such fluid membranes have focused on 2D macroscopic hydrodynamic effects such as the diffusion and interaction of inclusions, with fewer experimental investigations of microscopic properties such as the flow field. We have measured the 2D flow field generated by a rigid, oscillating post inserted in a freely suspended smectic liquid crystal film surrounded by air by analyzing the motion of tracer particles in the film. Our experiments confirm Saffman’s prediction that the far-field flow velocity decays as 1/r (where r is the distance from the post) in the longitudinal direction, and as 1/r² in the tangential direction. The measurements are in good agreement with flow fields computed using a model that generalizes the Levine/MacKintosh point-force response functions. We have also investigated confinement effects when the post is located near the film boundary.

10:24AM Y43.00011 Liquid crystal-enabled electro-osmosis through spatially separated charges in photo-patterned surface alignment1, CHENHUI PENG, YUBING GUO, SERGIJ SHIYANOVSKI, QIHUO WEI, OLEG LAVENTOVICH, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH 44242, USA — Electrically-controlled dynamics of fluids and particles at microscales is a fascinating area of research with applications ranging from microfluidics and sensing to sorting of biomolecules. We demonstrate that anisotropic conductivity of liquid crystals in combination with photopatterned surface alignment enables highly efficient electro-osmosis (LCEO) rooted in space charging of regions with distorted orientations. LCEO velocities grow with the square of the field, which allows one to use an AC field to drive steady flows and to avoid electrode damage. By controlling the director patterns, one can dramatically change the nature of LCEO flows, for example, trigger a pumping effect in dipolar configuration and reverse the flow direction in quadrupolar patterns. Ionic currents in liquid crystals that have been traditionally considered as an undesirable feature in displays, offer a broad platform for versatile applications such as liquid crystal enabled electrokinetics, micropumping and mixing.

1NSF DMR-1104850 and NSF DMS-143485
10:36 AM Y43.00012 Elastic Response of Liquid Crystalline Mixtures, JONATHAN WHITMER, Department of Chemical and Biomolecular Engineering, University of Notre Dame — Liquid crystalline (LC) materials comprised of multiple mesogenic species, or mesogenic species and dopants, are widely used industrially to obtain materials having specific viscous, optical, or elastic properties. While commonly used materials exhibit additive elastic constants in the homogenous liquid phase, it is less clear how these materials respond to inhomogenous applied stresses often occurring in confinement. Here we utilize coarse-grained LC models and a recently developed formalism for free-energy calculations to investigate the elastic coefficients of LC mixtures and their behavior under asymmetric stress.

10:48 AM Y43.00013 Viral nematics in confined geometries1, KYLE LAWLER, OKSANA MANYUHINA, MARK BOWICK, CRISTINA MARCHETTI, Syracuse Univ — Motivated by recent experiments on the rod-like virus bacteriophage fd confined to circular and annular regions, we present a theoretical study of confined nematic liquid crystals in such two-dimensional geometries. It is well known that a dense suspension of the fd-virus exhibits nematic order. Recent experimental work and comparison with numerical modeling predicts that in this system the ratio of the bend and splay elastic constants is close to unity. Using the one-constant-approximation for the Frank free energy of nematic liquid crystals, we examine the competition between bulk elasticity and surface anchoring in controlling confined director configurations. We show that many of the observed configurations can be described in terms of bulk and surface topological defects. A similar effect is known to occur in 3D nematic droplets, where a change in anchoring conditions can drive the splitting of a bulk defect into surface defects. In contrast, in our 2D systems, such a splitting is driven by changes in the size and geometry of the system. We show that the continuum theory is capable of accounting for many of the observed configurations.

Session Y44 GSOFT: Focus Session: Jamming in Granular Media II 214D

8:00 AM Y44.00001 Percolation and jamming transitions in particulate systems with and without cohesion1, LOU KONDIC, LENKA KOVALCINOVA, New Jersey Institute of Technology, ARNAUD GOULLET, Rutgers University — We consider percolation and jamming transitions for particulate systems exposed to compression. For dry granular systems, interacting by repulsive forces in addition to friction and viscous damping, it is found that these transitions are influenced by a number of effects, and in particular by the compression rate. In a quasi-static limit, we find that for the considered type of interaction between the particles, percolation and jamming transitions coincide. For cohesive systems, however, we find that the differences between the considered transitions persist in quasi-static limit.

1Supported by NSF Grant No. DMS-0835611

8:12 AM Y44.00002 The birth and the growth of Boson peak — insights from the normal modes analysis of granular experiments2, JIE ZHANG, LING ZHANG, JIE ZHENG, Shanghai Jiaotong University — The origin of the Boson peak in amorphous solids has been a long-lasting puzzle for more than decades for researchers in the field. In order to understand the physics of the boson peak, we have experimentally measured the density of states (DOS) from the hexagonal lattice to the disordered structures in 2D packing of granular materials, which are made of photo-elastic disks allowing a precise measurement of contact forces between disks to determine the dynamical matrix of the system. These disks are wrapped with Teflon tapes to mimic frictionless particles so that the rotational degree of freedom can be ignored to a good approximation. By varying which are made of photo-elastic disks allowing a precise measurement of contact forces between disks to determine the dynamical matrix of the system. These disks are wrapped with Teflon tapes to mimic frictionless particles so that the rotational degree of freedom can be ignored to a good approximation. By varying

8:24 AM Y44.00003 Shear Modulus Heterogeneities in Disordered Frictionless Particle Packings, LEO SILBERT, SIU Carbondale, HIDEYUKI MIZUNO, MATTHIAS SPERL, German Space Agency (DLR) — It is understood that amorphous solids, ranging from thermal glasses to athermal granular packings, exhibit spatially inhomogeneous mechanical properties. Here, we explore the spatial extent of elastic modulus heterogeneities using computer simulations of a model granular material composed of frictionless, monodisperse spheres, through the implementation of an equilibrium fluctuation formalism. This protocol allows us to decompose the elastic moduli into their affine and nonaffine components. We first validate our numerical scheme by examining how the macroscopic values of the bulk and shear moduli vary as we tune the density of the packing towards its state of marginal stability, that lies at a critical solids packing fraction. Poking particular attention to the shear modulus, we find that it is the fluctuations in the shear modulus that control the mechanical stability of the solid. Furthermore, we are able to associate a characteristic length scale with the relative heterogeneities in the local shear modulus that grows on approach to the critical packing density.

8:36 AM Y44.00004 Shear Jamming in Granular Media1, THIBAULT BERTRAND, Yale University — We numerically study two-dimensional packings of bidisperse disks created using an isotropic compression and simple shearing protocols. To create jammed packings by compression, we start with $N$ particles with random initial positions and grow their diameters by successive small packing fraction increments each followed by relaxation of particle overlaps using energy minimization until the system cannot be compressed further without particle overlaps in the relaxed state. Jammed packings created via isotropic compression exist over a range of packing fractions $\phi$. Because of the spread of jammed packing fractions, during compression the system may reach a packing fraction above the minimum value before jamming. If an unjammed packing is then sheared by a strain $\gamma$, it can jam. Using a combination of compression and shearing, we can define jamming protocols as trajectories in the ($\phi, \gamma$) plane that yield jammed packings. In this plane, we can reach a particular point ($\phi_0, \gamma_0$) in many ways. We will focus on two of these: (1) shearing to $\gamma_0$ at $\phi = 0$ followed by compression to $\phi_0$ at $\gamma = \gamma_0$, and (2) compression to $\phi_0$ at $\gamma = 0$ followed by shearing to $\gamma_0$ at $\phi = \phi_0$. For protocol 1, we find that the probability of obtaining a jammed packing at $\phi$ and $\gamma$, $P(\phi, \gamma) = Q(\phi)$, is independent of $\gamma$. For protocol 2, we use a simple theory to deduce $P(\phi, \gamma)$ from $Q(\phi)$. Furthermore, we find that frictionless jammed packings form one-dimensional families in the ($\phi, \gamma$) plane. The one-dimensional families are projections from the 2$N$-dimensional configuration space onto the ($\phi, \gamma$) plane. The system reaches a given packing fraction by isotropic compression without jamming, the system will eventually “hit” one of the families and jam during shear. In packings composed of frictionless particles, the range of accessible jammed packing fractions shrinks with increasing $N$. However, in packings composed of frictional disks, we have shown that the families are no longer one-dimensional, the range of jammed packing fractions is broad even for large $N$ and depends on the number of missing contacts $m$. Therefore, the theoretical predictions used above for packings of frictionless disks must be modified to explain packings formed under shear in frictional systems. We predicted and measured the probability of forming a jammed packing with friction coefficient $\mu$ and $m$ missing contacts, $P_m(\mu, \phi, \gamma)$. Here, we extend these studies to include the dependence of the jamming probability on packing fraction and shear strain, $P_m(\mu, \phi, \gamma, \gamma)$, and relate this function to shear-jammed packings in frictional systems.

9:12AM Y44.00005 The onset of geometric rigidity in granular systems below jamming, PETER MORSE, ERIC CORWIN, University of Oregon — We report on a new purely geometric phase transition in soft athermal spheres which occurs significantly below the jamming density. This state is characterized by the onset of local rigidity as evidenced by changes in the symmetry of the local Voronoi cell. We relate this local rigidity onset to the eventual mechanical jamming transition through a rigidity percolation picture. We present a functional transformation mapping a minimized packing to a new packing by replacing every particle with the maximum inscribed sphere in its Voronoi cell. We demonstrate that there exists a line of fixed points between the onset of local rigidity and the jamming point under this transformation. Surprisingly, this transformation has a second attractor to systems with mean contact number of \( d + 1 \). We identify these as random loose packings in polydisperse systems.

9:24AM Y44.00006 Jamming Percolation in Three Dimensions, EIAL TEOMY, Tel Aviv University, ANTINA GHOSH, Weizmann Institute, YAIR SHOKEF, Tel Aviv University — We introduce a three-dimensional kinetically-constrained model for jamming and glasses [1], and prove that the fraction of frozen particles is discontinuous at the directed-percolation critical density. In agreement with the accepted scenario for jamming- and glass-transitions, this is a mixed-order transition; the discontinuity is accompanied by diverging length- and time-scales. Because one-dimensional directed-percolation paths comprise the backbone of frozen particles, the unfrozen rattlers may use the third dimension to travel between their cages. Thus the dynamics are diffusive on long-times even above the critical density for jamming. Our new model is a non-trivial extension of the two-dimensional spiral model [2].

9:36AM Y44.00007 Renewal Events in Glass-Forming Liquids – Glass Dynamics with Ideal Age Zero, JULIAN HELFFERICH, FALKO ZIEBERT, Institut Charles Sadron, CNRS, Strasbourg, France and Universität Freiburg, Freiburg, Germany, HENDRIK MEYER, STEPHAN FREY, JÖRG BASCHNAGEL, Institut Charles Sadron, CNRS, Strasbourg, France, KATHARINA VOLLMAYR-LEE, Department of Physics and Astronomy, Bucknell University, Lewisburg, Pennsylvania 17837, USA, ALEXANDER BLUMEN, Université de Freiburg, Freiburg, Germany — When a glass-forming liquid is cooled through the glass transition temperature, the system falls out of equilibrium and evolves slowly over time in a process called physical aging. During aging, dynamic observables depend on the history of the process, i.e. the time since vitrification and the quenching procedure, hampering any attempt to directly compare the dynamics of different glass formers. The continuous-time random walk (CTRW) interpretation, however, offers a remedy for the history dependence of the dynamic observables. This interpretation is based on the observation that single-particle trajectories display hopping-like motion, i.e. long periods of localization interrupted by fast “jumps.” In the CTRW picture, these jumps are renewal events, i.e. each particle carries its own “internal clock” which can be reset on any jump. This “internal time” can be treated as the ideal age. All particles display identical (ensemble averaged) dynamics with respect to this time, regardless of their history. In this talk, I will discuss how to decide whether jumps in the single-particle trajectories can be treated as jumps of a CTRW and demonstrate how these events can be utilized to gain history-independent dynamic observables.

9:48AM Y44.00008 Local structure as a mechanism for dynamical arrest: tackling the length-scale conundrum, PADDY ROYALL, ANDREW DUNLEAVY, KAROLINE WIESNER, University of Bristol, RYOICHI YAMAMOTO, Kyoto University, THOMAS SPECK, Johannes Gutenberg-Universität Mainz, STEPHEN WILLIAMS, Australian National University — Among the key challenges to our understanding of the process by which supercooled liquids transform into solid glasses is that it is accompanied by little apparent change in structure. Recently geometric motifs representing locally favoured structures have been identified in supercooled liquids, but a causal link between these locally favoured structures (LFS) and solidification remains elusive. One “smoking gun” for such a link would be coincidence of dynamic length-scales which reflect solidification and length-scales associated with structural features. However, this coincidence remains elusive, at least in the dynamical regime accessible to numerical simulations and colloidal experiments. Here we re-evaluate the lack of coincidence of dynamic and static lengthscales in the regime accessible to simulation. We consider the isochronal ensemble, in which any spatial heterogeneity in dynamics is encoded in the structure. Using an information theoretic method we extract a new dynamic length-scale which is matched very closely by structural length-scales associated with geometric motifs. This provides a possible resolution of the discrepancy in dynamic and structural lengthscales found in conventional studies.

10:00AM Y44.00009 Cluster Analysis of Particle Jumps in SiO2 Glass1, JONATHAN COOKMEYER, Haverford College, KATHARINA VOLLMAYR-LEE, Bucknell University, HORACIO CASTILLO, Ohio University, JUERGEN HORBACH, Heinrich-Heine-University Düsseldorf, Germany — With a Molecular Dynamics simulation, we study the behavior of 115248 SiO2 particles after a quench from a fully equilibrated configuration at a high temperature to a temperature below the glass transition. By analyzing single particle trajectories, we identified “jumps” when particles moved significantly relative to their fluctuations. We consider the collective motion of these jump events by identifying jumps that occur close in space and time. We will show preliminary results of the cluster size distribution for different temperatures (i.e. 2500 K, 2750 K, and 3000 K), as well as the dependence of this distribution on waiting time.

1. We acknowledge the support via NSF REU grant #PHY-1156964, DoD ASSURE program, and NSF-MRI CHE-1229354 as part of the MERCURY high-performance computer consortium.

10:12AM Y44.00010 Softness and Kinetic Heterogeneities in Glassy Liquids, SAMUEL SCHOENHOLZ, University of Pennsylvania, EKIN CUBUK, EFTHIMIOS KAXIRIS, Harvard University, ANDREA LIU, University of Pennsylvania — One signature feature of glassy liquids is the existence of kinetic heterogeneities. Isoconfigurational approaches show that there is a connection of these kinetic heterogeneities to the underlying structure of the liquid, but do not identify the particular structural features that are important in leading to enhanced mobility. We use machine-learning methods to show that the thermally-induced rearrangements that correspond to enduring displacements in glassy liquids occur at “flow defects” that can be identified from the liquid structure. We will discuss the dynamics and structural space of the defect population, as well as the connection between the defect population and kinetic heterogeneities.

10:24AM Y44.00011 Jamming in Quasi-2D Self-Assembled Nanoparticle Monolayers, LEANDRA BOUCHERON, JACOB STANLEY, YELING DAI, Univ of California - San Diego, SEAN YOU, University of Chicago, SURESH NARAYANAN, ALEC SANDY, ZHANG JIANG, Advanced Photon Source, Argonne National Lab, MATI MEROZ, BINHUA LIN, Center for Advanced Radiation Sciences, University of Chicago, OLEG SHPYRKO, Univ of California - San Diego — In this work, we experimentally probed the interparticle dynamics of iron oxide nanoparticle thin films self-assembled at the liquid-air interface. Upon deposition on a water surface in a Langmuir-Blodgett trough by the drop-casting technique and subsequent lateral compression, iron oxide nanocrystals coated in oleic acid ligands self-assembled into a relatively uniform quasi-2D monolayer. Utilizing X-Ray Photon Correlation Spectroscopy (XPCS) at beamline 8-ID-I of the Advanced Photon Source at Argonne National Lab, we measured the characteristic timescale of in-plane interparticle dynamics. We quantified the aging behavior of the film utilizing both second-order and two-time autocorrelation analysis. We also determined the degree of jamming in the system by a stretched exponential model, yielding exponents varying between a value of 1.5 and 2. We have concluded that despite the quasi-2D nature of our system, verified by x-ray reflectivity, interparticle diffusion in our nanoparticle monolayers bears the signature of a largely three-dimensional jammed system.
8:00AM Y45.00001 Shear jamming for highly strained granular materials, JONATHAN BARES, ROBERT BERHINGER, Duke University — Bi et al. (Nature 2011) have shown that, if sheared, a granular material can jam even if its packing fraction ($\phi$) is lower than the critical isotropic jamming point $\phi_J$. They have introduced a new critical packing fraction value $\phi_J$ such that for $\phi < \phi < \phi_J$ the system jams if sheared. Nevertheless, the value of $\phi_J$ as a function of the shear strain or the shear strain rate is not yet accessible due to the experimental complexities. We present our theoretical results of jamming in an ideal 2D periodic shear apparatus of highly strained granular systems, each of which can be moved independently which permits us to impose any desired shear profile. The circular geometry allows access to any strain value. The forces between grains are measured using reflective photoelasticity. This talk will present this novel apparatus and discuss initial results.

8:12AM Y45.00002 Ergodicity in a model for earthquake fault systems undergoing hydraulic fracturing, JAMES SILVA, WILIAM KLEIN, Boston Univ, HARVEY GOULD, Clark University, NICK LUBBERS, Boston Univ — The frequency of large seismic events in regions with a large amount of hydraulic fracturing activity has been of great interest in recent media reports of earthquake events in Oklahoma. In this talk, a model for earthquake fault systems undergoing hydraulic fracturing will be introduced. The question of how seismic failure events occur and how the individual systems will be addressed. This will be done by presenting work on the statistics of events and ergodicity within this model.

8:24AM Y45.00003 Continuum modeling of secondary rheology in slow granular flows, DAVID HENANN, DAREN LIU, Brown Univ, KEN KAMRIN, MIT — Recent dense granular flow experiments have shown that shear deformation in one region of a granular medium fluidizes its entire, including regions far from the sheared zone, effectively erasing the yield condition everywhere. This enables slow creep deformation to occur even when an external force is applied to a probe in the nominally static regions of the material. The apparent change in rheology induced by far-away primary motion is termed the "secondary rheology" - a curious phenomenon that arises due to the cooperativity of slow granular flows. Recently, the new nonlocal granular fluidity (NGF) model was successfully used to predict a wide variety of steady granular flow fields. In this talk, we show that the NGF model is also capable of capturing secondary rheology. Specifically, we will demonstrate (i) the vanishing of the yield condition in the presence of primary flow, (ii) the rate-independent nature of secondary rheology for sufficiently slow primary flow rates, (iii) an exponential-type relationship between the force applied to the intruder and the consequent creep rate, and (iv) the anisotropy of secondary rheology, in which the observed phenomenology changes depending on whether the intruder is forced along with or counter to the primary flow.

8:36AM Y45.00004 Fragmentation, Acoustic Effects, and Flash Heating in Sheared Granular Materials: Implications of Geophysical Processes and Physical Constraints for Dynamic Friction, JEAN CARLSON, Department of Physics, University of California, Santa Barbara — Incomplete understanding of friction, deformation, and failure is a primary limiting factor in forecasting seismic hazards. We report recent progress on a physics-based framework for constitutive laws. Our methods are rooted in the underlying statistical thermodynamics of amorphous materials, and bridge the gap between microscopic dynamics, laboratory experiments, and dynamic rupturing experiments. We explore the conceptual framework of the Shear Transformation Zone (STZ) model and non-traditional study of the frictional response of sheared gouge layers over a wide range of velocities and normal stresses, to stresses for geophysically relevant processes such as breakage and thermal heating, as well as grain shapes. We combine theoretical advances with quantitative fits to experimental data obtained within the rock mechanics community. Fragmentation is described by a constitutive equation for grain size reduction involving the applied work rate and pressure, constrained by energy balance. We show that grain breakage is a potential weakening mechanism at high strain rates. It promotes strain localization and may explain long-term persistence of shear bands in natural faults. Shape effects are modeled by an orientational bias that describes grain interlocking and geometrical frustration. We interpret inter-particle friction as an additional source of acoustic noise. We obtain quantitative agreement between experimental measurements and theoretical predictions for both internally generated acoustic noise and externally applied vibrations. Frictionally generated thermal heating is incorporated using a contact strength model that accounts for local increases in temperature at grain contacts during sliding. The magnitude of this effect depends on grain size and porosity of the granular layer. Our model predicts logarithmic rate dependence of steady state shear stress in the quasi-static regime. In the dense flow regime frictional strength decreases rapidly with increasing slip rate due to thermal softening at granular interfaces. The transient response following a step in strain rate includes a direct effect and subsequent evolution effect, both depending on the magnitude and direction of the velocity step. The resulting friction models are appropriate for dynamic rupture simulations that extrapolate results to geophysically relevant regimes that are beyond reach of laboratory experiments. Our work offers experimentalists and field workers insights for interpreting data, identifying features to target in future work, and estimating seismic hazards.

9:12AM Y45.00005 Interaction of intruding objects within granular media using continuum modeling, HESAM ASKARI, KEN KAMRIN, Massachusetts Institute of Technology — The interaction of objects with granular media is very common in various aspects of our lives. Interestingly, such a broad problem is not easy to solve due to the complexity of the response of the granular materials to deformation and lack of understanding of the mechanics and physics of their deformation. Exclusively on the topic of the interaction with intruding objects, attempts have been made - mostly driven by experimental observation and validation - to describe this interaction using Resistive Force Theory (RFT), which works based on superposition rules. Understanding the origin of these empirical rules and delving deeper into the requirements on the validity of such hypotheses are crucial to understanding this theory. In an attempt to explain this theory, we hypothesize that the RFT is arising from the laws of continuum frictional plasticity. To demonstrate this, we use the Finite Element Method to study the interaction of an intrusion with a continuum granular media. We use a custom user-material definition in ABAQUS using a friction-based law for the flow rule as well as adjustments required to represent a discrete granular system in a continuum model. The findings of our model are in agreement with the experiments and numerical discrete element method results in the literature. These results are suggesting that the superposition rule can be obtained by the plasticity approach and the effects of the shape, size and depth of the object can be represented by a universal scaling law.
The influence of particles on the properties of a system can be described using a theory of dynamic interactions. We explore the role of yolk-shell particles in the context of shell-shell interactions. In the absence of yolk-shell interactions, we find that the yolk-shell system behaves similarly to a free Brownian system, which allows for an approximate self-consistent description of the simulated self-diffusion properties.

We use Langevin equations to model the system and derive results for the mean squared displacement and intermediate scattering function of the yolk-shell complex. These results are compared with theoretical predictions to understand the effective behavior of the system.

Brownian dynamics simulations are used to determine the mean squared displacement and intermediate scattering function of the yolk-shell complex. These results are compared with theoretical predictions to understand the effective behavior of the system.

Theoretical predictions are derived for the mean squared displacement and intermediate scattering function of the yolk-shell complex. These results are compared with theoretical predictions to understand the effective behavior of the system.

In the absence of yolk-shell interactions, the system behaves similarly to a free Brownian system, which allows for an approximate self-consistent description of the simulated self-diffusion properties. In this approximation, the system can be described using Langevin equations. These equations are solved numerically to determine the mean squared displacement and intermediate scattering function of the yolk-shell complex. These results are compared with theoretical predictions to understand the effective behavior of the system.

of Self-Propelled Particles

monolayers in micropatterned environments. The model stresses. We consider a minimal physical model of an expanding cell monolayer described as a self-propelled elastic medium coupled to the kinetics of active contractile units. These contractile units represent actomyosin stress fibers that generate local contractile stresses through ATP hydrolysis. Using the particle tracking technique and flow reconstruction method we investigated the structure of the flow generated by bacteria and pairwise interactions between bacteria in liquid crystals. We demonstrated that while the rotation rate of bacterial flagella is reduced by an order of magnitude due to increased viscosity, the bacteria swimming speed is slowed only by 25-30\%. Due to the strong anisotropy of viscosity in liquid crystal the bacteria-induced flow is localized along a bacterial body: the flow along a line coaxial with the bacterial body is much stronger than in perpendicular direction and decays rather slowly. We found that interaction between flagella bundles of two close-by bacteria is negligible and the observed convergence of the swimming speeds and flagella waves may occur due to viscoelastic interaction between bacterial bodies.

8:12AM Y47.00002 A Combined Light Sheet Fluorescence and Differential Interference Contrast Microscope for Live Imaging of Multicellular Specimens

R. BAKER, M. T. M. JEMIELITA, R. S. M. RUVÉER PARTHASARATHY, University of Oregon — We present a microscope capable of both light sheet fluorescence microscopy (LSFM) and differential interference contrast microscopy (DICM). The two imaging modes, which to the best of our knowledge have not previously been combined, are complementary: LSFM provides high speed threedimensional imaging of fluorescently labeled components of multicellular systems, large fields of view, and low phototoxicity, while DICM reveals the unlabeled neighborhood of tissues, organs, and other structures with high contrast and inherent optical sectioning. Use of a shared detection path for both imaging modes enables simple integration of the two techniques in one microscope. To demonstrate the instrument’s utility, we provide several examples which focus on the digestive tract of the larval zebrafish. We show that DICM can sometimes circumvent the need for fluorescence based techniques, augmenting the number of parameters obtainable per experiment when used alongside LSFM, and that DICM can be used to augment each experiment by imaging complementary features, such as non-fluorescent local environments near fluorescent samples (e.g. fluorescent enteric neurons imaged alongside the non-fluorescent gut wall), interactions between fluorescent and non-fluorescent samples (e.g. bacteria), and more.

8:24AM Y47.00003 Mechanical origins of rightward torsion in early chick brain development

Z. CHEN, Dartmouth College, Q. GAO, Fuzhou University, E. DAI, L. TABER, Washington University — During early development, the neural tube of the chick embryo undergoes a combination of progressive ventral bending and rightward torsion. This torsional deformation is one of the major organ-level left-right asymmetry events in development. Previous studies suggested that bending is mainly due to differential growth, however, the mechanism for torsion remains poorly understood. Since the heart almost always loops rightwards that the brain twists, researchers have speculated that heart looping affects the direction of brain torsion. However, direct evidence is lacking, nor is the mechanical origin of such torsion understood. In our study, experimental perturbations show that the bending and torsional deformations in the brain are coupled and that the vitelline membrane applies an external load necessary for torsion to occur. Moreover, the asymmetry of the looping heart gives rise to the chirality of the twisted brain. A computational model and a 3D printed physical model are employed to help interpret these findings. Our work clarifies the mechanical origins of brain torsion and the associated left-right asymmetry, and further reveals that the asymmetric development in one organ can induce the asymmetry of another developing organ through mechanics, reminiscent of D’Arcy Thompson’s view of biological form as “diagram of forces”.

8:48AM Y47.00005 Modeling the fusion of cylindrical bioink particles in post bioprinting structure formation

M. MCCUNE, A. SHAFIEE, G. FORGACS, I. KOSZTIN, University of Missouri — Cellular Particle Dynamics (CPD) is an effective computational method to describe the shape evolution and biomechanical relaxation processes in multicellular systems. Thus, CPD is a useful tool to predict the outcome of post-printing structure formation in bioprinting. The predictive power of CPD has been demonstrated for multicellular systems composed of spherical bioink units. Experiments and computer simulations were related through an independently developed theoretical formalism based on continuum mechanics. Here we generalize the CPD formalism to (i) include cylindrical bioink particles often used in specific bioprinting applications, (ii) describe the more realistic experimental situation in which both the length and the volume of the cylindrical bioink units decrease during post-printing structure formation, and (iii) directly connect CPD simulations to the corresponding experiments without the need of the intermediate continuum theory inherently based on simplifying assumptions.

9:00AM Y47.00006 Modeling the Epithelial Morphogenesis of Germ Band Retraction in Three Dimensions

W. TYLER MCCLEERY, Vanderbilt Univ., J. VELDHUIS, G. WAYNE BRODLAND, Univ. of Waterloo, S. CREWS, M. SHANE HUTSON, Vanderbilt Univ. — Embryogenesis of higher-order organisms is driven by an intricate coordination of cellular mechanics. Mechanical analysis of certain developmental events, e.g., dorsal closure in the fruit fly D. melangaster, has been sufficiently described using two-dimensional models. Here, we present a three-dimensional modeling technique to investigate germ band retraction (GBR) - a whole-embryo, irreducibly 3D morphogenetic event. At the start of GBR, the epithelial tissue known as the germ band is initially wrapped around the posterior end of an ellipsoidal fly embryo. This tissue then retracts as an adjacent organ-level left-right asymmetry event. Previous studies suggested that bending is mainly due to differential growth, however, the mechanism for torsion remains poorly understood. Since the heart almost always loops rightwards that the brain twists, researchers have speculated that heart looping affects the direction of brain torsion. However, direct evidence is lacking, nor is the mechanical origin of such torsion understood. In our study, experimental perturbations show that the bending and torsional deformations in the brain are coupled and that the vitelline membrane applies an external load necessary for torsion to occur. Moreover, the asymmetry of the looping heart gives rise to the chirality of the twisted brain. A computational model and a 3D printed physical model are employed to help interpret these findings. Our work clarifies the mechanical origins of brain torsion and the associated left-right asymmetry, and further reveals that the asymmetric development in one organ can induce the asymmetry of another developing organ through mechanics, reminiscent of D’Arcy Thompson’s view of biological form as “diagram of forces”.

9:12AM Y47.00007 Signaling Delays Preclude Defects in Lateral Inhibition Patterning

R. J. RIEDEL-KRUSE, D. GLASS, X. JIN, Stanford University, Bioengineering — Developmental biology is extraordinarily robust in its ability to self-organize spatiotemporal patterns despite an intrinsically noisy set of parts. Lateral inhibition is a classic example of a mechanism behind such precise emergent behavior. However, the models through which we understand lateral inhibition’s capabilities usually assume that cells signal to one another without delay, a supposedly minor source of error at most. Here we explicitly investigate the effects of signaling delays as well as their relation to cis-interactions in lateral inhibition patterning. We reduce the patterning problem effectively to a two-parameter phase space (signaling delay and coupling strength), and we found that rather than being a source of error, signaling delays enable significant decrease of error rates. Together with cis-interactions, these delays lead to patterning that can be both fast and robust to noise and parameter variation. This suggests that overlooking time delays in developmental signaling does not just ignore a potential source of error, but rather ignores a knob with which evolution may tune patterning robustness in general.
Waves of ratcheting cancer cells in growing tumor tissue layer

YANG, TAE KWON, HYUN KIM, KYOUNG LEE, Korea Univ, CENTER FOR CELL DYNAMICS TEAM — Over many years researchers have shown that the mechanical forces generated by, and acting on, tissues influence the way they grow, develop and migrate. As for cancer research goes, understanding the role of these forces may even be as influential as deciphering the relevant genetic and molecular basis. Often the key issues in the field of cancer mechanics are to understand the interplay of mechanics and chemistry. In this study, we discuss very intriguing population density waves observed in slowly proliferating tumor cell layers. The temporal periods are around 4 hr and their wavelength is in the order of 1 mm. Tumor cell layer, which is initially plated in a small disk area, expands as a band of tumor cells is “ratcheting” in concert in radially outward direction. By adding Cytochalasin D and Latrunculin B, an inhibitor of actin polymerization, or Mytomycin, a chemotherapeutic agent, we could halt and modulate the wave activities reversibly. The observed waves are visually quite similar to those of chemotaxing Dictostelium discoideum amoeba population, which are driven by nonlinear chemical-reaction-diffusion waves of cAMP. So far, we have not been able to show any relevant chemotactic factors inducing the collective behavior of these tumor cells. Researchers have been investigating how forces from both within and outside developing cancer cells interact in intricate feedback loops. This work reports the example of periodic density waves of tumor cells with an explanation purely based on nonlinear mechanics.

Pattern formation in a growing bacterial colony facilitated by extra-cellular polymeric substances

PUSHPITA GHOSH, Center for Theoretical Biological Physics, Rice University, Texas, 77005, USA, JAGANNATH MONDAL, Department of Chemistry, Columbia University, New York 10027, USA, ESHEL BEN-JACOB, HERBERT LEVINE, Center for Theoretical Biological Physics, Rice University, Texas, 77005, USA — Self-organization in bacterial colony is quite pervasive and diverse phenomena. Bacteria are known to self-organize into multicellular communities, commonly known as biofilms, in which microbial cells live in close association with a solid surface and are embedded in a self-produced extracellular polymeric substances (EPS). In such dense systems mechanical interactions among the structural components can be expected to significantly contribute to the morphological properties. By a simple particle-based simulation model of nonmotile rod-shaped bacterial cells and EPS secreted in a growing colony, we investigate how the combined mechanical effects can give rise naturally spatial heterogeneity observed in a biofilm. In our individual-based simulation model all the components interact mechanically via repulsive forces by pushing each other away as bacterial cells grow and divide consuming diffusing nutrient and produce EPS. We show that mechanical interactions control the collective behavior of the system, particularly, we show that the presence of non-adSORbing EPS leads spontaneous aggregation of bacterial cells by depletion attraction and generates phase separated patterns in a nonequilibrium growing colony.

Evaporation-driven convection observed in a suspension of non-motile bacteria

JOCELYN DUNSTAN, DAMTP, Univ of Cambridge, KYOUNG JIN LEE, Physics department, Korea University, SIMON PARK, Faculty of Health and Sciences, Univ of Surrey, RAYMOND E. GOLDSTEIN, DAMTP, Univ of Cambridge — We report a novel form of convection in a suspension of non-motile bioluminescent bacteria. The patterns appear like those of conventional bioconvection driven by oxygenaxis, yet the bacteria are observed to have limited if any motility. While the phenomenon also resembles chemo-convection, in which a chemical reaction (or metabolic activity) alters the local buoyancy balance at the air-water interface, the convention actually derives from evaporation of the salty bacterial growth medium. We corroborate this through control experiments using polystyrene beads in pure and salty water, and establish that there is a threshold of salt concentration needed to observe plumes. The dynamics of the plumes is rich, with striking coalescence events and a complex internal structure. A mathematical model is formulated for the process and studied analytically and numerically, reproducing most of the observed experimental features. Evaporation-driven convection on the millimeter scale has not been studied extensively and its effect may have been underestimated in a variety of contexts. It may naturally occur in marine settings.

Optoporation to deliver impermeable molecules and genes for visualization and activation of cells

KAMAL DHAKAL, SUBRATA BATBYAL, YOUNG-TAE KIM, SAMARENDRA MOHANTY, Univ of Texas, Arlington — Visualization, activation, and detection of the cell(s) and their electrical activity require delivery of exogenous impermeable molecules and targeted expression of genes encoding labeling proteins, ion-channels and voltage indicators. While genes can be delivered by viral vector to cells, delivery of other impermeable molecules into the cytoplasm of targeted cells requires microinjection by mechanical needle or microelectrodes, which pose significant challenge to the viability of the cells. Further, it will be useful to localize the expression of the targeted molecules not only in specific cell types, but to specific cells in restricted spatial regions. Here, we report use of focused near-infrared (NIR) femtosecond laser beam to transiently perforate targeted cell membrane to insert genes encoding blue light activatable channelrhodopsin-2 (ChR2) and red-shifted opsin (ReachR). Optoporation of nanomolar concentrations of rhodamine phallodin (an impermeable dye molecule for staining filamentous actin) into targeted living mammalian cells (both HEK and primary cortical neurons) is also achieved allowing imaging of dynamics and intact morphology of cellular structures without requiring fixation.

Corn-in-chip: Mesofluidic Device for Corn Root

KEVIN KREIS, SANGJIN RYU, University of Nebraska-Lincoln — Plants have a collection of beneficial microorganisms in a region surrounding their roots called the rhizosphere. Although rhizosphere management could increase crop yield, little is known about the interaction between plant roots and their associated microorganisms. Thus we aim to simulate the rhizosphere and monitor root-microbe interactions in the lab environment, and have chosen corn as a model plant because of its economic significance. Here we present our preliminary study to develop a transparent mesofluidic device accommodating the root of corn seedlings into its channel and allowing further growth of the root.

Excitable Pattern Formation in Inhomogeneous Systems

KAUMUDI PRABHAKARA, Cornell University, Max-Planck Institute for Dynamics and Self-Organisation, AZAM GHOŁAMI, VLADIMIR ŽYKOV, Max-Planck Institute for Dynamics and Self-Organisation — On starvation, the amoebae Dictyostelium discoideum signal via the chemo-attractant cyclic adenosine monophosphate (cAMP). The amoebae sense cAMP through membrane receptors and produce their own cAMP. Simultaneously they produce a basal level of Phosphodiesterase, an enzyme that degrades cAMP. Soon a pattern of rotating spiral waves or circular waves is formed at the multi-cellular level. The causal reasons for the selection of one or the other pattern are still unclear. Here we report experimental and theoretical investigations of the pattern-formation of mixtures of cells starved for different times. The excitability of the amoebae depends on the starvation time due to time dependent gene expressions. Cells starved for longer times are known to exhibit increased excitability. We report phase maps of the patterns for mixtures of different combinations of excitability. Numerical simulations of a modified Kessler-Levine model allow us to explain the experimental results and provide new insights into the dynamical behavior of the system.

8:00AM | Y49.00001 Yielding, Plasticity, and Microstructure in a 2D Jammed Material under Shear Deformation. PAOLO ARRATIA, NATHAN KEIM, University of Pennsylvania — In this talk, we discuss an experimental investigation on the yielding and plastic deformation of disordered solids. Experiments are performed on colloidal particles that are adsorbed at an oil-water interface and form a dense disordered monolayer. The rheological properties (G', G'') of this dense monolayer are obtained in a custom-built interfacial stress rheometer that uses a magnetic needle within the material. This configuration allows for the simultaneous characterization of both microstructure (tracking ~ 10^5 particles) and bulk rheology. Results show that for oscillatory shear below a certain strain amplitude, the microstructure becomes reversible after a transient. Above this strain amplitude, the microstructure continues to evolve through many irreversible events. We argue that this boundary between a reversible and irreversible steady state is yielding transition, and that our experiments measure a meaningful irreversible event. Further, we find that reversible plastic deformation is possible. That is, the material can reorganize itself so that the link between plasticity and irreversibility is broken: the material flows slightly, and yet at the end of each deformation cycle, it is exactly unchanged.

8:12AM | Y49.00002 Stress localization, stiffening, and yielding in a model colloidal gel. EMANUELA DEL GADO, Department of Physics and Institute for Soft Matter Synthesis and Metrology, Georgetown University, JADER COLOMBO, Department of Civil, Environmental and Geomatic Engineering, ETH Zurich, GEORGETOWN UNIVERSITY COLLABORATION, ETH ZURICH COLLABORATION — We investigate the yielding of a model colloidal gel using numerical simulations and different shearing protocols. Under increasing deformation, the elastic regime is followed by a significant stiffening before yielding takes place. A space-resolved analysis of deformations and stresses unravel how the complex load curve observed is the result of stress localization and that the yielding can take place by breaking a very small fraction of the network connections. The strong localization of tensile stresses triggers the breaking of a few network nodes at around 30% of strain and increasing the deformation further favors breaking but also shear-induced bonding, eventually leading to the damage and the reorganization of the gel structure upon yielding. In particular, at low enough shear rates, density and velocity profiles display significant spatial inhomogeneity during yielding in agreement with experimental observations.

8:24AM | Y49.00003 Structure and Rheology of Concentrated Emulsions. JUNG-REN HUANG, YI-CIAN LAI, CHE-HAO OU, Physics Department, National Taiwan Normal University, JIH-CHIANG TSAI, Institute of Physics, Academia Sinica — We construct a shearing apparatus combining light scattering and stress measurement to study the structure and rheology of concentrated monodisperse emulsions. The emulsions are subjected to oscillatory shear of variable amplitude and frequency. The light scattering data reflect droplet deformation as well as shear history-dependent inter-droplet structures. The stress measurements display pseudoplasticity near zero shear rate and shear-thinning behavior at finite shear rates. In addition, the time-resolved measurement of light scattering and rheology reveal detailed information about the complex structure-rheology relationship of emulsions. Shear disorders the droplets at low and high shear rates but induces order at medium shear rates. Furthermore, the effective viscosity increases as the degree of inter-droplet order decreases.

8:36AM | Y49.00004 The viscous forces acting on quasi-2D emulsions under fast flow. CARLOS ORELLANA, XIA HONG, JANNA LOWENSOHN, ERC WEEKS, Emory University — We study the flow of dense emulsions in a quasi-two-dimensional sample chamber. Our samples are oil-in-water emulsions confined between two close-spaced parallel plates, so that the oil droplets are deformed into pancake shapes. By means of microscopy, we measure the droplet positions and their deformation, which is related to the forces on the individual droplet. Here we study the velocity dependence of the force on the droplets, and show that the main contribution is from the viscous friction between droplets rather than from viscous drag from the two confining plates. Our results can be applied to study the forces and rearrangements in fast flow in amorphous materials.

8:48AM | Y49.00005 Linear and nonlinear rheology of dense emulsions across the glass and the jamming regimes. FRANK SCHEFFOLD, CHI ZHANG, Department of Physics, University of Fribourg, THOMAS G. MASON, Department of Chemistry and Biochemistry, University of California Los Angeles — We discuss the linear and nonlinear rheology of concentrated silicone oil-in-water emulsions, amorphous disordered solids composed of repulsive and deformable soft colloidal spheres. Based on recent results from simulation and theory, we derive quantitative predictions for the dependences of the elastic shear modulus and the yield stress on the effective droplet volume fraction [1]. The remarkable agreement with experiments we observe supports the scenario that the repulsive glass and the jammed state can be clearly identified in the rheology of soft gels under shear.

9:00AM | Y49.00006 The Role of Free Surfaces on Plastic Deformation of Colloidal Micropillars. DANIEL STRICKLAND, ALEXANDER KLEBNIKOV, University of Pennsylvania, Department of Materials Science and Engineering, JYO LYN HOR, DAEYEON LEE, University of Pennsylvania, Department of Chemical and Biomolecular Engineering, DANIEL GIANOLA, University of Pennsylvania, Department of Materials Science and Engineering — The effect of free surfaces on the strength and deformation behavior of amorphous solids remains an area of intensive research in materials science. We present experiments on the evolution of particle-level strain in amorphous colloidal micropillars compressed uniaxially. The unique micropillar geometry allows us to study the effect of free surfaces, which are believed to be fertile sites for STZ activity, on deformation behavior. The micropillars, which are composed of fluorescent 3 um PMMA particles, are suspended in a fluid so that we can use laser scanning confocal microscopy to image through the micropillar at each increment of macroscopic deformation. The particle positions, which are measured using image analysis algorithms, are recorded to track the positions of more than 100,000 individual particles during the duration of a compression experiment. Particle-level position information allows us to quantify the spatiotemporal evolution of microscopic strain with macroscopic strain and explore differences in deformation behavior between bulk and surface regions.

2 National Science Foundation through PENN MRSEC DMR-1120901.

9:12AM | Y49.00007 Echoes in x-ray speckles track nanometer-scale plastic events in colloidal gels under shear. ROBERT LEHENY, Johns Hopkins University, MICHAEL ROGERS, University of Ottawa, KUI CHEN, Johns Hopkins University, LUKAS ANDRZEJEWSKI, University of Ottawa, SURESH NARAYANAN, Argonne National Laboratory, SUBRAMANIAM RAMAKRISHNAN, FAMU, JAMES HARDEN, University of Ottawa — Any solid under applied stress possesses an elastic limit above which it yields. The microscopic signatures of yield are irreversible changes to the material’s structure. We describe x-ray photon correlation spectroscopy experiments on a concentrated nanocolloidal gel subject to in situ oscillatory shear strain that provide information about the spatial character of rearrangements above yielding at the nanometer scale. The oscillatory strain causes periodic echoes in the x-ray speckle pattern, creating peaks in the intensity autocorrelation function. The peak amplitudes are attenuated above a threshold strain, signaling the onset of irreversible particle rearrangements. The gel displays strain softening well below the threshold, indicating a range of strains at which deformations are nonlinear but reversible. Above the threshold strain, the peak amplitudes decay exponentially with the number of shear cycles, demonstrating that all regions in the sample are equally susceptible to yielding and that the probability of a region yielding is independent of previous shear history. The wave-vector dependence of the decay rate reveals a power-law distribution in the size of rearranging regions, suggesting a nonequilibrium critical transition at yielding.
9:24AM Y49.00008 Yielding of colloidal gels under steady and oscillatory shear. GEORGE PETEKIDIS, ESMAEEL MOGHIMI, NICK KOUKAKIS, IESL-FORTH, FORTH TEAM — The structural and rheological properties of intermediate volume fraction colloidal gels are examined during and after steady and oscillatory shear flow using rheometry, confocal microscopy, light scattering and Brownian Dynamics simulations. Our main objective is to rationalize the microscopic mechanisms through which one can tune the mechanical properties of such metastable colloidal gels by imposing different types of external shear and flow. Experimentally, the gels consist of model hard sphere particle dispersions of \( \varphi = 0.44 \) with the addition of non-adsorbing linear chains, while BD simulations are conducted for hard spheres with the superposition of an AO potential for depletion attractions. Structural analysis shows that variation of the applied shear rate produces strong changes in the structure of the gels both when under shear and during gel reformation at cessation. Larger rates are characterized by disperse particles and the total breakage of structures at rest, which after cessation evolve with time into strong solids with relatively homogeneous structures. However, smaller rates show large inhomogeneous structures under flow, which do not evolve after cessation and additionally exhibit reduced mechanical stability and as such are weaker solids. Furthermore oscillatory shear is far more efficient than steady shear creating gels with stronger differences in their elastic modulus. Thus by tuning the way a gel is sheared, one may vary the final strength and structure of the resulting gel. Work in collaboration with R. Besseling, W. C. K. Poon and J. F. Brady.

9:36AM Y49.00009 Matrix polymer species have distinct effects on the mechanics of bacterial biofilms. KRISTIN KOVACH, MEGAN DAVIS-FIELDS, VERNITA GORDON, Univ. of Texas, Austin — Biofilms are aggregates of microorganisms embedded in a self-produced extracellular polymer matrix. The matrix confers protection to these microorganisms against mechanical and chemical stresses that they may experience in their environment. The bacterium *Pseudomonas aeruginosa* that they experience in their environment. The bacterium *Pseudomonas aeruginosa* is widely used as a model biofilm-forming organism because it is an opportunistic pathogen common in hospital-acquired infections, in chronic wounds, and in cystic fibrosis lung disease. *P. aeruginosa* strain PA01 forms biofilms that are primarily structured by the extracellular polysaccharides Pel and Psl. Using bulk rheological measurements, we show that these polysaccharides each play a unique role in the mechanical robustness of the biofilm. Pel increases the elastic storage modulus while Psl increases the ductility of the biofilm. Increased expression of either Psl or Pel increases the yield stress by about the same amount. Identifying the mechanism(s) by which these polymers contribute to the mechanical toughness of the biofilm could allow new approaches to effective biofilm clearance, by revealing targets for disruption that would weaken the biofilm.

9:48AM Y49.00010 ABSTRACT WITHDRAWN —

10:00AM Y49.00011 A simple feature of yielding of dense suspensions of soft micro-hydrogel particles. KENJI URAYAMA, Dept. Macromol. Sci. & Eng., Kyoto Institute of Technology, TAKU SAEKI, SHEN CONG, Dept. Mater. Chem., Kyoto University, SYOTA URATANI, Dept. Macromol. Sci. & Eng., Kyoto Institute of Technology, TOSHIKAZU TAKIGAWA, Dept. Mater. Chem., Kyoto University, MASAKI MURAI, DAISUKE SUZUKI, Shinshu University — The highly dense suspensions of soft micro-hydrogels with a narrow size distribution, which form a regular lattice structure, exhibit a simple feature in the yielding behavior: the yield strain \( \gamma_c \) (ca. 2.5% and ca. 4.8% for NIPNMA) and NIPNA hydrogel particles, respectively) is nearly independent of the cross-link concentration, particle diameter, and particle concentration \( c \) in the limited \( c \) range examined here, and \( \gamma_c \) is almost constant in a wide range of equilibrium shear moduli over two orders of magnitude. Further, no appreciable difference in \( \gamma_c \) is observed in the dense pastes with crystalline and glassy structures which are formed by mono- and bidisperse microgels, respectively. In addition, the highly dense suspensions of NIPA core–NIPMA shell microgels are similar in \( \gamma_c \) to those of NIPMA microgels. These results indicate that \( \gamma_c \) for the highly dense suspensions of soft micro-hydrogels depends primarily on the kind of constituent polymer near the particle surface. The yield strain \( \gamma_c \) is expected to be governed by short-range interactions such as adhesion and friction. [Reference] K. Urayama, T. Saeki, S. Cong, S. Uratani, T. Takigawa, M. Murai, Suzuki, Soft Matter, DOI: 10.1039/c4sm01841a.

10:12AM Y49.00012 Plasticity and fracture of curved colloidal crystal shells. CARLOTTA NEGGI, ALESSANDRO SELLERIO, IENI CNR, Institute for Energetics and Interphase, National Research Council, Via R. Cozzi 53, Milano 20125, Italy, M.-CARMEN MIGUEL, Departamento de Fisica Fonamental, Facultad de Fisica, Universitat de Barcelona, Av. Diagonal 645, 08028 Barcelona, Spain, STEFANO ZAPPERI, IENI CNR, Institute for Energetics and Interphase, National Research Council, Via R. Cozzi 53, Milano 20125, Italy — Crystalline shells display peculiar equilibrium properties resulting from the interplay between geometrically necessary topological defects and curvature induced stresses. Here we report the results of large scale numerical simulations of the deformation of colloidal particles arranged in crystalline shells showing that the dynamics of topological defects exhibits a rich and non-trivial phenomenology. Depending on the mode of deformation, we observe intermittent plastic deformation with collective particle reorganization mediated by the proliferation of disclinations pairs and grain boundary reorientation or abrupt structural failure induced by crack nucleating at defects. Our work clarifies the role of topology and curvature in the mechanical deformation of crystalline shells.

Session Y51 DCMP: Invited Session: Origin and Manifestations of Electronic Nematicity in Iron-Based Superconductors

Grand Ballroom C1

8:00AM Y51.00001 A New Magnetic Phase in Hole-Doped BaFe\(_2\)As\(_2\): Implications for the Origin of Nematicity. RAYMOND OSBORNE, Argonne National Laboratory — Establishing the origin of nematic order has emerged as one of the most important goals of research into iron pnictides and chalcogenides, because of its implications for the origin of their unconventional superconductivity [1]. It is well known that superconductivity emerges when antiferromagnetism is suppressed with doping or pressure. Across the phase diagram, the magnetic transition occurs just below, or is coincident with, a structural phase transition from tetragonal (\( C\_4\)) to orthorhombic (\( C\_2\)) or nematic, symmetry. A symmetry analysis indicates that the \( C\_2 \) transition is electronically driven, but it could be due either to orbital interactions that then induce magnetic stripe order or to magnetic interactions that then induce orbital order. In the latter, magnetic fluctuations from interactions between the hole pockets at \( Q = 0 \) and the electron pockets at \( Q = (\pi, 0) \) and \( Q = (0, \pi) \) break the Ising X/Y symmetry before time-reversal symmetry is broken. As part of a comprehensive neutron diffraction study of the phase diagram of hole-doped BaFe\(_2\)As\(_2\) [2], we have recently observed an entirely new magnetic phase that occurs close to the suppression of the \( C\_2 \) phase, in which the spins reorient along the c-axis and \( C\_4 \) symmetry is restored [3]. This reentrant \( C\_4 \) transition has now been observed in other hole-doped compounds as well. In spin-nematic theory, a restoration of \( C\_4 \) symmetry is predicted to occur when doping weakens Fermi surface nesting, favoring an order parameter that involves \( Q\_X \) and \( Q\_Y \) simultaneously, so our observation provides evidence for magnetically-driven models of nematicity.

1Supported by the U.S. DOE, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division
8:36AM Y51.00002 Who is in charge of the nematic order in iron-based superconductors?. ANDREY CHUBUKOV, Univ of Minnesota — Although the existence of nematic order in iron-based superconductors is now a well-established experimental fact, its origin remains controversial. Nematic order breaks the discrete lattice rotational symmetry by making the $x$- and $y$-directions in the iron plane non-equivalent. This can happen because of a regular structural transition or due to a electronically-driven instability — in particular, orbital order and spin-driven Ising-nematic order. The latter is a magnetic state that breaks rotational symmetry but preserves time-reversal symmetry. Symmetry dictates that the development of one of these orders immediately induces the other two, making the origin of nematicity a physics realization of the "chicken and egg problem." will argue that the evidence strongly points to an electronic mechanism of nematicity, placing nematic order in the class of correlation-driven electronic instabilities, like superconductivity and density-wave transitions. I will discuss different microscopic models for nematicity and link them to the properties of the magnetic and superconducting states, providing a unified perspective on the phase diagram of the iron pnictides. (Based on R.M. Fernandes, A.V. Chubukov, and J. Schmalian, Nature Physics 10, 97 (2014).)

9:12AM Y51.00003 Nematic charge fluctuations in iron-based superconductors by Raman scattering . YANN GALLAIS, Université Paris Diderot — Electronic analogues of nematic states, in which rotational symmetry is broken but translational invariance is preserved, have been proposed in a variety of correlated materials, such as quantum Hall systems, cuprates, ruthenates, heavy fermions, and, more recently, iron based superconductors. In the iron-based superconductors (Fe SC) several experiments have collected evidence that the tetragonal- to-orthorhombic structural transition is driven not by the lattice, but by electronic nematicity. However it remains a challenge to disentangle the roles of the lattice, spin and charge/orbital degrees of freedom in driving the nematic instability. In my talk I will discuss electronic Raman scattering measurements which demonstrate the presence of charge nematic fluctuations in the tetragonal phase of several Fe SC systems. I will discuss the implications of our results for the mechanism of the nematic/orthorhombic transition in these systems.

9:48AM Y51.00004 Unusual disorder-limited transport in Fe-based superconducting materials1 , PETER HIRSCHFELD, University of Florida — The unusual temperature dependence of the resistivity and its in-plane anisotropy observed in the Fe-based superconducting materials, particularly Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$, has been a longstanding puzzle. I discuss first the effect of impurity scattering on the temperature dependence of the average resistivity within a simple two-band model of a dirty spin density wave (SDW) metal. Within this framework[1], many of the qualitative features of the transport can be understood by accounting for the growth of spin correlations pinned by impurities above the Neel temperature, and SDW-induced Lifshitz transitions below. I then discuss implications of this picture for the anisotropy observed in unwinned crystals. [1] Y. Wang, M. N. Gaviassorio, B. M. Andersen, M. Tomic, H. O. Jeschke, Roser Valenti, I. Paul and P. J. Hirschfeld, arXiv:1408.1933

10:24AM Y51.00005 Electronic nematicity in Iron Pnictide superconductors probed via STM , ABHAY PASUPATHY, Columbia University — The microscopic origin of electronic nematicity and its relationship to superconductivity in the iron pnictides remains poorly understood. I will present recent scanning tunneling microscopy (STM) and spectroscopy (STS) measurements that directly visualize the nematicity in the electronic states of the pnictide superconductor Na(Fe,Co)As. The spatial and energy dependence of features seen in the spectroscopic images sheds light on the nature of the important interactions responsible for nematicity in this material, and measurements taken above and below the superconducting transition temperature reveal the interaction between the nematic electronic structure and superconductivity. I will describe measurements across the entire temperature-doping phase diagram and present a simple, unified picture for understanding nematicity as visualized by STM in the pnictides.

Friday, March 6, 2015 8:00AM - 10:24AM –
Session Y52 DCMP: Invited Session: Geometrical Properties of Quantum Hall Fluids Grand Ballroom C2 - Eduardo Fradkin, University of Illinois at Urbana-Champaign

8:00AM Y52.00001 Geometry of Fractional Quantum Hall Fluids1 , GIL YOUNG CHO, University of Illinois at Urbana-Champaign — Fractional quantum Hall (FQH) fluids of two-dimensional electron gases (2DEG) in large magnetic fields are fascinating topological states of matter. As such they are characterized by universal properties such as their fractional quantum Hall conductivity, fractionally charged anyonic excitations and a degeneracy of topological origin on surfaces with the topology of a torus. Quite surprisingly these topological fluids also couple to the geometry on which they 2DEG resides and have universal responses to adiabatic changes in the geometry. These responses are given by a Wen-Zee term (which describes the coupling of the currents to the spin connection of the geometry) and a gravitational Chern-Simons term which reflects the universal energy and momentum transport along the edges of the FQH state. We use a field theory of the FQH states to derive these universal responses [1,2]. To account for the coupling to the background geometry, we show that the concept of flux attachment needs to be modified and use it to derive the geometric responses from Chern-Simons theories. We show that the resulting composite particles minimally couple to the spin connection of the geometry[1]. Taking account of the framing anomaly of the quantum Chern-Simons theories[2], we derive a consistent theory of geometric responses from the Chern-Simons effective field theories and from parton constructions, and apply it to both abelian and non-abelian states.

1This work was supported in part by the NSF grant DMR-1408713.

8:36AM Y52.00002 Theory of the quantum Hall nematic transition1 , JOSEPH MACIEJKO, University of Alberta — The discovery of novel types of macroscopic order in quantum many-particle systems is an important goal of condensed matter physics. The fractional quantum Hall (FQH) nematic is a conjectured state of matter in which a fractional quantized Hall conductivity indicative of topological order coexists with the spontaneous breaking of rotational symmetry characteristic of a nematic liquid crystal. Recent experiments suggest that this state may form in 2D electron gases in the first Landau level. In this talk I will present a theory of the quantum phase transition between an isotropic FQH liquid and a FQH nematic state.

1Support from the Simons Foundation and NSERC of Canada are gratefully acknowledged.
9:12AM Y52.00003 Hall viscosity

NICOLAS READ, Yale University — Viscosity is a transport coefficient relating to transport of momentum, and usually thought of as the analog of friction that occurs in fluids and solids. More formally, it is the response of the stress to the gradients of the fluid velocity field, or to the rate of change of strain (derivatives of displacement from a reference state). In general, viscosity is described by a fourth-rank tensor. Invoking rotation invariance, it reduces to familiar shear and bulk viscosity parts, which describe dissipation, but it can also contain an antisymmetric part, analogous to the Hall conductivity part of the conductivity tensor. In two dimensions this part is a single number, the Hall viscosity. Symmetry of the system under time reversal (or, in two dimensions, reflections) forces it to vanish. In quantum fluids with a gap in the bulk energy spectrum and which lack both time reversal and reflection symmetries the Hall viscosity can be nonzero even at zero temperature. For integer quantum Hall states, it was first calculated by Avron, Seiler, and Zograf, using a Berry curvature approach, analogous to the Chern number for Hall conductivity. In 2008 this was extended by the present author to fractional quantum Hall states and to BCS states in two dimensions. I found that the general result is given by a simple formula $n\pi/2$, where $n$ is the particle number density, and $s$ is the "orbital spin" per particle. The spin $s$ is also related to the shift $S$, which enters the relation between particle number and magnetic quantum $\nu=\pm S$, and ground state on a surface of non-trivial topology with introducing defect excitations, by $s=2\nu$; the connection was made by Wén and Zee. The values of $s$ and $S$ are rational numbers, and are robust—unchanged under perturbations that do not cause the bulk energy gap to collapse—provided rotation as well as translation symmetry are maintained. Hall viscosity can be measured in principle, though a simple way to do so is lacking. It enters various theoretical calculations of other properties, and can be used as a diagnostic tool to distinguish phases. The talk will review these results, describing different microscopic approaches to calculating Hall viscosity, robustness, and the relation with effective field theories.

9:48AM Y52.00004 Spacetime symmetries, Newton-Cartan geometry and the quantum Hall effect

DAM SON, University of Chicago — Spacetime symmetries place powerful constraints on the physics of quantum Hall states from spacetime symmetries. These symmetries can be seen by putting the quantum Hall system on a curved manifold. By doing so, one discovers that the action is invariant with respect to time-preserving diffeomorphisms. The diffeomorphism invariance remains nontrivial on the lowest Landau level when inter Landau level mixing is negligible. In the talk we will extract physical consequences of the diffeomorphism invariance for physical observables in flat space. In particular, we relate the leading dependence of the Hall conductivity on wavenumber to the shift. We show how the spectral densities of the components of the stress tensor satisfy several sum rules, one of which involves the static projected structure factor and another involves the shift. From the sum rules one can deduce an inequality between the leading $k^2$ coefficient of the static structure factor and the shift. The inequality is saturated for a large class of trial wavefunctions. The sum rules suggest that if the magneto-roton continues to exist as a sharp resonance at small wavenumber, it should be a "chiral massive graviton," i.e., a particle with spin 2 of one circular polarization. This is demonstrated explicitly in a toy model, where which the sum rules are saturated by one single gapped mode. We argue that the circular polarization of the magneto-roton can be in principle observed by polarized Raman scatterings. The most convenient formalism to write down effective actions satisfying local diffeomorphism invariance turns out to be the Newton-Cartan formalism, introduced by Elie Cartan in 1922-1923 in his attempt to rewrite Newton's gravity in a coordinate-invariant way. We describe the structure of the Newton-Cartan space, including the construction of the connection.

**Friday, March 6, 2015 8:00AM - 11:00AM — Session Y53 DCMP: Invited Session: Cuprate Pseudogap, Charge Density Wave and Pair Density Wave**

Grand Ballroom C3 - Steven Kivelson, Stanford University

8:00AM Y53.00001 The microscopic structure of charge order in cuprates

RICCARDO COMIN, University of British Columbia — The spontaneous self-arrangement of electrons into periodically modulated patterns, a phenomenon commonly termed as charge order or charge-density-wave (CDW), has recently resurfaced as a prominent, universal ingredient for the physics of high-temperature superconductors. In such context, resonant x-ray scattering (RXS) has rapidly become the technique of choice for the study of charge order in momentum space, owing to its ability to directly identify a breaking of translational symmetry in the electronic density. In this talk, I will present our recent RXS studies of charge order in Bi2201, which reconciled years of apparently disconnected findings in different cuprate families by showing how charge order is a universal phenomenon in hole-doped cuprates [R. Comin, et al., Charge Order Driven by Fermi-Arc Instability in Bi2Sr2–xLaSrCuO6–y, Science 343, 390 (2014)]. Contextually, I will discuss very recent findings of charge order in NCCO, which project such phenomenology to the electron-doped materials [E. da Silva Neto*, R. Comin*, et al., Charge ordering in the electron-doped superconductor Nd2–xCeCuO4, accepted (2014) – preprint at: http://arxiv.org/abs/1410.2253]. Furthermore, in YBCO, we have succeeded to fully reconstruct the CDW order parameter in the two-dimensional momentum space and demonstrate how resonant x-ray methods can be used to peer into the microscopic structure and symmetry of the charge order. Using this new method, we have been able to demonstrate the presence of charge stripes at the nanoscale [R. Comin, et al., Broken translational and rotational symmetry via charge stripe order in underdoped YBa2Cu3O6–y, under review (2014)], as well as evaluate the local symmetry in the charge distribution around the Cu atoms, which was found to be predominantly of a d-wave bond-order type [R. Comin, et al., The symmetry of charge order in cuprates, under review (2014) – preprint at: http://arxiv.org/abs/1402.5415].

8:36AM Y53.00002 Searching for spectroscopic signatures of density wave correlations in cuprates

RUI-HUA HE, Boston College — Recent developments in the research on high-temperature cuprate superconductors highlight the relevance of some density wave correlations to the superconductivity and its normal state in this generic class of materials. Depending on specific cuprate systems, these density wave correlations can have diverse manifestations in different (charge, spin, pairing) sectors and likely break (time reversal, space inversion, point group, gauge) symmetries in addition to the lattice translation. A unified understanding of their microscopic nature hinges on further characterizations using direct (imaging scattering) probes for these correlations themselves, as well as indirect probes for their interplay with other degrees of freedom in the system. ARPES can provide information about a density wave order through probing modifications in the electron structure it induces, while other spectroscopy techniques can shed unique lights on the broken symmetry aspect of the order. In this talk, I will review the density-wave signatures that have been or yet to be found in ARPES mainly in terms of the spectral weight, energy gap, and renormalized band dispersions. These experimental observations/proposals, coupled with simple theoretical modeling, promise new insights into the (wavevector, order parameter, form factor) characters of associated density wave correlations. Time permitting, I will introduce a novel x-ray spectroscopy technique that can detect broken time-reversal versus space-inversion symmetry of an electronic order in a way complementary to the polar Kerr effect.
9:12AM Y53.00003 Amperean (2k_F) pairing and the pseudo-gap phase in HiTc Cuprates

PATRICK LEE, Massachusetts Inst of Tech-MIT — We propose that the pseudogap phase is a novel pairing state where electrons on the same side of the Fermi surface are paired, in strong contrast with conventional BCS theory which pairs electrons on opposite sides of the Fermi surface. The pair carries a net momentum 2k_F, forming a pair density wave. The microscopic pairing mechanism comes from a gauge theory formulation of the resonating valence bond (RVB) picture, where spinons traveling in the same direction feel an attractive force in analogy with Ampere's effects in electromagnetism. We call this Amperean pairing. Charge order appears as a subsidiary order parameter even when pair order is destroyed by phase fluctuations. Our theory gives a prediction of the ordering wave vector which is in good agreement with experiment. Furthermore, the quasiparticle spectrum from our model explains many of the unusual features reported in photoemission experiments. Finally, we propose an experiment that can directly test the idea of Amperean pairing.

9:48AM Y53.00004 Charge ordered normal ground state and its interplay with superconductivity in the underdoped cuprates

SUCHITRA SEBASTIAN, University of Cambridge — Over the last few years, evidence has gradually built for a charge ordered normal ground state in the underdoped region of the cuprate high temperature superconductors. I will address the electronic structure of the normal state of the underdoped cuprates as accessed by quantum oscillations, and relate to it to complementary measurements by other experimental techniques. The interplay of the charge ordered ground state with the antinodal gapped pseudogap state, and overarching magnetic and superconducting correlations will be further explored.

This work was performed in collaboration with N. Harrison, G. G. Lonzarich, B. J. Ramshaw, B. S. Tan, P. A. Goddard, F. F. Balakirev, C. H. Mielke, R. Liang, D. A. Bonn, and W. N. Hardy.

10:24AM Y53.00005 Local Dimensionality of the Charge Density Wave in the Superconducting Cuprate Bi2201

JENNIFER HOFFMAN, Harvard University — Charge density wave (CDW) states were recently recognized as universal throughout the surface and bulk of a number of cuprates [1], prompting widespread effort to understand both their detailed phenomenology and their relationship to the mechanism of superconductivity. However, the dimensionality of the charge modulations remains unclear, including whether the modulation wavevector is unidirectional or bidirectional in-plane, and also the extent of inter-plane coherence of the charge modulations. In bismuth-based cuprates, severe material disorder precludes answering these questions through bulk scattering techniques. We use a local technique, scanning tunneling microscopy, to image the static charge modulations in (Pb,Bi)2Sr2La2CuO8+δ (Bi2201). We find that the charge modulations are more consistent with an underlying tendency to unidirectional than bidirectional CDW. Using recently developed cluster analysis techniques, we further show that these locally unidirectional CDWs extend coherently into the bulk of the material throughout the doping range. Finally, we comment on their relationship to a Fermi surface transition and quantum critical point observed in Bi2201 [3].

Friday, March 6, 2015 11:15AM - 2:03PM —
Session Z1 DMP: Focus Session: Graphene - Multilayer and Interfacial Effect 001A - Rui He, University of Northern Iowa

11:15AM Z1.00001 Layer breathing vibrations in AB-stacking few layer graphene and twisted bilayer graphene

RUI HE, Department of Physics, University of Northern Iowa — Interlayer interactions in few layer graphene can create a set of shear modes and layer breathing modes (LBMs) that involve lateral and vertical displacement of individual layers, respectively. LBMs are of importance because they can facilitate interlayer current conduction and are sensitive to external perturbations, such as the presence of substrate or surface adsorbates. We investigated low-frequency fundamental layer breathing vibrations in AB-stacking few layer graphene and twisted bilayer graphene using Raman spectroscopy. In AB-stacking few layer graphene we observed the Raman peaks from phonons at the Brillouin zone center for the lowest-frequency branch LBM vibration. The mode frequency depends strongly on the number of graphene layers. Notably, the LBM Raman response is unobservable at room temperature, and it is turned on at higher temperature (>600 K) with a steep increase of Raman intensity. The observation suggests that the LBM vibration is strongly suppressed by molecules adsorbed on the graphene surface but is activated as desorption occurs at high temperature. In twisted bilayer graphene, the fundamental LBM is observed in a small range of twisting angle at which the intensity of the G Raman peak is strongly enhanced. The dependence of this mode’s frequency and linewidth on the rotational angle can be explained by the double resonance Raman process (LBM phonon with nonzero wavevector) mediated by the twisted graphene lattice which lacks long-range translational symmetry. The angle dependence also reveals the strong impact of electronic band overlaps of the two rotated graphene layers.

11:51AM Z1.00002 Probing the Ni(111)-graphene interface using Raman spectroscopy

GUANGJUN CHENG, IRENE CALIZO, ANGELA HIGHT WALKER, PML, NIST — Theoretical simulations have shown that due to the hybridization of Ni d-electrons with the p-orbitals of graphene, graphene phonon dispersion is significantly altered (Nano Lett, 2010, 10, 4335-4340). There is no Raman signal from graphene on Ni(111) due to the suppression of the Kohn anomaly. In our work, we deposit a Ni thin film by thermal evaporation onto mechanically exfoliated graphene, few-layer graphene (FLG), and graphite, and probe the Ni-graphene interface using Raman spectroscopy. When the sample is annealed in forming gas, a Ni(111) thin film is produced on graphene, FLG, and graphite. We observe the disappearance of Raman signals from graphene underneath Ni(111) when using low laser power and the re-appearance of the Raman signals from the graphene with a higher power excitation laser. This work provides direct experimental evidence for the strong interaction between Ni(111) and graphene.
The dynamical exponent \(z\) of electron-electron interactions in ABC stacked graphene trilayers. In the gapless regime, we show that the self-energy corrections lead to the renormalization of both for intermediate-ranged interactions. However, if the interaction becomes too long-ranged or too weak, then the system will exhibit no instabilities.

We construct maps of the leading instability (or instabilities) of the system for the screened Coulomb-like interaction as a function of the overall interaction strength and interaction range for four values of the applied electric field. We find that the pattern of leading instabilities is the same as that found in the zero-field result.

ROBERT THROCKMORTON, University of Maryland — We extend previous renormalization group (RG) analyses of electron-electron interactions in gapless and metallic systems, including single-layer graphene, any possible coupling of physical quantities to components of the electric field has a counterpart where the analogous component of the magnetic field couples to exactly the same quantities. For example, a purely electric spin splitting appears as the magneto-electric analogue of the magnetic Zeeman spin splitting. The measurable thermodynamic response induced by magnetic and electric fields is thus completely symmetric. The Pauli magnetization induced by a magnetic field takes exactly the same functional form as the polarization induced by an electric field. Although they seem counterintuitive, our findings are consistent with fundamental principles such as time reversal symmetry. For example, only a magnetic field can give rise to a macroscopic spin polarization, whereas only a perpendicular electric field can induce a macroscopic polarization of the sublattice-related pseudospin in bilayer graphene. These rules enforced by symmetry for the matter-field interactions clarify the nature of spins versus pseudospins. We have obtained numerical values of prefactors for relevant terms.

WINKLER, Northern Illinois University, U. ZULICKE, Victoria University of Wellington, New Zealand — We present a theoretical study of bilayer-graphene’s electronic properties in the presence of electric and magnetic fields. In contrast to known materials, including single-layer graphene, any possible coupling of physical properties to components of the electric field has a counterpart where the analogous component of the magnetic field couples to exactly the same quantities. For example, a purely electric spin splitting appears as the magneto-electric analogue of the magnetic Zeeman spin splitting. The measurable thermodynamic response induced by magnetic and electric fields is thus completely symmetric. The Pauli magnetization induced by a magnetic field takes exactly the same functional form as the polarization induced by an electric field. Although they seem counterintuitive, our findings are consistent with fundamental principles such as time reversal symmetry. For example, only a magnetic field can give rise to a macroscopic spin polarization, whereas only a perpendicular electric field can induce a macroscopic polarization of the sublattice-related pseudospin in bilayer graphene. These rules enforced by symmetry for the matter-field interactions clarify the nature of spins versus pseudospins. We have obtained numerical values of prefactors for relevant terms.

12:39PM Z1.00006 Ordered states in spatially separated Coulomb-coupled double graphene AB bilayers, JUNG-JUNG SU, National Chiao Tung University, ALLAN H. MACDONALD, University of Texas at Austin — Electron-electron interaction effects are strong in graphene bilayer systems because of the approximately quadratic crossing between conduction and valence bands at the Brillouin-zone corners. In isotropic circular bilayers, this circumstance leads to an external electric field were systematically investigated. Although the crossing band structures remain at any stacking configurations (i.e., no energy gap opens), the wavefunction characteristics around the Fermi level can differ qualitatively for different stackings.

While the flattened region, the band structure approaches that of a bilayer ribbon in which the electron motion in the ribbon-width direction is disentangled. In chiral nanotubes, inter-wall interaction can essentially be neglected except in the vicinity of non-chiral tubes. Inter-wall interactions diminish rapidly when chiral angle deviates from zigzag or armchair, although the decay is slower in the vicinity of the armchair tube. When the flattened region has the structure of AA and AB stacked bilayer graphene, the same results can be derived by calculating boundary conditions corresponding to the closed-edge structure in which the top and bottom layers are smoothly connected through a monolayer graphene.

This work was supported by JSPS KAKENHI Grant Numbers 24540339, 26107534.

12:51PM Z1.00007 ABSTRACT WITHDRAWN —

1:03PM Z1.00008 Quantum multistability in bilayer graphene with a tunable energy gap, ROBERT THROCKMORTON, University of Maryland — We extend previous renormalization group (RG) analyses of electron-electron interactions in gapless bilayer graphene at finite temperature to include the effect of an electric field applied perpendicular to the sample. We determine the possible outcomes of the resulting RG equations, represented by fixed points along which ratios of the coupling constants remain constant and map out the leading instabilities of the system for an interaction of the form of a Coulomb interaction that is screened by two parallel conducting plates placed equidistant from the electron. We then construct maps of the leading instability (or instabilities) of the system for the screened Coulomb-like interaction as a function of the overall interaction strength and interaction range for four values of the applied electric field. We find that the pattern of leading instabilities is the same as that found in the zero-field case, namely that the system is unstable to a layer antiferromagnetic state for short-ranged interactions, to a nematic state for long-ranged interactions, and to both for intermediate-ranged interactions. However, if the interaction becomes too long-ranged or too weak, then the system will exhibit no instabilities.

1:15PM Z1.00009 Quasiparticle renormalization in ABC graphene trilayers, XU DOU, AKBAR JAEFARI, University of Oklahoma, YAFIS BARLAS, University of California at Riverside, BRUNO UCHOA, University of Oklahoma — We investigate the effect of electron-electron interactions in ABC stacked graphene trilayers. In the gapless regime, we show that the self-energy corrections lead to the renormalization of the dynamical exponent \(z = 3 + \alpha_1/N\), with \(\alpha_1 \approx 0.52\) and \(N\) is the number of fermionic species. Although the quasiparticle residue is suppressed near the neutrality point, the lifetime has a sublinear scaling with the energy and the quasiparticles are well defined even at zero energy. We calculate the renormalization of a variety of physical observables, which can be directly measured in experiments.

Supported by LPS-CMTC and ARO-MURI.

12:15PM Z1.00004 Electromagnetic coupling of spins and pseudospins in bilayer grapheneR, WINKLER, Northern Illinois University, U. ZULICKE, Victoria University of Wellington, New Zealand — We present a theoretical study of bilayer-graphene’s electronic properties in the presence of electric and magnetic fields. In contrast to known materials, including single-layer graphene, any possible coupling of physical quantities to components of the electric field has a counterpart where the analogous component of the magnetic field couples to exactly the same quantities. For example, a purely electric spin splitting appears as the magneto-electric analogue of the magnetic Zeeman spin splitting. The measurable thermodynamic response induced by magnetic and electric fields is thus completely symmetric. The Pauli magnetization induced by a magnetic field takes exactly the same functional form as the polarization induced by an electric field. Although they seem counterintuitive, our findings are consistent with fundamental principles such as time reversal symmetry. For example, only a magnetic field can give rise to a macroscopic spin polarization, whereas only a perpendicular electric field can induce a macroscopic polarization of the sublattice-related pseudospin in bilayer graphene. These rules enforced by symmetry for the matter-field interactions clarify the nature of spins versus pseudospins. We have obtained numerical values of prefactors for relevant terms.

12:27PM Z1.00005 Effective-mass theory of flattened carbon nanotubes as bilayer graphene with closed edges, TAKESHI NAKANISHI, Natl Inst of Adv Indust Sci & Tech, TSUNEYA ANDO, Tokyo Inst. Tech. — We theoretically study effects of inter-wall interaction in collapsed carbon nanotubes, first directly calculating effective inter-wall interaction within an effective-mass scheme and second regarding collapsed tubes as ribbons of bilayer graphene with closed edges described by boundary conditions explicitly derived. Within the effective-mass scheme, effects of inter-wall interactions are shown to be important in non-chiral nanotubes such as zigzag and armchair. In fact, with the increase in the width of the flattened region, the band structure approaches that of a bilayer ribbon in which the electron motion in the ribbon-width direction is disentangled. In chiral nanotubes, inter-wall interaction can essentially be neglected except in the vicinity of non-chiral tubes. Inter-wall interactions diminish rapidly when chiral angle deviates from zigzag or armchair, although the decay is slower in the vicinity of the armchair tube. When the flattened region has the structure of AA and AB stacked bilayer graphene, the same results can be derived by calculating boundary conditions corresponding to the closed-edge structure in which the top and bottom layers are smoothly connected through a monolayer graphene.

1:21PM Z1.00003 Electronic properties of bilayer graphenes strongly coupled to interlayer stacking and an external electric field, CHANGWON PARK, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, JUNGA RYU, SUKLYUN HONG, Department of Physics and Graphene Research Institute, Sejong University, BOBBY SUMPTER, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, GUNN KIM, Department of Physics and Graphene Research Institute, Sejong University, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — In the design of bilayer graphene (BLG)-based switching devices, it is critical to understand the complex stacking structures observed experimentally and their impact on the overall electronic properties. Using a maximally localized Wannier function, a highly accurate tight-binding Hamiltonian based on density functional theory was constructed and the stacking-dependent evolution of BLG electronic band structures and their response to an external electric field were systematically investigated. Although the crossing band structures remain at any stacking configurations (i.e., no energy gap opens), the wavefunction characteristics around the Fermi level can differ qualitatively for different stackings.

This difference is conveyed to energy gap opening properties in the presence of an external electric field. We, for the first time, established a phase diagram summarizing the stacking-dependent electronic structures of BLG, separating metallic and semiconducting characteristics for a given external field.

The research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.

12:03PM Z1.00003 Electronic properties of bilayer graphenes strongly coupled to interlayer stacking and an external electric field, CHANGWON PARK, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, JUNGA RYU, SUKLYUN HONG, Department of Physics and Graphene Research Institute, Sejong University, BOBBY SUMPTER, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, GUNN KIM, Department of Physics and Graphene Research Institute, Sejong University, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — In the design of bilayer graphene (BLG)-based switching devices, it is critical to understand the complex stacking structures observed experimentally and their impact on the overall electronic properties. 1:27PM Z1.00010 Density of states and tunneling conductance of ABC-stacked trilayer graphene. JONGBAE HONG, POSTECH/APCTP, DAVID ABERGEL, Nordita, KTH Royal Institute of Technology and Stockholm University — Experimental studies on ABC-stacked trilayer graphene suggest that the trilayer graphene may have a strongly correlated ground state which drives the opening of a band gap at the Fermi level. We propose a theoretical model for the tunneling conductance of strongly correlated trilayer graphene based on a Kondo-like mechanism of coherent transport where electrons tunnel into the correlated sample via an entangled singlet state. Our theory fits current experimental data extremely well, including peculiar features such as two pairs of kinks at low bias and a peak and shoulder at a relatively high bias. No other theoretical study has previously explained these features of the line shape. We also suggest a phenomenological estimate of the density of states in the strongly correlated regime. This has not previously been studied.

1:39PM Z1.00011 Rich Magneto-electronic spectra of AAB-stacked trilayer graphene. THI NGA DO, PhD. candidate, Dept. of Physics, National Cheng Kung University, Tainan, MIN-FA LIN, Professor of the Dept. of Physics, National Cheng Kung University, Tainan — We develop the generalized tight-binding model to study the magneto-electronic properties of AAB-stacked trilayer graphene. Three groups of Landau levels (LLs) are characterized by the dominating sub-envelope function on distinct sub-lattices. Each LL group could be further divided into two sub-groups in which the wave-functions are, respectively, localized at 2/6 and 4/6 of the total length of the enlarged unit cell. The unoccupied conduction and the occupied valence LLs in each sub-group behave similarly. For the first group, there exists certain important differences between two sub-groups, including the LLL energy spacings, quantum numbers, spatial distribution and the field dependent spectra. The LL crossings and anti-crossings occur frequently in each sub-group during the variation of field strength, which thus leads to the very complicated energy spectra and the seriously distorted wave-functions.

Friday, March 6, 2015 11:15AM - 2:03PM – Session Z2 DMP: Focus Session: Beyond Graphene - Devices II

11:15AM Z2.00001 Doping Dependent Electronic Properties of Atomically Thin Two-dimensional Crystals. TING CAO, ZHENGLU LI, STEVEN G. LOUIE, Physics Department, UC Berkeley and Lawrence Berkeley National Lab — Using first-principle calculations, we find that the electronic structure of atomically thin 2D crystals such as GaSe and NbSe2 can be modified significantly through doping, which can lead to major changes in their other properties. We elucidate the origins of the trends observed in experimental studies, and connect our theoretical predictions to experimental measurements since high level of doping can be achieved in 2D materials.

11:27AM Z2.00002 Ferroelectric Controlled Nanoscale MoS2 Transistor. ZHIYONG XIAO, JINGFENG SONG, STEPHEN DURCHAME, XIA HONG, University of Nebraska - Lincoln — We report the study of the device characteristics of MoS2 field effect transistors with a SiO2 backgate and a ferroelectric polymer top gate. We mechanically exfoliated MoS2 flakes on 300 nm SiO2 substrates. The thinner MoS2 pieces were identified by Raman spectroscopy and atomic force microscopy (AFM), and flakes of 1 – 5 nm thick were fabricated into two point devices via e-beam lithography with Ti/Au (5nm/50nm) as the contact electrodes. We then deposited on the top of the device a ferroelectric polymer layer, 20-40 nm polycrystalline poly(vinylidene-fluoride-trifluoroethylene) (PVDF-TrFE), using the Langmuir-Blodgett approach. At room temperature, we achieved a current modulation of a factor of 10^3 using the SiO2 back gate. The field effect mobility of the devices is ~ 20 cm^2V^-1s^-1. We then used conducting AFM to control the polarization of the top ferroelectric gate, and examined the SiO2-gated I-V characteristics of different polarization states of PVDF-TrFE. By switching the ferroelectric polarization, we induced a 30 V shift in I-V. At fixed backgate voltage, we achieved a maximum switching ratio in the drain current of ~ 15.

11:39AM Z2.00003 Controlled n-doping of monolayer MoS2 by atomic hydrogen. JYOTI KATOCCH, TIANCONG ZHU, Department of Physics, The Ohio State University, Columbus, OH 43210, HUA WEN, Department of Physics and Astronomy, University of California, Riverside, CA 92521, ROLAND KAWAKAMI, Department of Physics, The Ohio State University, Columbus, OH 43210, Department of Physics and Astronomy, University of California, Riverside, CA — Molybdenum Disulfide (MoS2) is a 2D layered material with potential applications in optoelectronics, electronics and spintronics. The injection of electrons in MoS2 is affected and limited by the Schottky barrier formed between metal contact and MoS2. There is a great deal of research interest to experimentally demonstrate ohmic contacts onto MoS2 in order to fully unravel the potential of this exciting material. We will present our results on controlled doping of single layer MoS2 surface by hydrogen to improve the contact resistance. We measured the transport properties of the MoS2 as a function of successive atomic hydrogen dosage at low temperature in ultra-high vacuum. Atomic hydrogen is generated using a hydrogen cracker. We observe that hydrogen adsorption results in negative doping due to charge donation by hydrogen to MoS2. Furthermore we will discuss the stability of the MoS2 as a function of successive atomic hydrogen dosage at low temperature in ultra-high vacuum. Atomic hydrogen is generated using a hydrogen cracker.

12:27PM Z2.00005 Thickness-dependent Electrical and Thermoelectric Transport in few-layer MoS$_2$, MORTEN KAYALHA, Purdue Univ, LI SHI, University of Texas at Austin, YONG CHEN, Purdue Univ — Layered semiconducting Transition Metal Dichalcogenides such as MoS$_2$ have recently gained a lot of attention as promising 2D materials for electronic and optoelectronic device applications. Here, we present a systematic study of thickness-dependent electrical and thermoelectric transport in few-layer MoS$_2$. MoS$_2$ flakes with various thickness ranging from 1-23 layers are prepared using the standard scotch-taped exfoliation technique and are then transferred onto a SiO$_2$/Si substrate. Electrical and thermoelectric measurements are carried out using AC and DC techniques with samples in vacuum. We observe five-fold enhancement in the electrical conductivity of two-layer MoS$_2$ compared to the bulk. However, the thermopower (TEP) exhibits less change except for monolayer where TEP is twice smaller. We also observe six times larger power factor in two-layer MoS$_2$ compared to the bulk. Additionally, we used a back gate to modulate the Fermi energy inside MoS$_2$ where an enhancement in TEP is observed close to the off state. Our results give insight into future prospects of MoS$_2$-based devices in thermoelectric applications.

12:39PM Z2.00006 Effects of Contact Geometry on Measurements of Contact and Film Resistance in Thin MoS$_2$ Films, JINSONG XU, YUNQIU LUO, Department of Physics, Ohio State University, ROLAND KAWAKAMI, Department of Physics, Ohio State University; Department of Physics and Astronomy, University of California, Riverside, JONATHAN PEZ, Department of Physics, Ohio State University — There is great interest in MoS$_2$ films and other 2D materials for fundamental studies and possible applications. However, the critical contacts to these films are not well understood, in part because of the strong band bending, depletion, and lateral Schottky barriers (SB). We report measurements and finite-element modeling of Au contacts on few-layer MoS$_2$ films on SiO$_2$/Si substrates, and find that certain common contact geometries produce mixing of contact and film resistance and highly/completely misleading results in 3- and 4-probe measurements, and that lateral depletion can produce errors in TLM measurements. However, with appropriate contact geometry and comparison to modeling, contact and film resistances can be independently monitored. Both are found to have strong back-gate and temperature dependence, with small (∼10 – 30 meV) but different activation energies (AEs) near 100 – 300 K. The contact AE is similar to several previous reports. The activated film resistance has not been previously reported, though evidence can be seen some previous published data. Possible origins of these temperature dependences will be discussed, as well as implications for determining contact SB heights.

12:51PM Z2.00007 Junction properties of MoS$_2$ between 1T and 2H phases, JUNSUK KIM, JEASU KIM, BYOUNGHEE MOON, HAMZA GUL, JUNGHO KIM, YOUNG HEE LEE, SEONG CHU LIM, Center for Integrated Nanostructure Physics, Institute for Basic Science — MoS$_2$ is locally transformed into 1T phase. In this study, we prepare MoS$_2$ in-plane junction of 1T and 2H phase by locally intercalating Li ions into MoS$_2$ multilayer that is confirmed using Raman and PL spectroscopics and will discuss the electrical properties of the junction of two different phases of MoS$_2$.

1:03PM Z2.00008 Electrical edge contacts to monolayer MoS$_2$, BYOUNG HEE MOON, GANG HEE HAN, HYUN KIM, HOMIN CHOI, YOUNGJO JIN, HYE YUN JEGON, SEONGCHU LIM, YOUNG HEE LEE, Center for Integrated Nanostructure Physics, Institute for Basic Science(IBS), Sungkyunkwan University, Suwon 440-746, Korea — Charge injection through the metal contacts to nanostructures has been the interesting issue for the physical mechanism involved as well as the device applications. In this talk, we discuss the effects of electrical edge contact to CVD grown monolayer MoS$_2$. The edge contacts are achieved by sandwiching MoS$_2$ with hexagonal boron nitrides (BN) [1]. It appears to show that charge injection by thermionic emission is suppressed, while tunneling effects take over.

1:15PM Z2.00009 MoS$_2$ Transistors Operating at Gigahertz Frequencies, DARIO KRASNOZHON, DOMINIK LEMBEKE, CLEMENS NYFFELER, YUSUF LEBLEBICI, ANDRAS KIS, Electrical Engineering Institute, Ecole Polytechnique Federale de Lausanne (EPFL) — The presence of a direct band gap and an ultrathin form factor has caused a considerable interest in 2D semiconductors from TMD family with MoS$_2$ being the most studied representative of this family of materials. While diverse electronic elements, integrated circuits and optoelectronic devices have been demonstrated using ultrathin MoS$_2$ and related materials, very little is known about their performance at high frequencies. We fabricated top-gated MoS$_2$ transistors operating in the gigahertz range of frequencies. The presence of a band gap also gives rise to current saturation, allowing voltage gain higher than 1. The RF transistors are fabricated from exfoliated MoS$_2$ with different layer thickness. All our devices presented transconductance typical of n-type materials with on-state current reaching 300 $\mu$A/$\mu$m for $V_{DS} = 2$ V and gate voltage $V_{G} = 10$ V in the case of monolayer MoS$_2$. The current gain of the MoS$_2$ transistors decreases with increasing frequency and shows the typical 1/f dependence. In conclusion, we studied top-gated MoS$_2$ transistors with a 240 nm gate length. Our MoS$_2$ RF-FETs show an intrinsic transconductance higher than 50 $\mu$S/um and a drain-source current saturation with a voltage gain higher than 1. Our devices show cut-off frequencies in the GHz range and are able not only to amplify current in this frequency range but also power and voltage, with the maximum operating frequency $f_{max}$ = 8.2 GHz.

1:27PM Z2.00010 Experimental evidence for inhomogeneous charge transport in MoS$_2$ nanoflakes, CHI-TE LIANG, Department of Physics, National Taiwan University, THAI JIN, Institute of Applied Physics, National Taiwan University, DAVID HU, School of Materials Science and Engineering, National Taiwan University, TAIWAN LI, OLEH KLOCHAN, School of Physics, University of New South Wales, Australie, C.-H. LIU, W.-H. WANG, Institute of Atomic and Molecular Sciences, Academia Sinica, ALEX R. HAMILTON, School of Physics, University of New South Wales, Sydney, Australia — We study electron transport in a monolayer MoS$_2$ nanoflake over a wide range of density, temperature, and electric bias. We find that the transport is best described by a percolating picture in which the disorder breaks translational invariance, breaking the MoS$_2$ system up into a series of puddles, rather than previous pictures in which the disorder is treated as uniform and homogeneous. Our work provides insight to a unified picture of charge transport in monolayer MoS$_2$ nanoflakes and contributes to the development of next-generation MoS$_2$-based devices.

3We would like to thank funding from the MOST, Taiwan (grant numbers: 103-2918-I-002-028, 102-2119-M-002-016-MY3 and 102-2917-I-002-106) and the Australian Research Council through the DP scheme.
Recently, Ni-treated-graphene electrodes were fabricated on MoS2. The development involved the Centre, National University of Singapore, Singapore 117543, JOHN T.L. THONG, Department of Electrical and Computer Engineering, National University of Singapore, Singapore 117543, K.H. KHOON, S.Y. QUEK, Department of Physics and Graphene Research Centre, National University of Singapore, Singapore 117543, JOHN T.L. THONG, Department of Electrical and Computer Engineering, National University of Singapore, Singapore 117543. X. LUO, Department of Physics and Graphene Research Centre, National University of Singapore, Singapore 117543, Y. LI, Department of Electrical and Computer Engineering, National University of Singapore, Singapore 117543. The fabrication process involved using a dry transfer technique and metal-catalyzed graphene treatment process, yielding contact resistances as low as 200 Ωm and a substantial contact enhancement of ~ 2 orders of magnitude relative to Ni-MoS2 interfaces. By performing a Schottky barrier height (SBH) analysis on Ni-MoS2 and Ni-graphene-MoS2 interfaces using first-principles DFT calculations, we have found that the smaller contact resistance in Ni-treated-graphene-MoS2 can be attributed to the smaller SBH of Ni-graphene-MoS2 contacts. This reduction in SBH can in turn be related to the lower work function of Ni-graphene electrodes relative to Ni. The effect of Ni treatment further reduces the contact resistance due to stronger coupling between Ni and graphene edges.

For a memory erasure procedure, which is a logically irreversible operation, a detailed Jarzynski Equality is verified, retrieving that the mean dissipated heat saturates at the Landauer bound in the limit of long erasure cycles. This result demonstrates the intimate link between information irreversibility and the Landauer principle. Bennett and, independently, Penrose later pointed out a link to Maxwell’s Demon: Were Landauer’s principle to fail, it would be impossible to useably extract work from a heat bath. We report tests of Landauer’s principle in an experimental system consisting of a charged colloidal particle in water. To test stochastic thermodynamic ideas, we create a time-dependent, “virtual” double-wall potential via a feedback loop that is much faster than the relaxation time of the particle in the virtual potential. In a first experiment, the probability of “erasure” (resetting to one) is unity, and at long cycle times, we observe that the average work is compatible with kT ln2. In a second, the probability of erasure is zero; the system may end up in two states; and, at long cycle times, the average measured work tends to zero. In individual cycles, the work to erase can be below the Landauer limit, consistent with the Jarzynski equality.

We experimentally show the existence of the Landauer principle for situations involving information processing. To this end, we consider an information reservoir which provides the means to store and retrieve information. We use this reservoir to study the thermodynamics of information processing. In particular, we will focus on the generalizations of the second law of thermodynamics and the Jarzynski equality in the presence of feedback control, where information contents and thermodynamic quantities are treated on an equal footing. We will also discuss recent experimental results that realized Maxwell’s demon by colloidal particles and single electrons.

Friday, March 6, 2015 11:15AM - 2:15PM – Session Z3 GSNP: Invited Session: Thermodynamics of Information Processing 002AB - Massimiliano Esposito, University of Luxembourg

11:15AM Z3.00001 Stochastic thermodynamics of information processing. ANDRE CARDOSO BARATO, Universität Stuttgar — We consider two recent advancements on theoretical aspects of thermodynamics of information processing. First we show that the theory of stochastic thermodynamics can be generalized to include information reservoirs. These reservoirs can be seen as a sequence of bits which has its Shannon entropy changed due to the interaction with the system. Second we discuss bipartite systems, which provide a convenient description of Maxwell’s demon. Analyzing a special class of bipartite systems we show that they can be used to study cellular information processing, allowing for the definition of an entropic rate which quantifies how much a cell learns about a fluctuating external environment and that is bounded by the thermodynamic entropy production.

11:51AM Z3.00002 High-Precision Test of Landauer’s Principle in a Feedback Trap. JOHN BECHHOEFER2, Simon Fraser University — Landauer’s principle, formulated in 1961, postulates that irreversible logical or computational operations such as memory erase require work, no matter how slowly they are performed. For example, to “reset to one” a one-bit memory requires at least kT ln2 of work, which is dissipated as heat. Bennett and, independently, Penrose later pointed out a link to Maxwell’s Demon: Were Landauer’s principle to fail, it would be possible to repeatedly extract work from a heat bath. We report tests of Landauer’s principle in an experimental system consisting of a charged colloidal particle in water. To test stochastic thermodynamic ideas, we create a time-dependent, “virtual” double-wall potential via a feedback loop that is much faster than the relaxation time of the particle in the virtual potential. In a first experiment, the probability of “erasure” (resetting to one) is unity, and at long cycle times, we observe that the average work is compatible with kT ln2. In a second, the probability of erasure is zero; the system may end up in two states; and, at long cycle times, the average measured work tends to zero. In individual cycles, the work to erase can be below the Landauer limit, consistent with the Jarzynski equality.

12:27PM Z3.00003 Information Processing and the Second Law of Thermodynamics: An Inclusive Hamiltonian Approach. SEBASTIAN DEFFNER, Los Alamos Natl Lab — We obtain generalizations of the Kelvin-Planck, Clausius, and Carnot statements of the second law of thermodynamics for situations involving information processing. To this end, we consider an information reservoir (representing, e.g., a memory device) alongside the heat and work reservoirs that appear in traditional thermodynamic analyses. We derive our results within an inclusive framework in which all participating elements – the system or device of interest, together with the heat, work, and information reservoirs – are modeled explicitly by a time-independent, classical Hamiltonian. We place particular emphasis on the limits and assumptions under which cyclic motion of the device of interest emerges from its interactions with work, heat, and information reservoirs. Finally, our findings are illustrated with a simple, analytically solvable example – a quantum Maxwell demon.

1:03PM Z3.00004 Thermodynamics of Nonequilibrium Systems with Feedback Control. TAKAIRO SAGAWA, The University of Tokyo — In modern nonequilibrium physics, “Maxwell’s demon” has attracted renewed attentions in both terms of theory and experiment. The demon plays a key role to unify thermodynamics and information theory, which can extract the useful work from a heat bath by using the obtained information via feedback control. In this talk, I will talk about the recent development of thermodynamics of information. In particular, I will focus on the generalizations of the second law of thermodynamics and the Jarzynski equality in the presence of feedback control, where information contents and thermodynamic quantities are treated on an equal footing. I will also discuss recent experimental results that realized Maxwell’s demon by colloidal particles and single electrons.

1:39PM Z3.00005 Information and thermodynamics: Experimental verification of Landauer’s erasure principle. SERGIO CILIBERTO, ENSL-CNRS — Rolf Landauer argued that the erasure of information is a dissipative process. A minimal quantity of heat, proportional to the thermal energy, is necessarily produced when a classical bit of information is deleted. A direct consequence of this logically irreversible transformation is that the entropy of the environment increases unavoidably by a finite amount. We experimentally show the existence of the Landauer bound in a generic model of a one-bit memory. Using a system of a single colloidal particle trapped in a modulated double-well potential, we establish that the mean dissipated heat saturates at the Landauer bound in the limit of long erasure cycles. This result demonstrates the intimate link between information theory and thermodynamics. For a memory erasure procedure, which is a logically irreversible operation, a detailed Jarzynski Equality is verified, retrieving the

11:15AM Z4.00001 In-situ Studies of Structures and Processes at Model Battery Electrode/Electrolyte Interfaces1. PAUL FENTER, Argonne National Laboratory — The ability to understand and control materials properties within electrochemical energy storage systems is a significant scientific and technical challenge. This is due, at least in part, to the extreme conditions present within these systems, and the significant structural and chemical changes that take place as lithium ions are incorporated in the active electrode material. In particular, the behavior of interfaces in such systems is poorly understood, notably the solid-liquid interface that separates the electrode and the liquid electrolyte. I will review our recent work in which we seek to isolate and understand the role of interfacial reactivity in these systems through in-situ, real-time, observations of electrochemically driven lithiation/delithiation reactions. This is achieved by observing well-defined model electrode-electrolyte interfaces using X-ray reflectivity. These results reveal novel understandings of interfacial reactivity in conversion reactions (e.g., Si, Si, Ge, NiO) that can be used to control the complex reaction lithiation pathway through the use of thin-film and multilayer electrode structures.

11:51AM Z4.00002 Hybrid Functional Calculations of Acceptor Doping in Protonic Conductor SrZrO3. LEIGH WESTON, University of Sydney; ANDERSON JANOTTI, University of California, Santa Barbara; XIANGYUAN CUI, CATHERINE STAMPFL, University of Sydney, CHRIS VAN DE WALLE, University of California, Santa Barbara — Perovskite oxides such as SrZrO3 (SZO), which exhibit high temperature proton conductivity, are promising electrolyte materials for use in solid oxide fuel cells (SOFCs). Proton conductivity in SZO is typically achieved via acceptor doping with trivalent cations substituting at the Zr site, where the formation of charge compensating oxygen vacancies facilitates proton solvation. We present a detailed study of Sc and Y dopants in SZO based on first-principles, hybrid density functional calculations. When substituting at the Zr site, both dopants form deep acceptors, where the neutral charge state forms a localized hole polaron state. Under certain growth conditions Sc and Y will form auto-compensating donor species by substituting at the Sr site, which would inhibit proton solubility. Moreover, the proton - dopant association was found to be strong, with proton binding energies of -0.41 eV and -0.31 eV for ScZr and YZr respectively, indicating that proton transport is limited by trapping. These new results will be useful in the development of zirconate based proton conducting electrolyte materials for solid oxide fuel cells.

12:03PM Z4.00003 Effect of Fe doping on O vacancy/interstitial formation and migration in PrBaCo2O5+δ. OMOTAYO SALAWU, LIYONG GAN, UDO SCHWINGENSCHLOGL, King Abdullah Univ — Oxygen vacancy formation and migration are key factors considered for the operation of cathodes in solid oxide fuel cell. First-principles calculations are used to investigate Fe doped PrBaCo2O5+δ as cathode material for intermediate temperature solid oxide fuel cells. We discuss the electronic properties of the pristine system and the effect of Fe doping on the structural and electronic properties. Different concentrations of the dopants are calculated. We find that the volume of the unit cell and O vacancy formation energy increase linearly with the Fe content concentration. We also investigate the formation of oxygen interstitial as a function of Fe substitution and the possibility of anisotropic diffusion of the O ion was also studied.

12:15PM Z4.00004 Short-lived K2S Molecules in Superionic Potassium Sulfide. YUSUKE OKEYA, KAZUO TSUMURAYA, Meiji University — The first principles molecular dynamics method allows us to elucidate the formation of short-lived K2S molecular states in superionic potassium sulfide. The covalent and the Coulomb bonds exist between the ionized mobile potassiums and the ionized immobile sulfurs. Both the bonds induces indirect covalent and indirect Coulomb attractions between the di-interstitial potasiums on the mid-sulfurs, which forms the short-lived K2S molecular states. The covalent electron density also exists between short-lived potassium dimers. The three attractions reduce Haven’s ratios of the potassiums in the conductor. The molecule formation indicates the electronic state of the conductor is intermediate between the ionic and covalent crystals. The absence of the long-lived potassium dimers implies a failure of the caterpillar diffusion model or the Frenkel-Kontorova chain model for the superionic diffusion of the potassiums in the sulfide. The incompletely ionized cations and anions reduce the Coulomb attractions between them which induces the sublattice melting of smaller size of the potassiums than the sulfurs.

12:27PM Z4.00005 First principles calculations of stability and lithium intercalation potentials of ZnCo2O4. L.C. YU, J. WU, H. LIU, Chengdu Green Energy and Green Manufacturing Technology R&D Center, Sichuan, 620107, China, Y.N. ZHANG, Chengdu Green Energy and Green Manufacturing Technology R&D Center, Sichuan; Beijing Computational Science Research Center, Beijing, China — Among the metal oxides, which are the most widely investigated alternative anodes for use in lithium ion batteries (LIBs), binary and ternary tin oxides have received smaller size of the potassiums than the sulfurs. The incompletely ionized cations and anions reduce the Coulomb attractions between them which induces the sublattice melting of smaller size of the potassiums than the sulfurs. The covalent and the Coulomb bonds exist between the ionized mobile potassiums and the ionized immobile sulfurs. Both the bonds induces indirect covalent and indirect Coulomb attractions between the di-interstitial potasiums on the mid-sulfurs, which forms the short-lived K2S molecular states. The covalent electron density also exists between short-lived potassium dimers. The three attractions reduce Haven’s ratios of the potassiums in the conductor. The molecule formation indicates the electronic state of the conductor is intermediate between the ionic and covalent crystals. The absence of the long-lived potassium dimers implies a failure of the caterpillar diffusion model or the Frenkel-Kontorova chain model for the superionic diffusion of the potassiums in the sulfide. The incompletely ionized cations and anions reduce the Coulomb attractions between them which induces the sublattice melting of smaller size of the potassiums than the sulfurs.

12:39PM Z4.00006 Density Functional Theory Study of the Conductivity of Manganese Dioxide Nanowires during Li+ Insertion. RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA 92697, USA, HUI WANG, Department of Physics, Fudan University, Shanghai 200433, China, MAY LE THAI, REGINALD M. PENNER, Department of Chemistry, University of California, Irvine, CA 92697, USA — Manganese oxide (δ-MnO2) as a battery material has various advantages such as low cost, high earth abundance and environmentally safe, and it has large interlayer space for lithium ion insertion and migration. In this work, the system of 200 MnO2 nanowire array is used to study the electrochemical changes through in situ conductivity measurements during the lithium ion insertion process. The result indicates that the conductivity of each MnO2 nanowire array increases as the lithium ion concentrations increases corresponding to more negative insertion potential. We perform ab initio molecular dynamic (AIMD) simulations and density functional theory (DFT) calculations with the van der Waals (vdW) correction to understand the fundamental electrochemical and structural properties of δ-MnO2 nanowires. We find that water molecules are important for the expansion of the interlayer distance of δ-MnO2, and reveal that the variation of conductivity of δ-MnO2 nanowires with different Li+ concentrations stems from the Li+-produced gap states.

1HW and RW were supported 1000 talent fund in Fudan U and by DOE-BES (Grant No. DE-FG02-05ER46237). MT and RP were supported by the U.S. DOE-EFRC (Award Number DESC0001160).
12:51PM Z4.00007 In Situ Correlation of Volumetric Expansion with Charge Storage in Nanostructured MnO2, Tetyana Ignatova, Brad Corso, Deng Pan, O. Tolga Gul, Phillip G. Collins, Department of Physics and Astronomy, University of California at Irvine — Pseudocapacitors aim to meet developing energy storage needs by combining the high energy density of batteries with the power performance of capacitors. However, degradation remains a critical issue for pseudocapacitor electrodes. After many cycles, nanostructured metal oxides lose their capacity through mechanisms that remain poorly understood. In this work, we studied the volumetric changes that accompany charge storage in nanoscale MnO2 electrodes by combining in-liquid atomic force microscopy (AFM) with 3-terminal electrochemical cycling. Typical samples consisted of thin films (100 to 400 nm) of porous, amorphous MnO2 deposited onto 2 µm Pt electrodes and then cycled in aqueous LiClO4 electrolyte. In situ measurements of film expansion during charge insertion observed 5-6% volumetric expansion for partial charging of 0.1 electron per Mn atom over a wide range of scan rates and voltage windows, even though these parameters change the balance between fast, double-layer capacitance and bulk, redox pseudocapacitance mechanisms. In fact, volume expansion is universally attributed to bulk charging, so the invariance highlights an unexpected role for surface processes in nanostructured electrode materials.

1:03PM Z4.00008 Topological defect dynamics in operando battery nanoparticles, Andrew Uleveland, Shirley Meng, Oleg Shpyrko, University of California: San Diego — Topological defects are ubiquitous in physics and manifest themselves as magnetic monopoles in quantum field theories and crystallographic imperfections in condensed matter systems. In the latter, the defect properties determine many of the material’s properties and such represent substantial novel opportunities for design and optimization of desired functionalities through deliberate defect engineering and manipulation. However, this approach of “defect choreography” currently suffers from the lack of suitable nanoscale probes to track buried single defects in situ and in operando. Here we report 3D imaging of single edge dislocations and their motion in an individual nanoparticle under operando conditions in a Lithium ion battery. We further observe the dislocation act as a nucleation point during the structural phase transformation. We find that the region near the dislocation enters a negative Poisson’s ratio, or auxetic, regime at high voltage. Dislocation imaging is thus a powerful nanotechnology approach to measure performance indicators such as exact Li vacancy concentration and hopping energy barriers. We hope that the “map” between structure and property provided here will speed optimization of the ionic conductivity via targeted doping strategies.

1:15PM Z4.00009 Structure and Stoichiometry in doped LLZO (Li2La3Zr2O12), Michelle Johnnies, Naval Research Laboratory, NOAM BERNSTEIN, NRL, ASHIA HUQ, Oak Ridge National Laboratory, SAIKAT MIKHOPADAY, ONRL, JEFF WOLFENTINE, Army Research Laboratory, JAN ALLEN, ARL, TRAVIS THOMPSEN, University of Michigan, JEFF SAKAMOTO, UMich, DEREK STEWART, HGST — LLZO has a tetragonal, Li-ordered phase with very low ionic conductivity and a cubic, Li-disordered phase with two orders of magnitude higher conductivity, relevant for solid electrolyte usage. The jump in conductivity can be correlated to dopant-induced Li vacancies that disorder the Li sublattice and cause the structural phase transitions this work presents a high-throughput, first-principles technique to show how both overall structure and selected local structural elements change as a function of dopant concentration. In particular, we examine how the local structure that defines the Li ion pathways changes with the lattice constant and how important microscopic quantities such as different Li site energies and hopping barriers change accordingly. Our work provides a link between the easily measurable lattice constant and extremely important but difficult to measure performance indicators such as exact Li vacancy concentration and hopping energy barriers. We hope that the “map” between structure and property provided here will speed optimization of the ionic conductivity via targeted doping strategies.

1:27PM Z4.00010 Compressive Sensing Cluster Expansion Studies of Lithium Intercalation and Phase Transformation in MoS2 for Energy Storage, Chi-Ping Liu, University of California, Los Angeles, FEI ZHOU, Lawrence Livermore National Laboratory, MIEDVUDZ OZOLINS, University of California, Los Angeles, UNIVERSITY OF CALIFORNIA, LOS ANGELES COLLABORATION, LAWRENCE LIVERMORE NATIONAL LABORATORY COLLABORATION — Bulk molybdenum disulfide (MoS2) is a good electrode material candidate for energy storage applications, such as lithium ion batteries and supercapacitors due to its high theoretical energy and power density. First-principles density-functional theory (DFT) calculations combined with cluster expansion are an effective method to study thermodynamic and kinetic properties of electrode materials. In order to construct accurate models for cluster expansion, it is important to effectively choose clusters with significant contributions. In this work, we employ a compressive sensing based technique to select relevant clusters in order to build an accurate Hamiltonian for cluster expansion, enabling the study of Li intercalation in MoS2. We find that the 2H MoS2 structure is only stable at low Li content while 1T MoS2 is the preferred phase at high Li content. The results show that the 2H MoS2 phase transforms into the disordered 1T phase and the disordered 1T structure remains after the first Li insertion/deinsertion cycle suggesting that disordered 1T MoS2 is stable even at dilute Li content. This work also highlights that cluster expansion treated with compressive sensing is an effective and powerful tool for model construction and can be applied to advanced battery and supercapacitor electrode materials.

1:39PM Z4.00011 Binder-free Carbon Nanotube Flexible Solid State Supercapacitor1, Kofi ADU, The Pennsylvania State University Altoona College, DANHAO MA, The Pennsylvania State University, RAMAKRISHNAN RAJAGOPALAN, The Pennsylvania State University-DuBois, CHENG-YU WANG, ANGELA LUEKING, CLIVE RANDELL, The Pennsylvania State University — We present a post synthesis self-assemble protocol that transforms the trillions of CNTs in powder form into densely packed flexible, robust and binder-free macroscopic membranes with hierarchical pore structure. The binder-free CNT membranes could be as thin as <10µm with mass density greater than that of water (1.0g/cc). As the thickness of the CNT membrane is increased, we observed a gradual transition from high flexibility to buckling and brittleness in the flexural properties of the CNT membranes. We have demonstrated the use of the CNT membranes as electrode in two-electrode 1M H2SO4 aqueous double layer supercapacitor that shows very high power density ~ 1040 kW/kg based on the mass of both electrodes and time constant of ~ 15 ms with no degradation in performance even after 10,000 cycles. Furthermore, we will show the designing of flexible 3-stack bipolar solid-state ultracapacitor and present results on energy/power densities, voltage, cyclability, temperature stability in relation to flexibility and weight. Preliminary results indicate high temperature stability >85°C and CV voltage ~ 3V with very low leakage current ~ 10nA.

This Work is Supported by Penn State Altoona Undergraduate Research Sponsored Program and Penn State Materials Research Institute, University Park.

1:51PM Z4.00012 X-ray absorption spectroscopy as a probe of dissolved polysulfides in lithium sulfur batteries, TOD PASCAL, DAVID PRENDERGAST, Lawrence Berkeley National Lab — There has been enormous interest lately in lithium sulfur batteries, since they have 5 times the theoretical capacity of lithium ion batteries. Large-scale adoption of this technology has been hampered by numerous shortcomings, chiefly the slow rate of utilization of the active material and rapid capacity fading during cycling. Overcoming these limitations requires methods capable of identifying and quantifying the products of the poorly understood electrochemical reactions. One recent advance has been the use of X-ray absorption spectroscopy (XAS), an element-specific probe of the unoccupied energy levels around an excited atom upon absorption of an X-ray photon, to identify the reaction products and intermediates. In this talk, we’ll present first principles molecular dynamics and spectral simulations of dissolved lithium polysulfide species, showing how finite temperature dynamics, molecular geometry, molecular charge state and solvent environment conspire to determine the peak positions and intensity of the XAS. We’ll present a spectral analysis of the radical (-1e charge) species, and reveal a unique low energy feature that can be used to identify these species from their more common dianion (-2e charge) counterparts.

Session Z5 DMP DCOMP: Focus Session: Competing Order and ARPES in Fe-Based Superconductors
Jude Gorman Room 005 - Andrei Chubukov, University of Minnesota
Competing phases in iron-based superconductors — DONGHUI LU, SSRL SLAC — Stanford
A common aspect of high temperature superconductivity in both cuprates and iron-based superconductors is that it always appears in the vicinity of other competing phases, whose suppression brings the full emergence of superconductivity. In iron-based superconductors, the competing phases take the form of collinear spin-density-wave phase and nematic phase. Characterization of these competing phases and associated phase transitions is essential to establishing a comprehensive understanding of the phase diagram of high temperature superconductors and ultimately the mechanism of unconventional superconductivity. In this talk, I will present our angle-resolved photoemission study of different family of iron-based superconductors. Our early data on detwinned BaFe$_1-x$Co$_x$As$_2$ and NaFeAs not only revealed a symmetry breaking orbital anisotropy in the nematic phase, but also identified the spectroscopic signatures associated with each phase transition in our ARPES spectra [1,2]. More recent results from underdoped Ba$_1$Fe$_2$As$_2$, on the other hand, provided the direct spectroscopic evidence for the coexistence and competition between SDW phase, nematic phase, and superconducting phase [3]. Finally, our latest data on multilayer FeSe film demonstrate the presence of a nematic state without long range magnetic order, suggesting the importance of orbital degree of freedom in driving the nematicity [1,3]. M. Yi, D. H. Lu, J.-H. Chu, J. C. Analytis, A. P. Sorini, A. F. Kemper, B. Moritz, S.-K. Mo, R. G. Moore, M. Hashimoto, W.-S. Lee, Z. Hussain, T. P. Devereaux, I. R. Fisher, and Z.-X. Shen, Proc. Natl. Acad. Sci. 108, 6878 (2011). [2] M. Yi, H. Wen, Z.-X. Shen, and D. H. Lu; Nature Communications 5, 3711 (2014).

Electron correlation tuned superconductivity in iron chalcogenide superconductors — MING YI, MENG WANG, Univ of California - Berkeley, DONGHUI LU, Stanford Synchrotron Radiation Laboratory, ALEXANDER KEMPER, Lawrence National Laboratory, SUNG-KWAN MO, Advanced Light Source, Lawrence National Laboratory, ZHI-XUN SHEN, Stanford University, ROBERT BIRGENAU, Univ of California - Berkeley — The iron chalcogenide superconductors, A$_x$Fe$_2$-Se$_2$ (A=K, Rb, Cs), is an interesting system where superconductivity occurs without the existence of hole Fermi pockets, hence lacking the nesting conditions needed under a spin fluctuation mediated pairing scenario. It is then important to understand the ingredients needed for superconductivity in these materials. It has been shown that sulfur substitution for selenium in this system can continually reduce the $T_c$ from 30K to zero, providing an opportunity for understanding the occurrence of superconductivity in these materials. In this talk, I will present angle-resolved photoemission spectroscopy data on the Rb$_x$Fe$_2$(Se$_{1-y}$S$_y$)$_2$ series, where we show that electron correlation strength is the crucial parameter that tunes superconductivity in this family.

ARPES of K-doped iron selenide superconductor — TAKAYOSHI YOKOYA, MASANORI SUNAGAWA, KENSEI TERASHIMA, TAKAHIRO HAMADA, HIROKAZU FUJIIWARA, Okayama University, MASASHI TANAKA, HIROYUKI TAYEKA, YOSHIHIKO TAKANO, NIMS, MASASHI ARITA, KENYA SHIMADA, HIROFUMI NAMATAME, MASAKI TANIGUCHI, HISOR, Hiroshima University, KAT-SUHIRO SUZUKI, HIDETOMO USUI, KAZUHIKO KUROKI, Osaka University, TAKANORI WAKITA, YUJI MURAOKA, Okayama University — In iron pnictide superconductors, the characteristic Fermi surface (FS) peak, namely a nesting of hole-like FS at the zone center and electron-like FS at the zone corner, is considered to induce spin/orbital fluctuation leading to high-Tc superconductivity [1,2]. In K-doped iron selenide superconductors, however, ARPES studies reported absence of hole-like FS at the zone center, which is different from that observed in iron pnictides [3]. So far, proposed models for the superconductivity based on the FS topology appear to fail to explain available experimental results. In this talk, we present our recent ARPES studies on a K-doped iron selenide superconductor performed with careful tuning of experimental conditions, which show a hole-like FS around the zone center. [1] I. I. Mazin et al., Phys. Rev. Lett. 101, 057003 (2008); [2] K. Kuroki et al., Phys. Rev. Lett. 101, 087004 (2008); [3] Y. Zhang et al., Nat. Mater. 10, 273 (2011); T. Qian et al., Phys. Rev. Lett. 106, 187001 (2011).

What do we actually see in ARPES? Generalized unfolding method and application to Fe-based superconductors — MILAN TOMIC, HARALD O. JESCHKE, ROSER VALENTI, Goethe University — Interpretation of angle resolved photoemission (ARPES) measurements relies heavily on comparison with ab-initio (DFT) band structures. However, ARPES-observed band structures and DFT band structures often disagree on the unit cell periodicities as well as position of band structure features relative to the Brillouin zone. We present a novel, symmetry-based approach to band structure unfolding which utilizes irreducible representations of space groups. Within the unified framework we can treat both the translational and point group symmetries and explain how ARPES measurements sometimes reflect crystal structure features with a reduced unit cell. We will present some examples in the context of Fe-based superconductors.

ARPES investigations of parent compounds of 122 Fe-based superconductors and their 3d transition metal cousins — PIERRE RICHARD, W.-L. ZHANG, S.-F. WU, A. VAN ROEKEGHEM, P. ZHANG, H. MAO, T. QIAN, A. Kiryukhin, F. Milot, Institute of Physics, Chinese Academy of Sciences, T. KIM, M. HOESCH, Laboratoire de Photonique et d’Optique, Lyon, France (France), H. MIYAGAWA, H. MIAO, TIAN QIAN, XUN SHI, PIERRE RICHARD, Institute of Physics, Chinese Academy of Sciences, T. KIM, M. HOESCH, Diamond Light Source, LINGYI XING, XUAN GENG, HONG DING, Institute of Physics, Chinese Academy of Sciences — In conventional BCS superconductors, the quantum condensation of superconducting electron pairs is understood as a Fermi surface instability, in which the low-energy electrons are paired by attractive interactions. Whether this explanation is still valid in high-Tc superconductors such as cuprates and iron-based superconductors remains an open question. In particular, a fundamentally different picture of the electron pairs, which are believed to be formed locally by repulsive interactions, may prevail. Here we report a high-resolution angle-resolved photoemission spectroscopy study on LiFe$_1-x$Co$_x$As. We reveal a large and robust superconducting gap on a band sinking below the Fermi energy upon Co substitution. The observed Fermi surface free superconducting order is also the largest over the momentum space, which rules out a proximity effect origin and indicates that the superconducting order parameter is not tied to the Fermi surface as a result of a Fermi surface instability.

Observation of strong electron pairing on band without Fermi surfaces in LiFe$_1-x$Co$_x$As — HU MIAO, TIAN QIAN, XUN SHI, PIERRE RICHARD, Institute of Physics, Chinese Academy of Sciences, T. KIM, M. HOESCH, Diamond Light Source, LINGYI XING, XUAN GENG, HONG DING, Institute of Physics, Chinese Academy of Sciences — In conventional BCS superconductors, the quantum condensation of superconducting electron pairs is understood as a Fermi surface instability, in which the low-energy electrons are paired by attractive interactions. Whether this explanation is still valid in high-Tc superconductors such as cuprates and iron-based superconductors remains an open question. In particular, a fundamentally different picture of the electron pairs, which are believed to be formed locally by repulsive interactions, may prevail. Here we report a high-resolution angle-resolved photoemission spectroscopy study on LiFe$_1-x$Co$_x$As. We reveal a large and robust superconducting gap on a band sinking below the Fermi energy upon Co substitution. The observed Fermi surface free superconducting order is also the largest over the momentum space, which rules out a proximity effect origin and indicates that the superconducting order parameter is not tied to the Fermi surface as a result of a Fermi surface instability.

Dynamic coexistence of competing orders in multi-component superconductors — MAXIM DZERO, Kent State University, ALEX LEVCHENKO, Michigan State University — We study the nonequilibrium dynamics of an electronic model with competing spin-density wave and unconventional superconductivity in the context of iron-pnictides. Focusing on the collisionless regime we find that magnetic and superconducting order parameter varies may coexist dynamically after the quench even though the equilibrium state has only one order parameter. We consider different initial conditions concomitant with the phase diagram and in a certain regime identify new oscillatory amplitude modes with incommensurate frequencies for magnetic and superconducting responses. At the technical level we solve equations of motion for the electronic Green’s functions and self-consistency conditions by reducing the problem to a closed set of Bloch equations in the pseudospin representation.
1:03PM Z5.00008 Correlation-induced self-doping in iron-pnictide superconductor Ba$_2$Ti$_2$Fe$_{2}$As$_{1}$O$_{4}$, TIAN QIAN, JUNZHANG MA, Institute of Physics, Chinese Academy of Sciences, A. VAN ROEKEGHEM, Ecole Polytechnique, PIERRE RICHARD, Institute of Physics, Chinese Academy of Sciences, GUANGHAN CAO, Zhejiang University, SILKE BIERMANN, Ecole Polytechnique, HONG DING, Institute of Physics, Chinese Academy of Sciences — The electronic structure of the iron-based superconductor Ba$_2$Ti$_2$Fe$_{2}$As$_{1}$O$_{4}$ ($T_{ onset}^{c} = 23.5$ K) has been investigated by using angle-resolved photoemission spectroscopy and combined local density approximation and dynamical mean field theory calculations. The electronic states near the Fermi level are dominated by both the Fe 3d and Ti 3d orbitals, indicating that the spacer layers separating different FeAs layers are also metallic. By counting the enclosed volumes of the Fermi surface sheets, we observe a large self-doping effect, i.e. 0.25 electrons per unit cell are transferred from the FeAs layer to the Ti$_2$As$_2$O layer, leaving the FeAs layer in a hole-doped state. This exotic behavior is successfully reproduced by our dynamical mean field calculations, in which the self-doping effect is attributed to the electronic correlations in the 3d shells. Our work provides an alternative route of effective doping without element substitution for iron-based superconductors.

1:15PM Z5.00009 Extraordinary Doping Effects on Quasiparticle Scattering and Bandwidth in Iron-Based Superconductors, DONGLAI FENG, Dept. of Physics, Fudan University — Iron-based superconductors exhibit very rich phenomena with doping. We systematically investigate the behavior of dopants in a variety of iron-based superconductors with angle-resolved photoemission spectroscopy (ARPES), we find that dopants modify the carrier density, introduce quasiparticle scattering, and vary the bandwidth in extraordinary ways [1]. Particularly, we find that instead of Fermi surface topology or carrier density, the bandwidth, which is closely related to electronic correlations, is likely the most important parameter that determines the change in the electronic properties. By investigating the change in the coupling strength between electron and a bosonic mode, in addition, the size of the band splitting between the middle and inner hole bands at the Gamma point which was suggested to represent the size of Fermio-orbital fluctuation does not change, in a sharp contrast to the case of Co doped LiFeAs. This result suggests that the band splitting is not related to the $T_c$ suppression in LiFe$_1$-xMnxAs system.

1:39PM Z5.00011 Nematic order and Fermi surface reconstruction of chalcogen Fe-based superconductors, JUJUN-YUAN LIN, Institute of Physics, National Chiao Tung University, Hsinchu 30010, Taiwan — We utilized the transport property measurements and polarized Fe L-edge XAS to explore nematic order and Fermi surface reconstruction in FeSe. Temperature-dependent magnetoresistance— the Hall coefficient, and angle-resolved photoemission spectroscopy (ARPES) measurements on the charge density wave system’s (CDW) CeTe$_2$O$_4$. We found that the slopes of the middle and inner hole bands near the Fermi energy decrease upon Mn doping, resulting in downward shift of the band tops. Meanwhile, band positions away from the Fermi energy remain more or less the same. We attribute such change to the suppression in LiFe$_1$-xMnxAs system.

2:27PM Z5.00010 Electronic structure of LiFe1-xMnxAs (x=0, 0.04), JONGJIN SEO, Yonsei Univ, BUMSUNG LEE, KEE HOON KIM, Seoul National Univ, CHANGYOUNG KIM, Yonsei Univ — We studied the Mn substitution effect in LiFeAs with Angle Resolved Photoemission Spectroscopy. We found that the slopes of the middle and inner hole bands near the Fermi energy decrease upon Mn doping, resulting in downward shift of the band tops. Meanwhile, band positions away from the Fermi energy remain more or less the same. We attribute such change to the suppression in LiFe$_1$-xMnxAs system. This work is to elucidate the existence of Fermi surface reconstruction in FeSe in which no SDW was observed. Moreover, whether this electronic structure change has a nematic or magnetic origin will be answered.

This work was supported by MOST of Taiwan.

2:51PM Z5.00012 On the Phase Diagram of FeSe$_{1-y}$As$_y$, KHALIL ZIQ, T. OWOLABI, King Fahd University of Petroleum and Minerals, Physics Department — Structural, magnetic and transport measurements have been performed on FeSe$_{1-y}$As$_y$ samples in the normal and superconducting state in an effort to obtain the phase diagram. It is found that As-substitution drastically suppress the superconducting state while it has little effect of structural transformation as the temperature decreases. Moreover, low As-concentration (x ∼ 1%As) has been found very effective in stabilizing the β-FeSe phase.

This work has been supported by NSTIP under 11-ADV1631.

11:15AM Z7.00001 Electronic structure origins of the extremely large magnetoresistance in tungsten ditelluride, IVO PLETIKOSIC, MAZHAR ALI, ROBERT CAVA, Princeton Univ, TONICA VALLA, Brookhaven Natl Lab — WTe$_2$ is a layered transition metal dichalcogenide showing a structural reduction to one-dimensional tellurium-surrounded tungsten chains. The material exhibits an extremely large positive anisotropic magnetoresistance of a few million percent that increases as the square of the field and shows no saturation up to 60 T. We explored the possible electronic structure origins of the magnetoresistance by means of angle-resolved photoelectron spectroscopy (ARPES) and found electron and hole pockets of equal size along the direction of tungsten chains, forming a highly anisotropic quasi-two-dimensional Fermi surface. The perfect carrier compensation at low temperatures has been identified as the primary source of the magnetoresistive effect, and the change of the Fermi surface shape as well as the high-density-of-states band slightly below the Fermi level recognized as the cause of its diminishing at rising temperatures. [1] M.N. Ali et al. Nature 514, 205 (2014) [2] I. Pletikos? et al. arXiv:1407.3576 (2014)

11:27AM Z7.00002 Near Gap Excitation of Collective Modes in a Charge Density Wave, DOMINIK LEUENBERGER, JONATHAN SOBOTA, SHUOLONG YANG, Stanford University, ALEXANDER KEMPER, Lawrence Berkeley National Laboratory, PAULA GIRALDO, ROB MOORE, IAN FISHER, PATRICK KIRCHMANN, THOMAS DEVEREAUX, ZHI-XUN SHEN, Stanford University — We present time-and-angle-resolved photoemission spectroscopy (trARPES) measurements on the charge density wave system’s (CDW) CeTe$_2$. Optical excitation transiently populates the unoccupied band structure and reveals a CDW gap size of $\Delta = 0.59$ eV. In addition, the occupied Te-5p band dispersion is coherently modified by three collective modes. First, the spatial polarization of the modes is analyzed by fits of a transient model dispersion and DFT frozen phonon calculations. We thereby demonstrate how the rich information from trARPES allows identification of collective modes and their spatial polarization, which explains the mode-dependent coupling to charge order. Second, the exciting photon energy $h\nu$ was gradually lowered towards $2\Delta$, at constant optical excitation density. The coherent response of the amplitude mode deviates from the optical conductivity, which is dominated by direct interband transitions between the lower and upper CDW bands. The measured $h\nu$ dependence on the CDW gap size for transition between bands with different orbital character. This finding suggests, that the coherent response of the CDW amplitude mode is dominated by photo-doping of the charge ordering located in the Te-planes.
CaC$_6$ and BaC$_6$, we rule out C$_{xy}$ phonon mode as the origin of the superconductivity in CaC$_6$, which strongly suggests interlayer state driven superconductivity. For BaC$_6$, the graphene band Dirac point energy is smaller than that of CaC$_6$. Based on data from cell is supposed to contain three graphene layers. This suggests that c-axis ordering of Ca has little effect on the electronic structure of CaC$_6$. In addition to band possesses a weak $k_z$ dispersion. The overall electronic structure shows a peculiar single graphene layer periodicity in the $k_z$ direction although CaC$_6$ unit structures to investigate the interlayer states. The results reveal a spherical interlayer Fermi surface centered at the $\Gamma$ point.

BERG, JONATHAN DENLINGER, Advanced light source, CHANGYOUNG KIM, Yonsei Univ, YONSEI UNIVERSITY TEAM, POSTECH COLLABORATION, LEEM, CHUL KIM, YOONYUNG KOH, BEOMYOUNG KIM, Yonsei Univ, YEONGWOOK KIM, JUNSUNG KIM, KEUNSU KIM, Postech, ELI ROTEN.

Driven Superconductivity

Institute of Physics, Chinese Academy of Sciences, KEHUI WU, State Key Laboratory for Surface Physics, Institute of Physics, Chinese Academy of Science, DENLINGER, Advanced Light Source, Lawrence Berkeley National laboratory, Berkeley, California 94720, USA, MATS LEANDERSSON, Beamline I3, MAX LAB, SE-221 00, Lund, Sweden, CHANGYOUNG KIM, Institute of Physics and Applied Physics, Yonsei University, Seoul, 120-749, Korea. — Theoretical understanding of spin orbit coupling (SOC) effects in SrTiO$_3$ under 50-layers. This systematic study will provide insight in understanding the evolution of electronic structure and superconductivity from the single-layer up to 50-layers. This systematic study will provide insight in understanding the evolution of electronic structure and superconductivity from the single-layer to multiple-layer FeSe/SrTiO$_3$ films and eventually to the bulk FeSe superconductor.

CHEN, ZUYAN XU, Chinese Academy of Sci (CAS), XI CHEN, Tsinghua university, XUCUN MA, Chinese Academy of Sci (CAS), QIKUN XUE, Tsinghua university, XINGJIAN ZHOU, Chinese Academy of Sci (CAS) — the recent discovery of high-Tc superconductivity in a single-layer FeSe/SrTiO$_3$ film has attracted much attention... Our previous ARPES studies on the FeSe/SrTiO$_3$ films have observed distinct electronic structure of the single-layer FeSe/SrTiO$_3$ film, established a phase diagram and observed a signature of high Tc over 65K in the annealed single-layer FeSe/SrTiO$_3$ films, revealed the dichotomy of electronic structure and superconductivity between the single-layer and double-layer FeSe/SrTiO$_3$ films, and observed an insulator-superconductor transition in the single-layer FeSe/SrTiO$_3$ films. In this talk, we will present our new ARPES results on the FeSe/SrTiO$_3$ films with many different layers, from single-layer up to 50-layers. This systematic study will provide insight in understanding the evolution of electronic structure and superconductivity from the single-layer to multiple-layer FeSe film, to multiple-layer FeSe film and eventually to the bulk FeSe superconductor.
possible on the surface of a 3D SPT phase. The obstruction to defining a consistent topological theory involving both the original anyons and the gauge fluxes. We point out that a class of obstructions are necessary for identifying an anomalous SET which has a discrete unitary symmetry group $G$. SETs are anomalous in that they can only occur on the surface of a 3D symmetry protected topological (SPT) phase. In this paper we describe a procedure for identifying an anomalous SET. While the symmetry fractionalization is relevant for observing quantized transport. The phonons then smoothen this out leading to a non-trivial isotropic nonequilibrium distribution which has no memory of the initial state and initial switch-on protocol, and yet is distinct from a thermal state. An analytical expression for the distribution at the Dirac point is obtained. The general relations among fractional quantum numbers carried by different fractionalizations, including those relevant to space group symmetry and time reversal symmetry. Examples are given to apply this framework to exactly solvable local bosonic models with abelian or non-abelian topological order. In addition, the general relations among fractional quantum numbers carried by different anyon species are derived. This framework is applicable in particular to gapped quantum spin liquids, fractional Chern insulators, and fractional topological insulators. This research is supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES) under Award # DE-FG02-10ER46686. This work was supported by US Department of Energy (DOE-BES) under Award No. DE-SC0010821. We show that Se doping does not alter the behavior of topological insulators within staggered flux. Interestingly, gapless edge states consisting of counter-propagating states with opposite spins survive, and in some regions, a phase with two such pairs of edge states emerges. We examine the robustness of these phases in the presence of disorder and study the topological phase transitions by varying the disorder strength. These systems demonstrate topological properties similar to but different from the ones predicted by the well-known $Z_2$ topological theory.
12:03PM Z10.00005 Modular Anomalies in the Topological Classification of 2+1D and 3+1D Edge Theories1, MOON JIP PARK, Univ of Illinois - Urbana, CHEN FANG, B. ANDREI BERNEVIG, Princeton Univ, MATTHEW GILBERT, Univ of Illinois - Urbana — Classification of topological phases of matter in the presence of interactions is an area of intense interest. While much progress has been made on classification of interacting bosonic systems, the classification of fermionic systems is less established. One possible means of classification is via studying the partition function under modular transforms, as the presence of an anomalous phase arising in the edge theory of a D-dimensional system under modular transforms, or modular anomaly, signals the presence of a (D-1)-dimensional nontrivial bulk. In this work, we discuss the modular transforms of conformal field theories along a (2+1)-D and (3+1)-D edge. By both analytical and numerical methods, free chiral complex fermions in (2+1)-D and (3+1)-D are shown to be modular invariant, however, we show in (3+1)-D that a background U(1) gauge field results in the presence of a modular anomaly that is the manifestation of a quantum Hall effect in a (4+1)-D bulk.

12:15PM Z10.00006 Z2 topological invariants and gauge transformation of time reversal polarization, KLAUS KOEPERNIK, JEROEN VAN DEN BRINK, IFW Dresden, Germany — The $Z_2$ topological indices for 2D and 3D (strong and weak) topological materials can be calculated from the time reversal polarization as shown by Fu and Kane. These polarizations are defined up to a sign, which represents a gauge choice, since these signs do not influence the topological indices. We discuss the origin of this gauge invariance and its physical interpretation for materials with inversion center.

12:27PM Z10.00007 An exactly solvable model for twisted symmetry-enriched phases, NICOLAS TARANTINO, LUKASZ FIDKOWSKI, Stony Brook University — Topological phases in 2D have a long history of exotic behaviour, producing anyons and protected edge states. This trend continues when we impose an extra symmetry $G$, producing a symmetry-enriched topological (SET) phase. While the ground state will remain invariant under $G$, the set of anyons $\mathcal{A}$ may transform non-trivially. The different ways of implementing the symmetry are classified by the elements of the group cohomology $H^2(G, \mathcal{A})$, where $\mathcal{A}$ describes the action of $G$ on the set of anyons. Previously constructed models fix $\rho$ to be the identity, meaning that $G$ can only modify anyons by a phase, whereas we could easily envision a case where $G$ permutes anyon types, which we call twisted SETs. In this talk, we will propose a modified string-net model which allows $G$ to act on the anyons in exactly that manner, for any choice of $\rho$. We will also introduce a constructive method of gauging the global symmetry, which allows us to verify that the obtained twisted SETs are distinct by showing that discrete gauge theories produced by gauging $G$ are distinct.

12:39PM Z10.00008 “Gauging” Non-on-site Symmetries and Symmetry Protected Topological Phases1, CHANG-TSE HSIEH, GIL YOUNG CHO, SHINSEI RYU, Univ of Illinois - Urbana — We gauge non-on-site symmetries, such as parity symmetries, for a general (1+1)D conformal field theory (CFT) which is the boundary of (2+1)D symmetry protected topological (SPT) phases. This provides an efficient method to diagnose stability of SPT phases with the discrete non-on-site symmetries. To gauge the non-on-site symmetries, we are naturally led to consider field theories defined on a non-oriented manifold, such as Klein bottle. The partner states of the “vortices” (or twist operators) of the gauged non-on-site symmetries, the so-called crosscap states, provide information about the classification of the corresponding SPT phases. Our method also provide a way to gauging time-reversal symmetry, which is “topologically” related to parity symmetry by CPT theorem.

12:51PM Z10.00009 Twist liquids and gauging anyonic symmetries, JEFFREY TEO, University of Virginia, TAYLOR HUGHES, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — Topological phases of matter in (2+1)D are frequently equipped with global symmetries that label anyons without changing the fusion and braiding structures. Twist defects are static symmetry fluxes that permute the labels of orbiting anyons. Gauging or melting these symmetries by quantizing defects into dynamical excitations leads to a wide class of more exotic topological phases known as twist liquids. We formulate a general gauging framework, characterize the anyon structure of twist liquids and provide soluble lattice models that capture the gauging phase transitions. Generalizing a discrete gauge theory, we represent the anyons by a phase, whereas we could easily envision a case where $G$ permutes anyon types, which we call twisted SETs. In this talk, we will propose a modified string-net model which allows $G$ to act on the anyons in exactly that manner, for any choice of $\rho$. We will also introduce a constructive method of gauging the global symmetry, which allows us to verify that the obtained twisted SETs are distinct by showing that discrete gauge theories produced by gauging $G$ are distinct.

12:03PM Z10.00010 Fluctuating Domain Wall Wavefunctions for Symmetry Protected Topological Phases1, SHENG-JIE HUANG, MICHAEL HERMELE, Department of Physics, University of Colorado at Boulder — Symmetry protected topological (SPT) phases have been argued to be classified by the group cohomology of the symmetry group. In general, it has been challenging to connect this classification directly and intuitively to physical properties. In this talk, we provide a simple picture of SPT ground state wave functions in terms of fluctuating domain walls, for SPT phases in one and two dimensions with a finite internal symmetry group. The structure of group cohomology has a simple physical manifestation in the wave functions we construct. We also employ the fluctuating domain wall picture to analyze physical properties of SPT phases, and relate these directly to the group cohomology structure of the wave function.

12:15PM Z10.00011 Holographic entanglement renormalization of topological insulators, XUEDA WEN, Department of Physics, University of Illinois at Urbana-Champaign, 1110 West Green St, Urbana IL 61801, USA, YINGFEI GU, Department of Physics, Stanford University, Stanford, California 94305, USA, PEDRO LOPES, Instituto de Fisica Gleb Wataghin, Universidade Estadual de Campinas, Campinas, SP 13083-970, Brazil, GIL YOUNG CHO, Department of Physics, University of Illinois at Urbana-Champaign, 1110 West Green St, Urbana IL 61801, USA, XIAO-LIANG QI, Department of Physics, Stanford University, Stanford, California 94305, USA, SHINSEI RYU, Department of Physics, University of Illinois at Urbana-Champaign, 1110 West Green St, Urbana IL 61801, USA — In this work we study the real-space entanglement renormalization group (RG) flows and associated emergent holographic geometry of topological band insulators in (2+1) dimensions with continuum multi-scale entanglement renormalization ansatz (cMERA). Given a ground state of a topological insulator at the UV layer, we study how the Berry curvature as well as the quantum metric evolve in the bulk of cMERA. Besides the nontrivial topological properties in the bulk of cMERA, it is found that the UV state flows to a nontrivial IR state which carries a nonzero Berry flux. Our result is in parallel with the picture in lattice MERA that a nontrivial UV state corresponds to a nontrivial IR state. On the other hand, if we try to construct the UV state with a trivial IR state, we find there is a “phase transition” feature in the bulk of cMERA.
1:27PM Z10.00012 Classification of topological phases with reflection symmetry. TSUNEYA YOSHIDA, TAKAHIRO MORIMOTO, AKIRA FURUSAKI, RIKEN — In $Z_2$ topological band insulators, the time-reversal symmetry protects their topological structure. In these years such a notion is extended to correlated systems including bosonic systems, and these nontrivial phases are referred to as symmetry protected topological (SPT) phases. Parallel to this progress, a topological crystalline insulator, protected by spatial symmetry, is found for SnTe. Thus, SPT phases protected by this type of symmetry are naturally expected, and classifications of such phases are desired. In this article, we address this issue by focusing on a reflection symmetry. Our analysis based on the Chern-Simons approach proposes periodic tables for bosonic and fermionic SPT phases in two dimensions. Besides that, we show an SPT phase with the reflection symmetry is stabilized in a spin model of honeycomb lattice.

1:39PM Z10.00013 Gauging and Orbifolding Topological Phases[1], XIANG CHEN, UIUC, ABHISHEK ROY, Institute for Theoretical Physics, University of Cologne, JEFFREY TEO, Department of Physics, University of Virginia, Charlottesville, VA 22904 USA — Topological phases of matter in $2+1$D are commonly equipped with global symmetries, such as electric-magnetic duality in gauge theories and bilayer symmetry in fractional quantum Hall states. Gauging these symmetries into local dynamical ones is one way of obtaining exotic phases from conventional systems. We study this using the bulk-boundary correspondence and orbifolding the $(1+1)$D edge described by a conformal field theory (CFT). Our procedure puts twisted boundary conditions into the partition function, and predicts the fusion, spin and braiding behavior of anyonic excitations after gauging. We demonstrate this for the twofold-symmetric $Z_N$ gauge theory and the $S_3$-symmetric so(8)$_1$ state.

1:51PM Z10.00014 Sensing Coulomb impurities with 1/f noise in 3D Topological Insulator. SEMONTI BHATTACHARYYA, MITALI BANERJEE, HARIHARAN NHALIL, SUJA ELIZABETH, ARINDAM GHOSH, Indian Institute of Science, Bangalore — Electrical transport in the non-trivial surface states of bulk Topological Insulator (TI) reveal several intriguing properties ranging from bipolar field effect transistor action, weak antilocalization in quantum transport, to the recently discovered quantum anomalous Hall effect. Many of these phenomena depend crucially on the nature of disorder and its screening by the Dirac Fermions at the TI surface. We have carried out a systematic study of low-frequency 1/f noise in Bi$_2$Se$_3$ single crystals, to explore the dominant source of scattering of surface electrons and monitor relative contributions of the surface and bulk channels. Our results reveal that while trapped coulomb impurities at the substrate-TI interface are dominating source of scattering for thin (10 nm) TI, charged crystal disorder contribute strongly in thick TI (110 nm) channels. An unexpected maximum at 25K in noise from thick TI devices indicate scattering of the surface states by a cooperative charge dynamics in the bulk of the TI, possibly associated with the Selenium vacancies. Our experiment demonstrates, for the first time, impact of the bulk charge distribution on the surface state transport in TIs that could be crucial to the implementation of these materials in electronic applications.

Session Z16 DMP: Focus Session: Graphene - Growth

11:15AM Z16.00001 First-Principles Simulations for the Initial Stage of Graphene Growth Induced by Si Sublimation from Stepped SiC Surface[1], YOKY ONO, RIST, MARCEED, TAKAHIRO YAMASAKI, NIMS, MARCEED, TAKAHISA OHNO, NIMS, IIS Univ. of Tokyo, MARCEED — An epitaxial graphene sheet can be obtained by heat sublimation of Si atoms from the stepped SiC surface. Although this method is expected as one of the most encouraging procedure to make clean sheets, its atomic scale growth mechanism is yet not understood in detail. In this study, the initial stage of the graphene growth processes on a stepped SiC(0001) surface are analyzed by first-principles molecular dynamics (FPMD) simulations. A first-principles calculation code “PHASE”[1] which is appropriate for efficient large scale parallel calculations is used. Our FPMD simulations proceed as follows. Before the start, some of the Si atoms on the top layer are intentionally removed from the initial SiC substrate to emulate the Si heat sublimation. MD is executed for 1 ps, under the condition of high temperature and then relaxed. Next, additional Si atoms are removed from the 2nd top layer, and then the same MD is repeated again. We tracked the behavior of the redundant C atoms during the series of these procedures. Where, when and how do those C atoms start to re-create the new C-C networks will be discussed in detail by comparing the results from several different patterns of the SiC substrates.

A portion of this research was supported by the grant from MEXT’s project and carried out in partnership with the University of Tokyo.

11:27AM Z16.00002 Energy Efficient Growth of Epitaxial Graphene on Hexagonal SiC Surface with Molybdenum Plate Capping during UHV Annealing[1], KIBOG PARK, HAN BYUL JIN, YOUNGEUN JEON, SUNCHUL JUNG, VIJAYAKUMAR MODEPALLI, HYUNG-JOON SHIN, JUNG-WOO YOO, SUNG YOUB KIM, SOON-YONG KWON, UNIST, HYUN SUK KANG, BYUNG CHEOL LEE, KAERI, JAE-HYEON KO, Hallym University, DAEJIN EOM, KRISS — The quality of epitaxial graphene (EG) grown on a hexagonal SiC substrate is found to be improved greatly by capping the surface with a molybdenum plate (Mo-plate) during UHV annealing. The significant reduction of D-peak and increase of 2D-peak in the measured Raman spectra, compared with the spectra for no capping, confirm the crystallinity enhancement of EG film grown with Mo-plate capping. Mo-plate capping is considered to induce heat annealing on SiC surface by thermal radiation mirroring and raise Si partial pressure near surface by confining the sublimated Si atoms between SiC substrate and Mo-plate. These two phenomena can cooperatively facilitate an environment favorable for growing high-quality EG films. A top-gated field effect transistor is fabricated on EG film grown on Si-face 6H-SiC surface at ~ 950 degree C, showing the field effect mobility of ~ 1800 cm^2/Vs. With no need to heat the entire SiC substrate to high temperature over 1300 degree C as in the conventional annealing under UHV or Ar atmosphere, the Mo-plate capping can be an efficient method to reduce energy consumption significantly in growing high quality EG films.

V. I. Artyukhov, Y. Hao, R. S. Ruoff, and B. I. Yakobson, Proc. Natl. Acad. Sci. U.S.A. 11:51AM Z16.00004 CVD growth of single-crystal monolayer graphene on H-terminated germanium surface, DONGMOK WHANG, Sungkyunkwan University — Large-area graphene has been grown by catalytic chemical vapor deposition (CVD) on various metal substrates. However, the uniform growth of single-crystal graphene over wafer-scale areas remains a challenge toward the commercial realization of various electronic, photonic, mechanical, and other devices based upon the outstanding properties of graphene. In this talk, we present the growth of single-crystal monolayer graphene on hydrogen-terminatd germanium (Ge) surface. A single-crystal Ge substrate is a promising candidate for the growth of single-crystal graphene, because of (i) its catalytic activity for the catalytic decomposition of the formation of graphitic carbon on the surface; (ii) the extremely low solubility of carbon in Ge even at its melting temperature, enabling growth of complete monolayer graphene; (iii) the anisotropic atomic arrangement of single-crystal Ge surface, enabling aligned growth of multiple seeds; (iv) the availability of a large area single-crystal surface via epitaxial Ge growth on Si wafers. We observed that well-defined atomic arrangement on the single crystal Ge surface enabled aligned growth of multiple seeds which can merge to single crystal graphene. Furthermore very weak van der Waals interaction between graphene and underlying Ge surface enabled facile transfer of graphene and recycling of the Ge/Si wafer for continuing growth.

Supported by USNSF, USDOE, and NNSF of China.

11:39AM Z16.00003 Atomic Scale Studies of Graphene on Germanium, BRIAN KIRALY, Department of Materials Science and Engineering, Northwestern University, ROBERT JACOBBERGER, Materials Science and Engineering, University of Wisconsin - Madison, ANDREW MANNIX, MARK HERSAM, Department of Materials Science and Engineering, Northwestern University, MIKE ARNOLD, Materials Science and Engineering, University of Wisconsin - Madison, NATHAN GUISINGER, Center for Nanoscale Materials, Argonne National Laboratory — The successful growth of single crystal wafer-scale graphene directly on semiconducting Ge(110) substrates drastically shifted the graphene growth paradigm set in 2009. To further understand the interface between graphene and germanium, we performed ultra-high vacuum scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) experiments of graphene grown on Ge(001), Ge(110) and Ge(111) wafers. The STM studies confirm that graphene grown on the Ge(111) contains rotational disorder resulting in strongly scattering grain boundaries; conversely graphene on the Ge(110) surface demonstrates strong epitaxy. STS shows that the graphene on Ge(111) retains a nearly free-standing character. Upon in-situ annealing, reconstructed surface domains appear underneath the graphene covering up to 90% of the Ge(110) and Ge(111) surfaces. Raman spectroscopy reveals band shifts in graphene G/2D band of up to 12 cm$^{-1}$/50 cm$^{-1}$, attributed to substantial increase in doping from the underlying substrate. This work shows the electronic interaction between graphene and germanium is both tunable and closely related to the atomic reconfiguration of the underlying germanium surfaces.

11:51AM Z16.00004 CVD growth of single-crystal monolayer graphene on H-terminated germanium surface, DONGMOK WHANG, Sungkyunkwan University — Large-area graphene has been grown by catalytic chemical vapor deposition (CVD) on various metal substrates. However, the uniform growth of single-crystal graphene over wafer-scale areas remains a challenge toward the commercial realization of various electronic, photonic, mechanical, and other devices based upon the outstanding properties of graphene. In this talk, we present the growth of single-crystal monolayer graphene on hydrogen-terminatd germanium (Ge) surface. A single-crystal Ge substrate is a promising candidate for the growth of single-crystal graphene, because of (i) its catalytic activity for the catalytic decomposition of the formation of graphitic carbon on the surface; (ii) the extremely low solubility of carbon in Ge even at its melting temperature, enabling growth of complete monolayer graphene; (iii) the anisotropic atomic arrangement of single-crystal Ge surface, enabling aligned growth of multiple seeds; (iv) the availability of a large area single-crystal surface via epitaxial Ge growth on Si wafers. We observed that well-defined atomic arrangement on the single crystal Ge surface enabled aligned growth of multiple seeds which can merge to single crystal graphene. Furthermore very weak van der Waals interaction between graphene and underlying Ge surface enabled facile transfer of graphene and recycling of the Ge/Si wafer for continuing growth.

11:51AM Z18.00002 The magnetic genome project
12:27PM Z18.00003 Distributed databases for materials study of thermo-kinetic properties
CORMAC TOHER, Duke Univ — High-throughput computational materials science provides researchers with the opportunity to rapidly generate large databases of materials properties. To rapidly add thermal properties to the AFLLOWLIB consortium [1, 2, 3, 4] and Materials Project repositories [5], we have implemented an automated quasi-harmonic Debye model, the Automatic GIBBS Library (AGL) [6, 7]. This enables us to screen thousands of materials for thermal conductivity, bulk modulus, thermal expansion and related properties. The search and sort functions of the online database can then be used to identify suitable materials for more in-depth study using more precise computational or experimental techniques. AFLLOW-AGL source code is public domain and will soon be released within the GNU-GPL license.

1:03PM Z18.00004 High-throughput evaluation of descriptors for thermoelectric materials
GEORG MADSEN, Ruhr Univ Bochum — Achieving optimal carrier and minimal thermal conductivity is necessary for a given material to be suitable for thermoelectric energy conversion. Both properties are computationally too demanding for brute force approaches which demands that simplified descriptors are developed. Based on the recent computational discovery of favorable thermoelectric performance in the commercially viable and environmentally friendly Ag:SnS [1], we discuss how doping limits can be computationally screened. We will discuss the effects of two ubiquitous effects that can result in decreasing the hole concentration and show how the surprising results of Li doping can be rationalized based on data made available through on-line repositories. Furthermore, we show how the lattice thermal conductivity can be rapidly and reliably screened based on the quasi harmonic approximation [2]. We contrast this to the information covered by the available phase space for three-phonon scattering processes.

1:39PM Z18.00005 Predicting lattice thermal conductivity with help from ab initio methods
DAVID BROIDO, Boston College — The lattice thermal conductivity is a fundamental transport parameter that determines the utility a material for specific thermal management applications. Materials with low thermal conductivity find applicability in thermoelectric cooling and energy harvesting. High thermal conductivity materials are urgently needed to help address the ever-growing heat dissipation problem in microelectronic devices. Predictive computational approaches can provide critical guidance in the search and development of new materials for such applications. Ab initio methods for calculating lattice thermal conductivity [1] have demonstrated predictive capability, but while they are becoming increasingly efficient [2], they are still computationally expensive particularly for complex crystals with large unit cells. In this talk, I will review our work on first principles phonon transport for which the intrinsic lattice thermal conductivity is limited only by phonon-phonon scattering arising from anharmonicity. I will examine use of the phase space for anharmonic phonon scattering and the Gruneisen parameters as measures of the thermal conductivities for a range of materials and compare these to the widely used guidelines stemming from the theory of Lieb fried and Schöllmann [3]. Session Z19 DFD GSOFT: Invited Session: Shear Thickening of Dense Suspensions Mission Room 103B - Heinrich Jaeger, University of Chicago

11:15AM Z19.00001 Dynamics of Discontinuous Shear Thickening suspensions
ERIC BROWN, Yale University — Concentrated suspensions of hard particles such as cornstarch in water exhibit Discontinuous Shear Thickening, in which an increasing shear rate drives a transition from liquid- to solid-like mechanical behavior. In steady-state shear this phenomena is a result of a dynamic version of jamming in which forces are transmitted along particle contact networks that span to system boundaries and repeatedly form and break up. Several dynamic phenomena observed in such suspensions have long been assumed to be a consequence of this shear thickening, but cannot be explained as a direct result of shear thickening, for example a uniquely strong impact response which allows a person to run on the fluid surface. We perform experiments in which a concentrated suspension is subjected to transient impact. In which we find that the strong impact response is due a short-lived jammed contact network spanning to the boundaries and a delay time required for this dynamically jammed region to propagate to the boundary. The resulting ability of this system-spanning solid-like region to support loads can explain the ability of a person to run on the surface of these fluids. This delay before a solid-like response may also explain several other dynamic phenomena observed in these fluids.

11:51AM Z19.00002 Disentangling the role of hydrodynamic and frictional forces in a shear-thickening suspension
ITAI COHEN, Cornell University — Who among us has not spent countless hours squeezing, rubbing, and smushing gooey substances like, tooth paste, silly putty, corn starch, and even bodily fluids between our fingers? If we could magnify our view and look deep within the substances we are handling what structures would we find? How, do these structures lead to the fascinating mechanical properties that we experience on the scale of our fingers. In this talk I will address the phenomenon of shear thickening in which the viscosity of a suspension increases with increasing shear rate. I will describe recent measurements we have made using a newly developed confocal rheoscope that, for the first time, experimentally visualize the hydrodynamically induced particle clusters. Such clusters have been implicated in continuous shear thickening. It remains controversial as to whether thickening in such suspensions also arises from frictional interactions between particles. The distinct contributions of frictional and hydrodynamic forces are typically difficult to measure independently using conventional techniques. Here, I will describe our approach for using both bulk rheometry techniques and our confocal rheoscope to disentangle their contributions to the total stress response.
12:27PM Z19.00003 Discontinuous Shear Thickening and Dilatancy: Frictional Effects in Viscous Suspensions, JEFFREY MORRIS, Levich Institute, City College of New York — Shear thickening in concentrated suspensions has been well-known for quite a long time, yet a firm consensus on the basis for very abrupt or “discontinuous” shear thickening (DST) seen in suspensions of large solid fraction, $\phi$, has not been reached. This work addresses the DST phenomenon, and proposes a simulation method based in the Stokesian Dynamics algorithm to explore the role of various forces between the particles, including hydrodynamic, conservative potential, and frictional interactions. This work shows that allowance for friction between spherical particles suspended in a viscous liquid causes a significant reduction in the jamming solid fraction of the mixture, $\phi_{\text{max}}$, taken as the maximum fraction at which the suspension will flow. A consequence of this is a shifting of the singularity in the effective viscosity, $\eta$, to smaller $\phi_{\text{max}}$, and the frictional suspension has a larger viscosity than does the frictionless suspension of the same solid fraction, as is clear from the standard empirical modeling of $\eta(\phi) = (1 - \phi)/\phi_{\text{max}}^{1-\alpha}$, $\alpha \approx 2$. When a counterbalancing repulsive force between the particles, representative for example of charge-induced repulsion, is incorporated in the dynamics, the mixture undergoes a transition from frictionless to frictional interactions, and from low to high effective viscosity, at a critical shear rate. Comparison with experimental data shows remarkable agreement in the features of DST captured by the method. The basic algorithm and results of both rate-controlled and stress-controlled simulations will be presented. Like the shear stress, the magnitude of the normal stress exerted by the suspended particles also increases abruptly at the critical shear rate, consistent with the long-standing notion that dilatancy and shear-thickening are synonymous. We will show that all shear thickening materials as dilatant is a misconception, but demonstrate the validity of the connection of dilatancy with DST in concentrated suspensions.

1:03PM Z19.00004 Role of frictional particle interactions for the jamming of dense suspensions, CLAUS HEUSSINGER, Institute for theoretical Physics, University of Goettingen — The jamming paradigm aims at providing a unified view for the elastic and rheological properties of materials as different as foams, emulsions, suspensions or granular media. The usefulness of such a unifying concept hinges on the presence or absence of phenomena that are in some sense universal. One such question is the form of the jamming phase itself. It has long been known that certain suspensions can undergo arrest when driving is strong enough. By way of contrast, standard yield-stress fluids, like dense emulsions, yield when the driving exceeds a threshold. This inversion of the jamming phase diagram can now be linked to the action of frictional forces between the suspended particles. Without frictional forces the material yields and flows at high forces, with friction the material only flows for low forces. As a corollary of this inversion one finds a discontinuous and hysteretic jamming transition as well as continuous and discontinuous shear-thickening regimes.

1:39PM Z19.00005 Setting of an object in a dense suspension, DEVARAJ VAN DER MEER, University of Twente — Constarsh suspensions exhibit remarkable behavior. Here, we present two surprising observations for an object settling in such a suspension. First, in the bulk of the liquid the velocity of the object oscillates around a terminal value, without damping. And secondly, near the bottom of the container the object comes to an expected full stop, but then accelerates again towards a second stop. This stop-go cycle is repeated up to seven times before the object comes to a final standstill close to the bottom. For the bulk oscillations we show that common shear thickening models cannot account for the observed phenomena and that the history of the suspension needs to be taken into account. A hysteretic model that goes beyond the traditional viscoelastic ones describes the experiments adequately, but due to its phenomenological origin lacks a solid physical interpretation. Subsequently, we propose a minimal jamming model to describe the behavior at the bottom. Finally, we will compare our experiments to other transient and steady state phenomena observed in dense suspensions and discuss them in the context of compressional and shear jamming.

Friday, March 6, 2015 11:15AM - 2:15PM — Session Z20 DPOLY: Invited Session: Physics of Entanglements
Ballroom B - Scott Milner, Pennsylvania State University

11:15AM Z20.00001 Shear banding in time dependent flows of polymers and wormlike micelles, SUZANNE FIELDING, Durham University — We study theoretically the formation of shear bands in time-dependent flows of polymeric fluids and wormlike micellar surfactant solutions, focussing in particular on the commonly studied experimental protocols of step shear stress and shear startup. For each protocol, we perform a linear stability analysis to provide a fluid-universal criterion (with some caveats in the case of shear startup) for the onset of shear banding (following Moorcroft and Fielding Phys. Rev. Lett. 2013). In each case this criterion depends only on the shape of the experimentally measured rheological response function for that protocol, independent of the constitutive properties of the material in question. In this way our criteria in fact concern all complex fluids and not just the polymeric ones of interest here. (See Fielding Rep. Prog. Phys. 2014 for a study of these effects in a broad class of soft glassy materials including dense emulsions, microgels and dense colloids.) An important prediction is that pronounced shear banding can arise transiently in each of these time-dependent protocols, even in fluids for which the underlying constitutive curve of the material (stress as a function of strain-rate) is monotonic and a steadily flowing state is accordingly unbanded. Further details can be found in Moorcroft and Fielding J. Rheol. 2014.

11:51AM Z20.00002 How polymer entanglement responds to fast large deformation: are we there yet?, SHI-QING WANG, University of Akron — Nearly all polymeric materials are of high molecular weight and therefore entangled in their liquid state. Significant melt elasticity arises from the transient networking due to chain entanglement. All rheological behavior stems from how the entanglement responds to external deformation of various forms. Unfortunately, the concept of entanglement still remains theoretically elusive to describe. On other hand, modeling the evolution of chain entanglement is the core questions in polymer rheology: a) where chain deformation comes from? b) when affine-like elastic molecular deformation ceases? In other words, yielding at both macroscopic (which is obviously taking place, e.g., signified by the stress overshoot response to startup shear) and molecular levels (through chain disentanglement) is an essential ingredient of any theoretical description of nonlinear polymer rheology. Macroscopic observations are valuable to afford useful insights, but it is the molecular dynamics simulations that are expected to address the foundational issues. This presentation will attempt to make a coherent discussion of what is known and where we are going from here.

1 National Science Foundation (DMR-1105135)

12:27PM Z20.00003 From molecules to non-linear rheology of highly branched, entangled polymers: getting your priorities right, DANIEL READ, The University of Leeds — The tube model for polymer dynamics offers the promise of predicting the flow properties of entangled polymeric liquids. Given a knowledge of the sizes and shapes of the polymers, the tube model suggests dynamical rules for the relaxation of stress carried by the molecules. Over the last couple of decades these rules have been, for the most part, established through experiments and simulations on liquids containing molecules of well-defined size and shape. For prediction of small amplitude flows, these rules are now codified in computer algorithms such as Larson’s hierarchical model (http://www.ingin.umich.edu/dept/che/research/larson/) and our own “BoB” model (http://sourceforge.net/projects/bob-rheology). As a result, it is now possible to make meaningful predictions for flow properties of industrial polymeric resins with distributions of randomly branched structures. Since real polymers are subjected to large deformations in realistic processing, we have recently extended the above work to prediction of the large-deformation response of branched polymers. This talk will describe the extra physics that applies in the non-linear flow regime, and how this has been implemented in our model: the central message is that one needs to know three quantities for every strand in the resin: 1) an orientation relaxation time, (2) a stretch relaxation time, and (3) a limiting value for the chain stretch. The latter is often discussed in terms of a topological quantity known as “priority.” Motivated by recent experiments on well defined “comb” molecules, we discuss some shortcomings in our current prediction of the “priority” and how this may be improved upon.
1:03PM Z20.00004 Entangled linear, branched and hyperbranched polymers in shear flow. DIMITRIS VLASTOSPOULOS, FORTH-IESL and University of Crete — Despite substantial progress in understanding the dynamics of long flexible polymers, several outstanding challenges remain. We address some of them. We discuss the response of well-characterized linear and branched (stars, combs, H) polymers to simple shear flow. The start-up stress behavior at high shear rates exceeding the inverse Rouse time, where according to tube-model theories polymer chains are oriented (and eventually stretched), is considered. We identify conditions under which combs are considered as effective diluted linear chains. We address the failure of stress-optical and Cox-Merz rules and the role of branching. Relaxation upon flow cessation is analyzed and a connection to convected constraint release is suggested. We apply the “probe rheology” approach to branched polymers diluted in polymeric matrix. Careful choice of matrix molar mass allows controlling constraint release effects. The shear response of asymmetric linear chain mixtures is also discussed in the context of recent studies in uniaxial extension suggesting enhancement of extensional viscosity. Entanglement-like effects are observed in dendronized polymers with branches below the entanglement limit, which interpenetrate to reduce inherent density heterogeneity.

1:39PM Z20.00005 Polymer twist: entanglement and packing ansatz. JIAN QIN, University of Chicago — Polymers in dense liquids (molten plastics) are severely constrained by surrounding chains, due to the fact that chains cannot cut through each other. Effectively, polymers may be considered as being confined inside a tube-like region. The tube diameter is the key parameter needed by the modern molecular theory for polymer rheology. But a molecular understanding of the tube diameter is missing. We summarize our recent attempts at estimating the tube diameter from simulated topologically equilibrated ring polymers, which have well-defined topological states and are free from the complication caused by chain end relaxation dynamics. We consider two non-invasive methods for estimating the tube diameter, one based on the extent of bead position spreading over an ensemble of short dynamic trajectories, and another based on statistics of topologically distinct states collected with the help of a generalized knot invariant.

Relaxation dynamics. We consider two non–invasive methods for estimating the tube diameter, one based on the extent of bead position spreading over an ensemble of short dynamic trajectories, and another based on statistics of topologically distinct states collected with the help of a generalized knot invariant. For simulated polymer melts, we get a tube diameter value that agrees with values obtained by more heuristic methods. We then present results on the effects of chain stretching and neutral solvent dilution on the tube diameter, and examine the three possible variants of the Lin-Noolandi packing arguments for the tube diameter, which all yield the same prediction for unperturbed polymer melts, but each gives different prediction when applied to stretched and diluted systems. The analyses are in favor of a binary view of polymer entanglement.

Friday, March 6, 2015 11:15AM - 1:15PM – Session Z21 Vanadium Oxides II

201 - Mengkun Liu, Stony Brook University

11:15AM Z21.00001 Study of microstructure effects on the photo-induced Metal-insulator transition in VO₂ thin films grown on Al₂O₃ and TiO₂¹. ELIZABETH RADUE, LEI WANG, College of William and Mary, SALINPORN KITTIWATANAKUL, JIWEI LU, STUART WOLF, University of Virginia, ENRICO ROSSI, R.A. LUKASZEW, IRINA NOVIKOVA, College of William and Mary — We studied the optical response of the VO₂ thin films undergoing photo-induced metal-insulator transition (MIT) of VO₂ and found the change in reflectivity over time to be highly dependent on the substrate on which the film was grown [1]. Specifically, we have looked at two different VO₂ thin film samples, one grown on TiO₂ and one grown on Al₂O₃, in a pump-probe configuration, and found that the strain and differences in microstructure resulted in substantial difference in the fluence threshold needed to induce MIT, as well as in the relaxation times back to the insulating state. By mounting the films in a cryostat, we also found that the fluence needed to achieve full MIT for the film on TiO₂ substrate did not depend on the sample temperature, implying that different mechanisms may be playing a stronger role in one film rather than the other for an optically induced transition.

11:27AM Z21.00002 Surface Plasmon Resonance and Insulator-Metal Transition in Gold and Vanadium Dioxide Bilayer Films. MELISSA BEEBE, LEI WANG, SCOTT E. MADARAS, J. MICHAEL KLOPF, ZHAOZHU LI, DAVID BRANTLEY, MATTHEW HEIMBURGER, COLLEGE OF WILLIAM & MARY, RUSSELL A. WINCHESKI, JIWEI LU, STUART A. WOLF, University of Virginia, R.A. LUKASZEW, College of William & Mary — Under certain conditions, thin films of noble metals such as gold and silver exhibit intense surface plasmon polaritons (SPP), in what is called surface plasmon resonance (SPR). These are charge oscillations along the air/film interface resulting from the interactions between an illuminating wave and the free electrons at the conductor’s surface. There are many possible applications of the SPR, including new plasmonic optoelectronic devices, biological sensors, and new imaging methods [1,2]. We now present correlated experimental studies and simulations on the modulation of the SPP in Au/VO₂ bilayers by the metal insulator transition (MIT) of VO₂, opening up new possible applications. The modification of the SPP wave vector by the thermally-induced MIT in VO₂ was investigated by measuring the optical reflectivity of the sample when SPP’s were excited via gratings patterned on the Au surface and also in Kretschmann configuration in Au/VO₂ bilayers.

11:39AM Z21.00003 Low-frequency noise spectroscopy of vanadium dioxide along the metal to insulator transition. SAHAR KESHAVARZ, PATRICK LECLAIR, Center for Materials for Information Technology (MINT), Department of Physics and Astronomy, University of Alabama Tuscaloosa, Al 35487, USA; ARUNAVA GUPTA, Center for Materials for Information Technology (MINT), Department of Chemistry, University of Alabama Tuscaloosa, Al 35487, USA; SANJOY SARKEY, Department of Physics and Astronomy, University of Alabama Tuscaloosa, Al 35487, USA — VO₂ exhibits ultrafast, reversible metal-insulator transition (MIT) around T ~ 340K. Origin and mechanism of VO₂ MIT has been controversial, since it simultaneously undergoes a structural transition. One key feature of the MIT is coexistence of metallic and insulating regions over a broad temperature range. We propose low-frequency noise spectroscopy to clarify the nature of this phase coexistence. Noise spectroscopy is more sensitive to details of current distribution, and thus the distribution of metallic and insulating regions, than traditional transport. Epitaxial films of VO₂ have been deposited on (100), (110) and (001) TiO₂ substrates by CVD and were tested by XRD, resistivity versus temperature, and AFM to ascertain quality. As the result, low-frequency 1/f noise amplitude diverges around onset of transition along c-axis, with noise depending non-monotonically on resistivity. On the other hand, it depends monotonically on resistivity along a-axis. This indicates the critical role of structural dynamics during the transition, and in particular strongly suggests that fluctuations of the V-V dimers along c-axis play a prominent role in MIT. Our findings contradict expectations for noise behavior based on simple percolation models.

12:51PM Z21.00009 Direct Hall effect measurement on a single vanadium dioxide nanowire.
1:03PM Z21.00010 Crossbar structures of vanadium dioxide nanobeams1, ZHENG YANG, KETAKI SARKAR, University of Illinois at Chicago, YANG RESEARCH GROUP TEAM — A crossbar structure composed of two individual one-dimensional nanostructure such as nanowire, nanotube, graphene nanoribbon crossed with each other has been of great interest for nanoelectronic, photonic, and memory device applications as well as novel phenomena in fundamental science. Here we report crossbar nanostructures based on crossed vanadium dioxide nanobeams. Vanadium dioxide show a metal-insulator transition at \( \approx 340K \) with a sharp (3-5 orders of magnitude) resistance change accompanying with a structural change from monoclinic to tetragonal structures. Besides the thermal-triggering, other excitations in form of electrical, photo, strain can also trigger the phase transition. In recent years lots of efforts have been focused on how to utilize the metal-insulator phase transition in vanadium dioxide for device applications (ref: Zheng Yang et al, Oxide electronics utilizing ultrafast metal-insulator transitions, Annual Review of Materials Research, 2011, 41, 337). In this presentation, the growth, fabrication, structural and electrical properties of the vanadium dioxide nanobeam crossbars will be reported. The potential device applications of vanadium dioxide nanobeam crossbars will be discussed.

11:15AM Z22.00001 Atomtronics: The Application of Organometallic Bis-Hexahapto Bonding to the Electrical Interconnection and Electronic Conjugation of the Graphitic Surfaces of Carbon Nanotubes and Graphene, ROBERT HADDON, University of California at Riverside — We have demonstrated the functionalization of epitaxial graphene with nitrophenyl groups and by the application of the Kobe reaction. The chemical formation of covalent carbon-carbon bonds involving the basal plane carbon atoms offers an alternative approach to the control of the electronic properties of graphene; the transformation of the carbon centers from sp\(^2\) to sp\(^3\) introduces a barrier to electron flow by saturating the carbon atoms and opening a band gap which potentially allows the generation of insulating, semiconducting and magnetic regions in graphene wafers.1 This raises the question of the role of covalent bonding in the interconnection of graphitic surfaces and the prospects for the use of such bonds in electronically conjugating neighboring carbon nanotube and graphene surfaces without saturating and destructively rehybridizing the carbon atoms at the point of attachment while simultaneously maintaining the band structures of the intact benzoid nanostructures. In this talk I will discuss our recent results on the covalent modification of the electronic structure and properties of graphene, and the application of organometallic chemistry to facilitate the interconnection of single-walled carbon nanotubes and to increase the dimensionality of graphitic surfaces. 1. 12:03PM Z22.00003 Theory of Chiral Transport in Chiral Carbon Nanotubes1, MASAKI NORO, Tokyo Institute of Technology, JYUNYA TANAKA, None, SHUICHI MURAKAMI, TAKEHITO YOKOYAMA, Tokyo Institute of Technology — In a chiral carbon nanotube, lower crystallographic symmetry allows chiral transport. Namely, when carriers exist by doping, an electric current along the tube axis induces a current around the tube. We calculate the chiral conductivity in carbon nanotubes induced by an electric field along the nanotube axis. We use a tight-binding model for various carbon nanotubes with different chiralities, and apply a constant relaxation time in Boltzmann transport equation. Because the band structure is different for each chiral carbon nanotube, we set electron concentration to be constant to compare quantitatively the chiral conductivity for each nanotube. We find that the chiral conductivity in chiral nanotube is in general non zero, and have either signs depending on their chiralities. We discuss the dependence on the chirality in comparison with the band structure in single-layer graphene, and attribute the chiral transport to the warping of the Fermi surface around the K and K’ point in graphene.

12:15PM Z22.00004 Electron and Optical Spectroscopies of Graphene Nanoribbons on Au(111): Insights from Ab-Initio Calculations, ANDREA FERRETTI, SHUDONG WANG, DEBORAH PREZZI, 53 Center, Istituto Nanoscienze, I-41125, Modena, Italy, ALICE RUINI, ELISA MOLINARI, University of Modena and Reggio Emilia, FIM dept & S3 Center, Istituto Nanoscienze, I-41125, Modena, Italy — Narrow graphene nanoribbons (GNRs) exhibit substantial electronic band gaps and optical properties expected to be fundamentally different from the ones of their parent material graphene. Unlike graphene the optical response of GNRs may be tuned by the ribbon width and the directly related electronic band gap. In this work we perform ab initio calculations and compute quasiparticle energies and optical properties of GNRs within the so-called GW-BSE scheme. We focus on a specific armchair nanoribbon (7-AGNR). The presence of the substrate is accounted for by means of a classical image charge model for the screened Coulomb interaction. Our findings show that the metallic substrate induces a significant reduction of the energy gap as compared to the isolated 7-AGNR, bringing the GW gap from 3.7±0.1 eV to 2.3-2.7 eV on Au(111). On the contrary, the position of the optical peaks remains unaltered. Our results are in very good agreement with the experimental values obtained by STS, ARPES, and differential reflectance data, indicating that this scheme can provide quantitative predictions for electron and optical spectroscopies of nanoribbons on weakly coupled substrates such as Au.

12:27PM Z22.00005 First-principles calculations of the phonon transport in carbon atomic chain systems based on atomistic Green’s function formalism1, HU SUNG KIM, YONG-HOON KIM, Graduate School of EEEWS, Korea Advanced Institute for Science and Technology — We report on the phonon transport in carbon chain systems, and cumulene. We utilized first-principles calculation with localized atomic basis sets to calculate interatomic forces. Calculated phonon dispersion of polyyne and cumulene were well-matched with theoretical expectations. In addition, we considered the strain effect on the phonon properties of the carbon chain systems. The applied strain affected bond-length alternation (BLA) and force interaction range. Finally, even and odd carbon atomic chains bridging two zigzag graphene nanoribbons were investigated. Increase in the phonon contribution on thermal conductivity was found in case of even carbon chains with proper amount of strain.

12:51PM Z22.00007 Exploring SAMO states of fullerenes with angle-resolved fs photoelectron spectroscopy

Eleanor Campbell, Elvira Bohl, Olof Johansson, University of Edinburgh, Benjamin Mignolet, Stanford University, Francois Remacle, University of Liege — Femtosecond photoelectron spectroscopy of fullerenes provides a powerful means to study excited Rydberg-like states that cannot be probed via conventional spectroscopy. The photoelectron spectra (PES) show a thermal electron background with a superimposed peak structure for photoelectron kinetic energies that lie below the laser photon energy. The peak structure has been assigned to one-photon ionisation of diffuse low-angular momenta states, so-called superatom molecular orbitals (SAMOs) centred on the hollow fullerene core, based on photoelectron angular distributions (PADs) and TD-DFT calculations. The relative photoionisation probabilities of the s-SAMO to p-SAMO were analysed for photon energies from 2-3.5 eV and showed good agreement with theoretical calculations. Here we look at the photoionisation probabilities and photoelectron angular distributions as a function of laser wavelength and, in particular, directly probe the influence of an endohedrally-trapped atom on the photoelectron spectra by directly comparing C60 and Li@C60. We also provide preliminary measurements to probe the timescale for thermal emission prior to coupling to vibrational degrees of freedom.

12:59PM Z22.00008 Relative stability of excitonic complexes in quasi-one-dimensional semiconductors

Igor Bondarev, North Carolina Central University — A configuration space approach first implemented in Ref.[1] to evaluate biexciton binding energies in carbon nanotubes (CNTs), is developed to obtain the universal asymptotic relations for the lowest energy trion and biexciton binding energies in quasi-1D semiconductors. Triions are shown to be generally more stable (have greater binding energy) than biexcitons in strongly confined quasi-1D structures with small reduced electron-hole masses, while biexcitons are more stable than triions in less confined quasi-1D structures with large reduced electron-hole masses. As such, there is a crossover behavior whereby triions get less stable than biexcitons as the nanostructure transverse size increases — an interesting, quite a general effect which could likely be observed through comparative measurements on semiconducting CNTs of increasing diameter. For a specific case of CNTs with diameters ≤ 1 nm, the model predicts the triion binding energy greater than that of the biexciton by a factor ≈ 1.4, decreasing with the CNT diameter, thus revealing the general physical principles that underlie recent experimental observations [2,3].

12:59PM Z22.00009 Optical detection of highly delocalized superorbitals in fullerenes

Guoping Zhang, Yihua Bai, Indiana State University; Thomas F. George, University of Missouri-St. Louis — Superatom molecular orbitals (SAMOs) in C60 are a group of highly delocalized orbitals, extending several nanometers outside the carbon cage, but unfortunately they are hard to detect optically. Here we employ three independent first-principles methods to show that the optical detection of SAMOs is possible for the multiphoton excitation, where successive absorptions of photons boost the optical cross section. In the case of the 1f orbital, we find that our theoretical photoelectron angular distribution matches the unpublished experimental one quantitatively. Experimental confirmation of our prediction will help explain why the mysterious 4-nm separation between C60 and organic compounds is essential to the efficiency of all the fullerene-based organic solar cells.

12:59PM Z22.00010 Understanding Faceting in Boron-Nitride and Carbon Nanotubes

Robert Guerra, International School for Advanced Studies (SISSA), Via Bonomea 265, 34136 Trieste, Italy; Itai Leven, Department of Chemistry School of Chemistry, The Raymond and Beverly Sackler Faculty of Exact Sciences, Tel-Aviv University, Tel-Aviv 69978 (Israel); Andrea Vanossi, CNR-IOM Democritos National Simulation Center, Via Bonomea 265, 34136 Trieste, Italy; Erio Tosatti, International School for Advanced Studies (SISSA), Via Bonomea 265, 34136 Trieste, Italy; Oded Hod, Department of Chemistry School of Chemistry, The Raymond and Beverly Sackler Faculty of Exact Sciences, Tel-Aviv University, Tel-Aviv 69978 (Israel); NanoFriction Group Trieste TEAM, Oded Hod Group @ Tau TEAM — Graphite and hexagonal boron nitride (h-BN) are known to share many structural characteristics such as interlayer spacing and bond length, in spite of their completely different atomic bond types, nonpolar homonuclear and strongly polar, respectively. Only recently, a connection of static polarizability and bond polarity with the interlayer spacing and stacking energetics in the two materials has been elucidated [1]. Yet, in the case of curved sheets forming a nanotube (NT), the presence of angular strain and non-uniform stacking between the layers give rise to complex force patterns that subtly differ in the two cases. By means of classical MD simulations of h-BN and carbon NTs we reveal how the interplay between angular strain and lateral interlayer forces enable the formation of facets in the two materials. The role of the curvature (NT size) and of chirality is discussed along with the important consequences of faceting in the static and frictional properties of multiwall NTs.

1:55PM Z22.00011 Exploring SAMO states of fullerenes with angle-resolved fs photoelectron spectroscopy

Eleanor Campbell, Elvira Bohl, Olof Johansson, University of Edinburgh, Benjamin Mignolet, Stanford University, Francois Remacle, University of Liege — Femtosecond photoelectron spectroscopy of fullerenes provides a powerful means to study excited Rydberg-like states that cannot be probed via conventional spectroscopy. The photoelectron spectra (PES) show a thermal electron background with a superimposed peak structure for photoelectron kinetic energies that lie below the laser photon energy. The Origin of Negative Thermal Expansion in sp-sp² Hybridized Carbon Systems: Rigid Unit Modes

1:39PM Z22.00011

Cheol-Woon Kim, Seoung-Hun Kang, Young-Kyun Kwon, Kyung Hee University — Based on first-principles density functional theory, we investigate the thermal expansion behaviors of three kinds (α, β, and γ) of graphene, which is two-dimensional carbon allotrope composed of sp² and sp³ hybridized bonds. Using quasi-harmonic approximation, their Gibbs free energies are calculated as a function of 2D area and temperature to evaluate their temperature-dependent area variations. We find that all three kinds of graphene exhibit negative thermal expansion behaviors up to quite high temperature as similarly seen in graphene. Their thermal contraction can be explained partially by the ripple effect as observed in graphene, which seems, however, somewhat insufficient for their much larger thermal contraction than that of graphene. Their anomalously huge thermal contraction behaviors are attributed mainly to unusual phonon modes with a frequency of a few hundreds of cm⁻¹, which do not exist in graphene. These modes are identified to "rigid unit modes (RUMs)". The librational modes of "rigid units" composed only of sp³-bonds. RUMs are unusual in 2D materials, but known to be resolvable for the negative thermal expansion in various metal oxides composed of rigid polyhedra, such as MoO₃, where M is a metal cation.

Spectroscopy and microscopy of coronene-carbon nanotube hybrid structures

Katalin Kamaras, Beata Nagy, Hajnalka Tohati, Wigner Research Centre for Physics, Budapest, Hungary, Bea Botka, Rudi Hackl, Walther Meissner Institute, Garching, Germany, Thomas Chamberlain, Andrei Khlobystov, University of Nottingham, United Kingdom — The flat, disc-shaped polyaromatic hydrocarbon coronene and its derivatives can form various hybrid structures with carbon nanotubes: its size makes encapsulation possible for the most abundant carbon nanotubes, and its conjugated π-electron structure enables π–π bonding on the surface of the nanotubes. Depending on synthesis conditions, adsorption, encapsulation and polymerization reactions are all possible, resulting in coronene-based polymers, graphene nanoribbons or double-walled carbon nanotubes. Synthesis and characterization of such hybrid structures will be reported. Synthesis variations included sublimation temperature and exchanging the hydrogen atoms on the perimeter of the molecule for other atoms. Characterization was performed by transmission electron microscopy, as well as infrared, Raman and photoluminescence spectroscopy. We will present how synthesis conditions affect the reaction of the molecular species to form polymers or nanoribbons. We find that the nanotube surface catalyses the polymerization of coronene, and that non-carbon atoms other than hydrogen on the perimeter facilitate nanoribbon formation.

Classifying symmetry-protected topological phases through the anomalous action of the symmetry on the edge

Dominic Else, Chetan Nayak, Department of Physics, University of California, Santa Barbara, CA — It is well known that (1 + 1)-D bosonic symmetry-protected topological (SPT) phases with symmetry group G can be identified by the projective representation of the symmetry at the edge. Here, we generalize this result to higher dimensions. We assume that the representation of the symmetry on the spatial edge of a (d + 1)-D SPT is local but not necessarily on-site, such that there is an obstruction to its implementation on a region with boundary. We show that such obstructions are classified by the cohomology group H^{d+1}(G, U(1)), in agreement with the classification of bosonic SPT phases proposed by Chen et al [Science 338, 1604 (2012)]. Our analysis allows for a straightforward calculation of the element of H^{d+1}(G, U(1)) corresponding to physically meaningful models such as non-linear sigma models with a theta term in the action. SPT phases outside the classification of Chen et al are those in which the symmetry cannot be represented locally on the edge. With some modifications, our framework can also be applied to fermionic systems in (2+1)-D.

Topological phase transition in a bilayer toric code model

Hong-Chen Jiang, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Yuan-Ming Lu, Department of Physics, The Ohio State University, Ashvin Vishwanath, Department of Physics, University of California, Berkeley — We study a bilayer toric-code model in two spatial dimensions by density matrix renormalization group approach. We show that as the interlayer coupling is increased, the system goes through a continuous phase transition from two decoupled copies of Z₂ topological orders (bilayer limit) to a single Z₂ topological order (monolayer limit). This phase transition is revealed by a jump of topological entanglement entropy. Moreover, the two phases are featured by distinct topological properties: in the bilayer limit the system supports symmetry protected gapless edge states, while the edge states are fully gapped in the monolayer limit. The nature of this continuous topological phase transition is also investigated.

Predicting Heat Transport across Multiple Tokamaks with Neural Networks

Christopher Luna, Arizona State University, Robert Budny, Princeton Plasma Physics Laboratory, Orso Meneghini, Sterling Smith, General Atomics, James Penna, MIT — Three multi-layer, feed-forward, back-propagation neural networks have been built and trained on heat transport data from DIII-D, TFTR, and JET respectively. A comparative analysis shows that previous success of neural networks in predicting heat transport in DIII-D [1] is reproduced for TFTR and JET. The effect of using different neural network topologies has been investigated across all of the devices. It is found that the neural networks can consistently predict the total species' heat fluxes for all of the devices, however they have difficulty in predicting the individual transport modes identified to "rigid unit modes (RUMs)", the librational modes of "rigid units" composed only of sp³-bonds. RUMs are unusual in 2D materials, but known to be resolvable for the negative thermal expansion in various metal oxides composed of rigid polyhedra, such as MoO₃, where M is a metal cation.

Incompleteness of General Relativity, Einstein’s Errors, and Related Experiments

C.Y. Lo, Applied and Pure Research Institute — General relativity is incomplete since it does not include the gravitational radiation reaction force and the interaction of gravitation with charged particles. Einstein’s covariance principle is invalid. There is no bounded dynamic solution for the Einstein equation. Thus, Gullstrand is right and the 1993 Nobel Prize for Physics press release is incorrect. Awards to Christodoulou reflect the blind faith toward Einstein and accumulated errors. The Einstein equation with an electromagnetic source has no valid solution unless a photonic energy-stress tensor with an anti-gravitational coupling is added. Thus, the photonic energy includes gravitational energy and Einstein’s theory needs improvement. The existence of anti-gravity coupling implies that the energy conditions in space-time singularity theorems of Hawking and Penrose cannot be satisfied in physics. The positive mass theorem of Yau and Schoen is misleading in physics, though considered an achievement by the Fields Medal. E = mc² is not valid for the electromagnetic energy alone. The discovery of the charge-mass interaction establishes the need for unification of electromagnetism and gravitation and would explain many puzzles. Experimental investigations for further results are important.

12:39PM Z23.00008 Derivative Structure Enumeration: Trimming a Combinatoric Tree1. WILEY S. MORGAN, Department of Physics and Astronomy Brigham Young University, RODNEY W. FORCADE, Department of Mathematics Brigham Young University, ANDREW RAPPE, University of Pennsylvania — In computational material science, one frequently needs to have a list of the “derivative superstructures” of a given lattice. For example many phases in metal alloys are merely “superstructures” of fcc, bcc, or hcp lattices (L12, B2, D019, etc.). When modeling potential alloys one needs to explore all possible arrangements of atoms on the lattice sites. The simple solution to this combinatorics problem is to generate the list of all possible configurations and then eliminate those that are symmetrically equivalent. This approach, however, suffers from the combinatoric explosion that happens when the supercell size is large or when there are more than two atom types. This problem persists even when there are only a relatively small number of unique configurations that survive the elimination process. Our new algorithm avoids this problem by generating “partial configurations,” then using group theory, it eliminates large classes of configurations in a single step. With this approach one can consider larger systems, such as multinary ground state searches, high entropy alloys, etc.

12:51PM Z23.00009 Robust Computational Physics and Automated Sanity Checks1, CONRAD W. ROSENBROCK, GUS L.W. HART, Brigham Young University - Provo — A good computational physics course teaches students to say ‘well that’s completely wrong’ anytime the computer gives them a result. Once cast in doubt, it is the scientist’s responsibility to convince themselves that the result is in fact correct. As programs become more complicated, it usually becomes more difficult to guarantee that the final output is right. I will present a new framework that automates the production of robust, high quality Fortran code. The talk will include a brief overview of good coding principles and a demonstration of the most useful features of the framework that help automate implementation of these principles. By providing an XML-based documentation standard and automated unit testing, Fortpy1 helps researchers ensure that their code produces accurate physics and is easier to use by others.

1:03PM Z23.00010 Equilibrium shape of colloidal crystals. DIMITRIOS MAROUDAS, RAY SEHGAN, Univ of Mass - Amherst — Clusters of colloidal crystals exhibit a wide range of size dependent properties. Leveraging such properties requires a strong fundamental understanding of the thermodynamics of colloidal clusters. A first step in developing this understanding is to accurately describe the equilibrium structure and morphology of these assemblies. In this presentation, we report the results of a generalized Wulff construction that is able to accurately describe the equilibrium, i.e., of minimum free energy, shape of an assembly of colloidal particles. The colloidal system that we focus on is modeled with an interparticle interaction consisting of two terms, an electrostatic repulsion and an Asakura-Oosawa (AO) depletion attraction. The generalized Wulff construction can account for both surface facet and surface edge effects on the stable colloidal crystalline morphology. This construction results in a configuration of minimum free energy for given crystal volume. We carry out these equilibrium shape calculations over a range of crystal sizes to examine size dependent effects on the stability of colloidal clusters. These calculations enable the determination of cluster sizes which exhibit improved stability (lower free energy) compared to that of similar-size clusters.

1:15PM Z23.00011 Coarsening Simulation with an Energy-Stable, Semi-Implicit Time Step. BENJAMIN VOLLMAYR-LEE, Bucknell University — Coarsening dynamics is effectively described by phase field models, which provide nonlinear field equations of motion that can be integrated numerically. However, these simulations are hampered by a numerical instability that imposes time marching with a fixed-size time step decomposition in any model and use an artificial viscosity, which adds an additional restriction, and that has the additional feature of being linear in the implicit fields, allowing for efficient calculation with fast Fourier transforms. Using this method enables simulations to extend decades farther into the coarsening scaling regime. I will report measurements of a variety of coarsening exponents obtained with this method.

1:39PM Z23.00013 Developing Accurate and Transferable Artificial Neural Network Potentials for Li-Si Alloys1. BERK ONAT, EKIN DOGUS CUBUK, BRAD MALONE, EFFTHIMIOS KAXIRAS, Department of Physics and School of Engineering and Applied Sciences, Harvard University — Investigation of the lithiation and delithiation of Si anode in Li-ion batteries using realistic simulations is important and requires large numbers of atoms and long time scales which is generally inaccessible with first-principle approaches. These simulations can be carried out using interatomic potentials that can capture the dependence of structure on chemical composition. Compared with the fixed functional form of empirical potentials, a promising approach to construct the potential energy surface is using artificial neural networks (ANN) that extends the time scales of simulations without sacrificing the accuracy and transferability. Using ab-initio density functional theory data for training, we developed an environment-dependent high-dimensional ANN potential for Li-Si alloys. Our calculations based on the geometry optimizations and molecular dynamic simulations show that the developed potential can accurately predict total energies and equilibrium structures of Li, Si and Li-Si alloys. Using several training databases that include different concentrations of Li in the alloy, we investigated the range of the validity of the ANN potential. Our results show that ANN potentials are widely transferable to Li-Si alloys with various concentrations of Li.

11:15AM Z24.00001 Tenfold speed up of DFT: Improving k-point integration. GUS HART, Brigham Young University, DEREK C. THOMAS, University of Texas at Austin, JEREMY J. JORGENSEN, MATTHEW M. BURBIDGE, BRENT C. HESS, CONRAD W. ROSENBROCK, Brigham Young University, IAN H. SLOAN, University of New South Wales, RODNEY W. FORCADE, Brigham Young University, STEFANO CURTAROLO, Duke University — The amount of recent cpu time (> 100 mega cpu hours) spent in our group on high-throughput materials prediction led us to re-examine convergence issues in standard DFT calculations. For total energy calculations, k-point convergence can be increased two-fold and ten-fold for semiconductor and metals, respectively. For semiconductors, the popular “rectangle approximation method” using Monkhorst-Pack grids converges much faster than expected (for reasons that will be explained), which explains why it gained popularity in the early development of DFT codes. (Its simplicity is also a likely factor.) However, it is not possible to adapt the method to the case of partially-occupied bands in metals while preserving the rapid convergence of semiconductors. Using a rectangle rule for metals, irrespective of any smearing method, leads to the well-known problem that convergence rates are 100s times worse than for semiconductors. Revisiting the k-point integration issue in light of modern DFT practice, we demonstrate that this “metal deficit” can be reduced to only a factor of 5–10 worse than semiconductors. The further complication of integrating inside the Fermi surface for metals is solved with our approach without the need for smearing and its associated ad hoc parameters.

11:27AM Z24.00002 Strongly Interacting Molecular Subsystems Using DFT-in-DFT Embedding Theory with External Orbital Orthogonality. PATRICK TAMUKONG, MARK HOFFMANN, Univ of North Dakota, YURIY KHAIT, None — Since most ab initio methods for molecular electronic structure are limited in applicability by polynomially increasing computational costs with system size, localization and embedding techniques are among the leading research efforts in the development of methods that can well describe large systems. Since embedding schemes naturally use a “divide and conquer” approach, they are particularly attractive. We recently introduced a new variant of DFT-in-DFT embedding theory that enforces orbital orthogonality between subsystems, thereby completely obviating the use of error-prone kinetic energy functionals; moreover, no calculation of the total system is required at any stage. Here, we present density difference maps and potential energy curves for selected strongly interacting subsystems, including complete dissociation of covalent bonds, obtained with our new embedding protocol. The electron density difference maps presented here compare densities obtained with the new embedding method, and with conventional DFT-in-DFT, to Kohn-Sham (KS)-DFT selected strongly interacting subsystems, including complete dissociation of covalent bonds, obtained with our new embedding protocol. The electron density difference maps presented here compare densities obtained with the new embedding method, and with conventional DFT-in-DFT, to Kohn-Sham (KS)-DFT densities. It is shown that whereas conventional DFT-in-DFT leads to large density deviations, particularly at the interfaces between subsystems, the new method accurately represents the density at all points in space and leads to only negligible density deviations ($\approx 10^{-5} e/\text{a}_0^3$). To our knowledge, this new embedding method is the first variant of DFT-in-DFT to accurately dissociate actual covalent bonds.

11:39AM Z24.00003 Effect of uniaxial and biaxial strain on the electronic and dynamical properties of CdO: ACBN0 functional study. JACOB GALLAWAY, University of North Texas, PRIYA GOPAL, MARCO FORNARI, Central Michigan University, STEFANO CURTAROLO, Duke University, MARCO BUONGIORNO NARDELLI, University of North Texas — We have investigated the influence of uniaxial and biaxial strain on the electronic and vibrational properties of CdO in the rocksalt structure using Density functional theory calculations with our newly developed ACBN0 pseudo–hybrid Hubbard density functional. ACBN0 is a fast, accurate and parameter-free extension of traditional DFT+U proved to correct both the band gap and the relative position of the different bands in transition metal compounds. CdO is a technologically important materials with a direct band-gap of 2.2 eV, which makes it a potential candidate for applications as transparent conductor (TCO) in optoelectronic devices. In such devices, CdO is often grown as a thin film on a substrate and this substrate induces strain that alters the electronic properties. It is clearly very important to understand this phenomenon to properly predict the performance of these devices. All earlier first principles making the system semi-metallic. In this talk, we show that the newly developed ACBN0 functional opens up the gap in closer agreement with the experiments, thus making possible to study band-gap modulation. We will discuss in detail the variation of the electronic and vibrational properties under epitaxial strain.

1Agapito, L. et.al., arXiv:1406.3259

11:51AM Z24.00004 Bulk and surface properties of rutile TiO$_2$: an ACBN0 case study. LAALITHA LIYANAGE, University of North Texas, PRIYA GOPAL, Central Michigan University, LUIS AGAPITO, University of North Texas, MARCO FORNARI, Central Michigan University, STEFANO CURTAROLO, Duke University, MARCO BUONGIORNO NARDELLI, University of North Texas — Using the newly developed Agapito–Curtarolo–Buongiorno–Nardelli (ACBN0) functional, we investigate bulk and surface properties of rutile TiO$_2$. ACBN0 is a pseudo-hybrid Hubbard density functional that is a fast, accurate and parameter-free extension of traditional DFT+U that has been proved to correct both the band gap and the relative position of the different bands in transition metal compounds. Within ACBN0, the values of U and J are functionals of the electron density and depend directly on the chemical environment and crystalline field, thus providing a direct way of computing the Hubbard corrections for any individual atom in any local environment. With rutile TiO$_2$ as a stringent test-bed, we have applied ACBN0 to the evaluation of a broad range of physical and electronic properties of the bulk and surfaces (((100), (110), and (001)), including electronic structure, vacancy formation energy, surface formation energy and water adsorption energy. Our results compare favorably with existing GGA, traditional GGA+U$^+$ and hybrid functional calculations, demonstrating the versatility and accuracy of the ACBN0 approach.

12:03PM Z24.00005 Improved predictions of the electronic and structural properties of Zn- and Cd-based compounds. An ACBN0 study , PRIYA GOPAL, MARCO FORNARI, Central Michigan University, STEFANO CURTAROLO, Duke University, LUIS AGAPITO, LAALITHA LIYANGAN, MARCO BUONGIORNO NARDELLI, University of North Texas — In this talk, we will present our results of the performance of the recently developed ACBN0 pseudo-hybrid Hubbard density functional in predicting the electronic and structural properties of the Zn- and Cd-based semiconductors. ACBN0 is a fast, accurate and parameter-free extension of traditional DFT+U proved to correct the band gap in transition metal compounds. Within ACBN0, the values of U and J are functions of the electron density and depend directly on the chemical environment and crystalline field. We will compare the structural and electronic properties of ZnX and CdX (X=0,S,Se,Te) semiconductors calculated in rs,kz and zb phases using ACBN0 with the results obtained by semi-local PBE, hybrid HSE06 functionals and experiments whenever available. Our results demonstrate that the lattice constants, bulk modulii and band-gaps are more accurately described by ACBN0 compared to the PBE functionals. Overall, we show that ACBN0 is a powerful tool which preserves the accuracy of the HSE calculations with higher computational efficiency.

1L. Agapito, S. Curtarolo and M. Buongiorno Nardelli, arXiv:1406.3259

12:15PM Z24.00006 First-principles Evidence for Intermediate Hole Polaron in ZnO , HONGHUI SHANG, CHRISTIAN CARBONOGO, Fritz-Haber-Institut der MPG, Berlin, DE, PATRICK RINKE, Fritz-Haber-Institut der MPG, Berlin, DE and Aalto University, Helsinki, FI, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, DE, HIKMET SEZEN, FABIAN BEBENSEE, CHENGWU YANG, MARIA BUCHHOLZ, ALEXEI NEFEDOV, STEFAN HEISSLER, CHRISTOF WÖLL, Karlsruhe Institute of Technology, Karlsruhe, DE — We performed density functional theory calculations at the hybrid-functional level (HSE06) to investigate the nature of the polaronic states in ZnO. Our calculations confirm that neither small (i.e., strong coupling) electron nor hole polarons are stable in ZnO, in agreement with previous studies [1]. The binding energy of large polarons (i.e., weak coupling) was determined by evaluating the renormalization of the band edges due to the zero-point motion of the atoms [2]. However, for intermediate polarons at intermediate coupling strength, the harmonic approximation breaks down, and there is currently no first-principle theory. We use the HSE06 effective mass matrices to calculate the Fröhlich coupling constants \( \alpha \). Feynman’s path integral technique then yields an intermediate hole polaron, whose binding energy of 245 meV and associated peaks in the optical absorption spectrum are consistent with infrared reflection absorption spectroscopy.

12:27PM Z24.00007 Numerical detection of symmetry enriched topological phases with space group symmetry 1, LING WANG, ANDREW ESSIN, California Institute of Technology, MICHAEL HERMELE, University of Colorado at Boulder, OLEXEI MOTRUNICH, California Institute of Technology — Topologically ordered phases of matter, in particular so-called symmetry enriched topological (SET) phases, can exhibit quantum number fractionalization in the presence of global symmetry. In \( Z_2 \) topologically ordered states in two dimensions, fundamental translations \( T_x \) and \( T_y \) acting on anyons can either commute or anticommute. This property, crystal momentum fractionalization, can be seen in a periodicity of the excited-state spectrum in the Brillouin zone. We present a numerical method to detect the presence of this form of symmetry enrichment given a projected entangled pair state (PEPS); we study the minima of spectrum of correlation lengths of the transfer matrix for a cylinder. As a benchmark, we demonstrate our method using a modified toric code model with perturbation. An enhanced periodicity in momentum clearly reveals the nontrivial anti-commutation relation \( \{ T_x, T_y \} = 0 \) for the corresponding quasiparticles in the system.

1This work was supported by the Institute for Quantum Information and Matter through Grant GBMF1250, by the U.S. Department of Energy (DOE), under Award # DE-FG02-10ER46686 (M.H.), and by the National Science Foundation through grant DMR-1206096 (O.M.).

12:39PM Z24.00008 Chiral d-Wave Superconductivity in coupled ladders 1, JEAN PAUL LATYR FAYE, Université de Sherbrooke, Québec, Canada, SYED R. HASSAN, P.V SRLUCKSHMY, The Institute of Mathematical Sciences, Chennai, India, GANAPATHY BASKARAN, The Institute of Mathematical Sciences, Chennai, India and Perimeter Institute of Theoretical Physics, Waterloo, Ontario, Canada, DAVID SÉNÉCHAL, Université de Sherbrooke, Québec, Canada — We study the Hubbard model on the trellis lattice, a two-dimensional frustrated lattice of coupled two-leg ladders, with hopping amplitude \( t \) within ladders and \( t' \) between ladders. For large \( U/t \) this is a model for the cuprate \( Sr_{1−x}Ca_xCu_2O_4 \). We use the variational cluster approximation (VCA), with clusters of sizes 8 to 12. We investigate the phase diagram as a function of doping, \( U/t \) and \( t'/t \) and find a superconducting dome ending at roughly 20% doping. Repulsion-induced spin singlet correlations within ladders block inter-ladder single electron tunneling, but allow pair tunneling and help establish 2D superconductivity. However, the nature of the order parameter depends on doping. At small doping \( (t < 3\% \) for \( t' = 0.15t \) and \( U = 10t \)), the order parameter is real and its interladder component grows steeply with \( t' \). Beyond that value, the order parameter becomes complex for a finite range of doping and gives the bulk chiral, PT violating, two-dimensional superconductivity. In all cases, the ladder component of the order parameter has d-wave character.

12:51PM Z24.00009 Density matrix of disjoint regions as a way of determining dominant correlations in interacting systems , HITESH CHANGLANI, OLABODE SULE, SHINSEI RYU, University of Illinois at Urbana-Champaign — In the context of strongly correlated systems, studying the ground state reduced density matrix (or derived quantities, such as the entanglement entropy and spectrum) of a local region has turned out to be useful for characterizing a wide variety of phases. However, to make definitive quantitative mappings of lattice simulations to field theories one needs to go beyond the density matrix of a single region. We use critical spin chains to demonstrate how information from the density matrix of disjoint regions (obtained from the density matrix renormalization group) [1,2] can be used to calculate the low-lying scaling dimensions (and operators) of the corresponding conformal field theory. In a related context, we will also discuss the use of density matrices that involve more than just the ground state, as a way of detecting order in the system [3]. [1] W. Muender, A. Weichselbaum, A. Holzer, J. von Delft, C. L. Henley, New. J. Phys., 12, 075027 (2010) [2] H.J. Changlani, O. Sule, S. Ryu (in preparation) [3] C. L. Henley and H.J. Changlani, J. Stat. Mech. 2014(11), 11002 (2014)
1:03PM Z24.00010 Real-time decay of a highly excited charge carrier in the one-dimensional Holstein model\footnote{Supported by the DFG through FOR 1807, and Alexander von Humboldt foundation.}. LEV VIDMAR, FLORIAN DORFNER, FABIAN HEIDRICH-MEISNER, University of Munich, CHRISTOPH BROCKT, ERIC JECKELMANN, University of Hanover — We study the real-time dynamics of a highly excited charge carrier coupled to quantum phonons via a Holstein-type electron-phonon coupling \cite{1}. This is a prototypical example for the non-equilibrium dynamics in an interacting many-body system where excess energy is transferred from electronic to phononic degrees of freedom. We use an efficient numerical method \cite{2,3}, i.e., diagonalization in a limited functional space, to study the non-equilibrium dynamics on a finite one-dimensional chain. We perform a comprehensive analysis of the time evolution in different parameter regimes by calculating the electron, phonon and electron-phonon coupling energies, and the electronic momentum distribution function. For example, we demonstrate that in the weak coupling regime, the relaxation dynamics obtained from the Boltzmann equation agrees very well with the numerical data. We also study the time dependence of the eigenstates of the single-site reduced density matrix, the so-called optimal phonon modes, unveiling that their structure in non-equilibrium contains very useful information for the interpretation of the numerical data. \cite{1} Dorfner et al, submitted (2014) \cite{2} Vidmar et al, PRB 83, 134301 (2011) \cite{3} Golez et al, PRL 109, 236402 (2012)

1:39PM Z24.00013 Basic Variables of Quantum Mechanics for Electrons in Electrostatic and Magnetostatic Fields, XIAO-YIN PAN, Ningbo University, VIRAIHT SAHNI, The Graduate Center, CUNY — We consider a system of \(N\) electrons in an external electrostatic \(E = -\nabla v(r)\) and magnetostatic \(B(r) = \nabla \times A(r)\) fields, and the Hamiltonian to include the interaction of the latter with both the orbital and spin angular momentum. We prove the one-to-one relationship \{\(v(r)\), \(A(r)\)\} \(\rightarrow\) \{\(\rho(r)\), \(j(r)\)\}, where \(\rho(r)\) and \(j(r)\) are the nondegenerate ground state density and current operator, respectively. The proof accounts for the many-to-one relationship between the \{\(v(r)\), \(A(r)\)\} and the ground state \(\Psi\). In parallel with the Hohenberg-Kohn theorem proof in which the wave function \(\Psi\) of the different physical systems considered is constrained to a fixed electron number \(N\), the corresponding \(\Psi\) in our proof is constrained to having the same total orbital \(L\) and spin \(S\) angular momentum. Thus, \{\(\rho(F)\), \(j(F)\)\} constitute the basic variables in the rigorous HK sense.

1:51PM Z24.00014 Corner Contributions to the Entanglement Entropy of Strongly Interacting Systems in 2+1 Dimensions, EDWIN MILES STOUDENMIRE, Perimeter Institute for Theoretical Physics, PETER GUSTAINIS, RAVI JOHAL, University of Waterloo, STEFAN WESSEL, RWTH Aachen University, ROGER MELKO, University of Waterloo, Perimeter Institute for Theoretical Physics — In \(D=2+1\) quantum critical systems, the entanglement entropy of a region with a sharp corner in its boundary contains a subleading logarithmic scaling term with a universal coefficient. In certain cases it is known that this coefficient captures the number of low-energy degrees of freedom in the associated field theory. Using a combination of density matrix renormalization group and numerical linked cluster calculations to isolate the corner coefficient for critical systems in the \(O(N)\) Wilson-Fisher universality class, we observe a striking confirmation of the universality of this quantity and find that, to leading order, the corner coefficient is proportional to the number of field components \(N\).

2:03PM Z24.00015 Spin-coherent states and instanton calculus on a Riemann surface, TOBIAS GULDEN, MICHAEL JANAS, Department of Physics, University of Minnesota, ALEX KAMENEV, Fine Theoretical Physics Institute, University of Minnesota — Semiclassical instanton calculations require solutions to the classical equations of motion, however in complexified phase space of spin-coherent states these are rarely attainable. But identification of the constant energy submanifold of the phase space with a Riemann surface allows to evaluate the semiclassical actions without explicitly knowing the actual classical paths. Furthermore we show that such actions may be solely derived from monodromy properties of the corresponding Riemann surface. Among other results, we prove that the period of quenched tunneling in an external magnetic field is semiclassically exact.

11:15AM Z25.00001 The 2D Hubbard Model: Diagrammatic Extensions from Two-Particle Vertex Functions, JAMES LEBLANC, EMANUEL GULL, Univ of Michigan - Ann Arbor — There are now a number of approaches to computing self energies at finite temperatures in the 2D Hubbard model. The dynamical mean field theory, and finite cluster extensions such as the dynamical cluster approximation (DCA), has typically provided an excellent image of local properties of correlated systems. However, towards low temperatures finite size effects occur due to the neglect of non-local correlations beyond the length scale of the impurity cluster. We explore one proposal to mitigate this effect by simulating on the two-particle level. By computing the full and two-particle irreducible vertex functions from DCA we present a first quantitative description on the reliability of this approach and compare against existing large cluster DCA results.

11:27AM Z25.00002 Antiferromagnetism, Superconductivity and Pseudogap of the 2D Hubbard Model\footnote{University of Michigan, Simons foundation}. XI CHEN, EMANUEL GULL, JAMES LEBLANC, Univ of Michigan - Ann Arbor — The phase diagram of the two-dimensional Hubbard model in the strongly correlated regime captures some important features that have been observed in high \(T_c\) cuprate superconductors such as superconductivity and pseudogap states. We study the model on a square lattice using dynamical mean field theory and dynamical cluster approximation at various doping, temperature and next nearest neighbor hopping. By measuring the two-particle correlation functions we are able to extend beyond previous work to determine the antiferromagnetic and d-wave superconducting phase transition temperatures. Further, the pseudo gap crossover is estimated by the density of states obtained via analytic continuation, and also from the imaginary time Green’s function. We will discuss the relation between pseudo gap and superconductivity based on the simulation results.
11:51 AM Z25.00044 Cluster dynamical mean-field theory study of Mott transition in the triangular lattice Hubbard model. **HUNG DANG,** Institute for Theoretical Solid State Physics, JARA-FIT and JARA-HPC, RWTH Aachen University, 52056 Aachen, Germany, XIAO YAN XU, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, KUANG-SHING CHENG, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany, ZI YANG MENG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, STEFAN WESSEL, Institute for Theoretical Solid State Physics, JARA-FIT and JARA-HPC, RWTH Aachen University, 52056 Aachen, Germany — In strongly correlated electron systems, geometric frustration can significantly affect the Mott metal-insulator transition. Using the dynamical cluster approximation, a cluster extension of the dynamical mean-field theory, we examine the evolution of the metal-insulator transition phase boundary as a function of temperature and interaction strength for the anisotropic triangular lattice Hubbard model as the degree of geometric frustration varies. We show that (i) the slope of this phase boundary changes systematically along with the frustration, and (ii) there exists a critical frustration at which this phase boundary is vertical. We discuss in details the connection between this critical degree of frustration and the suppression of the antiferromagnetic order due to frustration, which may be related to the emergence of exotic insulator phases as observed in several organic charge transfer salts.

12:15 PM Z25.00006 ABSTRACT WITHDRAWN —

12:27 PM Z25.00007 Mott metal-insulator transition in a metallic liquid — Gutzwiller molecular dynamics simulations. **KIPTON BARROS,** GIA-WEI CHERN, CRISTIAN D. BATISTA, JOEL D. KRESS, Los Alamos National Laboratory, GABRIEL KOTLIAR, Rutgers University — Molecular dynamics (MD) simulations are crucial to modern computational physics, chemistry, and materials science, especially when combined with potentials derived from density-functional theory. However, even in state of the art MD codes, the on-site Coulomb repulsion is only treated at the self-consistent Hartree-Fock level. This standard approximation may miss important effects due to electron correlations. The Gutzwiller variational method captures essential correlated-electron physics yet is much faster than, e.g., the dynamical-mean field theory approach. We present our efficient Gutzwiller-MD implementation. With it, we investigate the Mott metal-insulator transition in a metallic fluid and uncover several surprising static and dynamic properties of this system.

12:39 PM Z25.00008 Quantum electrodynamical time-dependent density functional theory for many-electron systems on a lattice1. **MEHDI FARZANEHPOUR,** ILYA TOTAKLY, Nano-Bio Spectroscopy group and, Departamento de Fisica de Materiales, Universidad del Pais Vasco UPV/EHU, NANO-BIO SPECTROSCOPY GROUP AND ETSF SCIENTIFIC DEVELOPMENT CENTRE TEAM — We present a rigorous formulation of the time-dependent density functional theory for interacting lattice electrons strongly coupled to cavity photons. We start with an example of one particle on a Hubbard dimer coupled to a single photonic mode, which is equivalent to the single mode spin-boson model or the quantum Rabi model. For this system we prove that the electron-photon wave function is a unique functional of the electronic density and the expectation value of the photonic coordinate, provided the initial state and the density satisfy a set of well defined conditions. Then we generalize the formalism to many interacting electrons on a lattice coupled to multiple photonic modes and prove the general mapping theorem. We also show that for a system evolving from the ground state of a lattice Hamiltonian any density with a continuous second time derivative is locally v-representable.

1:03 PM Z25.00010 Spontaneous Breaking of $U(N)$ symmetry in invariant Matrix Models1. **FABIO FRANCHINI,** SISSA/M.I.T. — Matrix Models have a strong history of success in describing a variety of situations, from nuclei spectra to conduction in mesoscopic systems, from strongly interacting systems to various aspects of mathematical physics. Traditionally, the requirement of base invariance has lead to a factorization of the eigenvalue and eigenvector distribution and, in turn, to the conclusion that invariant models describe extended systems. I will show that deviations of the eigenvalue statistics from the Wigner-Dyson universality induce an effect on the eigenvectors and that the phase transition observed when the eigenvalue density become disconnected correspond to a breaking of the $U(N)$ symmetry to a smaller one. This spontaneous symmetry breaking is essentially a Higgs mechanism, due to the strongly correlated nature of matrix models and opens the possibility to a variety of applications.

1:15 PM Z25.00011 Free fermion description of a paramagnetic Mott insulator. **JOHAN NILSSON,** Uppsala University — A scheme is presented that enables a description of a paramagnetic Mott insulator in terms of free fermions. The main idea is to view the physical fermions as a part of a multi-band system and to allow for a correlation between the physical fermions and the auxiliary ones. Technically this is implemented through a non-linear canonical transformation, which is conveniently formulated in terms of Majorana fermions. The transformed Hamiltonian is in the next stage approximated with a free fermion theory. The approximation step is variational and provides an upper bound on the ground state energy at zero or the Free energy at finite temperature. In this way we are able to extend the domain of applicability of mean field theory and free fermions.
misalignment is then shown by extensive sliding simulations to increase the dynamic friction by a considerable factor over the aligned case. More generally, this recent importance as a frictional model, also develops in full equilibrium a small rotation angle, easy to detect in the Moiré pattern. The colloidal monolayer epitaxial rotation from aligned to misaligned relative to a periodic substrate. We show first of all that a model 2D colloidal monolayer in an optical lattice, of ICTP, SISSA and CNR-IOM Democritos — It is well known in surface science that incommensurate adsorbed monolayers undergo a spontaneous, energy-lowering

... positions of rutile TiO2 (110) and WO3 (001) surfaces in water. We obtain non-negligible solvation effects of such surfaces. We develop minimally-empirical continuum solvation models suitable for treating such surfaces ing of new materials. However, traditional solvation models are extensively fit to describe organic solutes and hence extrapolate poorly to highly-polar inorganic photo-electrochemical cell. Direct theoretical calculations of solid-liquid interfaces are expensive and simplified models are desirable for rapid theoretical screen-

... of the superfluid state in repulsively interacting three-component (colors) fermionic atoms in optical lattices. When two of the three color-dependent repulsions are much larger than the other, pairing symmetry is an extended s wave although the superfluid state appears adjacent to the paired Mott insulator in the phase diagram [1]. As the difference between the three repulsions is decreased in square optical lattices, the extended s-wave pairing changes into a nodal d-wave pairing, and then into a d−x2+y2-wave pairing. This change in pairing symmetry is attributed to the competition among the density fluctuations of unpaired atoms, the quantum fluctuations of the color-density wave, and those of the color-selective antiferromagnet [2]. This phenomenon can be studied in Li atoms and Yb,Yb mixtures in optical lattices using existing experimental techniques.

...energies & limit, where only ring exchange occurs, the Hamiltonian is sign problem free. Using Green’s function Monte Carlo, we investigate the phase diagram of this ring exchange only fermionic model and report our results.

1:39PM Z25.00013 Môbius molecules and fragile Mott insulators, LUKAS MEUCHELR, Department of Chemistry, Princeton University, Princeton, New Jersey 08544, USA, JOSEPH MACIEJKO, University of California, Santa Barbara — There has been significant recent interest in understanding non-Fermi liquid phases and searching for candidate Hamiltonians which may support them. DMRG and variational Monte Carlo students on 2-leg ladders have suggested the presence of such a phase, the d-wave metal, in certain regime of the t = J − K model on the 2D square lattice. K is a nearest neighbor exchange term. Non-variational quantum Monte Carlo studies of this model are hampered by the presence of a fermionic sign problem over most of the parameter space. However, in the t = J = 0 limit, where only ring exchange occurs, the Hamiltonian is sign problem free. Using Green’s function Monte Carlo, we investigate the phase diagram of this ring exchange only fermionic model and report our results.

1:51PM Z25.00014 Controlled superfluid pairing symmetry of repulsively interacting three-component fermionic atoms in optical lattices, SEI-ICHIRO SUGA, University of Hyogo — We investigate the pairing symmetry of the superfluid state in repulsively interacting three-component (colors) fermionic atoms in optical lattices. When two of the three color-dependent repulsions are much larger than the other, pairing symmetry is an extended s wave although the superfluid state appears adjacent to the paired Mott insulator in the phase diagram [1]. As the difference between the three repulsions is decreased in square optical lattices, the extended s-wave pairing changes into a nodal d-wave pairing, and then into a d−x2+y2-wave pairing. This change in pairing symmetry is attributed to the competition among the density fluctuations of unpaired atoms, the quantum fluctuations of the color-density wave, and those of the color-selective antiferromagnet [2]. This phenomenon can be studied in Li atoms and Yb,Yb mixtures in optical lattices using existing experimental techniques.

...energies & limit, where only ring exchange occurs, the Hamiltonian is sign problem free. Using Green’s function Monte Carlo, we investigate the phase diagram of this ring exchange only fermionic model and report our results.

11:27AM Z26.00002 Friction boosted by spontaneous epitaxial rotations, DAVIDE MANDELLI, SISSA, ANDREA VANONI, CNR-IOM Democritos and SISSA, NICOLA MAJNIINI, Università degli studi di Milano, SISSA and CNR-IOM Democritos, ERIOS TOSATTI, ICTP, SISSA and CNR-IOM Democritos — It is well known in surface science that incommensurate adsorbed monolayers undergo a spontaneous, energy-lowering epitaxial rotation from aligned to misaligned relative to a periodic substrate. We show first of all that a model 2D colloidal monolayer in an optical lattice, of recent importance as a frictional model, also develops in full equilibrium a small rotation angle, easy to detect in the Moiré pattern. The colloidal monolayer misalignment is then shown by extensive sliding simulations to increase the dynamic friction by a considerable factor over the aligned case. More generally, this example suggests that spontaneous rotations are rather ubiquitous and should not be ignored in all tribological phenomena between mismatched lattices.

11:39AM Z26.00003 Surface Electric Potential of Macroions between the Limits of Small Ions and Charged Nanocolloids, BENXIN JING, Y. ELAINE ZHU. Department of Chemical and Biomolecular Engineering, University of Notre Dame — The surface electric potential of macroions in the size of 1-10 nm in aqueous solutions is critical to understand the supramolecular assembly involving biomacromolecules, charged nanoparticles and nanoclusters and their resulting material properties. However, the electric potential of these macroions could not be accurately determined because their sizes fall in between the limits of small ions and plain charged nanocolloids, while solving the non-linear Poisson-Boltzmann equation remains a grand challenge to date. In this work, we investigate polyether oligomeric silsesquioxane (POSS) with 8 amine terminal groups as a model macroion. We employ a new computational technique, fluorescence correlation spectroscopy (FCS), to measure the excited electron and core hole (PCH) to quantitatively measure the local proton concentration, which is the local co-ion concentration in vicinity of POSS with 1.5 nm in diameter. By changing the ionic strength of aqueous solution and the distance between pH-sensitive fluorescence probe and POSS, we quantitatively determine the proton concentration gradient. The distance dependent local pH can be simply analyzed to obtain the surface electric potential of the POSS macroion without the necessity to solve the non-linear Poisson-Boltzmann equation.

11:51AM Z26.00004 X-ray absorption spectroscopy of lithium sulfur battery reaction intermediates, KEVIN VUJCIK, Dept. of Chemical and Biomolecular Engineering, University of California, Berkeley, TOD PASCAL, DAVID PRENDERGAST, Molecular Foundry, Lawrence Berkeley National Laboratory, NITASH BALSARA, Dept. of Chemical and Biomolecular Engineering, University of California, Berkeley — Lithium sulfur batteries have a theoretical energy density nearly five times greater than current lithium ion battery standards, but questions still remain regarding the reaction pathways through which soluble lithium polysulfide (Li2Sx, “x” ranging from 2 to 8) reaction intermediates are formed. Complicating spectroelectrochemical approaches to elucidate redox pathways is the challenge of obtaining spectral standards for individual Li2Sx species. Lithium polysulfides cannot be isolated as individual component and exist only in solution as a distribution of different Li2Sx molecules formed via disproportionation reactions (e.g. 2Li2S4 goes to Li2S3 + Li2S5). X-ray absorption spectroscopy (XAS) at the sulfur K-edge has recently been employed as a technique to study Li-S chemistry. We have recently obtained XAS standards for individual Li2Sx species via first principles DFT simulations and the excited electron and core hole approach. Here, experimental sulfur K-edge XAS of Li2Sx species dissolved in poly(ethylene oxide) are compared to spectra obtained from analogous theoretical calculations. The impact that polysulfide solution concentration and the presence of other lithium salts (e.g. LiNO3) have on X-ray spectra of Li2Sx species is explored via experiment and theory.

12:03PM Z26.00005 Depth profile of halide anions under highly charged biological membrane, WOONGMO SUNG, Department of Physics, Sogang University, WENJIE WANG, Ames National Lab., JONGGWAN LEE, Department of Physics, Sogang University, DAVID VAKNIN, Ames National Lab., DOSEOK KIM, Department of Physics, Sogang University — Halide ion (Cl− and I−) distribution in cationic Langmuir monolayer consists of 1.2-palmitoyl-3 dimethylammonium-propane (DPTAP) molecules was investigated by vibrational sum-frequency generation (VSFG) and X-ray spectroscopy. From VSFG spectra, it was observed that large halide anions (I−) screen surface charge more efficiently so that interfacial water alignment becomes more randomized. On the other hand, number density of ions directly measured by X-ray fluorescence spectroscopy at grazing incidence angle reveals that the ion densities within 6 ~ 8 nm are the same for both I− and Cl−. Since the observed ion densities in both cases are almost equal to the charge density of the DPTAP monolayer, we propose that larger halide anions are attracted closer to the surface making direct binding with the charged headgroups of the molecules in the monolayer, accomplishing charge neutrality in short distance. This direct adsorption of anions also disturbs the monolayer structure both in terms of the conformation of alkyl chains and the vertical configuration of the monolayer, with iodine having the stronger effect. Our study shows that the length scale that ions neutralize a charged interface varies significantly and specifically even between monovalent ions.

12:15PM Z26.00006 Electrochemical Growth of Ag Junctions and Diffusion Limited Aggregate (DLA) Fractal Simulation, ZAK OLSON, SAM TUPPAN, WOO-JOONG KIM, Seattle Univ, SEATTLE UNIVERSITY TEAM — We attempt construction of a single atom connection between two copper wires. By applying a DC voltage across the wires when immersed in a silver nitrate solution, we deposit silver until a junction is formed. The deposited silver forms a fractal structure that can be simulated with a diffusion limited aggregation model.

12:27PM Z26.00007 Single crystal growth and properties of two layered oxytellurides1, TIGLET BESARA, DANIEL RAMIREZ, THEO SIEGRIST, National High Magnetic Field Laboratory/Florida State University, JIFENG SUN, JEFFREY WHALEN, TAKAHISA TOKUMOTO, STEPHEN MCGILL, RYAN STILLWELL, STANLEY TOZER, National High Magnetic Field Laboratory, DAVID SINGH, Oak Ridge National Laboratory — We report on the synthesis, structure, and physical properties of two layered oxytellurides: Ba2Yb2O6Te and Ba2TeO. Both compound were grown in single crystalline form using a molten metal flux, and crystallize in a tetragonal space group: P43/mmm for Ba2Yb2O6Te and P43/mmm for Ba2TeO. Ba2Yb2O6Te consists of Ba2Yb2O6 perovskite double layers separated by a CsCl-type BaTe slab, while Ba2TeO consists of an inverse PbO-type BaO layer separated by an NaCl-type BaTe slab. Ba2Yb2O6Te displays short range 2D magnetic ordering below 4 K, and a sharp optical absorption feature at 1.27 eV consistent with a F7/2 → F5/2 transition of Yb3+. For Ba2TeO, optical measurements display a sharp increase in absorbance, a manifest of a band edge. DOS corroborates the band gap, at 2.93 eV, indicating semiconducting behavior.

12:39PM Z26.00008 ABSTRACT WITHDRAWN —

12:51PM Z26.00009 Superhydrophilic - Superhydrophobic Transition in Vertically Aligned Titania Nanotubes, OOMMAN VARGHESE, RAM NEUPANE, MAGGIE PAULOSE, University of Houston — Both hydrophilic (wetting) and hydrophobic (non-wetting) surfaces find applications in a variety of technological areas. For example, hydrophilic surfaces are used in microfluidic devices to provide antifoaming and antifouling functions whereas hydrophobic coatings are used in clothes to attribute stain resistance. While in superhydrophilic surfaces the contact angle that water droplets make with the surface is nearly zero, the surfaces that make contact angles greater than about 120° are considered superhydrophobic. Oxide ceramics generally exhibit hydrophilic behavior. Surface texturing or organic coatings are often used to make the surface hydrophobic or superhydrophobic. We prepared highly ordered titania nanotube arrays on titanium foils using anodic oxidation that showed superhydrophobic behavior upon fabrication. We noticed a strong correlation between fabrication conditions and the wettability. We have become successful in converting such a superhydrophobic nanostructure into superhydrophobic without modifying the surface with organic molecules or texturing. Contact angles in excess of 145° have been obtained. We will present these results and discuss the physiochemical processes that decide wetting properties of oxide nanostructures.
1:03PM Z26.00010 Size-dependent melting of single and stacked silver alkanethiolate layers: experiment and phenomenological model1, ZICHAO YE, Univ of Illinois - Urbana, LITO DE LA RAMA, SanDisk Corporation, LIANG HU, Intel Corporation, MIKHAIL EFREMOV, University of Wisconsin-Madison, LESLIE ALLEN, Univ of Illinois - Urbana — We report a systematic study of melting of silver alkanethiolate (AgSCn) lamellar crystals. A new synthesis method enables us to control their thickness by either modulating alkanethiol chain length (n = 7-18) or stacking them to a specific layer number (n = 1-10). Nanocalorimetry shows stepwise increase in the melting point, T\text{m}_n, of single layer AgSCn as an increment of chain number. Layer stacking also results in a size-dependent melting. An odd/even alternation is observed in the T\text{m}_n of 2, 3, and 4-layer lamellae, but absent in that of single and multilayer samples. We develop a phenomenological model for lamellae melting based on the cumulative excess free energy contributions of four spatially separate layers in Ag\text{SCn} crystal: free surface, Ag–S central plane, substrate interface, and interlayer interface. Surface excess free energy is revealed to be independent of chain length. The selective appearance of the odd/even effect is due to the significant stabilization of interlayer interfaces of odd-chain samples, possibly due to registration/packing. Such interface stabilization occurs most significantly for 2-layer samples. XRD results support the model as the measured van der Waals gap is smaller for crystals with odd chains.

1Supported by NSF-DMR-1409953 and NSF-DMR-1006385.

1:15PM Z26.00011 Control and expression of –NH\textsubscript{2}, –SH, –COOH and SiO\textsubscript{2} on the surface of silicon carbide quantum dots, MUNUVE MWANIA, SUSANA AGUINRE-MEDEL, PETER KROLL, None — We present simple protocols of interlayer interfaces of odd-chain samples, possibly due to registration/packing. Such interface stabilization occurs most significantly for 2-layer samples. 4-layer lamellae, but absent in that of single and multilayer samples. We develop a phenomenological model for lamellae melting based on the cumulative excess free energy contributions of four spatially separate layers in Ag\text{SCn} crystal: free surface, Ag–S central plane, substrate interface, and interlayer interface. Surface excess free energy is revealed to be independent of chain length. The selective appearance of the odd/even effect is due to the significant stabilization of interlayer interfaces of odd-chain samples, possibly due to registration/packing. Such interface stabilization occurs most significantly for 2-layer samples. XRD results support the model as the measured van der Waals gap is smaller for crystals with odd chains.

1:27PM Z26.00012 Effects of Surface Treatments on Nylon 6,6 via Non-thermal Atmospheric Plasma for Thermoplastic Adhesives, CHI-CHIN WU, ANDRES BUJANDA, JOHN DEMAREE, JASON ROBINETTE, AMANDA WEERASOORIYA, DAVID FLANAGAN, Army Research Laboratory, ARL PLASMA GROUP, CCEP, WMRD TEAM — This work aims to modify the properties of Nylon 6,6 surfaces for attaining improved interfacial adhesion to thermoplastic composites utilizing atmospheric non-thermal plasma treatments followed by silane treatments using 3-aminopropyltriethoxysilane (APS) in some cases. An L-shaped dielectric barrier discharge configuration was employed to expose nylon substrates to oxygen-containing gas plasmas such as He/O\textsubscript{2} and He/H\textsubscript{2}O, respectively, at room temperature. The chemically-modified surface of the substrate after plasma exposure was immediately examined by static water contact angle wettability measurements and X-ray photoelectron spectroscopy. It was found that the surface hydrophilicity was substantially enhanced and the amount of surface oxygen was significantly increased after a three-minute plasma exposure due to the increased surface energy and additional O-H bonds. The enhancements on interfacial adhesion were evaluated with lap shear tests using three types of adhesives: EPON 825/D230, EPON 825/D2000 and sikaflex252, respectively. The results of tensile tests on the adhesive joints showed an almost 300% increase in interfacial adhesive strength for EPON 825/D230 bonds after plasma treatments. Finite element modeling of adhesive joints for bond strength is underway to compare with experimental results and study the quantitative relations between the mechanical properties within the bond and at interfaces.

1:39PM Z26.00013 Theoretical evidence for unexpected O-rich phases at corners of MgO surfaces, DANIEL BERGER, Technische Universität München, Garching, DE, KARSTEN ROESCH, Technische Universität München, Garching, DE, LUCA M. GHIRARDELLI, Fritz-Haber-Institut der MPG, Berlin, DE, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, DE, Technische Universität München, Garching, DE — Introducing charge carriers into MgO via p doping greatly reduces formation energy of an O-vacancy in the bulk and at the (100) surface [1]. In this work, we use hybrid density functional theory to explore O-vacancy and O/O\textsubscript{ad}-species defects at corners of MgO surfaces. The defects are modelled using MgO clusters embedded into a field of norm-conserving pseudopotentials and point charges. The long-range response of the oxide to the charge carriers trapped at the defects is taken into account using a polarizable force field. The low-energy defect atomic structures are found using an \textit{ab initio} genetic algorithm [2]. Concentrations of O-vacancies and O-ad-species at realistic temperatures and pressures are obtained with \textit{ab initio} atomistic thermodynamics. Unexpectedly, we find that O-ad-species rather than O-vacancies are dominating defects at realistic conditions. The stability of the O-ad-species over O-vacancies and pristine corners is explained by an interplay between bond-breaking, bond-making, and charge-carrier trapping. — [1] N. Richter et al., Phys. Rev. Lett. 111, 045502 (2013); [2] S. Bhattacharya et al., New J. Phys., in press (2014)

Friday, March 6, 2015 11:15AM - 2:03PM – Session Z28 GMAG DMP: Focus Session: Kagome Antiferromagnets II

11:15AM Z28.00001 Simplex valence-bond crystal in the spin-1 kagome Heisenberg antiferromagnet1, WEI LI, Ludwig-Maximilians-Universität, TAO LIU, University of Chinese Academy of Sciences, ANDREAS WEICHSELBAUM, JAN VAN DELFT, Ludwig-Maximilians-Universität, GANG SU, University of Chinese Academy of Sciences — We investigate the ground state properties of a spin-1 kagome antiferromagnetic Heisenberg model using tensor-network (TN) methods. We find a ground state with trimerization (simplex) valence-bond order, and obtain the energy per site $\varepsilon_{0} = -1.4099 \left( D = 16 \right)$ by accurate calculations directly in the thermodynamic limit. The symmetry between the two kinds of triangles is spontaneously broken, with a relative energy difference of $\delta \approx 20\%$. The spin-spin, dimer-dimer, and chirality-chirality correlation functions are found to decay exponentially with a rather short correlation length, showing that the ground state is gapped. We thus identify the ground state be a simplex valence-bond crystal (SVBC). We also discuss the spin-1 bilinear-biquadratic Heisenberg model on a kagome lattice, and determine its ground state phase diagram, find a quantum phase transition between the SVBC and a ferro-quadrupolar nematic state. Moreover, we implement non-abelian symmetries, here spin SU(2), in the TN algorithm, which improves the efficiency greatly and provides insight into the tensor structures.

11:27 AM Z28.00002 Quantum Kagome Ice. JUAN CARRASQUILLA, Perimeter Inst for Theo Phys, ZHIHAO HAO, University of Waterloo, ROGER MELKOV, University of Waterloo and Perimeter Institute — Two-dimensional quantum spin liquids (QSLs) are exotic phases of matter where magnetic moments remain disordered even at extremely low temperatures. Despite ongoing searches, QSLs remain elusive, due to a lack of concrete knowledge of the microscopic mechanisms that inhibit magnetic order in real materials. Here, we study a theoretical model for a broad class of frustrated magnetic rare-earth pyrochlore materials called “quantum spin ices”. When subject to an external magnetic field along the [111] crystallographic direction, the resulting spin interactions create a mix of geometric frustration and quantum fluctuations in decoupled two-dimensional kagome planes. Using large-scale quantum Monte Carlo simulations, we identify a simple set of interactions sufficient to promote a groundstate with no magnetic long-range order, and a gap to excitations, conjectured to be a $Z_2$ spin liquid phase. This suggests a systematic experimental procedure to search for two-dimensional QSLs within the broader class of three-dimensional pyrochlore quantum spin ice materials.

11:39 AM Z28.00003 The $J_1$-$J_2$ Kagome Heisenberg Model with Dzyaloshinskii-Moriya Interaction. TZEZAR SEMAN, Northern Illinois University, CHENG-CHIEN CHEN, Argonne National Laboratory, RAJIV SINGH, University of California, Davis, MICHEL VAN VEENENDAAL, Northern Illinois University, Argonne National Laboratory — We study the static and dynamic properties of an $S = 1/2$ kagome antiferromagnetic (AFM) Heisenberg model using large-scale exact diagonalization. We map out the phase diagram as functions of the next-nearest-neighbor exchange $J_2$ and the $z$-axis Dzyaloshinskii-Moriya interaction $D_z$. In particular, the phase boundary between a magnetically disordered state and a $Q = 0$, $120^\circ$ AFM state appears. We also identify a long-range spin-spin correlation function. We also compute the dynamical structure factor for the resulting spin-liquid phase. The implications of our numerical results to AFM long-range order is identified through finite-size extrapolation of the transverse spin-spin correlation function. We also compute the dynamical structure factor of Na4Ir3O8. Starting from these states, we will discuss.

11:51 AM Z28.00004 Frustration and Dzyaloshinsky-Moriya anisotropy in the kagome francisites Cu$_3$Bi(SeO$_2$)$_2$O$_X$. ALEXANDER TSIRLIN, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, IOANNIS ROUSOCHATZAKIS, Max Planck Institute for Complex Systems, Dresden, Germany, RONALD ZINKE, JOHANNES RICHTER, Institute for Theoretical Physics, University of Magdeburg, Germany — Kagome spin lattice is an abundant source of magnetic frustration. We will present density-functional as well as analytical and numerical calculations that elucidate the microscopic magnetic model of spin-1/2 francisite materials Cu$_3$Bi(SeO$_2$)$_2$X ($X =$ Cl, Br). Their weakly distorted kagome lattice features ferromagnetic nearest-neighbor and antiferromagnetic next-nearest-neighbor couplings that result in an infinitely degenerate classical ground state for the isotropic spin model restricted to Heisenberg exchanges. This degeneracy is lifted by quantum fluctuations, although the canted magnetic order observed experimentally is only marginally lower in energy than other competing states. We argue that in francisites this canted state is primarily stabilized by the Dzyaloshinsky-Moriya (DM) anisotropic quantum magnet. We derive the hierarchy of the DM exchanges in francisites and explain qualitatively the anisotropic magnetic response of these frustrated quantum magnets.

12:03 PM Z28.00005 Using the Density-Matrix Renormalization Group to Explore a Proposed Hamiltonian for Volborthite. EDWARD PARKER, Univ of California - Santa Barbara — Volborthite (Cu$_3$V$_2$O$_7$(OH)$_2$: 2H$_2$O) is a strongly geometrically frustrated system of spin-1/2 ions on a Kagomé lattice whose magnetic ordering temperature is more than two orders of magnitude below its Curie temperature. Measurements of its magnetization curve show an extremely broad magnetization plateau extending over a range of at least 100 Tesla. Density functional theory calculations suggest a nontrivial anisotropic spin coupling structure with both ferromagnetic and antiferromagnetic bonds. Prior studies of similar (but simpler) systems suggest the possibility of a spin nematic phase containing gapless bound states of two or more magnons, which can condense and spontaneously break the $U(1)$ spin symmetry about the applied field down to a discrete cyclic symmetry. We will report Density-Matrix Renormalization Group studies of this model to investigate plateau formation and possible spin nematic and spin density wave phases. Techniques include approximating the full 2-D lattice using interchain mean-field theory and spin ladders.

12:15 PM Z28.00006 Thermal transport study of $S = 1/2$ kagome frustrated system Volborthite. DAIKI WATANABE, Kyoto University, MINORU YAMASHITA, MASAAKI SHIMOZAWA, YOSHITAKA SUZUKI, HAJIME ISHIKAWA, ZENJI HIROI, ISSP, University of Tokyo, YUJI MATSUDA, Kyoto University — The nature of spin liquid states of 2D frustrated magnetic systems has been discussed over decades. Recently, some candidate materials of 2D quantum spin liquid have been reported from the absence of long range order in low temperatures. However, the elementary excitations which characterize the ground state have yet to be observed. It is suggested that thermal Hall measurement is a powerful probe to identify the elementary excitations of 2D quantum spin liquid[1]. Here we report the results of thermal-transport measurements of Volborthite (Cu$_3$V$_2$O$_7$(OH)$_2$: 2H$_2$O) which possesses the 2D kagome planes. We observed double anomalies in the thermal conductivity around 1K. These anomalies correspond magnetic orderings reported by the NMR measurements and the specific heat measurements[2,3]. We will also talk about our thermal Hall measurements above the ordering temperature. [1] H. Katsura et al., Phys. Rev. Lett. 104, 066403 (2010). [2] H. Yoshida et al., Nat. Commun. 3, 860 (2012). [3] M. Yoshida et al., J. Phys. Soc. Jpn. 81, 024703 (2012).

12:27 PM Z28.00007 New Realisations of Frustrated Quantum Spin Systems from Vanadium Based Oxyfluorides. LUCY CLARK, FARIDA AIDOUDI, CAMERON BLACK, RUSSELL MORRIS, PHILIP LIGHTFOOT, University of St Andrews — We recently presented the first example of a material containing a kagome network of antiferromagnetically interacting V$^{4+}$ $S = 1/2$ cations, DQVOF (Diammonium Quinolinilidium Vanadium Oxyfluoride). The $S = 1/2$ kagome layers within DQVOF are separated by V$^{4+}$ $S = 1$ cations. Our low temperature magnetic study of DQVOF suggested that the kagome layers remain decoupled from these inter-layer spins and that the system adopts a gapless QSL ground state[1]. Here, we will discuss how variations in the chemical methods used to prepare DQVOF can be employed to extend this family of frustrated V$^{4+}$ based oxyfluorides. In particular, we will focus on a new phase InMVOF (Imidazolium Vanadium Oxyfluoride), which consists of V$^{4+}$ $S = 1/2$ kagome layers like DQVOF, but the connectivity between the kagome layers is remarkably different. Single crystal X-ray diffraction reveals that the inter-layer vanadium species in InMVOF also sit on a kagome network. Magnetic susceptibility data of InMVOF reveal an absence of long range magnetic magnetic order down to 2 K despite significant antiferromagnetic exchange exchange (6~ ~ 50 K), which suggests that interesting physics is at play. [1] L. Clark et al., Phys. Rev. Lett. 110, 207208 (2013)

12:39 AM Z28.00008 ABSTRACT WITHDRAWN —
1:03PM Z28.00010 Quantum Phase Transitions and De-Coupling of Magnetic Sublattices in the Quasi-Two-Dimensional Ising Magnet Co3V2O8 in a Transverse Magnetic Field, K. FRITSCH, Helmholtz-Zentrum Berlin für Materialien und Energie (HZB), Berlin, Germany; Dept. of Physics and Astronomy, McMaster University, Hamilton, Canada, G. EHLERS, Neutron Scattering Science Division, ORNL, Oak Ridge, USA, K. C. RULE, HZB; ANSTO, Lucas Heights, Australia, K. HABICHT, HZB, M. RAMAZANOGLU, Dept. of Physics and Astronomy, McMaster University, H. A. DABKOWSKA, Brockhouse Institute for Materials Research (BIMR), Hamilton, Canada, B. D. GAULIN, Dept. of Physics and Astronomy, McMaster University; BIMR, Canadian Institute for Advanced Research, Toronto, Canada - The application of a magnetic field transverse to the easy axis, Ising direction in the quasi-two-dimensional Kagome staircase magnet, Co3V2O8, induces three quantum phase transitions at low temperatures, ultimately producing a novel high field polarized state, with two distinct sublattices. New time-of-flight neutron scattering techniques, accompanied by large angular access, high magnetic field infrastructure allows the mapping of a sequence of ferromagnetic and incommensurate phases and their accompanying spin excitations. At least one of the transitions to incommensurate phases at \( \mu_0 H_{c3} \approx 6.25 \text{T} \) and \( \mu_0 H_{c2} \approx 7 \text{T} \) are discontinuous, while the final quantum critical point at \( \mu_0 H_{c3} \sim 13 \text{T} \) is continuous.

1:15PM Z28.00011 \(^{17}\)O Single Crystal NMR Evidence for a Gapped Spin-liquid Ground State in the S=1/2 Kagome Lattice ZnCu3(OH)6Cl2, MINGXUAN FU, Department of Physics and Astronomy, McMaster University, TAKASHI IMAI, Department of Physics and Astronomy, McMaster University and Canadian Institute for Advanced Research, TIANHENG HAN, Department of Physics, University of Chicago, YOUNG S. LEE, Departments of Applied Physics and Photon Science, Stanford University and SLAC National Accelerator Lab — The two-dimensional S=1/2 Kagome lattice in Herbersmithite ZnCu3(OH)6Cl2 is the best candidate for experimental realization of a quantum spin liquid ground state known to date. The recent discovery of a continuum of spinon excitations using inelastic neutron scattering in this material has drawn strong attention to its exotic magnetic properties. Understanding the nature of the paramagnetic ground state of ZnCu3(OH)6Cl2, however, remains a challenge, due to excess magnetic Cu defects occupying the interlayer Zn sites. We conducted single crystal NMR measurements of the \(^{17}\)O Knight shift, and succeeded in measuring the intrinsic spin susceptibility of the Kagome layer down to \( T \approx 0.011 \text{(J} \sim 17 \text{meV}) \) for the first time. We demonstrate that the intrinsic spin susceptibility decays exponentially at low temperatures, revealing the presence of a spin gap \( \Delta \approx 0.13 \). Moreover, we show that application of a high magnetic field suppresses the gap. These results provide direct evidence for a gapped spin-liquid ground state realized in ZnCu3(OH)6Cl2.

1:27PM Z28.00012 Spin liquid state in the S=1 vanadium kagome YCa3(VO)3(BO)4, CHRISTOPHER WIEBE, University of Winnipeg, HARLYN SILVERSTEIN, University of Manitoba, JASON GARDNER, NIST NCNR, HAIDONG ZHOU, University of Tennessee-Knoxville — Over the last decade, the search for model kagome compounds has been fruitful for S=1/2 Cu\(^{2+}\) spins in the minerals Herbersmitheite and Volborthite [1-2]. There are fewer comparable materials for S=1 analogues, but recent progress has been made with the discovery of YCa3(VO)3(BO)4, which has a network of V\(^{3+}\) kagome spins [3]. Previous reports were made of no magnetic ordering down to 1.5 K in this compound, despite strong antiferromagnetic exchange [3]. Here we report a new synthesis method for this material which reduces impurity levels, resulting in high quality polycrystalline samples of YCa3(VO)3(BO)4. Neutron scattering experiments show no evidence for long-ranged magnetic ordering down to 50 mK, with gapped inelastic excitations developing similar to S=1/2 kagome compounds. Heat capacity and susceptibility measurements also show a lack of long-range magnetic order and a lack of spin glassiness, placing this compound as a new spin liquid candidate.

1:39PM Z28.00013 Infrared phonons as a probe of spin liquid in kagome antiferromagnet Herbertsmithite, ANDREI SUSHKOV, GREGORY JENKINS, DENNIS DREW, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742, USA, TIAN-HENG HAN, University of Chicago, Chicago, IL 60637, USA, YOUNG LEE, Massachusetts Institute of Technology, Cambridge, MA 20139, USA — Phonons are sensitive to magnetic interactions between ions through the spin-phonon coupling mechanism where the phonon resonance frequency is proportional to \( S_i S_j \) spin-spin correlation function. In our earlier work [1], we observed strong magnetic phonon splitting at the magneto-structural transition in cubic spinel ZnCr2O4. In Herbertsmithite ZnCu3(BO)4Cl2, neither magnetic ordering nor structural transition was observed down to mK temperatures. Recent theoretical work predicts a resonating bond ground state in Herbertsmithite that breaks p6 chiral symmetry and lifts the degeneracy between two zone center optical phonon modes [2]. From fits to reflectivity spectra we have obtained the temperature dependence of all IR-active phonons polarized both in and perpendicular to the kagome plane. Observed signatures of magnetic interaction effects on the phonon parameters will be discussed.

1:51PM Z28.00014 Barlowite: a new mother compound of spin liquids, TIAN-HENG HAN, University of Chicago, JOHN SINGLETON, Los Alamos National Laboratory, JOHN SCHLUETER, Argonne National Laboratory — Experimental investigations of spin liquids start with finding suitable materials. Existing candidate compounds have limitations, even though the observation of spinons in herbertsmithite has marked a breakthrough. I will introduce a new mother compound of kagome spin liquids, barlowite, with its properties characterized using thermodynamic techniques. The advantages of barlowite will be discussed.
11:15AM Z29.00001 High precision measurements of quantum critical properties for 3D quantum antiferromagnets. ZI YANG MENG, YAN QI QING, Institute of Physics, Chinese Academy of Sciences, BRUCE NORMAND, Renmin University, ANDERS SANDVik, Boston University — Using large-scale quantum Monte Carlo (QMC) simulations, we study the quantum phase transitions in three-dimensional $S=1/2$ dimerized Heisenberg antiferromagnets. We obtain high precision results on the quantum critical properties of the transition from antiferromagnetically ordered phase to the magnetically disordered dimerized phase. With careful finite size scaling analysis and improved estimator of physical observables in the QMC simulations, we are able to extract the precise logarithmic corrections to quantum phase transition in our system governed by the $3+1$ O(3) universality class. Finite temperature quantum critical properties in excitation spectra are obtained as well.

11:27AM Z29.00002 Calculation of the Curie temperature of Ni using first principles based Wang-Landau Monte-Carlo. MARKUS EISENBACH, Oak Ridge National Lab, JUNQI YIN, University of Tennessee, YING WAI LI, Oak Ridge National Lab, DON NICHOLSON, University of North Carolina, Asheville — We combine constrained first principles density functional with a Wang-Landau Monte Carlo algorithm to calculate the Curie temperature of Ni. Mapping the magnetic interactions in Ni onto a Heisenberg like model to underestimate the Curie temperature. Using a model we show that the addition of the magnitude of the local magnetic moments can account for the difference in the calculated Curie temperature. For ab initio calculations, we have developed our Locally SelfConsistent Multiple Scattering (LSMS) code to constrain the magnitude of the local moments in addition to their direction and apply the Replica Exchange Wang-Landau method to sample the larger phase space efficiently to investigate Ni where the fluctuation in the magnitude of the local magnetic moments is of importance equal to their directional fluctuations. We will present our results for Ni where we compare calculations that consider only the moment directions and those including fluctuations of the magnetic moment magnitude on the Curie temperature. This research was sponsored by the Department of Energy, Offices of Basic Energy Science and Advanced Computing. We used Oak Ridge Leadership Computing Facility resources at Oak Ridge National Laboratory, supported by US DOE under contract DE-AC05-00OR22725.

11:39AM Z29.00003 Thermodynamic properties of a 2D itinerant ferromagnet - a sign-problem free quantum Monte Carlo study. SHENG-LONG XU, University of California, San Diego, YI LI, Princeton Center for Theoretical Sciences, Princeton University, CONGJUN WU, University of California, San Diego — We investigate thermodynamic properties of itinerant ferromagnetism by using the non-perturbative method of quantum Monte Carlo simulation, which is shown free of the sign problem in a multi-orbital Hubbard model in the square lattice in a large region of fermion density. The spin magnetic susceptibility is local-moment-like exhibiting the Curie-Weiss law in the off-critical temperature region, while the compressibility typically exhibits the itinerant nature, which is finite and weakly temperature-dependent. The spin magnetic susceptibility further grows exponentially as approaching zero temperature for the SU(2) invariant models. The long-range ferromagnetic ordering appears when the symmetry is reduced to the Ising class, and the Curie temperature can be accurately determined.

11:51AM Z29.00004 A benchmark study of the two-dimensional Hubbard model with auxiliary-field quantum Monte Carlo. MINGPU QIN, HAO SHI, SHIWEI ZHANG, College of William and Mary — The ground state properties of the two-dimensional Hubbard model are calculated with the auxiliary-field quantum Monte Carlo (AFQMC) method. With general twist boundary conditions, the shell effect is eliminated. We use large lattice sizes ($L \times L$ lattices with $L$ up to 24) and average over many twist angles to extrapolate to the thermodynamic limit and ensure convergence of the calculated physical quantities. At half filling, we obtain accurate results for the ground-state energy, sublattice magnetization and double occupancy, while the compressibility typically exhibits the itinerant nature, which is finite and weakly temperature-dependent. The spin magnetic susceptibility further grows exponentially as approaching zero temperature for the SU(2) invariant models. The long-range ferromagnetic ordering appears when the symmetry is reduced to the Ising class, and the Curie temperature can be accurately determined.

11:03PM Z29.00005 Entropic and magnetic properties of Ni-Mn-In magnetocaloric materials. JING-HAN CHEN, Department of Physics and Astronomy, Texas AM University, NICKOLAUS BRUNO, Department of Mechanical Engineering, Texas AM University, IBRAHIM KARAMAN, Department of Materials Science and Engineering, Texas AM University, YUJIN HUANG, JIANGOU LI, School of Materials Science and Engineering, Shanghai Jiaotong University, JOSEPH H. ROSS, JR., Department of Physics and Astronomy, Texas AM University — We report magnetization and field-dependent calorimetry studies of phase transitions in Ni-Mn-In. Off-stoichiometric alloys based on NiMnIn have drawn attention due to the coupled first order magnetic and structural transformation, and the large magnetocaloric entropy associated with this martensitic transformation. We have analyzed materials with compositions NiMnIn, NiMnInNd, NiMnInMn, which differ in that the former exhibits a paramagnetic to antiferromagnetic transition, while the others exhibit an additional ferromagnetic transition. Our results show that in the NiMnIn materials, the total entropy change at the phase transition can be modeled solely according to a magnetic contribution due to local moments on the Mn sites. On the other hand, NiMnInMn includes a larger contribution which can be described in terms of a magneto-elastic coupling. This we will discuss in terms of the Bean-Rodbell model and a renormalization of the Debye temperature coupled with magnetism. We will also discuss the low-temperature properties, which show divergent behavior including antiferromagnetic, ferrimagnetic and superparamagnetic behavior.

12:03PM Z29.00006 Abstract Withdrawn —

12:27PM Z29.00007 Magnetoelectric effect in non-centrosymmetric Kondo lattices. Ilya Vekhter, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA, USA, Leonid Isaev, JILA and Department of Physics, University of Colorado, Boulder, CO, USA — We study magnetoelastic (ME) response in Kondo lattices without the center of inversion. In such materials the conduction electrons move under the influence of an odd in momentum spin-orbit interaction (SOI). The interplay between this SOI and Kondo screening enables manipulation of the net magnetization of the system by an applied electric field. As a simple model for this phenomenon, we consider a Kondo bilayer (a pair of two-dimensional Kondo lattices) with Rashba-type SOI, and treat it within a generalized hybridization mean field theory. We demonstrate that the ME response, strongest inside the heavy-fermion phase, has a very pronounced dependence on the magnitude of the spin-orbit coupling. These results provide a new pathway to the ME effect in strongly correlated materials.
related to a Fermi surface effect. 

Our recent measurements using both time-of-flight and reactor based inelastic scattering reveal magnetic excitations that are again greater in magnitude than the exchange constant in the basal plane. Despite this unusual feature the observed excitations could be described using a classical description. 

derived both the Nambu-Goldstone mode, already known for ferromagnetic systems, as well as another massive, gapped mode. This mode was found to be associated with fluctuations in the order parameter by Zhang, Farinas, and Bedell and was identified as the Higgs amplitude mode, which had never been identified in a weak ferromagnetic system [2]. They applied their model to the weak ferromagnet MnSi using existing experimental results for the material, 

Our recent measurements using both time-of-flight and reactor based inelastic scattering reveal magnetic excitations that are again greater in magnitude than the exchange constant in the basal plane. Despite this unusual feature the observed excitations could be described using a classical description. 

A large number of these materials reported. (ND4)2[FeCl5-D2O] is a rare case where improper ferroelectricity has been observed in a molecular material. 

We have used single crystal and powder neutron diffraction to study its crystal and magnetic structures and hence determine the mechanism of multiferroicity in this compound. From the crystal structure determinations above and below 79 K, we have observed an order-disorder phase transition, which is related with the ordering of the ammonium counterion. Below TN, at zero magnetic field, we have determined the magnetic structure, which corresponds with a cycloidal spin arrangement where the magnetic moments are confined in the ac-plane and propagate along the c-direction. All the cycloids in (ND4)2[FeCl5-D2O] compound have the same chirality and therefore the ferroelectricity can be explained via the inverse Dzyaloshinskii-Moriya mechanism.

Laboratory — We study the electronic and magnetic properties of individual transition metal atoms (Ti, V, Cr, Mn, Fe, Co and Ni) deposited on a Cu surface topological transition at Joseph Betouras, Loughborough University, ANDREY CHUBUKOV, Department of Physics, University of Wisconsin-Madison, Madison, WI 53706, USA. — We analyze the temperature and doping dependence of the specific heat \(C(T)\) in \(\text{Na}_2\text{CoO}_2\). This material was conjectured to undergo a Lifshitz-type topological transition at \(x = x_c = 0.62\), in which a new electron Fermi pocket emerges at the \(\Gamma\) point, in addition to the existing hole pocket with large \(k_F\). The data show that near \(x = x_c\), the temperature dependence of \(C(T)/T\) at low \(T\) gets stronger as \(x\) approaches \(x_c\) from below and then reverses the trend and changes sign at \(x ≥ x_c\). We argue that this behavior can be quantitatively explained within the spin-fluctuation theory. We show that magnetic fluctuations are enhanced near \(x_c\) at momenta around \(k_F\), and their dynamics changes between \(x ≤ x_c\) and \(x ≥ x_c\), when the new pocket forms. We demonstrate that this explains the temperature dependence of \(C(T)/T\). We show that at larger \(x (x > 0.65)\) the system enters a magnetic quantum critical regime where \(C(T)/T\) roughly scales as \(\log T\). This behavior extends to progressively lower \(T\) as \(x\) increases towards a magnetic instability at \(x ≈ 0.75\).

Friday, March 6, 2015 11:15AM - 1:51PM – Session Z30 GMAG DMP: Focus Session: Frontiers in Magnetism II

11:15AM Z30.0001 Electronic properties of transition metal atoms on Cu2 N/Cu(100): a DFT comparative study1, ALEJANDRO FERRON, JOSÉ LADO, JOAQUIN FERNÁNDEZ-ROSSIERS, International Iberian Nanotechnology Laboratory — We study the electronic and magnetic properties of individual transition metal atoms (Ti, V, Cr, Mn, Fe, Co and Ni) deposited on a \(\text{Cu}_2\text{N/Cu}(100)\) surface by means of spin-polarized density functional theory (DFT) calculations. We focus our work on a comparative study of the various quantities, such as magnetic moment, orbital occupation, structural properties, hybridization with the substrate and spin polarization of the substrate, paying attention to the trends as the transition metal is changed. In this work we try to go beyond existing theoretical works by providing a comprehensive and comparative study of the electronic, magnetic and structural properties of these seven atoms including also Ni, for which there are no published calculations to the best of our knowledge. In the case of Mn, Fe and Co, we connect our results with the existing scanning tunneling microscope experiments [1,2].

11:27AM Z30.0002 Ni adsorption on MgO(001): A Comparison of DFT and DFT+U, OLIVER ALBERTINI, AMY LIU, Georgetown University, BARBARA JONES, IBM Almaden Research Center — The study of magnetic atoms on surfaces has drawn recent attention due to possible applications in the realm of magnetic storage and quantum computing. Researchers are looking across the 3d transition metal series for candidates with high magnetic anisotropy. Here we examine the MgO/Ag surface with a Ni adatom using DFT and DFT+U computational approaches. We investigate the preferential binding site and the interesting physics involved in the resulting magnetic moment, drawing comparisons with a recent study of Co on MgO/Ag.

11:39AM Z30.0003 Magnetocrystalline anisotropy “space” distribution over atoms from different first principles approaches, ROMAN CHEPULSKYY, DMYTRO APALKOV, New Memory Technology, Samsung Semiconductor R&D Center, Samsung Electronics — Interplays between bulk vs interface and electron hybridization vs stress contributing into the magnetocrystalline anisotropy are studied from first principles. Fe/MgO system is considered as example with variable Fe thickness. The effect of stress is modeled by consideration of a number of fixed in-plane lattice parameters with full relaxation in z-direction. Different approaches to calculate separate atom contributions into the total magnetocrystalline anisotropy are compared and controversies are discussed.

11:51AM Z30.0004 Electric field control of Martensitic Phase Transitions in Thin Films of Ni-Mn-In, NABIL AL-AQTASH, University of Nebraska - Omaha, ANDREI SOKOLOV, University of Nebraska Lincoln, RENAT SABIRIANOV, University of Nebraska - Omaha — We propose the electric field control of martensite transformation of Ni-Mn-In thin films deposited on ferroelectric (FE) substrate. DFT- based calculations indicate that the off-stoichiometric Ni2Mn1.5In0.5 alloy shows that the ferromagnetic (FM) cubic phase undergoes transformation to tetragonal ferromagnetic (FIM) martensite phase at low temperature. The presence of FE substrate changes the relative stability of FM austenite and FIM martensite phases. \((\text{SrZrO}_3/\text{PbZrO}_3)\) superlattices were considered as FE substrates with polarization perpendicular to the interface. The relative stability of two phases of the thin films can be tuned by polarization reversal in FE due to the change in sign of induced charges at the interface. The energetically favorable structures of the FE/Ni2Mn1.5In0.5 systems depend on interface structure between FE and Ni2Mn1.5In0.5 layers, e.g. Ni-(Pb-O) interface. The energy difference \((\text{per NiMnIn } \text{f.u.})\) between FM austenite and FIM martensite states of the film on FE substrate is \(\Delta E = 0.22 \text{ eV}\) with polarization away from interface, upon polarization reversal \(\Delta E = 0.75 \text{ eV}\), compared to \((\Delta E = 0.24 \text{ eV})\) in the bulk. Additionally Pb atoms in PbO3 planes shifted in opposite direction with respect to oxygen planes and alter the chemical bonding of Pb with Ni atoms of the thin films. These changes possibly cause the shift of the martensite transition temperature. These results clearly indicate the possibility of control of martensitic transition in Ni-Mn-In thin films by FE substrate.

12:03PM Z30.0005 Ab initio calculation of magnetic interactions and time-dependent density functional theory simulation for ultrafast magnetic dynamics, ZHANGHUI CHEN, LIN-WANG WANG, Lawrence Berkeley Nat Lab — The competition between exchange interaction and spin-orbital coupling, especially in the presence of the symmetry-breaking of interfaces, provides a path to magnetic interactions which can cause novel magnetic structures like skyrmions. We will use a noncollinear spin ab initio calculation to predict the spin-spin interactions near such interfaces. A new algorithm is developed for such calculations. Similarly, a newly developed fast time-dependent density functional theory algorithm will be used to study femtosecond spin relaxation after an initial excitation by a fast laser pulse. Such simulation is mean to reveal the underlying mechanism which causes fast magnetic decays.
The use of supercritical fluids was found to lead to a homogeneous microstructure with an average grain size of 35 nm. The magnetic properties show an enhancement of magnetization and coercivity from $M(3T)$. They also observed that the magnetic phase by subjecting ball milled powders with micron size grains to the supercritical conditions of fluids at high pressure of 850 psi and temperature of 250 °C. The study concludes that the Mn-based alloys have attracted much interest lately for the development of rare earth-free permanent magnets.

**Enhancement of Magnetization and Coercivity from $M(3T)$**

AHMED A. ELGENDY, GEORGE HADJIPANAYIS, University of Delaware — Mn-based alloys have attracted much interest lately for the development of rare earth-free permanent magnets. The work was funded by NSF-G8. References: Cui, B. Z.; Marinescu, M.; Liu, J. F., Nature Comm., 5, 3333 (2014).

**Magnetization studies and spin Hamiltonian modelling of Li2(Li1-xFex)N**

JAMES H. ATKINSON, Department of Physics, University of Central Florida, Orlando, FL, USA, ANTON JESCHE, The Ames Laboratory, Iowa State University, Ames, Iowa, IA, and the Institute for Physics, University of Augsburg, Augsburg, Germany, ENRIQUE DEL BARCO, Department of Physics, University of Central Florida, Orlando, FL, USA, PAUL C. CAPFIELD, The Ames Laboratory, Iowa State University, Iowa, USA — The study of ferromagnetic materials that yield many examples of compounds which exhibit large energy barriers to a reversal of magnetization and correspondingly wide magnetization versus field hysteresis loops. Some materials, such as members of the class called “single-molecule magnets” (SMMs), even display vivid signatures of quantum tunneling effects, manifested as step-like features in hysteresis loop measurements of crystalline ensembles. The compound Li2(Li1-xFex)N has been previously shown to display an extremely high blocking temperature ($\sim 20$ K) and large coercive fields ($\sim 11$ T), as well as step-like features like those seen in SMMs. Here we report the results of low-temperature Hall sensor magnetization studies on a crystalline sample of Li2(Li1-0.006Fe0.006)N in which we detailed evidence of a preferential orientation for the observed features, as well as their dependence upon transverse component fields in their magnitude, behavior which we attempt to model with a giant spin Hamiltonian. [1] A. Jesche, R.W. McCallum, S. Thimmaiah, J.L. Jacobs, V. Taufour, A. Kreyszig, R.S. Houk, S.L. Bud'ko & P.C. Canfield. Nature Comm., 5, 3333 (2014).

**Nanostructured Mn2Ga Alloys with High Magnetization and Coercivity**

AHMED A. ELGENDY, GEORGE HADJIPANAYIS, University of Delaware — Mn-based alloys have attracted much interest lately for the development of rare earth-free magnets because of their high magnetocrystalline anisotropy. [1] In this study, we have prepared nanostructured Mn2Ga alloys with the pure D022 phase by subjecting ball milled powders with micron size grains to the supercritical conditions of fluids at high pressure of 850 psi and temperature of 250 °C. The use of supercritical fluids was found to lead to a homogeneous microstructure with an average grain size of 35 nm. The magnetic properties show an enhancement of magnetization and coercivity from $M(3T)= 30$ emu/g and $HC = 3$ kOe in the micron size powders to $M(3T)$ and $HC$ of 48 emu/g and 4.7 kOe, respectively in the nanosize powders. This new method of grain size reduction to nanoscale with the subsequent increase in coercivity via the high pressure cell opens new routes for rare earth-free permanent magnet development. The work was funded by NSF-G8. References. Cui, B. Z.; Marinescu, M.; Liu, J. F. Ferromagnetic Tetragonal L10-type Mn2Ga Isotropic Nanocrystalline Microparticles. IEEE Trans. Mag. 2013, 49(7), 3322-3325.

**Application of Barkhausen noise and ferromagnetic hysteresis for magnetic non-destructive evaluation of multiphase composites and structures**

NEELAM PRABHU GAUNKAR, ORFEAS KYPRIS, CAJETAN NILEBEDIM, DAVID JILES, Department of Electrical and Computer Engineering, Iowa State University — Composite ferromagnetic materials with multiple magnetic phases are increasingly used in applications such as magnetic data storage, magnetic sensors and actuators and exchange-spring magnets. These materials occur in single or multiphase conditions and can undergo phase changes over time or during processing. For these materials, we examine the interrelation between magnetic hysteresis, Barkhausen noise and the material microstructure. We observe that the presence of a second phase in these materials can be detected with the help of Barkhausen noise signals due to the occurrence of additional peaks in the magnetization envelope. This behavior in the magnetic response can serve as a tool for non-destructive evaluation of ferromagnetic materials for which phase constitution and phase changes affect the structural performance.

**Development of Gallium-Indium Alloys, Nonmagnetic Test Masses for Exotic Spin-Dependent Force Searches**

MARIAN KHOSRAVI, RAKSHYA KHATIWADA, WILLIAM M. SNOW, Indiana Univ - Bloomington, Center for the Exploration of Energy and Matter — Possible new spin-dependent short-range forces of nature in the mm to μm range which couple to nucleons are now sought in most experiments. Most experiments search for this possible interaction through NMR frequency shifts of polarized nuclei with the introduction of an unpolarized test mass nearby [1]. However, any nonzero magnetic susceptibility of this test mass can produce a systematic error in the measurement. We therefore seek materials with magnetic susceptibilities as close as possible to zero. We synthesized Gallium-Indium (Ga-In) alloys with various Indium percentages which are liquid at room temperature and measured their magnetic susceptibilities using a torsion balance-based commercial device. The measured magnetic susceptibilities range from $-0.06E-06$ to $-0.12E-06$ cgs volume susceptibility and are consistent with the weighted average of the component susceptibilities. The values are about an order of magnitude lower than water for a substance possessing 4.7 times larger nuclear density. [1] P. H. Chu, A. Dennis, C. B. Fu, H. Gao, R. Khatiwada, G. Laskaris, K. Li, E. Smith, W. M. Snow, H. Yan, and W. Zheng, Phys. Rev. D 87, 011105(R) (2013)

11:15AM Z31.00001 Tuning Dirac states at grain boundaries in the topological insulator Bi2Se3. LIAN LI, University of Wisconsin, Milwaukee — Symmetry protected Dirac states have been experimentally observed in topological insulator (TI) bismuth chalcogenides. Recently, we have further demonstrated direct electrical generation and detection of spin accumulation induced by spin-momentum locking of Dirac surface states in Bi2Se3, a critical step forward towards future electronic and spintronic applications. In this talk, I will give an overview of the opportunities and challenges in the epitaxial growth of these layered TIs that exhibit a strong (covalent) intra-layer bonding and weak (van der Waals) inter-layer bonding. Using Bi2Se3 as an example, I will show that this characteristic anisotropic bonding facilitates a spiral growth mode on virtually any substrates by molecular beam epitaxy [2]. The coalescence of these spirals results in a high density of grain boundaries (GBs) [3,4]. Using scanning tunneling and transmission electron microscopies, and density functional theory calculations, I will further show that near the zero-angle GBs (i.e., anti-phase domain boundaries), caused by vertical shifts of a fraction of a Bi2Se3 quintuple layer, the Dirac states are robust against scattering by these extended structural defects. However, electrostatic fields on the order of 108 V/m are found, which locally charge the Dirac state, shifting the Dirac point by up to 120 meV [3]. On the other hand, low-angle (<15°) GBs are found to be of the tilt variant, consisting of alternating edge dislocation pairs [4], resulting in periodic in-plane stretching and compression. Scanning tunneling spectroscopy reveals that in-plane stretching reduces the van der Waals gap, enhancing the Dirac states; while in-plane compression expands the inter-quintuple separation, therefore destroying the Dirac states and opens a gap in the local density of states. These findings demonstrate the tunability of Dirac states by electric field and strain at the atomic scale, and also highlight the inherent formation of GBs during vapor phase epitaxy of layered TIs. Finally, I will discuss methods to possibly control the density and types of GBs to minimize their impact on carrier transport. [1] C. H. Li, O. M. J. van’t Erve, J. T. Robinson, Y. Liu, L. 11:51AM Z31.00002 Magnetic Correlations in the Quasi-2D Semiconducting Ferromagnet CrSiTe2. TRAVIS WILLIAMS, ADAM ACZEL, MARK LUMSDEN, STEVE NAGLER, MATT STONE, JIANQIANG YAN, Oak Ridge National Laboratory, DAVID MANDRUS, University of Tennessee — The quasi-two-dimensional, semiconducting ferromagnet CrSiTe2 is a particularly attractive candidate for spintronics applications due to its relatively accessible magnetic phase transition and large magnetic moment. In this study, we use neutron scattering to measure the static and dynamic magnetic properties. Neutron diffraction shows 3D ordering below TC = 33K, but two dimensional static correlations persist up to at least 300K. The inelastic neutron scattering data shows two distinct spin wave bands, which are nearly dispersionless along the c-axis. The exchange constants extracted from the data suggest that the spins are very nearly Heisenberg, but only weakly coupled perpendicular to the 2D planes. Above the Curie temperature, the spin wave intensity decreases drastically but, like the static correlations, these dynamic magnetic correlations persist within the 2D planes up to room temperature.

12:03PM Z31.00003 Infrared spectroscopy of Cr and V doped Sb2Te3: dilute magnetic semiconductors. DAVID CRANDLES, JASON MANSON, ANTHONY MADUBUONU, Department of Physics, Brock University, Canada, CTIRAD UHER, Department of Physics, University of Michigan, USA, PETR LOSTAK, Department of General and Inorganic Chemistry, Faculty of Chemical Technology, University of Pardubice, Czech Republic — Temperature dependent optical reflectance measurements on well characterized samples of non-intentionally doped, Cr-doped and V-doped Sb2Te3 show that both the parent compound and the Cr-doped version are narrow-gap semiconductors (Eg ≈ 0.25 eV) with a conventional Drude free carrier absorption. The carrier density increases slightly with decreasing temperature while the scattering rate increases quadratically with temperature which is a sign of optical phonon scattering. Vanadium doping introduces a change in the temperature dependence of the scattering rate as well as higher electrical resistivity than Cr-doped Sb2Te3. Analysis of the literature values of the saturation magnetization for H || c suggests that V is in a mixed valence state V3+/V4+.

12:27PM Z31.00005 Electrical detection of spin-momentum locking in topological insulators\textsuperscript{1}, CONNIE LI, OLAF VAN ’T ERVE, JEREMY ROBINSON, Naval Research Lab, YAOYI LI, LIAN LI, University of Wisconsin, Milwaukee, BERRY JONKER, Naval Research Lab — One of the most striking properties of topological insulators (TIs) is that of spin-momentum locking – the spin of the TI surface state lies in-plane, and is locked at right angle to the particle momentum. While anticipated by theory, direct electrical access to this spin system in a simple transport structure had been challenging, due to that the bulk is typically unintentionally doped and contributes to transport. Using a ferromagnet/tunnel barrier detector contact that preferentially probes surface/ interface spins, we have demonstrated the first direct electrical detection of spin-momentum locking in the TI surface states in Bi\textsubscript{2}Se\textsubscript{3}.\textsuperscript{1} However, as the bulk carrier concentration for Bi\textsubscript{2}Se\textsubscript{3} is typically in the 10\textsuperscript{19} cm\textsuperscript{-3} range, the Fermi level is well within the conduction band, where a significant portion of the current is shunted through the bulk. Moving the Fermi level to within the gap is desirable to eliminate current shunting, as well as contribution from Rashba 2DEG states that may dilute the signal.\textsuperscript{[2]} These results, as well as how they affect the spin signal measured will be discussed at the meeting.\textsuperscript{[1]} C. H. Li, et. al., Nat. Nanotech. 9, 218 (2014).\textsuperscript{[2]} S. Hong et. al., PRB 86, 085131 (2012).

12:39PM Z31.00006 The effect of low-symmetry defects in semiconductors on spin Hall conductivity\textsuperscript{1}, MATTHEW D. MOWER, MICHAEL E. FLATTÉ, University of Iowa — We study the effect of low-symmetry defects in semiconductors on the spin Hall conductivity of carriers. It has previously been shown that these defects, e.g. DX centers in direct-gap III-V semiconductors, couple to carriers via a rather large, novel spin-orbit interaction. Compared to translational- or bulk-asymmetry based spin-orbit interactions, this spin-orbit interaction considerably enhances the carrier spin relaxation rate. However, we find that it does not make appreciable contributions to transverse spin currents. At the level of the 1st and 2nd Born approximations, there is neither side-jump nor skew scattering from these defects. Thus, we imagine a scenario where shifting impurities between substitutional and interstitial (low symmetry) positions quickly relaxes a spin system with negligible effects on existing transverse spin currents.

12:51PM Z31.00007 Intraband and interband spin-orbit torques in non-centrosymmetric ferromagnets, H. LI, KAUST, K. VYBORNY, T. JUNGWIRTH, Institute of Physics ASCR, H. GAO, J. SINOVA, Texas A&M University, A. MANCHON, KAUST — Experimental observations of the spin-orbit torque in non-centrosymmetric ferromagnets such as multilayered ferromagnetic metals and dilute magnetic semiconductors, have recently been reported\textsuperscript{[1]}. Two scenarios have been invoked to explain the origin of these current-driven torques. In the first one, the spin orbit coupling generates an in-plane non-equilibrium spin density and exerts a field-like torque on the magnetization. In the second one, the torque originates from the spin Hall effect occurring in the normal metal placed below the ferromagnet. Recently, a large (anti-)damping-like torque has been observed in a single magnetic GaMnAs layer\textsuperscript{[2]}. Obviously, the torque cannot be attributed to the spin Hall effect owing to the absence of the adjacent heavy metal. Such a torque might be attributed to the interband contribution to the non-equilibrium spin polarization in the linear-response Kubo formula. This intrinsic (scattering-independent) mechanism is related to (a specific type of) the Berry curvature and our calculations corroborate its link to actual experiments. Our numerical results show the paramagnetic dependence of the different torque components, they exhibit similarities to the analytical results for the Rashba two-dimensional electron gas in the weak disorder limit and open new perspectives in the development of current-driven spin-orbit torques by structural design.\textsuperscript{[1]} A. Chernyshev, et.al., Nat. Phys. 5, 656(2009).\textsuperscript{[2]} L. Liu et al. Science 336, 555 (2012)

1:03PM Z31.00008 Current induced spin orbit torques in antiferromagnets, HUAWEI GAO, Texas A&M University, JAKUB ZELEZNY, T. JUNGWIRTH, Institute of Physics ASCR, Czech Republic, JAIRO SINOVÁ, Institute fur Physik, Johannes Gutenberg Universität Mainz, Germany — In magnetic material with bulk inversion asymmetry or structure inversion asymmetry, unpolarized electric current can induce non-equilibrium spin polarization due to spin orbit coupling. This non-equilibrium spin polarization is exchange coupled with the magnetic order and act on them as torques. These torques are called spin orbit torques(SOT) which can be used to manipulate the magnetic orders. In ferromagnets, SOT effects have been observed experimentally. We extend the study of SOT to antiferromagnetic systems. Besides similar effects as in ferromagnets, we show staggered SOT in antiferromagnets following exactly the antiferromagnetic lattice which couple with the Neel order directly. We’ll report the study in both a 2D collinear antiferromagnetic model and a non-collinear antiferromagnet IrMn.

1:15PM Z31.00009 Spin Hall Effect and Irreversible Thermodynamics; Center-to-Edge Transverse Current-Induced Voltage, WAYNE SASLOW\textsuperscript{1}, Texas A&M University — For the first time the Dyakonov and Perel theory of the Spin Hall Effect (SHE) is examined from the viewpoint of irreversible thermodynamics, which is significantly more constraining than the symmetry arguments of pure phenomenology. As thermodynamic driving forces we include the thermal gradient, the gradient of the electrochemical potential (rather than the potential gradient and density gradient separately), and the “internal” magnetic field that is thermodynamically conjugate to the magnetization. In turn, we obtain the form of bulk transport coefficients relating the fluxes to the thermodynamic forces. Relative to Dyakonov and Perel, in addition to the new terms due to thermal gradients, the Onsager relations require three new (non-linear) terms in the current density, and minor revisions in the current density and spin current density. For a longitudinal current along a strip, the center-to-edge transverse voltage difference, due both to the $-β\vec{P} \times \vec{E}$ term of the number current density $\vec{q}$ and to one of the new current density terms, is determined. An ac capacitative probe likely would not significantly disturb this effect. We estimate a $\Delta V_{\perp}$ as large as $10^{-1}$ V for GaAs, but only $10^{-8}$ V for Pt.

1:27PM Z31.00010 Disentangling the spin torques in a ferromagnet/semiconductor bilayer, TIMOTHY D. SKINNER, London Centre for Nanotechnology, University College London, KAMIL OLEJNIK, Institute of Physics, ASCR, LUCY K. CUNNINGHAM, University of Cambridge, HIDEKAZU KUREBAYASHI, London Centre for Nanotechnology, University College London, RICHARD P. CAMPION, BRYAN L. GALLAGHER, University of Nottingham, TOMAS JUNGWIRTH, Institute of Physics, ASCR, ANDREW J. FERGUSON, University of Cambridge — Current-induced spin torques measured in ferromagnet/paramagnetic metal bilayers can originate from the spin-Hall effect (SHE) and inverse spin galvanic effect (ISGE). Distinguishing the two effects has proved difficult as they can both possess the same symmetries, but it is essential for our basic physical understanding of the spin torques at the ferromagnet/paramagnetic interface to experimentally disentangle the SHE and ISGE contributions. In our approach, we look to zinc-blende crystals (such as III-V semiconductors), where the ISGE has a symmetry which depends on the crystal orientation. The field-like [1] and antidamping [2] torques, arising from the ISGE in the magnetic III-V semiconductor (Ga,Mn)As, are well understood because of low-temperature spin-torque ferromagnetic resonance (ST-FMR) measurements. Through new ST-FMR measurements, we show that in a room-temperature ferromagnetic metal/paramagnetic semiconductor bilayer, the SHE and ISGE co-exist and can be unambiguously separated and quantified by their symmetries.

1:39PM Z31.00011 ABSTRACT WITHDRAWN
11:15AM Z32.00001 Turning a strongly correlated Mott insulator into a weakly correlated metal\textsuperscript{1}, Y. F. KUNG, SIMES, SLAC National Accelerator Laboratory and Stanford University, E. A. NOWADNICK, Cornell University, C. J. JIA, SIMES, SLAC National Accelerator Laboratory and Stanford University, S. JOHNSTON, University of Tennessee, Knoxville, B. MORITZ, SIMES, SLAC National Accelerator Laboratory, T. P. DEVEREAUX, SIMES, SLAC National Accelerator Laboratory and Stanford University — As Mott insulators, such as cuprate superconductors, are doped with charge carriers, strong electron-electron interactions give rise to fascinating novel phenomena. Much of the interesting physics arises in the intermediate doping regime where the system displays metallic behavior strongly renormalized by correlations, in contrast with the naive expectation that the correlations would weaken rapidly away from half filling. To shed light on this issue, we examine the doping evolution of spin and charge excitations in the strongly correlated single-band Hubbard model using determinant quantum Monte Carlo (DQMC). Compared to the behavior predicted by the random phase approximation (RPA), the evolution of the excitations from DQMC shows that significant correlations remain up to relatively high doping levels (40\% hole doping and 15\% electron doping), near the maximum of what can be achieved in cuprates. The comparison improves with additional doping (up to 75\% hole doping) as the system approaches a metallic state in which the spin and charge excitation spectra are essentially the same.

11:15AM Z32.00002 The electromagnetic field induced excitation of magnons in spin-orbit coupled Mott insulators\textsuperscript{2}, ROHIT HEGDE, ALLAN MACDONALD, University of Texas, Austin — The spin-only description of the Hubbard model’s low-energy states belies an active charge degree of freedom that can in principle couple to external electromagnetic fields. The precise way in which the charge and current densities manifest in the spin sector is constrained when the electronic system possesses SU(2) spin-rotational symmetry, thus limiting the response to electric and magnetic fields. This constraint lifts in the presence of spin-orbit coupling, leading to the emergence of novel responses like that of an electron’s spin to an external magnetic field resulting from induced orbital currents in addition to the usual direct Zeeman coupling. Magnons mediate the linear response of electrons to time varying fields of low-frequency ($\hbar \omega \ll U$). We study the electric and magnetic susceptibilities of single band Hubbard models with spin-dependent hopping on various lattices, and comment on the applicability to magnetically ordered materials like the iridates.

11:27AM Z32.00003 Sub-gap optical conductivity in the Mott insulator in one-dimensional Hubbard model with randomness, CHENG-JU LIN, OLEXEI MOTRUNICH, California Institute of Technology — We demonstrate a non-zero optical conductivity within the Mott gap in the one-dimensional Hubbard model with randomly distributed onsite potential. The effective Hamiltonian in the spin sector is described by the random exchange coupling spin-$\frac{1}{2}$ antiferromagnetic Heisenberg model, which is in the random-singlet phase. An electric field couples to the electric polarization operator, and we first find its expression in terms of the spin variables in the Mott insulator regime. We then apply the decimation renormalization-group analysis pioneered by Dasgupta, Ma and Fisher to keep track of the polarization operator. Via Kubo formula, we find the optical conductivity to be $\sigma(\omega) \sim \frac{\psi}{(\ln \omega)^{\frac{5}{2}}} \omega^{\frac{3}{2}}$ at low frequencies, where $\psi = (1 + \sqrt{5})/4$.

11:51AM Z32.00004 A 1D, $\times 1$D, Heisenberg-Kondo Lattice compound Nb$_2$O$_{29}$\textsuperscript{3}, WARREN PICKETT, University of California Davis, KWAN-WOO LEE, Korea University — Local moments embedded in conducting systems form a rich platform for unusual phases, with phenomena including Kondo, heavy fermion, and non-Fermi liquid physics. Using first principles based methods and the refined crystal structure based on columns of 3×4 planar units of NbO$_6$ octahedra, we determine that mixed valent Nb$_2$O$_{29}$ displays tightly bound local moments forming spin chains along one direction cross-coupled by conducting “nanowires” in the perpendicular direction. Just how local moments – very rare for Nb – emerge and coexist with itinerant electrons, an enigma for decades in this system, is elucidated based on the local structure of the NbO$_6$ octahedra and orbital-$s$ spin ordering. The resulting 1D, $\times 1$D, Heisenberg-Kondo lattice ($s=$spin, $c=$charge) picture will be discussed.

12:03PM Z32.00005 Competition between heavy-fermion and Kondo interaction in isoelectronic A-site ordered perovskites, DEREK MEYERS, S. MIDDEY, University of Arkansas, J.-G. CHENG, Beijing National Laboratory for Condensed Matter Physics, S. MUKHERJEE, Department of Condensed Matter Physics and Materials Science, B.A. GRAY, Y. CAO, University of Arkansas, J.-S. ZHOU, J.B. GOODENOUGH, University of Texas, Y. CHOI, Advanced Photon Source, D. HASKEL, Advanced Photon Source, J.W. FREELAND, Advanced Photon Source, T. SAHA-DASGUPTA, S.N.Bose National Centre for Basic Sciences, J. CHAKHALIAN, University of Arkansas — With current research efforts shifting towards the 4d and 5d transition metal oxides, understanding the evolution of the electronic and magnetic structure as one moves away from 3d materials is of critical importance. Here weX-ray spectroscopy and electronic structure calculations on A-site ordered perovskites with Cu in the site and the B-sites descending along the 9th group of the periodic table to elucidate the emerging properties-orientals change from partially filled 3d, 4d, to 5d. The results show that when descending from Co to Ircharge transfers from the cuprate like Zhang-Rice state on Cu to the t2g orbital of the B site. As the Cuorbital occupation approaches the Cu$^{2+}$ limit, a mixed-valence state in CaCu$_3$RhO$_{4}$O$_{12}$ and heavy fermion CaCu$_3$IrO$_{4}$O$_{12}$ are observed. The investigated d-electron compounds are mapped onto the Doniach phaseof the competing RKKY and Kondo interactions developed for f electron systems.

12:51PM Z32.00007 Stability of the AFM phase in the three-band Hubbard-Holstein model . EDWIN HUANG, Stanford Univ, STEVE JOHNSTON, University of Tennessee, YVONNE KUNG, Stanford Univ, BRIAN MORITZ, SLAC, TOM DEVEREAUX, Stanford Univ / SLAC — The interplay between electron-electron interactions and electron-phonon coupling in cuprates can be explored via the Hubbard-Holstein model. Here, we use determinant quantum Monte Carlo simulations to study the three-band version of the model with electron coupling to c-axis optical oxygen vibrations. The model exhibits competition between an antiferromagnetic phase and a charge density wave phase. The corresponding phase diagram is compared against that from existing single-band Hubbard-Holstein results. Finally we investigate the evolution of the phase diagram due to changes in doping and temperature.

1:03PM Z32.00008 Geometrical Effects in Orbital Magnetism , YANG GAO, UT Austin, SHENGYUAN YANG, SUTD, QIAN NIU, UT Austin — Within the wave-packet semi classical approach, the Bloch electron energy is derived to second order in the magnetic field and classified into gauge-invariant terms with clear physical meaning, yielding a fresh of the complex behavior of orbital magnetism. The Berry curvature and quantum metric of the Bloch states rise to a geometrical magnetic susceptibility, which can be dominant when bands are filled up to a small energy gap.is also an energy polarization term, which can compete with the Peierls-Landau and Pauli magnetism on a Fermi surface. These, and an additional Langevin susceptibility, can be calculated from each single band, leaving the Vn Vleck susceptibility the only term truly from interband coupling.

1:15PM Z32.00009 Effective transient states for nonequilibrium charge density wave systems under ultrafast control pulses . BIN HWANG, JENNI PORTMAN, PHILLIP DUXBURY, Michigan State University — A central challenge for implementing Mott-insulator transition in nonequilibrium time-dependent charge density wave systems is finding an effective pulse to achieve the goal. Effective ultra laser pulses have been found for the transient states in nonequilibrium time-dependent charge density wave systems based on a promising optimal-control method. Intense ultrafast laser pulses allow the preparation of transient states of matter exhibiting strong non-equilibrium between electrons and lattice. By controlling the laser pulse, we are able to change the transient states of these quantum systems. The optical and structural properties as well as the temporal evolution of such states provide insights into the mutual dependence of electronic and atomic structure. We approach the problem by showing examples from charge-density-wave systems. Nonequilibrium techniques can be used to qualitatively describe the common short-time experimental features. Through simulations based on non-equilibrium Green’s function formalism we show how to achieve effective transient states for nonequilibrium systems under ultrafast control pulses.

1:27PM Z32.00010 Interplay of 3d-5d interactions in high-T_c osmium-based double perovskites , A.E. TAYLOR, S. CALDER, Quantum Condensed Matter Division, Oak Ridge National Laboratory, R. MORROW, P.M. WOODWARD, Department of Chemistry, The Ohio State University, J.Q. YAN, Materials Science & Technology Division, Oak Ridge National Laboratory, B. WINN, M.D. LUMSDEN, A.D. CHRISTIANSON, Quantum Condensed Matter Division, Oak Ridge National Laboratory — In 3d-5d systems the strongly magnetic 3d orbitals and extended 5d orbitals with enhanced spin-orbit coupling lead to a range of high T_c magnetic states and novel behavior not present in systems consisting solely of 3d or 5d ions. The two distinct octahedral sites in double perovskites A_2BB'O_6 allow an ordered 3d-5d structure to form, providing a variety of systems to be investigated. Unravelling the interactions controlling these systems, however, is an open challenge. The highest known T_c in such a system, 725K, is found in insulator Sr_2CrOsO_6. This questions the theory for high-T_c systems such as T_c=400K Sr_2FeReO_6 which relies on half-metallic behavior. To unravel the nature of the interactions in 3d-5d systems, we have studied the series of compounds Sr_2XOsO_6. We have utilized elastic and inelastic neutron scattering to probe the spin states in the systems, and therefore test predictions that the magnetic interactions are controlled by a frustrated AFM Heisenberg model [1]. By studying the series, we are able to relate changes in the spin wave spectrum to dramatic changes in the magnetic order from T_N = 95K antiferromagnetism to T_c = 725K ferrimagnetism.

Friday, March 6, 2015 11:15AM - 1:51PM – Session Z34 DMP: Hydrogen Production, Storage, Delivery 210A - Zachary Gabelle, Carnegie Institute for Science

11:15AM Z34.00001 Gettering of Hydrogen and Methane from a Helium Gas Mixture . ROSA E. CARDENAS, Department of Physics, The University of the Incarnate Word, 4301 Broadway, San Antonio, TX 78209, DONALD F. COWGILL, KENNETH D. STEWART, Sandia National Laboratories, Hydrogen and Metallurgical Sciences, 7011 East Avenue, Livermore, CA 94550 — In this study, we developed an approach for accurately quantifying the helium content in a gas mixture also containing hydrogen and methane using commercially available getters. We performed a systematic study to examine how both H2 and CH4 can be removed simultaneously from the mixture using two SAES St 172 getters operating at different temperatures. The remaining He within the gas mixture can then be measured directly using a capacitance manometer. The optimum combination involved operating one getter at 650°C to decompose the methane, and the second at 110°C to remove the hydrogen. This approach eliminated the need to reactivate the getters between measurements, thereby enabling multiple measurements to be made within a short time interval, with accuracy better than 1%. We anticipate that such an approach will be particularly useful for quantifying the He-3 in mixtures that include tritium, tritiated methane, and helium-3. The presence of tritiated methane, generated by tritium activity, often complicates such measurements.

11:27AM Z34.00002 Effects of the Electronic Doping In the Stability of the Metal Hydride NaH1, MONICA-ARACELI OLEA-AMEZCUA, JUAN-FRANCISCO RIVAS-SILVA, OMAR DE LA PEÑA-SEAMAN, Institute of Physics (IFUAP), Benemérita Universidad Autonoma de Puebla (BUAP), ROLF HEID, KLAUS-PETER BOHNEN, Institute of Solid State Physics (IFP), Karlsruher Institute of Technology (KIT) — Despite metal hydrides light weight and high hydrogen volumetric densities, the Hydrogen desorption process requires excessively high temperatures due to their high stability. Attempts for improvement the hydrogenation properties have been focus on the introduction of defects, impurities and doping on the metal hydride. We present a systematic study of the electronic doping effects on the stability of a model system, NaH doped with magnesium, forming the alloying system Na_1-xMg_xH. We use the density functional theory (DFT) and the self-consistent version of the virtual crystal approximation (VCA) to model the doping of NaH with Mg. The evolution of the ground state structural and electronic properties is analyzed as a function of Mg-content. The full-phonon dispersion, calculated by the linear response theory (LRT) and density functional perturbation theory (DFPT), is analyzed for several Mg-concentrations, paying special attention to the crystal stability and the correlations with the electronic structure. Applying the quasiharmonic approximation (QHA), the free energy from zero-point motion is obtained, and its influence on the properties under study is analyzed.

11:39AM Z34.00003 High Efficiency, Surface Stable Photocatalytic H2 evolution on TiO2-passivated GaAs1. JING QIU, GUANGTONG ZENG, University of Southern California, STEPHEN B. CRONIN, STEPHEN B. CRONIN NANO RESEARCH LAB TEAM — III-V compounds, such as GaAs, are used widely for high efficiency photovoltaic solar energy conversion. The electrochemical instabilities of these materials, however, has limited their applicability in photocatalysis. Here, we demonstrate that thin (1-5nm) films of TiO2 deposited by atomic layer deposition on planar GaAs provide electrochemical stability and substantial improvements in the efficiency of photocatalytic water splitting. The TiO2-passivated GaAs shows no photochemical degradation or corrosion after 48 hours, while bare GaAs shows substantial degradation after just 15 minutes. This TiO2 passivation layer produces a 32-fold enhancement over bare GaAs, with an overall photoconversion efficiency of 11%. We find that just 1nm of TiO2 produces the optimum conditions for photocatalysis. This is not thick enough to form a continuous film, and instead produces small regions of non-stoichiometric TiO2, which is rich with Ti3+ surface states that are known to be catalytically active sites. These charged sites stabilize, or lower the energy of, OH- intermediate species in this reaction, thus lowering the reaction barrier height. X-ray photoemission spectroscopy and photoluminescence spectroscopy provide further evidence for these Ti3+ surface states.

11:51AM Z34.00004 Aging Effects on the Hydrogen Storage Characteristics of Li-Mg-B-N-H Complex Hydrides1. SESHA SRINIVASAN, Florida Polytechnic University, College of Innovation and Technology, ERIC VICKERS, JAMES MUL-HARAN, Florida Polytechnic University, College of Engineering, GHAZI DARKAZALLI, Florida Polytechnic University, YOGI GOSWAMI, ELIAS STEFANAKOS, University of South Florida, Clean Energy Research Center. FLPOLY-CERC COLLABORATION — The aging effects on the hydrogen storage characteristics and chemical formulations of the complex hydrides are discussed in this study. The aging effects due to atmospheric events such as oxygen and moisture coverage and self-decomposition are currently under investigation. The candidate material chosen for this study is Lithium/Magnesium based complex hydride LiBH4/LiNH2/MgH2. These materials were prepared using high energy ball milling under Ar/H2 atmosphere with different milling durations. The chemical, structural and microstructural characteristics of the synthesized and aged materials were compared and investigated using TGA/DSC, FTIR, XRD, BET and SEM analytical tools. Hydrogen storage properties such as hydrogen sorption kinetics, cycle life and pressure-composition isotherm (PCI) was examined via high pressure, high temperature Sievert’s type apparatus. This current study will shed light to compare and contrast the above mentioned characteristics for the aged samples practically at the same experimental conditions. Furthermore, we have investigated the relationship between the aging effects with respect to the crystallite sizes of the candidate materials and their nano-dopant variants.

1We acknowledge the grant from Florida Energy Systems Consortium and support from Florida Polytechnic University.

12:03PM Z34.00005 Molecular simulation of hydrogen storage on hydrogen storage in layered graphite oxide: effect of functional group and intercalated ion, JAEHYUN BAE, JISOON IHM, Seoul Natl Univ, SEOUL NATIONAL UNIVERSITY TEAM — The adsorption of molecular hydrogen gas into layered graphite oxide (GO) has been studied using both classical grand-canonical Monte-Carlo simulations and ab initio calculations. Different from graphite, interlayer distance of graphite oxide can be varied by controlling the functional group density or introducing alkali metal ion in the synthesis process, this gives new ways of searching for efficient hydrogen storage in porous materials. Our ab initio calculations show that average hydrogen binding energy in the graphite oxide layers is enhanced due to the dipole interaction and small hybridization between hydrogen and functional groups. Introducing alkali metal inside the graphite oxide layers further increases average binding energy by 0.1eV and interlayer distance and hydrogen storage capacity increases close to 3wt% at 300K and 10MPa, similar to recent experiments. In the grand-canonical Monte-Carlo simulations, we use ab initio fitted H2-GO and H2-H2 interaction potential and simulation results are understood by equilibrium of interacting gases in the quasi 2-dimensional potential landscape inside the GO layers. Our computational results suggest the best way of synthesizing the optimal chemical and atomic structure of GO for hydrogen storage medium.

12:15PM Z34.00006 ABSTRACT WITHDRAWN —

12:27PM Z34.00007 Hydrothermal synthesis and characterization of CuFeO2 Delafossite Crystals1, M. SARABIA, S. ROJAS, Pontificia Universidad Catolica de Chile, Z. LOPEZ-CABANA, Universidad de Talca, Chile, R. VILLALBA, G. GONZALEZ, Instituto Venezolano de Investigaciones Cientificas, Caracas, Venezuela, A.L. CABRERA, Pontificia Universidad Catolica de Chile — In this study we synthesized CuFeO2 compounds using as precursors CuO and FeOOH with fused NaOH. The synthesis takes place in a Teflon vessel lasting 97 (Synthesis I) or 48 hrs (Synthesis II) at 210 °C. The compound obtained were analyzed for crystal structure and morphology with Raman Spectroscopy, X-Ray Diffraction (XRD), X-Ray Photoelectron Spectroscopy (XPS), Scanning Electron Microscopy (SEM), Energy Dispersive Spectroscopy (EDS). Optical properties were obtained by UV-Vis Spectroscopy and Gas adsorption measured with a Quartz-Crystal Microbalance (QCM). Our results show that this type of hydrothermal synthesis is capable to recreate the Delafossite structure of this copper-iron oxide. This material chemisorbs water and carbon dioxide.

13:39PM Z34.00008 Rapid Facile Microwave-assisted Solvothermal Synthesis of Rod-like CuO/TiO2 for High Efficiency photocatalytic Hydrogen Evolution, YI-HSIEN YU, YING-PIN CHEN, ZHENGDONG CHENG, Texas A&M Univ — Rod-like CuO/TiO2 was prepared by a rapid facile microwave-assisted solvothermal method for high efficiency photocatalytic hydrogen evolution. The structure of obtained CuO/TiO2 samples were characterized by X-ray diffraction (XRD), field emission scanning electron microscopy (FE-SEM), high resolution transmission electron microscopy (HR-TEM), and the amount of produced hydrogen was analyzed by gas chromatography (GC). CuO decorated TiO2 rods exhibited greatly improvement of photocatalytic hydrogen evolution. Utilizing 30 mg of CuO/TiO2 rods sample showed highest hydrogen evolution rate over utilizing 50 mg and 100 mg. Comparing to hydrogen evolution rate of 45.4 µmol h−1 g−1 by using bare Rod-like TiO2, 1 wt% CuO loaded TiO2 rods presented the highest hydrogen evolution rate of 3508.7 µmol h−1 g−1 while hydrogen evolution rate of 0.5 wt%, 5 wt%, and 10 wt% CuO loaded TiO2 rods were 157.1, 2817, and 2595 µmol h−1 g−1, respectively. Such enhancement of photocatalytic activity could be ascribed to that CuO improves not only light harvesting but also enhanced separation of electron-hole carriers.
12:51PM Z34.00009 The Electrical and Structural analysis of degraded Single Junction Amorphous Silicon Solar Modules1. GILBERT OASAYEMWENYE, Fort Hare Institute of Technology, ENERGY EFFICIENCY TEAM — This paper outlines a systematic approach used in evaluating the quality, performance and reliability of single junction amorphous silicon solar modules (a-Si:H).

The analytical techniques include an electrical and structural analysis. These techniques were used to obtain a holistic view of the state of affairs of these readily available PV modules for small stand-alone systems. Specifically, current-voltage (I-V) characterization and scanning electron microscopy (SEM) will be presented as diagnostic tools in this article. The SEM (JEOL, JED-2300) was used to study the surface morphology of the affected regions, results show structural damage in the affected regions. The experiment shows that the energy output of the modules varies a degradation variation of 2.5% to 25.7%, was observed. The detailed results will be presented in the final paper. In conclusion, this research established the degradation which occurs and correlate it to the morphological damage. The module with the worst case scenario has an efficiency of 59% decrease, this could be unacceptable in a device where stability is of priority.

1We sincerely thank GMDRC and Eskom for financing this project.

1:03PM Z34.00010 First-principles quantum-mechanical investigations: The role of water in catalytic conversion of furfural on Pd(111)1, WENHUA XUE, University of Tulsa, MIGUEL GONZALEZ BORJA, DANIEL E. RESASCO, University of Oklahoma. SANWU WANG, University of Tulsa — In the study of catalytic reactions of biomass, furfural conversion over metal catalysts with the presence of water has attracted wide attention. Recent experiments showed that the proportion of alcohol product from catalytic reactions of furfural conversion with palladium in the presence of water is significantly increased, when compared with other solvents including dioxane, decalin, and ethanol. We investigated the microscopic mechanism of the reactions based on first-principles quantum-mechanical calculations. We particularly identified the important role of water and the liquid/solid interface in furfural conversion. Our results provide atomic-scale details for the catalytic reactions.

1:15PM Z34.00011 Study of effects of transport properties of a biodiesel derived from soybean on the mixture process formation using CFD OpenFOAM1, ADOLOF BENITEZ MOLINA, OSCAR ALEJANDRO DE LA GARZA LEON, SIMON MARTINEZ MARTINEZ, FAUSTO ALEJANDRO SANCHEZ CRUZ, Universidad Autonoma de Nuevo Leon-FIME, LIITE-Laboratory for Research and Innovation in Energy Technology, Mexico — In this work has been studied the effects of the transport properties of biodiesel derived from soybean on the mixing process, using a CFD code OpenFOAM. For this the most relevant properties in this mixing process have been determined: density, viscosity, surface tension and vapor pressure. These fuel properties govern the spray formation however, there are only very limited studies that determined for its subsequent implementation in a CFD code, such as the OpenFOAM code. Such properties were obtained using empirical correlations based on the molecular structure of the fatty acids that compose the biodiesel and applying nonlinear regression are implemented in the programed models used in the OpenFOAM code for a diesel spray simulation. The results achieved in the present study on the one side, have been confirmed how the biodiesel properties affect the mixture process, and on the other side, the obtained coefficients which can be used in the proposed models by the CFD code OpenFOAM for the implementation of this properties as a temperature function without the correlations based on the molecular structure of the fatty acid.

1Also they thank the CONACYT from Mexican Government for granting the Master degree of Adolfo Benitez

1:27PM Z34.00012 Catalytic hydrogenation of cresol: first-principles density-functional calculations and ab initio molecular dynamics simulations1, YAPING LI, Department of Physics and Engineering Physics, University of Tulsa, ZHIMIN LIU, FRIEDERIKER JENTOFT, School of Chemical, Biological and Materials Engineering, University of Oklahoma, SANWU WANG, Department of Physics and Engineering Physics, University of Tulsa — Biomass is an important renewable energy resource. Cresol is one of components in crude bio-oil generated from biomass, and hydrogenation of cresol is often involved in the upgrading process. We studied catalytic hydrogenation of cresol on the Pt(111) surface with and without the presence of water. In particular, we used first-principles density-functional theory and ab initio molecular dynamics simulations to obtain adsorption geometries, binding energies, reaction energies, activation energies, and reaction pathways for hydrogenation of cresol with possible products of 2-methylcyclohexanone and 2-methylcyclohexanol. Our theoretical results are used to explain the available experimental measurements, which show a strong influence of water.

1:39PM Z34.00013 Hybrid functional calculation of Na and K impurities in CuInSe2 and CuIn5Se8 solar cell materials1, JANOS KISS, Max Planck Institute for Chemical Physics of Solids Dresden, ELAHEH GHORBANI, Institute of Inorganic and Analytical Chemistry JGU Mainz, HOSSEIN MIRHOSSEINI, Max Planck Institute for Chemical Physics of Solids Dresden, GUIDO ROMA, Service de Recherches de Metallurgie Physique DMN/DEN CEA-Saclay, CLAUDIA FESLER, Max Planck Institute for Chemical Physics of Solids Dresden — Although it is widely known that the presence of Na and K dopants increase the efficiency of CuIn1−ySey (CIGS) thin film solar cells, the incorporation of these impurities and their effect upon the atomic and electronic structure of the light absorber materials is not yet well understood. Using the HSE06 hybrid functional we studied the structure and energetics of Na and K impurities and also Na-Na, K-K and Na-K dumbbells in different substitutional and interstitial positions in CuInSe2 and CuIn5Se8 solar cell materials. We found that among substitutional positions, occupying Cu position is energetically more favorable compared to In and Se positions. The interstitial position, where the impurity is tetrahedrally coordinated by four Se atoms is the most stable site to form Na or K interstitials in CuInSe2, whereas in CuIn5Se8 the pristine copper vacancy positions are more stable. Our data show that Na-Na, Na-K and K-K dumbbells can form both in CuInSe2 and in CuIn5Se8 as well. Comparing the formation energy of various dumbbell configurations, creating dumbbells in a pristine vacant copper site in CuInSe2 has the highest association energy between the impurities.

Session Z36 DAMOP: Focus Session: Non-equilibrium Dynamics in Quantum Systems 211 -
Stefan Natu, University of Maryland, College Park
11:15 AM Z36.00001 Locality in quenched systems with long-range interactions, MICHAEL FOSS-FEIG, Joint Quantum Institute, NIST, and the University of Maryland — For more than a decade, ultracold atomic and molecular systems have been exploited to simulate non-equilibrium models of strongly correlated materials. However, the extremely low (often sub nano-kelvin) temperatures required to realize the most interesting equilibrium states of such models have proven extremely difficult to achieve. When these ultracold systems are driven far from equilibrium, however, very small temperatures get traded in for very long time-scales, which enable the observation of dynamic phenomena that were never even envisioned in the context of real materials. In this talk, I will describe some recent experimental and theoretical explorations of non-equilibrium dynamics in quenched AMO systems, and will discuss some of the interesting questions that arise naturally from their remarkable tunability. In particular, I will describe recent efforts to understand the fate of locality — i.e. constraints on the propagation of information/entanglement — as interactions become increasingly long-ranged.

11:51 AM Z36.00002 Slowest local operators in quantum spin chains, HYUNGWON KIM, Rutgers University, MARI CARMEN BANULS, IGNACIO CIRAC, Max-Planck-Institute for Quantum Optics, MATTHEW HASTINGS, Station Q, Microsoft Research, DAVID HUSE, Princeton University — We numerically construct slowly relaxing local operators in a nonintegrable spin-1/2 chain. Restricting the support of the operator to M consecutive spins along the chain, we exhaustively search for the operator that minimizes the Frobenius norm of the commutator with the Hamiltonian and show that the Frobenius norm bounds the time scale of relaxation of the operator. We find operators with significantly slower relaxation than the slowest slow operator. Using both exhaustive search and tensor network techniques, we find similar slowly relaxing operators for a Floquet spin chain and for quantum circuits on spin chains; these systems are hydrodynamically “trivial,” with no conservation laws restricting their dynamics. We argue that such slow relaxation may be a generic feature following from locality and unitarity.

12:03 PM Z36.00003 Limit cycle phase in driven-dissipative spin systems, CHING-KIT CHAN, TONY LEE, ITAMP, Harvard University, SARANG GOPALAKRISHNAN, Harvard University — Quantum simulator experiments based on trapped ions and atomic ensembles offer an attractive platform to study nonequilibrium many-body phases and phase transitions. We theoretically explore the phase diagram of a driven and dissipative Heisenberg spin system featured by a time-dependent limit cycle phase in which the magnetization oscillates in time. We present a Gaussian-Floquet theory to study the fluctuation of this phase that spontaneously breaks time-translational symmetry. As a time-dependent generalization of the Mermin-Wagner theory, we show how spatial fluctuations destroy the limit cycle ordering for dimension $d \leq 2$. We also demonstrate how the limit-cycle phase leads to new features in the power spectrum measurable in fluorescence experiments.

12:15 PM Z36.00004 ABSTRACT WITHDRAWN —

12:27 PM Z36.00005 Ramping through a topological critical point in two dimensions, MARIN BUkov, PHILLIP WEINBERG, MICHAEL KOLODRUBETZ, Boston University — The recent realization of Floquet Chern insulators has resulted in a prolific study of periodically driven models. In order to probe equilibrium physics, the driving protocol is gently ramped up, in the process of which the system undergoes a dynamical phase transition to a topologically non-trivial state. Since such transitions are controlled by closing and re-opening a band gap, the notion of adiabaticity inevitably breaks down and the system gets excited. In this talk, I shall present recent results based on scaling arguments within Kibble-Zurek theory to study the excitations due to a ramp through a topologically critical point in 2 dimensions. I shall show convincing evidence that the occupation of the chiral edge modes follows similar universal scaling as the bulk as a function of the ramp speed and the system size. Further, I shall apply these results to study the build-up of magnetisation due to the non-adiabatic population of the edge states in Haldane’s model of graphene, which has recently been proposed to detect the topological character of the state of the system. Finally, I shall show that the quantisation of magnetisation is robust against non-adiabaticity due to crossing the critical point.

12:39 PM Z36.00006 The Floquet Adiabatic Theorem revisited, PHILLIP WEINBERG, MARIN BUkov, Boston University, LUCA D’ALESSIO, Boston University, Penn State University, MICHAEL KOLODRUBETZ, SHAINEN DAVIDSON, ANATOLI POLKOVNIKOV, Boston University — The existence of the adiabatic theorem for Floquet systems has been the subject of an active debate with different articles reaching opposite conclusions over the years. In this talk we clarify the situation by deriving a systematic expansion in the time-derivatives of a slow parameter for the occupation probabilities of the Floque states. Our analysis shows that the in a certain limit the transition between Floquet eigenstates are suppressed and it is possible to define an adiabatic theorem for Floquet systems. Crucially we observe however that the conditions for adiabaticity in ordinary and Floquet systems are different and that this difference can become important when the amplitude of the periodic driving is large. We illustrate our results with specific examples of a periodically driven harmonic oscillator and cold atoms in optical lattices which are relevant in current experiments.

12:51 PM Z36.00007 Thermal Steady States in Fermionic Dissipative Floquet Systems, KARTHIK SEETHARAM, CHARLES-EDOUARD BARDYN, California Institute of Technology, MARK RUDNER, University of Copenhagen, NETANEL LINDNER, Technion - Israel Institute of Technology, GIL REFAEL, California Institute of Technology — The possibility to drive quantum systems periodically in time offers unique ways to deeply modify their fundamental properties, as exemplified by Floquet topological insulators. It also opens the door to a variety of non-equilibrium effects. Resonant driving fields, in particular, lead to excitations which can expose the system to heating. Inspired by existing studies of photoexcited semiconductors, we demonstrate that the analog of thermal states can be achieved in a fermionic Floquet system including carrier-carrier interactions, phonon scattering, and spontaneous emission. We show that inelastic “Floquet-Umkopp” processes are responsible for non-thermal heating effects, and identify practical conditions under which they are suppressed. We propose to use suitably engineered external reservoirs of carriers to further stabilize thermal features and control the effective chemical potential of the resulting Floquet distributions.

1:03 PM Z36.00008 Dynamical preparation of Floquet Chern insulators: A no-go theorem and the experiments, LUCA D’ALESSIO, MARCOS RIGOL, Pennsylvania State University — Recently, it has been proposed that time-periodic perturbations can induce topological properties in otherwise non-topological materials, opening the exciting possibility of studying non-equilibrium topological transitions. Here we address what should happen in an experiment when one turns on the periodic driving. On the one hand, for infinite (translationally invariant) systems we prove a no-go theorem. We show that the Chern number is conserved under unitary evolution, i.e., it is impossible to change the possible to define an adiabatic theorem for Floquet systems. Crucially we observe however that the conditions for adiabaticity in ordinary and Floquet systems are different and that this difference can become important when the amplitude of the periodic driving is large. We illustrate our results with specific examples of a periodically driven harmonic oscillator and cold atoms in optical lattices which are relevant in current experiments.

1:15 PM Z36.00009 Universal post-quench prethermalization at a quantum critical point, PETER P. ORTH, PIA GAGEL, JOERG SCHMALIAN, Karlsruhe Institute of Technology (KIT) — We consider an open system near a quantum critical point that is suddenly moved towards the critical point. The bath-dominated diffusive non-equilibrium dynamics after the quench is shown to follow scaling behavior, governed by universal exponents that differ from those for equilibrium and critical exponents. We determine this exponent and show that it describes universal prethermalized coarsening dynamics of the order parameter in an intermediate time regime. Implications of this quantum critical prethermalization are a powerlaw rise of order and correlations after an initial collapse of the equilibrium state and a crossover to thermalization that occurs arbitrarily late for sufficiently shallow quenches. [1] P. Gagel, P. P. Orth, J. Schmalian, Phys.Rev. Lett. (in press) arXiv:1406.6387
The distribution of the times in-between the quantum jumps reveals quantitative information about the population and dynamics of quasiparticles [3]. The amplifier (a Josephson Parametric Converter) we can observe quantum jumps between the 0 and 1 states of the qubit in thermal equilibrium with the environment.

11:15AM Z39.00001 Measurement of recombination and single-vortex trapping of quasiparticles in a superconducting qubit, CHEN WANG, Y.Y. GAO, I.M. POP, U. VOOL, C. AXLINE, T. BRECHT, R.W. HEERES, L. FRUNZIO, Yale Univ, G. CATELANI, Peter Gruberg Institut (PGI-2), M.H. DEVORET, L.I. GLAZMAN, R.J. SCHOELKOPF, Yale Univ — We measure the dynamics of quasiparticle relaxation over multiple orders of magnitude in density in superconducting transmon qubits using a contactless injection technique by microwave pulses. We demonstrate the power-law decay characteristics for quasiparticle recombination and exponential decay for single quasiparticle loss due to trapping effects, and find both mechanisms play a significant role in quasiparticle relaxation depending on device geometry. We observe quantized changes in quasiparticle trapping rate due to individual vortices, and thus quantitatively measure the interaction between non-equilibrium quasiparticles and a single vortex in a superconducting aluminum film. These results are described in Ref. [1]. [1] C. Wang et al. arXiv:1406.7300 [quant-ph]

11:27AM Z39.00002 Suppressing decoherence of superconducting qubits by trapping non-equilibrium quasiparticles, YVONNE GAO, CHEN WANG, I.M. POP, U. VOOL, C. AXLINE, T. BRECHT, R.W. HEERES, L. FRUNZIO, M.H. DEVORET, Yale University, G. CATELANI, Peter Gruberg Institute, L.I. GLAZMAN, R.J. SCHOELKOPF, Yale University — We report a counter-intuitive observation that vortices can improve the coherence of superconducting qubits by suppressing non-equilibrium quasiparticles. This effect is systematically studied by measuring the magnetic-field dependence of qubit coherence times and quasiparticle lifetimes in transmons with different geometries in a 3D cQED architecture. Varying quasiparticle dynamics by vortices allows separation of dissipation mechanisms and measurement of the stray generation rate of quasiparticles in our devices. More details are described in Ref [1]. Our results indicate that quasiparticles contribute significantly to qubit decoherence. Hence suppression of quasiparticle density in the device is essential for further improvement of coherence times of superconducting qubits and we will present recent results aimed at alleviating decoherence due to quasiparticles. [1] C.Wang, Y.Y.Gao et al arXiv:1406.7300

11:39AM Z39.00003 Coherent Suppression of Quasiparticle Dissipation in Superconducting Artificial Atom1, IOAN M. POP, Department of Applied Physics, Yale University — We demonstrate immunity to quasiparticle dissipation in a Josephson junction. At the foundation of this protection rests a prediction by Brian Josephson from fifty years ago: the particle-hole interference of superconducting quasiparticles when tunneling across a Josephson junction [1]. The junction under study is the central element of a fluxonium artificial atom, a Josephson junction. At the foundation of this protection rests a prediction by Brian Josephson from fifty years ago: the particle-hole interference of superconducting quasiparticles when tunneling across a Josephson junction [1]. The junction under study is the central element of a fluxonium artificial atom, a Josephson junction. 12:15PM Z39.00004 From quantum jumps to quasiparticle population1, . U. VOOL, I.M. POP, K. SLIWA, B. ABDO, C. WANG, Y.Y. GAO, A. KOU, W.C. SMITH, T. BRECHT, S. SHANKAR, M. HATRIDGE, Department of Applied Physics, Yale University, G. CATELANI, Peter Grünberg Institut (PGI-2), Forschungszentrum Jülich, L. FRUNZIO, R.J. SCHOELKOPF, L. GLAZMAN, Department of Applied Physics, Yale University, M. MIRRAHIMI, Department of Applied Physics, Yale University and INRIA Paris Rocquencourt, M.H. DEVORET, Department of Applied Physics, Yale University — Superconducting quasiparticles (QP) play a dominant role in the relaxation of the fluxonium qubit in the vicinity of the half-flux-quantum bias point. Recent experiments integrating the fluxonium with a quantum-limited amplifier have measured quantum jump trajectories between the ground state and the first excited state. These trajectories show a change in the characteristic lifetime of the fluxonium qubit as a function of time, arising from a change in the number of QP’s in the sample [1]. Using a simple model of QP dynamics and their effect on the fluxonium qubit, we can access the QP population with temporal resolution better than a 100 microsecond. Such rapid monitoring of QP dynamics is essential for understanding the sources of QP’s and ultimately suppressing them.

1Work supported by: IARPA, ARO, and ONR.

12:27PM Z39.00005 Simulation and measurement of a fluxonium qubit inductively coupled to a readout resonator1, W.C. SMITH, A. KOU, U. VOOL, I.M. POP, R.J. SCHOELKOPF, M.H. DEVORET, Department of Applied Physics, Yale University — Prototypical circuit QED experiments can be performed using a fluxonium qubit that shares a portion of its superinductance with an on-chip LC oscillator, dubbed an “antenna”, that is used as a readout resonator. However, the complete fluxonium-antenna artificial atom had not been previously understood in all coupling regimes. We have measured Hamiltonian parameters and decay rates by channeling microwave pulses into a rectangular waveguide containing the antenna-qubit system. Accurate modeling of energy spectra, dispersive shifts, and Purcell loss is achieved by diagonalizing the effective circuit Hamiltonian. We will present spectroscopy data, coherence times, and simulation results.

1Work supported by: IARPA, ARO, and ONR.

12:39PM Z39.00006 Quantum and Ionic Transport Across Superconductor-based Heterostructures. OSAMA NAYFEH, SON DINH, BENJAMIN TAYLOR, MARCIO DE ANDRADE, PAUL SWANSON, BRUCE OFFORD, ANNA LEESH ESCOBAR, Spawar Systems Center Pacific, STEPHANIE CLAUSSSEN, Colorado School of Mines, SAM KASSEGNE, San Diego State University — We present analysis of quantum and ionic transport across superconductor/normal metal/normal metal/superconductor heterostructures. Calculations for various ionic configurations demonstrate modification of the quantum transport coherence length and energy profile with moderate ionic transport away from the superconductor-barrier interface. The effect of electric field and cryogenic temperature on the stability of the ionic configurations for quantum information state storage is examined. Characterization and analysis of fabricated normal metal and superconductor-based device structures are presented. Acknowledgements: We acknowledge the support of the SSC Pacific In-house Laboratory Independent Research Science and Technology Program managed by Dr. Dave Rees, the Naval Innovative Science and Engineering Program managed by Mr. Robin Laird, and the ONR Summer Faculty Research Program. Interactions with Dr. Van Vechten (ONR) and Dr. Manheimer (IARPA) are appreciated. The views and conclusions contained in this document are those of the authors and should not be interpreted as representing the official policies, either expressed or implied, of SPARWAR or the U.S. Government. Approved for Public Release; distribution is unlimited.

12:51PM Z39.00007 Correlations of microwave photons emitted by inelastic Cooper pair tunneling, ALEXANDER GRIMM, SALHA JEBARI, DIBYENDU HAZRA, CEA, INAC-SPSMS, F-38000 Grenoble, France, CARLES ALTIMIRAS, OLIVIER PARLAVECCCHIO, FABIEN PORTIER, CEA, IRAMIS-SPEC, F-91911 Gif-sur-Yvette, France, MAX HOFHEINZ, CEA, INAC-SPSMS, F-38000 Grenoble, France — A simple DC voltage-bias on a small Josephson junction leads to emission of microwave radiation via inelastic Cooper-pair tunneling. In this process a tunneling Cooper pair emits one or several microwave photons with a total energy of 2eV. The observed average photon emission rate is well explained within the so-called P(E) theory, but this theory does not make any predictions about the statistics of the emitted photons. Recent theory indicates that these statistics can be highly nontrivial. Depending on the bias conditions and the impedance of the circuit in which the junction is embedded, correlations can range from strongly bunched to anti-bunched. I will present experiments investigating photon correlations in circuits with specifically engineered environments. This type of devices might offer a new way of generating useful photon states for circuit quantum optics experiments, without the need of carefully calibrated control pulses. Moreover, the frequency of the emitted radiation is only limited by the gap of the superconductor. We are building our devices using NbN-MgO-NbN tunnel junctions which should in principle allow operation up to the THz regime.

1:03PM Z39.00008 Can a strain yield a qubit?1, COLIN BENJAMIN, National Institute of Science education and Research, Bhubaneswar, India — A Josephson qubit is designed via the application of a tensile strain to a topological insulator surface, sandwiched between two s-wave superconductors. The strain applied leads to a shift in Dirac point without changing the conducting states existing on the surface of a topological insulator. This strain applied can be tuned to form a π-junction in such a structure. Combining two such junctions in a ring architecture leads to the ground state of the ring being in a doubly degenerate state—“0” and “1” states of the qubit. A qubit designed this way is easily controlled via the tunable strain. We report on the conditions necessary to design such a qubit. Finally the operating time of a single qubit phase gate is derived.

1:15PM Z39.00009 Nonequilibrium noise and current fluctuations at the superconducting phase transition1, DMITRY BAGRETS, University of Cologne, ALEX LEVCHENKO, Michigan State University — We study non-Gaussian out-of-equilibrium current fluctuations in a mesoscopic NSN circuit at the point of a superconducting phase transition. The setup consists of a voltage-biased thin film nanobridge superconductor (S) connected to two normal-metal (N) leads by tunnel junctions. We find that above a critical temperature fluctuations of the superconducting order parameter associated with the preformed Cooper pairs mediate inelastic electron scattering that promotes strong current fluctuations. Though the conductance is suppressed due to the depletion of the quasiparticle density of states, higher cumulants of current fluctuations are parametrically enhanced. We identify experimentally relevant transport regime where excess current noise may reach or even exceed the level of the thermal noise.

1:27PM Z39.00010 Manipulating the Quantum State of a Single Cooper Pair in a One-Atom Contact, CRISTIAN URBINA, CAMILLE JANVIER, LEANDRO TOSI, ÇAĞLAR GIRIT, MICHAEL STERN, PATRICE BERTET, DENIS VION, PHILIPPE JOYEZ, DANIEL ESTEVE, MARCELO COFFMAN, HUGUES POTTHIER, Quantronics Group, CEA-Saclay — Superconducting qubits presently used in quantum information experiments are based on Josephson tunnel junctions. Nevertheless, these circuits exploit only partially the richness of the Josephson effect, as they overlook the existence of an internal, spin-like degree of freedom, inherent to all Josephson structures. Each conduction channel of a weak-link gives rise to a doublet of discrete subgap states (the Andreev bound states), which represents the two possible states of a localized Cooper pair. We spotlight these doublets with experiments on the simplest Josephson weak-link: a one-atom contact between two superconductors. The atomic contact is inserted in a superconducting loop coupled to a microwave resonator. This standard circuit-QED architecture allows performing single shot measurements of the state of a localized Cooper pair, and to manipulate coherently its quantum state, as illustrated by Rabi oscillations, Ramsey fringes and spin echoes.

1:39PM Z39.00011 Flux Solitons Studied for Energy-Conserving Reversible Computing, KEVIN D. OSBORN, WALTRAUT WUSTMANN, Laboratory for Physical Sciences, College Park, MD — On-chip logic is desired for controlling superconducting qubits. Since qubits are very sensitive to photon field noise, it is desirable to develop an energy-conserving reversible logic, i.e. one which can compute without substantial energy dissipation or applied drive fields. With this goal in mind, simulations on discretized long Josephson junctions (DLJJs) have been performed, where the flux soliton is a potential information carrier. Undriven soliton propagation is studied as a function of discreteness, dissipation, and uncertainty in the junction critical current. The perturbing parameters are low in the simulations such that the solitons fit well to an ideal Sine-Gordon soliton. Surprisingly, using realizable parameters a single flux soliton in a DLJJ is found to travel hundreds of Josephson penetration depths without backscattering in the absence of a driving force. In addition, even with a non-ideal launch, solitons are found to propagate predictably such that they show potential for synchronous routing into reversible logic gates.

2:03PM Z39.00013 Long Time Electrical Stability of Plasma Oxidized Aluminum Tunnel Barriers, ZACHARY BARCIKOWSKI, JOSH POMEROY, National Institute of Standards and Technology, Gaithersburg, MD — By measuring resistance-area product values over time, we assess the electrical stability of tunnel junctions with plasma oxidized AlOx tunnel barriers. AlOx is a commonly used material in the superconducting qubit community due to its ease of fabrication, but often has a high density of electrically active defects. We believe that plasma oxidation, as opposed to the standard thermal oxidation, can lead to tunnel barriers with lower defect densities and improved electrical properties. This talk will present measurements taken on tunnel barrier devices taken over a period of months and correlate observed stability/instability with the process conditions used to fabricate them.

2:03PM Z39.00012 Flux Soliton Interactions in Coupled Long Josephson Junctions, WALTRAUT WUSTMANN, KEVIN D. OSBORN, Laboratory for Physical Sciences, College Park, MD — Flux solitons and long Josephson junctions are being studied as structures for energy-conserving reversible computing. The solitons in long Josephson junctions are generally described by the Sine-Gordon equation. Simulations have been performed on discrete long Josephson junctions (DLJJs), where the soliton extends over at least a few unit cells. We will report on the dissipation and mutual interaction of two solitons in separate DLJJs. Single fluxon dissipation in DLJJs is found to arise from junction damping as well as radiation loss created by discreteness and perturbed soliton oscillations. Dissipation of interacting solitons in coupled DLJJs will be compared to the single fluxon case.

2:15PM Z39.00014 Fluctuation-dissipation relations of a tunnel junction driven by a quantum circuit, DANIEL ESTEVE, OLIVIER PARLAVECCHIO, CARLES ALTIMIRAS, Service de Physique de l’Etat Condensé (CNRS URA 2464), IRAMIS, CEA Saclay, 91191 Gif-sur-Yvette, France, JEAN-RENE SOUQUET, PASCAL SIMON, INES SAFI, Laboratoire de Physique des Solides, Université Paris-Sud, 91405 Orsay, France, PHILIPPE JOYEZ, DENIS VION, PATRICE ROCHE, FABIEN PORTIER, Service de Physique de l’Etat Condensé (CNRS URA 2464), IRAMIS, CEA Saclay, 91191 Gif-sur-Yvette, France, NONELECTRONIC-QUANTRONICS GROUPS COLLABORATION, THEORY GROUP TEAM — We derive fluctuation-dissipation relations derived for classical forces hold, provided the effect of the circuit's quantum fluctuations is incorporated into a modified non-linear I(V) curve. We also demonstrate that all quantities measured under a coherent time-dependent bias can be reconstructed from their直流 counterpart with a photo-assisted tunneling relation. We confirm these predictions by implementing the circuit and measuring the dc current through the junction, its high frequency admittance and its current noise at the frequency of the resonator. Results available in arXiv:1409.6696.

Friday, March 6, 2015 11:15AM - 2:15PM –
Session Z41 DPOLY: Focus Session: Biopolymers II: Phase Behavior, Rheology, and Mechanics
11:15AM Z41.00001 Chirality-selected phase behavior in ionic polypeptide complexes, MATTHEW TIRELL, University of Chicago — We demonstrate that chirality determines the phase state of polyelectrolyte complexes formed from mixing dilute solutions of oppositely charged polypeptides. In these systems, the physical state of the resultant complex is determined by the combination of electrostatic and hydrogen bonding interactions. The formation of fluid complexes occurs when at least one of the polypeptides in the mixture is racemic, which disrupts backbone hydrogen bonding networks. Pairs of purely chiral polypeptides, of any form, sense compact, fibrillar solids with a β-sheet structure on mixing. Analogous behavior occurs in micellar cores formed from polypeptide block copolymers with polyethylene oxide, where microphase separation into discrete, self-assembled aggregates with either solid or fluid cores, and eventually into ordered phases at high concentrations, is possible. Chirality is an exploitable tool for manipulating material properties in systems based on polyelectrolyte complexation. Its role in these systems gives insight into polyelectrolyte complex phase behavior more broadly.

11:51AM Z41.00002 Biomimetic Coacervate Environments for Protein Analysis, SARAH PERRY, Univ of Mass - Amherst, PATRICK MCCALL, SAMAVAYAN SRIVASTAVA, DAVID KOVAR, MARGARET GARDEL, MATTHEW TIRELL, University of Chicago — Living cells have evolved sophisticated intracellular organization strategies that are challenging to reproduce synthetically. Biomolecular function depends on both the structure of the molecule itself and the properties of the surrounding medium. The ability to simulate the in vivo environment and isolate biological networks for study in an artificial milieu without sacrificing the crowding, structure, and compartmentalization of a cellular environment, represent engineering challenges with tremendous potential to impact both biological studies and biomedical applications. Emerging experience has shown that polypeptide-based networks for study in an artificial milieu without sacrificing the crowding, structure, and compartmentalization of a cellular environment, represent engineering challenges with tremendous potential to impact both biological studies and biomedical applications. Emerging experience has shown that polypeptide-based coacervate-based systems are particularly attractive for use in biochemical assays because the compartmentalization afforded by liquid-liquid phase separation does not necessarily inhibit the transport of molecules across the compartmental barrier.
12:03PM Z41.00003 Molecular Rigidity and Entropy-Enthalpy Compensation in DNA Hybridization , JACK DOUGLAS, FERNANDO VARGAS-LARA, Materials Science and Engineering Division, NIST, Gaithersburg, MD 20899 — Entropy-enthalpy compensation (EEC) is a general and relatively poorly understood pattern in the energetic parameters governing both binding constants and relaxation processes in condensed matter. After defining the basic phenomenology, we focus on how polymer additives, chain confinement, chain length variation affect a well-studied molecular binding process, the hybridization of duplex DNA. Our study is based on a coarse-grained model of DNA that does treat water explicitly. We find that both crowding due to polymer additives and geometrical confinement lead to a change of the effective chain rigidity and that changes in DNA generally lead to a pattern entropy-enthalphy compensation in the DNA association similar to experimental observations. Modulation of the rigidity of binding sites by constraints associated with chain structure or environmental conditions can greatly influence both the location and cooperativity of molecular binding transition and the relative enthalpy and entropy contributions to the free energy of binding. Entropy-enthalpy compensation arises in numerous synthetic and biological molecular binding processes and we suggest that that changes in molecular rigidity might provide a common explanation of this ubiquitous phenomenon.

12:15PM Z41.00004 Spider Silks-Biomimetics Beyond Silk Fibers: Hydrogels, films & Adhesives from Aqueous Recombinant Spider Silk dopes: A Synchrotron X-Ray Nano-Structural Study , SUJATHA SAMPATH, University of Utah, JUSTIN JONES, THOMAS HARRIS, RANDOLPH LEWIS, Utah State University — With a combination of high strength and extensibility, spider silk’s (SS) mechanical properties surpass those of any man made fiber. The superior properties are due to the primary protein composition and the complex hierarchical structural organization from nanoscale to macroscopic length scales. Considerable progress has been made to synthetically mimic the production of fibers based on SS proteins. We present synchrotron x-ray micro diffraction (SXRD) results on new fibers and gels (hydrogels, lyogels) from recombinant SS protein water-soluble dopes. Novelty in these materials is two-fold: water based rather than widely used HFIP acid synthesis, makes them safe in medical applications (replacement for tendons & ligaments). Secondly, hydrogels morphology render them as excellent carriers for targeted drug delivery biomedical applications. SXRD results reveal semi-crystalline structure with ordered beta-sheets and relatively high degree of axial orientation in the fibers, making them the closest yet to natural spider silks. SXRD on the gels elucidate the structural transformations during the self-recovery process through mechanical removal and addition of water. Studies correlating the observed structural changes to mechanical properties are underway.

12:27PM Z41.00005 Seeing believes: Watching entangled sculpted branched DNA in real time , AH-YOUNG JEE1, JUAN GUAN, KEJIA CHEN, STEVE GRANICK, Univ of Illinois - Urbana — The importance of branching in polymer physics is universally accepted but the details are disputed. We have sculpted DNA to various degrees of branching and used single-molecule tracking to image its diffusion in real time when entangled. By ligating three identical or varying length DNA segments, we construct symmetric and asymmetric Y scaffolds. These constructs form gel-like phases of micelles arranged with cubic order at room temperature. A 10 base pair and a 25 base pair DNA ladder were used as samples in gel electrophoresis. The monotonically decreasing mobility with increasing length observed in the agarose separations is not observed in separations in Pluronics®. Rather, a complicated dependence of mobility on DNA length is observed, where mobility vs. length increases for short DNA molecules then decreases for longer molecules. There is also a variation of mobility with length correlated to the micelle diameter. Brownian dynamics simulations of a discrete wormlike chain model were performed to simulate short DNA molecules migrating in free solution and in a face-centered cubic matrix. By incorporating hydrodynamic interactions, the trend of simulated length-dependent mobility qualitatively agrees with experimental measurements.

12:39PM Z41.00006 DNA electrophoresis in tri-block copolymer gels—experiments and Brownian dynamics simulation , LING WEI, DAVID H. VAN WINKLE, Department of Physics, Florida State University — The mobility of double-stranded DNA ladders in Pluronics® P105, P123 and P127, was measured by two-dimensional gel electrophoresis. Pluronics® are triblock copolymers which form gel-like phases of micelles arranged with cubic order at room temperature. A 10 base pair and a 25 base pair DNA ladder were used as samples in gel electrophoresis. The monotonically decreasing mobility with increasing length observed in the agarose separations is not observed in separations in Pluronics®. Rather, a complicated dependence of mobility on DNA length is observed, where mobility vs. length increases for short DNA molecules then decreases for longer molecules. There is also a variation of mobility with length correlated to the micelle diameter. Brownian dynamics simulations of a discrete wormlike chain model were performed to simulate short DNA molecules migrating in free solution and in a face-centered cubic matrix. By incorporating hydrodynamic interactions, the trend of simulated length-dependent mobility qualitatively agrees with experimental measurements.

12:51PM Z41.00007 Injectable Self-Assembling Peptide Hydrogel: Effects of Hydrophobic Drug Encapsulation and Delivery , JESSIE SUN, BRANDON STEWART, ALISA LITAN, University of Delaware, SIGRID LANGHANS, Nemours Alfred I duPont Hospital for Children, JOEL P. SCHNEIDER, National Institute of Health, DARRIN J. POCHAN, University of Delaware — We successfully encapsulated and continuously delivered a hydrophobic drug over the course of a month at effective, significant concentrations in a beta-hairpin chain model were performed to simulate short DNA molecules migrating in free solution and in a face-centered cubic matrix. By incorporating hydrodynamic interactions, the trend of simulated length-dependent mobility qualitatively agrees with experimental measurements.

1:03PM Z41.00008 Anomalous diffusion dynamics of associating artificial proteins in hydrogels , SHENCANG TANG, MUZHOU WANG, BRADLEY OLSEN, Massachusetts Institute of Technology — Associative polymer gels have attracted a great deal of interest as responsive materials and biomaterials; while a great deal is known about their mechanical properties, knowledge about self-diffusion in these materials is still limited. Using coiled-coil proteins as a model associative polymer system where the number of stickers per polymer and molar mass of chains between stickers are exactly defined, we investigate self-diffusion in associative polymeric hydrogels using forced Rayleigh scattering on the length scales ranging from 0.3 to 50 μm. Although the presence of associative groups reduces the rate of diffusion, “superdiffusive” scaling is observed for the first time up to a length scale of 10 μm. Fickian diffusion is recovered at larger length scales. The anomalous diffusion strongly depends on the hydrogel concentration. We propose a simple two state model to capture the interplay between the diffusion of the proteins and the association of the coiled-coil segments. The model is able to both the anomalous regime and the Fickian regime, and provides estimation of the apparent diffusivities and the dissociation rates of the coiled-coil domains.

1:15PM Z41.00009 Physics of soft hyaluronic acid-collagen type II double network gels , SVETLANA MOROZOVA, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — Many biological hydrogels are made up of multiple interpenetrating, charged components. We study the swelling, elastic diffusion, mechanical, and optical behaviors of 100 mol% ionizable hyaluronic acid (HA) and collagen type II fiber networks. Dilute, 0.05-0.5 wt% hyaluronic acid networks are extremely sensitive to solution salt concentration, but are stable at pH above 2. When swelled in 0.1M NaCl, single-network hyaluronic acid gels follow scaling laws relevant to high salt semidilute solutions; the elastic shear modulus $G^*$ and diffusion constant $D$ scale with the volume fraction $\phi$ as $G^* \sim \phi^2$ and $D \sim \phi^{4.1}$, respectively. With the addition of a collagen fiber network, we find that the hyaluronic acid network swells with rigid collagen fibers, providing extra strength to the hydrogel. Results on swelling equilibria, elasticity, and collective diffusion on these double network hydrogels will be presented.
heterogeneously. Stress autocorrelation and elongation results were analyzed as a function of the nano-filler concentration. Globally, as we increase the filler fraction, into fibrous structures. We observe the formation of a percolated nework of these fibrous structures, with ordered local structure but disordered short-range attraction between the nanofillers and polymer chain ends. The structure, dynamics and mechanics of this polymer gel was studied as function was studied by Molecular Dynamics simulation. Nanofillers were modeled as rigid bodies of disk-like shapes and crosslinks were simulated by introducing a...
11:27AM Z42.00002 Polymer Crowding and Depletion-Induced Interactions in Polymer-Nanoparticle Mixtures¹, WEI KANG LIM, ALAN DENTON, Dept. of Physics, North Dakota State University — Macromolecules in crowded environments, such as biopolymers (DNA, RNA, proteins) in biological cells or synthetic polymers in nanocomposite materials, adopt conformations that can differ substantially from those in unconfined spaces. In mixtures of nanoparticles and nonadsorbing (free) polymers, depletion of polymers induces effective interactions between the nanoparticles. Depletion-induced interactions in turn affect the structure and thermodynamic phase behavior of polymer-nanoparticle mixtures. Such interactions can drive bulk demixing and may be involved in compartmentalization of macromolecules in the cell nucleus. Within a coarse-grained model of hard-sphere nanoparticles and ellipsoidal polymer, we perform Monte Carlo simulations to compute polymer shape distributions², depletion-induced pair potentials, and pair distribution functions, and to explore demixing of polymer-nanoparticle mixtures in the protein limit. We compare our results with theoretical predictions and available experimental data.

11:39AM Z42.00003 Depletion potential between nanoparticles: From small molecule liquids to dense polymer melts, DEBAPRIYA BANERJEE, KENNETH SCHWEIZER, University of Illinois at Urbana Champaign — An entropic depletion attraction generically exists between two hard spheres dissolved in a nonadsorbing fluid. PRISM integral equation theory is used to study this problem over an exceptionally wide range of polymer-particle size ratio and chain length (N) including the monomer limit. To mimic constant atmospheric pressure conditions, the dimensionless melt compressibility is fixed at realistic values and polymer density varied with N accordingly. At constant polymer size, the attractive contact minimum of the particle potential of mean force (PMF) scales roughly as particle radius. At fixed particle size, this contact minimum deepens logarithmically with N before generically saturating beyond a crossover N ≈ 150. The equilibrium aggregation behavior is dominated by this local feature. However, the PMF beyond contact has features (including repulsive barriers) of a spatial range and amplitude that vary non-monotonically with N which are most pronounced when the particle radius is of order the polymer radius of gyration, Rg. At fixed particle size, this implies a value of N exists that maximizes kinetic stabilization. A weak but long range (Rg-scale) component of the PMF is also found when the radius of gyration is smaller than, or comparable to, the particle radius.

11:51AM Z42.00004 Self-assembled chains of polymer-grafted nanorods in homopolymer films, CHRISTINA TING, Sandia Natl Labs, BORIS RASIN, RUSSELL COMPOSTO, University of Pennsylvania, AMALIE FRISCHKNECHT, Sandia Natl Labs — An understanding of the self-assembly of nanoparticles in a polymer matrix is needed to utilize their tunable optical and electrical properties. In particular, for anisotropic nanoparticles, the inter-particle distance and orientation are important variables to consider. Using self-consistent field theory (SCFT), we study the self-assembly of polymer-grafted nanorods in homopolymer melts of the same chemistry. The theoretical calculations are performed over a range of parameters for an experimental system of CdSe/CdS nanorods coated with polystyrene brushes of varying molecular weights. Previously, we have shown that polymer-grafted nanorods were found to transition from dispersed to aligned (side by side) as the matrix chain lengths were increased, depending also on the grafting density and the dimensions of the nanorods. Here, we explore the parameters required for end to end linking, where it has been shown that coupling of localized surface plasmon resonances in a chain of end-linked nanorods can result in a periodic array of enhanced electric fields (hot spots).

Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under Contract DE-AC04-94AL85000

12:03PM Z42.00005 Field-theoretic study on polymer-depletion interaction between colloids in solution, WEI LI, KRIS DELANEY, GLENN FREDRICKSON, Univ of California - Santa Barbara — Using field-theoretic simulations, we study the depletion interaction between colloidal particles in a solution of free block copolymers. Our system consists of two solid non-adsorbing plates and polymer solution in between. A field theory model formulated in the grand canonical ensemble is used for our simulations, and the potential of mean force between two colloids is computed by means of Derjaguin approximation. We begin the investigation with solvent that is neutral to the copolymer blocks. Several effects on the depletion interaction are considered, including surface affinity of the plates to the copolymer, and block copolymer architecture and composition.

12:15PM Z42.00006 Field Theoretic Simulations of Polymer Nanocomposites in the Presence of Adsorbing Block Copolymers¹, JASON KOISKI, ROBERT RIGGLEMAN, University of Pennsylvania — The immersion of nanoparticles in a polymer matrix has given rise to improved mechanical, electrical, and optical properties of polymer-based materials. Understanding the phase behavior and controlling the spatial distribution of nanoparticles in these systems plays a critical role in controlling the resulting material properties. Polymer field theory continues to play an important role in our understanding of polymeric materials, and recently we have extended the field theoretic framework to incorporate nanoparticles with arbitrary shape and surface grafting. In this talk, I will demonstrate some more recent extensions that incorporate local surface attraction either between nanoparticles or between the particles and a strongly adsorbing polymer, which could be important for systems where one block of the polymer has strong preferential interactions with the particle surface. Our approach enables the study of systems where many-body particle effects could become important and systems that can macro- or microphase separate while fully incorporating fluctuation effects.

¹NSF DMR-1410246

12:27PM Z42.00007 Theory and Simulation Studies of Effect of Entropic and Enthalpic Driving Forces on Morphology in Polymer Grafted Particle Filled Nanocomposites, TYLER MARTIN, Chemical and Biological Engineering - University of Colorado at Boulder, Chemical and Biomedical Engineering - University of Delaware, ARTHI JAYARAMAN, Chemical and Biomedical Engineering - University of Delaware, Materials Science and Engineering - University of Delaware — Polymer nanocomposites are a class of materials that consist of a polymer matrix embedded with nanoscale fillers or additives that enhance the inherent properties of the matrix polymer. To engineer polymer nanocomposites for specific applications it is important to have design rules that relate molecular features to morphologies of the composite. Using theory and simulation, we previously studied polymer nanocomposites with homopolymer grafted particles in a homopolymer matrix with chemically identical graft and matrix polymers. Specifically, we found that increasing the polydispersity in grafted chain lengths or decreasing the graft and matrix chain flexibility stabilizes the dispersed phase of polymer nanocomposites, due to increased wetting of the grafted layer by matrix chains. We now explore composites with chemically different graft and matrix polymers, that allow us to tune in enthalpic driving forces in addition to the entropic driving forces for particle dispersion/aggregation. We vary the grafting density, composition of the graft and matrix polymers, and strength of the attractive interactions between the grafts and matrix monomers, to study their impact on the phase behavior and structure of polymer grafted particles in a polymer matrix.
12:39PM Z42.00008 Disentanglement in polymer-star mixtures, HENDRIK MEYER, Institut Charles Sadron, CNRS UPR22, Strasbourg, France — Recent molecular dynamics simulations provide new insights to entangled polymer melts and mixtures with compact stars as a model system of nanocomposites without polymer-particle adsorption. The particle size is in the order of the tube diameter, the particles remain well dispersed over the whole concentration range and the stars are sufficiently compact that the pure system is jammed. For this system, we observe a weak compression of the matrix chains with increasing volume fraction of stars. Short (untangled) matrix chains get slowed down by adding particles to the system. When the matrix chains become significantly longer than the entanglement length, this trend is inverted and the matrix chains become faster because the particles dilute the entanglement network. The center-of-mass (CM) dynamics exhibits regimes of anomalous diffusion in accordance with viscoelastic hydrodynamic interactions (VHI) [1]. At low and intermediate star-particles concentration, the particles themselves vary little in mobility, only at high concentration (above percolation), they become slowed down because of colloidal packing. 1:03PM Z42.00010 Detailed atomistic simulations of functionalized graphene/polymer systems, PETRA BACOVA, ANASTASSIA RISSANOU, Institute of Applied and Computational Mathematics (IACM), Foundation for Research and Technology Hellas (FORTH), GR-70013, Heraklion, Crete, Greece, VAGELIS HARMANDARIS, Department of Mathematics and Applied Mathematics, University of Crete, GR-70013, Heraklion, Crete, Greece — Graphene structures produced by the reduction of the graphene oxide contain some oxygen percentage coming mainly from the carboxyl groups remained on the edges of the graphene. With the increasing importance of the graphene in the material science, here we draw our attention to the effect of these groups on the properties of the graphene-based materials. Molecular simulations can be a valuable tool for the study of such complex materials at the molecular level. We have performed detailed atomistic simulations of hybrid nanostructured polymer/graphene materials for different polymer matrices. We study the behaviour of polymer nanocomposites with three types of dispersed graphene: (a) the pure non-functionalized sheet, (b) graphene with hydrogens grafted on the edges and (c) carboxyl-functionalized graphene. Data concerning the structural and dynamical properties of the polymer chains are presented. In addition, we compute the dynamic properties of the particular graphene sheets and we discuss in detail the importance of the strong electrostatic interactions present in the systems. The information obtained on the molecular scale in our work contributes to the understanding of the miscibility and the mechanical properties of the graphene/polymer nanocomposites.

1:15PM Z42.00011 Surface Tension of Nano-Confined Lattice Polymers, PENGFEI ZHANG, QIANG WANG, Department of Chemical and Biological Engineering, Colorado State University — Surface tension at solid/liquid interface is a key concept in understanding many important surface and interfacial phenomena such as wetting and capillarity. It is, however, not trivial to accurately calculate surface tension in lattice Monte Carlo (LMC) simulations, which are much faster than simulations in continuum. Here we propose a novel, efficient, and accurate method for calculating the surface tension of polymers confined between two parallel and impenetrable surfaces in LMC simulations, and examine how surface tension varies with the degree of confinement (i.e., separation distance between the two surfaces). Direct comparisons between our LMC results and the corresponding lattice self-consistent field (LSCF) calculations also unambiguously and quantitatively reveal the fluctuation/correlation effects on surface tension neglected in LSCF theory. Keywords: Surface tension, lattice polymers, Monte Carlo simulations.

1:27PM Z42.00012 Polymer adsorption transition: Applications of the Wang-Landau and partition function zeros methods, MARK TAYLOR, SAMIP BASNET, Dept. of Physics, Hiram College, JUTTA LUETTMER-STRATHMANN, Dept. of Physics, University of Akron — The Wang-Landau (WL) algorithm is a Monte Carlo simulation technique providing a direct computation of the density of states (and thus the partition function) of a many-body system. The partition function encodes all thermodynamic information about a system, and thus, its construction allows for an efficient determination of phase behavior. Here we describe the application of the WL approach to the adsorption transition for both lattice [1] and continuum chains tethered to an attractive surface. We compute the canonical partition function for chains up to length \( N=1536 \) and analyze the zeros of these functions in the complex inverse-temperature plane. These zeros define a nearly closed circular region, centered on the origin, intersected near the positive real axis by two flaring tails. With increasing chain length the intersection point pinches down towards the positive real axis, dividing the real axis into two distinct regions or phases in accord with Yang-Lee theory. We apply finite size scaling theory for the leading partition function zeros to locate the adsorption transition in the thermodynamic limit and obtain values for the polymer crossover, order parameter, and specific heat exponents. \[1\] M.P. Taylor and J. Luettmerr-Strathmann, J. Chem. Phys., in press, (2014).

1:39PM Z42.00013 Molecular Simulation studies of adsorption of polymers on non-planar surfaces: Influence of surface characteristics, ABISHEK VENKATAKRISHNAN, University of Cincinnati, ANNE SHIM, Ohio State University, AQUIL FROST, Central State University, JOHN LEWNARD, VIKRAM KUPPA, University of Cincinnati — Molecular simulations are employed to investigate the adsorption of freely rotating polymer chains adsorbing on to non-planar surfaces. Adsorption studies on planar surfaces have been studied extensively and fairly well understood. However, in reality, surfaces are non-planar and cannot be represented using smooth surface models. We investigate the effect of surface characteristics on adsorption via molecular dynamics and Monte Carlo molecular simulations in the NVT ensemble. Both regular (uniform) and irregular (self-affine) roughness parameters are studied. The adsorbed polymer chains are characterized by density and orientation profiles, adsorbed fraction and chain topologies. Our results elucidate the extent to which surface roughness influences adsorption, in competition with other factors such as chain length and monomer-surface interaction. We also demonstrate how both adsorption and desorption can be controlled solely by tuning surface inhomogeneities.
streaming and the generation of higher harmonic oscillations. Both steady and time-harmonic flows are considered.

The entrance length is estimated from the exponential spatial decay of the lowest components, and/or velocity gradients are specified at the entrance boundary. The entrance length is estimated from the exponential spatial decay of the lowest

gradients, excess entry pressure, and vorticity. Various types of appropriate entrance conditions are identified in which combinations of pressure, velocity components, and/or velocity gradients are specified at the entrance boundary. The entrance length is estimated from the exponential spatial decay of the lowest normal-mode solution; the estimated entrance length is one-tube-radius for axisymmetric flow and two-tube-radii for non-axisymmetric flow. As a special case, the backbone methylene groups have a broad angular distribution and on average tilt along the surface plane, independent of tactility and temperature. We have compared the SFG results with theoretical spectra calculated using MD simulations and ab initio calculations.

11:51 AM Z43.00004 Effect of surface elasticity on the rheology of nanometric and micrometric liquids. ELISABETH CHARLAIX, Université Joseph Fourier Grenoble France — The rheological properties of liquids confined to nanometer scales are important in many situations, yet are still a widely debated topic. The change in bulk viscosity and apparition of visco-elasticity under confinement is a particularly controversial question. In this talk, we use a new approach for this problem by addressing the effect of the long-range elastic deformations of the confining surfaces on the liquid flow. This effect could help reconciling some discrepancies within the literature concerning the intrinsic mechanical behavior of nanometric liquids. In the case of a squeeze-flow geometry, we show that below a critical distance Dc, the liquid is clamped by its viscosity and its intrinsic properties cannot be disentangled from the global system response. The theoretical approach [1] is confirmed by nanorheology experiments [2, 3] on various simple liquids, using both very soft (PDMS) and very rigid (Pyrex) confining surfaces. In every case we demonstrate that the elastic deflections of the confining surfaces, even if they are of very small amplitude, can dominate the overall mechanical response of nanometric liquids confined between solid walls.

12:27PM Z43.00005 The Effect of Compression Frequency on the Collapse Dynamics of Langmuir Monolayers. JEREMY EATON, MICHAEL DENNIN, Univ of California - Irvine — We investigate the effects of compression speed and particle size on the collapse dynamics of an SDS-DODAB monolayer uniformly interspersed with fluorescent polystyrene nanoparticles ranging from 40 to 1000 nm in diameter. Folding and buckling are induced in the monolayer-particle system by compressing and expanding it between Teflon barriers which move at areal speeds ranging from 5 to 90 cm²/min. Video capture and fluorescence microscopy were used to image the monolayer over five compression-expansion cycles. Image processing is used to measure the surface particle density and is further used to characterize the number, structure and reversibility of the folds over time. These details provide insight on dynamics of monolayer collapse and will serve useful in determining the role folding plays in particle transport both within and across the monolayer interface.

We gladly acknowledge the support of NSF grant DMR-1309402.

12:39PM Z43.00006 Plateau-Rayleigh Instability and Capillary Droplet Propulsion on a Fiber. SABRINA HAEFNER, Saarland University, Experimental Physics, D-66041 Saarbruecken, Germany, MICHAEL BENZAQUEN, PCT Lab, UMR CNRS 7083 Gulliver, ESPCI ParisTech, PSL Research University, Paris, France, OLIVER BAEUMCHEN, Max-Planck Institute for Dynamics & Self-Organization (MPIDS), 37077 Goettingen, Germany, THOMAS SALEZ, PCT Lab, UMR CNRS 7083 Gulliver, ESPCI ParisTech, PSL Research University, Paris, France, ROBERT PETERS, McMaster University, Dept. of Physics & Astronomy, Hamilton, ON, Canada, JOSHUA D. MCGRAW, KARIN JACOBS, Saarland University, Experimental Physics, D-66041 Saarbruecken, Germany, ELIE RAPHAEL, PCT Lab, UMR CNRS 7083 Gulliver, ESPCI ParisTech, PSL Research University, Paris, France, KARI DALNOKI-VERESS, McMaster University, Dept. of Physics & Astronomy, Hamilton, ON, Canada — The Plateau-Rayleigh instability (PRI) of a liquid column underlies a variety of hydrodynamic phenomena. Compared to the classical case of a free liquid column, the description of a liquid layer on a fiber requires the consideration of the solid-liquid interface in addition to the free surface. We revisit the PRI of a liquid layer on a solid fiber by varying the hydrodynamic boundary condition at the fiber-liquid interface from no-slip to slip. We find that the growth rate depends on the system geometry and the boundary condition, which is in agreement with theory. In the late stages of liquid column breakup on slip-fibers, a three-phase contact line can be formed on one side of the droplet. The resulting capillary imbalance leads to droplet propulsion, which is studied as a function of temperature and molecular weight.

12:51PM Z43.00007 Parametric study of Newtonian droplet entering smaller confinement— a numerical study. ZHIFENG ZHANG, Washington State Univ, JIE XU, University of Illinois at Chicago, XIAOLIN CHEN, Washington State Univ, COMPUTER AIDED ENGINEERING LAB TEAM, XU GROUP: MICROFLUIDICS LAB COLLABORATION — Model of droplet entering a micro-confinement has wide applications in either design of microfilter or understanding of biological process such as Circulating Tumor Cell metastasis/ capillary blockage et al. In present numerical study, we explore the transient behavior of soft matter being squeezed through a micro-confinement by Newtonian droplet model. Parameter study quantify the relation between squeezing pressure under different channel/droplet size, channel geometry influence (circular, square, triangular) and flow velocity variance.

1:03PM Z43.00008 Line tension and entropy in a liquid crystal Langmuir film. ELIZABETH MANN, PRITAM NANDAR, JOSEPH YARZEBINSKI, NABIN THAPA, Department of Physics, Kent State University, J. ADIN MANN, Department of Chemical Engineering, Case Western Reserve University — Often two or more phases coexist within a monolayer or bilayer: the connection between these and possible dynamic or static microdomains within cell membranes is still debated. The line tension associated with the boundary between two phases within a monolayer or bilayer controls the size distribution, shape, and dynamics of domains. Theoretical models for this energy remain relatively untested. This work considers a model fluid system, trilayer/monolayer coexistence within a Langmuir film. The line tension associated with the boundary between these phases is measured as a function of temperature over a large range (12-37°C). Compact, isolated trilayer domains are stretched from their equilibrium circular shape, and the free relaxation is analyzed with a hydrodynamic model previously tested by Wintersmith et al. [1] Line tension decreased with rising temperature. A careful treatment of the thermodynamics of the line boundary allow us to estimate the line entropy associated with the trilayer, and test possible models for the boundary.

1:15PM Z43.00009 Active nemato-hydrodynamics in toroidal microchannels. RICHARD GREEN, Instituut-Lorentz, Leiden University, JOHN TONER, Department of Physics and Institute of Theoretical Science, University of Oregon, VINCENZO VITELLI, Instituut-Lorentz, Leiden University — We investigate flow driven by activity in nematic and polar fluids confined in a toroidal geometry. Using a perturbative expansion in the activity strength, we obtain closed form analytic solutions for the activity-driven flow. A distinguishing feature of this system is that there is no critical threshold which the activity needs to overcome in order to initiate the flow; rather, the flow is a consequence of the combination of activity and curved geometry at any non-zero activity, however small.
1:27PM Z43.00010 Can a hard-sphere fluid feel the topology of a confining pore? 1 GERD SCHROEDERTURK, JOHANNES KNAUF, Friedrich-Alexander University Erlangen-Nuremberg, ROLAND ROTH, University Tuebingen, KLAUS MECKE, Friedrich-Alexander University Erlangen-Nuremberg — The confinement of simple fluids to narrow pore spaces changes the phase behaviour. A central question is the dependence of thermodynamic properties on the pore shape \( K \). The morphometric approach for simple fluids is derived by assuming that the grand potential \( \omega(K,\mu,T) \) on a functional of \( K \). Hadwiger's theorem states that \( \omega(K,\mu,T) \) only depends on \( K \) as a linear combination of the Minkowski functional, \( \Omega = -p(\mu,T)V(K) + q(\mu,T)A(K) + \kappa(\mu,T)C(K) + \gamma(\mu,T)K(K) \) where \( V \) and \( A \) are the volume and interface and \( C(K) \) the integrated mean curvature. \( X(K) \) is the Euler number that characterises the pore topology. We use density functional theory to demonstrate that this theory is consistent, for the case of triply-periodic network-like pore geometries. For these, the formula \( \langle X \rangle(K,\mu,T) = -\partial\Omega/\partial\mu \) can be inverted to give an estimate of \( X \) deduced from the simulated densities – the Euler number 'felt' by the fluid. We show that for the Primitive, Gyroid and Diamond minimal surfaces the obtained values are close to \( X \). Counter-intuitively, this result suggests that hard sphere fluids can feel topological properties of a confining space, in addition to geometric ones.

1:39PM Z43.00011 Controllable Coexistence of Multiple Instabilities on a Single Liquid Filament 1, MICHAEL HEIN, JEAN-BAPTISTE FLEURY, RALF SEEMANN, Saarland University — Droplet based microfluidics exploits the decay of a liquid filament or cylinder into droplets of micrometric size. While the physics of droplet breakup on small scales remains a field of vivid interest, droplet based microfluidics has become widely used both in fundamental science and application such as (bio-)analytics or micro-chemistry. We present experimental research on the formation of droplets by breakup of a squeezed liquid filament surrounded by an immiscible phase that flows over a topographic step. This non-equilibrium process arises from the interplay between flow properties and interfacial instabilities when the filament is suddenly released from confinement at the step. In contrast to previous studies, a rich variety of different droplet breakup regimes was observed for the used geometry which are characterized by the coexistence of multiple liquid instabilities on a single filament. Surprisingly, these instabilities can be of different type while the filament is exposed to a symmetric flow-field. This spontaneous symmetry breaking is a nontrivial consequence of volume throughput constraints of each individual instability and allows for the specific production of heterogeneous droplet families from one single filament under constant flow rates. (Submitted 2014)

1:51PM Z43.00012 Ginzburg-Landau and Weakly Nonlinear Analysis of 3D Pillar Growth in NanoBenard Instability 1, CHENGZHE ZHOU, SANDRA TROIAN, California Institute of Technology, MC 128-95, Pasadena, CA — We examine the nonlinear response of a molten nanofilm subject to strong interface deformation and patterned growth by destabilizing thermocapillary forces and stabilizing capillary forces. The equation for the moving boundary describes 3D growth induced by large thermocapillary stresses in the long wavelength approximation. A bifurcation analysis via the method of multiple scales elucidates the influence of initial conditions, system geometry and material properties on the regimes describing stable and unstable flow. Investigation of the corresponding Ginzburg-Landau amplitude equation by finite element simulations reveals the existence of rich spatio-temporal phenomena. We will discuss how tightly ordered symmetric growth can arise from resonance effects induced by spatially periodic external forcing in analogy to behavior recently reported for the spatially forced version of the Swift-Hohenberg equation in 1- and 2- dimensions.

2:03PM Z43.00013 Influence of Film Thickness and Substrate Geometry on the Growth of Taylor Cones in Perfectly Conducting Films 1, THEODORE ALBERTSON, SANDRA TROIAN, California Institute of Technology, MC 128-95, Pasadena, CA — Liquid metal ion and droplet sources are finding application in many different fields ranging from high resolution focused ion beam imaging and lithography to space micropropulsion to nanofabrication and nanomanufacturing. These applications require ever improved understanding of the process by which Maxwell forces deform a smooth molten metal film into a liquid cusp known as a Taylor cone. While recent computational studies have elucidated how the cone-jet transition controls the mass and charge flux, less attention has been paid to the regime involving very thin coating films and how frictional effects influence the shape and timescale of the evolving conical elongations. We describe recent efforts in our group using moving mesh techniques to quantify the influence of substrate geometry and film thickness on the shape and formation of transient Taylor cones in perfectly conducting films. Our results appear to confirm self-similar exponents predicted theoretically upon onset of cone formation. Under certain conditions, we find not only Taylor cone formation at the tip of a sharp axisymmetric emitter but also Taylor coronal rings away the sharpest point. Such secondary formations can ultimately enhance mass and charge flux.

Friday, March 6, 2015 11:15AM - 1:03PM – Session Z44 GSNP GSÖFT: Focus Session: Jamming in Granular Media III 214D - Justin Burton, Emory University

11:15AM Z44.00001 Short time intermittency and long time plastic correlations in jammed systems 1, ARKA ROY, CMU, CRAIG MALONEY, NEU — Using numerical simulations of model amorphous, frictionless, soft discs, we study the effect of strain rates (\( \dot{\gamma} \)) and volume fractions (\( \phi \)) on the microscopic dynamics and plastic activity near, but above, the jamming point (\( \phi_j \)). Well above \( \phi_j \), at slow shear rate, the system responds in a highly intermittent way, reminiscent of other dynamically critical systems with a power law distribution of energy dissipation rates. With increasing \( \dot{\gamma} \) at fixed \( \phi \) or letting \( \phi \rightarrow \phi_j \) from above at a fixed rate, the intermittent behavior vanishes. All displacement distributions show non-Fickian behavior at short time crossing to Fickian behavior at longer times. Very surprisingly, the characteristic strain for that crossover is independent of \( \phi \). We also find that, despite the dramatic differences in the short time dynamics, the long time plastic rearrangements are essentially identical. Long-range spatial correlations in strain are cut off only by the size of the simulation cell.
11:27AM Z44.00002 Local origin of global contact numbers in frictional ellipsoid packings, FABIAN SCHALLER, University Erlangen-Nürnberg, Erlangen, Germany, MAX NEUDECKER, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany, MOHAMMAD SAADATFAR, Applied Maths, RPPhysSE, ANU, Australia, GARY DELANEY, CSIRO, Clayton South, Victoria, Australia, GERD SCHRODER-TURK, University Erlangen-Nürnberg, Erlangen, Germany, MATTHIAS SCHROTER, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — In particulate soft matter systems the average number of contacts $Z$ of a particle is an important predictor of the mechanical properties of the system. Using X-ray tomography, we analyze packings of frictional, oblate ellipsoids of various aspect ratios $\alpha$, prepared at different global volume fractions $\phi_l$. We find that $Z$ is a monotonically increasing function of $\phi_l$ for all $\alpha$. We demonstrate that this functional dependency can be explained by a local analysis where each particle is described by its local volume fraction $\phi_l$ computed from a Voronoi tessellation. $Z$ can be expressed as an integral over all values of $\phi_l$: $Z(\phi_l, \alpha, X) = Z_l(\phi_l, \alpha, X) \Phi(\phi_l) \Phi_l$. The local contact number function $Z_l(\phi_l, \alpha, X)$ describes the relevant physics in term of locally defined variables only, including possible higher order terms $X$. The conditional probability $\Phi(\phi_l)\Phi_l$ to find a specific value of $\phi_l$ given a global packing fraction $\phi_g$ is found to be independent of $\alpha$ and $X$. Our results demonstrate that for frictional particles a local approach is not only a theoretical requirement but also feasible.

11:39AM Z44.00003 Mechanical Response in Particulate Media, NIRANJAN WARNAKULASOROY, LEO SILBERT, Department of Physics, Southern Illinois University Carbondale, 62901, USA — We study the mechanical behavior of granular particle system in two dimensions in response to a dynamical intrusive or perturber simulations. We created mechanically stable granular packings of bidisperse discs with various coefficients of friction spanning several orders of magnitude and packing fractions in the vicinity above the critical packing fraction $\phi_c$. For each packing, we find the critical force $F_c$, the minimum force required to induce motion of a probe particle that we are trying to drag through the packing. Below the critical force the probe particle does not sustain continued motion. Just at the critical force, the probe particle moves through the system strongly intermittently. When the force is slightly larger than the $F_c$, the probe moves with well-defined average velocity. We find how the critical force and the average probe velocity depend on the packing pressure and particle fractions.

11:51AM Z44.00004 Rigidity percolation in generic and regular isostatic lattices, LEYOU ZHANG, D. ZEB ROCKLIN, Univ of Michigan - Ann Arbor, BRYAN CHEN, Institutus-Lorentz, Leiden University, XIAOMING MAO, Univ of Michigan - Ann Arbor — Rigidity percolation, the emergence of rigidity as bonds are randomly added to a structure, has been studied using various models, yielding a rich variety of behaviors including continuous/discontinuous transitions as well as mean field/analomalous scalings. Here we present our study of rigidity percolation in isostatic lattices, which are at the verge of mechanical instability and thus adding a vanishing fraction of next-nearest-neighbor bonds ("braces") can rigidify the lattice. However, we find that how the lattice rigidifies as braces are added depends on the lattice architecture in interesting ways. We study this problem in both regular (periodic lattices) and generic (sites are randomly moved, keeping only the topology of the connectivity) versions of isostatic square and kagome lattices via simulation. We discover that (1) rigidity percolation in generic isostatic lattices is discontinuous, with a sudden emergence of a rigid bulk, before which no stress can appear, sharing intriguing similarities with jamming, and (2) regular isostatic lattices, in contrast, show mixed features of continuous and discontinuous transitions. We propose analytic theories to explain our observations.

12:03PM Z44.00005 Experimental avalanches in a two-dimensional rotating drum: Universal- ity or a first-order phase transition?1, ALINE HUBARD, CUNY Graduate Center and Levich Institute and Physics Department of City College of New York, COREY O’HERN, Department of Mechanical Engineering & Materials Science, Department of Applied Physics, and Department of Physics, Yale University, MARK SHATTUCK, CUNY Graduate Center and Levich Institute and Physics Department of City College of New York — We study experimentally the dynamics of steel spheres in a quasi-two dimensional rotating drum to investigate whether avalanches occur as continuous or first-order transitions. In our experiments, monodisperse steel spheres are confined within a cylindrical region between the glass walls of the drum, and the drum rotation axis is perpendicular to the direction of gravity. The drum and spheres first rotate as a solid body, and the slope of the sphere packing increases until the packing becomes unstable. The avalanche proceeds until the system finds another stable packing. Using high-speed video, we track the particle displacements during each avalanche to quantify the statistics of the avalanche sizes and durations as a function of the rotation rate and particle size distribution. We find that the avalanche size and duration distributions display power-law scaling over several decades, which suggests universal behavior in this system.

12:15PM Z44.00006 Mean-field approach for random close packings of non-spherical and adhe- sive particles, ADRIAN BAULE, School of Mathematical Sciences, Queen Mary University of London, ROMAIN MARI, Levich Institute, City College of New York, LIN BO, LOUIS PORTAL, Levich Institute and Physics Department, City College of New York, WENWEI LIU, SHUIQING LI, Department of Thermal Engineering, Tsinghua University, HERNAN MAKSE, Levich Institute and Physics Department, City College of New York — Random packings of objects of a particular shape are ubiquitous in science and engineering. However, such jammed matter states have eluded any systematic theoretical treatment due to the strong positional and orientational correlations involved. Here, a mean field theory based on a statistical treatment of the Voronoi volume is presented, which allows for the calculation of the random close packing of spherical as well as non-spherical hard particles. The extension of the framework to packings of adhesive particles is discussed. A phase diagram is presented that describes non-spherical and adhesive particles in terms of analytic continuations from the spherical random close packing.

12:27PM Z44.00007 Jamming aids jumping in granular media, JEFFREY AGUILAR, Georgia Tech School of Mechanical Engineering, ANDRAS KARSAI, DANIEL L. GOLDMAN, Georgia Tech School of Physics — Little is known about the impulsive force and flow fields generated during jumping on granular media. We use a simple robot jumping on poppy seeds to explore maneuvers that induce jammed (non-yielding) states, and find sensitive dependence of jumping performance to movement strategy. On loose packings (volume fraction $\phi \approx 0.57$), a preliminary hop followed by a delay ("delayed stumper jump") improves the height of a push-off maneuver ("single jump"). Constant speed intruration force measurements suggest that reentry of the foot during the preliminary hop reintroduces surface resistance. An optimal delay time ($t \approx 5$ ms) leads to maximal jump heights, while a short delay time ($t \approx 0$ ms) produces the lowest jumps. Velocimetry of grain flow reveals that non-delay stutters induce fluid-like granular states into which the robot sinks before jamming occurs, lowering jump heights. While simulations of single and delayed stumper jumps are well described using a frictional (depth dependent) plus drag (velocity dependent) penetration resistance, this model does not capture stumper jump performance at low $\phi$. However, addition of an added mass term improves agreement, signaling the need for a more complex reactive force theory in impulsively forced granular media.

12:39PM Z44.00008 Exploring the Bernoulli effect on airfoils in a granular flow, YASIN KARIM, ERIC CORWIN, University of Oregon — The Bernoulli effect describes the decrease in pressure that results from a fluid accelerating over an airfoil. While granular materials lack many of the features of fluids (i.e. they are compressible, do not have a well-defined viscosity, and are non-cohesive) they nonetheless can be made to flow. We report experiments carried out on cylindrical Bernoulli lift in granular flows as a function of flow speed, density, airfoil shape. Using velocimetry and force sensors we probe the existence of a Bernoulli lift on an airfoil as glass beads flow around it in a quasi-two dimensional system.
Non-crystalline states in a 2D dusty plasma. Juan-Jose Liетor-Santos, Caо Cong, Justin Burton, Emory University — When suspended in a plasma, colloidal particles become negatively charged due to a preponderance of collisions with free electrons. If the plasma is weakly-ionized, the resulting repulsive electrostatic forces cause the particles to self-organize into a single 2D layer in the plasma sheath near a surface. At high concentrations and particle charging, a hexagonal crystalline lattice is formed which supports the propagation of underdamped, phonon-like waves. This "dusty plasma" is an ideal model system to study low-temperature dynamics in solids, where the individual particle motions can be visualized and tracked [1]. We have reported the creation of non-crystalline states in a dusty plasma by combining two particle species of different size and material density. By finely-tuning these variables, we show that both particle populations lie in the same plane, leading to a 2D amorphous structure which can be used to study the dynamics of glassy and jammed systems at low temperatures and frequencies.

11:15AM Z44.00009 Non-crystalline states in a 2D dusty plasma. Juan-Jose Liетor-Santos, Caо Cong, Justin Burton, Emory University — When suspended in a plasma, colloidal particles become negatively charged due to a preponderance of collisions with free electrons. If the plasma is weakly-ionized, the resulting repulsive electrostatic forces cause the particles to self-organize into a single 2D layer in the plasma sheath near a surface. At high concentrations and particle charging, a hexagonal crystalline lattice is formed which supports the propagation of underdamped, phonon-like waves. This "dusty plasma" is an ideal model system to study low-temperature dynamics in solids, where the individual particle motions can be visualized and tracked [1]. We have reported the creation of non-crystalline states in a dusty plasma by combining two particle species of different size and material density. By finely-tuning these variables, we show that both particle populations lie in the same plane, leading to a 2D amorphous structure which can be used to study the dynamics of glassy and jammed systems at low temperatures and frequencies.

11:27AM Z45.00002 Enhanced Methanol Diffusion in Homogeneous Isotropic and Anisotropic Silica Aerogels1. Jongseop A. Lee, YiZhou Xin, A.M. Zimmerman, Northwestern University, Evanston, IL 60208, Yang Shen, Tongji University, Shanghai, China, 200092, William Halperin, Northwestern University, Evanston, IL 60208 — It has recently been shown that the ballistic mean free path of silica aerogels can be directly measured by measuring diffusion of adsorbed fluids that are in fast exchange with vapor state using nuclear magnetic resonance [1-2]. With this technique we have studied the effect of compression on the mean free path of radially shrunken and isotropic silica aerogels with 98% porosity. We have found unusual behaviors of pore geometry as a function of compression. Our preliminary findings suggest that the average pore geometry and the corresponding anisotropy thereof do not follow classical stress-strain relations suggesting more complex mechanism is at play.

11:39AM Z45.00003 Diffusive and Rotational Dynamics of Condensed n-H2 Confined in MCM-411. Paul Sokol, Matthew Bryan, Indiana University, Timothy Prisk, Oak Ridge National Laboratory — We report neutron scattering studies of the condensed phases of normal-hydrogen confined within MCM-41. This is a high surface area, mesoporous silica glass with a narrow pore size distribution. The neutron scattering data suggests a picture of condensed normal-hydrogen within small mesopores in which the adsorbed hydrogen may be conceptually divided into an interfacial layer and the inner core volume. Preferential adsorption of ortho-hydrogen makes the interfacial layer rich in ortho-hydrogen, while the inner core volume consists of a depleted mixture of ortho- and para-hydrogen. In the liquid state, the hydrogen molecules making up the interfacial layer are immobile and tightly bound to adsorption sites, unable to diffuse on picosecond time scales. Molecules within the inner core volume undergo liquid-like jump diffusion, but with residence times much longer than the bulk liquid. In the solid state, only the hydrogen molecules occupying the inner core volume show the free quantum rotor behavior characteristic of the bulk crystal. The ortho-hydrogen molecules bound to the pore walls experience an orientational hindering potential which perturbs their rotational energy levels. Comparison with Vycor suggests the pore walls of MCM-41 are smoother on the atomic-scale.

11:51AM Z45.00004 Moleculely thin metal organic framework (MOF) film at air-water interface: Fabrication and buckling under compression1. Pritim Mandal, Sahraoui Chaieb, King Abdullah University of Science and Technology (KAUST), Thuwal, KSA — A metal organic framework (MOF) - a hybrid of inorganic (metal) nodes and organic linkers - is an emerging class of highly crystalline porous materials that provide an extremely high surface area/volume ratio making them very suitable candidates in selective separation, filtration and storage of gases. Though MOFs are usually produced as powders, for many applications such as selective gas separation and filtration, MOFs as flat membrane is the most appropriate candidate. To our knowledge no large-scale fabrication of 2D MOFs has been reported. In this work, we prepared large area MOF film at an air/water interface and employed Brewster angle microscopy (BAM) to directly image the film-formation (surface pressure during and after the film-formation was tracked, although this measurement for a solid film is not accurate due to the elasticity of the film). Metal-ligand coordination was confirmed through FTIR results. Surface morphology as seen via scanning electron microscopy (SEM) shows the film was smooth over several hundred microns. Finally, we discuss the buckling/fracture of the MOF film due to compression by two symmetrically movable barriers, which hinted to the existence of a solid molecular thin film.

12:03PM Z45.00005 Mechanism of breakup of electrospun jet at the nozzle. Kostya Kornev, Vladislav Vekselman, Gilles Mohl, Clemson University. Department of Materials Science & Engineering Team — In the electrostatic formation of nanofibers, a high voltage is applied to a polymer solution to withdraw it through the nozzle as a jet. We report on an interesting instability leading to the jet breakup right at the supporting meniscus making the generation of sequential jets sporadic and inconsistent. The conventional electrospinning setup was modified to provide visualization of the meniscus inside the nozzle. A glass capillary was used as a nozzle. A wire connecting a high-voltage power supply was inserted into a tube and secured inside the glass capillary. The end of the wire was positioned far away from the free end of the glass capillary where meniscus was formed. In this method, the body of polymer solution was held at the same potential. Using fluorescence microscopy it was observed that meniscus is very sensitive to the applied voltage and is able to move inside the nozzle as the voltage increases. As meniscus moves inside the nozzle, it forms a liquid film leaning to the inner wall of the nozzle. This film connects meniscus and the jet. The jet breakup is caused by the thinning and rupturing of this film. A simple scaling model showing interplay between the capillary pressure and Maxwell stress is proposed and used to explain the jet instability.
12:15PM Z45.00006 Atomic scale images of polyvinylidene fluoride nanofibers by electron microscopy1. DARRELL RENEKER, University of Akron, CHRISTIAN KISIELOWSKI, Lawrence Berkeley National Laboratory, GEORGE CHASE, DINESH LOLLA, JOE CORSE, University of Akron — Atomic scale electron micrographs of polyvinylidene fluoride (PVDF) molecules in thin (∼ 3 nm) nanofibers revealed twist around the axes of molecular chains, small relative motions of adjacent molecular chains and many other structural and dynamical phenomena. The positions and relative motions of CF2 groups, spaced 0.25 nm apart, on (PVDF) molecules, were followed along polymer segments. Atomic scale, aberration corrected electron microscopy is presently at its best when the sample is less than about 3 nanometers thick. Conformations of segments of polymer molecules, and the relations between more ordered and less ordered segments are displayed in this thickness range. The TEAM 0.5 aberration corrected microscope at the Lawrence Berkeley Laboratory “Molecular Foundry,” was used to create hundreds of high magnification images of PVDF molecules in nanofibers, at electron doses much smaller than the doses that produce extensive chain scission or other such chemical changes in the molecules. A commonly held view, that useful high magnification electron micrographs of polymer molecules cannot be obtained without causing overwhelming changes to the molecule, is misleading.

12:27PM Z45.00007 Flow in wavy walled microchannels, RAGHAVI RAO, PUSHPAVANAM S, IIT Madras — Improving the efficiency of mass transfer processes in microchannels is of significance in many applications. Here the flow is primarily laminar and mass transfer occurs by diffusion. Making the surface of the channel rough allows us to induce convection in transverse directions to the flow. In this work, we will study the effect of periodically varying surface of a channel wall using a perturbation solution. The modification in the velocity profile and its effect on improving mass transfer will be analyzed. The analysis will be illustrated for the case of extraction of a solute from one liquid phase to another. The effect of various parameters like surface tension, density ratio and viscosity ratio of the fluids will be studied and the regions in parameter space where a significant improvement in performance is expected will be determined. The results of the perturbation series solution will be compared with numerical results. Two cases, that of a constant and a deformed interface between the liquid phases, will be analyzed.

12:39PM Z45.00008 Micropillar sequence design for inertial fluid flow sculpting1, DANIEL STOECKLEIN, BASKAR GANAPATHYSUBRAMANIAN, Iowa State University, CHUEH-YU WU, DINO DI CARLO, University of California at Los Angeles — New methods for controlling fluid flow in microchannels make use of inertial fluid flow deformation around pillar structures spanning the height of the channel. A small set of micropillar sizes and locations has been shown to produce a rich phase space with a wide variety of flow transformations, demonstrating the untapped wealth of possibilities in this fluid flow manipulation scheme. Previous work has successfully demonstrated the potential, with experimental validation, for manual hierarchical design where sequences of pillars are stacked to create flow sculpting. But such a method is not ideal for seeking out complex sculpted flows where the search space quickly becomes too large for efficient manual construction. This is further complicated by the non-uniqueness of pathways to a desired fluid transformation, and the effect of diffusion as the number of micropillars increases. We formulate the inertial fluid flow transformation as a set of state transition matrix operations. This allows rapid simulation of different design configurations, enabling efficient optimization over a large search space. We show how this framework can be used for novel fluid sculpting targets with application in microelectronics and medical diagnostics, and also show validation via confocal imaging.

1This research is supported in part by the National Science Foundation through XSEDE resources provided by TACC under grant number TG-CTS110007 and supported in part by NSF-1306866, NSF-1307550, and NSF-1149365.

12:51PM Z45.00009 Three-dimensional microstreaming flows1, BHARGAV RALLABANDI, Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, ALVARO GOMEZ-MARIN, MASSIMILIANO ROSSI, Institute of Fluid Mechanics und Aerodynamics, Bundeswehr University Munich, CHENG WANG, Mechanical and Aerospace Engineering, Missouri University of Science and Technology, CHRISTIAN KAEHLER, Institute of Fluid Mechanics und Aerodynamics, Bundeswehr University Munich, SASCHA HILGENFELDT, Mechanical Science and Engineering, University of Illinois at Urbana-Champaign — Streaming due to acoustically excited bubbles has been used successfully for applications such as size-sorting, trapping and focusing of particles, as well as fluid mixing. Many of these applications involve the precise control of particle trajectories, typically achieved using cylindrical bubbles, which establish planar flows. Using astigmatic particle tracking velocimetry (APTV), we show that, while this two-dimensional picture is a useful description of the flow over short times, a systematic three-dimensional flow structure is evident over long time scales. We demonstrate that this long-time three-dimensional fluid motion can be understood through asymptotic theory, superimposing secondary axial flows (induced by boundary conditions at the device walls) onto the two-dimensional description. Beyond microbubble streaming, this leads to a general framework that describes three-dimensional flows in confined microstreaming systems, guiding the design of applications that profit from minimizing or maximizing these effects.

1:03PM Z45.00010 Retarded desorption from porous media caused by wetting/dewetting of the external surface, THOMAS LEE, BENOIT COASNE, ROLAND J.-M. PELLENOQ, FRANZ-JOSEF ULM, Department of Civil and Environmental Engineering, Massachusetts Institute of Technology, Cambridge, MA, LYDÉRIC BOCUET, Laboratoire de Physique Statistique, École Normale Supérieure, Paris, France, MULTISCALE MATERIAL SCIENCE FOR ENERGY AND ENVIRONMENT COLLABORATION1 — Despite the increasing attention devoted to nanofluidics, the role of external surfaces on transport in nanopores has not been fully investigated. Here, we report molecular dynamics simulations showing that methane recovery from a hydrophobic nanoporous membrane is retarded by the presence of liquid water at the external surface. Despite the pressure gradient used to trigger methane desorption and the hydrophobicity of the membrane, methane remains trapped for long times until water desorbs from the external surface. Using umbrella sampling calculations, we show that this retardation effect is induced by the free energy cost of dewetting the external surface as water is replaced by an adsorbed methane film. To account for this effect, we propose a simple thermodynamic model which describes the increase in free energy during extraction (dominated by the large methane-water surface tension). We also extend our approach to hybrid external surfaces made up of hydrophilic/hydrophobic regions, and consider fluids other than water (CO2), as these are relevant to practical applications such as gas/oil recovery from shale. Such retarded processes also have implications for transport in nanofluidic systems and adsorption/transport in solid catalysts, chromatographic devices, etc.

The sorting process is passive and relies on large forces induced by the streaming flow that lead to particle migration across streamlines. While a thresholded size sorting can be understood from simple arguments about the uniaxial stretching, we show that more sophisticated size separation is achievable through a better understanding of the flow at short time scales. We present experimental data (high-speed videography) and theoretical analysis (asymptotic description of the flow fields) that show how particles undergo significant migration and separation on time scales ranging from milliseconds to microseconds, and on length scales of about 10 μm. The highly tunable experimental set-up and the accurate analytical description of the flow field make this system an extremely fast and versatile device for applications ranging from flow cytometry to lab-on-a-chip micromanipulation.

We acknowledge support by the National Science Foundation for this work under grant number CBET-1236141.

**1:15PM Z45.00011 Particle Migration and Sorting in Microbubble Streaming Flow*** SASCHA HILGENFELDT, RAQEEB THAMEEM, BHARGAV RALLABANDI, RUI YANG, Mechanical Science and Engineering, University of Illinois at Urbana-Champaign — Ultrasonic driving of sessile semicylindrical bubbles results in powerful steady streaming flows that are robust over a wide range of driving frequencies. In a microchannel, this flow field pattern can be fine-tuned to achieve size-sensitive sorting and trapping of particles at scales much smaller than the bubble itself. The sorting process is passive and relies on large forces induced by the streaming flow that lead to particle migration across streamlines. While a thresholded size sorting can be understood from simple arguments about the uniaxial stretching, we show that more sophisticated size separation is achievable through a better understanding of the flow at short time scales. We present experimental data (high-speed videography) and theoretical analysis (asymptotic description of the flow fields) that show how particles undergo significant migration and separation on time scales ranging from milliseconds to microseconds, and on length scales of about 10 μm. The highly tunable experimental set-up and the accurate analytical description of the flow field make this system an extremely fast and versatile device for applications ranging from flow cytometry to lab-on-a-chip micromanipulation.

**1:39PM Z45.00013 Effects of the uniaxial elongation of a polymer/CNT fiber on its electrical properties**, HYUN WOO CHO, BONG JUNE SONG, Department of chemistry, Sogang University, Seoul 139-701, Republic of Korea — We elucidate the effects of the uniaxial elongation of a polymer/CNT fiber on its electrical properties. Polymer fibers containing conductive nanofillers (such as carbon nanotubes (CNTs), and silver nanoparticles) have been utilized extensively for fabricating various forms of stretchable electronics including artificial muscles or electric conductive fabric. The electric conductivity of the polymer fiber usually decreases when it is stretched along the fiber axis, which would limit the scope of application. In addition, the reason and mechanism of decrease in the electrical conductivity remain elusive. In this work, we employ a coarse-grained model for the polymer/CNT fiber, and obtain the configurations of the fiber with respect to the strain via dynamic Monte Carlo (MC) simulations. Using global tunneling network (GTN) model, we calculate the electric conductivity as a function of strain. We find that the electric conductivity decreases during the elongation of the polymer/CNT fiber as was in experiments. We also find from tunneling network diagrams and critical path approximation (CPA) that the topological structure of the electrical network of the CNTs changes collectively during the elongation, which is responsible for the reduction of the electrical conductivity.

**1:51PM Z45.00014 High thermal conductivity polymers**, MORTAZA SAEIDIJAVASH, Graduate Student at University Of Oklahoma, Department of Aerospace and Mechanical Engineering, JIVTESH GARG, University of Oklahoma — In this work we investigate the effect of mechanical stretching on polymer thermal conductivity. Polymer materials are used as electrical insulators, but their poor thermal conductivity also makes them thermal insulators making removal of heat generated in such electronic systems challenging. Enhancement of polymer thermal conductivity can allow for better thermal management including design of low cost heat sinks and compliant thermal interface materials. Stretching is known to induce alignment of molecular chains in a polymer system increasing thermal conductivity. In this work we explore this idea by mechanically stretching ultra-high molecular weight (UHMW) polyethylene bars using a tensile load cell. The in-plane thermal conductivity of stretched polymer is measured using laser-flash method. We have measured thermal conductivity enhancement of almost 100% for stretch ratios of 6 to 10. These results are consistent with previous studies of thermal conductivity enhancement through such stretching. Ways to chemically achieve this molecular alignment are being explored using techniques of spin coating and electrospinning.

Friday, March 6, 2015 11:15AM - 2:15PM
Session Z46 DBIO: Invited Session: Mechanical Interactions and Pattern Formation in Multi-cellular Systems 217A - Ingmar Riedel-Kruse, Stanford University

**11:15AM Z46.00001 Tissue mechanics and dynamics during development**, FRANK JULICHER, Max Planck Institute for the Physics of Complex Systems — The fly wing is an important model system for the study of tissue dynamics during development. During pupal stages, the early fly wing undergoes a spectacular dynamic reorganization that involves cell flows, cell divisions and cell shape changes. In this dynamic process, the final shape of the wing is generated. We characterize tissue remodelling by the contributions of specific cellular processes such as cell shape changes and cell neighbour exchanges to macroscopic shear at different times. We discuss the dynamics and the mechanics of this dynamic tissue using an active medium theory that captures the essential physics of tissue remodelling. Our work suggests that local tissue contraction together with anisotropic active processes drive tissue remodelling in the fly wing. This process is guided by external stresses mediated via elastic attachments of the tissue to an external scaffold. We test our model by experiments in which perturbations are imposed by laser ablation or by mutant conditions.

**11:51AM Z46.00002 Spatiotemporal control of the forces that drive cell rearrangements within multicellular tissues**, KAREN KASZA, Sloan Kettering Institute — The local rearrangements of cells within multicellular tissues are actively driven by forces generated in the actin-myosin cytoskeleton. During development, these forces are patterned to bias or orient cell rearrangements, resulting in changes in tissue shape and structure that build functional tissues and organs. We use the fruit fly embryo as a model system, where polarized patterns of myosin activity are required for oriented cell rearrangements that drive rapid tissue elongation along the head-to-tail axis. To uncover mechanisms of how active, myosin-generated forces drive cell rearrangement, we quantify how perturbations to myosin activity influence the number, speed, and orientation of rearrangements. First, to investigate microscopic mechanisms by which myosin drives contraction of cell edges to initiate rearrangement, we generated myosin variants predicted to alter the speed at which myosin translocates actin filaments. These myosin variants display slowed turnover dynamics at cell edges and result in decreased numbers of cell rearrangements, indicating a role for myosin-driven actin sliding during rearrangement. Next, to study how myosin activity levels influence cell rearrangements, we generated myosin variants that mimic the active, phosphorylated state of myosin. These variants accelerate rearrangements but, surprisingly, also alter the spatial pattern of forces in the tissue and result in reduced tissue elongation. These myosin variants increase the rate of cell edge contraction but cause defects in the formation of new contacts between cells. Finally, we discuss how higher-order, collective cell rearrangements called rosettes are influenced by these perturbations to myosin activity. This work is in collaboration with D. Farrell and J. Zallen at the Sloan Kettering Institute.
12:27PM Z46.00003 Cell mechanics and non-genetic developmental defects. M. SHANE HUTSON, Vanderbilt University — Genetic mutations are not the only, nor necessarily the most prevalent route to misregulation of morphogenesis. In fact, remarkably specific developmental defects can be caused by non-specific environmental stress — e.g., heat shock, anoxia or chemical exposure. I will discuss one example from Drosophila embryos in which the funneling from broad-spectrum insult to specific developmental defects can be traced to cell and tissue mechanics. In particular, I will discuss heat shocks applied to Drosophila embryos at the onset of gastrulation. These lead to common developmental defects in head involution and germ band retraction — the latter phenocopying U-shaped mutants. Although these heat shocks induce a wide range of transient effects — on protein synthesis, cytoskeletal structures, and the cell cycle — morphogenetic movements resume after heat shock and proceed nearly normally for several hours. Then, four to ten hours after heat shock, dramatic holes open between cells in the amnioserosa, disrupting the integrity of this monolayer epithelium. The presence of holes in the amnioserosa at this stage (germband extension) is highly correlated with later defects in retraction of the germ band — a tissue adjacent to the amnioserosa. This observation begs two questions: (1) how does heat-shock of the entire embryo lead to mechanical disruption of this specific tissue; and (2) how does this mechanical disruption lead to morphogenetic defects in adjacent tissues? Using a combination of quantitative live imaging, laser-micsurgery, FRAP and computational models, we find answers to both questions in the underlying cell- and tissue-level mechanics.

1:03PM Z46.00004 Surface cell expansion drives radial cell intercalations in zebrafish gastrulation. CARL-PHILIPP HEISENBERG, IST Austria — Radial cell intercalations are commonly associated with tissue spreading in many developmental and disease-related processes. Yet, how radial cell intercalations are controlled and function in tissue spreading remains unknown. Here, we use a combination of experiments and theory to analyze radial cell intercalations during doming, the initial spreading of the blastoderm over the yolk cell at early zebrafish gastrulation. Strikingly, we found that radial cell intercalations do not drive doming, but rather determine the viscous relaxation behavior of the blastoderm in response to tissue surface tension (TST)-driven deformation. We further show that radial cell intercalations and, consequently, doming are triggered by surface epithelial cells expanding their surface area and thus reducing TST. Thus, radial cell intercalations are required for translating changes in tissue-scale forces into tissue deformation.

1:39PM Z46.00005 Glass transition originating from a rigidity transition in confluent biological tissues. DAPENG BI, Syracuse University — Cells must move through tissues in many important biological processes, including embryonic development, cancer metastasis, and wound healing. Often these tissues are dense and a cell’s motion is strongly constrained by its neighbors, leading to glassy dynamics. Although there is a density-driven glass transition in self-propelled particle (SPP) models for active matter, these cannot explain liquid-to-solid transitions in confluent tissues, where there are no gaps between cells and the packing fraction remains fixed and equal to unity. We have recently described a different type of rigidity transition that occurs in confluent tissue monolayers in the limit of vanishing cell motility, where the onset of rigidity is governed by changes to single-cell properties such as cell-cell adhesion and cortical tension. Here we alter the model to include cell motility using an equation for polarization similar to those in SPP models. We identify a glass transition line that originates at the critical point of the rigidity transition, and compare the results to an analytic trap model. The model provides a novel signature for mechanical behavior in confluent tissues, which has been successfully tested in experimental systems. I will also demonstrate that this model provides a framework for studying the Epithelial-to-Mesenchymal transition in cancer invasion and cell sorting during embryonic development.

Friday, March 6, 2015 11:15AM - 2:15PM — Session Z47 DBIO: Physics of Genome Organization 217B - Alexandre Morozov, Rutgers University

11:15AM Z47.00001 The Stochastic Signature of Mixed Promoter States. LEONARDO SEPULVEDA, Department of Biochemistry and Molecular Biology, Baylor College of Medicine and Center for Theoretical Biological Physics, Rice University, IDO GOLDING, Department of Physics and Center for the Physics of Living Cells, University of Illinois at Urbana-Champaign — Gene promoters typically contain multiple binding sites for transcription factors. This allows for distinct transcription-factor binding configurations, each characterized by a different transcriptional activity of the regulated gene. However, at a given transcription-factor concentration, the promoter is not expected to exhibit a single configuration, but, instead, a “mixed state” with fractional probabilities for the different configurations. What is the nature of these mixed promoter states at the single-cell level? We investigate this question by measuring simultaneously, in individual cells, the concentration of the CI transcription factor and the transcriptional output of the regulated promoter, P_{RM}, in E. coli. We use the mRNA copy-number statistics to reconstruct the stochastic kinetics of the different promoter configurations and calculate their probabilities at each CI concentration. We find that the mRNA distribution for cells in a mixed state can be described as a convolution of the pure-state distributions, indicating rapid switching between the pure promoter states. Thus, mixed promoter states do not result in different cell populations but instead appear as a new, well-defined promoter activity.

11:27AM Z47.00002 Direct Quantification of Transcriptional Regulation at an Endogenous Gene Locus. HENG XU, Department of Biochemistry and Molecular Biology, Baylor College of Medicine; Center for Theoretical Biological Physics, Rice University, ANNA SOKAC, Department of Biochemistry and Molecular Biology, Baylor College of Medicine, IDO GOLDING, Department of Physics and Center for the Physics of Living Cells, University of Illinois at Urbana-Champaign — The stochastic kinetics of gene activity in individual cells has been well characterized, but how this kinetics is modulated by the transcription factors that regulate expression remains largely unknown. We address this question using the Bicoid (Bcd) transcription factor and hunchback (hb) gene in early Drosophila embryos. We measure, simultaneously, the number of nascent hb mRNAs, nuclear Bcd concentration, and number of bound Bcd proteins, at individual gene loci. Using stochastic theoretical analysis, we find that Bcd modulates the probability of hb switching to an active transcriptional state, while not affecting the probabilities of transcription initiation or gene inactivation. Gene activation is achieved through the cooperative binding of 6 Bcd copies. Our data also reveals additional Bcd binding states of unknown function. In contrast to Bcd, binding of the Hunchback transcription factor represses hb transcription. Our approach can be used to elucidate the combinatorial activity of multiple transcription factors without the need for genetic perturbation.
11:39AM Z47.00003 Fast Chromatin Assembly facilitated by Nucleosome Breathing and Replication-Guided Packing . JOHANNES NUEBLER, BRENDAN OSBERG, Theory of Complex Biosystems, Physik-Department, Technische Universität München, James-Franck-Str. 1, 85748 Garching, Germany, PHILIPP KORBER, Adolf-Butenandt-Institut, University of Munich, Schillerstrasse 44, 80336 Munich, Germany, ULRICH GERLAND, Theory of Complex Biosystems, Physik-Department, Technische Universität München, James-Franck-Str. 1, 85748 Garching, Germany — The condensation of eukaryotic DNA into chromatin entails the formation of nucleosome arrays with high density at species-dependent nucleosome spacing. These arrays are frequently destroyed by transcription and replication, such that reassembly is required. Due to a well-known jamming effect in the random adsorption of mutually exclusive objects (aka the "car parking problem"), the question was raised how in vivo nucleosome densities, and patterns, can be reached in the biologically relevant timescale of minutes [1]. We show that the "softness" of nucleosomes alleviates the kinetic challenge [2]. Nucleosome softness arises due to transient DNA unwrapping (breathing) and stepwise nucleosome assembly. From a physics perspective, the "soft car parking problem" differs fundamentally from its hard counterpart by exhibiting non-monotonic density and rapid equilibration. We also discuss scenarios how the progression of the replication fork can promote rapid reassembly in its wake. For example, tight packing arises naturally if the fork progresses slowly compared to the reassembly rate.

11:51AM Z47.00004 Topology, structure and energy landscape of human chromosomes , BIN ZHANG, PETER WOLYNES, Rice University — The genomes' three-dimensional (3D) organization is crucial in regulating many biological processes, including gene regulation, DNA replication, and cell differentiation. We develop a statistically rigorous approach based on maximin entropy principle to determine a least-biased potential energy landscape that reproduces experimentally determined Hi-C contact frequency between genome pairs. The resulting energy landscape supports a knotless chromosome conformation, which has been highly anticipated since complex knotted conformations prohibit the access of gene information for transcription and hinder DNA replication. We further show that the topologically associating domain signal alone also enforces a chromosome structure free of knots. Our results highlight the importance of local interactions in determining the global topology of the chromosome structure. Finally, the derived landscapes for multiple chromosomes support the formation of territories that have long been observed in microscopy experiments. Together with Hi-C experiments, our approach provides a coherent picture of the 3D architecture of the genomes that is consistent with many the available experimental data.

12:03PM Z47.00005 Expediting the Sequencing Process: Using Soft Lithography to Fragment Aligned DNA Molecules1 . MEENA JAGADEESAN, Phillips Exeter Academy, Exeter NH 03833, ADINA SINGER, Stella K. Abraham High School for Girls, Hewlett Bay Park NY 11557, NAHYUN CHO, KE ZHU, JULIA BUDASSI, JONATHAN SOKOLOV, Stony Brook University — Current sequencing technologies output short read lengths on the order of 10 kb, requiring DNA to be fragmented into small pieces, analyzed separately and recombined to obtain the full sequence. The accuracy and cost efficiency of sequencing has been limited by the computer algorithms required to assemble the random subsequences. The fragmentation method in this study can significantly simplify the assembly process with a novel lithographic cutting procedure that retains the position and order of DNA fragments. DNA was stretched linearly on a polymer coated silicon wafer. A polydimethylsiloxane (PDMS) lithographic stamp was coated in DNase I (DNA cutting enzyme) solution. The stamp was placed in contact with the surface aligned DNA, producing 3.5 micron (10 kbp) DNA fragments. Fluorescence imaging of dye labeled DNA was used to monitor the cutting effectiveness. The improved enzyme application procedure presented in this study enabled uniform, ordered cutting of the surface aligned DNA over approximately 80% of the 2 cm x 3 cm samples. Means to extract the cut DNA from the polymer surface were also explored. The effectiveness of solution methods, electric field desorption, and microfluidics will be discussed.

1 NSF funding (DMR-0606387) is gratefully acknowledged.

12:15PM Z47.00006 New insights into nucleosome positioning , RAZVAN CHEREJI, JOSEFINA OCAMPO, TARA BURKE, DAVID CLARK, Natl Inst of Health - NIH — A human body contains enough DNA to circle the Earth's Equator more than 2.5 million times. Nevertheless, the entire genetic material is packed inside the tiny nuclei of our cells. The basic units of DNA packaging are called nucleosomes. Their locations on the chromosomes play an essential role in gene regulation. We study nucleosome positioning in yeast, fly and mouse, both in vivo and in vitro, and build biophysical models in order to explain the genome-wide nucleosome organization. We show that DNA sequence is not the major cause of the phased arrays of nucleosomes observed in vivo near the transcription start sites. We discuss simple models which can account for the formation of nucleosome depleted regions and nucleosome phasing at the gene promoters. We analyze the effects of different factors which influence the chromatin organization in living cells: existence of potential barriers and wells, sequence-dependent nucleosome affinity, nucleosome unwrapping, competition between different DNA-binding proteins, action of ATP-dependent remodelers, among others.

12:27PM Z47.00007 Statistical mechanics of nucleosome assembly and chromatin packaging , ALEXANDRE MOROZOV, Rutgers University, Department of Physics and Astronomy — Eukaryotic genomes are organized into arrays of nucleosomes. Each fully wrapped nucleosome consists of 147 base pairs of genomic DNA bent around a histone octamer core. The resulting complex of DNA with histones forms a multi-scale structure called chromatin. At the most fundamental level of chromatin organization, arrays of nucleosomes form 10-nm fibers which resemble beads on a string; these in turn fold into higher-order structures. Depending on the organism and cell type, 75-90% of genomic DNA is packaged into nucleosomes. The question of how cellular functions are carried out on this chromatin template is one of the outstanding puzzles in biology. Nucleosomal DNA may transiently peel off the histone octamer surface due to thermal fluctuations or interactions with chromatin remodelers. Thus neighboring nucleosomes can invade each other’s territories through DNA unwrapping and translocation, or through initial assembly in partially wrapped states. A recent high-resolution map of distances between neighboring nucleosomes in baker’s yeast [1] has revealed that at least 25% of all nucleosomes overlap with DNA territories of their neighbors. To explain this observation, we have developed a statistical mechanics model of nucleosome assembly and unwrapping [2]. Our model is in agreement with genome-wide nucleosome positioning data and in vitro measurements of accessibility of nucleosome-covered target sites. Furthermore, it explains nucleosome-induced cooperativity between DNA-binding factors. The observed extent of nucleosome crowding in the yeast genome strongly suggests that its treatment should be included in all future models of chromatin structure and energetics.

1:03PM Z47.00008 Exploring telomeric DNA-protein-DNA interactions under nanofabrication . MAEDEH ROUSHAN, PARMINDER KAUR, JIANGUO LIN, HONG WANG, ROBERT RIEHN, North Carolina State University, RIEHN LAB TEAM, WANG LAB COLLABORATION — Genomes are organized through DNA binding proteins. In particular, telomeres are organized into ~ 10 kbp loops by a multi-protein complex. For understanding how proteins interact with DNA we have investigated the effect of different DNA-binding proteins on DNA configuration by injecting different proteins inside a nanofabricated channel system. DNA molecules stretch in nanochannels with a channel cross-section roughly about 100x100 nm2, so allowing analysis by observation of a fluorescent dye. The length and configuration of DNA can be directly observed, as well as the binding location of proteins. Here we show the binding patterns and molecular action of a set of telomere-associated proteins, namely TRF1, TRF2,RAP1, SA1, as well the model protein T4 DNA ligase. In particular, we demonstrate formation of stable loops, sliding, and general DNA condensation.
1:15PM Z47.00009 Computational modeling of autocatalytic heteropolymer replication, HEMACHANDER SUBRAMANIAN, ROBERT GATENBY, Moffitt Cancer Center — We computationally study replication of a hypothetical autocatalytic heteropolymer using Kinetic Monte Carlo. When cooperativity is included in the model, we observe better replication characteristics and higher fitness in strands with certain symmetries broken. We correlate this symmetry-breaking with the observed broken mirror symmetry of extant heteropolymers.

1:27PM Z47.00010 A unified description of biological effects caused by radiation exposure: Whack-a-mole (WAM) model, TAKAHIRO WADA, Department of Pure and Applied Physics, Kansai University, YUCHIRO MANABE, Graduate School of Engineering, Osaka University, ISSEI NAKAMURA, State Key Laboratory of Polymer Physics and Chemistry, Changchun Institute of Applied Chemistry, MASAKI BANDO, Research Center for Nuclear Physics (RCNP), Osaka University — We present our novel rate equations to study DNA mutation in cells caused by artificial radiation exposure, accounting for the DNA damage and repair simultaneously. In our theory, the dependence of mutation frequencies on the dose rate is critically important to predict both the time course and the stationary effect of the DNA mutation in cell cycles. Experimentally, irradiation at high dose rates causes linear increases in the mutation frequency with total dose, whereas the saturation of the mutation frequency is observed at low dose rates. We demonstrate that this fact arises from counteracting effects among the DNA damage and mutation, the DNA repair, and the proliferation and apoptosis of cells. Our theory thus captures observed quantities at both high and low dose rates, marking a substantial difference from conventional theories based only on the total dose. Importantly, we have derived a scaling function from our rate equations that predicts a universal feature in the mutation frequency of living organisms. In this study, we have analyzed the experimental data of five species; mouse, drosophila, chrysanthemum, maize, and tradescantia. Despite the difference between animal and plant, all these data reasonably fall on a single line for our scaling function.

1:39PM Z47.00011 Extracting free energies of interaction from chromosome conformation capture data, ELDON EMBERLY, Physics, Simon Fraser University, Burnaby, BC — A variety of DNA binding proteins are involved in regulating and shaping the packing of chromatin. They aid the formation of loops in the DNA that function to isolate different structural domains. A recent experimental technique, Hi-C, provides a method for determining the frequency of such looping between all distant parts of the genome. Given that the binding locations of many chromatin associated proteins have also been measured, it is possible to make estimates for their influence on the long-range interactions as measured by Hi-C. However, a challenge in this analysis is the predominance of non-specific contacts that has made making quantitative estimates for the strengths of interactions between chromatin factors difficult. In this talk I will show that transforming the Hi-C contact frequencies into free energies of interaction gives a natural method for separating out the distance dependent non-specific interactions. In particular, using Principal Component Analysis (PCA) on the transformed free energy matrix can identify the dominant modes of interaction within the genome. Some of these modes correspond to systematic biases that can then be subtracted out. I will then show that a pairwise interaction model can be fit to the corrected free energies to determine the couplings between known bound chromatin factors. By correcting for the systematic effects identified by PCA, a consistent set of predictions for the couplings among the various chromatin factors can be made. Many of the known interactions within the network of chromatin factors are found along with several novel predictions. Finally, I will present efforts to predict the local 3D structure of chromatin using the fitted interaction model and the locations of bound factors.

Friday, March 6, 2015 11:15AM - 1:51PM — Session Z49 GSOF: Focus Session: Self-Phoretic Colloids and Active Emulsions II 217D - Michelle Driscoll, New York University

11:15AM Z49.00001 Building a dynamic cell from the bottom up, VIVA R. HOROWITZ, THOMAS G. DIMIDUK, Department of Physics, Harvard University, IREP GOZEN, School of Engineering and Applied Sciences, Harvard University, YUE N. REN, Harvard University, VINOTHAN N. MANOHARAN, School of Engineering and Applied Sciences, Harvard University — We aim to understand cellular processes, particularly intracellular transport, at a physical level by building simple, well-controlled systems that mimic the functions of a cell. We have created a simple artificial cell using a bilayer phospholipid vesicle containing Janus swimmers as microscale motors. These Janus swimmers are propelled by the catalytic breakdown of hydrogen peroxide on their platinum hemispheres. We encapsulate these Janus swimmers in the interior of the artificial cell. We investigate the superdiffusive motion using multimodal imaging tools, including digital holography and fluorescence, to shed light on how the dynamics of Janus swimmers depends on the confinement. These dynamics and transport processes may prove necessary to sustain gene expression, growth, and reproduction in future artificial cells.

11:27AM Z49.00002 Internally driven solids, ANANYO MAITRA, SUROPRIYA SAHA, Indian Inst of Science, RAMIN GOLESTANIAN, Rudolf Peierls Center for Theoretical Physics, University of Oxford, 1 Keble Road, Oxford OX1 3NP, United Kingdom, SRIRAM RAMASWAMY, TCIS, TIFR — What is the long-wavelength, long-time dynamics of an elastic solid composed of motile orientable particles? Can different types of interactions between the motile particles lead to different varieties of active solid? What is the dynamics if the motile particles orient along a spontaneously chosen axis? Is it different from a passive solid which is driven externally? What if the inter-particle interactions instead favour aster-like configurations? I will present an answer to these questions and point out the differences and similarities between internally driven and externally driven solids.

11:39AM Z49.00003 Controlling Compartmentalization Through Active Confinement, MATTHEW SPELLINGS, MICHAEL ENGEL, DAPHNE KLOTHSA, Univ of Michigan - Ann Arbor, KYLE BISHOP, The Pennsylvania State University, SHARON GLOTZER, Univ of Michigan - Ann Arbor — Active matter is an exciting area of study that displays promising new behaviors previously unobtainable in equilibrium systems and could help bridge the gap between equilibrium colloidal- and nanoscale particles and living cells. In this talk, we will discuss novel, emergent behavior observed simulations of confined "cells" comprised of active particles. We show how the results of a microscopic model are reproduced in a continuum model.

11:51AM Z49.00004 Self Propelled nanorods at an interface, JEREMIE PALACCI, Department of Physics, UCSD/ Courant Institute NYU, TAKUJI ADACHI, NYU Chemistry, JUN ZHANG, NYU Physics/ Courant Institute NYU, LEIF RISTROPH, Mike SHELLEY, Courant Institute NYU — Self-propelled colloids are micron-scale particles which can harvest the energy from the surrounding medium and convert it into propulsion and work. Here we study the impact of the interface —solid, fluid, slipping, non-slipping— on the dynamics of the self-propulsion for a suspension of active nanorods.
12:03PM Z49.00005 Velocity distributions in self-assembled phases of active magnetic colloids\textsuperscript{1}, ALEXEY SNEZHKO, Argonne National Laboratory — Colloids of strongly interacting particles driven out-of-equilibrium by an external periodic forcing often develop nontrivial collective dynamics and dynamically assembled structures. We use ferromagnetic colloidal micro-particles suspended over a water-air interface. The system is energized by a single-axis alternating magnetic field applied in-plane of the interface. Experiments revealed a rich variety of self-assembled phases (in particular, “wires,” “rotators”) emerging in such systems in a certain range of excitation parameters. Velocity distributions of particles in driven magnetic colloids in “rotators” phase were carefully examined. The studies revealed strongly non-Maxwellian nature of velocity statistics for both subsystems: single particles and self-assembled rotators. The high energy tails of velocity distributions are stretched exponential. Dissipations due to inelastic collisions and viscous damping contribute to the form of the high energy tails. When viscous damping dominates over collisional dissipation the distribution is nearly exponential (such behavior is observed for the gas of rotators) while in the opposite case (single particles driven by field) the core of the distribution is Gaussian and only high energy tails are close to exponential.

\textsuperscript{1}The research was supported by the U.S. DOE, Office of Basic Energy Sciences, Division of Materials Science and Engineering, under the Contract No. DE AC02-06CH11357

12:15PM Z49.00006 Strongly confined active brownian particles, YAOQUEN FILY, APARNA BASKARAN, MICHAEL HAGAN, Brandeis University — We explore the effect of boundaries on active suspensions by considering non-aligning self-propelled particles confined by hard frictionless walls. In small boxes, the density and pressure are sensitively controlled by the shape of the box. We show those quantities can be predicted for arbitrary box shapes, and discuss the role of concavity and dimensionalities. This in turn provides a tool to design and understand such confining boxes.

12:27PM Z49.00007 Using light patterns to manipulate self-propelled particles, MELISSA FERRARI, MICHELLE DRISCOLL, Department of Physics, New York University, JEREMIE PALACCI, Department of Physics, University of California, San Diego, STEFANO SACANNA, Department of Chemistry, New York University, DAVID PINE, PAUL CHAIKIN, Department of Physics, New York University — Soft active matter systems, characterized by their ability to extract energy from their environment to perform mechanical work, exhibit phenomena far from equilibrium. We study a class of synthetic light activated colloidal swimmers which self-propel osmotically on a surface. Here we propose a method to manipulate the migration of the light activated colloids by carefully tuning their macroscopic environment. Through integration of a modified commercial projector with an optical microscope, we are able to shine static and dynamic light patterns onto the sample plane where the light activated swimmers live. We can use specific light patterns to set up swimmer density gradients in our sample.

12:39PM Z49.00008 Active droplets as biomimetic model swimmers\textsuperscript{1}, CORINNA MAASS, Max Planck Institute for Dynamics and Self-Organization, Göttingen — Large ensembles of biological swimmers form one of the biggest ecosystems on earth: marine phytoplankton. Investigating the dynamics of such a system is of prime ecological importance, however, as any modelling would need to include the interplay of turbulence, long-range hydrodynamics, buoyancy, as well as the self-propelled motion of the swimmers, this proves a daunting task both analytically and numerically. A scalable system of artificial swimmers with well understood and tunable interactions should help with decoupling some of these effects and studying them separately. Active emulsions of self-propelled droplets present a suitable experimental model system for the collective behaviour of biological swimmers, as they exhibit both autonomous motion and chemotaxis, move freely in three dimensions, can be produced and stored in large, monodisperse quantities and are stable over time scales comparable to biological systems. We demonstrate some of these features on a system of liquid crystal droplets driven by solubilisation into a micellar aqueous surfactant solution.

\textsuperscript{1}Supported by the DFG SPP 1726 “Microswimmers.”

1:15PM Z49.00009 Active Brownian and Run-and-Tumble particles: A comparison of the large scale dynamics, BENJAMIN HANCOCK, APARNA BASKARAN, Brandeis Univ — Active Brownian particles, such as self phoretic colloids, are a class of self propelled particles which swim at fixed speed with orientation that gradually changes through rotational diffusion. Some bacteria obey Run-and-Tumble dynamics, in which particles swim along a fixed orientation until a tumble event occurs that randomly selects a new orientation. At long time and length scales the diffusive-drift limit of the above dynamics appear to be identical. In this large scale limit, we study the effects of external fields on the dynamical properties of these two classes of self propellled particles.

1:27PM Z49.00010 The role of hydrodynamics and confinement on the collective behavior of active emulsions, SHASHI THUTUPALLI, DELPHINE GEYER, HOWARD STONE, Princeton Univ — Active droplets i.e. emulsion droplets which exhibit self-propelled motion are of tremendous interest in understanding the collective dynamics of systems far from thermal equilibrium. A particularly appealing feature of these active droplet systems is that the coupling between the individuals is well-controlled and mediated by purely physical effects such as steric interactions and hydrodynamics. We create such active droplet systems using liquid crystalline emulsions in aqueous phases stabilized by surfactants. The propulsion of the individual droplets is fully 3 dimensional and occurs via a spontaneously broken symmetry (unlike colloidal swimmers which are often asymmetric by design) which is sustained via dissipation of chemical energy. Here, we show that hydrodynamics and geometry play a crucial role in the emergent self-organization of the active droplets. In particular, we describe the pair-correlations emerging in a population of active droplets confined in Hele-Shaw geometry. We further demonstrate that these interactions result in the formation of stable travelling bands in reduced confinement and self-organize into crystalline vortices at a single interface.

1:39PM Z49.00011 Glassy dynamics of self-propelled particles: computer simulations and a mode-coupling-like theory\textsuperscript{1}, GRZEGORZ SZAMEL, ELIJAH FLENNER, Department of Chemistry, Colorado State University, LUDOVIC BERTHIER, Laboratoire Charles Coulomb, Universite Montpellier II — We use a combination of computer simulations and theory to elucidate glassy dynamics of self-propelled particles. We compare the relationship between the steady state structure of the self-propelled system and its long-time dynamics with that of an equilibrium Brownian system. We find that an athermal self-propelled system can have a more pronounced local structure but faster relaxation than a similar equilibrium system. Interestingly, the dependence of the dynamics on the persistence time of the self-propulsion can be non-monotonic, with the dynamics speeding up and then slowing down with increasing persistence time. We show that these effects are captured by a mode-coupling-like theory.

Friday, March 6, 2015 11:15AM - 2:15PM – Session Z50 GSOFT: Membranes, Micelles and Vesicles 218 - Haskell Taub, University of Missouri, Columbia
11:15 AM Z50.00001 Dynamic Heterogeneity in Lipid Structures. CHRISTINA OTHON1, Wesleyan Univ, NEDA DADASHVAND, Wesleyan University — We have characterized the temperature and pressure dependent scaling of dynamic heterogeneity in a homogenous liquid phase of a lipid monolayer using time-resolved fluorescence anisotropy (TRFA) microscopy. Rotational diffusion is far more sensitive to highly correlated motions than translational diffusion due to the enhanced influence of nearest neighbor interactions. Highly correlated motion results in regions of high-density, low mobility lipids, and low-density, high mobility lipids; and are observed as the bimodal distribution of rotational correlation times. For biological lipid membranes the presence of highly correlated motion will greatly influence the rates of protein sorting and self-assembly, as particles suspended in the fluid can become kinetically trapped. Rotational diffusion timescales (~ ns) are far shorter than the lifetime of dynamic clusters and lipid raft-like structures (~ 10 µs), and thus the distribution of rotational correlation times can provide critical insight into the presence of these structures. We have characterized rotational dynamic distributions for a variety of phosphocholine moieties, and found dynamics consistent with highly correlated motion. Using the proximity to the phase transition, and the scaling of the temperature dependence of the heterogeneity we apply theoretical models developed for other condensed matter systems help us define limits on the size and lifetime of dynamic clusters in lipid structures.

11:27 AM Z50.00002 Interplay between group function of kinesin based transport and lipid bilayer mobility. JOSEPH LOPES, LINDA HIRST, JING XU, University of California, Merced — Motor proteins, discovered in recent decades, are important building blocks to life. These molecular machines transport cargo and although indispensable to cell function, are not well understood at present. Single kinesin transport properties have been documented, but their group function remains unknown. In this project, the properties of kinesin-based transport by multiple motors are investigated in-vitro to establish a link between travel distance and lipid diffusion in the vesicle membrane. In the experiments, silica beads coated in a supported lipid membrane and giant vesicles are transported along a microtubule by embedded kinesin motors. In an alternate geometry, this system can be inverted, whereby motors are bound to a surface of a lipid bilayer and microtubules are deposited. We have characterized motor function with respect to the fluidity of the membrane. To measure the diffusion properties of different membranes, planar lipid bilayers are prepared on silica slides and supported by bovine serum albumin protein. To establish a diffusion constant at room temperature for the lipid membrane we use the FRAP technique (fluorescence recovery after photobleaching). Using this method we can investigate if there is any interplay between group travel function and membrane fluidity.

11:39 AM Z50.00003 Nanoscopic Dynamics of Phospholipid Based Unilamellar Vesicles: Effect of Phase Transition and Addition of Melittin Peptide and Cholesterol. V. K. SHARMA, Biology and Soft Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, E. MAMONTOV, Chemical and Engineering Materials Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, D. B. ANUNCIADO, H. O’NEILL, V. URBAN, Biology and Soft Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — Dynamics of DMPC phospholipid in unilamellar vesicles (ULV) has been investigated using quasielastic neutron scattering (QENS) techniques and reported here. Effect of addition of melittin and cholesterol on the dynamics of the lipid molecules in the ULV is also investigated. For DMPC ULV, a sharp fall in the elastic scan intensity is observed at 296 K, which is an indication of a solid gel to fluid phase transition. The addition of cholesterol or melittin inhibits this steep fall indicating that these molecules do have an influence on the main phase transition of DMPC ULV. QENS experiments have been carried out on DMPC ULV solution in the presence and absence of these additives at 280 K, in the solid gel phase, and at 310K, where lipids are in the fluid phase. The nanomolar concentration shows the presence of two distinct motions: lateral and internal motions of the DMPC monomer. Both lateral and internal motions are found to be affected by the main phase transition. The addition of cholesterol or melittin influences the dynamics significantly in a different way, depending on the phase of lipid bilayers and the nature of additives. Effect of phase transition and additives on the dynamics of lipid in ULV will be discussed in details.

11:51 AM Z50.00004 A Molecular Understanding of the Toxic Interactions of Ionic Liquids Towards a Lipid Biomembrane1, BRIAN YOO, EDWARD MAGINN, YINGXI ZHU, Univ of Notre Dame — There is a growing urgency to understand the toxicity of ionic liquids (ILs) due to their potential leakage into aquatic environment via aqueous waste streams in many large-scale commercial applications. Better understanding in the molecular interactions of ILs, primarily those in the popular imidazolium-class, with biological systems can serve as a physical foundation for their future design into ecologically benign ones. Here we investigate the toxic interaction of IL aqueous solutions with a supported lipid bilayer as a model cell membrane, using a combined experimental (fluorescence microscopic measurements) and multiscale simulation-based analysis. Both experimental and computer simulation studies have shown that the interactions of ILs with a supported lipid bilayer can lead to the insertion of ILs into the lipid bilayer, causing biomembrane morphological changes into multilayers, fibers, and/or vesicles with a strong dependence on the alkyl side chain length of IL cations. Using atomistic and coarse grained simulations, we have examined the potential of mean force of IL upon approaching a lipid bilayer and resulting changes in the mechanical compliance of lipid bilayer induced by IL interactions. We find that the resulting IL-lipid bilayer complexes can be strongly dependent on the ILs’ ability to form cationic micelles.

12:15 PM Z50.00006 Curvature coupling influences lipid phases and morphologies on substrates. JUKKA MÄÄTTÄ, SAMPSA VIERROS, MARIA SAMMALKORPI, Aalto Univ — The shape of a lipid aggregate contributes to many crucial biological processes like motility, fusion, fission and trafficking. At a molecular scale, the shapes lipids self-assemble in aqueous solution are coupled to molecular spontaneous curvature. At interfaces, the interface imposes an additional external constraint, which influences the assembled morphology. In this study, we examine the coupling between molecular spontaneous curvature and imposed external curvature in self-assembling lipid systems via molecular simulations. We map the adsorption morphologies for lipids of varying curvature as a function of substrate characteristics; the external curvature imposed by the substrate acts as a control factor in determining the morphology. In two-component systems external curvature introduced by the substrate can result in phase separation. We compare and connect our findings with experimental findings on lipid adhesion and adsorption morphologies.

12:27 PM Z50.00007 Interaction measurement of particles bound to a lipid membrane. RAPHAEL SARFATI, ERIC DUFRESNE, Yale University — The local shape and dynamics of the plasma membrane play important roles in many cellular processes. Local membrane deformations are often mediated by the adsorption of proteins (notably from the BAR family), and their subsequent self-assembly. The emerging hypothesis is that self-assembly arises from long-range interactions of individual proteins through the membrane’s deformation field. We study these interactions in a model system of micron-sized colloidal particles adsorbed onto a lipid bilayer. We use fluorescent microscopy, optical tweezers and particle tracking to measure dissipative and conservative forces as a function of the separation between the particles. We find that particles are driven together with forces of order 100 fN and remain bound in a potential well with a stiffness of order 100 fN/micron.
12:39PM Z50.00008 Effects of water models and simulation system size on dynamic heterogeneity of single component lipid membranes, YOUNGHOON OH, JEONGMIN KIM, BONG JUNE SUNG, Department of Chemistry, Sogang University, Seoul 121-742, Republic of Korea — Biological membranes are composed of various different types of molecules and their composition is usually spatially heterogeneous. Recently it has been reported that the dynamics of lipids could also become spatially heterogeneous, where fast and slow regions of lipids could coexist. A recent simulation study showed that the diffusion of lipids even in single component lipid membranes could be spatially heterogeneous in liquid-ordered phase at sufficiently low temperature. [1] On the other hand, in the liquid-disordered phase at relatively high temperature, the dynamics of lipids was homogeneous in membranes. In this work, we systematically investigated the diffusion of lipids in single component DPPC lipid bilayers by employing three different water models (Big Multipole Water, Polarizable MARTINI and LJ MARTINI) and three different simulation cell sizes (L = 5nm, 10nm and 20nm). We find that even though the liquid-disordered to liquid-ordered phase transition occurs at different temperatures for different water models, the diffusion of lipids become spatially heterogeneous in liquid-ordered phases for all three different force fields. 12:51PM Z50.00009 Modulation of MscL activity in droplet interface bilayers through tailored interfacial mechanical properties, JOSEPH NAJEM, Virginia Tech, ERIC FREEMAN, University of Georgia, SERGEI SUKHAREV, University of Maryland, DONALD LEO, University of Georgia — MscL, a large-conductance mechanosensitive channel, is an osmolyte release valve that aids bacteria in surviving hypo-osmotic shocks. The large scale of its tension-driven opening transition makes it a strong candidate to serve as a transducer in stimuli-responsive biomolecular materials. In the previous work, a V23T mutant of MscL produced a reliable activation in a droplet interface bilayer (DIB) with applied axial droplet compression. Near the maximal compression, the aqueous droplets deform and the resulting increase in surface area leads to an increase in tension in the water-lipid-oil interface. This increase in tension is the product of the relative change in the droplet surface area and the elastic modulus of the DPhPC monolayer (120 nN/m). Here, we study the interfacial properties of the droplets as a way for modulating the activity of the embedded MscL channels. This is accomplished through varying mixtures of diphantanol phospholipids. The results show that gating probability of MscL in DIBs increases when lipids with a higher elastic modulus are used or when cholesterol is added to the monolayer. Moreover, an intrinsic electrical bias inside the lipid membrane is created when having DPhPC lipids with higher dipole in one droplet and DOPhPC characterized with lower dipole, in the other.

1:03PM Z50.00010 Structural dynamics of surfactant solutions in planar extensional flow, BINBIN LUO, WESLEY BURGHARDT, Northwestern University — We report in situ x-ray scattering investigation of the structure of aqueous surfactant solutions in planar extensional flow. Samples were studied in a cross-slot stagnation flow cell fed by a syringe pump using a highly collimated synchrotron x-ray beam that provides for spatially resolved measurements of fluid structure in the stagnation region of the flow. Prior attempts to use planar stagnation flows for either x-ray or neutron scattering employed low-aspect ratio flow geometries in which the kinematics are dominated by parasitic velocity gradients along the incident beam direction. In contrast, our cross-slot flow cell employs an aspect ratio of 5:1, providing a much more ideal two-dimensional extensional flow field in the stagnation region. This device has been used to study two different surfactant systems, one a wormlike micelle solution at high salt concentration which exhibits rheology similar to that of entangled polymers. Here the focus is on the degree of micelle orientation produced as a function of extension rate. We have also studied a system that forms lamellar ordering. In addition to induced alignment of the mesophase structure, it is also possible to interrogate flow-induced changes in lamellar d-spacing in this material.

1:15PM Z50.00011 Toward a unified view of the structure and dynamics of water associated with single-supported zwitterionic and anionic membranes, ZACHARY BUCK, Univ of Missouri, ANDREW MISKOWIEC, Oak Ridge National Lab, HELMUT KAISER, Univ of Missouri Research Reactor, GAVIN KING, HASKELL TAUB, Univ of Missouri, FLEMMING HANSEN, Technical Univ of Denmark, MADHUSUDAN TYAGI, NIST Center for Neutron Research, SOULEYMANE DIALLO, EUGENE MAMONTOV, KEN-NETH HERWIG, Oak Ridge National Lab — High-resolution quasielastic neutron scattering was used to investigate the diffusive motion of water associated with single-supported bilayers of the zwitterionic lipid DMPC [1] and the anionic lipid DMPG [2]. The temperature dependence of the elastically-scattered neutron intensity from these samples indicates a series of freezing and melting transitions of the hydration water which differ greatly depending on the charge state of the lipid [2]. We interpret these distinct transitions as evidence of different types of water common to the two membranes: bulk-like water probably located above the membrane and two types of confined water in closer proximity to the lipid head groups. The temperature dependence of the diffusion coefficient of the hydration water determined for both membranes supports the interpretation of distinct water types each with its characteristic translational diffusion rate. Although sharing water types, the two membranes differ greatly in the temperature range over which their water freezing and melting transitions occur. [1] M. Bai et al., Europhys. Lett. 98, 48006 (2012). [2] A. Miskowiec et al., Europhys. Lett. 107, 28008 (2014).

1:39PM Z50.00013 Observation of Iron Specific Interaction with a Charge Neutral Phospholipid, WENJIE WANG, HONGHU ZHANG, SHUREN FENG, JOSUE SAN EMETIERO, Ames Laboratory, Iowa State University, IVAN KUZMENKO, Argonne National Laboratory, MARIT NILSEN-HAMILTON, SURYA MALLAPRAGADA, DAVID VAKNIN, Ames Laboratory, Iowa State University — Using surface sensitive X-ray scattering and spectroscopic techniques we show that phosphatidyl choline (PC) head groups attract positively charged iron ions and complexes even at pH values that are lower than 3. DPPC (1,2-dipalmitoyl-sn-glycero-3-phosphocholine) is a zwitterionic lipid typically used as a model system for cell membranes. Within a large pH range (3-11), it carries a negative charge on the phosphate group and a positive charge on the quaternary ammonium cation, thus appears charge neutral. Further lowering the pH, i.e. adding a proton to the phosphate group, results in a positively charged headgroup. Surprisingly, we detect significant enrichment of iron at the interface of the DPPC monolayer and the aqueous subphase with the pH maintained at 3 or even lower. With a supposedly charge neutral or even positive surface, the observation of surface bound, charge positive iron ions or iron hydroxides is counter-intuitive and suggests iron-specific interaction with the phospholipid headgroup, which is not governed by electrostatic interaction. The effect of the integration of Mms6, a membrane protein that promotes the formation of magnetic nanocrystals, into the DPPC monolayer will also be discussed.

11:15AM Z51.00001 Significant Tc enhancement in FeSe films on SrTiO3 due to interfacial mode coupling , ROBERT MOORE, SLAC National Accelerator Laboratory — The enhanced superconductivity in monolayer FeSe films grown on SrTiO3 (STO) substrates has generated a lot of attention. Several previous studies have shown a dramatic difference between the superconducting monolayer and non-superconducting bilayer films suggesting the substrate or interface plays a critical role in the enhancement of superconductivity. Utilizing Molecular Beam Epitaxy (MBE) and in situ Angle Resolved Photoemission Spectroscopy (ARPES), we explore the role of the substrate on the electronic structure of superconducting monolayer FeSe films. The electronic structure at the Fermi surface of the monolayer film consists of two electron pockets at the M point of the Brillouin zone, in contrast to bilayer and thicker films that show an electronic structure similar to bulk FeSe. The orbital character of the two pockets has been resolved which shows two distinct gaps and places strict constraints on the possible pairing symmetry. Surprisingly, we observe exact replicas of the FeSe bands which are attributed quantum shakeoffs arising from strong electron phonon coupling. Shakeoff bands have never been resolved with such clarity in a solid before and are only observed in the monolayer films. The coupling is between a high energy oxygen phonon in the STO substrate and electrons in the FeSe monolayer. Oxide MBE has been used to grow STO with oxygen 18 to explore the isotope effect on the electron phonon coupled shakeoff bands and will be discussed. Theoretical investigations show how these distinct features result from strong forward scattering which enhances superconductivity. This enhancement does not depend on the origins of superconductivity as it exists in all channels and is responsible for the increase in Tc. These results suggest a possible avenue for engineering superconductors with higher Tc.

11:51AM Z51.00002 Interface-induced high-temperature superconductivity in FeSe/TiO2(001) heterostructure , HAO DING, Tsinghua University — The recently discovered high transition temperature (Tc) superconductivity at the interface of single unit-cell (UC) FeSe films on SrTiO3(001) has generated considerable excitement [1,2], which may eventually lead to the discovery of a new family of high-Tc superconductors at many different interfaces. In this talk, we will present our recent work on a new interfacial system with high-Tc superconductivity, 1 UC FeSe films on anatase TiO2(001). Using molecular beam epitaxy (MBE) techniques, we have successfully prepared high-quality 1 UC FeSe films on anatase TiO2(001) formed onSrTiO3. In situ scanning tunneling spectroscopy (STS) reveals large superconducting gap (Δ) ranging from 17 meV to 22 meV, which is nearly one order of magnitude larger than Δ = 2.2 meV of bulk FeSe with Tc = 9.4 K, indicating the signature of high-Tc superconductivity. The superconductivity of this heterostructure system is further verified by imaging vortex lattice under external magnetic field. By examining the distinct properties of anatase TiO2 films from SrTiO3, as well as their influences on superconductivity, we will discuss about the possible pairing mechanism of this system. Together with our previous work of 1 UC FeSe/SrTiO3 [1,2], this work demonstrates that interface engineering is a powerful way to fabricate new high-Tc superconductors and investigate the mechanism of high-Tc superconductivity.

12:27PM Z51.00003 Tuning the superconductivity in single-layer FeSe/oxides by interface engineering , RUI PENG, State Key Laboratory of Surface Physics, Department of Physics, Fudan University — The discovery of high Tc in single-layer FeSe films has enormous implications for both searching new high Tc superconductors and exploring the important factors for high temperature superconductivity. In this talk, I will present our recent angle-resolved photoemission studies on various FeSe-based heterostructures grown by molecular beam epitaxy. We systematically studied the electronic structures and superconducting properties of FeSe with varied strain, different interfacial oxide materials and different thicknesses, and uncovered that electronic correlations and superconducting gap-closing temperatures are tuned by interfacial effects. We exclude the direct relation between superconductivity and tensile strain, or the energy of an interfacial phonon mode, and demonstrate the crucial and non-trivial role of FeSe/oxide interface on the high pairing temperature. By tuning the interface, superconducting pairing temperature reaches up to 75K in FeSe/Nb:BaTiO3/KTaO3 with the in-plane lattice of 3.99 Å, which sets a new superconducting-gap-closing temperature record for iron-based superconductors, and may paves the way to more cost-effective applications of ultra-thin superconductors. Besides, in extremely tensile-strained single-layer FeSe films, we found that the Fermi surfaces consist of two elliptical electron pockets at the zone corner, without detectable hybridization. The lifting of degeneracy is clearly observed for the first time for the iron-based superconductors with only electron Fermi surfaces. Intriguingly, the superconducting gap distribution is anisotropic but nodeless around the electron pockets with minima at the crossings of the two pockets. Our results provide important experimental foundations for understanding the interfacial superconductivity and the pairing symmetry puzzle of iron-based superconductors, and also provide clues for further enhancing Tc through interface engineering.
1:03PM Z51.00004 First-principles study of the electron/spin-phonon interaction in compressed FeSe crystal and FeSe/STO system, ZHONG-YI LU, Department of Physics, Renmin University of China — By using the first-principles calculations with van der Waals corrections, we have studied the electronic structures, lattice dynamics, and magnetic properties of crystal FeSe under hydrostatic pressure [1] and FeSe/STO system [2,3]. For bulk FeSe, the frequency of all optical phonon modes increase with pressure. In a range between 5 and 6 GPa, the frequency of the A_1g mode, which related to the Se height from the Fe-Fe plane, shows a sudden jump. This is also the pressure range within which the highest superconducting transition temperature Tc of FeSe is reached in experiments. In comparison with the other phonon modes, the zero-point atomic displacement of the A_1g mode also induces the strongest variation of local magnetic moment on Fe, which reaches the maximum around 5 GPa. These results suggest that the effect of phonon via spin-phonon coupling could not be omitted. For monolayer FeSe epitaxial film on SrTiO_3, the combined effect of electron doping and phonon readily leads to magnetic frustration between the collinear antiferromagnetic state and checkerboard antiferromagnetic Neel state. For bilayer FeSe epitaxial film on SrTiO_3, such a magnetic frustration is much easier induced by electron doping in its bottom layer than its top layer. The underlying physics is that the doped electrons are accumulated at the interface between the FeSe layers and the substrate. These results are consistent with the existing experimental studies. 1:39PM Z51.00005 Density Functional Plus Dynamical Mean Field Theory of Correlated Oxides, ANDREW MILLIS, Columbia University — The density functional plus dynamical mean field method is outlined and a few recent successes including applications to spin crossover molecules, oxide superlattices and metal-insulator transitions in bulk transition metals are outlined. Insights from the method into the essential role played by lattice distortion (both rotations and bond length changes) in determining the phase diagrams of correlated materials are presented. The key theoretical issue of the double counting correction is outlined, different approaches are compared, and a connection to the energy level differences between strongly and weakly correlated orbitals is presented. Charge transfer across oxide interfaces shown to depend crucially on the double counting correction, suggesting that experiments on oxide superlattices may provide insights into this important problem. Future directions are discussed. This work is performed in collaboration with Jia Chen, Hung Dang, Hyowon Park and Chris Marianetti.

Friday, March 6, 2015 11:15AM - 2:15PM — Session Z53 DCOMP: Invited Session: Thermal Transport: Modelling and Ab Initio Calculations Grand Ballroom C3 - Matthias Scheffler, Fritz-Haber, Berlin, Germany

11:15AM Z53.00001 Interfacial Heat Conduction in Modern Semiconductor Nanostructures, KENNETH GOODSON, Stanford University — Heat conduction through interfaces in electronic nanostructures grows more important with the dimensional scaling trends throughout the semiconductor industry. The complexity of interfacial transport has increased owing to frequent examples of severe lattice mismatch and strain, boundaries with nanoscale planar-features and, in some cases, the critical role of electron-phonon interactions. This talk will describe measurements and modeling of phonon heat conduction through interfaces in some of the latest semiconductor nanotechnologies and feature a range of material combinations. Examples include GaN-diamond and silicon-diamond composites, chalcogenide-metal multilayers, metal-semiconductor nanolayer stacks, and nonplanar interfaces in modern nanotransistors and interconnect structures. Applications range from conventional CMOS electronics and phase change memory to quantum cascade lasers and RF amplifiers for satellites.

11:51AM Z53.00002 Phonon hydrodynamics in two-dimensional materials, NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne (EPFL) — The conduction of heat in two dimensions displays a wealth of fascinating phenomena of key relevance to the scientific and technological applications of novel layered materials. Here, we use third order density-functional perturbation theory and an exact, variational solution of the Boltzmann transport equation to study fully from first-principles phonon transport and heat conductivity in graphene and related materials (boron nitride, functionalized derivatives, transition-metal dichalcogenides...). Very good agreement is obtained with experimental data, where available, together with a microscopic understanding of the collective character of heat-carrying excitations, and the unusual length scales involved. Last, and at variance with typical three-dimensional solids, normal processes dominate over Umklapp scattering well above cryogenic conditions, extending to room temperature and more. As a result, novel hydrodynamics regimes, hitherto typically confined to ultra-low temperatures, become readily apparent.

Work done in collaboration with Andrea Cepellotti, Giorgia Fugallo, Lorenzo Paulatto, Michele Lazzieri, and Francesco Mauri.

12:27PM Z53.00003 Accurate Thermal Conductivities from First Principles, CHRISTIAN CARBONO, Fritz-Haber-Institut der MPG — In spite of significant research efforts, a first-principles determination of the thermal conductivity at high temperatures has remained elusive. On the one hand, Boltzmann transport technique include anharmonic effects in the nuclear dynamics only perturbatively become inaccurate or inapplicable under such conditions. On the other hand, non-equilibrium molecular dynamics (MD) methods suffer from enormous finite-size artifacts in the computationally feasible supercells, which prevent an accurate extrapolation to the bulk limit of the thermal conductivity. In this work, we overcome this limitation by performing ab initio MD simulations in thermodynamic equilibrium that account for all orders of anharmonicity. The thermal conductivity is then assessed from the auto-correlation function of the heat flux using the Green-Kubo formalism. Foremost, we discuss the fundamental theory underlying a first-principles definition of the heat flux using the virial theorem. We validate our approach and in particular the techniques developed to overcome finite time and size effects, e.g., by inspecting silicon, the thermal conductivity of which is particularly challenging to converge. Furthermore, we use this framework to quantify the degree of anharmonicity expectation on the heat resistance mechanism active in this material, which eventually allows us to discuss how the thermal conductivity can be controlled by doping and co-doping.

This work has been performed in collaboration with R. Ramprasad (University of Connecticut), C. G. Levi and C. G. Van de Walle (University of California Santa Barbara).

1:03PM Z53.00004 Modeling and Ab initio Calculations of Thermal Transport in Si-Based Clathrates and Solar Perovskites\(^1\), YUPING HE, University of California, Davis — We present calculations of the thermal transport coefficients of Si-based clathrates [1,2] and solar perovskites [3], as obtained from ab initio calculations and models, where all input parameters derived from first principles. We elucidated the physical mechanisms responsible for the measured low thermal conductivity in Si-based clathrates [1] and predicted their electronic properties and mobilities, which were later confirmed experimentally [2]. We also predicted that by appropriately tuning the carrier concentration, the thermoelectric figure of merit of Sn and Pb based perovskites may reach values ranging between 1 and 2, which could possibly be further increased by optimizing the lattice thermal conductivity through engineering perovskite superlattices.

1:39PM Z53.00005 The Importance of Complex Electronic Structures in Thermoelectric Materials\(^1\), DAVID SINGH, Oak Ridge National Laboratory — Thermoelectric performance as characterized by the figure of merit, ZT, is a counter-indicated property of matter, meaning that high ZT depends on a combination of transport properties that do not generally occur together. A particularly important conundrum in thermoelectrics is the requirements for simultaneously having high electrical conductivity and high thermopower. I will argue that the resolution of this conundrum is through complex band structures and discuss how these arise in various known and predicted high performance thermoelectric materials.

\(^1\)This work was done in collaboration with David Parker, Mao-Hua Du, Xin Chen and Hongliang Shi. We are grateful for support from the Department of Energy, through the Office of Basic Energy Sciences, S3TEC Energy Frontier Research Center and the Materials
